not without its share of complicated difficulties. One of the upper platforms of the tier was found to have been crushed by the enormous weight upon it, and it was necessary to replace it by a new one; but, in piercing the masonry all around for this purpose it was found, with surprise, that a large hollow or bell-shaped cavern was behind the masonry. Fortunately this sort of vault was strong enough to prevent the top soil from falling in, and to fill up the cavity no less than 700 fascines had to be stowed away. Other obstacles have arisen since the *calcaire grossier* has been reached; the water springs up in such abundance, that the two pumps at work are not sufficient, and as there is not room for a third, the sinking of the well by manual labour must be abandoned, and recourse had to the trepan. This boring implement weighs no less than 5 tons, and is composed of six branches, each armed with a steel chisel. At the orifice of the well a space has been cleared 13 ft. square, and 20 ft. deep; this is the sort of chamber in which the various operations of boring will be conducted. It is not expected that the works will be free from unforeseen obstacles, till the chalk is reached at an estimated depth of 472 ft., only one-fourth, or 118 ft. being at present gained.

## LIFE STATISTICS, PARIS.

A LETTER has been addressed by the Prefect of the Seine to M. Le Verrier, stating that the municipal administration of the capital are about to issue a monthly *bulletin* of municipal statistics, comprising, for Paris, all the facts which can be expressed numerically. This sheet is to contain principally a return of births and deaths, with the nature of the malady in the latter case, and is to be completed by a return of climatic and meteorological events observed at the same period. It is to be in form somewhat similar to that of the weekly official return published in London, a copy of which accompanied the letter.

## DUBLIN CATHEDRAL.

TWO or three correspondents have addressed to us comments on the ill-advised course pursued in "restoring" St. Patrick's, Dublin, the completion of which was described in our last impression. At a time when the works had not proceeded far, and objection and advice might have had a good effect, both were offered in our pages on various occasions, nor do we cease to regret that the advice was not taken, although, honoring the munificent liberality of Mr. Guinness, we refrained from any great complaint in recording the completion of the work. For the sake of the future, however, the evil of the precedent must not be lost sight of. One of our correspondents thus writes:—  
"If there is any work which more than another requires learning in an architect, it is the patient restoration from crumbled and decayed fragments of the forms of some fast-perishing building of ancient date. If there is any work which requires a rare combination of genius, taste, and sound judgment, with great knowledge of archaeology, it is the labour,—to quote your own words,—of endeavouring 'to reproduce a building such as may have been the aim and design of' a fourteenth-century bishop and his architect. Yet, sir, we find that these duties have been allowed to be undertaken either by a builder, or (for it is understood that 'Mr. Guinness was his own architect' by a private individual of whom we do not learn that he has other qualifications than liberality, wealth, and zeal.

"I cannot but think, that even if Mr. Guinness had been one of the most accomplished amateur archaeologists of the day, the dean and chapter of Dublin would be held to have committed a great indiscretion in intrusting to his superintendence a work for which his amateur is thoroughly qualified. Still, had this recommendation existed, it might have served as an excuse for what has been done, and, as such, I think we should have heard of it. I greatly fear, therefore, from the silence maintained on this point, that the chief reason why Mr. Guinness was allowed to do as he liked, was because he made so munificent an offer.

"If this be so, and the cathedral be really splendidly spoiled, rather than restored, is it not true that a breach of trust has been committed of the gravest kind, and one against which all interested in the preservation of ancient monuments ought to protest?"

## COMPETITIONS.

*New Boarding Houses for Cheltenham College.*—We understand that twenty-two designs were sent in in answer to the advertisement which appeared in our columns, and that the committee of selection have preferred those bearing the following mottoes and marks, for final selection by the directors, viz., "Alpha," one marked with double triangle in a circle; one with single triangle in a circle; "Fines respice;" "Experience;" "Hors du combat."

*The Swindon Central Market Company (Limited) very!*—Sir: Four designs were submitted for this competition, and the magnificent premium which the directors offered for the best design, viz. 107.1 has been awarded to the author of the drawings bearing the happy motto, "Support home talent," which proved to be the production of Mr. Lansdowne, of Swindon, who has recently joined the profession, and declined the business of a builder.—W.

*Cambridge: "The Union."*—The proceedings with reference to obtaining an architect for the proposed Debating Hall, Reading Rooms, and Library, have been a little out of the common way. In the first instance, the committee proposed Mr. Scott; but the general body afterwards determined that any member might name an architect, that from the list thus sent in the committee should select three, and that the whole body should then elect one of these three by vote. The committee's list showed—1. Mr. Scott; 2. Mr. Waterhouse; 3. Mr. D. Wyatt; Mr. Gordon Hills coming fourth. On going to the general poll, the numbers came out—Mr. Waterhouse, 233; Mr. Scott, 135; Mr. Wyatt, 16; and Mr. Waterhouse was accordingly appointed. The Hall will be erected on a piece of land immediately behind the Round Church.

## "COMPETITIONS AND THE ALLIANCE."

In reply to "W." we have received a letter from the Honorary Secretary of the "Alliance," of which we print a part. Mr. Pritchett says:—"I was glad to see the letter on this subject signed 'W.'—not because his objections are, to my mind, valid, but because the delegates of the Alliance wish to ascertain the views of the profession in every point, and, if possible, act for their good according to the wishes of the majority. The circular as now used was adopted last July for a year, and meanwhile the opinions of the allied societies are asked on matters of detail; so if, as I hope, your correspondent 'W.' is a member of one of the allied societies, he will have an opportunity of bringing the matters he wishes to be altered *officially* before the next meeting of delegates in July, by getting his Association to adopt his views, and report accordingly. . . . If 'W.' or any other gentleman, will communicate his views on this subject to me by letter, they shall be considered at next July meeting."

## A STRONG ROOM.

SOME particulars of a strong room, for cash and securities, recently constructed for a London bank, may be of use to some of our readers.—The walls are 2 ft. thick, of hard bricks, laid in cement, and with strong hoop-iron in the courses. In the interior there is placed a fire-proof Chubb's safe, weighing 13 tons. This is 10 ft. long, 8 ft. high, and 8 ft. deep, made of plates 1 inch thick, and secured by two iron and steel doors, having twenty-eight bolts. The remaining part of the brick room is lined with iron, ½-in. thick. The whole is again further secured by an iron and steel door, having ten bolts, let into the centre of the brickwork; and there is a gate for ventilation in the daytime. A large alarm is fixed in the bedroom of a clerk on the account-door, which goes off whenever the outer door is opened; and a porter who sleeps in the office, and whose bed is in front of the door, can also, by pulling a trigger, set the alarm going. The whole of the ironwork, we should mention, was executed by Messrs. Chubb & Son. Mr. P. C. Hardwick is the architect under whom it was set up.

*OPENING OF THE TELEGRAPH TO INDIA.*—The Indo-European Telegraph has been opened throughout, and telegrams have since been received which travelled the whole distance from India to London in eight hours and a half!

GOTHIC ARCHITECTURE IN SPAIN.

Fig. 1.—Barcelona Cathedral. Interior of West End of Nave.

[See p. 155, ante.]

INNS OF COURT HOTEL, LONDON. VIEW OF THE INNER COURT.

*Messrs. Lockwood & Mason, Architects.*

Fig. 2.—Valencia. The Casa Lonja.

## INNS OF COURT HOTEL, LONDON.

In our recent notice of this hotel,\* it was mentioned that an interior court was formed as shown on the plan, having a roof of iron and glass. We now add to our illustrations of the structure a view of this court. It is to be faced with stone, and will have an ornamental fountain in the centre.

## CONTINENTAL NEWS.

**Paris.**—The Hôtel de Dieu is now being pulled down, as also a house adjoining belonging to the Public Charities Commissioners, in order to clear and enlarge the space in front of the Cathedral of Notre Dame. The hospital will be re-erected to the left of the old site, and the costs are estimated at 22 millions of francs.—The Jews of Paris have held a general meeting to consider the propriety of erecting two new synagogues. Both have been determined upon, and a sum of four millions of francs was voted to carry them out. Half of this sum will be borne by the City, the other half by the Jews of Paris.—The Empress has conceived the idea of calling upon all the Christian princesses of Europe to unite in erecting a new church over the Holy Grave at Jerusalem! It is said that several crowned ladies have already responded to this appeal; amongst others Queen Mary of Hanover.

**Rome.**—The minister of public works has just published an interesting list of buildings and other works in and about Rome, which have been "restored" between the years 1859 and 1864. For the word "restored," our readers must, of course, substitute "repaired" in many instances. Amongst the ancient buildings enumerated are, the Palace of Lancelotti, at Frascati; the Pyramid of Cestius; the wall of Servius Tullius; the Villa Adriana, at Tivoli; the Circus of Caracalla; the Conduit of Vopiscus, at Tivoli; the Etruscan graves at Corneto; the baths of Titus and Caracalla; the tombs of the Scipios; the Colosseum; the Columns of Trajan; the Tabularium; the Circus Maximus; the Pantheon; the Forum of Augustus; Nero's Aqueduct, &c.; and amongst the buildings of Mediaeval origin are mentioned, the Abbey Alo Tre Fontane, San Lorenzo, the house of Cola di Rienzi, &c. Fourteen churches were restored, and have received internal mural decoration.—The statue of Hercules, lately discovered, will in future be known by the name of the "Mastai Hercules," in honour of the pope.—A new method of painting and preserving plaster casts has just been applied at the Redemptorist Church of San Alfonso, which, perhaps, in a great measure approaches to the lost encaustic process of the ancients. Mr. H. Schuber, a German sculptor here, made a present to the church of a plaster cast of the great *telamo* piece which he exhibited in London in 1852; but inasmuch as all the other sculptures, as well as the walls of the church, are in colours, it became desirable that this cast should also be painted. Mr. Schuber, therefore, together with the artists Winger and Becklin, applied common water-colours to the cast, which had been previously well saturated with water. The colours were taken rather lighter than required, and when perfectly dry the whole was coated with a solution of wax and resin, applied hot, partly in order to fix the colours, and partly to obtain a firm transparent coating by means of the resin. This process seems to secure the cast from damp and dust, and the colours stand out with unusual brilliancy.—Schloth, the Swiss artist, is giving the finishing touches to his Arnold von Winkelried, to be erected in one of the four cantons. Another work, in course of execution by the same artist, is a monument of the battle of St. Jacob, in Switzerland. The design represents a group of five figures,—Helvetia, the tutelary protectress of Switzerland, on a high pedestal, holding the crown of victory, and surrounded by four fighting and wounded warriors at the base.—Architects intending a visit to this city should not omit seeing the curious collection of the various kinds of stone employed by the ancients in their works. The originator and founder of this very interesting collection is Professor Sanguinetti, who has succeeded in collecting no less than 607 different kinds of marble and alabaster. They will be found in the Collegio della Sapienza.—A local paper gives a very curious list of payments made to artists, showing with what moderate remunera-

tion men like Michelangelo and Raffaele were content. The tomb of Pope Clement XIV., in the church of Santi XII. Apostoli, cost 12,000 scudi, or about 2,400*l.* Canova was engaged four years upon it, and only received 4,561 scudi for his trouble, equal to about 912*l.* A receipt for 1,200 scudi (240*l.*), signed "Michelangelo," is still preserved; it was for the execution of the monument to Julius II.; and Raffaele received 20*l.* for one of his pictures, from Alexander VII.

**Florence.**—The Dante Monument consists of a pedestal 22 ft. high, having bas-reliefs on three sides, surmounted by a figure of Dante, 18 ft. high, executed by the sculptor Pazzi, of Ravenna. The author of the "Divina Commedia" is in the habit of a Franciscan monk, but without scapula and hood; the head is encircled by a laurel wreath. The right hand grasps the manuscript of the "comedy," whilst the left holds some folds of the dress. The features were carefully worked from the cast taken after death, and now in the possession of the Torrigiani family.

**Naples.**—A marble bust of Alexander von Humboldt is to be erected in the aula of the university here.—An archaeological discovery of considerable interest has just been made at Bagnoli, near Pozzuoli, by the proprietor of the baths of that place. In excavating for some alterations, he found undoubted antique remains, and on continuing the excavations a complete set of Roman Thermes, of the time of the Empire, was brought to light. The various apartments can be readily traced, and over the sulphuric springs were found, which originally gave rise to this establishment. The works must have been used from a very early period, and thence for a long time, since the inscriptions go back to the first years of the Republic, and down to the first century after Christ.

## THE PROGRESS OF THE SEWING MACHINE.

This ingenious piece of mechanism is, month after month, coming into more extensive use, and will before long drive the chief part of the hand-work with the needle out of use. Nor should we regret this, for labour of this sort has become a miserable source of existence, as women starve when engaged in this kind of industry. It is also to be noted that steam is now becoming extensively used in connexion with the sewing machine; and instead of poor women working in garrets and miserable apartments, they are in some instances gathered into roomy and well-ventilated places. In other instances of steam-sewing factories, this is unfortunately not yet the case; and there is great need of inspection, in order to prevent such extensive factories from becoming as bad in their condition as are some of the City and West-end dress-making and millinery establishments. Even at the present day we hear of complaints of the way in which some are managing these machines. Persons who have driven, or "sweated," as it is called, the poor needle-women and tailors into much distress, are using the sewing-machine to produce similar effects; for capitalists lead machines to *middle-men*, who reap a separate profit; and those again dispose of their work so that the workers having to support these drones do not get what is actually their due. It is hoped, however, that this evil may in time be remedied, and that, as in the factories of Lancashire, there may be in connexion with the sewing-machine a certain amount, in ordinary times, of what may be considered fair remuneration.

The advantages to this and other countries of the sewing-machine, will be shown by the following figures:—Men's shirts, made by machine, take 3 hours and 10 minutes each to do; by hand, 16 hours 20 minutes; a lady's dress, by the machine, takes 12 hours 6 minutes; by hand, 20 hours 35 minutes; a merino dress, by machine, 10 hours 35 minutes; by hand, 16 hours 27 minutes; a calico dress, by machine, 6 hours 20 minutes; by hand, 11 hours 38 minutes. Other articles are in somewhat similar proportions; and we will, therefore, only mention that a silk apron is made by machine in 2 hours 30 minutes; by hand, 6 hours 16 minutes; and a muslin skirt, by machine, in 4 hours 50 minutes; by hand, 10 hours 10 minutes.

A like saving of time is to be noticed in the making of male attire; for instance, a common frock-coat, by the machine, occupies 17 hours 20 minutes; by the hand, 27 hours 40 minutes; a linen vest, by machine, 3 hours 44 minutes; by

hand, 7 hours 18 minutes; a fine overcoat, by machine, 28 hours 13 minutes; by hand, 31 hours 20 minutes; a fine frock-coat, by machine, 21 hours 25 minutes; by hand, 35 hours 16 minutes; a fine business coat, by machine, 19 hours; by hand, 26 hours 40 minutes; a satin vest, by machine, 8 hours 14 minutes; by hand, 12 hours 55 minutes.

Notwithstanding all that has been argued to the contrary, it is certain that the means which save the need of human labour are a great advantage to the community. In this way the general amount of saving in Great Britain alone must be in each year enormous. Not only in the preparation of clothing, but also of linen, woollen, and other fabrics, the sewing-machine has come into extensive use. In the manufacturing of leather articles, and especially in the boot and shoe trade, it is doing useful service. The sewing-machine has been objected to by many workmen, who when drawing as they call it "the strings of misery," have a sort of dread of being relieved from a difficulty. At Northampton, one of the chief places where boots and shoes are made on an extensive scale, the machine was introduced in the following manner. A wholesale shoemaker of that town, seeing the value of the machine in his own trade, determined to introduce it, but fearing the opposition it would produce, thoroughly mastered the working of the machine himself. Having done so, and sewn a pair of upper leathers, he entered his shop, and put them into the hands of his foreman, with the remark, "What do you think of these?" The man, after carefully examining them, remarked, "Why, they are splendid! I never saw such work in my life!" The boots were passed round the shop, the men being chiefly members of the trade society, and were admired by every one who saw them. The master then said, "The party who made them wants work; shall I take him on?" The foreman replied, that nothing could be better, and that for his part he should be glad of such a hand. "But," said the master, "he is deaf and dumb." "Dear me," replied the foreman, "what a misfortune! Not much fear, however, of him quarrelling with his mates, sir." The master, with emphasis,—"And he neither eats nor drinks." "Ah! it is the sewing-machine!" exclaimed the foreman, and the excitement in the shop became intense. "But," said the master, "listen to me for a moment. I have seen the working of this thing in the States, and its introduction here is a positive certainty; it is the merest question of time. To attempt to stay the introduction of machinery into any branch of trade is something worse than madness; it never has succeeded, and it never will. I have made up my mind to introduce the sewing-machines into my trade,—and introduce it I must and will; but not at your cost. I know that it will decrease your labour, but it shall increase your pay. You may not think so, but I will guarantee that for twelve months your wages shall never be less than now, and as much more as you can earn you shall have." The trade-union men agreed to these terms. The movement has been successful; and in Northampton the machine is extensively in use, and the patentees sell them under a system of weekly payments, so that many men have their own machines and work in their own cottages; and this, it is reported, has had an excellent effect upon the habits of the people. One machine gives employment to four people, in preparing the work for the process of sewing. In Stafford, it is said that the machine already finds work for more hands than can be obtained; and women, in this way, can earn from 12*s.* to 20*s.* a week.

Up to the present time the sewing-machine is far more extensively used in America than it is in this country. In the United States it is believed that the value of the sewing done by it has been more than 53,000,000*l.* It is estimated that there are at present at work in the whole world more than 300,000 sewing-machines. Out of this number, 200,000 are at work in America, 50,000 in England, and the remainder elsewhere. These figures will serve to show to what an enormous extent this power has to be developed in Great Britain alone. In the United States there is a manufactory which is especially devoted to the construction of these machines, in which some thousands of men are employed; and from this place 1,000 machines can be turned out weekly.

The history of the inventor of the sewing-machine is a most curious and interesting one. The name of this man is Elias Howe. He was

\* See p. 154, ante.

a mechanic of New York. Not succeeding well with this effort of ingenuity in America, he came to England, and sold his patent right in this country to Mr. Thomas, of Cheapside, for 250*l*. Mr. Thomas, some time later, paid 2,000*l*. to a person who made some improvement in the feeding apparatus. Howe was engaged by Mr. Thomas at a salary of 3*l*. a week, to adapt the machine to the stay-making trade. About this time the inventor had fallen into such extreme poverty, that his family were destitute of the necessities of life; but, fortunately, he had not disposed of his patent rights in America: to that country he returned; and it is stated that the royalty which he now reaps from home sale and for exportation, amounts to 50,000*l*. a year.

#### CRYSTAL PALACE.

*The Triennial Handel Festival.*—Early preparations are being made for this great festival, which will take place on three days in June—Monday, the 26th, when "Messiah" will be performed; Wednesday, the 28th, when a selection from Handel's other works will be given; and Friday, the 30th, when the "Israel in Egypt" will be performed. The hour has been altered from one to three p.m. The full rehearsal will take place on Friday, the 23rd of June, at one p.m. instead of ten a.m. Tickets will be issued from Monday, the 13th March, for the securing of seats, at the rate of 2*s*. and 2*s*. each for each day, or three guineas and two guineas and a-half for the three days of the festival.

The progress of the works for the station of the High Level Railway is encouraging, and from the remarks of the chairman of this new line (Sir Cusack Roncy) at the meeting on Tuesday last, it was clear that the contractors, Messrs. Peto, Betts, & Crompton, are determined that the works should be so pushed on that they may be certain of completion by the 1st of July. It is stated that the station will be an imposing architectural structure; it is understood that the cost of it will exceed 100,000*l*. It is being erected by Messrs. Lueas.

An interesting collection of Chinese objects of rare beauty and great value, formed by Capt. Negroni, of the French army—mostly taken from the Summer Palace at Peking—and worth, it is stated, over 300,000*l*. will be opened for exhibition on the 18th of March.

#### STOVE REGISTERS.

The recent-use of charcoal placed in a brazier in a closely shut-in bed-room, which ended in the destruction of one life and was attended with great risk to a second person, is one of several similar instances which have occurred within a comparatively recent period. Not long since some men were suffocated by the fumes of charcoal which had been burnt in the cabin of a ship: having lighted their fire, they, either in ignorance or from carelessness, placed the hatches of the cabin over the entrance, for the purpose of keeping out the cold. Other instances might be mentioned of a somewhat similar description; but in connexion with the Kentish-town accident, it is to be particularly noted that the register of the stove after the death had taken place was found closed; and, no doubt, it must be owing to this cause that the fatal result is chiefly to be attributed. This circumstance ought to be a warning in various ways. In the case of charcoal smothering we suddenly see the deadly results: more slowly, but no less surely, does the pent-up breathing of human beings destroy life and health. We have said so much on this subject that it would be scarcely worth while to refer to it at present, but for the belief that the danger of closed flues is far too often overlooked, and that those who would not willingly cover up the fireplaces in bed-rooms with boards, do not remember that the closing of the register produces exactly the same ill effect.

In far too many instances, especially in houses let in tenements, where a family may have say two rooms, and it is not usual to light a fire in the apartment used as a bed-room, there is a necessity for keeping the fire-place closed, to prevent the down-draught of smoke, which comes from other fires in consequence of the bad arrangement of the chimneys. The unpleasantness of this invasion is great; for, besides the smoke of the coal, there is often an adulteration of the fumes of the refuse of vegetables, such as

the peelings of potatoes, onions, and other unpleasant matters, which are put on the fires instead of being carried to the dust-bins. However, when it is absolutely necessary to close the chimney, and prevent it from being a means of ventilation, care should be taken in both summer and winter to ventilate and admit air in other ways. Want of care in this respect is a common cause of fever and other complaints.

#### PROPOSED NEW REREDOS AND ALTAR, WESTMINSTER ABBEY.

The proposed restoration of the altar and reredos in Westminster Abbey, from designs by Mr. G. G. Scott, has moved a correspondent to address to us some violent words of denunciation, founded partly, at any rate, on wrong information. The matter, as we learn, stands thus. The old reredos, of the fifteenth century, was defaced some time in the last century, and a "classic" one was erected against it. This was taken down about 1824, and Bernasconi was employed to restore the original design, as well as he could ascertain it, in his artificial stone. At the same time a sham stone altar was erected, which, we are told, consists of a pile of street paving as a core, which is covered with cement, and finished above with a black marble slab.

A feeling has recently arisen to do something more worthy than this artificial work, and the Dean and Chapter are about to substitute alabaster and marble for as much of the plaster-work of the reredos as they can afford, and to introduce a mosaic picture of "The Last Supper" over the altar, below the fine central canopies. The sham stone altar is to be removed, and, as the Order in Council seems to forbid the use of stone, the altar-table is made of cedar inlaid with other woods, and of very rich design. This will be of the size of the ancient altar as indicated by the retabulum which is preserved in the church, viz., 11 ft. long. The old marble slab will be retained, and enlarged by means of a mosaic border to the increased size.

The mosaic picture alluded to, representing "The Last Supper," will be executed by Signor Salvati, from a cartoon by Messrs. Clayton & Bell. This picture will be 11 ft. long and 4 ft. deep, and the figures in it will be projected upon a gold field generally, with the exception of that of Our Lord, which will be against a diaper of black and gold, while the colours used on the whole work will be bright and interesting. The cost of the mosaic work will amount to about 550*l*. Over the canopy of the altar there will be a cornice, 36½ ft. long and 18 in. deep. The commission for this piece of carving has been placed in the hands of Mr. H. H. Armistead, the sculptor. It will be executed in white alabaster, something in the style of the ancient cornice at the back of the present altar facing Edward the Confessor's Chapel, and the subjects represented will be various events in the life of the Saviour. The reredos is being executed by Messrs. Poole & Son, and the altar-table by Mr. Farmer.

#### THE ARCHITECTURAL ASSOCIATION.

The usual meeting of members was held on Friday evening (the 3rd inst.), at the House in Conduit-street.

The chair was occupied by the president, Mr. J. H. Christian.

The following gentlemen were elected members of the Association:—Messrs. H. T. Bonner, Edward O'Brien, Thomas Floyd, E. G. Hayes, G. Walsh, C. W. Griffith, C. W. Hall, Ernest Flint, Malcolm Watson, and H. T. Gordon.

The only business discussed had reference to a memorial recommended by the committee of the Association for presentation to the Royal Institute of British Architects, suggesting certain alterations in the regulations and conditions for voluntary examination.

On the motion of Mr. Plimbe, seconded by Mr. Blashill, the memorial was approved, and after a short discussion, in which Mr. Spiers, Mr. Lemon, Mr. Webber, and other gentlemen took part, it was moved that it be presented to the Institute.

Mr. Harris called attention to an announcement from a publishing and lithographing firm, in Lincoln's-inn-fields, offering to execute architectural drawings as a part of their trade, and gave notice that he intended on a future day to bring the subject under the notice of the Association.

He also expressed a hope that the Institute, towards whom the public naturally looked as a conservator in matters relating to the character of the profession, would also deem it to be its duty to take some action in the matter.

The meeting was then converted into a *soirée*, and the members and their friends amused themselves with glees, musical selections, recitations, &c.

#### THE BUILDING TRADES.

*Birmingham.*—A large meeting of the carpenters and joiners was held last week at the Odd Fellows' Hall, when there were some 1,500 of the trade present. The delegates from the trade laid before the meeting the following rules, as agreed to by the representatives of masters and workmen, at a joint meeting held at the Public Office, Birmingham, on the 20th February, Mr. Thomas Lloyd presiding:—

1. The rate of wages to be 6*d*. per hour for skilled workmen, during ordinary working hours; superior and inferior workmen to be paid at such rate of wages as may be decided by the foreman or employer.
2. The ordinary hours of work to be from 6 a.m. to 5:30 p.m. on each of the five first days, and from 6 a.m. to 4 p.m. on Saturday in every week, 1½ hour excluded for meals; but during winter (that is, during the six weeks before and the six weeks after Christmas), on exposed buildings, where artificial light is not furnished, from 7 a.m. to 5 p.m. on each of the five first days, and from 7 a.m. to 4 p.m. on Saturday in every week, one hour excluded for meals.
3. All overtime to be paid for at the rate of 1*d*. per hour extra till 8 p.m., and after that hour at the rate of 9*d*. per hour; on Sundays, double time.
4. All wages to be paid at 4 p.m. on Saturday in every week, and not in a public-house or a beer-shop.
5. If the distance of the work or job be not more than 2 miles from Stephenson-place, Birmingham, the men shall walk in their own time; if more than 2 miles, then walking time shall be allowed at the rate of 3 miles per hour beyond the first ½ mile; but the men shall walk back in their own time, except on Saturdays, when the wages are not paid on the job or place of work. Lodgings and railway fare to be paid by the master, subject to special arrangement between masters and men,—for all works at a distance of more than 4 miles from Stephenson-place, Birmingham.
6. A quarter of a day's notice shall be given by the master or workman of any intention to put an end to the service, and in default thereof, either party shall forfeit and pay to the other a quarter of a day's wages.
7. Each master shall have power to conduct his own business in any way he may think advantageous, in the matter of letting piece-work, in taking apprentices, in using machinery and implements, and in all details of management not infringing the individual liberty of the workman; but no master shall take or employ more than one article improver to every ten workmen in his service.
8. Trade societies will not countenance any interference with a workman because he is not a member of a trade society; and as regards individual members—it being impossible to bind them by any present resolution—the societies pledge themselves to discourage all such interference.
9. All trade regulations, and all disputes that may arise between masters and workmen, shall be settled by six delegates appointed by each party to the dispute, who shall, if necessary, appoint an independent chairman with a casting vote; and if either masters or workmen desire any alteration in, or addition to, the foregoing rules, a notice in writing, stating the nature of the proposed alteration or addition, shall be given on or before the 1st day of January in any year, and the proposal shall be accepted or rejected before the 1st day of March then next; if accepted, the new rule shall come into force on the 1st of May then next.
10. These rules to come into operation and force on the 1st day of June next. THOMAS LLOYD, Chairman.

The meeting unanimously approved of the rules.

*Stourbridge.*—The members here of the General Builders' Association write us, by their local honorary secretary, saying,—“Since our meeting on the 20th ult., the bricklayers and plasterers have agreed to unite with the other branches of the trade, in order to draw up local trade rules, and form an arbitration court for settling disputes; so that now we have carpenters and joiners, bricklayers, plasterers, painters and plumbers, and laborers. Delegates from all these branches met an equal number of masters and agreed upon an independent chairman, not engaged in the building trade, according to the resolution passed at our public meeting. I would say that the meeting of delegates was exceedingly amicable.” In mentioning these facts, the secretary expresses a hope that it may “be the means of encouraging other towns to try and settle the perplexing difficulties of trade rules,” a hope in the expression of which we earnestly unite with him.

*Kidderminster.*—A meeting of the building trade has been held in the Guildhall, in regard to the settlement of trade disputes by arbitration. The attendance of employers and workmen was very numerous. The mayor took the chair. A friendly tone pervaded the meeting, and it was resolved to adopt the principle of arbitration, and appoint delegates in equal numbers from masters and men. From the carpenters there were appointed: masters, Messrs.

Thompson and Binnian; men, Messrs. C. Croft and J. Lane. Bricklayers; masters, Messrs. Fisher and Herrin; men, Messrs. W. Hooper and T. Marden. Labourers; masters, Messrs. Bale and Williamson; men, Messrs. Frailey and Webb.

**Widness (Lancashire).**—The brickmakers and bricklayers' labourers have turned out on strike, on account of the master brickmakers introducing brickmaking machines into Widness. There are now three in the town, and it is feared disturbances will take place, the men having expressed their determination to break them. The master builders of the town have passed a resolution not to employ any men belonging to the union.

**Leeds.**—At a large meeting of the Leeds branch of the Yorkshire Association of Master Builders, the following resolution has been unanimously agreed to:—"That the operative masons be requested to appoint a deputation of six to meet the same number of masters, with full powers to settle the questions at present pending." A similar resolution was agreed to respecting the joiners.

**Stockton.**—The whole of the bricklayers employed at Stockton have turned out for an advance of wages. They were in receipt of 4s. 6d. per day, their hours being by mutual consent of themselves and employers "from daylight to dark." They demand generally 5s. a day, and in some cases 5s. 3d., and ask that the hours of labour be modified so far as beginning on the Monday morning and ending on the Saturday night are concerned. They will be content if allowed to commence the week at seven o'clock in the morning, and terminate it at half-past three o'clock in the afternoon. A general meeting of the masters was held, and it was decided to offer 5s. a day, from the third Monday in March until the month of November. There is said to be an understanding on the part of the Stockton employers to form forthwith a combination of the master bricklayers of Stockton, Middlesbrough, Hartlepool, West Hartlepool, and Darlington, as strikers. The labourers have not yet turned out, and it has been intimated to them that they will receive 21s. per week simultaneously with the rise in the wages of the bricklayers; at present the labourers are in receipt of 20s. per week.

**Carlisle.**—The working masons in this city, to the number of about sixty, have left work on strike, having refused to adopt the system of payment by the hour, insisted upon by the masters. The only masters who have acceded to the demands of the men are Messrs. Dodd, Ward-roppe, Brongh, Scott, and Simpson. The bricklayers have also gone out on strike. They have formed themselves into a co-operative association, and announced that they are "prepared to do all kinds of jobbing in connexion with their trade at 10 per cent. below the masters' prices."

**The Strike and Lock-out in the Iron Trade.**—The strike in North Staffordshire against a reduction of wages, and the threat of the South Staffordshire men and others to support the strike, have led the masters to adopt the fearful alternative of a general lock-out till the North Staffordshire men be compelled to give in. It is said that wages to the extent of 120,000*l.* a week are already stopped (since the lock-out took place on Monday). On the other hand, however, it is also reported that some masters have not carried out the lock-out, and that it is believed the misunderstanding will be at an end in a week or two. It is to be earnestly hoped that the iron trade of the whole country will not continue at a stand even for a week or two, and that something like the Midland builders' mode of settling the question will be immediately agreed to by the parties in dispute. Mean time, we hear, there are already 40,000 men out of work, and that by the end of the week this number will be increased to 70,000,—a great proportion of them, probably, heads of families.

#### RAILWAY MATTERS.

COMMUNICATION between passengers and guards is hoped to be at last in a fair way of settlement. The Government inspector of railways has for some time been investigating the various proposals that have been submitted and plans tried by different railway companies, and has forwarded his report to the Board of Trade. The railway clearing-house have also formed a committee of managers, who have been similarly occupied, but who have not yet produced their report. It is, however, known that their decision

is against the adoption at present of any general plan, chiefly from the want of experience in the working of the electrical system favourably noticed and approved by the Government inspector. It is arranged that the London and South-Western, the London and North-Western, and one or two other railway companies, shall try for a short period different plans, and then, after full and mature experience, the clearing-house committee will again meet and recommend for general use the most successful system. The system recommended by the Board of Trade is the design of Mr. W. H. Preece, the telegraph superintendent of the London and South-Western Company.

The directors of the South-Western Railway, having promised the Queen to do all they could to prevent accidents on their line, seem to be honestly trying to fulfil their promise. They are carrying out various experiments for the purpose of providing communication between the passengers and guard; and, according to the account given of a trial between Waterloo and Wimbledon, they have achieved considerable success. The apparatus is thus described:—On both sides of the partitions of each compartment, within easy reach of the passenger, is a small circular box, with a glass face; and, to attract the attention of the guard, a passenger must break the glass, which liberates a spring-hitherto confined, and causes a small arm to drop out from beside the window of that compartment where assistance is required. At the same time an electric current is called into play, which establishes communication with another wire, causing a bell to ring in the guard's van; and he has only to look out of the window to see the precise compartment where his assistance is required, indicated by the outstretched arm. Of course we conclude that the guard can do something more than merely look or ascertain the whereabouts of the warning. The danger of the passenger cutting his hand in breaking the glass to set the machinery in motion will, the reporter supposes, prevent his playing with it; and in the grave emergencies to which alone it is intended to apply, a cut or a scratch is a small matter. It is said that the cost of the apparatus will be about 4*l.* for each carriage.

Whatever plan may be finally adopted, we think we may safely say that none will be efficient without arrangements for the free movement of the guard along the train, either outside or inside; and such arrangements, if regularly made use of by the guards, would obviate entirely all occasion for any other arrangement. Thus the watchman's bent may be said to be the *sine qua non* or the *ne plus ultra*, and the guard is no guard till he have such a bent and be such a watchman. The knowledge of the public, victims and victimizers, that at any moment a watchman might look into a carriage, would restore both confidence and safety to railway travelling; and nothing else, we fear, will so effectually do so.

A correspondent, "D. M. P.," suggests, as a safeguard against collisions, that a fender truck, padded, or rather filled, with such material as that used in ship's fenders, should be placed in front of every engine and behind every train, so that in collisions these fenders would always receive and alleviate the shock.

At the last meeting of the Manchester Literary and Philosophical Society, a paper was read concerning the construction of a swing bridge for carrying a railway over the Sankey Canal, in which the girders are made of Bessemer steel plates. The object of using steel instead of wrought iron was to reduce the weight of the girders. These are four in number, about 56 ft. long, with bearings varying from 30 ft. to 40 ft., and 2 ft. deep. The weight of the girders was a little more than half the weight they would have been if wrought iron had been used.

A gentleman owning an estate at Bexhill brought an action against the Brighton Railway Company, for damage done to his plantations by the sparks from their engines. Between the 17th of July and September, 1863, there were six fires in the plantations, which destroyed 943 trees. The only question was as to the amount of damage done, the company admitting their liability, and the jury gave 200*l.*, after being locked up for some time. The damage had been laid at 20,000*l.*

The traffic receipts of railways in the United Kingdom amounted, for the week ending the 25th of February, on 11,821 miles, to 564,951*l.*, and for the corresponding week of last year, on 11,476 miles, to 539,150*l.*, showing an increase of 345 miles, and of 25,801*l.* in the receipts.

Ever since the commencement of the American war, we have been accustomed to hear of the utter inadequacy of the Indian railways to the immense goods traffic which has been poured upon them from the interior. In Bombay, cotton in great quantities will sometimes be at a remote station for weeks before the single line of rail or the scanty rolling stock of the company admits of its being forwarded to the port of shipment. And now come similar complaints from Bengal. The line between Allahabad and Calcutta, the *Englishman* informs us, is literally at a dead-lock, goods of every description being delayed in transit for want of carriage.

#### SANITARY MATTERS.

**Brighton.**—A court of inquiry has been held at Hove, to settle the boundaries of a district, comprising Hove and St. Anlyn, for the purposes of the Local Government Act. Mr. R. Rawlinson, C.E., was the inspector appointed by the Home Department. At the close of the inquiry, the inspector stated that he should report in favour of the adoption of the boundaries. He had previously expressed his opinion, however, that the whole of Brighton and Hove should be under one head for sewage purposes.

**Cheltenham.**—The question of the water supply for Cheltenham is now being warmly agitated by the inhabitants, who have vigorously endeavoured to thwart the proposed plan of the existing water company in its object of obtaining its water supply from the Severn. A Bill, brought in by the Cheltenham and Gloucestershire Waterworks Company, for supplying the town with water direct from the Boxwell springs, was thrown out on the second reading. A large public meeting has been held to protest against the present Bill of the Waterworks Company, as the waters of the Severn were polluted in the greatest degree, and totally unfit for domestic use. An abundant supply of water might be obtained from other sources in the neighbourhood of the Waterworks company terminated the proceedings.

**Maldstone.**—The second annual report of the Maldstone Cottage Improvement Company states that during the past year twenty-one cottages have been purchased, and the directors call attention to the fact that their capital is all invested, and that it is desirable more shares should be taken for the purchase of more cottages. The whole property of the company is stated to be paying, on an average, over 8 per cent. per annum, net.

**Liverpool.**—A townsman has offered 10*l.* as a premium for the best essay "On dwellings for the poor, and how to provide them, as applicable to Liverpool." His object is to aid the Sanitary Committee in getting information on the subject. The referees are to be the borough engineer, Mr. H. Shimmis, and the donor.—Fever still prevails at Liverpool, there being forty-one deaths last week from typhus alone, or twenty-seven above the average. The relative mortality of Liverpool as well as other towns, will be seen from the following return for the week that ended Saturday before last:—The ratio of mortality was 28 per 1,000 in London, 33 in Edinburgh, and 36 in Dublin; 41 in Liverpool, 33 in Manchester, 26 in Salford, 28 in Birmingham, 32 in Leeds, 27 in Bristol, and 47 in Glasgow.

**Preston.**—The report on the sewerage and private improvements, for 1864, by the borough engineer, Mr. John Newton, C.E., states that previous to the adoption of the Public Works Act for behoof of the cotton-spinners, the local Board had executed main sewerage, amounting to 49,414*l.*, and private street improvements, amounting to 26,477*l.*, and they had also drained 13,973 houses, at an average cost of 1*l.* 16s. each, making a total expended on sanitary works alone exceeding 100,000*l.*; and that the local Board, nevertheless, were the first to apply for loans under the Act, and that their expenditure has been upwards of 24,000*l.*, nearly one half of which was for wages. The number of men at present employed is 320. Notwithstanding the comparatively high rate of mortality throughout the country of late, and at Preston as well, the sanitary works have already reduced the average death-rate from 29.65 per 1,000 to 28.68 per 1,000, instead of allowing it to show any excess here as elsewhere for 1864. In the previous year it was down to 25.25 per 1,000, and for next year, unless a generally high death-rate continue throughout the country, we have not

the least doubt that the death-rate will fall below 25 per 1,000.

**Nottingham.**—The report of the Sanitary Committee states that the rate of mortality in this town for the year ending 30th September, 1864, was 26 per 1,000. No typhus or typhoid epidemic is reported on.

**Typhus Fever in Scotland: Greenock.**—In the quarterly reports for 1864 to the Registrar-general for Scotland, he observes there was nothing in the meteorological phenomena of the year to account for the great epidemic of typhus which prevailed in Scotland. It attacked large masses of the people in the early months of the year, abated in the warmer season, but again resumed its violence in September, and increased more and more till the year closed. The epidemic appeared among the people while in the midst of plenty,—plenty of work, high wages, and cheap food being characteristics of the year. The town where the demand for labour has been greatest and wages highest, and in which there need not be a single person idle—viz., Greenock, has been the town where typhus has been most virulent and fatal, causing above 14 per cent. of the deaths of the year, including among its victims four of the medical practitioners. Taking the experience of the Royal Infirmary of Edinburgh—namely, one death in every 12 cases of this epidemic,—above 7 per cent. of the population of Greenock must have been attacked with typhus fever in 1864. But Greenock is shown by the register year after year to be by far the most unhealthy of the eight principal towns of Scotland, if not the most unhealthy town in Scotland. The inhabitants have to contend with two adverse causes which tend to induce predisposition to attacks of epidemics,—a low-lying, damp site, and greatly overcrowded dwellings, the house accommodation not keeping pace with the increase of the inhabitants. The report records an extremely unhealthy year.

The four medical practitioners who have died from fever constituted one-fourth of the medical men resident in the town. One of them, Dr. Dowie, who was the youngest, and was only twenty-one years of age, had himself treated no less than twenty-eight fever cases on the day when he was attacked by it. Greenock has long been infamous for its unsanitary state.

**New York.**—Small-pox has become so fearful in New York that the legislature of the State has been appealed to to take immediate action to make vaccination compulsory with the inhabitants of the metropolis. It is estimated that from 100 to 125 persons die daily in the city, while it is known that several thousand cases of sickness exist. Many of the streets—among others Pell, Clinton, and Columbia—have been barricaded, or "boarded up," to prevent the passage of the plague.

**St. Petersburg.**—Fever is now raging at St. Petersburg, and the streets are placarded with notices issued by a "committee of public health." The fever, which these notices is said not to be dangerous if properly treated forthwith, but in the contrary case mortal. The water from three of the canals, and from all the springs near the drains or near bath-houses, is declared unfit to drink. Impure bread and excess of brandy are reprobated. Overcrowding and filth, however, do not seem to come under notice as likely causes, although these are doubtless the great evils which are here, as elsewhere, marking out the seats of confined sanitary neglect.

#### CISTERNS IN FROSTY WEATHER.

HAVING suffered much annoyance from cisterns freezing and pipes bursting during frost, which misery is common to all houses having the "closets" and cisterns near to or outside the main walls, which is usually the case, I beg to send you a plan by which I overcame this inconvenience.

Over the gas-burner in the closet I placed a thin lead pipe, about 2 in. diameter at the bottom, and 1 in. at the top. The low end of the pipe comes through the ceiling, and is finished and fitted with a coved block-in-disc, having an opening in the centre to allow the beat to ascend. The pipe is soldered to the bottom of the cistern, and goes up above the water, and is turned down at the top, which partly confines the heat.

By this means, with a jet of gas burning, and a cistern containing about 1,400 gallons of (being rain water, and also used for the rooms) in an exposed situation, during all the long frost this winter, with the thermometer down to 20 degrees

below the freezing point, there has been no inconvenience or trouble.

Where there is no gas, and where there are hot-water pipes leading to baths or rooms, a small pipe from the hot-water pipe, with a tap on it near the cistern, could be used to allow a portion of hot water to run into the cistern during frosts, or the pipe could be carried into the cistern and finished with a hollow copper or lead ball, into which the hot water could be allowed to flow by opening the tap in frosts, and so keep the water from freezing.

By either of the above means, much discomfort, destruction, and expense, can be saved by an outlay of a few shillings. R. C.

#### ON LAYING OUT HOUSES.

NUMEROUS are the publications that profess to exhibit designs of, or else for, country mansions and villas of different grades, scarcely any instruction is to be gathered from them relative to the skillful laying out of buildings of that class. The "Vitruvius Britannicus" and its successors are perfect blanks in that respect. In a church—which, however large, consists of little more than a single large room—there is, properly speaking, nothing to plan: widely different is it in the case of an extensive mansion, containing perhaps a hundred rooms, or even more, of various kinds, in which the most conflicting requirements have to be reconciled, and the *utile* so completely to be mingled with the *dulce* as to coalesce inseparably. Nevertheless, eminently deserving of particular attention and study as the matter of planning is, very little indeed is to be met with on the subject in books.

At length, under the attractive title of the "English Gentleman's House," Mr. Kerr has given us a volume professedly on laying out houses of that description, which, however, is so comprehensive as to require a good deal of subdivision, embracing as it does the studiously-comfortable, perhaps even luxuriously appointed though small and unpretending cottage residence, the ornate Palladian villa, or the aristocratic family mansion, adapted for a large establishment and the reception of a concourse of the locusts yelped "staying visitors." To quote, as Mr. Kerr does, Blenheim, that national monumental pile, as a sample of a gentleman's house, seems to me rather preposterous.

A positive omission—a not little serious one, unfortunately—is that nothing at all is said in regard to a very important matter indeed, namely, the respective advantages or the contrary of two directly opposite systems of planning; the one being that of keeping the domestic offices out of sight, by placing them beneath the house proper; the other, that of erecting them above ground, and along side of it—a separate though contiguous structure. The first mode insures compactness; the other is attended with more or less of the *straggling*, with its accompanying inconveniences, to say nothing of comparative extravagance as to cost, when the offices are stretched out till they occupy as much ground as the house itself, although no more than a supplementary adjunct to it, which, so far from improving the general design, usually degrades it. Mere juxtaposition of an additional range of building tacked on to a house, as a separate habitation for the domestics, is inimical to artistic unity of composition. Suppressing here, for the present, a great deal that would detain me longer than suits my inclination, I just now content myself with remarking that however it may have occurred or been occasioned, the absence of all comment or advice relative to so very fundamental a point for decision at the very outset, certainly does not add either to its interest or its value.

As it seems to me,—and not to myself alone,—instead of endeavouring to correct it, the writer rather countenances that laxity, not to call it downright slovenliness of both composition (rather merc putting together) and detail, which has become the characteristic of too much of the architecture of the day, when, though it is now the latter half of the nineteenth century, we are exhorted by some to revert to Mediaevalism, in architecture at least, notwithstanding that we are advancing further and further every day from the state of society in those exquisitely blissful days, when a prince was far worse lodged and accommodated in every respect than is now a well-to-do shopkeeper: but I am digressing. Therefore I here conclude at once, by observing that Mr. Kerr's book would have been none the worse had he both taken up and

brought down the history of our domestic architecture much later than he has done. Hypothral or ceiling fenestration is, for instance, a most important modern improvement, one connected with planning, and that deserves to have been spoken of at some length. ART-LOVER.

#### ENCOURAGEMENT FOR ARTISANS.

SIR,—In reference to your article headed "Drawing for Artisans," I beg to say a few words of encouragement to those to whom you allude. I believe it is possible for any man, with the slightest idea to begin with, to attain sufficient knowledge of drawing to enable him to fill any ordinary situation of trust that may arise in his own branch, or to take the entire charge of works, if he have but the will to go into it: the greatest difficulty lies not in learning, but in beginning to learn. Take my own case, for example: apprenticed in a country village, without a relative or friend in any branch of the trade, you may guess I had no royal road before me; but I had a will. I am proud to say that I have filled situations of trust in my own branch on works of almost every description and magnitude, and also as general foreman of not small jobs, without intermission, for fifteen years (I am now forty-five), and I commenced to learn to draw after I had a family about me to provide for. Not being able to purchase instruments, I began with a pair of iron compasses, with a pencil tied on one leg with a piece of string; but my will carried me through. I managed to get a few old instruments, one at a time, and without a half-hour's instruction from any man, in my own home; and by the light of the candle, and after many a hard day's work, did I study and persevere and succeed so far that (although far from being a clean clever draughtsman) I am enabled to make any ordinary working drawing, plan section, &c., and strike out any geometrical figure in ordinary use in the trade, and many others that are not; intersections of lines, &c.; and set out any work that comes before me on any plan, and without the assistance of any one. In conclusion, I say to them, persevere, and you will, I am certain, never lose if you never gain. A BRICKLAYER.

#### THE NEW ART CODE OF "THE DEPARTMENT."

SIR,—In reply to your correspondent of last week, "A Master," touching the "New Art Code," as the schedule appended to the Council of Education Minute of the 8th ult. may be called, it is quite true that an intelligent school-boy could take, and has taken, the second-grade drawing-certificate; but it is not so that this forms the standard of art-knowledge which will future be required in masters of art-schools.

The new art-code takes cognizance of elementary drawing alone as a basis on which to calculate State payments in aid, and very properly, I think, greatly extends the area of instruction in elementary drawing, by proposing to make payments whenever it is taught to artisans, provided only the teacher has himself a certificate for elementary drawing—the second-grade certificate. The managers of art-schools are left at liberty to provide the highest and best instruction adapted to the requirements of their locality, and to charge remunerating fees for it. This tends to cause art-school managers to investigate the qualifications of candidates for masterships, and to secure the best available talent, rather than to rely upon the validity of a so-called art-master's certificate, which, I can assure you, under the old rules did not require an overwhelming amount of art-knowledge to obtain.

The accounts of the art grant are in future to be kept separate from the grant for the museum, so that the public will be able to judge to what extent it is misappropriated. Because payments for art pupil-teachers are abolished, it does not follow that a master with three or four classrooms will find himself without assistance. If he can fill a large school with paying pupils, there is no doubt that efficient assistants may be found, and money to pay them.

Art-masters are not the only professional men who study at great expense to themselves and some cost to the State, and yet have to strive to live without direct or indirect State assistance. This minute may displace a few bad art-masters; but it resists with the local committees, who by this minute have become entities, to see that

the art-master holding his appointment from them faithfully and loyally discharges his duties. To state that the art-master is interested in preventing the spread of art-knowledge because every person possessing the elementary certificate becomes a rival teacher, as well paid by the State as himself, is mere halderdash.

The promotion of elementary drawing-classes in mechanics' institutes and night-schools, taught by second-grade teachers, is likely to strengthen greatly the hands of the art-master, as these classes will act as feeders to a good central school.

"A Master" makes no allusion to the removal by the new minute of much irritating and harassing surveillance; to the withdrawing of the restriction as to the amount of fees; and the liberation from the dry, illogical, heart-wearing course of instruction in twenty-three stages and sixty-one sections, under which art-masters have groaned for years; and many minor relaxations, which are like the glimpses of liberty to the life-long toiling slave.

DAVID W. RAINBACH.

#### DRYING BY GAS.

To attempt to dry by combustion of gas appears to be a mistake, for in small chambers at least, where there is no ventilation, instead of evaporation, moisture is produced, and condenses upon the walls. This I have found from repeated experiments, and was much puzzled for some time by a solicitor's strong room, which I had built, obstinately refusing to become dry, although favourably situated for the process, and a jet of gas being kept burning day and night. The consequence, however, was, that the papers and parchments became acid and damp. The mischief has been entirely and speedily remedied by inserting two terra-cotta ventilating bricks, and extinguishing the gas. In a washing lobby, also, in one case the gas was left burning for five hours, when the paper on the walls was found to be saturated with moisture for about 1 ft. in width, and below the level of the light, and where, as on varnished parts, it could not be absorbed, the moisture hung in great drops as if a pipe had leaked. The combustion of gas, therefore, in confined chambers produces a moist atmosphere instead of a dry one.

T. G.

#### CHRISTIAN GRAVES.

No one can walk through our churchyards and cemeteries without being impressed with a conviction that an earnest and affectionate regard is being paid to the memories of the dead, in the many and varied forms of Christian memorials which mark their resting-places.

One cannot help feeling, however, that hitherto we have been expressing our affection rather upon the memorials of our dead than on the actual abode to which we consign them.

Surely there is an opportunity afforded to us for expending a loving care on the tomb itself, before we commit those dear to us, who sleep in death, to their last resting-place, if only to relieve ourselves from that association of gloom which falls upon us when our minds revert to the spot wherein we have laid all that is earthly of those loved ones who are lost to us.

The Pagans in ancient times lavished more care on, and rendered more cheerful, the sepulchres of their dead than do we Christians of the present day.

The custom that now prevails with ourselves is, simply or at most, to build a common brick vault, which at best has but a bare and repulsive aspect, but which might be made to form the groundwork of a cheerful sepulchre, if converted from a gloomy prison-house; if then would tend to soothe the lacerated feelings of sorrowing relatives, who would feel that the expressions of their care and love surrounded and enshrined the object of their affections, instead of only being expressed on the surface memorial.

It is but recently that two great funerals have taken place, and nothing that affection could suggest, or that money could procure, seemed wanting to surround the remains of the two illustrious personages; but all exhibition of feeling terminated on this side the grave, instead of, as it were, following them into it. The contrast was very striking when the richly-decorated coffins were consigned to common brick vaults,—the one vault, I am informed, being a white-washed pit in the earth, perhaps meant as a slight attempt at decoration; the other, which

I witnessed, was a common brick vault, wherein lay exposed the coffins of the illustrious predecessors of the deceased.

I was lately present at the funeral of the son of an eminent architect, whose grave seemed to me to be free from the objections I have alluded to. It was formed of the brickwork, the internal faces of which were lined with encaustic tiles, having some simple Christian emblems introduced, together with ornamental and plain tiles, in simple forms, surrounded by ornamental border-tiles, the whole treatment giving a cheerful aspect to the tomb; and doubtless it conveyed to the sorrowing relatives a train of more pleasing associations than a gloomy brick vault could possibly have suggested.

I am aware that many difficulties present themselves, owing to the necessarily limited time allowed for the preparation; but tile-manufacturers would doubtless be prepared for an emergency of this sort if a demand were created, and would keep a supply of tiles of suitable designs ready to be used at a short notice, the other materials being easily procurable. C.

#### MAIN DRAINAGE OF THE METROPOLIS.

ANOTHER section of this work has been just completed, namely, the Northern Middle Level Sewer, by the admission of the sewage into the aqueduct crossing the Metropolitan Railway at the back of the Sessions House, Clerkenwell. This aqueduct is of the extreme length of 150 ft. over the bearings, and is constructed of boiler-plate, the tube being suspended between two girders, which are 12 ft. deep, and are calculated to bear a load of 600 tons, they having been tested to 250 tons, with a deflection of half an inch only. The tube itself is 8 ft. 9 in. in the clear, and is calculated to contain 60,000 gallons. The tube weighs 240 tons. The contract for the construction of this portion of the Main Drainage embraced the formation of twelve miles of sewers, of sizes varying from 4 ft. to 12 ft., and the whole has been carried out by the firm of Brassey, Ogilvie, & Harrison, under the superintendence of Mr. Bazalgette, the engineer in chief; Mr. Lovick, the resident engineer; and the staff of the Metropolitan Board of Works.

His Royal Highness the Prince of Wales has accepted the invitation of the Metropolitan Board to open the Main Drainage Works: Tuesday, the 4th of April, is appointed for the ceremony.

#### GALVANIZED IRON TANKS.

Sir,—Will your correspondents inform me as to the effect of a severe frost on a riveted iron tank which is filled with rain-water? I want to substitute a tank for the rain-water butts. May the water safely remain in the tank during a severe frost? F. K. C.

#### COMPENSATION CASES.

*Hart v. Metropolitan Railway.*—An inquiry was held in January and February last before an umpire (Mr. B. Brandon) as to the compensation to be paid to the occupier for his leasehold interest, nine years unexpired, in No. 1, Chapel-street, Edgware-road, at 80l. a year, with the contingent extension by the lease of the tenants for a further term of twenty-one years if he should obtain a renewal. Mr. Hawkins, Q.C., appeared for the claimant, and Mr. Horace Lloyd for the company.

It appeared that the company had encroached on the rear of the premises in question used as a beerhouse, and preferred exercising their power to purchase to altering their buildings.

The claimant and his manager were called to prove the extent of the trade at 200l. per annum net profit, and Mr. E. Roberts for the valuator (of the lease and goodwill). The company did not call witnesses, but relied on a speech by counsel, who denied that there was any profit, and that there was any value in the contingency of a renewal, and suggested 100l. or 500l. as the maximum.

The claim was for—  
 Lease and goodwill..... £1,280 0 0  
 Contingent renewal and probable  
 spirit license..... 500 0 0  
 Fixtures, removal, &c..... 225 0 0  
 £2,005 0 0

The award has now been given for 1,230l.  
*Faulkner v. Metropolitan Railway Company.*—An inquiry under similar circumstances was held in January, before Mr. B. Brandon, umpire, to assess the compensation of a term of 2½ years unexpired term in a lease and occupation of No. 6, Chapel-street, Edgware-road. The claimant carries on the trade of a coffee-house, and proved a net profit of 570l. a year. Mr. Barrow appeared for the claimant, and Mr. Holloway for the company.

The witnesses for the claimant were Mr. F. Roberts, Mr. F. Chinnock, and Mr. Driver. Their estimates were from 500l. to 600l. The company's witnesses, Messrs. F. Clarke, Shaw, and Pownall, ignored the lease, as being of no value, and estimated the compensation at 300l. to 322l.

The award has been published at 481l. 14s. 6d.

#### CHEDDLETON CHURCH, STAFFORDSHIRE.

THE restoration of Cheddleton Church, near Leek, has received a further instalment towards completion, by the fixing of the churchyard cross, which has been restored from the designs of Mr. G. G. Scott, architect. The old cross stood on a base of four large steps: these, with about 5 ft. of the shaft, were all that remained. The shaft is a clustered column of four smaller ones, placed midway on the faces of a square pillar. The newly-added portion consists of a continuation of the shaft, with capitals, canopies, and cross. The canopies or niches contain the figures of four kings: these are surmounted by a cross of foliated designs, bearing the figure of our Lord. The kings, as nursing fathers of the Church, are represented as follows:—Melchisedec, as priest and king, bearing chalice and sceptre; David, as warrior, king, and musician, with sword and harp; Solomon, with sceptre, holding a model of the temple; Edward the Confessor (to whom the church is dedicated) with sword and shield of five martlets about a cross fleury. On the back of the cross are five small shields, bearing the emblems of the Passion. The whole is carved in Wetley Rocks and Roche stone, by Mr. Farmer, of London. The stone was supplied by Mr. H. Goldstraw, of Wetley Rocks, builder, under whose direction the cross was fixed. The total height is almost 20 ft. It is, we believe, the offering of a parishioner.

#### CHURCH-BUILDING NEWS.

*Boys Hill (near Maidenhead).*—The tower, with spire, of All Saints' Church is now in progress. It is in the Decorated style, 80 ft. high from the foundation, and the spire rising 70 ft., makes a total of 150 ft. The architect is Mr. Street, and the work is in the hands of Messrs. Silver & Son, Boys Hill. The tower will be handed with red and black bricks (monied by Messrs. Silver), with Bath stone dressings, and the spire will be faced with Bath stone. The bell-chamber will be constructed for eight bells, and the ground-plan is 20 ft. square. The contract is to be completed by August next. A curate's and governess's house and three almshouses have been erected, and four of the windows in the church have been filled with stained glass (by Mr. Wailes, of Nowenstlo), of which the following are the subjects:—On the north side, the Slaying of the Innocents, the Flight into Egypt, the Presentation in the Temple, Jesus disputing with the Doctors, and the Baptism of Jesus; on the south side, the Incandulity of St. Thomas, and Jesus walking on the Sea. We understand that the two in the western end will shortly be filled with stained glass by Messrs. Connor, when the whole of the windows will be of stained glass.

*Taunton.*—St. James's Tower, having of late shown signs of external decay, a vestry meeting has been held, at which a report by Mr. Metford, architect, as to what was requisite to restore the tower without destroying it, was read, and it was resolved that measures should be taken to that end. In the event of Mr. Metford declining to undertake the superintendence of the work, it was resolved to employ Mr. Pollard.

*Stoke Priory (Herefordshire).*—The parish church has been re-opened, after being closed for restoration during the last six months. A new roof has been put upon the nave. Almost the whole of the west wall has been rebuilt, and a new window of stained glass (by Messrs. Chance & Co., Birmingham) has been inserted, being the gift of Mr. J. Corbett, churchwarden. Two coronas, from Messrs. Hardman & Thomason, of Birmingham, with eight standards and four altar candlesticks, have also been placed in the church by subscriptions. The walls of the nave and chancel have been scraped and pointed. Other improvements have been made. The whole of the work was carried out under the superintendence of Mr. Bohill, foreman over the Stoke Prior Salt-works. The whole expense is estimated at about 1,000l.

*High Ercall (Salop).*—St. Michael's Church has been restored and re-opened. The plaster ceilings and ornamental plaster-of-Paris cornices have been taken down, and the original carved trusses and corbels have been restored to their former character. The timbers have been cleaned, oiled, and plastered between the rafters. The roofs have been retiled and finished with an ornamental crest from Mr. Burton's works, Ironbridge. The external walls have been divested

of plastering, and the stonework repaired and painted. The stone carving to pier caps and bases has been restored. The gallery at the west end, including the organ, and the lath-and-plaster partition in the tower arch, and ringed-loft floor, removed, and the tower thrown open to the nave. The high pews and sittings have been removed, and the whole re-seated with oak benches. Various other restorations have been effected. The architect employed was Mr. G. E. Street, of London; and the works have been carried out by Messrs. Nevett, Ironbridge, under the superintendence of Mr. Mellors. Two stained glass windows, from the establishment of Messrs. Lobin et Fils, Tours, have been presented to the church by Mr. Patric Hunter, of Roden and Mount Allyn. The whole of the other windows in the church were supplied by Messrs. Done & Davies, of Shrewsbury.

**Derby.**—Christ Church has been re-opened. The alterations consist of the formation of a new chancel, with organ chamber and vestry. The new chancel is 18 ft. in width, and 26 ft. in length, with octagonal termination. The four lancet windows have been fitted with stained glass, presented "In memoriam" by Mr. John Walters. The floor is laid with Maw & Co's encaustic tiles. The total number of additional seats provided by the extension of the church, the extra seats in the chancel, and the removal of the organ from the gallery into the new chamber, is 100. The edifice has been heated with hot water. A new infants' school, 40 ft. long and 20 ft. wide, has been erected in connexion with the present schools, at the back of the church. The external walls are faced with Whitwick white bricks, relieved with blue and red brick dressings. Mr. Crump supplied the stained glass and hot-water apparatus for the church, and Mr. Woodhouse the gas-fittings. The whole of the remaining works were executed by Mr. E. Thompson, builder, all under the direction of Messrs. Giles & Brookhouse, architects, at a cost of about £1,000.

**Dewsbury.**—The recently completed Gothic church, in Halifax-road, dedicated to St. Mark, has been consecrated by the Bishop of Ripon. The edifice is from designs by Messrs. Mallinson & Henley, of Bradford, architects. The nave is separated from the side-aisles by arches springing from plain circular freestone pillars. These arches are eight in number. Above them rises the clerestory, which is lighted by a corresponding number of spherical-triangle windows. The roof of the nave is open-timbered, and of steep pitch. The aisles have lean-to roofs corresponding to the nave, and both are lighted by three-light tracery windows at the sides. The transepts have windows of four lights at the end, besides others of smaller dimensions at the sides. The chancel, which rises a couple of steps from the body of the church, is separated from it by a lofty arch springing from carved capitals, which surmount polished pillars made of Aberdeen granite. The floor is laid with encaustic tiles. The east window has four lights, and is filled with tracery; but in none of them is placed any stained glass. All the seats are free and open, made of stained pine: they will accommodate about 650 people. The tower, which is surmounted by a spire, and is a principal feature of the church, rises to a height of about 180 ft. It is almost wholly of dressed stone, and bears several lights, which are similar in design to the windows. To Mr. J. Chadwick, now of Miffield, is due the origination of the scheme for building the church. He gave the site and land for a school-house and parsonage, of the value of 2,000l., besides 400l. to the building fund, and 600l. towards the endowment. By October, 1862, 3,000l. had been obtained; nearly 1,500l. were realised by a hazard at that month; and in the November following the foundation-stone was laid.

#### RECENT PATENTS CONNECTED WITH BUILDING.\*

CONSTRUCTING OR FRAMING LIGHTHOUSES, HOLLOW METAL PILES, AND CYLINDERS, &c.—*J. N. Douglass.* Dated 5th April, 1864.—In constructing or framing lighthouses, hollow metal piles, and cylinders, the patentee employs a series of quadrilateral frames or panels, each frame being complete in itself, and made of angle iron or metal of any convenient section, welded up or otherwise fixed together, so as to make rigid frames. If the structure to be framed be cylindrical, the frames may be similar from

end to end, and each frame is curved to the radius of the cylinder. In forming the structure, the frames are put together edge to edge, so that the diagonals of each frame run longitudinally and transversely of the structure. The sides of the frames or panels are each of them riveted or fixed to the side of another frame or panel which is in contact with it, and the angles of the frames so meet that their junctions are perfectly fished, the angles of four frames meeting in a point, and then one pair of frames serves to fish the other pair; thus the sides form double ribs or webs crossing each other, and running continuously and spirally from end to end of the structure in opposite directions. If the structure is to be taper, and not cylindrical, the frames will not be exactly similar throughout, but will gradually decrease in size as the structure tapers away. To a framing thus constructed, metal plating may be applied, as may be convenient, being riveted or otherwise fixed to the webs of the frames. The patentee prefers that the plates should be of sufficient size to pass over two or more frames, as the strength of the structure is thereby increased.

GLAZING HORTICULTURAL AND OTHER STRUCTURES.—*C. Beart.* Dated 7th April, 1864.—For the purpose of this invention, in place of supporting the squares of glass with which the building is to be glazed, on iron bars, made with the usual sash-bar rabbet, as is common when iron sash-bars are employed, the squares of glass are supported by bars of T iron, or of other suitable section, having one flat side upon which the said edges of the squares of glass are to rest, and the squares of glass are held against the flat side of the T or other iron by bars of half-round or other suitable section of iron, having a flat side, the edges of the squares of glass being nipped between the flat side of the T and the flat side of the half-round iron. Between the surfaces of the glass and the flat side of bar iron, strips of very soft thick paper, or paper wadding, or materials manufactured from a pulpy substance, or any soft elastic fabric, are placed, thus avoiding the use of putty; the outer bars of iron are drawn towards the inner bars of T or other iron by means of screws or otherwise; the squares of glass are cut to any suitable length, and are of a width slightly less than the distance between any two of the T or other sash bars, so that the flat side of each sash bar may support the side edges of two squares of glass. The squares of glass are so placed together that each corner of a square of glass meets the corners of three other squares, and the corners of all the squares are cut away in order to form spaces wherever the corners of four squares of glass come together, through which the screws which draw together the upper and under bars may pass.

#### Books Received.

*Fraser's Magazine* for March (Longman & Co., publishers), contains a paper advocating Working Men's Clubs and Institutes, with the purpose of engaging the attention and interest of the higher classes in favour of the movement, as one highly beneficial to the working classes, and capable of withdrawing them from the meretricious attractions and abominable influences of the beer and gin shops. Our warmest sympathies are in favour of the Workmen's Clubs and Institutes. *Fraser* also contains the concluding part of Miss Frances Power Cobbe's able though a little transcendental paper on the "Hierarchy of Art."—A "Familiar description of the old Delabole Slate Quarries," by Mr. J. T. E. Turner, has been published (price 6d.), at Stonehouse, by J. Lewis, Union-street.—"Report upon the System of Weaving, by Compressed Air in the Patent Pneumatic Loom." By Thomas Page, C.E., Cambridge; Naylor, Chronicle Office, Market-hill.—"We have already given an abstract of Mr. Page's Report on this ingenious and important invention of Mr. Charles Weightman Harrison, whose name will doubtless be henceforth permanently associated with those well-known geniuses by whom the power-loom has been created and matured. His simple but beautiful invention relates exclusively to the shuttle, which it shoots forth by the force of compressed air, directly applied, thus doing away with complicated mechanism, and uncertainty, and even danger in working. It also compels a continual supply of fresh air in factories and workshops, and must thus promote health and vigour in the work-

people.—"British Rainfall, 1864." Compiled by G. J. Symens. London: Stanford." This thick pamphlet contains an elaborate account of the distribution of rain over the British Isles during the past year, as observed at about 900 stations. It is illustrated by a map and other engravings.

#### Miscellaneous.

LITERARY FUND.—The annual dinner will take place at the Albion, on May 10th. The Archbishop of York will preside.

LIVERPOOL.—The new building for which the tenders are given in their proper place, is the first structure in a new line of street to extend from North John-street, by Temple-court, to the foot of Manchester-street, opposite St. George's Hall.—We hear with great pleasure that within the last few days Mr. J. A. Picton, architect, has been placed on the commission of the peace.

THE ROMAN REMAINS AT BRADWELL, ESSEX.—A *soirée* in connexion with the Chelmsford and Essex Museum has been held, at which various objects of interest from Bradwell were exhibited, and the Rev. F. Spurrell read a paper on Bradwell as the Roman Othone, in which he maintained that the chapel remains must have been a basilica in Roman times.

TRIBUTE TO SIR ROWLAND HILL.—A deputation of gentlemen, representing the merchants and shipowners of Liverpool, have presented to Sir Rowland three pictures, as a testimonial of the high estimation in which they hold his improvements in the postal arrangements of the country. Sir Rowland had been consulted on the form which he would desire the testimonial to take, and selected pictures by Stanfield, Creswick, and Cooke.

APPOINTMENT OF SURVEYOR AT COCKERMOUTH. At a meeting of the Local Board on the 20th ult., on the motion of the chairman, seconded by Mr. Mitchell, it was unanimously resolved, "That Mr. T. F. Middlemiss, C.E., of Sunderland, be appointed surveyor to the Board, at a salary of 50l. a year, with liberty to practise without the district, but not within the district, and to reside in the district." There were thirty-two candidates for the situation.

PARAPET ON THAMES EMBANKMENT.—I understand that the terrace walk of the Thames Embankment is to have a parapet 4 ft. high. Even if this is open balustrade, would it not go a long way towards destroying by its height the cheering open effect which ought to be the chief consideration in the splendid promenade which we may expect from this great work? When crossing Waterloo Bridge, it will be seen that unless people are walking close to the parapet, they will see nothing of the beautiful river and its busy highway. I mention this in the hope that those in power may perhaps reconsider this important feature, which an artistic eye will fully realize.—FATHER THAMES.

BOMBAY CATHEDRAL.—Supplementing particulars already given, we may mention that a large organ has been built for Bombay by Messrs. Bishop & Starr, and seems a fine instrument. It includes three complete manuals, and the total number of pipes is 1,604. The interior woodwork is of hard mahogany, to suit the climate of India, and the metal pipes are of spotted metal. It has two fronts; one towards the choir, and the other to the aisle. The case, which is of oak, with a superstructure of iron-work enriched with copper and brass, was designed by Mr. Roger Smith.

PARIAN CEMENT.—Some time ago in describing the Charing-Cross Hotel, we mentioned incidentally our inference from personal experience, that this material does not always bear painting on so quickly as is supposed, and is not so hard as another cement that was named. Messrs. Bellman & Ivey combat this opinion, and attribute our own disappointment to the fact that some of the material sold as Parian cement is of a very inferior quality to what it should be. They state positively, "after large experience with Parian cement, commencing before its introduction to the public, and up to the present time, and constantly using it upon works large and small of various kinds, without one single failure, that it will always bear painting on not only quickly, but the quicker the best."

\* Selected from the *Engineer's* lists.

**THE COURTS OF JUSTICE BUILDING BILL.**—This Bill has been read a third time, and passed the House of Commons.

**CAMBRIDGE PROFESSORSHIP OF ARCHEOLOGY.** Notice has been given that the Disney Professorship of Archeology having become vacant by the resignation of Professor Marsden, the election of a person to fill the office will take place on April 4, 1865. The professor must be a member of the University of Cambridge, and of the degree of Master of Arts, or of some higher degree.

**A PUBLIC PARK FOR SWANSEA.**—The *Cambrian* says:—"We cannot see without regret our noble sands being gradually cut up and demolished by the extension of docks and the carrying out of railway schemes, field after field being laid out for building purposes. In a few years opportunities which now present themselves for a people's park will present themselves no longer; the few green spots which now dot the outskirts of our locality will be covered with villas, or still more humble homes. We sigh in vain for some nobleman or princely merchant to devote some few acres of his estate to such a noble purpose as a public park."

**NEW DOCKS, BLACKWALL.**—In anticipation of the increasing demand for graving docks to receive the largest class of vessels, the Thames Iron Works Company are now constructing two dry docks at Blackwall: one will be 450 ft. long, 64 ft. entrance, and 23 ft. deep; the other, 350 ft. long, 55 ft. entrance, and 21 ft. deep. The works, which are being executed by Messrs. John Aird & Sons, from the designs of Mr. Alfred Giles, C.E., will be completed in October, at a total cost of about 80,000*l.*, inclusive of pumping engines.

**SALE OF CONTRACTOR'S PLANT.**—The surplus plant remaining at the completion of the Northern Outfall Sewer, at Barking and Plaistow, was brought to the hammer during the week, by Messrs. Fuller & Horsey, and attracted a large attendance of buyers. Three locomotives brought respectively 1,000*l.*, 550*l.*, and 270*l.*; six hundred tons of rails, 5*l.* 17s. 6d. to 4*l.* 7s. 6d. per ton; sixty-six iron-bodied earth-wagons, 13*l.* to 13*l.* 5s. each; fifty-four ballast trucks, 12*l.* 10s. to 14*l.* each; sixty-eight end-tip waggon, 11*l.* to 11*l.* 10s. each; one hundred and thirty side and end tip waggon, 7*l.* 15s. to 8*l.* each; six thousand sleepers, 6d. to 1s. each; and the other odd lots found plenty of buyers. The total amount will exceed 10,000*l.*

**THE AMALGAMATED SOCIETY OF ENGINEERS.**—A Birmingham contemporary, in allusion to a recent meeting of this society at Birmingham, says:—"The Amalgamated Society of Engineers may justly claim to stand at the head of all trade-unions. Possessing branches in all parts of the United Kingdom, gradually sending out new shoots into the continent of Europe, and numbering their members by tens of thousands, their funds are enormous, and their weight in any trade dispute necessarily almost irresistible. Yet for many years past they have engaged in no great strike; nor, so far as we are aware, have they been charged with using their vast influence to encroach upon the rights of the masters. The secret of all this prudence and moderation, we suspect, lies in the fact that their trade-union is also a great mutual benefit society. Since 1851, they have spent in this way half a million of money. In 1862, they spent 34,000*l.*; in 1863, 84,000*l.*; and they have at the present time a balance in hand of 85,000*l.*"

**MONKSILVER, SOMERSET.**—An unusually good example of a monumental cross has recently been erected in the village churchyard of Monksilver, in memory of the Rev. W. F. Chilcott, of that parish. It stands on the site of the old churchyard cross, and is about 12 ft. high. The steps are of red sandstone, and the remaining portions of the yellow Ham Hill stone, the contrasted colours producing a pleasing effect. At the angles of the base are sculptured the conventional emblems of the four evangelists. At the ends of the four arms of the cross on the east side, are the symbols of our Lord's gifts to His Church;—Himself in the Lamb, Baptism in the Dove, Holy Communion in the Chalice, and the power of Remission in the Keys. Between these symbols the vine is introduced. On the west side are sculptured the symbols of the Passion;—the crown of thorns, spear, reed, sponge and dice, the hammer, pliers, and the nails. The work was executed by Mr. John Seymour, of Taunton, from the designs of Mr. C. E. Giles.

**SWANAGE: QUARRIERS' v. "PURBECK MARBLERS."**—The quarriers of this neighbourhood, says the *Dorset Chronicle*, appear now to be divided into two parties—first, those who believe in the solidity and value of their code of laws, rules, customs, and usages as an ancient order, having certain privileges, and who accordingly act and say they can keep and secure the stone trade in their own families and company; secondly, those who do not believe in the same, and who accordingly act and say that there is and must be more freedom, openness, or liberty in their trade.

**NEW MAP OF THE PARISHES OF ST. GILES-IN-THE-FIELDS AND ST. GEORGE, BLOOMSBURY.**—The old map of these parishes was made in 1815, by Mr. Mawley, but owing to the great alterations in every direction since that time, it has been rendered entirely useless. The new map was entrusted to Mr. George J. J. Mair, and has just been handed over to the vestry. A plan of each property is shown, and at a glance is distinguished from the adjoining properties by an arrangement of cross hatching; a book of reference gives a further description. The parishes contain 215 acres (38 of which are open ground in squares), and 4,701 dwelling-houses. The parish churches in the margin, and the whole map (5 ft. by 5 ft. 6 in.), are drawn by Mr. J. H. Swan. It is framed, glazed, and mounted on an easel with castors, for the use of the appeal committee.

**THE CHURCH OF ST. CROSS, WINCHESTER.**—A gentleman of position in the county, a lessee of the Hospital, has undertaken, at his own expense, the decoration of the eastern wall of the church, after a pattern prepared by the architect, and approved by the master. In the letter in which this offer is made, the writer says, "That this work of restoration should be brought to a successful issue in a manner worthy of the subject, is a matter of not merely local interest, but one which has a claim on the sympathy of the whole county. As one who has an interest in all that concerns this county, I therefore trust that I may be permitted to offer as a gift to the church the decoration of the east wall according to Mr. Butterfield's design. It would give me the highest satisfaction if others should be induced thereby to apply to the two side walls of the choir similar decoration, so that all this portion of the church may be brought into harmony."

**ACCIDENTS.**—The outer walls of a warehouse in St. Rumbold's-lane, Lincoln, have fallen, but fortunately no person was injured. The warehouse contained from 1,200 to 1,400 quarters of malt, and the walls, being thin, were unable to bear the pressure of so great a weight. One of the buildings of the Leeds Old Foundry, Mill-street, has suddenly given way, and injured three persons. The accident was a very old one. A large portion of the side wall fell in without the slightest warning, and the support being removed from the roof and flooring, they also gave way. —A fire has occurred in the Manchester United Bank, from the ignition of the trimmer, on which a hearthstone rested, and which extended into the fire of the Bank Board-room. —The Roman Catholic convent of St. Benoit, at Calata, Constantinople, has been destroyed by fire. One of the walls suddenly fell outwards, hurrying a great crowd of people, and some of the fire-engines at work on the fire. A shocking slaughter must have resulted.

**IMPROVEMENT IN CHATHAM DOCKYARD.**—The sum of nearly 100,000*l.* has been taken by the Admiralty in the Navy Estimates for 1865-6, for the new works to be executed during the year for the enlargement and improvement of Chatham Dockyard, as well as for the other undertakings connected with the extension of that establishment. Of this amount the sum of 70,000*l.* will be required this year for the construction of the additional docks and basins, and other works for the enlargement of the dockyard. The original estimate for the extension of the dockyard by throwing into the establishment the whole of St. Mary's Island, containing between 300 and 400 acres, was 943,876*l.*, a further sum of 306,124*l.* being required for additional work now proposed to be executed by contract, making the total estimated outlay 1,250,000*l.* Hitherto the whole of the works have been executed by convicts, some 800 or 900 of whom have been daily employed on the undertaking for some years past; but the Admiralty have decided on supplementing their efforts by the employment of skilled labour, at an additional outlay of 300,000*l.*

**CAMBRIDGE.**—The question of a new corn exchange is mooted in the town council. The site and a design have been already provided.

**TENDERS**

For Commercial Buildings for Messrs. Fowler, Brothers, Temple-court and Temple-lane, Liverpool. Messrs. J. A. Panton & Son, architects. Quantities supplied:—

Yeal & Son	410,175 0 0
Holme & Nichol	3,730 0 0
Mullin	9,687 0 0
Burroughs & Son	9,617 0 0
Bowe & Son	9,581 0 0
Tomkinson	9,500 0 0
Georges	9,500 0 0
Hay	9,498 0 0
Urmon (accepted)	9,398 0 0

For new infirmaries and other works to the Ipswich Union House. Mr. H. M. Phipson, architect:—

Morley	42,457 0 0
Cannold	2,373 0 0
Bennet	2,313 0 0
Blackell	2,243 0 0
Girling	2,247 0 0

For Southsea Beach Mansion, for the Southsea Mansion Company (Limited). Mr. Whitchord, architect. Quantities supplied:—

Foster	414,350 0 0
Light & Roberts	14,100 0 0
Backhurst	13,600 0 0
Ball & Sons	13,862 0 0
Abraham	13,755 0 0
Stephens	12,540 0 0
Stevens & Marten (accepted)	12,440 0 0

For Tavern on Miss Kell's estate, Curtain-road. Mr. Reddall, architect:—

Maers	1,172 0 0
Smithers	1,156 0 0
Kell	1,140 0 0
Kiddle	1,141 0 0
Killy	1,128 0 0
Browne & Robinson	1,115 0 0

For the erection of three houses, Stafford-road, Old Ford, Bow, for Mr. Ames. Messrs. T. & W. Stone, architects:—

Sonster, Brothers	1,257 18 0
Wise	958 0 0
Davies	950 0 0
Evans	832 0 0
Norman	907 0 0
Higgs	907 0 0

For the erection of a pair of residences, Forest-park, Stratford, for Mr. B. Warner. Messrs. T. & W. Stone, architects:—

Higgs (accepted)	4,800 0 0
------------------	-----------

For the erection of a pair of semidetached residences, with stabling, for Captain Morris, at Anerley, near Penge. Mr. J. H. Rowley, architect:—

Rivett	43,803 0 0
Rider	3,567 0 0
Brass	3,517 0 0
Manley & Rogers	3,457 0 0
Piper & Wheeler	3,440 0 0
Hill & Keddell	3,366 0 0
Longman	2,965 3 0

For the erection of five cottages at Penge, Surrey, for Mr. Wrenn. Mr. Theodor Barber, architect:—

Dunk	8,285 0 0
Jarrett	796 0 0
Evans	718 0 0
Lamberton	718 0 0
Loze (accepted)	687 15 0

For new warehouses and offices, for Mr. Wood, Bank-side, Southwark. Messrs. E. Habonson, Spalding, & Brock, architects. Quantities supplied:—

Carter & Son	42,336 0 0
Patman & Potheringham	2,175 0 0
Shippington & Cole	2,109 0 0
Simpson	2,053 12 6
Kawlings	1,987 0 0
Manley & Rogers	1,984 0 0
Dover	1,869 0 0
Newman & Mann	1,856 0 0
Stephenson	1,846 0 0
Sawyer (accepted)	1,825 0 0

For taking down and re-building three houses at Nine Elms, for Messrs. Robbins & Miller. Mr. Charles Bowes, architect. Quantities not supplied:—

Nixon	41,165 0 0
Wootton	1,073 0 0
Young	1,058 0 0
Hancock	940 0 0
Lathley, Brothers (accepted)	923 0 0

For building a public-house in the City-road, and house in Providence-street, for Mr. Whittett. Mr. W. E. Williams, architect:—

Faxon & Chapman	42,547 0 0

# The Builder.

VOL. XXIII.—No. 1154.

Restorations in Northern Italy: Milan.

LATE visit to Milan sufficed to convince us that the Italian Government, notwithstanding many preoccupations, is actuated by a generous and intelligent spirit in regard to public works, and that not in the sphere of the utilitarian only but also of the monumental; and moreover, spite of antagonisms now so irritably active between civil and ecclesiastical powers,—in that class which pertains to the sacred and Medieval. Besides the complicated works at the wonderful Duomo, presented (as we understand) without intermission since the Lombardic provinces were annexed to the Italian Crown, other undertakings of high antiquarian interest have been progressing in the local metropolis, which ranks third (after Naples and Turin) among cities of the newly-constituted kingdom, Milan being peopled (according to the last census) by 196,109 persons in the midst of her fertile province, whose inhabitants number 948,320.

After having satisfied the feeling naturally excited by that marvellous cathedral, which seems like a "great ambassador from earth to heaven," to sanctify and elevate the very life around its sculptured walls, we first bent our steps towards the most venerable and characteristic among this city's subordinate sanctuaries, the Basilica of St. Ambrose, one of the most perfect examples of its style in architecture, and especially renowned for the sacred treasures under its olden vaults, though the edifice has indeed passed through great transformations since it served as the Cathedral of St. Ambrose himself, from whose portals that heroic prelate personally expelled the guilt-stained Emperor Theodosius after the massacre at Thessalonica. In the ninth century it was entirely rebuilt by the Bishop Anspertus, assisted for the costs sustained by the Emperor Louis the Pious; but that later construction was also destined to disappear, all except its apse and one of the two campanili, when another restoration was effected in the twelfth century, the actual vaulting, which is clumsy and ill-adapted, being of the century subsequent. Its brick façade is admirable of its class.

In the general aspect of this church, repose and quiet dignity, with the appearance of great solidity and venerably-simple antiquity, are characteristics that most impress. Its leading features are the arcades, with circular arches in two stories, the upper forming a gallery once appropriated to females; the ribbed vaulting, spacious crypt, altar-tabernacle (or baldacchino) amboles, and apse adorned with numerous mosaic figures; externally, the two towers divided into stories of blind arcades, the ample quadrilateral atrium (or *paradisus*) surrounded by arcades that rest on slight piers with capitals in imitation of the Corinthian; façade with gable summit and double arcade string-course under a cornice of very simple character; five arched windows rising in height from the lateral to the central, and single doorway with curious reliefs (animals and other bizarre figures) on the jambs, massive flat lintel, and archway above entirely covered with rich mouldings, one of the

signal examples of the Lombardic portal carried to its perfection in the cathedrals of Verona, Como, Ferrara, Ancona, and elsewhere in Northern Italy,—the region in which sacred architecture became first, after the fall of empire, enriched with a complete and intelligently-organized style, partaking of the Roman and Byzantine, yet in certain respects differing from both, and which continued to be dominant from the fifth to the eleventh century, wherever the Latin Church had obtained ascendancy,—though, unfortunately, scarcely a single building of this style remains unaltered to the present day, one only exception being pointed out in a small chapel at Friuli.

To return to S. Ambrogio: we found works there in progress for a restoration of its interior, intended to be in strict conformity with primitive types, and, so far as could yet be judged, giving promise of intelligent purpose. The double-storied arcades, between the nave and aisles, are to be cleared of the stucco and whitewash long disfiguring them; their archivolt reconstructed, where necessary, in a peculiar brickwork that seemed to us, in the parts finished, of appropriate character; the spandrels to be filled with fresco-painting; of what sacred subjects we could not obtain certain notice; nor could we learn from the *custode* the name of any artists commissioned for these works. Most interesting among the ancient paintings here, some of which cover the surfaces of massive square piers, is that brought to light by removal of the modern coating that had concealed it in 1863, representing St. Ambrose and his sister, St. Marcellina, in act of interring their brother, Satyrus, beside the body of the martyr St. Victor, in the basilica of Fausta, a still more ancient church, whose origin is referred to the period of Pagan persecution, and whose buildings were eventually absorbed into those of S. Ambrogio. The bodies of Satyrus and St. Victor were discovered and identified, to the satisfaction of ecclesiastical authorities, so recently as 1860. But another discovery, which could not fail to excite high interest both in the ecclesiastical and antiquarian circles of Italy, occurred within the walls of the same basilica in 1864, as first reported, by the Canon Biraghi (a Milanese clergyman distinguished in the walks of sacred archeology) in the pages of the *Osservatore Cattolico*, a periodical of the same city. On the 14th of January in that year, researches having been ordered in the hope of finding some saintly tomb, and a perforation made in the massive stonework behind the high altar, the explorers came in sight of a large urn of finely-tinted porphyry, built up under the *mensa*, with covering formed by two ponderous slabs of the same stone; and here at once authorities concluded that no less sacred a sepulchre had been brought to light than that containing the bodies of the three saints so revered at Milan,—Ambrose, Gervasius, and Protasius,—whose relics are known to have been removed from other—their original—resting-places to this more honoured tomb under the chief altar. On the following day the works were resumed, and the ground opened below the adjacent pavement in the sanctuary, where soon was found, right of the altar, a long sepulchral niche, lined with precious marbles, Phrygian porphyry, green, white, and other variegated species; the cavity being filled with fine soil, in which lay embedded some small fragments of bone, also a broken *ampolla*, like those found in Roman catacombs. Next was opened, in the prosecution of the same labours, another similar place of interment, left of the high altar, alike filled with soil, in which lay, besides bones, several teeth, portions of gold thread, and fourteen small coins, one with the effigy of Flavius Victor, son of the usurping emperor, Magnus Maximus, and on the reverse the legend, "*Spes Romanorum*;" another with the effigy of Theodosius, and on the reverse two Victories holding crowns and

palms; two other coins, of silver, with the head of the emperor Anastatius, and also the monogram of Theodoris, surmounted by a cross, a star below, with the legend, "*Invieta Roma, C.M.*," the rest being of the very smallest species, without intelligible symbols. Near this tomb was opened another cavity, like a well, covered by a slab of white marble, containing another broken *ampolla* and several marble fragments, which, pieced together, formed the base, part of the mouldings, and shaft of a classically-wrought column, supposed to have served for some penal purpose at the martyrdom of SS. Gervasius and Protasius,—therefore been thought worthy of such careful preservation. The story of these Milanese martyrs, of the discovery and transfer of their bodies to this very church by St. Ambrose, A.D. 386, is well known in local hagiography; and it is a like attested fact that those remains, together with the body of St. Ambrose himself, were exhumed by the Archbishop Angelbertus, in the ninth century, to be deposited in a more sumptuous tomb of porphyry, secured by massive constructions all around, under the high altar, above which that magnificent prelate caused to be placed (A.D. 835) the splendid shrine, or altar-pallium, of silver gilt, unrivalled for richness and beauty, studded with innumerable gems, and adorned with a series of elaborate reliefs (most interesting for their character and period in art-history); twelve of their subjects representing scenes in the life of St. Ambrose.\* Still the special treasure of this basilica is only exhibited to the public on a few solemn anniversaries, but at other times is to be seen with permission from authorities. We shall not here attempt to describe in detail this marvel of Mediaeval art and material richness, perhaps the most precious tomb in which mortal relics were ever enshrined.

Another church we found also undergoing restorations, apparently extensive and suitable, was S. Eustorgio, a curious and perplexing edifice, a labyrinth of chapels and different styles, rebuilt, in its main structure, in the ninth century, but with many lateral chapels of various dates, and one a graceful octagonal building of Renaissance architecture, added by Bramante, in the sixteenth century. Visiting this on a Sunday evening, we fell in with a stream of people thronging in the same direction, and soon discovered this to be a great festival at the same church; rich draperies being suspended from house to house across the long wide street (one of the ancient quarters) leading to it; and the temple itself alike decorated with showy hangings, anything but suitable to its venerable character, or the dusky solemnity of its vaulted aisles—an epigraph above the portal announcing this to be the fête especially for the benefit and at the cost of the Guild of Silk Weavers. Notwithstanding these devotions and pre-occupations, we were able to examine, fully and at leisure, the most celebrated and beautiful monument at S. Eustorgio, the sculptured shrine of St. Peter Martyr, which stands isolated, under a pavilion of curtains, behind the altar centrally placed in Bramante's chapel. This elaborate work, the masterpiece of Giovanni Baldaccio, a pupil of Giovanni Pisano, was finished in 1339, at the expense of the Milanese citizens, and of the King and Queen of Cyprus, whose effigies are introduced among the many sculptured groups; the subjects of the reliefs referring to the story of the canonized Dominican Inquisitor as follows:—St. Peter visiting and healing the sick; his assassination, near Como; his body exposed for public veneration; his funeral; a ship in a tempest, whilst the crew invoke and obtain miraculous aid from him; other miracles ascribed

\* In Di Rossi's "*Bulletin of Christian Archeology*," this pallium is described as plated with laminae of gold; and, if we remember rightly, the same report as to its material is given at the church. It was briefly described in our papers "*Going Along*."

to his intercession; besides which are twenty-four statues of saints and personified virtues, and on the highest story, under canopies with trefoil arches, the Virgin and Child, St. Dominic, and St. Peter Martyr. It seemed to us that rather than in the expression of heads, the merit of this most interesting monument consists in the movement of its groups, and able treatment of draperies; its heauty of effect, in the general architectonic character and intelligent accord between the two arts, the sculptor's and architect's. In Cicognara's work is a full and appreciating description of it, with the engraved outline.

Turning from monuments to humanity, we may add our testimony as to the manifest improvement, the increased signs of quickened life and energies, in Milan, under a constitutional Italian King, as compared with that under the Austrian ruler, and contrasted with Verona, where we had recently been. "Look but on this picture and on this!" should we be inclined to say if desiring to refute any advocate of the overthrown despotisms in this land, by the proof afforded to all whose eyes are open, in the two cities' conditions,—of gloom and decay on one hand, vitality and eagerly-directed progress on the other.

Among the public works at Milan should be mentioned two monuments to the illustrious dead—that (in project) of the humanitarian philosopher, Beccaria; and that recently finished, in bronze, at Florence, of Cavour; the latter with two colossal figures, the statesman erect, in rhetorical action, a folded paper in one hand, his dress the plain costume of every day, by Tabacchi; beside him, Italy, seated, writing on a surface before her with a stylus, by Santarini—both these artists Milanese. The work of the former, as it struck us, truthful and full of animate expression; that of the latter scarcely equal to the dignity of its idealized subject.

Let us add that the Italian King has laid the first stone of an extensive improvement in the centre of the city of Milan, based on plans by Signor Mengoni, architect, selected by a building committee from a large number sent in. The scheme, of which we have before spoken, comprises the formation of a spacious new square in front of the cathedral, the construction of a great "Victor Emmanuel Gallery," and a general systematizing of the adjacent streets, whereby piles of mean, damp, and unhealthy buildings will be substituted by large and well-lighted and ventilated dwellings. Further improvements in streets, to radiate from the centre and replace gloomy lanes and alleys, are also contemplated.

#### CONDITION OF OUR TOWNS: PERTH.

The ride from Stirling to Perth via the Scottish Central Railway, carries the traveller through the beautiful valley of Strathern, and round the base of the Ochil hills. These hills appear quite dwarfish when compared with the Grampian range, which constitutes the north-western boundary of the prospect; indeed, in many respects they form a complete contrast. The Ochils are smoother and more rounded on their surface, and being clothed to their summit with verdure, they possess a greater degree of pastoral beauty; and it has often been observed that they give a serene and pleasurable tone to the mind of the traveller, who is, perhaps, overpowered with the wilder magnificence of the scenery in the High-lands.

The undulating surface of this valley will, by a geological eye, be easily attributed to its true source, namely, to the successive groups of moraines, or isolated heaps of rocky debris, which the action of the glaciers of a former age had scooped out from the gorges and river courses of the neighbouring hills. The magnificent view from the Ochil hills of the valley of the Tay will not be overlooked.

Perth is fortunate in possessing the largest and certainly the finest railway station in Scotland. This is, perhaps, explained by the fact that it constitutes a central terminus for no less than four of the principal Scottish railways—the Scottish Central, the North British, the North-Eastern, and the Inverness and Perth Junction (the last only finished last year), and also for two local railways,—the Dundee and Perth and the Perth and Almond Valley, all of which lines converge towards and terminate at the Perth station. It is a large and extremely well built edifice, resembling a good deal the general station at Newcastle, which we have frequently

noticed in our pages. The roof is of extraordinary span, and is skilfully managed with malleable iron girders and bracings, and tie rods of light and elegant construction. The architectural design is Tudor. The external walls, doorways, and window openings are varied, and grouped with much taste, although some of the details are loose enough; and there is an elegant hall for the booking-office, with open timber roofing of elaborate construction. This station, we may add, contains sleeping apartments for her Majesty and the Royal Family, who sometimes make use of it during their long journey to Balmoral; and who are certainly safer here than they would be in the town.

The town itself, when viewed from any of the distant prospect places, has a regular and picturesque appearance. To quote the language of the guide-books, it possesses a rich and rather sumptuous aspect. But this certainly does not improve on closer acquaintance. To begin with the state of the roads: those leading from the station to the town, such as the Leonard causeway and Pomarium; and generally speaking those in the outskirts of the town, are mostly in that particular stage of order and repair which might best be compared to a newly ploughed field. The lower suburbs through which we pass are excessively mean and dirty, and the houses not unfrequently half ruinous and dilapidated. The whole streets are also uncommonly dirty and ill kept. Indeed, it is not until we reach the magnificent terraces and crescents of the modern part of the town, which look outward on the North and South Inches, that we can cease to fancy ourselves in a town of the seventeenth century.

These "inches" (or islands, as we believe the word literally signifies) are the grand and most characteristic feature of the fair city. Perth is situated on the west bank of the river, on a level and extensive plain, which has originally been divided on the plan, we suppose, into three equal portions; the centre being appropriated as site for the town, and the two wings for those beautiful meadows, each\* of which, although probably much curtailed, is about a mile and a half in circumference. In addition to their uses as public parks, or as "common good," as they say in the north, they serve the useful purposes of pasturing cattle; and the weekly cattle market is, we believe, still held on the North Inch, which is also the racecourse of the Caledonian Hunt. Both inches are furnished with seats; but the South Inch alone is planted with trees. Some two or three years ago we were told the town council took a fancy to adorn the North Inch by planting a shrubbery. This, of course, would effectually interfere with the game of golf, to which the inhabitants are much attached. A public meeting was held in consequence, which ended in the indignant citizens proceeding to the spot and tearing up the obnoxious plants by the roots! It would appear that in Perth, as well as some other places we know, it is not always safe for the municipal government to run counter to the popular will.

Perth is said to be one of the most regularly planned towns in Scotland; and next to Edinburgh this would appear to be the case. Its three principal thoroughfares, the High-street, South-street, and Canal-street, run at right angles from the very embankment of the river, from which they are protected by an iron railing. From these main streets others of a much narrower order branch at right angles, connecting them, such as St. John's-street and the Meal Vennel, Ruthven-street, &c., all of which are in the older parts of the town. The newer parts of the town, although containing the best streets, are not so regularly planned, consisting as they do of terraces and crescents, facing the inches, and circumscribed by the configuration of the river.

The bridge of Perth, which crosses the Tay from the southern extremity of the North Inch on the one bank to the village of Bridgend on the other, is one of the most remarkable structures of its kind in Scotland. It was designed by Mr. Smeaton, commenced in 1766, and finished in 1772. This simple and elegant structure consists of ten arches, one of which is a land arch; its whole length is 906 ft., and its breadth 22 ft. between the parapets. The piers are founded 10 ft. beneath the bed of the river upon piles of oak and beech; the stones are bedded in puzzolano, and cramped with iron. Such unusual precautions were not unnecessary; for the Tay, it is well known, discharges more water into the ocean than any other river in Great Britain, and it is likewise distinguished for its prodigious velocity and irresistible force during a flood.

We have no doubt whatever that this bridge of Perth has resisted a greater accumulated pressure of water and ice than any other bridge in the kingdom; but the force of the elements begin to tell even on its superstructure after the lapse of a century. It appears to have been built of the new red sandstone of the district, which is full of nodules of flint and water-worn pebbles; and, judging from the manner in which these project from the plane of the parapet and coping, one might form some estimate of the terrific force of the northern tempests, which can cut so deep into so hard a stone. The cost of this bridge was over 26,000*l.*, which sum was partly supplied (about 14,000*l.*) from the High-land estates which were forfeited during the rebellion, partly by the magistrates of Perth, and partly by subscription. At one period, indeed, the works were at a dead stop for want of funds; but Lord Kinross, a neighbouring proprietor, advanced about 6,000*l.* on the security of the tolls; and so the bridge was at length finished.\*

Some idea of the engineering difficulties which must have attended the construction of the Perth Bridge may be obtained from the recent experience in the railway viaduct which crosses the Tay at an oblique angle lower down the river. Those almost insuperable difficulties, and the manner in which they were surmounted, were fully detailed in our columns at the time.

But, to proceed, Perth, although such an ancient town, possesses very few specimens of architectural antiquities. Of these the chief remaining is the venerable church of St. John, which is a low cruciform Gothic edifice of great antiquity, sadly deformed and defaced, but still retaining some features of its original magnificence. It is now divided into the East, West, and Middle Scottish churches; but when these three were in one, the interior must have been very fine. It still contains the original groined arches in the crypt and chancel. The lantern tower is in good preservation; and the roof, which had been destroyed, is covered with lead; and the peal of bells which it possesses are still the finest in Scotland. Some curious specimens of ancient domestic architecture may still be seen in Skimmergate; and in the Fountain-close, the ruins of a house, which once belonged to the Bishop of Dunkeld, are still discernible. The old jail, at the foot of the High-street, has a curious octagonal tower, part of which is very ancient, and is supposed to have been designed by Cochrane, the court architect to Robert III. St. Bartholomew's Chapel in Carlew-row still shows the niche in which the curfew-bell hung. These, and a few other remains of old houses in obscure recesses, are the only vestiges of antiquity in a town which, as Mr. Morrison tells us, boasted a greater number of really fine and interesting buildings than any other place of the same extent in Scotland. The removal of Gowrie House, which stood on the site of the present County Buildings, connected, as it was, with one of the darkest problems of Scottish history, is more to be regretted than that of any other building; but it does credit to the local antiquaries that they have done their best to preserve accurate plans of this memorable mansion.

Of strictly modern buildings worthy of notice are the County Buildings, designed by Sir Robert Smirke, noticeable from the heavy Corinthian portico; the Literary and Antiquarian Museum, in George-street; the Lunatic Asylum; the City Hall, which contains some valuable paintings; and an elegant bank, with Italian front and cornice, in St. John-street. Most of the churches are very poor in point of design. The Domestic architecture of the High-street is itself very poor and unmeaning, and, in fact, we may say the same of all the older parts of the town. As a set-off to this, some of the chimney-stacks are curious. That which adorns the water-house, for instance, vomits its smoke through a nicely-turned Roman vase, which seems resting on the

\* Some account of this bridge will be found in Mr. Smirke's "Lives of the Engineers," vol. ii. A curious anecdote is told us of the stoppage of the works in connection with the corporation of Dundee. This corporation offered to advance the money on the security of the beautiful bells of St. John's Church, which in that event were to be removed to Dundee. But, in the mean time, Lord Kinross's more generous offer turned up; and the town clerk of Perth (who, it should seem, was a witty fellow) returned the following poetical and sarcastic answer:—

"Ye cottars o' Forfar,  
Tak care o' yer bells;  
Keep ye your money,  
And we'll keep our bells!"

Dundee, it must be remembered, is in the county of Forfar; but, although the largest, it is not the principal town in the county.

top of a freestone column. Another one, we observed, was trained to resemble an obelisk. Some of the suburban villas are neat enough; but, in the majority of instances, they transgress every principle of taste and usefulness. The mixture of styles is curious, ranging from bad Gothic to worse than debased Italian; sometimes mixed with Scotch, and sometimes with Chinese. The best architectural features of Perth, as we have said, is that range of buildings which fronts the North Inch, where the public schools present an imposing façade in the centre of the terrace.

Close to this point the statue of Prince Albert, by Brodie, is placed. The very cursory examination we could afford to give this work of art did not produce on our mind a high impression of its merit. The likeness is good enough; but the posture is wanting in dignity; and the limbs are decidedly too stout, or rather too fat; besides being somewhat too conspicuously poised in the third position. There is also a disagreeable unmeaningness about the design of the pedestal; and it being of a different and rather opposing hue of colour from the yellow sandstones of the statue, it gives the tone of the latter an undue predominance. Knowing Mr. Brodie's previous works (in particular his statue of Lord Cockburn), we must own that we were rather disappointed with this statue of the Prince.

But, after all, we did not go to Perth to study the artistic character of the place, otherwise we should require to betake ourselves, in addition, to the noblemen's seats in the neighbourhood, such as Scone Palace, Kinfauns Castle, and Duppinn Castle, which are already well known to our readers. We will only notice further in this connexion one other remarkable building, which must attract the attention of all strangers, viz., the Perth Penitentiary, or general prison for Scotland. This is a huge ugly structure, such as one might take for a factory were it not built on that famous spoke-wheel plan which Sir Samuel Bentham first designed for the model prison at Millbank. This building was originally erected as a depot for the French prisoners of war, in 1812; but about twenty-five years ago, it was converted, at a great expense, for its present purpose, partly by public grant, but chiefly by assessments. The prison is under the management of a board of twenty-one directors, who also exercise a general superintendence of all the prisons in Scotland. The prisoners are confined on the separate system. There are 360 cells, of which 260 are for males and 100 for females. There is also a provision for thirty-five male and eighteen female criminal lunatics, which has, we understand, been found inadequate. It was a great mistake, on the part of the Government of the day, to set down this huge social necessary in a situation otherwise so picturesque.

We must now turn to what is really the most important part of our subject—to the vital statistics of the town. Perth, although one of the smallest of the eight principal towns in Scotland, which are usually classified together by the Registrar-General, is yet in many respects the most important. Perth might be easily made a sort of testing point in Scotland of the connexion of mortality with sanitary neglect. We shall do our best to lend what assistance we can in this direction, but of course our efforts must necessarily be limited. If we can succeed in indicating a method by which local reformers may be assisted or encouraged to attempt reform, our object will be served; and we must say, that it has been a source of great satisfaction to us to see that the local authorities are beginning to recognise their position. Within the last two or three weeks, Mr. Baist, the registrar of births, &c., in Perth, has issued a set of elaborate tables on the mortality returns of the district, from which we are enabled to supply our readers with the following authentic facts. The population of the town (census 1861) is 26,094. In the year 1864, the number of births was 860; and the number of deaths, 871; so that the population was *actually reduced* last year to the amount of 11, by an excess of deaths over births. The death-rate of Perth, or as it is stated the per cent. of deaths to the population, is 3.33,—a proportion which is only exceeded in Scotland by Glasgow, Greenock, and Dundee. The infantile mortality is equally high. Of the children under one year, there died, last year, 162; and of those under six years, 171. "This is rather a mournful sheet," says the registrar, "which I submit to the town council and inhabitants of Perth. The deaths

this year exceed the births by 11; they also exceed the deaths of last year [1863] by 219; and those of 1862 by 253. Fever and bronchitis seem to have been the great causes of this mortality. The other large towns appear also to have suffered from fever; but I fear that Perth will show a larger proportion than any of them!"

We shall endeavour, as we proceed, to connect these statistics with what we conceive its their natural cause. But it is, first of all, necessary to keep the physical properties of the surrounding soil in view when treating of Perth. In the first place, the town is founded upon one of these low-lying inches, or islands, which have at one time or another been surrounded with water, and which are still only a few feet above the level of the river. Indeed, at high-water, and particularly during stream tides, a considerable portion of the town lies below the level of the river. We shall return to this when we come to the drainage. Again, Perth, thus situated in the zone, as it were, where those Highland valleys, Strathmore, Strathmore, and the Carse of Gowrie, coalesce and merge into the Lowlands, is subject to all the varieties of climate and all the variations of temperature which are common to the different counties. West winds predominate; but the cold blast from the German Ocean is also felt. The rain-fall, although not so heavy as some towns on the coast of Scotland, is yet considerable. In the Carse of Gowrie, on the shores of the Firth of Tay, the mean quantity for twelve years was 24 in.; at Perth, for a period of sixteen years, 26.95 in.; and at Belmont, in Strathmore, for a period of thirty years, it was 30.40 in. Once more, look at the disadvantage in which the town stands in respect to the great highland river of which it is the chief ornament? Perth has always been exposed to inundations of a serious character; and the recent process of drainage all over the Highland counties—which has undoubtedly ameliorated the climate—has also rendered the lower levels exposed to the disastrous influence of floods and spates, just as much after a heavy fall of rain as after a snow-storm. Of these phenomena Perth has experienced her full share; and with respect to their consequences, however evil, the inhabitants,—or rather, we should say, their local government,—must be clearly exonerated.

The remaining principles, then, over which they can exercise control, and for the exercise of which they must be held responsible, are those which are connected with the sanitary condition of the town itself. Of this condition we shall proceed to speak in another article.

#### THE HERBERT HOSPITAL; WOOLWICH.

The acknowledged part which this journal has had in the correction, so far as it has gone, of certain defects of hospital-planning, leads us to take an even more than professional interest in the closely-approaching completion of the Herbert Hospital, near Woolwich, the building that will be regarded as the grand experimental test of the soundness of the views which have been maintained by Mr. Robertson, of Manchester, by Miss Nightingale, and others in England, and have been accepted as conclusions by different Royal Commissions. The same circumstance has led us to give attention to the reports which have been industriously circulated, of serious failures in the construction of the building near Woolwich, and to assertions imputing that the site had been selected badly for the especial purposes of a hospital.

The building is situated at Kidbrook Common, on the westward slope of Shooter's Hill, and south of the Dover Road. It may be seen on approaching from the Artillery Barracks, and crossing Woolwich Common, and is reached by the Eltham Road, which passes west of the Royal Military Academy, or Cadets' Barracks. Perhaps the best view of the building is that from the south-east.

To the matter of the arrangement on plan, of the Herbert Hospital, our attention is immediately called by what is reported to have been said in a recent debate on military hospitals, in the House of Lords. We discover that there are persons amongst those who should be the best acquainted with the subject, who can regard with complacency the arrangement of Netley Hospital, and that the Secretary of State for War seemingly is amongst the number. The Earl of Dalhousie, who called the attention of the House "to the condition of the mili-

tary hospitals at Netley and Woolwich," went so far as to stigmatize the principle of the plans of the new hospitals of Woolwich and Hounslow, as "the glass and glare principle," one which would not conduce to recovery from illness, but would have the reverse tendency. According to the newspapers, he said of the Herbert Hospital, that it was certainly "most gorgeous," having "a very handsome façade in which there was no architectural fault," but that it was "built in blocks and wards of glass, in which, in his opinion, it would be absolute cruelty to put an invalid,"—"the first anxiety in illness," as he said their lordships would be aware, being "to relieve the brain and the eyes from too much light,"—and that if intended for a flower-show, or a museum, the building would have been admirable, whilst for its present destination it was absurd. It is worthy of observation that the "glass and glare" or pavilion principle was reported upon favourably by a committee, in 1856, with reference to a hospital at Aldershot, and by the Sanitary Commission of which originally Lord Herbert was chairman,—both committee and commission being, all honour to Lord Dalhousie, due to him. Lord Dalhousie did not omit to mention the failures to which we have alluded; and when we read of "rents in the blocks," "almost as likely to be fatal as the 'rent the envious Casca made,'" and that required "formidable supports and buttresses," many, and "still unremoved," we felt prepared to find on a visit to the building, evidence of malconstruction of the most serious nature. We are obliged to say that what is thus reported to have been said concerning the pavilion-principle, and of the actual plan of the Herbert Hospital, is incorrect in every particular; and that as regards structural defects, there are none which we can now discover to have been ever of the alarming nature that would be supposed, or that are not such as may be found often in extensive works, even where the stratum of foundation is more favourable than was that on the site selected for the Herbert Hospital. Whether the actual site was wisely selected, economy of construction, and suitability for hospital uses being in view, we would not say in the absence of information concerning other sites, some of which were suggested by a correspondent, in our journal, in 1859. The present one is finely placed for prospect, though, for a general hospital, a cemetery as a conspicuous feature in the view in one direction, would have been objectionable; but the ground is undeniably clay, of the worst kind; and in the natural drainage, the flow comes from a higher level towards the site of the building, and passes transversely to the lines of the wards. The site was determined upon by those who have the best knowledge of what have been the pronounced disadvantages of clay as the soil under and about a building; and we cannot doubt that resources which experience would suggest, were largely called into use to intercept the upland water, and to drain the actual area of the structure. In the report of 1863, "of the Commission appointed for Improving the Sanitary Condition of Barracks and Hospitals," we read,—“Why build a hospital on ground which does not admit of being drained? That certain provisions were actually made to exclude damp from the wards, is shown by portions of the work which are above the ground-line. The difficulties experienced may be understood by reference to those which there have been between New Cross and Forest-hill, on the line of the railway, where the slopes of the cutting have been said to be not capable of resting at any angle. On the site of the Herbert Hospital, the clay was veined with gravel. The site, in general, was drained before the building was commenced, so far as the clay could be by drains 25 ft. apart; and other drains were put in afterwards to provide for land-springs. Some of the drains were built into the concrete. This latter material has an average thickness of 5 ft. 6 in., excepting some spots where the thickness is 8 ft. The concrete provided for 3 ft. The concrete of course is stepped in suitable lengths.”

Whilst we are referring to failures which certainly there were in the construction, we may do well to say all that requires to be added concerning them. There was a settlement in one of the side-walls of one of the pavilions, in the middle of the length, which opened some of the joints of window-arches, whilst cracks extended in two or three of the bays up the brickwork, as from the arch of one window to the sill of a window above; but they do not appear to have been of any such importance as those which may

be seen in the Palace at Westminster, both in the front to Old Palace-yard, and that to New Palace-yard. Proper tests applied, proved that the cracks did not increase in width; greater strength at the spot was given to the foundations; and we imagine that some description of shoring during the operation of filling in concrete, may have attracted Lord Dalhousie's attention. The traces of recent pointing up, externally, would now almost escape a practised eye; and, internally, a hair-crack, or two, in the plaster, and a trifling unevenness under a window, require to be pointed out, to be seen or felt by the hand. As to the work generally, in this building, it deserves the highest praise. Mr. Myers, who is the contractor, has had in his hands some undertakings of extraordinary magnitude; and he has never done better than in the Herbert Hospital. The principle for hospital-planning of which the building under notice claims to be an exemplification, requires that materials and workmanship should be of the highest class; moreover, in this case, there was the disposition on the part of the Government, to provide a building in all respects worthy of the nation,—a disposition so seldom found as to occasion surprise when made manifest; and the contractor, here, seems to have been able to work up to both demands. If there be defects, they are not in the work: everything is good, true, well-fitting, and well-acting.

We return to the point raised in the House of Lords, of the respective merits in plan, of Netley Hospital, and those of the last exemplification of the pavilion-principle. Were there all the defects of site and construction that have been imputed to the Herbert Hospital, it would still be a model of arrangement for that class of building. We might have desired certain features of plan slightly different, and certain of the decorative features marked more as the produce of an artist's hand. There are stone dressings to all the windows; and equal, or even better, effect might have been produced at slightly less expense; but there is nothing "gorgeous." Referring to "glass and glazing," and suitability of the building to the purposes of flower-shows, Lord Dalhousie must have had in his recollection the corridors which connect the pavilions, or ward-buildings, and are lighted on both sides, where between the pavilions, by very large windows. The wards themselves have not the same amount of window-opening, though they have all that is required by the principles of the system of planning. His lordship cannot have considered the statements which are those of medical men, and of others who, like Miss Nightingale, are qualified to judge, that abundant light is not hurtful, but beneficial, unless in cases of ophthalmia. As to Netley, we very much doubt whether Earl de Grey and Ripon would be right in what seems to be his conclusion, that because "the fears which were expressed by some persons with respect to the state of Netley Hospital have not been realized" there would be no reason for them even still to exist. Perhaps on this question, we need only quote what was said in 1863. The report of the Commission on Barracks and Hospitals, said:—"If Netley Hospital should ever have its original destination changed from being a resort for invalids, three-fourths of whom would be able to walk about, to that of a general hospital for sick, most of whom would be confined to bed, it would have 1,000 sick beds under two roofs, 500 under each roof; and in that case it would present the largest aggregation of sick under a single roof of any hospital built in modern times." At the same time the Commissioners had to speak of Netley as "one of the worst ventilated places" found anywhere by them,—though at the moment referring to a particular instance of misjudgment and bad economy which it is to be hoped is no longer existent.

Readers of the *Builder*, who have our volume for 1859, will find in it, as well as in other volumes, several articles on hospital-planning,—partly in review of buildings erected, and of designs,—and in the course of them, some particulars of the points of difference between the French arrangement, of which we gave a plan from the example of the Hôpital de Lariboisière, and the English has shewn forth in the Blackburn Infirmary. In a subsequent volume we described the Marines' Hospital at Woolwich. This building is near the Dockyard. In the French plan, there is a central open court, oblong in the example we have named; it is surrounded by a corridor; and parallel with the corridor at each side, is a range of buildings containing dining-rooms and a staircase to each ward.

From this range of buildings, the pavilions, or buildings of the wards, on that side, project. In the English plan, the longitudinal axis passes not through an open court, but through a corridor of communication, which extends from end to end of the group of buildings, and across one end of each ward. There is a separate staircase to each pavilion as before; and the corridor connects these staircases with one another, and with the staircase of the central block, where may be a convalescents' room, as well as the kitchen. In the Herbert Hospital there is also a chapel. In passing from one end of the connecting corridor to the other, the transeptal pavilions may branch off alternately right and left,—or there may be a short projection on one side, on the same transverse line as the long one on the other,—the positions of the long and short arms being reversed in the next case. Otherwise the pavilions, right and left, may be both opposite one another and of equal length. By this latter, or the double-pavilion, arrangement, there will be half the number of staircases; but in any case it must be remembered that adequate space is to be left between blocks, for access of light; and the number of stories must not be too great. The patients in the wards of the top story should have a chance of seeing garden-ground in the space between the pavilions; and those in the ground-story should see enough of the sky to relieve the oppression of looking at an opposite wall. The practical result is that the number of stories which may be appropriated to wards, in the pavilions, is generally limited to two; though in the Hôpital de Lariboisière, three such stories have been attempted,—the consequence being that the spaces between the pavilions are insufficient, and that there are other disadvantages. In the Herbert Hospital the arrangement may be said to include both the dispositions of transeptal pavilions. The longitudinal corridor is intersected at seven positions; but only in five of the cases are there double transpents, and both of sufficient length for wards, namely in the two cases at each end of the line of corridor, and in the case of the central intersecting line,—where however the projection on one side is appropriated not to wards, in the different stories, but to the kitchen, the library, and the chapel. At the extreme ends of the longitudinal corridor are, in one case, certain separate wards, and at the other an operating-room and some other requisites of the hospital system. A separate building called the administrative block, and of which the purpose is explained by the name,—is placed parallel with the line of the longitudinal corridor, and parallel with the line of frontage and the road. When the number of patients is to be much less than that, 650, for which the Herbert Hospital is planned, or as in the case of the hospitals for 120 patients, built on the official plans which we published in 1862, the difficulty as to space between pavilions does not exist. These latter plans show the two fireplaces of each ward in one of the side-walls; but the Herbert Hospital has them in the middle of the floor, each with a descending flue.

In the disposition of the building on the ground, the transverse axes, otherwise the longitudinal axes of the wards, may be said to range north-north-east and south-south-west. The space occupied by the building and grounds is about ten acres.

The building, planned to receive 650 patients, will have 640 beds in the ordinary wards, and 10 in the supplementary wards. The ordinary wards occupy the two upper stories, in the pavilions, in the three stories into which the building is divided, inclusive of the basement. In each of the two double-pavilions next the ends, there are four wards, which contain each 32 beds. In each of the two single pavilions, or southward only of the longitudinal corridor, and which are next to the central intersecting block, the four wards are for 28 beds; and one ward on the upper floor in the central block will provide 20 beds. There is a lofty basement under the entire building; and this at the western end is wholly above ground. Thus, under the western wards, there are provided rooms for a board-room, museum, medical officers' library, non-commissioned officers' quarters, and stores. The spaces under the eastern wards are left unappropriated. The longitudinal corridor in the basement continues from end to end, of equal height and level, and has the kitchen, scullery, beer-cellar, and provision stores and other offices grouped together in the northern portion of the central double-pavilion. The kitchen, which has one of Benham's large cooking-stoves, similar

to one exhibited in 1862, has a large serving-window. From this, the meat will be conveyed along the corridor to the lifts, of which there is one communicating with each ward above. The lifts are worked by hydraulic power. Opening into the same passage are shoots for dust and dirty linen. The arrangement of the dust-shoot opening inside the building is different to that adopted in the model-lodging houses, but may be better than in those cases. A close receptacle will be fixed up to the mouth of the shoot; whilst, were the dust removed on the exterior of the building, it would probably be blown about by the wind. The extreme length of the corridor in the floor above this basement level is about 715 ft., whilst the width is 15 ft. in the clear. There is no corridor, properly speaking, to connect the pavilions, above the corridor of the ground story; but patients can be wheeled from one ward-building to another, along the flat, which will, moreover, form an agreeable place of promenade in the open air. The closed corridor below will form a most suitable place for promenading in wet weather. The greatest length of one of the double pavilions externally is 312 ft.

The ordinary wards, which are of three dimensions of length, measure 117 ft. 8½ in., 108 ft. 6 in., and 73 ft. 8½ in. in length, respectively; and are uniformly 26 ft. 9 in. in the clear width, and 14 ft. in height. The last dimension would seem to be a foot, or two feet, less than it should be; but an increased height of the pavilions would have made the distance of the wards apart, which (63 ft. 9 in.) is already too little, practically less than it is. The dimensions of the wards give an air-space of 1,200 cubic feet per patient. The beds are arranged two with heads against each pier; and there are eight windows each side in the length of the longest wards. These windows are 8 ft. 9 in. in height, and have an opening of 4 ft. 6 in.; whilst the sills are 2 ft. 9 in. from the floor. The sashes are 2 in. thick, of oak, and are glazed with plate-glass. The window at the end of each ward, and those to the corridor, are fitted with French-casements, having brass hinges and Espagnolette bolts. The closets and ablution-rooms are placed in square blocks, as appearing externally at the angles of the pavilion, at the end furthest from the longitudinal corridor. The entrance from the ward is directly to an outer lobby, which can be ventilated by the windows,—but not, as seems to us, so thoroughly as where there is provision for a straight current of air across the space between the door from the ward and the closet. Some of the arrangements in these adjuncts of the wards are varied in the pavilions; and we doubt whether there has yet been success in inventing anything that exactly meets the want of a urinal suitable for the interior of a building, and not liable to be broken. The walls of the wards are rendered, and the ceilings plastered, in Portland cement; and both are finished in Parian to a hard and polished surface.

The floors are laid with iron joists and concrete, on Fox & Barrett's principle; but upon this the sleepers running lengthways of the floor, and small timbers of 2 in. by 2 in. across them. The boarding is of oak battens, closely laid, and wrought to a smooth surface. In some of the wards the oak has been oiled and rubbed. What treatment will be adopted for the remainder of the whole of the floors does not seem to be decided at present. The spaces between the joists are ventilated through holes drilled in an oak sill, which forms a species of skirting.

The stoves, in the middle of the ward, with descending flues, seem to embody contrivances which will render them very important contributions to good hospital-construction. There has been difficulty hitherto in securing draft of downward flues; but here the whole of the objects of heating and ventilation, without returned smoke, seem to be accomplished. The back and splayed sides of the grate are formed of fire-clay; and the back has a long narrow opening to admit air from beneath the grate, to the back of the fire, to help the combustion of the smoke. The smoke-flue, of iron, in lengths fitting into one another, telescopic fashion, is placed in a trough which admits fresh air from the exterior, direct to the fire, being thus warmed in its passage. To prevent possibility of the air being "brnt" by contact with heated iron, the smoke-pipe has an outer iron-casing. The flues from the wards, upper and lower, are carried up in the external walls as the two outer channels of a group of three terra-cotta flue-channels. The

middle flue of the three is called the pilot-flue, and serves a very small fire in the basement, which will usually be lighted about one hour before ward-stove fires, to ensure draft. We have seen this contrivance in action,—the draft being perfect. It is found that a common fan-blower, inserted into a length of iron pipe, would answer a similar purpose. That the flues may be swept, a portion of the floor-boarding is made to be taken up; so that, a brush being inserted, the soot may be pushed towards a flue in the wall, down which it falls to openings on the exterior of the wall, at the basement.

Sheringham's ventilators for the admission of air are inserted in the upper part of the walls on each pier; whilst there are outlet-flues from the four corners of the ward to lowres which are placed on the roof. The gas-lights have each a cap over the burner, and an escape-pipe passing up to an outlet above the slope of the roof. There is no arrangement in the ceiling itself, for escape, either over the gas, or elsewhere.

We should mention that the staircases for the ward-buildings are specially designed for ease of ascent. The risers, rather more than 4½ in. in height, are iron; and the treads, 12½ in., with 14 in. nosings, are of oak,—the whole being carried by trussed iron carriages. The width of the stairs is 5 ft. The nurse's room, attached to each ward, has the inspection-window placed so that it scarcely commands every bed. A bow-window might be the best thing.

We may here add, as important to a description of the wards, that the walls throughout the hospital are built with a cavity, the bond being made by Jennings's bricks. There is a damp-proof course in the lower part of the walls next the ground; and there is a surface-drain channel close round the walls. The drainage is carried by 12-in. pipes into a sewer which is continued across Woolwich Common to the outfall sewer of the Metropolitan system.

The water, to the amount of 20,000 gallons per day, is supplied, by the Kent Waterworks Company, to softening reservoirs placed in a building on Shooter's Hill, whence it descends to the Hospital. The softening process is Clarke's. The arrangements for the water-supply were designed by Mr. S. C. Homersham.

Nearly opposite the Hospital is a large wash-house and laundry; and here also power is accumulated to work the lifts in the building. In the wash-house the most approved contrivances for beating and wringing are in use.

The materials used in the exterior of the buildings, are chiefly white Suffolk brick and Bath stone. Good effect is produced in the centre pavilion of the Administrative Block, by its archway and side-entrances, and by the interior perspective of the entrance.

Ground was first broken for the buildings, in September 1861; but the sewer had been commenced in the previous year, when the first votes were taken. The building is now all but ready for occupation. The total cost may be estimated as likely to amount to about 205,486*l.* Mr. Myers's original contract was for 153,100*l.*; but to that amount there have been large additions; and there were other and separate contracts by Sir Wm. Armstrong, and Messrs. Jeakes & Co., Mr. Barrett, and Mr. Jennings. The Hospital contracts may be taken as 167,617*l.*, and those for the Washhouse as 4,149*l.*; these making together 171,766*l.* Probably the ultimate cost may be found to be about as under:—

Myers, contract for Building and extra.....	153,000
Jeakes & Co., Gas and Water-Supply, exclusively of the Water Works.....	13,000
Sir Wm. Armstrong & Co., Hydraulic Lifts.....	2,450
Benham Brothers, Cooking Apparatus.....	450
Joseph Kennard, Ventilating Stoves.....	1,000
Jennings, Damp-proof Course, Stoves, &c.....	1,800
Barrett, Floor Joists.....	6,786
	£205,486

The drawings for the building were prepared at the Royal Engineer Department of the War Office, under the superintendence of Captain Galton. The Superintending Officer at the building is Captain Newsome. Mr. C. E. Ware, and for portions of the time, Mr. C. Tate and Mr. Perry, have acted as clerks of the works.

THE BISHOP OF LONDON'S FUND.—An anonymous donation of 4,000*l.*, which has been given to this fund has been applied, at the donor's wish, to the building a permanent church in the district of St. Andrew, Haverstock-hill.

THE SEPULCHRE OF CHRIST.

Mr. FERGUSON has delivered a lecture at the Royal Institution, with a view to show that the building in the sacred enclosure at Jerusalem, called by Europeans, the "Mosque of Omar" (but by the Mussulmans the "Dome of the Rock"), and supposed by some to have been built by Omar over the site of the altar of the Jewish Temple, is really the "Church of the Resurrection," built by Constantine over the rock which he believed to contain the sepulchre of Christ. In his former lecture, in March, 1862, on the same subject, he had argued the Christian and Constantinian origin of the "Dome of the Rock" mainly from the architecture of that building. No refutation of his arguments having been put forward, he said, and his own recent visit to the spot having confirmed him in his former views, he took this opportunity of re-enforcing them. This he did by the reverse process of argument to that formerly employed, viz., by describing the dimensions of the successive temples of the Jews. "If I can convince you that the rock which is situated in the centre of the building popularly known as the Mosque of Omar is, and always was known to be, outside the temple area, you will be forced to admit that it was not built by the Moslems—the only reason ever advanced by any one for assigning the building of it to them being that on that rock stood the Holy of Holies, or the altar of the Jews. If it was not built by the Moslems, it was by the Christians, and if by them, it could not be other than the church which Constantine erected over what he believed to be the cave in which the body of our Lord was laid. The architecture is of his age, and neither he nor any other Christian ever built a church in Jerusalem, or anywhere else, the whole floor of which was occupied by a great rock with a cave in it, but that which Eusebius describes as the one erected by that emperor."

He commenced with the Tabernacle, which was the model for Solomon's Temple. He showed that the apparent anomalies in the dimensions given in Exodus, which had hitherto so sorely encumbered restorers of the Tabernacle, vanished directly it was assumed that the Tabernacle had a "ridge." "It was a tent; and like every tent from before the time of Moses to the present day, it had a ridge. When once this is suggested the whole becomes clear. Thus, every dimension of the Tabernacle is a multiple of 5, except the curtains, which are 14, because they were measured along the slope. There were only four pillars in the interior, but five in the porch, as there must be if there was a ridge; and the same necessitated an unequal number of boards (nine) behind. In fact, the moment you assume the ridge, which was indispensable as a protection against the weather, all the difficulties disappear, and every part of the Bible description becomes intelligible.

"When the Tabernacle came to be superseded by a more permanent structure, it was copied literally in plan and arrangement, with this marked distinction, that in the edifice of the Temple every dimension of the Tabernacle was exactly doubled. Thus, the Holy of Holies in the Tabernacle was a cube of 10 cubits; in the Temple, of 20. The Holy place in the Tabernacle was a double cube of 10; in the Temple, of 20 cubits. The porch of the Tabernacle was 5 cubits by 10; of the Temple, 10 by 20. The verandah of the Tabernacle was 5 cubits wide, the chambers that surrounded the Temple measured 10. But perhaps the most remarkable coincidence is that the angle of the roof made the Tabernacle 15 cubits in height, and consequently the Temple was raised by a false roof, or upper chamber, till its height was 30 cubits."

The dimensions of the court are not given either in the Bible or Josephus, but it may safely be inferred that, like the edifice, they were double those of the Tabernacle; and that the court, therefore, measured 100 cubits by 200, or 150 ft. by 300 ft. This is the more probable because the courts of Ezekiel's Temple were of that size. In the edifice itself the only difference between Ezekiel's dimensions and those of Solomon arises from the introduction of a range of chambers between the Temple court and the north court.

The Temple of Zerubbabel followed the measurements of Solomon and of Ezekiel, as appears by comparing the notices of Esdras, Josephus, and Hecataeus of Abdera.]

So far the pre-Christian temples. The Temple of Herod is much more important, because its foundations can still be traced out, and it thus

becomes the turning-point of all topographical inquiries at Jerusalem. The authorities for restoring it are Josephus and the book *Middoth* in the Talmud. The house itself was only repaired. It was still standing as rebuilt by Zerubbabel when Herod took it in hand, and the dimensions were not altered; the only difference between it and Solomon's being that it retained the passage between the external chambers of Ezekiel, making the width 60 instead of 30 cubits. Two wings were also added to the facade, each 20 cubits square, so that the whole building measured 100 cubits long and 100 cubits wide. It is evident that a building 100 cubits wide could not stand in a courtyard of the same dimensions, and allow a passage round it. We consequently find the breadth of the court increased to 135 cubits, or 202 ft. 6 in., and the length between the porticoes 187 cubits, or 280 ft., leaving 20 ft. for the cloisters and the thickness of the walls. The court was strongly fortified, having three gates on the north and three on the south side, and one, the most magnificent of all, towards the east. What had been the outer court, or Court of the Gentiles, was cut in two, and appropriated to the women; its breadth was also 135 cubits. Its extent east and west can be fixed with very tolerable accuracy by the protraction of the outer court. It must have been as nearly as possible 40 cubits, or 60 ft. The important and characteristic addition which Herod made was the great Court of the Gentiles, with its "Royal Porch," 600 ft. long and 100 ft. wide, supported by 162 Corinthian columns, which divided it into three aisles, of which the centre one was 100 ft. high. The Court of the Gentiles surrounded the whole of the other courts, and formed a square, as Josephus expressly states, of which the external measurement was one stadium, or 600 ft., on each side.

Having obtained these general dimensions, the lecturer next proceeded to apply them to the existing remains. All agree that the south-western angle of the Harem enclosure is one of the angles of the Temple area. For 600 ft. eastwards from this angle along the south wall all is practically solid. But at that point a range of vaults is reached, unequally spaced, badly constructed, and not only of much more modern age, but too weak to have supported the Temple. So far, therefore, did the Temple extend, and in this direction the history and the topography are agreed. Returning to the south-west angle, and measuring 600 ft. north, we come to a second bridge or canopyway. Up to that point the great "bevilled" masonry of Herod extends, but there it ceases. On this side, again, the history and topography are at one, and thus two sides of the quadrangle are obtained. The other two, lying within the sacred inclosure, have not yet been investigated. The position of the great rock-cut reservoir in front of the Aksah, the watercourses, as far as they have been examined, all accord with the indications of Josephus and the Talmud. Everything tends to show that the Temple of Herod was, as Josephus tells us, 600 ft. square, and was situated in the south-western angle of the present Harem area. *The rock, therefore, which now stands under the Dome of the Rock was certainly outside the area of the Temple, at a distance of 150 ft. from its northern wall.* A few words were devoted to showing that the supposition that the altar in the Temple was placed upon a rock is unsupported by any evidence or implication of the Bible, Josephus, or the Talmud, and is, in fact, a mere Mohammedan tradition.

The remainder of the lecture was devoted to an examination of the post-Christian evidence. The lecturer said that he had had Sir H. Rawlinson's Arabic library examined by a competent Arabic scholar, who had extracted and translated all passages bearing on Jerusalem, the result being, that down to the time of Abd-el-Malik, and later, the limits of the Temple were well known to the Mohammedans, and that they neither built nor pretended to have built the structure now called the "Mosque of Omar."

"If, then," concluded Mr. Ferguson, "the Dome of the Rock was not built by the Saracens, it must have been built by the Christians: there is no third party in the field who could have done it. In that case I would ask, 'What church did Constantine or any other Christian priest or monarch build in Jerusalem over a great rock with one cave in it, but the Church of the Holy Sepulchre?' Till this question is answered—and no attempt has yet been made to reply to it, or to supply its place with any reasonable suggestion—the arguments of my opponents halt. As

I began let me conclude. I first took up the question on architectural grounds; I then examined it historically; and lastly, I investigated it on the topographical ground I have this evening laid before you. Whichever path I attempted to pursue, I always came back to the same point. I do not mean to say that the question is without difficulties, or the road without its ruts and roughnesses, but I do assert that, so far as I can judge, an immense preponderance of evidence, from whatever point it is viewed, is in favour of the conclusion that the building at Jerusalem known as the Dome of the Rock is the identical church which Constantine built over what he believed to be the Sepulchre of Christ."

#### WORK! AT MR. MADOX BROWN'S EXHIBITION OF PICTURES.

The ideas and convictions as to what constitutes "hard work" may be as diverse and numerous as the multifarious occupations of the busiest actors in this busy world, and each might claim for himself the best right of opinion, and to a solution of the question,—Who can prove that in whatever sphere he moved, he did all that one man could do. Mr. Ford Madox Brown, in his very cleverly-painted picture intended to illustrate the dignity of labour, appeals quite as eloquently in his own behalf to show effects of industry, as in that of the robust type he presents and describes as "the British excavator or navvy," in the full swing of his activity," whose well-developed physical strength, and rich glow of complexion, consequent on the healthful exercise of it, if it suggest the benefit of such employment, as, of course, it is meant to do, may also evoke something like a feeling of envy from those whose vocation does not conduce to those advantages, and to whom a day's exertion with a shovel and such concessionary relaxations as a light clothing and heavy refreshment as Mr. Brown's heroes are enjoying, would be looked upon as a holiday. Nevertheless, the moral inculcated in the work is a good one, though not new; but it has novelty, and what the application of everyday fact to point it does for it, is surprising. Its truthfulness of representation is its chief recommendation, helping to prove what has so often been asserted, that a story depends more upon the manner of telling it than upon the matter that has to be related,—for this is one of the most ordinary episodes of commonplace metropolitan life made interesting by picturesque but perfectly unexaggerated apprehension of it, and shows that incidents worth recording are of very constant occurrence; and, further, that the British navy has some reason to complain of artists' neglect, as he is made to appear quite as available for painting purposes as his hitherto more favoured compeers, peasants, rustic labourers, fishermen, and heggars of all times, countries, and counties.

However, that he should no longer be overlooked, he is here made to symbolize lusty manhood as "Work" which beads the brow and tans the flesh," in contrast to the illers by choice and others by necessity; for it is pretty certain that those poor immigrant harvesters who are resting by the wayside, travel-worn and despondent for the want of work, would only be too glad to invest what little strength they may have left to them in any way that would procure for them the "bite and sup" they have come in search of. Scarcely less ragged though, if less hungry, those home-grown, squalid children, indigenous to nearly all neighbourhoods, are but poor promise to any that come into their locality to better themselves, where so little has been done for those with more claims to relief; and they are a warning to that well-fed vagabond who has never been taught to work, to move on, and try elsewhere to find purchasers for his ferns and weeds. "But for a certain effeminate gentleness of disposition, and a love of nature, he might have been a burglar," remarks the painter, who has more confidence in these refining influences than some would have; but we do not like his restless gleaming eyes, to say nothing more, as it may be from prejudice, and from being personally unacquainted with the delicate scamp who is so tenderly introduced and charitably described. Belonging to a very different class, and with distinct obligations, is the young lady "whose only business in life as yet is to dress and look beautiful for our benefit." A very hard work this involves, too, with some of the most fastidious to be satisfied, including perhaps harder efforts on the part of those who are

called upon to support her appearance; but in this case, as is mentioned in the copious descriptive catalogue, "she probably possesses everything that can give enjoyment to life: how then can she not enjoy the passing moment, and, like a flower, feed on the light of the sun?" She is accompanied by an older lady distributing tracts, and a dainty little Italian greyhound, in a red jacket, that excites the ire of the workman's democratic "tike," with his less aristocratic adornment of shavings for a collar. A father and child on horseback, of the middle distance, typify further those who have no need to work; and two men, "who appear as having nothing to do," represent the brainworkers, who, seeming to be idle, work, and are the cause of well-ordained work and happiness in others.

Without attempting to follow the artist in his elucidation of the task he has imposed upon himself, it must be allowed that the result of so much patient labour, successful as it is, can but barely repay him for the amount of energy, study, and close adherence to a fixed and most praiseworthy purpose that a work of this kind entails. The trials of his patience, the constant recurrence to the one object of his thoughts, and the endurance that is necessary to the projector of this and of such undertakings, are too often put aside, and a word of approval thought commendation enough. It is to be hoped, then, that Mr. Brown's "Work" may be received that all the approval its most conscientious performance entitles him to, and that it may be admitted as one accepted example of the dignity of labour, as well as a pretty strong assertion that he is well entitled to give his opinion of what constitutes hard work.

A striking characteristic of the painting is its brilliant and forcible colour. There have been few instances wherein the most difficult effect of broad open sunshine has been so completely realised.

To secure his well-earned share of public attention for this picture, its author has organized an exhibition of his own in Piccadilly, and made it a loadstar besides, to attract re-inspection of earlier productions more or less known, according to the uncertainties that must ever attend individual contributions to large and general collections. These are, in most cases, very worthy of being seen again, and reconsidered, even by those who remember them. The earnestness of intention that always predominates, though it be allied with some peculiarity in the means adopted for expressing it, insures for them a respect that materially lessens the effects of their failings; and in the most noticeable instances, where there may be very questionable ideas as to form and taste, there is always this present to atone for some short-comings.

"Chaucer at the Court of Edward III." (1) was noticed in the *Builder* on the occasion of its first appearance at the Royal Academy—perhaps in 1851—and the very admirable scene from "King Lear" (7), which, with "Wickliff reading his Translation of the Bible to John of Gaunt" (4) are to be recollected by all who remember the two first experimental exhibitions at the Chinese Gallery of the "National Institution." Indeed, the recollection of most of the items will be their best praise, as it must be taken as acknowledgment of their worth, and an evidence of the impressiveness that some of the higher qualities in art impart to pictures, of the value of purpose and thoughtful observation above mere technical excellence and the merely agreeable charms of prettiness when they are not combined, even to those confessing all the value such additions possess.

#### PARLIAMENTARY.

LEAVE has been given to introduce a bill into the Commons to enable the Secretary of State for India to acquire additional lands for improving the site of the India Office and the approaches thereto.

LEAVE has also been given to bring in a bill to enable the Commissioners of Public Works and Buildings to acquire additional ground for improving the site of the new public offices in Downing-street and the approaches thereto.

In reply to a question as to the proceedings of the Westminster Improvement Commission in regard to the provision of dwellings for the poor in place of those removed on the Westminster estate, Mr. Tito stated that nothing had been done; that, in fact, the Commission was being wound up; but that a private individual, Mr. Gibbs, had liberally erected an enormous mass

of buildings for the purpose in question. The Commission had mortgaged all their surplus land for 300,000*l.*, and had also issued debentures for 700,000*l.* more. Their total expenditure had been 1,200,000*l.*; and they had then come to a standstill till the new Act was passed, which was, in fact, a mere winding-up Act.

Mr. Cowper stated in reply to a question as to the enclosure in Leicester-square, that the Metropolitan Board of Works were about to take some steps, on a notice already given to the owners, for the improvement of the centre of the square.

#### A NOTE ON THE NAMES OF METROPOLITAN STREETS AND ROADS.

THE officials connected with the Metropolitan Board of Works are unremittent in the exertions which they are making to re-name a vast number of metropolitan localities. The chief thoroughfares have been made to assume a name from one end to the other. The houses and shops now run in uninterrupted line until the number of several hundreds is reached. In the course of this operation the names of many well-known places have been destroyed, and will, together with the associations connected with them, soon be forgotten. Many of these streets, terraces, crescents, groves, &c., mark, as we have often said, either peculiar local circumstances, or remarkable passing events.

In suburban parts, many of the neighbourhoods sound pleasantly of the country. Some of these are of ancient date. Take, for instance, "the Grange-road;" the various London fields, which still retain the name, although covered with flag and paving stones; the Willow-walks; Elm-tree-street; Myrtle and other groves; and as regards the smart cottage dwellings and houses, Rose or Woodbine Cottages have now been transformed into plain Nos. 15 or 16, in Blank road; and the indications of personal affection shown in the names of Belinda, Martha, Jane, Lavinia, and other cottages, have been but little considered. The arrangements which vain individuals considered durable have been swept away by these remorseless public functionaries, who maintain that the long and even narrow rows of streets, with odd numbers arranged on one side and the even ones on the other, will be more convenient for the postmen, and for persons strangers to town, who require to find any particular house. In the more retired parts, the street name-changers have also been actively at work; and although it cannot be denied that some good has been done, still this work should be carried out with care and consideration. Throughout the wide district of the metropolis there are localities which fill important points in the present history of London. There are, for instance, the various greens, such as Bethnal-green, which are so much connected with the progress of this great city, that it would be a pity to be able only to find them in old maps. As far as possible, those names of places which indicate the former conditions should be retained. In the City, this should be especially the case, and many would not quietly see the Board of Works step in and change the names of the Old Bailey, Newgate, Barbican, or Bishopsgate-street; or Knight-riders-street, Ivy-lane, Cannon-street, Watling-street, by those of modern choice. John Stow was able to trace many of the names of the City streets to their origin; and the interest which they have is great. In fact, to wander over the pages of London's history. Besides, there are streets and neighbourhoods which mark important political events, in all directions, and without arrangement or consideration, Wellington and Nelson streets, squares, and terraces, sprang up; and, branching in various directions, are the Alma and Balaikava roads, Palmerston villas, and Gladstone avenues. We again call for care in making changes in these time marks.

A COLONIAL CHURCH.—Christ Church, Belleville, Diocese of Ontario, has been opened for Divine service. *The Echo of Montreal* says of it:—"The church is a neat and commodious structure, well lighted and warmed, and the seats are roomy and comfortable: the design of the pulpit and reading-desk is very pleasing, and the chancel arrangements in excellent keeping with the rest of the interior. The fresco painting, executed by Mr. Moser, was particularly admired."

## PARIS.

On the Boulevard de la Madeleine, was opened on the 12th instant, the Grand Café, situated underneath the Jockey Club at the corner of the Rue Scribe, surpassing in sumptuousness and luxury of decoration anything of the kind seen in Paris. The colossal vastness of the mirrors, the immense profusion of the gilding, and the richness of the painted ceilings, are truly wonderful as specimens of decorative art. There are three saloons. The ceiling of the first is the work of M. Gustavo Boulanger, and represents in groups of allegorical figures the fruit- and wine-bearing provinces of France, the Bordelais, Bourgogne, Champagne, Roussillon, Côtes du Rhone, &c. The second saloon contains a representation of the fraternal union of peoples, Persians, Arabians, Chinese, Europeans, Africans, all offering their homage and felicitations to Paris. This is the work of M. Emile Lévy. The ceiling of the third saloon, due to the pencil of M. Delannay, contains five female personifications.—Poetry, Science, Agriculture, Industry, and Commerce.

In continuing the Rue Fuchla, a new thoroughfare, opening a communication between the Seine at Bercy and La Villette, through the 20th arrondissement, a formerly country district of Paris, is about to be completely transformed; this is the Retrait, a place where workmen of the neighbouring faubourgs were wont to pass the Sundays and Mondays in the rustic cabarets in the midst of the vines and green fields. This formed portion of the domain of the Marchioness de Pompadour, and was known by the nickname of "Le Retrait de Cotillon II." corrupted into "Retrait," as did also the lands now occupied by the Orphelinat de la Chaussée Menilmontant, which institution has been recently purchased by the municipal authorities of Paris for 180,000 francs (7,200*l.*). This building was the site of the ancient habitation of Favart, author of "La Chérchense d'Esprit," and whose wife was a celebrated actress of the last century.

Considerable improvements have been made by the enlarging of the Bois de Vincennes, a magnificent park being laid out between the fortifications, Saint Mandi, Charenton, and the Bois de Vincennes. The ornamental lake in the grounds has been completed, and two verdant islands appear in this vast sheet of water supplied by the waters of the Marne. Two iron suspension bridges serve to join the islands together, and with the continent. This last forms, on the side next the Bois de Vincennes, a large promontory, which is a temple in shape of a rotunda, supported by an open colonnade. In the centre of this pavilion is a circular seat serving as a base to a vase filled with plants. From this resting-place a "natural" artificial rugged pathway leads downwards to the shore, where a wave-worn rock-work grotto, of remarkable effect, has been constructed,—and in Paris they do excel in rockwork,—so real that it is impossible almost to believe that it is man's handiwork, especially when we see the ledge of rocks cropping up above the water in front of the cavern to complete the illusion.

## THE DRAINAGE OF PARIS.

## INSTITUTION OF CIVIL ENGINEERS.

On March 7th, Mr. J. R. McClean, President, in the chair, the paper read was "An Account of the Drainage of Paris," by Mr. H. B. Hoderstedt.

Before describing the modern system, allusion was made to the manner in which the drainage of the city was effected up to the year 1808, when the subject first received thorough investigation, and after which numerous works were undertaken; so that by the commencement of 1832 there was a total length of drains of different kinds of 40,302 metres. The year 1832 marked an important epoch; for then the dreadful ravages of the cholera showed the absolute necessity for cleansing and draining the streets upon a better system than had previously prevailed. An accurate survey of the city, both above and below ground, having been made, levels were taken, and the principal features of each existing drain, or series, were recorded in a tabular form.

As Paris was situated wholly in the valley of the Seine, it was assumed that the drains should empty themselves into that river as far as possible, following the undulations of the streets in a more or less direct course. On the left, or

southern, bank, where the city occupied an even and almost unbroken slope, the drains discharged directly into the river, independent of each other, and without consideration of their ultimate connexion, by a transverse sewer parallel with the river, as in the system now in use. The islands of St. Louis and Notre Dame dipped on each side of a longitudinal ridge coinciding with the centre line of the river, and their surface water at once entered the river, by drains on each slope. On the right, or northern, bank, there was one slope bordering on the river, down which the drainage passed into the Seine, and beyond this there was a dip in a northerly direction, towards the brook of Menilmontant, or the track of the "great drain," as it was called, which received the drainage of all the streets on this northern slope, and which finally fell into the river at Chailot, some distance off on the west. The ridge of this slope was within the present fortifications, and from it descended another slope in a southern direction now lying beyond the fortifications, but the drainage of which could, if deemed desirable, be placed in connexion with the river on the north and beyond Paris. There were thus five principal divisions, the left bank, the island of St. Louis and Notre Dame, the right bank southernmost slope, the right bank northern slope, and the extramural slope. The Seine was subject to heavy floods, but these were fortunately rare, as during the past 216 years there were only nine on record. In 1658, the surface of the river rose 28*½* ft. above its ordinary level. In 1802, when the last flood occurred, the river only rose 6*½* ft. above the level of the discharging mouth of the modern drain at Asnières. These floods were all more or less disastrous, sometimes lasting fourteen days, and submerging large areas of the city. To check their recurrence, the low portions of the streets along the banks of the river were raised and walled in, to a point above the influence of floods so severe as that of 1658. There were, however, some parts of the city still exposed to floods, but their effects would be less disastrous, from the efficiency of the new drains, which carried off flood water almost as soon as the river level itself could subside, instead of leaving it to be absorbed or evaporated.

The progress of the drainage works might be gathered from this, that from the year 1832, to January, 1837, the length of drains was increased from 40,302 to 76,565 metres, while the new works in preparation and projected amounted to an additional 20,000 metres.

The position, cost, and object of the several drains, with the difficulties encountered in their construction, were then noticed. During 1833, thirty-three works were completed, of a total length of 15,008 metres, at a cost of about 5*l.* 13*s.* per metre. These included the first drain executed by tunnelling, the side-walls of which were built in masonry, and the arch in brickwork, at a cost of 8*l.* per metre. In 1834, there were twenty-eight works, having a length of 6,810 metres, and costing 3*l.* 17*s.* 6*d.* per metre. In 1835, twenty-two works were completed, being of the length of 8,713 metres, at a cost of 3*l.* 13*s.* 9*d.* per metre. In 1836, new drains were built in several places, and a sewer was constructed in a quicksand, the rate of progress of which was 8 metres per day.

With regard to the sections of the drains, those of the old and of the new systems differed in two respects,—the area of the latter was much larger though not more effective, and footpaths and rails for carrying waggons were provided. In the former it was arranged that, as far as possible, all the drains should have a clear height of 6 ft., in order to insure their being properly cleansed. When this height could not be given, shafts were frequently added, to allow the workmen occasionally to stand upright. The minimum inclination of the drains was 1 in 1,000; some were much steeper, and in these steps had been introduced in the inverts, principally at the points of junction with other drains. Up to the end of 1863 there were in operation 217 miles of drains, or more than four times the length in use in 1837.

As to the cleansing of the drains, before the introduction of the mechanical contrivances now in use, it was found necessary to employ hand-labour, assisted by flushing, in many of the drains having an inclination of 1 in 1,000, as that slope was found to be insufficient to carry off in suspension the solid materials of the drainage. In the smaller drains, rakes or scrapers of wood cut to the contour of the invert, were worked backwards and forwards, until the mud was drawn to a shaft, through which it was lifted.

In the larger ones the brush and rake were still made use of, aided by flushing. From both banks, and from the central islands, all the outlets poured direct into the river, and at the end of 1837 there were probably forty important outlets. Now, with three exceptions, all the discharging mouths had been abandoned, and longitudinal drains, parallel with the river, had been substituted. These finally discharged into the Seine at two places, one within and the other beyond the limits of the city.

A description was then given, showing the manner in which both the household and the rain water was disposed of. Night-soil, it was remarked, had no connexion whatever with the drains, except in one case. Most of the houses in Paris were built in blocks, with a central courtyard common to all, in which there was usually a cesspool for receiving the soil, whence it was removed at intervals. A new plan was now under trial in a few places, chiefly at barracks. This consisted in leading the night-soil into cylinders perforated with fine holes, which allowed the liquid portion to rise in an outer cylinder, while retaining the solid matter within. The liquid portion was drawn off daily, and the internal cylinder was emptied as required. In all cases the night-soil was carted away from the city, and was deposited in appointed places. A large quantity was converted into manure, at deodorising works; but only what found a ready sale was thus operated upon, so that much still went to waste.

The method of cleansing, and the appliances to effect it, were next noticed. Several of the main drains were composed of two principal parts, of which the lower, or water-way proper, formed but a small proportion of the entire sectional area. These drains which had no separate waterway were cleaned by hand. The waterway, when forming a distinct part of the work, was of three standard sizes, all cleaned on one principle, but by appliances differing in detail. One was by a cleansing-boat furnished with a scraper at the bow, which nearly filled the section, and was capable of motion in a vertical arc. This scraper formed a dam, and the water rising behind it formed a motive power, which pushed the boat forward, carrying the mud with it. This scraper, of course, required constant adjustment; and instead of being a solid disc, it was provided with three openings, the central one of which was always open, while the others were fitted with sliding shutters. A simple arrangement at the stern of the boat kept it true to the axis of the channel. Under the most favourable circumstances it seldom happened that a length of more than 800 metres could be thoroughly cleansed in one day, owing to the necessity for going over some places several times. Some of the drains were cleansed by means of a small truck, used with apparatus like that of the boats.

In order to provide for the safety of the workmen, in the event of their being overtaken by a sudden rise of water above its normal level, safety chambers had been built in the roofs, which were reached by openings in the side-walls of the drains. In June, 1855, the water rose in the outfall-drain on the right bank of the Seine to a height of 4 ft. 11 in. above the level of the side footpaths, and in that on the left bank the water rose to 7 ft. above the same level. Since then, many overflow weirs had been built along these main outfall drains, so as to carry off the surplus water after it had risen above the footpaths.

One leading feature of these works was the absence of small pipes, so constantly used in England; the smallest section ever built, under either the old or the modern system, being 5 ft. 6 in. in height, by 2 ft. 3 in. in width at the springing of the roof. As only a small portion of the total area was occupied by the waterway proper, the modern plan appeared to be very extravagant. In one case, the large space sacrificed for two water mains was instantaneous. Another source of heavy outlay arose from this circumstance: it might have been supposed that one drain of the prevailing large sizes would fully satisfy the requirements of one street. This, however, was not so. A recent Act compelled all householders to build, at their own cost, private branches in communication with the street-drains; and, apparently with a view of reducing the pressure of this Act, it had been established that in all new streets having a width of 72 ft., the City Commissioners should build a drain on each side of the street, so as to shorten the length of transverse drainage. These drains would be under the pavements, and the

effect of this Act upon the householders would then be scarcely felt. During the early part of 1861, when the author was in Paris, he noticed the rapid progress of new works in several parts of the city; but in these no provision appeared to be made for the branch drains, which it might naturally be supposed would be proceeded with simultaneously with the main drains, to avoid the expense and inconvenience of opening the ground a second time.

The velocity of the current on the Seine was not sufficient to carry off the heavy matter discharged from the drains; consequently mud accumulated in the river-bed, which was cleared by dredging, at an annual cost of 3,200*l.* being at the rate of tenpence to one shilling per cubic metre. The maintenance of the system was most expensive, involving an outlay, during a recent year, of about 30,000*l.* With respect to the drains at work, the author stated, as the result of several personal inspections, that there was a complete absence of unpleasant smell.

The materials used in the construction of the works of the old system were, a rough random rubble plastered,—a superior kind cement,—and ashlar, chiefly for the inverts. Concrete was frequently employed in the foundations, as it was now; but the selection of lime for the masonry was formerly not considered important. At present, a coarse gritty sandstone was extensively used, set in random rubble fashion, the stone forming, perhaps, not more than 40 per cent. of the work, the staple material being mortar. The sand for the mortar was coarse and fine together, as taken from the pit,—the result being a concrete rather than a mortar, which was employed in a dry stiff state. The work, nevertheless, was strong,—with a habit, it was believed, to good hydraulic lime being employed. Within the last three years a new building material, concrete, or biton "Coignet," had been introduced, the use of which had already been found to be satisfactory. This concrete was composed of sand, or ballast, dredged from the Seine, mixed with hydraulic lime and Roman cement. The cement was required to weigh 2,800 lb. to 3,100 lb. per cubic metre. This concrete cost 1*l.* 12s. per cubic metre in position in the drains, but the varieties of the mixture caused the price to fluctuate between 1*l.* and 3*l.* 5s. per metre. The mode of building with this material was described in detail.

In conclusion, the author offered his acknowledgments to M. Belgrand, the engineer-in-chief, for courteously placing at his disposal all the records connected with the works, as well as for allowing him permission to inspect them.

On the 14th a paper was read On the Metropolitan System of Drainage, and the Interception of Sewage from the River Thames," by Mr. J. W. Bazalgette. The two will be discussed together.

#### A LITERARY REVIEW FOR ITALY.

A FRIEND in Florence writes,—“I noticed in a recent number of the *Builder* a comment on there not existing a single journal in this city devoted exclusively to art, &c. I may tell you there appeared on the 1st of January a small publication of 16 pages, 2 columns, entitled *La Civiltà Italiana Rivista Settimanale di Scienze, Lettere, ed Arti*. Price 5 francs a year;—the paper, print, &c., inferior. The director, in his prefatory address, says that this is the first literary review ever published in Italy. It treats of Philosophy, Science of Language, Natural Science (the ancient sub-Lake Habitations of Vicenza), of Italian Literature, Foreign Literature, and Fine Arts. Under the latter head is a paper 'On the Preserving and Renewing of the Arts,' treating, principally, of the desirability of constructing in the new capital of Italy larger theatres, suggesting one large edifice to be dedicated to the opera, another to the drama; the elevation of musical and dramatic amusements above the very mediocre place they now hold in Italy, and the making them a means of refinement and intellectual improvement to the people, instead of, as now, that of affording a few hours' restless and useless pastime. As there is now one vast cathedral for the public worship, there should be one vast Basilica or Forum, or 'Palazzo di Citta' (Hôtel de Ville, or Town-hall) fit for the assembling of those appointed for the administration of justice, or for receiving the votes of the people. So, also, there should be one great theatre in which art might show its power; all classes of people be instructed, edified; the

feelings of the soul moved by the manifestation of the beautiful, the intellectual, and the moral. This has been effected at Milan and elsewhere; why not in the new capital of Italy?"

#### LILLE.

A CORRESPONDENT writes,—“The extensions to the limits of our town are proceeding tolerably well, but no buildings of any architectural character yet show themselves. The railway station at Lille is, as you may remember, a miserable pile; the plans for extending and improving it are made, and the works will probably be commenced this year. The facade is to be 'monumental.' A number of old places are to be demolished, to make room for a fine street upwards of 70 ft. wide, direct from the station to the Place du Théâtre; so that from the theatre a view of the railway station will be obtained, and of course vice versa. Much is required to render Lille a fine town; but that much will be done: the principal thing needed is time. In another ten years it will be a very handsome place; the system of decentralization now in vogue will tend to improve the aspect of the place, and the habits of the general population. Some new pictures have been added to the Museum, and further contributions to the Industrial Museum have been sent in. These collections are superintended by men who really take a pride and pleasure in their occupation, and will no doubt finish by forming a museum unique in its kind. The new cathedral is not quite at a stand-still: a stone now and then is added. The spirit that started this useless affair is willing, but the purse is very weak. They have already tried the effect of one lottery, and will not be allowed another.”

#### MR. EWART'S PROPOSAL FOR THE REMOVAL OF THE CARTOONS TO LONDON.

At the end of the present month Mr. William Ewart will bring forward a motion in the House of Commons that it is expedient to the artisans, as well as to the public, that the cartoons of Raffaele and the frescoes of Andrea Mantegna, he removed from Hampton Court to London.

For the most part, those who are anxious for the progress of art and the advancement of taste in this country, will wish Mr. Ewart success in the matter which he has taken in hand. At present those noble works are a great ornament to the famous palace of the Cardinal; but, notwithstanding the facilities of the railway and other means of conveyance, and the natural and artificial beauties of the place, the works of Raffaele are left comparatively unnoticed. When the summer sun shines, numerous companies of Londoners flock to Hampton Court; but, at no time is the gathering so great as during the races; and at other seasons we have noticed that more persons appear to enjoy themselves by puzzling in the maze, or wondering at the gigantic vine, or wandering by the margin of the Thames, or amid the pleasant trees and greenery, than go in real earnest to study those cartoons which many would gladly study often.

It is said that to deprive Hampton Court of those adornments would not be right, and that exposure to the smoky and polluted atmosphere of the metropolis would cause damage, and eventually destroy those noble works. As regards the first of these objections, it may be remarked that the cartoons were not original features of this palace any more than were the paintings of the heathens of Charles II.'s court; and with proper taste and judgment, and at no considerable cost, the general effect of the cartoons at Hampton Court might be easily replaced by characteristic ornamentation; and many good authorities are of opinion that works of art even as perishable as Raffaele's cartoons might,—by means of plate-glass, the proper exclusion of the atmosphere, and by the equal heating of the apartments in which pictures are kept; and, as regards oil paintings, by a plentiful supply of daylight; and in connexion with water-colours, by a sparing supply of that element,—be as safe at Charing-cross as at Hampton Court; and there can be no doubt that fifty times more persons would see the cartoons if they were placed at Charing-cross than now find the opportunity at Hampton Court.

In the course of a few years, the changes in connexion with rooms of the Royal Academy will afford a large extra space for the display of the national

collection, and afford an opportunity for the admission of many works of art which are now but little seen, but with which it is very desirable that the public should be acquainted. When these alterations are being made, it is to be hoped that care will be taken of the lighting, both in the daytime and in the evening. If the South Kensington Museum and picture galleries can conveniently and with apparent safety be shown by gaslight, what is there to prevent a similar application to the National Gallery?

When the Royal Academy vacate their half of the Trafalgar-square building, we trust that, besides making judicious alterations on the exterior, care will be taken to render the whole fire-proof, so that we may be under no apprehension respecting our treasures of art, which, if destroyed could never be replaced.

#### SANITARY AND SOCIAL MATTERS.

THE state of the dwellings of the poor in Bethnal-green again comes under notice in an inquest held on the body of a child aged six years. The deceased was one of several persons who had died in the neighbourhood of Chester-street, Bethnal-green, of diseases that there was every reason to believe had been aggravated by the bad condition of the locality. The evidence of several witnesses confirmed this suspicion, and Dr. Lethley said that the state of the dwelling in question was very bad, and tended to make fevers more malignant than they would otherwise be. The jury returned a verdict, that the deceased died from malignant scarlet fever; that the parish authorities ought to cause the houses to be put into a habitable state; and that their cleanliness ought to be enforced.

As to the excessive death-rate in Manchester, a correspondent of the *Manchester Courier* says:—"The article from the *Builder* which appeared in your impression on Monday, on the excessive death-rate of Manchester, contains a statement of facts which merits the serious attention of our corporate authorities and of the public of the city generally. . . . I find from the statistical returns of the Manchester police, that in 1864 there were 3,865 cellars in Manchester inhabited as dwellings, and in these no fewer than 12,028 persons were living. Undoubtedly some progress has been made, for I find that in the four years between 1860 and 1864 the number of people living in cellars has decreased by 5,450, so that the council has not been idle. The fact, nevertheless, remains that more than twelve thousand individuals, men, women, and children, are still housed in dwellings which, even under the best conditions, are inimical to health."

The engineer to the Stockport Corporation under the Public Works Act (Mr. Brierley), has presented to the council a report upon the present and prospective cost of sewage works completed or contemplated in the borough, in which he states that the sum already expended is 18,009*l.*, and the amount yet required to complete the sewage scheme 24,541*l.*

The returns made to the Registrar-General of Scotland show that in 1864 the births, deaths, and marriages have been considerably above the average of the nine previous years. 112,145 births were registered in Scotland in 1864, being in the proportion of 360 births in every 10,000 persons of the estimated population. This is the highest proportion of births in Scotland during the last ten years, and it exceeds the English birth-rate for the same period, which was 356 births in every 10,000 persons, also greatly above the average of former years. The birth-rate in the towns appears to be 386 in every 10,000 persons, while that in the country was only 324 in the like number. Of the 112,445 births, 101,376 were legitimate and 11,069 illegitimate, showing a proportion of 9.8 per cent. of illegitimate births, and 0.1 per cent. less than the proportion in 1863. To this proportion the rural districts contributed a per-centage of 10.1, while the towns only furnished 9.6 per cent. In the counties forming the northern division only 6 per cent. of the births were illegitimate, while in those of the southern division 15.5 per cent. were illegitimate! Wigtown furnished the highest proportion (17 per cent.) of illegitimate births! and Orkney the lowest 4.2 per cent.

Thus in Wigtown every sixth child born is illegitimate, and in the southern division of Scotland every seventh child born is illegitimate. About the boasted religion of such a country there must be something radically wrong. The Scottish clergy ought really to think seriously of it,

and consider whether the fire-and-brimstone system of terror thumped out from their pulpits be not fitter doctrine for a set of savage devil worshippers than for a civilized nation, on whose more thinking minds it can have no other result than a revolting, even though a covert and hypocritical, disbelief in all religion. Is there any other country in the world which could have produced so scandalous and grotesque an affair as that which recently occurred in Scotland, where all the young women in a village, with the approval of parents and clergymen, were examined by a medical man in order to prove that none of them could have been the mother of an infant which had been murdered?

Of the children born in Scotland in 1864, 57,455 were boys and 54,960 girls, or in the proportion of 104.5 boys to 100 girls. During the year 74,303 deaths were registered, being in the proportion of 235 deaths in every 10,000 persons. The mortality fell heaviest on the town populations, among whom it attained a proportion of 285 deaths in every 10,000 persons, while in the country districts the death-rate was only 181 deaths in the like number. There were 72 marriages in every 10,000 persons. Although this is the highest rate attained in Scotland since the Registration Act was passed, it falls short of that of England, which has averaged during ten years 83 marriages annually in every 10,000 persons.

The population was extremely unhealthy during the year, and was afflicted with an epidemic of typhus fever, which was most prevalent in February, March, September, and thence increasing till the year closed. The highest death-rate from this epidemic was attained in Greenock, where it rose to 1.42 per cent. of all the deaths. Scarlatina and diphtheria appear to have been the two other more prevalent diseases. The rainfall in Scotland was 38.4 in., which was considerably more than that in England, though closely adjoining, where it was only 16.7 in., the smallest rainfall in England of which there is certain record, while that in Scotland was above the average.

SCOTTISH PRINCE CONSORT MEMORIAL.

HER Majesty, having examined the designs for the Memorial selected by the Committee of Advice, and submitted by them to her Majesty, has expressed a preference for Mr. Steell's equestrian statue, with a solid pedestal, surrounded by groups at the base. The site proposed for it is on the level ground of the Queen's Park, in which her Majesty's site is considered appropriate from its close proximity to Holyrood, and also from the Prince Consort's presence on the occasion of the great review. The general form of this design is pyramidal, composed of several stages. On the sides of the upper pedestal are bas-reliefs, illustrative of the career and character of the prince—on the one side is a representation of his marriage, and on the other his opening of the International Exhibition, 1851. On the front panel the prince is represented in the midst of his family; and, on the back, awarding rewards of merit. On the second stage long quotations from the prince's public speeches enrich the surface; and, on each centre, a mass of classic emblems, indicative of his tastes and pursuits. At each of the angles of the first stage, or base, groups represent the people, of all classes, from the peer to the peasant, approaching the effigy of the prince, looking up to it with reverence and affection, and leaving at its base chaplets and wreaths, in token of their gratitude and love. One group is representative of the votive offerings of rank and wealth. Another group illustrates honest labour.

MOSAIC WORK, SOUTH KENSINGTON.

MR. LEIGHTON'S very effective representation of N. Pisano which adorns the wall of the East Court at the Brompton Museum, has been reproduced in mosaic, with gold background, by Dr. Salviati, very satisfactorily, and now fills one of the panels in the West Court. Some of the other figures will be similarly reproduced. Each painting should, of course, be rigorously examined before it is put into the hands of the mosaicist, and none should pass to which any strong objection can be urged. The material and process are too costly to spend on any but really fine works.

THE BATH FORUM-HOUSE COMPETITION.

THE Bath council have taken a step in this matter, or are about to take one, that will probably have considerable effect in preventing architects from wasting time in competitions for private works, and so far may be useful. They referred the selected first and second designs to Mr. J. A. Clark, of Bristol, to ascertain the probable cost of carrying them out. That gentleman in his report says:—

"I have most carefully measured both plans and ascertained the cubic quantities to be as follows:—Mr. Davis's plan, including the balconies, 1,214,165 ft. c.; and Messrs. Wilson & Wilcox's plan, 912,948 ft. c.

As near as I can judge in the absence of detail working drawings and specifications, and from the cost of other buildings of a similar description, taking into consideration the proximity of the local stone, I estimate that either design could be carried out with good ordinary new materials, and with suitable internal finishings, but exclusive of the pipes and extra fittings, heating apparatus of the baths, &c. at 5s. per cubic foot; this price would make the cost of Mr. Davis's design 27,824. 12s. 3d., and that of Messrs. Wilson & Wilcox 20,921. 14s. 6d."

The third and fourth designs were then referred to Mr. Clark, and he gave as result, —

"Mr. C. J. Phipps, 1,304,486 cubic feet. This plan being of a plainer character than the others, I have estimated it at 5d. per cubic foot, which amounts to 27,794. 13s. 4d."

Messrs. Giles, Hickles, & Isaac, 1,004,839 cubic feet at 5d.—23,027. 10s. 9d.; 69,836 cubic feet in drawing room and conservatory, if erected, at 1s., 1,472. 3s.—Total, 24,499. 13s. 9d."

The committee in consequence brought up the following report, which was, we believe, adopted:—

"The committee assuming that the council will not award the premiums formerly recommended to be given to Mr. Davis and Messrs. Wilson & Wilcox, suggest that the committee should be further empowered to resume negotiations with the architects who had already competed, with a view to some modification of the designs, similar premiums as were offered before to be awarded for the best plans."

Both Mr. Davis and Messrs. Wilson & Wilcox protest against Mr. Clark's statement. The former says, —

"Mr. Clark should not have included the balconies in his cubing; he might with equal reason have included the area of the quadrangle."

I have never erected a domestic building in the provinces at so high a cost as 5 1/2, the cubic foot; the prices in all such cases varying from 2 1/2 to 4d."

Mr. Clark has priced the second-premium design at the same rate precisely as that of the first; this is a great mistake."

I feel well assured that the estimate by cubing alone, according to Mr. Clark's report, exceeds by no less a sum than 10,000% the true cost for which my design can be executed."

And Messrs. Wilson & Wilcox send a tender from builders to carry out their design for 15,000%,—the sum named in the instructions.

Estimates by cubing, at an assumed price per foot, are altogether fallacious.

We must take the liberty of informing the Bath Council that, if they withhold the premiums offered to the architects who have already competed, they will perpetrate something very closely approaching a swindle; and we feel assured they would not willingly be thus guilty. Let them recollect the time, skill, and money that have been expended by the competitors in this matter on the faith of the Council's offer, and they will see they have no right to withhold the prize for which the competitors staked.

THE STRIKE AND LOCK-OUT IN THE IRON TRADE.

INSTEAD of being likely to come to an immediate close, the lock-out threatens extension into Scotland, where also announcements have been made of reductions of wages and a determination not to employ any of the English lock-outs or strikers. The London Trade Societies have resolved to aid the lock-outs, on the ground that the conduct of the masters is cruel and wrong. With regard to the resolution of the masters to lock out the workers in the Newcastle district, who were said to have denounced the conduct of the Staffordshire strikers as wrong, and resolved not to aid them, it is now said that the resolution of the masters to lock out the Newcastle workers arose from the fact that the Gateshead Union executive had contributed to the support of those on strike in North Staffordshire. In the Newcastle district, however, the first token of returning amity between masters and men has been manifested in the occurrence of a long conference, at which there was nothing decided certainly, but the questions at issue were referred to an adjourned meeting at York, where it is to be hoped some general system of arbitration will be adopted.

THE ABSORBING WELL, NEW BARNET, HERTS.

I HAD determined to give some account of one or more of the borings which I have made for the "British Land Company," in my forthcoming work, on "Specifications for Practical Engineering and Architecture,"\* but space could not be afforded. In case you should think the subject of sufficient interest for the *Builder*, I send you a description of the absorbing well which I have completed (some time ago) at New Barnet, and which is most successful in its operation. The London clay in this district comes nearly to the surface, or is but thinly capped with vegetable mould, or in "pot-holes," with drift gravel, mixed with clay, lumps of septaria, and occasional erratic boulders,† so that the only means of natural drainage is by open ditches; which, in a neighbourhood designed for building, would be out of question altogether. In forming new roads and sewerage over an extensive area, it became necessary to provide an outlet for the sewage, and this could only be done by carrying the water discharged by sewers into a brook (almost dry in summer), running in a valley, on the north side of the estate. This was objected to by an adjoining parish, and I recommended that the company should, on a convenient part of the estate, sink a well to some depth in the clay, and then bore (commencing with 9 in. diameter, and terminating with 7 in.) into the best water-bearing strata of the lower tertiary formations; but not into the chalk. The beds of hard grey sand arrived at, after passing through the mottled clay, yielded a supply of water which rose to within 30 ft. of the surface; but, on continuing the boring to a depth of 130 ft. from the surface, we came upon a bed of free light-coloured sand (a seam of 30 ft. thick), and the water immediately sank to a depth of 60 ft. from the surface, which appears to be its permanent level. Into this stratum I determined to carry both the storm water from the new roads and estate, and also the filtered water from the sewers, or house drainage. As the mottled clay, as well as the lower sand, in this district, is very liable to fall in when bored through, I had the boring lined with strong wrought-iron galvanised pipes, which were jointed as they were lowered.

The following is an account of the formations bored through, with the thickness of each deposit, commencing at the surface:—

	Feet.
Superficial gravel and yellow clay...	20
London clay .....	46
Dark shelly clay .....	5
Grey sands, pebbles, with water ...	2
Mottled clay .....	23
Green sand .....	9
Brown sand .....	9
Hard pebbles (conglomerate) .....	8
Fossil wood and sand .....	9
Hard pebbles and quick-sand (free light-coloured sand), level of water-bearing surface .....	14
Total, from the surface...	141

I cannot, without diagrams, make my account perfectly intelligible; and as I believe the method of performing this work will bear examination, I have sent plans and sections of the arrangement of the deposit wells, the filter-beds, the absorbing-well, and the stand-pipe and shafting for ventilation, and other particulars.

A is the inlet-pipe for the sewage; B, the settling-well; C, pipes connecting with D another well of the same description; E, the filtering tunnels; F, the absorbing well; G, stand-pipe; L, the boring; H, shoot for giving light to the well F, when it requires examination; N, side-entrance to absorbing-well; J, ventilating shaft.

On commencing the works, I first sank a well 24 ft. in depth, and 15 ft. in the internal diameter, steining the same with 9 in. brickwork, laid dry, with rims 1 ft. thick, set in cement, instead of using curbs, at every 4 ft. The bottom of this well is paved with brick on edge, in cement. At the bottom of this well the boring was commenced; and thus the staging otherwise necessary for this operation was avoided. When the boring was completed, and the pipes let down and driven home with moderate force, a York flag, pierced to the size of the bore-pipe, was fixed over it, at the bottom of the well, for

\* Spon & Co.

† Whit stone.

## THE ABSORBING WELL, NEW BARNET, HERTS.

receiving the stand-pipe, to the use of which I shall afterwards allude.

A side entrance, fitted with a safety grate and cover, in the manner of forming entrances to sewers, was built, and the well was domed over in brickwork, having a shoot lined with cement (fitted with an iron door), for giving light to the well when opened, and fitted in the centre with a York flag, pierced to receive the cast-iron ventilating shaft.

The filter beds, E, were then made: they consist of two short tunnels or culverts formed of brickwork, and arched at top and bottom, and are fitted with an examination shaft, K (which is covered with a safety grating), by means of which the material used for filtering can be removed and washed, or renewed if necessary from either tunnel, or from both at the same time.

B and D are settling wells, intended for assisting the deposit of the heavier portions of the sewage and storm water, before the filter beds are reached. They are covered with brick domes fitted with safety grates, so that they can be opened and cleaned at any time: they are connected by the pipes C, and M M M are iron cages or grates, to prevent any solid substance from passing, and the filtering material from escaping. As the bottoms of these wells are considerably lower than the pipes, they are capable of holding a large amount of deposit, and seldom require attention. All the safety covers are 2 ft. 6 in. by 2 ft., and are kept locked. They afford the most ready means of examining the

wells, and clearing them of deposit when necessary.

Perhaps an excess of caution was observed in fitting the boring, with the stand-pipe G, pierced with holes at the upper 9 in.; so that until there are 4 ft. of water in the large well, none can flow over the stand-pipe into the boring. It is necessary to prevent the escape of any matter held in mechanical suspension in the water from passing into the bore-pipe, whatever becomes of that held in solution, so that any possible escape of the finest sand through the filter-beds would be deposited in the large well F, and prevented from entering the boring by the height of the unperforated portion of the stand-pipe. There are also other advantages arising from having a quantity of still water in the large well. The side entrance affords the means of examining the stand-pipe, and the condition of the well at any time, and of removing any sediment.

The iron turret in the middle of the dome of the large well is hollow, and provided with loose movable tills for animal charcoal and chloride of lime, through which and over which any gases arising from the well must escape before reaching the atmosphere. I have some doubt as to the utility of this arrangement; but, at all events, the works are sufficiently distant from any of the intended nearest buildings to prevent the slightest chance of annoyance, whether permanent action be preserved at all times or not.

A is the termination of the sewer of the district (which includes eleven roads of considerable

length, with rapid fall for water and large building area partly appropriated), and the sketches clearly show the access of the water through the wells and filter-beds to the stand-pipe and into the boring.

The absorbing power of the boring and the efficiency of the arrangements have been severely tested during the late heavy storms. The water passed into the chamber and into the boring at the rate of 1,000 gallons a minute, without materially altering the level of the water on the stand-pipe.

I had suggested in the first instance the use of a gas-burner constantly lighted in the well F, to accelerate the escape of any accumulating gases through the ventilating turret, but the expense was deemed objectionable and unnecessary.

As the safety-covers all lock down, the key being kept by the clerk of works in charge of the estate, it is not possible for any one to incur any danger in consequence of the works, or to tamper with them in any way. In the course of a season all will be grassed over, and the only evidence of anything existing below the surface will be the ventilating-turret and the locked-down safety-covers.

A piece of land, to be let for pasturage, has been reserved near the works, on the estate, over which will be spread, from time to time, the matter collected in the deposit-wells, and the washings of the filtering materials. I am indebted to Mr. J. F. Fontems, one of the directors

THE NEWS ROOM OF THE INTENDED NEW EXCHANGE, LIVERPOOL.—MR. THOMAS H. WYAT, ARCHITECT.

of the company, for his wise liberality in allowing this useful work, in what will shortly become a populous and important neighbourhood, to be completed without question as to the necessary outlay.

JNO. BLENKARN.

*Note.*—It should be observed that the success of works of the kind described must depend on an acquaintance with the geology of the district to be drained, as many circumstances must be taken into consideration which may affect both the arrangement and the cost of such undertakings.

#### THE LIVERPOOL EXCHANGE.

At the close of the last century, the Exchange in Liverpool was held in the ground floor of the Town-hall. In April, 1801, the project of building a new Exchange was introduced, and in three hours the subscription-list, amounting to 80,000*l.*, was filled up, though no one was allowed to subscribe more than 1,000*l.*

Nearly two acres of land to the north of the Town-hall were cleared of buildings; the old streets were destroyed; and the site laid out with a large area or "quad," well known as "the Flags," the Exchange Buildings comprising three sides; the Town-hall the fourth; the statue of Nelson standing in the centre. The news-room, which forms an integral part of the Exchange, as at Manchester, Glasgow, and elsewhere, was placed in the east wing; and with it, though of smaller dimensions, the underwriters' room or local Lloyd's.

The remainder of the huge pile of building was divided into counting-houses and warehouses; a merchant usually having his office on the first floor, the rest of his taking being used for warehouses. The elevation next the Flags consisted of a Corinthian archway, columns, and pilasters, on a heavy rusticated basement, in which were the arcades for shelter in wet weather. The design is supposed to have been by the late James Wyatt. Mr. John Foster, who built the Custom House in Liverpool, held the office of architect, surveyor, and secretary to the Exchange Company.

For many years much inconvenience was felt from the limited size of the news-room, and from the inconvenient arrangements of the buildings, which were unsuited to modern wants. The site had become far too valuable for warehouses. After two or three makeshift enlargements, the directors became aware that the space was wholly inadequate for the accommodation of upwards of 3,000 subscribers; and finally, in 1857, they decided to apply to Parliament for powers to enlarge the news-room only. This, however, appeared so inadequate a provision, that the Chamber of Commerce determined to oppose the company on that ground. In 1859 a new company obtained an act of incorporation, with power to purchase the property of the old company, the site of the Sessions House belonging to the Corporation, and the street that divided these two properties. The capital of the new company was fixed at 480,000*l.* In 1862 the purchase of the existing buildings was made from the old company at the sum of 217,000*l.*, on the arbitration of Mr. Norton, of London;—a price equivalent to rather more than 70*l.* a square yard for ground and buildings. The Sessions House property was acquired shortly afterwards. Mr. Lewis Cubitt, who had held the appointment of architect and surveyor to the Company during the proceedings in Parliament, resigned the appointment at this time. The directors then determined to resort to competition for the design of their new buildings, and at the end of 1862 issued their instructions to architects, offering a premium of 1,000*l.* for the first design, and two of 250*l.* each for the second and third. In January, 1863, forty-four designs were sent in. The first prize was awarded to Mr. Thomas H. Wyatt, of London, and he was subsequently appointed architect to the new buildings.

The arcades, which bound three sides of the Flags, and formed so important a feature in the old Exchange, were, by the instructions for the competition, to be entirely omitted, and the office windows brought close to the boundaries of the property belonging to the company. The wording of their recent Act undoubtedly gave the directors power to have done so; but it was generally felt in Liverpool that the loss of the arcades, so necessary for shelter in rain and shade in summer, would be a great public inconvenience, and the Chamber of Commerce took an active part in urging their re-introduction. After considerable discussion, a compromise was

effected; the company giving up some of their ground, and taking upon themselves the cost of construction, the public and the corporation giving up some ground as a matter of compensation.

There can be little doubt that, in addition to the great public convenience, the effect of light and shade and outline gained by the arcing will be of great advantage to the design, and it was a matter of much satisfaction to the architect that this object was attained.

Owing to the necessity of providing accommodation for the news-room subscribers, for the underwriters, stock exchange and telegraph companies, occupying portions of the existing buildings, until they can be transferred into the new buildings, the works can only be done under two or three separate contracts. That for the western wing is now in active progress, and is being executed by Messrs. Holmes & Co., of Liverpool, who submitted the lowest tender for it, viz., 69,680*l.*

In this wing is comprised the future news-room, which, including the recesses for conversation or reading, will be 175 ft. long, by a clear width of 90 ft. This room forms the subject of the view given in this number. The height to the top of the dome is 75 ft. The pilasters and columns will be of Irish red marble; the plinth and dado round the room of Bardilla marble. The walls are to be lined with Caen stone. The floor will be in oak, teak, and pitch pine, so as to repeat, more or less, the lines of the ceiling. This floor will be laid on wrought-iron joists and concrete. In this wing the underwriters are to be temporarily housed until their new room in the eastern wing is built.

The public-sales room, a large restaurant, and several large sets of offices for brokers and insurance companies are also included in this division. This wing, we may add, is to be completed by May, 1866.

The total extent of stone frontages next the Flags and public streets will, when the whole design is complete, exceed 1,500 ft. lineal.

#### FOLIAGE AND HEALTH.

MANY would esteem it an act of vandalism to remove a well-grown tree from the neighbourhood of a dwelling. But, although we love the pleasant green trees as much as any one, observations made from time to time in various situations show that, in respect of health, a large quantity of foliage too close to a house is not desirable. In the first instance, it leads to dampness; the drip, without very careful drainage saps the foundations; and, under the branches, long after the sun or wind has dried up the other surface, all remains dank, and in some seasons uncomfortable. The foliage also abstracts the light to a greater extent than might at first be supposed. Those accustomed to the apartments do not notice this so particularly; but strangers seldom fail to note the unusual dimness, even at midday. The leaves and boughs also stop the proper current of air, and prevent ventilation; and in autumn, if the dead leaves are not carefully removed, there is the chance of a bad atmosphere, which has often been a cause of fever and sickness.

It is almost as easy a matter to part with a favourite dog as with a tree to which the eye has been for long accustomed; and many will run the risk of some damage to health rather than incur this loss. With skillful and tasteful woodcraft, much of the objection may be removed, and still a pleasant and picturesque piece of greenery allowed to remain. It requires, however, an artistic eye and able hand to manage this properly; and, while the branches which intercept the air and light are lopped away, so as to give admission to those necessities for health, the best of the natural forms should be kept with all possible care.

In many instances dampness and decay of both brick and stone work are seen to arise from allowing trees to grow against buildings. To this may be occasionally traced damp corners in churches; and sometimes damage is done by the branches fixing themselves into the joints of the masonry; but notwithstanding these disadvantages, there is a great charm in the conjunction of the vari-tinted foliage with ancient time-worn stone-work, and beautiful effects are produced by the occasional branch of a tree being allowed to grow in at some crack of a window, and flourish inside a sacred structure. Some years ago—it may be remaining yet—

a large part of a tree was flourishing most healthily near the altar of the church at Ross: it was said to overshadow the spot in which the "Man of Ross" was wont to take his seat.

Some creeping plants are more injurious to stone and brick than others. In several instances we have found ivy to act as a preservative. A few years since, in the King's-road, Camden-town, there stood a brick house, completely covered with ivy. This afforded a harbour for a multitude of sparrows, which in the pairing and breeding time made such a din, that it was some annoyance to the inhabitant, who made several attempts to drive away the colony by pulling out the nests; but this proving of no avail, he had the ivy altogether removed, and, underneath, the wall was found to be perfectly dry, and although the face of it had a north-east direction, there was not a single weather-stain on the whole of its extensive surface. Amid ruins the ivy preserves parts in an extraordinary manner; and although by its clinging it sometimes strangles the sturdy oak, it often serves a useful purpose, in binding together delicate mullions and tracery, and keeping intact portions of choice architectural ornamentation, which, but for its clinging arms, would have fallen many years before.

#### CONSUMPTION AND AIR.

IN a series of letters on pulmonary consumption and its proximate causes, published by a physician, in a manner, perhaps, not quite liked by his professional brethren, the writer points to the peculiarities of this fatal disease, which, says the doctor, causes in this country one-fourth of the deaths in respect of those who have passed the age of puberty. After directing attention to the dangerous effects of neglected colds and bronchitis, and explaining, amongst other matters, the construction of the air-tubes and the difficulty which there is of getting medicine administered which will act effectually, he proposes the inhalation of medicated vapours, which, together with the air, will be passed to those parts of the bronchial tubes and lungs that require medical treatment.

When we consider the large number of stone-masons and others connected with the building trades who suffer from affections of the lungs, the following seems to deserve attention:—"I have told you," says the writer, "that catarrh is a chronic inflammation of the mucous membrane lining the nose. The secretion which forms in the posterior nares falls into the throat and rapidly extends the irritation to the entrance of the wind-pipe. When once it has reached to this point, every slight change in the weather, every exposure to dust, increases the irritation and carries it onward to the larynx, producing slight hoarseness, and into the bronchial tubes, causing the secretion of sticky, bluish-white mucus. You see, then, that a catarrh produces the irritation on which this mucus depends. The wind-pipe and the bronchia in which it forms, are the tubes through which the lungs receive the air necessary for the removal of the carbon from the blood. Do you suppose you can obstruct those tubes and yet not diminish the air drawn through them at each respiration? If you diminish the air received into the air-cells, you cause a portion of the carbon to remain in the blood. The moment the air is shut off from a cluster of air-cells, the capillaries of those cells become gorged with imperfectly decarbonised blood, and are liable to become tuberculous. Kind nature may be patient with us for a long time, but sooner or later a deposit of carbon takes place in the obstructed part, and from that moment the disease has changed from a simple catarrh or bronchitis to the most fatal disease known to our race."

Looking at pulmonary consumption from this point of view, it is clear that while timely attention to the approximate causes of consumption above referred to is a necessity, the breathing at all of a sufficient quantity of pure air must also have a beneficial effect on the prevention of consumption; and it is also worth while to mention that the tubercles are little granular bodies deposited from the blood. They are most frequently located beneath the mucous membrane of the air-tubes; but they are also deposited in the air-cells, and on the free surface of the mucous membrane. When they are found on the mucous membrane of the air-tubes, it is not uncommon for small portions to become detached and be expectorated by the patient long before any part of the lung has been necrotic.

FINISHED WORK.

Οὐ γὰρ ἐτύγχευε τὸ φημί τίς τις χαριστήριον αἰτίας. Homer.

It stands at last—the vision of a dream—
Of my long dream, in timber and in stone—
Of my long toil with compass and with rule,
How silent now, where lately, day by day,
And week by week, the grating of the saw,
The chipping of the chisel ceaselessly,
And deafening ring of many hammers woke
A thousand echoes from the hollow ribs
And sharp reverberant timber of the roof;
And all day long, the busy bee-hive hum
Of workmen plying each his proper task
Resounded in the yet unshallow ditches.
Far other echoes they shall hear to-morrow!
The pure-voiced children's chant antiphonal,
Soft hymn, and holy prayer, and benison
Shall breathe around, till transept, nave, and choir,
That yet have been but consecrate in thought,
Be made for ever holy to the Lord;
Hallow'd from all profane and common use,
A home of prayer, none other than the house
Of God Himself, the very gate of Heaven,
How clear and white against the evening sky
(All disremember'd of its scaffolding)
The steeple rears its slender height to heaven;
Its holy symbol glittering in the light,
And all its bells depending silently
To wake to-morrow with a joyous clang
And herald in their dedication morn.
The lengthen'd beams of the declining sun
Pour through the western window like a flood,
Lighting the chancel with a glorious gleam,
Gilding the cross upon the chancel screen,
Gilding afresh the altar's broiler'd gold,
Gilding the quaintly-pattern'd organ-pipes
So soon to peal in rushing harmony;
Lighting the carven woodwork, bringing out
The floral emblems on the capitals,
The cunning tracery of the poppy-heads,
The angel-headed bosses, and the scrolls,
The holy texts engraven on the walls,
And all the hidden mouldings of the roof.
I did not think to see my work so fair,
And yet I look upon it not in pride,
As knowing best my own unworthiness:
Rather, with something of that loving awe
And trembling thankfulness a mother feels
Who gazes on her infant baptiz'd,
And knows, that ere a few short hours have run,
The healing dew, the touch of holy hands
Shall make him clean and pure, a child of Heaven,
A living temple of the Holiest.
I gaze upon my work unconquerate.
Yet as I gaze, there comes unto mine ear
A stealthy whisper on the evening air,
A sudden whisper of the world's cold breath,
Saying, "Unto what purpose all this toil
Of brain and hand of compass and of tool,
This spendthrift scattering of costly art?
Where scarcely one shall see it, one regard?
We hadd him build a church for common men
To meet in, and to worship and to pray,
And not a gallery of deep research
For mystic wise and learned antiquary,
Who else shall read his high-down symbolism?
Deems he our prayers shall he the more devout
Because our church's plan displays a cross,
Because we kneel on tessellated tiles?
Or will our organ give out sweeter sounds
For all the quaint devices on the pipes?
Or will our choir-boys be more reverent
For all the carving of the chancel-screen,
And cunning tracery of the poppy-heads?
These make not worship pleasing unto Him
Who dwelleth not in temples made with hands,
Who looks not on the appearance, but on the heart.
Even if the man would build himself a name,
A mighty monument, like him of Paul's,
That men might look around and marvel at him,
He has not gone the wisest way to work,
Who does he think will peer in every nook
And hidden corner of his fair design
To seek the impress of his master-mind
And master-hand?"
I answer, "Not for this—
I have not sought to build myself a name—
To row a gallery of deep research
For mystic wise and learned antiquary;
Nor only, though in part, a place for men
To meet in, and to worship and to pray;
But more, a House where He vouchsafes to dwell,
Whom Heav'n's consoling note: where He Himself,
In His own written Word, will speak with men,
Or by the mouth of His own chosen priests,
Or in the highest mysteries of our Faith.
And thus my work has been a work for God,
And being such, it is the very least
And poorest I could offer unto Him;
Ay, were it ten times fairer, all too mean
Aid all too poor for such an offering.
Ye that have given your wealth ungrudgingly
Regrudge me not the little I can give,
I have not gold and silver to bestow,
And yet I would not offer unto Him
Of that which costs me nothing. He hath spread
His microscopic wonders over earth,
And air and water, painted wondrously
Each little blade and flower that grows unsee,
To teach us men, that what we take in hand
Ourselves should make as perfect and as fair
(Though after our poor measure) as we may;
Then surely chiefest when we work for Him.
If He hath given His servants eyes to see,
A mind to know 'the glories from the base,'
A hand to guide the compass and the pen,
These are His gifts entrusted to my care,
A trust for which I have to give account.
Whether I strive to use it unto Him,
Or in my own conceits, or worse than all,
Keep the one talent buried in the earth
And worthless.
If your prayers shall be more pure
I know not, or your organ-strains more sweet,
Or if your choir shall be more reverent,
Because the place is fair wherein ye kneel;
These things are yours to answer and to heed,
But I would fain ye should not lack herein
For holy signs and remembrance.
For marks and symbols of our common Faith

To catch the wandering eye, and to bring back
The wandering thought from earthly things to heaven.
And I would fain, that, if ye held your peace,
Each stone, beneath, around you, should cry out
'Hosannas' unto Him; and every beam
Out of the vaulted timber answer it;
And every nook and every hidden spot
Where scarcely eye of mortal man will look
Should yet be perfect in its inmost part;
Should bear some impress, not of me, but Him
Who gives His servants all they have to give.
I do not seek to build myself a name.
A monument, that men may look around
And marvel at my genius and my skill:
Yet I would ask, of those who worship here,
Not to be unremember'd in their prayers,
If there shall be, of those who worship here,
One of CHRISST'S little ones, to whom the sight
Of lofty fans or storied glass has made
Some holy lesson plainer to his thought,—
Or if there be, among the worshippers,
One childlike heart, a little one of soul,
One who disdains not little outward helps,
To whom a holy picture, text, or sign
Seems like an angel whispering of heaven,
Then let him offer, of his charity,
A prayer before the Throne of Grace for him
Whose hand, unworthy, rear'd the sacred pile;
That however here, by many a blow
Of earthly sorrow, many a sculpture creak
Of earthly chastening, polish'd by the hand
Of Him in love who chastens all He loves,
He prove not quite rejected at the last;
But of CHRISST'S mercy, in the glorious Church,
The new Jerusalem, a living stone,
His resting-place, however lowly, find."

VOLUNTARY ARCHITECTURAL EXAMINATION.

EVERY one who wishes well for the success of
the above scheme must regret its failure this
year. I will not now occupy your space by de-
tailing the causes which I believe deter many
from presenting themselves as candidates, but
will simply note down what appear the most
prominent objections:—

- 1. The time required (six consecutive days,
should they require to pass both), which few
could spare from their daily avocations.
2. The total absence of vivâ voce examination.
3. The great mass of subjects, and the limited
time for examination in each subject, causing a
complete "drive" to get through a sufficiency
of the allotted work, leaving not a moment for
thought or deliberation; whilst a greater portion
of the work could be far better explained vivâ
voce, with the aid of rough diagrams on paper
or a black board, and in about one-sixth the
time.
4. The diversified nature of the subjects for
examination, some in branches probably neg-
lected by the candidate since leaving school, and
for which he has (at the expense of time he
might devote to professional studies, practical,
theoretical, or artistic) to grind up, probably to
drop them again the day after the examination.
5. The misnomer of "Class of Distinction,"
impossible in architecture without years of study
and experience, and resting gracefully only upon
older heads than will present themselves for the
examination.
6. The total absence of any certificate or defi-
nite result, candidates being expected to study
and present themselves for a varied but perfectly
aimless examination.

I would beg to suggest the following as outlines
for somewhat reconsidering the scheme:—

- 1. Let there be six examinations in the year,
consisting of one day in each alternate month,
each in a distinct branch of study.
2. The examination to be partly written and
partly vivâ voce.
3. A certain number of marks to be taken as
a maximum, and a certain scale of deductions
to be made for all errors during the examination.
4. A memorandum to be given, in each sub-
ject, to all who gain the requisite number of
marks.
5. The "Class of Distinction" to be abolished,
and "class lists" established; viz., Class I.,
Class II., Class III.
6. To be placed in Class I., a candidate must
have gained (say) 80 per cent. of the marks
allotted in each of the various branches of the
five days' examination, and also at least half the
number on the sixth day, which would be set
apart more especially for the higher branches
and languages.
7. To be placed in Class II., 60 per cent. of
the marks in each of the first five days' exami-
nation would be necessary; but attendance on
the sixth would not be required.
8. To be placed in Class III., a candidate
must have gained at least half the allotted
number of marks in each subject on any four
days out of the six he selected to present himself
for examination.

9. A final certificate of having passed the
examination, stating the "class" signed by the
examiners, and countersigned by the president
of the Institute, together with a copy of the
published class list to be given to each successful
candidate.

I trust some able pen will take the matter in
hand, and make more detailed suggestions, for I
cannot help thinking that the division of the
examination into parts has in it the elements of
success; that a large number of candidates
would present themselves; and that in a short
time the "Institute Class Lists" would be as
cagerly scanned and quoted by the profession as
the University class lists now are by others.

A. B.

BRITISH ARCHÆOLOGICAL ASSOCIATION.

At the meeting on March 8, Dr. Copland in
the chair, Mr. Gunston exhibited a collection of
leadn signacla, recently found in London,
especially on the site of the Old Steel-yard,
Upper Thames-street; and Mr. Cuming read a
paper upon their peculiarities. Many of them
were exceedingly interesting, formed of pewter,
calculated to hold the blood or other relics of
martyrs, and had representations of the murder
of St. Thomas à Becket. One vessel exhibited
a figure of St. Erasmus, with his emblematic
windlass. An image of St. Edmund the Con-
fessor was found near the place of his burial at
Westminster. The costume of the king fixes
this at the second half of the fourteenth cen-
tury. The remainder were of St. John the
Baptist and the Saviour. The latter as a nimbud
infant, the face only being visible, the body
covered with a rich pall. It had probably be-
longed to some relics of the Nativity, and is of
the fourteenth century. The image of St. John
the Baptist is late in the fourteenth century, and
was found in the progress of works now going on
for the Thames Embankment. It is presumed
to have been worn as an amulet.

A paper, by Mr. Read, of Ipswich, relating to
Joseph Grove's MSS. concerning Cardinal
Wolsey, was read; and, from the manner in which
his works appeared, accounted for the difficulty
of obtaining a complete copy. Miss Holden, of
Swathing Grange, exhibited three pennies of
William the Conqueror (William Rufus), form-
ing a portion of the remarkable find, in 1838, at
Beauvoir, near Winchester. Mr. Borgeus sent
a minute description of the coins, showing them
to have been severally minted at Norwich,
Taunton, and Dorchester.

A paper from the Rev. Mr. Kell was read, on
"the Discovery of a Roman Buiding at Gur-
nard's Bay, Isle of Wight," by Mr. J. C. Smith,
who sent a plan of the building, tessellated pave-
ments, &c.; specimens and drawings of the po-
tery, and other utensils obtained. The paper
gave rise to considerable discussion, and the
examination will be further pursued.

RATING IN THE METROPOLIS.

WHEN we consider the enormous amount of
taxation levied upon the metropolis and the
amount of rates for improvements, some of
which seem to have a national as well as a local
interest, and mark the strong and often ill-
tempered opposition which has been made by
provincial Members of Parliament to any assist-
ance being granted from the national exche-
quer, it is not wonderful that cases in which
property of various kinds belonging to the
nation, generally, situate in the metropolitan
districts and elsewhere, should be exempt from
the usual amount of local taxation. In con-
nexion with this question, a large and influen-
tial deputation has waited upon the Lords of
the Treasury, and directed attention to the fact,
that the parish of Chelsea contains 771 acres of
land, of which 761, or nearly one-tenth of the
whole area, were taken up by lands belonging
to the Crown or occupied for national purposes,
and were therefore withdrawn from parochial
rating; and this, as urged, operates as a detri-
ment to the ratepayers by increasing the com-
mon burden, whatever might be the amount of
expenditure. At the conference with Mr. F. Peel,
on the part of the Lords of the Treasury, Mr.
Titie rightly remarked that the public establish-
ments at Chelsea, unlike Portsmouth, Clatham,
Deptford, Woolwich, Plymouth, Devonport, and
other places, were of a class which, instead of
benefiting the locality, not only operated as
deductions from the rateable property, but by

their indirect effects added to the burden of pauperism, or further diminished the productiveness of the rates.

The rateable value of the assessed property in the parish at the last valuation was 235,899*l.*, and the amount of the rates at 4*s.* 4*d.* in the pound was 51,256*l.*; and what the deputation contended for was, that Chelsea should be treated in the same way as other places which were mentioned, and that the sum voted should be adequately proportioned to the parochial rates. Taking Plymouth as a criterion, where the rateable value was 198,421*l.*, and the average rate 6*s.* 2*d.* in the pound, and which received a subsidy of about 6,000*l.* from Parliamentary grant, Chelsea would be entitled to receive about 6,000*l.* instead of 700*l.* Taking, however, the principle of assessment adopted over the whole parish to be equitable, and the total assessment of the parish were increased, as it should be, by 51,600*l.*, then the same amount of money, which is raised by a 4*s.* 11*d.* rate, would be obtained by one of 4*s.* in the pound, and the annual equivalent for the property occupied by the Government would be about 19,000*l.* In reply to a question by Mr. Peel, Mr. Tito produced a plan of the parish, and said that upon the land occupied by the Government (70½ acres), 1,540 houses suitable to the neighbourhood could be erected, the rateable value of which would amount to about 54,600*l.* Mr. Peel expressed doubts about the space referred to being likely to be occupied by houses in the manner mentioned. Mr. Tito, however, said he had no doubt that the whole or part of the land would have been occupied by eligible and rateable property.

Mr. Finch contended that the grant of 700*l.* a year which the Lords of the Treasury gave in aid of the local rates, was not at all an equivalent for the very large amount of land occupied and the very deep injury inflicted by this class of Government establishments in their district. A portion of the site occupied by them was a most valuable river frontage, as well as some of the best parts of their district, and the character of the establishments brought pauperism into the parish, and a large amount of immorality. Indeed, they were overburdened in more ways than one. Thus they were bounded by the palatial residences of St. George on one side, and those of Kensington on the other; and the working class who had been erecting these residences made Chelsea their home, and when out of employment were thrown upon the parish.

Mr. Peel, in the usual official manner, endeavoured to show that no loss had been sustained by the parish.

Mr. Hall mentioned, that had not the Government taken the frontages of some of the best roads of the district, it was the intention of Mr. Brett, the owner, himself to have built some very fine residences.

Earl Cadogan urged that it was not only injury arising from exemption of the Government establishments from rating of which they complained, but the burden as well as the immorality this inflicted upon the parish. The Royal Hospital induced pensioners to flock from all parts of the country in the hope of obtaining admission; they brought their wives and children with them, and became located in the neighbourhood; and in the event of failure, and sickness, and death intervening, they became chargeable to the poor rates. The same remark applied to the Royal Military Asylum, and the recently erected barracks also added to the parochial evils.

After some further discussion, Mr. Peel admitting that there was something in the last points urged, promised to refer the matter to the consideration of the Lords of the Treasury.

#### RENTAL VALUE OF HOUSES—WHERE WILL IT STOP?

WITHIN ten years there has been a considerable increase in the rents of houses, which, as the metropolis extended and buildings multiplied, have become dearer to the occupier. About the year 1850, the rent might have been computed, on an average, at 5*l.* a room per annum, unless in exceptional positions;—for an eight-roomed house, 40*l.* per annum; one of ten rooms, 50*l.*; of twelve rooms, 60*l.*; and so on; and as the capital has spread out and swollen, the original and central portions have assumed a value that could never have been anticipated. The aggregation of residents from our own prosperous colonies, as well as from all other countries, tends to the further inflation and increase of population

in this mighty city, which, having housed two million souls fifty years back, now harbours three millions, and contains over 300,000 houses. Where this may stop it is difficult to imagine, as also how it can be possible that, if such growth and progression be continued, the metropolis shall still retain its attractions, or the supplies required by such multitudes can be provided through the ministrations of commerce, or even the mediation of railways.

In the outer boundaries of London, on all sides, there are still ranges of fair and clean-built dwellings, planned to suit persons of moderate income, at the rate of about 5*l.* a room; but these must be sought outside the circle, three miles from Charing Cross, within which range the enhancement of cost prohibits all the industrial and operative classes, some only in the old narrow streets, by-lanes, and more repulsive, because unimproved positions. Into these also the progress of amendment advances; and although there is much noise and stir about erecting model lodging-houses and abodes for the working classes within the bills of mortality, nothing commensurate to the occasion has been carried out in practice, or even been attempted. What little has been done by humanitarian associations is scarce a feather in the balance of exigent necessity. The efforts of the civic corporation to meet the growing evil have resulted in the allocation of a plot in Farringdon-road, and the drawing out of a plan for a structure to shelter a hundred families.

The interests of railway boards in reducing fares for operatives by cheap trains in the morning and evening, or while going to and returning from employment, is the more feasible and probable method to render some compensation for the extension of multitudes and subversion of whole districts of houses. In Paris the demolition of crowded quarters is met by a provision of suitable buildings in the suburban and less valuable parts. There, however, a ruling authority assumes the power and carries out the system. Here all rests with the parties interested in the localities affected.

As the intrinsic value of fixed property has of late so much increased, so the management, also, has received a different treatment. Formerly houses to let were ticketed and reference made direct to the proprietor or his agent. The class of negotiators called house agents were little known. Perhaps in all London there might have been a score, now there are much over a thousand! Although requiring no diploma, it has become a profession. Many there are who publish monthly lists of houses in town and country, mansions, parks, estates, villas, and suburban retreats. They engross the whole market, and, in order to enhance the value of their own peculiar office, it is suggested to proprietors to demand 5, 10, or 20 per cent. increased rent. Or, as of late, it has become common enough to require the rent of a year or two in hand by way of premium. This, of course, bestows a value on this mediation, and cannot be unacceptable to a landlord, while it secures the preference of employment.

Suggestions of this kind are often made; but there is a respectable class of agents who do not practise it; for in house agency, as in other settlements between parties in negotiation, there is, or ought to be, an equitable respect for the interests of either side, adjusting responsibilities, and reciprocating liabilities. To these new agencies, however, is in a great measure due the enormous increase in the value of house property, which, within eight years, has advanced in many instances 50 per cent., and, in general, full 20 per cent. throughout the metropolis.

Seeing that 5 per cent. for the first 100*l.* of rental, and also of premium is charged, besides the fees on agreements or leases, which house agents now draw out, instead of lawyers, the profits of this new trade make it a good one; and, as the repairs are not unfrequently entrusted to the same party, it would be difficult to estimate his share of the rental.

To stay or modify the enormous rise of rents and building sites in central positions or fashionable quarters would be impossible while the population increases and commerce flourishes in the present ratio; but it may be possible that the interests of house-owners in outer circles are not improved by the late advance of twenty per cent., which constrains five out of six house-holders to let out and subdivide their domicile; thus changing the old-fashioned notion that each man's house was his castle.

Whatever the cause may be, it is clear that the French plan of erecting many mansions in

one house is fast obtaining place in London: the success of chambers in Victoria-street and other districts, and the preference shown by the high rents they command, prove that such a system, even though accompanied by the controlling supervision of a "conierge," must find its place here also, from the grandest pile to the model lodging-house, or to the smaller abode of twelve or twenty rooms, by subdivision: economy in rent is met by safer returns and larger profit to the landlord, that is, in all cases where houses were planned and designed for the purpose. There are, of course, classes who will always require town mansions or private and reserved houses; but the industrial classes, the employes of trade, and those retired on limited means, must find cheap lodging, and the great mass of the community is composed of such.

QUONDAM.

#### THE NEW COURTS OF JUSTICE.

SIR,—Referring to the proposed limitation of the competition in this matter, may I ask you are to be regarded as the "architects who stand high in their profession?" We of course know some of those who have the good fortune to stand at the very top of the tree, but where is the line to be drawn, and justly by whom? What is to be considered the standard of eligibility in such a case? Is the limit to be marked immediately outside the circle of a favoured few in London (as, for instance, those invited to compete for the Prince Consort Memorial)? Or is a provincial element to be admitted? If it is not in some way, a grave injustice will be done; if it is, where is the line to be drawn there?

Any limitation whatever in a public matter of this kind would appear to be as unnecessary as it is injudicious.

I would venture to suggest, if there be no possibility of the authorities being induced to throw the matter open to public competition, that, as a modification of the extremely limited system, the principal architectural societies throughout the kingdom should be permitted to nominate from their ranks a limited number of candidates to enter the lists in competition. J. D.

#### WESTMINSTER ABBEY.

By all means, let the Dean and Chapter expend their means on this work; but let a plea at the same time be put in that really something should be done to render their church somewhat better than an ice-house, for the benefit of those who attend the services and do not merely seamer through the building as an exhibition. Eight months out of the twelve, it is positive privation of ordinary comfort to attend there. The officials, vergers and headmen, need only be asked to learn what they experience.

St. Paul's Cathedral, once far worse in respect of damp, chill, and draughts, has been rendered the most satisfactory place of worship in this metropolis. Why should the western (quasi) cathedral remain unimproved? Equal talent is at command to insure equal success. Granted the facilities are not so great for effecting the change, still something might and ought to be done. Pray, Mr. Builder, do make some stir in the matter.

Additional internal doors of entrance, and a free use of gas stoves (the gas is laid on in the nave) throughout the building, would do something in aid. C.

#### THE ARCHITECTURAL MUSEUM PRIZE SCHEME.

SIR,—I shall be pleased if you will kindly allow me to say a word or two on the above subject, as I believe it will partially explain what I am sure will be a matter of regret to the council of the Architectural Museum.

In the award of prizes this year, the wood-carvings were all considered too poor to deserve any reward. With one exception I can quite agree with this decision; but, at the same time, I should like to speak in defence of the competitors.

The prizes for the previous year were distributed in March; the prospectus for last year (1864-5) did not appear till the last week in August, five months afterwards, and the competitive works were to be sent in by the 1st of December, thus allowing only three clear months for the following very formidable task,—an illustration of the parable of "The Good Sa-

maritan," carved in oak: not less than three figures, and one animal, with foliage, &c., the panels to be 2 ft. 3 in. by 1 ft. 10 in., exclusive of mouldings.

To art-workmen, who have only their evenings and odd hours to devote to the competition, such a task in such a short time would simply oblige them either to "scamp it" or not compete at all.

A friend of mine, writing to me on the subject, about a week after the prospectus appeared, said (I quote his own words),—"The time allowed is so ridiculously short, I could scarcely get a piece of seasoned wood in the time."

If, therefore, I might take the liberty of suggesting that less time be lost in issuing a prospectus, and more time allowed for undertaking such extensive jobs, the competitors would have time to devote some thought to their design, turn out their work creditably, and, if I am not greatly mistaken, the council of the Architectural Museum would have the satisfaction of seeing (what I am, sure they wish) their prizes contested for in a more spirited manner.

I am afraid, sir, I am trespassing on your space; but you will be doing good service to the prize scheme if I successfully entreat you to notice this request of

A WOOD-CARVER.

DETECTION OF BURGLARS.

ALLOW me to suggest a contrivance for the better security of property, and by which a burglar might be detected at his work. A common gas lamp, provided with a red shade, similar to those used on the railways, should be suspended in the street in front of the bank or shop, where valuable articles are kept; the red shade should be held up above the lamp by a magnet, worked by a small electric battery, situate at any convenient place on the premises; the wire from the battery to the magnet should pass through the safe, doors, and drawers containing valuable articles; and as long as the connexion is complete between the battery and the magnet, the red shade would be held up in its place above the lamp, showing a white light; but as soon as the connexion was broken by opening any of the doors or cases, the magnet would immediately lose its power, and allow the shade to fall in front of the lamp, thus showing a red light, and giving notice to any one in the street that something was wrong inside; and when once the shade had fallen, it could not be replaced by the burglar. These magnets are very simple, being made of a piece of soft iron, bent in the form of a horse-shoe, with a coil of copper wire round the ends; and the cost of working the battery would be a trifle.

Geo. F. ELLIOTT.

STREET AND HOUSE INDICATOR.

HAVING frequently experienced considerable difficulty, not only at night, but also by day, and particularly during foggy weather, in ascertaining the name of the street or square in which I happened to be—as well as being at a loss to identify the place I wished to find,—I have devised a simple and very inexpensive plan by which this provoking and dangerous difficulty can be removed, and so prevent the necessity of making personal inquiry, which, in many parts of London, and our large towns, is neither a safe nor a pleasant thing to do; for it at once shows "the stranger," and exposes him to all the sharp practices of the disreputable characters that prey on "the lost" and "the wanderer."

It consists in having the name of the street, square, public building, or house (if in the suburbs) cut out in perforated letters on a strip of zinc plate, 1½ inch wide, with the numbers of the approximate houses before and after the name, and hanging it up by a bit of wire at each end, into small wire eyes, soldered in the inside corners of each street or private lamp, which will be readable by day as well as by night, the light of the lamp shining through the perforated letters. There should be two of these plates in each street-lamp, which street, we will say for illustration, runs east and west, one on the north, the other on the south side of the lamp; so that looking at the lamp from either the foot or carriage way, the inquirer will, at a glance, not only see the name of the street, but also the direction in which the numbers of the houses run, and so at once know if the number he requires is above or below him. In the lamps that are placed at the corners of streets, there should be other two plates hung up on the

east and west faces of the lamp, with a perforated pointing hand, after the name of the cross or by-street. This would indicate to all passengers, foot or horse, the name of the street they were approaching at a considerable distance before arriving at it,—a thing of great advantage to strange coachmen and carters. In the suburbs of our towns the names of the villas, cottages, &c. might be placed in their respective private lamps. In parks and large public gardens the names of the walks and the direction of the pathways might be indicated by the help of the lamps; also, and not least, all railway stations might have their name placed in each of their lamps, so that should a sleeping traveller wake up, he could at once see, without feeling any distrust in the station-crier's call, if he be the station where the friend is expected or where the journey ends.

All existing lamps round a square only require the wire eyes soldered in their top corners to be available. As the strips of zinc hang in the lamps, they can be lifted up or unhooked, to clean the glass of the lamp. Should the glass be broken, the plate remains perfect; or, if bent, may be straightened by hand, and being in the inside, it is not acted upon by soot or water, and so will last almost for ever.

I have fitted up a street-lamp which, through the kindness of the chairman of the Metropolitan Board of Works, has been exhibited to the members of the vestries of London. It is now deposited in the South Kensington Museum, for patents, for public inspection and *pro bono publico*.

LAURANCE WILLIAMS.

A CIRCUS IN CORNHILL.

THERE is now a capital opportunity for making a circus at the junction of Cornhill and Leadenhall-street. Nearly all the houses have been removed on what should constitute the northern half of the circus, and, if allowed to be substantially rebuilt, the blockade, which is perpetual on this spot, will continue,—a disgrace to the City for all time to come.

O. D.

HANGING A FIELD GATE.

A CORRESPONDENT of the *Hereford Times* says, farmers know that our gates frequently droop or sink on their hinges, so that the end farthest from the "hanging post" drags upon the ground, making it difficult to close the gate, and the friction ultimately shakes it to pieces; and, further, the unbalanced state of our gates throws a severe strain upon all the joints, and if not strongly made these joints soon give way. The Belgian farmer adopts a plan which avoids these evils. He balances his gate like a axle-beam—rudely enough, certainly, but the same principle can be applied in a neater manner. In Belgium the top bar of the gate is frequently a tree, suspended upon the top of the hanging post in such a manner that the butt or heaviest part of the tree hangs upon one side of the post, and the stem or lightest part on the other side. This lightest part forms the top bar of the gate, and to this the remaining bars are fixed. When complete, the weight of the gate about balances the butt; thus there is no tendency in the gate to droop, and instead of having to build a gate whose joints give way from the strain produced by our way of hanging, the lower bars of the gate may simply be suspended from the top bar, and thus durability and economy be obtained.

A neater method than using a tree would be to balance the gate by a stone or iron weight fixed to a bar (a continuation of the top bar of the gate) and projecting behind the hanging post; and perhaps, without incurring the cost of a wood cut, you may, by the aid of type lines, give a sketch of such a gate:—

1, hanging post; 2, top bar of gate; 3, weight to balance the gate, 4, 4.

A FEW FACTS CONNECTED WITH ISSUE OF PATENTS IN ENGLAND DURING THE PERIOD OF ELEVEN YEARS, FROM 1853 TO 1863 INCLUSIVE.

As you are evidently interested in any information connected with patents, I beg to send you an approximate compiled list of patents issued during the past eleven years, extending from 1853 to 1863 inclusive; in the abstracting of which from published report in the *Times* of February 9, 1865, I have been struck with the remarkable correspondence and coincidence of date, year by year, which reigns throughout, the fluctuations being scarcely perceptible, and exhibit a remarkable fact, that apparently there is a governing or regulating principle or code of action passing over the system of English patenting, which is certainly at the least very strange, and it may be interesting to your readers.

A PATENTEE AND CIVIL ENGINEER.

The number of applications for patents averaged, during the period...	3,000 each year.
Out of these, with complete specifications, were.....	50 "
Leaving residue, provisional specifications.....	2,950 "
And of these were English inventions.....	2,900 "
Leaving residue, foreign inventions.....	700 "
Out of these were sealed.....	2,900 "
And paid the third year's duty of £100.....	550 "
Leaving as lapsed or forfeited, at third year.....	1,460 "
And paid the seventh year's duty of £100.....	150 "
Leaving as lapsed or forfeited, at seventh year, an additional.....	350 "
Showing that out of the 2,950 patents annually sealed, there were lost before the expiration of seventh year, or half the duration of the English patent.....	1,810 "
And that one patent out of four, of 2,000 sealed, paid the 5th, third year's duty of £100.....	500 "
And that one patent out of eleven, of 2,000 sealed, paid the 10th, seventh year's duty.	

The termination of the year 1867 will develop the number of patents which will then have reached their fourteenth year of term, out of the 2,000 sealed in 1853.

THE CHURCHYARD CROSS AT CHEDDLETON.

WILL you allow me to intrude for one moment upon your columns, merely to mention that the design for the Churchyard Cross which you were so kind as to notice in your last number, is due, not to me, but to my son, G. G. Scott, jun.

Geo. GILBERT SCOTT.

COMPENSATION CASES.

WILKS v. METROPOLITAN RAILWAY.

ON February 28, a special jury was summoned before the Under Sheriff of Middlesex, to assess the compensation for Nos. 69 and 70, Acton-street, Dagenham Wells-road. Mr. Giffard and Mr. Harrison appeared for the claimant, and Mr. Lloyd and Mr. Holloway for the company. In the absence of the leaders, Mr. Harrison opened the case, by which it appeared that the claimant had an unexpired term of seven and a half years, at 21½ a year, and that the premises were underlet, part yearly, at 40s., and part on lease, at 7s. The claim was for 2,200l., a considerable portion being for the reversion after the expiration of the underlease, on which much discussion took place; the company contending that the lessor ought not to reckon on breaking the underlease. The witnesses for the claimant were—Mr. E. Roberts, Mr. Haines, and Mr. Green; Mr. Fownall and Mr. Lee, for the company. After a short time, the company agreed to a verdict of 1,900l.

DAMAGE SUSTAINED BY THE WORKING OF A RAILWAY.

An important case to claimants was recently heard at the Newington Sessions-house, before the Hon. George Denman, Q. C. assessor, and a special jury. Mr. Sergeant Parry, with Mr. Barnard, appeared for the claimant; Mr. Lloyd and Mr. Horace Lloyd for the railway company. William Henry Ball, a livery-stable keeper, of 29, Amies-street, Walworth, claimed from the London, Chatham, and Dover Railway Company a sum of 500l. for an alleged injury to his business, as livery-stable keeper, by reason of the noise and vibration caused by the traffic on the line. His premises were 100 feet from the railway, and other property intervened. Structural damage to the house from vibration was also alleged, but was not proved. After hearing evidence of considerable length, the assessor directed the jury that upon the case recently decided of *Ricketts v. The Metropolitan Railway*, and the case of *Penny v. The South-Eastern Railway Company*, the claimant was not entitled to any compensation for damage sustained by him consequent upon the working of a railway the traffic upon which was carried on under special powers conferred by the Legislature upon the railway company. The jury returned a verdict in accordance with that ruling.

SH.—The report in your paper of the cases of Hart and Faulkner v. The Metropolitan Railway is not quite correct as regards the claims made against the company: I shall therefore feel obliged by your giving the exact amounts, which were as follows:—

	Claim.	Award.
Hart .....	£2,434 0 0	£1,329 0 0
Faulkner .....	686 0 0	0 0 0

RAPHAEL BLANDON.

## FROM IRELAND.

*Dublin.*—The allotments of space to the exhibitors in the United Kingdom, at the Dublin International Exhibition, have been issued, but the space demanded is seven times in excess of the whole quantity at the disposal of the executive committee. The corporation of the city of London, the National Academy, the Royal Academy, and numerous private individuals, lend pictures for the exhibition. Glass will also be well represented. The colonial and foreign contributions will be varied and attractive. The Emperor of the French has promised to send Sevres china and other objects. A fine collection of textiles is promised from Rhenish Prussia; lamps and bronzes from Stobwasser, of Berlin; manufactures from Switzerland; and a good collection from Russia. A church has lately been erected, at the top of Rutland-square, for the use of Presbyterians. The cost of this building has been defrayed solely by Mr. Alexander Findlater, of Dublin. The architect was Mr. Andrew Heiton, of Perth, who had previously designed many churches in the Early English style. This is by far the largest Presbyterian church in the province of Leinster. About 1,000 persons can be conveniently seated in the interior. The pewing is constructed in the modern manner. There are stained-glass windows. Ventilation and heating are provided for. The chandeliers for gas-lighting consist of six Medieeval coronas, of thirty burners each, suspended from the roof. The church has been opened for divine service. St. Jude's Church was recently erected by the Ecclesiastical Commissioners for Ireland, for the new parish of St. Jude, near the Phoenix Park. It consists of nave, 100 ft. long, with transepts north and south, together 87 ft. long, and accommodates nearly 600 persons. The church was built by Messrs. Butler & Sons, from the designs of Messrs. Welland & Gillespie, and is in the Early English style. The chancel contains five stained-glass windows, by Messrs. Forrest & Sons, of Liverpool. The total cost of the building has been 4,000l. The site was a free gift from Mr. David M'Drury, a merchant and magistrato of the city of Dublin.

The ceremony of consecrating the new building erected on the site of the ancient Church of St. Douglagh has been performed by the Archbishop of Dublin. The old church having fallen into a very dilapidated condition, was obliged to be taken down; but the tower and oratory, and the portion immediately over the tomb of St. Douglagh, have been preserved. The ancient oratory now forms a vestry for the new building, which is similar to, though on a larger scale than, the old edifice, and as nearly as possible on the same site, the walls being raised in lines parallel to those of its predecessor. The new church is, in fact, symmetrically the same as the old, that being the chief object of the architects who designed it. The old church is supposed to have been founded in or previous to the reign of Henry II., and was originally a chapelry attached to Christ Church, amongst the records of which the original founder is styled "Episcopus et Confessor." The ancient church of St. Douglagh, says the *Dublin News Letter*, in describing it, was one of the few buildings in Ireland erected between the eighth and the twelfth centuries, and in a style of architecture different from any other to be found in Western Europe. They were evidently built in imitation of the original Christian churches of the South of Europe, modelled from the heathen temples of the Greeks and Romans, and which were probably introduced into this country by the clergy who may have retired thither on the irruption of the Goths and Vandals into the Roman Empire. These churches were all remarkably small, and that of St. Douglagh was no exception to the rule. They seldom exceeded 40 ft. in length and 20 ft. in breadth, and were covered with circular stone arches under stone pediment roofs. The walls and arches were not infrequently decorated with columns and pilasters in rude imitation of the Corinthian and Doric orders. The entire cost was 7000l., and sittings are afforded in the nave for one hundred, and in the chancel for thirty persons. The work was carried out under the direction of Messrs. Lanyon, Lynn, & Lanyon, by Mr. J. Douglas, of Dublin, contractor.

*Limerick.*—Considerable improvements and additions are in progress at the county gaol, to adapt it to a new system of discipline for prisoners. The authorities advertised for plans for the "remodelling of the old gaol," offering a premium of 50l. for the best. There were several

plans submitted by architects, and that of Mr. Atkins, of Cork, was selected for the reconstruction of the prison.

*Down.*—The new lunatic asylum for Down will probably be commenced in a short time. New tenders, on revised plans, had to be advertised for, and these tenders were not received by the Grand Jury Committee on the Board of Control until the 16th of December last. The committee lost no time in examining the tenders, and were prepared to accept that of Mr. Fras. M'Gaughey.

## FROM SCOTLAND.

*Paisley.*—A new Roman Catholic School has been opened here. The building stands beside the old English School in School Wynd. Fronting the wynd, the Roman Catholic School building is two stories in height, the entrance floor being occupied by three class-rooms, and the upper floor being arranged for two lodgings for the male and female principal teachers. The building is in the Gothic style, with mullioned windows, tall dormer gables reaching up into the roof, and with a main front gable the whole height of the building, surmounted by an ornamental cross with the sacred letters "I. H. S." carved upon it. The architect of the buildings was Mr. J. J. Lamb, from whose designs the new grammar school was lately erected.

*Maxwelltown (Dumfries).*—The new church about to be erected by the Free Church congregation, Maxwelltown, is from plans by Mr. James Barbour, architect, Dumfries. The building will not be erected on the site of the present church, but in Rosemount Nursery, at the lower end of Lauricknowe. The ground is higher than the street, and the base of the church will be 7 ft. above the street, access being had by a flight of steps. The church will be in the Decorated Gothic style of the fourteenth century. The ground-plan is an oblong, 75 ft. 6 in. in length, by 49 ft. wide, over the walls; with a semi-octagonal recess or apse at the end next Corberry Hill, for a platform; behind the apse is a vestry. The side walls of the church are broken by a projection 3 ft. deep and 32 ft. wide, forming shallow transepts. The principal elevation is the gable fronting Lauricknowe. In it there are two windows, each 18 ft. high by 7 ft. wide; divided into three compartments by mullions; the tops being filled with flowing tracery. The windows will be filled with obscured plate glass, cast with diagonal lines, so as to resemble leaden frames with lozenge-shaped panes. The gable is narrowed to 38 ft., and at each corner is flanked with buttresses, terminating in a pinnacle, the total height of the pinnacle being 60 ft. From the gable rises a bell turret, supported by a pier on inside of wall. The spire terminates in a carved stone finial. The total height from the ground is 94 ft. There will be accommodation for 800 sitters. The material for the walls will be red freestone; the front will be built of course and gango work; the other walls of broken coursed rubble, and the whole of the dressings will be polished.

*Morebattle.*—A new church has been contemplated by the congregation of the United Presbyterian Church here, and some practical steps have lately been taken in the matter, a plan for the new building having been recently adopted. The church will be of oblong form, with sittings for 415 people on the ground-floor, and in the gallery (which is confined to the end opposite the pulpit) there are 95 sittings. The principal elevation is to the north, and consists of three divisions. The centre, which is both wider and more lofty than the sides, projects 2 ft. The side elevations are kept low, and pierced with square-headed three-light windows. The cost of the whole is to be 1,000l. Mr. Pilkington, of Kelso, is the architect.

*Cupar.*—The Burnside United Presbyterian congregation here are about to erect a church in the Bonnygate. Two plans by Messrs. Peddie & Kincaid, architects, Edinburgh, were submitted to a congregational meeting, and it was unanimously resolved to adopt one which was the more ornamental than the other. It will have a spire of 95 ft. high, and a front with wheel windows. It will accommodate 600, and is estimated to cost 2,000l.

*St. Andrew's.*—The gable of a new house has been blown down by a gale. The damage is estimated at upwards of 100l.

*Kirkwall (Orkney).*—At a recent meeting of the Kirkwall Harbour trustees, Mr. Davison, the engineer, attended, and the tenders—three in

number—for the new pier were opened. The lowest tender, amounting to 10,490l., was sent in by Messrs. Laidlaw & Son, Glasgow. This is considerably above the estimate of the engineer, and so high that the trustees, with the amount of funds at their disposal, considered that they could not accept of the offer. They calculated that, with engineer's expenses and extras, the outlay would exceed 11,000l., the full amount which they have power to borrow by the Act. It was unanimously agreed that they should take time to consider the matter before taking any further steps.

## PROVINCIAL NEWS.

*Oxford.*—On Friday, the 24th ult., the University Masonic Hall, which has been erected for the Apollo Lodge of Freemasons, was consecrated and dedicated by the Provincial Grand Master of Oxfordshire, Lieut.-Colonel Henry Atkins Bowyer, in the presence of about 150 brethren. The new Lodge, designed by Mr. E. G. Bruton, of this city, architect, is situated at the west end of what was the Assembly-room of the Clarendon (late Star) Hotel, which has been shortened to the extent of about 27 ft. It is a vaulted room, of 52 ft. in length and 26 ft. in width and height, and it has one semicircular end. The walls, which are at present finished in coloured plaster, are formed into panels by pilasters, which are placed at intervals along the walls; upon these rest fluted brackets, which run into and break up a cornice at the springing of the vaulted ceiling. This ceiling is temporarily finished in blue plaster, and is nearly semicircular in section. The vault line is only broken by the ribs of the roof, which are at present painted in rainbow tints. The pilasters are placed on a deep plinth, and a raised platform runs along each side of the room. At the semicircular end of the room is a dais, rising a step above the platforms. In the centre of this there is a space still further raised by two more steps, to form a throne, and this, the place of the principal seat, is surmounted by two Corinthian columns of pedestals. The entrance doorway is marked by grouping the pilasters, and it is surmounted by a curved pediment, the tympanum of which is coloured. The centre of the floor is laid with tessellated pavement, having a fringe-like border, with tassels at the corners. The room being seldom used in the daytime has only a lantern light in the centre, but at night it is lighted by about a hundred jets of gas, ranged on each side just above the cornice. The heating is by means of hot water in pipes running under the platforms. Besides the Lodge proper there are waiting-rooms, robing-rooms, and other conveniences. The work was executed by Mr. Baker, of this city, builder. There are likewise two banqueting-rooms, one 63 ft. by 31 ft. and the other 33 ft. by 20 ft.; but as banquets and dinners are served by the Clarendon Hotel Company, the brethren have not the exclusive use of these rooms.

*Stockport.*—The subject of building a new Town-hall in this borough has been placed in the hands of the local General Purposes Committee, by the Town Council, for the purpose of making the necessary inquiries about an eligible site, cost, &c.

## SURVEYORS' CHARGES.

*In the Eschequer.*—Hickson, a Whitehead and Davis.—This was an arbitration reference, before Master George Pollock. Claim, 340l. 8s. 10d., chiefly for services rendered in getting up and giving evidence on an arbitration between defendants and the Midland Railway Company, to assess damages for injuries done to land on Wilford road, Nottingham, known as "Turner's Estate." The Master sat in chambers on the 22nd, 23rd, 24th, and 25th ult. Mr. Cave appeared for plaintiff, and Mr. Pridoux (western circuit) for the defendants. Mr. Norris, Mr. Williamson, and Mr. Cassell (of London), gave evidence in support of the claim. They considered it a just and reasonable bill. Mr. Goddard (of Lincoln), Mr. Simpson, and Mr. Bakewell analysed the various items, and said they, for the greater part, were most excessive. Mr. Goddard said charges to the extent of 170l. had been made for plans and tracings; 78l. 6s. 6d. for consultations; 24l. 6s. for estimates; 19l. 8s. 6d., instructing witnesses; 16l. 10s. attending arbitration; 11l. 4s. 6d., surveys and levels; 5l. 5s., reports; 6l. 14s. 6d., copies of reports; 2l. 10s., journey to Derby; and 18s. 10d. cash paid. All the larger items were greatly overcharged. Mr. Goddard's valuation of the bill was 130l. 10s. 10d.; Mr. Simpson's, 103l. 0s. 2d.; and Mr. Bakewell's, 100l. Each of the three witnesses for defendant's side the amount set down by him (witness) was much more than he himself should have charged. 160l. had been paid on account, and 40l. into court, making 200l., which defendants considered extravagant remuneration. At an adjourned sitting, on the 28th, the Master made the following award, namely:—1. Find for the defendants in this action, and as to the costs of the reference, I direct that the plaintiff pay the costs of the defendants.

## METROPOLITAN BOARD OF WORKS.

At the weekly meeting of this Board Mr. Taylor presented, in the names of his colleagues, to Mr. Thwaites, the chairman, a testimonial portrait of himself as a mark of their respect and appreciation of the uniform and courteous manner in which he had fulfilled, and continues to fulfil, the office of chairman.

The subject mainly discussed was a report from Mr. Coode and Mr. Rawlinson as to the material used for filling in behind the Thames Embankment. Mr. Corpmael said the sum and substance of the report which had been read was, that if the ballast taken out of the bed of the Thames were used for the filling-in in its wet condition, it would not be so effectual as it would be if it were allowed to dry first. He did not agree with the statement, and he begged, therefore, to move that it be printed, circulated, and referred to the Thames Embankment committee for their report. Mr. Samuda thought the gravel taken out of the river was the best material that could be used. The Chairman said the question was considerably narrowed because dredging was then going on at the particular spot, and he believed the material was all that could be desired.

Some further discussion ensued, and the question was ultimately referred to the Thames Embankment Committee for consideration.

The Streets Committee recommended the approval of designs for bridges to be erected at Battersea under the provisions of the London, Chatham, and Dover Act, 1864, and the London, Brighton, and South Coast Railway Act (Battersea Improvement), 1864, subject to certain conditions laid down by the engineer—namely, that the bridges should be made watertight, and should be so constructed as to deaden the sound of passing trains. Mr. Evans thought that the companies should be compelled to screen the traffic on these bridges. He said the objection made to this was, that heightening the bridges would make them ugly; but in his opinion nothing could make them uglier than at present. The sight of the passing train had caused several accidents, and he thought some remedy should be sought for this evil. The engineer said he believed the deadening of the sound would prevent accidents for the future. The report was adopted, and it was agreed to send a copy of it to the Board of Trade.

The Sewage Utilization and Essex Reclamation Company applied for permission to apply sewage to certain pieces of land adjoining the Northern Outfall Sewer. The engineer recommended that the application should be granted. Mr. Samuda said the sewage so applied would be a very great nuisance in the neighbourhood, and hoped the Board would not sanction such a proceeding. After some further discussion the application was referred to a committee.

## SOCIETIES FOR IMPROVEMENT OF DWELLINGS.

THE seventh and last half-yearly report of the directors of the London Labourers' Dwellings Society (limited) states that the net profit of the half-year exceeds that of the previous one by 40l. 18s. 6d., amounting to 279l. 2s. 9d., and is sufficient to pay a dividend at the rate of 6 per cent. per annum. After a trial of nearly four years, the directors state that they feel themselves justified in expressing an opinion, that (if nothing unforeseen occur) the rate of dividend which the members have hitherto received (viz., 5 per cent. per annum) will be fully maintained. "Doubtless," they continue, "there are investments which hold out to the capitalist the prospect of larger returns than this; but it is hoped that 5 per cent. per annum, with a secure investment, and the consciousness of doing a vast amount of good, will induce many persons to invest a portion of their capital in this society."—The thirteenth half-yearly report of the Hastings Cottage Improvement Society (limited) states, that during the last six half-years the society's average total income has been at the rate of 11.05 per cent. on the paid-up capital, and the net income has been at the annual rate of 5.83 per cent., out of which sum the shareholders have received an average dividend of 5.33l. per share, clear of income-tax (which is paid on the gross rental by the society), and the remainder has been added to the reserve fund. The present capital of the society consists of 17,000l., and is believed to be larger

than that of any similar society out of London. The total number of dwellings belonging to the society is now about 155, and the number of their tenants 183.

## SCHOOLS OF ART.

The Warrington School.—The exhibition of the works of the students of this school has been held, in the reading-room of the Museum, previously to their being sent to South Kensington, for medal awards, as required by the new Art Code. The four days the exhibition was open, it was visited by nearly 4,000 people. The works arranged were almost as numerous, if not quite so, as on previous occasions, and consisted of many designs, chalk drawings from the flat and round, and a large number of paintings in oil and water-colour, from the round and nature. Sixty-nine of these works were selected for competition, and sent to London. Of the many works exhibited those by William Jenkin deserve mention, particularly his three paintings from nature in water-colour, consisting of a bird's nest and primrose, bird's nest and bramble-leaves, and a study of fruit.

## CHURCH-BUILDING NEWS.

Hanslope (Bucks).—The parish church of St. James, Hanslope, has been re-opened for divine service, after the restoration, or rather the re-building of the chancel. The old chancel, which belongs to the lay proprietors, the corporation of the city of Lincoln, has been almost pulled down and a new chancel built. The roof was taken off, the walls lowered 5 ft., so as to bring them to their original height, and a high-pitched open timbered roof of red pine has been substituted for the old one. The roof has been slated with tiles. Two old Norman windows in the north and south walls have been restored from two halves that were found. In the course of the work many interesting features of the old architecture were discovered. During the progress of the work three sedilia and a piscina turned up, and have been restored. The size of the chancel is 48 ft. by 18 ft. The east window is a five-light one. There are seats for the choir in the chancel and two prayer desks. Mr. G. E. Street, of London, has been the architect, the whole cost of the restoration having been borne, with the assistance of some friends, by Mr. Reginald Walpole, of Hanslope Park, who has, in fact, been his own builder, and has superintended the work throughout. The cost has been about 600l., much of the labour having been done by the men on the estate. The work has been executed by Mr. R. Walpole, of Stony Stratford; the woodwork by Mr. Garaid, of Leighton Buzzard. The seats in the chancel are of carved oak. A west gallery has been taken down, and some open seats have been placed in the nave. The tower arch has been opened.

Boagrove.—The church here has been re-opened, after having been closed for nearly twelve months, during which period it has undergone repairs and restorations under the superintendence of Mr. C. G. Scott; the contractor for the works being Mr. Cane, of Brighton. The high pews have been removed, and the church is now re-seated with solid oak benches arranged in a uniform and indistinctive manner. Hot-water pipes have been laid down throughout the church, which is paved with red and black tiles. The exterior has undergone considerable repairs. All the walls have been underpinned; the west wall has been rebuilt: the flying buttresses, which were found in a dilapidated state, have also been rebuilt. These and other repairs, with the restoration, have occasioned an outlay of about 4,000l., which, with the exception of 400l. contributed by the parishioners and their friends, has been defrayed by the Duke of Richmond.

Corston (Somerset).—The parish church has been renovated and enlarged, from plans by Mr. Ferrey, architect, by Mr. Streeter as contractor. The sittings have been increased from 100 to 250. An aisle has been added to the old nave and chancel, which have been restored. A stained-glass window has been put up at the east end by Mr. Langton, M.P.

Orleton (Herefordshire).—The principal parts of the church here have been repaired and restored, and it is intended to complete the work as soon as funds can be realized. Mr. R. Drew, of London, was the architect employed, and Mr. J. Davis, of Leominster, the contractor. The

estimate was about 700l.; but it was found necessary as the work proceeded to take down the south wall and replace it; and other works were also requisite. In taking down the portions of the old work when the restoration was commenced, under the first coating of plaster, bands of blue and yellow, about 9 in. wide, were discovered, running in parallel lines round the walls of the whole building. This surface having been stripped off, a similar band of deep red was found; and stripping the walls further, tracery, either the fleur-de-lis or foliage, was brought to light, showing that in the days when that surface was uncovered the whole church was frescoed. Under these bands of colour, &c., which were under a very thick coat of plaster, stones were brought to view, upon which were some old paintings. The first portion of the stonework bare had on it a representation of Jacob watering a flock at a well; but the other paintings could not very well be distinguished. The removal of the western gallery brought to light the fact, that in 1720 some Puritan churchwarden drew upon the western wall a figure of Death, 7 ft. 6 in. high. This figure held in one hand a black coffin, the lid turning upon hinges of knuckle bones, and in the other a large spade. The inscription was "Memento mori." Both picture and gallery have been destroyed. It was found upon examination that the south wall must be taken down, as it had been built without foundations, and from the pressure of the heavy roof was no less than 22 in. out of the perpendicular. Again, upon stripping off the plaster from the chancel arch, cracks 4 or 5 in. in width were discovered, and it was found necessary to take that down also, and rebuild it, together with the south wall, erected this time upon a better foundation. The old decayed roof was removed, and an open one put in its place, Broseley tiles being used. The aisle running up the centre of the nave has been laid with red and black tiles from Staffordshire, with surrounding diamonds of the old stone. All the old seats have been removed, and free seats for 210 persons substituted, with an oak flooring.

## DISSENTING CHURCH-BUILDING NEWS.

Arnold (Notts).—The foundation-stone of a new chapel and school has been laid at Arnold, in connexion with the Methodist New Connexion body. The new building will be situate in Front-street. Besides the usual large room for public worship, there will be vestries to be used for schools. The estimated cost is about 620l. Mr. Collyer, of Nottingham, is the architect, and Mr. Worrall the contractor. According to the plan exhibited the chapel will accommodate about 500 persons.

Wilmslow (Cheshire).—The Congregational chapel here has been re-opened, upon the completion of the additions and alterations. The old building has been taken down and rebuilt in the Early English style, with the additions of transepts, vestry, class-rooms, belfry on the south side, &c. The roof is of high pitch, with open framed principals. Galleries are provided in the transepts. All the seats are open, of red deal, and will accommodate 500 persons. The chancel is lighted by coronas from the roof, and has been warmed and ventilated by Messrs. Haden & Co., of Trowbridge. All the works have been executed by Messrs. Royle & Mellor, of Wilmslow, builders, at an outlay of 1,750l., under the superintendence of Mr. John Lowe, of Manchester, architect.

Stockport.—The foundation-stone of a new Congregational chapel has been laid in Wellington-road, Stockport. The building, consisting of nave, aisles, transepts, chancel, and west gallery, will be erected in the Early Decorated style. The site immediately faces the Stockport Grammar Schools. The peculiar nature of the site has been taken advantage of in the design; the tower, with its attendant spire, forming a north-west porch, being situate at the corner of Mottram-street, with Wellington-road, having an altitude of 126 ft. above the crown of the street. As a pendant to the tower and facing the road, will be another entrance, which contains a stone staircase leading to the west gallery. Accommodation is provided for about 900 sittings in open benches. In the chancel will be placed the choir, and fronting to the congregation provision will be made for the reception of an organ, in a chamber having arches opening to the body of the church. The walls will be faced with Pierrepont wall-stone, mixed with stone bands and dressings. The architects

re Messrs. Spackman & Charlesworth, under those direction Messrs. David Cochran & Co. will carry out the works.

**Blackburn (Lancashire).**—The foundation stone of a Presbyterian church and schools, dedicated to St. George, has been laid at Blackburn. The designs are by Mr. Patterson, of Blackburn, architect, and the buildings will cost from £000 to £8,000.

**Pocklington (Yorkshire).**—A new Wesleyan chapel has been opened here. The edifice is situated in Champangate, and is a design by Mr. E. Taylor, who has superintended its erection. The inner walls of the chapel are 66½ ft. by 47½ ft., and afford accommodation for a congregation of 700 persons. The lower pews are on a sloping floor from the entrance down to the pulpit at the opposite end, to which they radiate in a semicircular form. The pews in the gallery run round the whole of the building. Behind the chapel is a vestry, 28 ft. square, as well as three smaller class-rooms. The front of the chapel is finished with red stock brick, with dressings of stone, and is furnished with a portico and balustrade, supported by six Tuscan stone columns. There are three doors in front, and a side door leading to the vestry and also to the gallery. The building has a frontage of 45 ft. of grass and gravel, and this is inclosed in iron railings. Adjoining the chapel is a residence for the minister. There is also a small dwelling for the chapel keeper. The whole of the work has been executed by Mr. Robert Widdop, of Snaithe, and its entire cost will be about £2,500.

**Books Received.**

*The Year Book of Facts in Science and Art.* By JOHN TIMBS, F.S.A. London: Lockwood & Co. 1865.

We need only announce the issue of this useful work, for 1865. Many an item of scientific and art progress is here preserved from utter oblivion, and brought under the notice of those who would otherwise have been totally ignorant of its occurrence. The present issue is preceded by a memoir of Major-General Sabine, R.A., the president of the Royal Society, illustrated by an engraving from a photograph of the president's pleasant countenance.

*The Medieval Architecture of England and France.* Illustrated by a series of Photographs of remarkable Buildings, principally of the Twelfth, Thirteenth, Fourteenth, and Fifteenth Centuries, with Historical and Archaeological Descriptions. By WILLIAM LIGHTLY, Cundall & Co., New Bond-street.

For the purposes of the Architectural Photographic Association, Messrs. Cundall & Co. were empowered to visit France, and obtain negatives from buildings, of which a list was furnished them. From the pictures thus made the committee selected as many as their funds allowed of. The rest, principally general views, remained in the publishers' hands; and these, with a certain number of views of English buildings of corresponding date, they have now begun to publish in Paris as a separate work. Mr. William Lightly, the honorary secretary of the Association, has undertaken to edit them, giving to each some descriptive matter. Each part contains four views, and twelve parts will complete the work. The first two parts are very satisfactory. No. 1 contains two views of Bourges Cathedral, and two of the abbey church, at Vézelay. No. 2 contains two of Rivaux Abbey, and two of Kirkstall Abbey.

*A Discourse upon Dilapidations, their Nature, and the Principles of Assessment succinctly demonstrated.* By THOMAS MORRIS, Architect. London: Simpkin & Marshall. 1865.

In this little book, as in his "Clue to Railway Compensation," Mr. Morris has sought to give, in a pleasant readable form, an outline of the law of dilapidations, considering himself "free, under the license of a 'discourse,' to relieve and lighten, to make, if it were possible, a rugged subject even occasionally picturesque;" and, from his own point of view, has succeeded. We are forced, however, to retain an opinion before expressed, that agreeable little digests of this kind are quite useless to the professional student, who must himself go to the fountain-head. Still there may be many non-professional readers who may desire

to get a general notion of their liabilities or powers in respect of dilapidations, and to these we may recommend the "Discourse." It includes a few pages on "fixtures" and "fire insurance."

**Miscellaneous.**

**THE ROYAL ACADEMY.**—Mr. John Lewis, associate, has been elected Academician.

**ST. DAVID'S CATHEDRAL.**—The restoration of St. David's Cathedral has been commenced.

**ARCHITECTS' BENEVOLENT SOCIETY.**—The annual general meeting of this Society was held at the House in Conduit-street, on the 8th inst., Professor Smirke, R.A., presiding. The Report stated that the financial position of the Society was satisfactory as compared with that of previous years. The amount funded in 1864 was £91; the balance in hand was 114½ 7s. 1d. Vacancies in the council were filled up, and votes of thanks were passed.

**THE ART-DEPARTMENT MINUTE.**—Resolutions in opposition to the new Minute have been passed by the Manchester School of Art, and by a meeting of gentlemen connected with the Yorkshire Schools of Art. By the latter it was arranged to send a deputation to Lord Granville.—Too late for consideration this week, we have received from Mr. Walter Smith, of Leeds, an angry reply to Mr. D. W. Rainblach's letter in our last.

**SITE FOR THE COURTS OF LAW.**—Mr. Bardwell, architect, under the direction of Mr. Rigby Wason, has published a plan, suggesting a site of seven acres (the area required) between Whitehall and the Embankment roadway. Amongst the advantages urged for it, it is said that it would prevent "the necessity of wasting nearly a million sterling in destroying the houses of above 4,000 of our fellow-creatures;" and that it would avoid deteriorating "the value of property in Westminster, in the vicinity of which the Courts of Law have existed for many centuries."

**THE WORKING MEN'S COLLEGE.**—At this institution, in Great Ormond-street—principal, the Rev. F. D. Maurice, M.A.,—the spring term has commenced. The mathematical classes are under the direction of Mr. Litchfield, Mr. Vernon Lushington, Mr. Mansley, and Mr. Cohen; language, under Mr. F. J. Furnivall, Mr. Godfrey Lushington, Mr. Oswald, Mr. E. S. Ford, Mr. Sonnenschein, Mr. Paterson, Mr. Mozley, and Mr. Albert Dicey; natural science, under Mr. Gruen and Mr. Ralph Tate; vocal music, under Mr. Litchfield; and drawing under Mr. W. Cavo Thomas, Mr. Lewis Dickinson, and Mr. Ruskin. During the term, lectures will be delivered by Mr. W. Travers, F.R.C.S., Mr. N. S. Maskelyne, M.A., and the principal.

**LIVERPOOL ARCHITECTURAL SOCIETY.**—The twelfth meeting of the session was held on the 8th, Mr. J. Boulton in the chair. Mr. W. Hay asked if the secretary had received any answer to the letter he had forwarded to the promoters of the new church at Cloughton. The secretary said he had received a letter, but it was not a very satisfactory one. Mr. Hay said, to issue such instructions was nothing less than an insult to the profession. It was agreed that the secretary should forward to the Architectural Alliance the resolution of the society on the subject, and the correspondence that had taken place. Mr. George Ansley read a paper, "Practical Notes on Modern Medieval Architecture."

**THE LIVERPOOL BUILDING SURVEYORSHIP.**—At the last meeting of the town council a special committee recommended the appointment of Mr. Rollett as building surveyor in the place of the late Mr. Rishon, at a salary of 800l. per annum. Mr. Alderman Shell moved the adoption of the recommendation, and Mr. Clarke Aspinall seconded the motion. Mr. Robinson moved that Mr. Newlands be appointed building surveyor. Mr. Hughes seconded the amendment. Mr. Picton said he thought it absurd to suppose that Mr. Newlands could attend properly to both offices. Mr. Whitby desired it to be understood that the borough engineer was quite willing to undertake the additional duties. The amendment was put to the vote, and carried by 19 votes to 16. Mr. Newlands was therefore appointed building surveyor.

**LIVERPOOL CORPORATION SALARIES.**—Some tables recently published show that the Corporation salaries of Liverpool amounted in 1864 to 63,000l. In 1854 they amounted to not quite 56,000l. Analysed, it is seen that 61 persons receive 200l. and above; or an average per head of 410l. 10s. 482 persons receive below 200l., averaging 79l. 17s. per head.

**CAMBRIDGE ARCHITECTURAL SOCIETY.**—At the meeting held on Thursday, March 2nd, the Rev. G. Williams in the chair, Mr. Russell read a paper on "The History and Manufacture of Mosaic." The paper was illustrated by some specimens of mosaic, made by Dr. Salviati, and lent by him. A discussion then ensued as to its application to the decoration of churches and public buildings. The society heard with great pleasure of its increasing use in this country.

**THE PRINCESS'S THEATRE.**—Pending the production of a fresh drama of interest, Mr. G. Vining has supplemented the continuing attraction of "The Streets of London" with two new farces,—one, "Heart Strings and Fiddle Strings," enabling Mr. David Fisher to display his versatile abilities, notably his skill as a violin player; and the other, "An Ample Apology," which affords Mr. Dominic Murray a part. Both are successful so far as they go.

**THE PARIS EXHIBITION OF 1867.**—A new feature of the Universal Exhibition of 1867 is to be living specimens of the human race, who are to accompany the productions of the remotest corners of the globe to Paris. The committee of the Exhibition is busily engaged in organizing means of transit for these novel goods. The committee meet at the Palais Royal, and have issued the necessary orders for the commencement of the buildings which will be required for the Exhibition; and as 160,000 metres of ground have to be covered in, there is no time to be lost.

**A TEMPLE TO THE THAMES.**—At the last meeting of the Ethnological Society, a paper by M. Larribe was read, giving an account of the discovery, some years ago, when he was sub-prophet of the department where the Seine takes its rise, of a Gallo-Roman temple at the sources of that river. The temple was dedicated to the Goddess of the Seine, and endeavours are being made in Paris to erect a monument on the spot. One of the objects of the writer was to suggest that a similar monument should be erected at the source of the Thames, and that search should be made there for the remains of some antique temple.

**THE ROYAL SOCIETY.**—The first of the two *conversations* given by General Sabine, as president of the Royal Society, took place on Saturday evening last, at Burlington House. The Prince of Wales was present. There was an interesting collection of philosophical instruments, apparatus, working models, objects of natural history, and works of art. Among these works of art were twelve original drawings by Bellini, Perugino, Albert Dürer, Claude Lorraine, &c., lent from the royal collection by permission of the Queen; a series of drawings by E. W. Cooke, R.A.; photographs of Turner's pictures, published by Messrs. Marion & Co.; Chinese enamels and bronzes, lent by Mr. Alfred Taylor; and an ancient stannette of Venus.

**MONUMENTAL.**—It is intended to erect a statue of James Watt in some public place in Birmingham. The idea was originated at a recent meeting of the Society of Mechanical Engineers, and a numerous signed requisition has since been presented to the mayor, asking him to call a meeting to carry out the suggestion. Several donations have been already promised.—Viscount Felding and other gentlemen have been formed into a committee for the purpose of promoting a memorial of the late Cardinal Wiseman, and a meeting is shortly to be held at the Stafford Club. "The erection of a splendid cathedral," in what the Roman Catholics call the diocese of Westminster, of which the cardinal was the archbishop, is spoken of.—The long-talked-of monument to Tyndale, on North Nibley hill, is now said to be likely to be carried out, notwithstanding the former failure. Messrs. Whitfield, builders, of Wootton-under-Edge, have lately entered into a contract with the committee for the erection of the monument, and the work is to be commenced at once.—The marble statue of the French Emperor, ordered by the Duke de Morny from M. Iselin, has been placed in one of the halls of the Palais du Corps Législatif, just when the duke himself has died.

**CHAUCER'S MONUMENT.**—The *Owl* says.—We are glad to learn that there is an intention, for which the greater part of the necessary funds have been already provided, to restore Chaucer's monument in Poet's Corner, Westminster Abbey. At the same time, a rumour reaches us that a proposal has been made to fill the window over the present monument with stained glass in honour of the poet. We imagine, however, that difficulties will be found to interfere in carrying out the latter idea in an appropriate manner.

**THE WHOLESALE AND IMPORT TIMBER COMPANY (LIMITED).**—A new company is being formed in London under this designation with a capital of 250,000l. in 25,000 shares of 10l. each, with power to increase to one million. The company is for the ordinary purpose of purchasing British and foreign timber, deals, and other woods, for supplying, wholesale, the trade generally with wood goods of every description, and is said to be originated by parties of great experience in the timber trade, who regard such an undertaking as a necessity in trade at the present moment.

**GAS.**—The Chelmsford Gas Company announce a dividend of 10 per cent. per annum, free of income-tax, and a reduction of price to 4s. 7d., and for public lamps 4s. 2d.—The Stratford-on-Avon Gas Company have agreed to a dividend of 10 per cent. on ordinary shares, and 5 per cent. on preference shares.—The South Shields Gas Company have made so large an expenditure on the erection of new works, that their usual dividend is absorbed in the mean time. They also speak of an increase of 46l. on the cost of coal, but an increase of revenue to the amount of 600l. more than covers that. A dividend of 4½ per cent. was declared.

**THIN SHEETS OF IRON.**—Brother Jonathan little thought what a hammering stir would be created in the old country when from Pittsburgh he sent that wonderful letter, written on a sheet made from iron, which took no less than 1,000 sheets to make 1 inch in thickness; the dimensions being 8 in. by 5½ in., or a surface of 44 in., and weighing 69 grains. Since then, Wales has been surpassing America, Staffordshire has been surpassing Wales, and Wales again surpassing Staffordshire, till at length Swansea has succeeded in making "a sheet of the finest appearance and thinnest that has ever yet been seen, by mortal eye, 10 in. by 5½ in., or 55 in. in surface, and weighing but 20 grains; which, being brought to the standard of 8 in. by 5½ in., or 44 surface inches, is but 16 grains, or 30 per cent. less than any previous effort, and requiring at least 4,800 sheets to make 1 in. in thickness!" Some one should tell us how many sheets of gold-leaf or how many sheets of tin-foil go to the inch, so that the public, who are familiar with these, might form some visible if not tangible idea of what a sheet of iron 4,800 to the inch can mean.

**LEARN OF THE SWALLOW.**—Take the first and most obvious comparison. It is said that builders of mud walls (taught by experience, or perhaps by observation of the swallow's method) work only for a short time, and then desist till the mud has had time to dry and harden, lest the freshly added superincumbent mass should pull down by its weight the part already completed. It would be well if some of our railway architects or contractors would take a lesson from the same wise little teacher. We should then, perhaps, hear less frequently of the sudden collapse of arches and the downfall of viaducts. But probably we are all liable to the temptation of over-haste, when we have begun to meddle with bricks and mortar. Who has ever watched the building or altering of his own house, without wishing to push on the workmen with unreasonable speed? It has been my good fortune to witness the restoration of my parish church; yet, while it was a daily delight to visit the sacred edifice, and see it rising from its ruins into more than its original beauty, so scanty a trial to find so little progress made, so scanty a course of stonework added, between my frequent visits. The tower seemed as if it never grew; and at last a frost set in as the workmen had almost reached the battlements, and a delay of months was inevitable; but all the consolation I received was, that it would be very good for the building, as it would give it time to settle and harden, and render the work more compact and secure. It was the lesson of the swallow's nest; but man was slow to learn and loth to practise the wisdom of the little bird.—*The Churchman's Family Magazine.*

**RESTORATION OF MELTON MOWBRAY CHURCH.** It is proposed to restore this church, at a cost of about 4,000l., if the money can be raised, and to that end a committee, presided over by the Duke of Rutland, has been formed; a subscription list is in progress, and more than one-half of the money has been subscribed or promised. Mr. Scott has been employed to examine the building, which is of vast dimensions, covering about a third of an acre of ground. The roofs of the nave, aisles, and transepts, are all dilapidated, it appears, and repairs are requisite for the safety of the building. The tower requires considerable repair, and a settlement of the staircase has taken place in consequence of the cutting of doorways through the stonework within the last century. The stonework of the church generally is in a very dilapidated state, both externally and internally, and all the internal arrangements require renewal and the edifice to be provided with warming apparatus. The Rev. W. M. Colles, M.A., the vicar, who has been the prime mover in this matter, is the secretary to the restoration committee.

**KNUTSFORD RACE STAND.**—A new grand stand is to be erected at Knutsford. Sir Harry Mainwaring, bart., has just laid the foundation-stone. The plans having been prepared by Mr. R. T. Bellhouse, architect, Knutsford, they were submitted to Lord Egerton of Tatton, who is the principal freeholder in the town and lord of the manor, and they received his lordship's approval. The surrounding gentry interested themselves in the promotion of the scheme, and the proprietary includes many influential residents in the locality and in Manchester. The contract was taken by Mr. J. Paul, builder, and the structure will cost about 1,168l., exclusive of fittings. The capital of the (limited) company consists of 1,500l., in 300 shares of 5l. each. The building is to be finished in June, the races being fixed for the 3rd of August. The structure will be of red brick and iron, with a square Venetian tower, 60 ft. high, at one end. The ground-floor is enclosed with woodwork and glass panels. The greater part of the area will be devoted to the purpose of a general refreshment-room; but rooms are provided for the committee and jockeys, with all other requisite accommodation for the public. On the first-floor there is also a small refreshment-room. The remaining space is occupied by raised tiers of seats, enclosed by an ornamental balustrade. The second-floor is similarly protected; and both floors command a view of the whole of the course.

**SPECULATIVE BUILDING.**—A correspondent, Mr. Trueman, who has before now addressed us on this subject, writes.—There is no necessity for me to allude to the horrors of Bethnal-green dwellings, or to the fearful overcrowding and consequent immorality caused by railway demolitions, but to appeal to the wealthy ground landlords to cure an evil, namely, "duffing buildings." An eminent builder, recently, in an open vestry, said, "A 30l. per annum house would tumble down in ten years;" but it is patent to all who read, that several have of late tumbled down before completion, even on ground with a ninety years' lease. One in Kingsland was lately blown down while in course of construction. If house-buyers have to meet such danger, they must do charge the risk on the poor, striving, hard-working tenant; who, in too many cases, stints and starves himself and family to meet a heavy rent, and overcrowds his stucco home with lodgers, to the injury of his own and his family's health. The editor of the *Builder* has devoted many pages to the evils of "sale houses;" but small progress is made in stopping such vile creations. Why is it that the district surveyors, who receive nearly 30,000l. annually in fees, do not enforce some honest solidity in the bricklayers' work? When the vices of construction have been concealed by fine surfaces of paint and paper it is too late to employ a surveyor, whose services can only have a full and proper scope while the works are in progress; ergo, the fault rests with the ground-landlord's surveyor, who allows the estate to be covered with cheap, flashy, contract-built edifices, instead of good sturdy erections.

**TENDERS**

For alterations and additions to shop and premises, Brackley, Northamptonshire, for Messrs. Clarke. Mr. J. Usher, architect:—

Jacklin	£670 0 0
Hawkins	650 0 0
Hackett	563 0 0

\* Simply because they have not the power to do so.—Ed.

For the restoration and enlargement of Baptist chapel schoolroom, and vestry, Sharbrook, Beds. Mr. Usher, architect:—

Scrivener	£754 0 0
Joy	680 0 0
Curvis	675 0 0
Stonebanks	653 0 0
White & Foster	631 8 0
Gostrick & Tysoe	539 4 0

For building two residences at Mottingham, near Egham, and an addition to another, allowing for all materials, Mr. Samuel Parr, architect:—

Gates	£8,821 0 0
Colls	7,862 0 0
Al'Isachan	7,210 0 0
Sanders	7,014 0 0
Dove	6,935 0 0
Robinson	6,686 0 0

For chapel, and dwelling-house adjoining, Pigott-street

Linehouse	£2,499 0 0
Kilby	2,443 0 0
Wood	2,370 0 0
Emmer	2,350 0 0
Forrest	2,303 0 0
Hack	2,287 0 0
Brown	2,157 0 0
Hearle	2,076 0 0

For alteration and addition to the Earl Russell Tavern Gloucester-road, Croydon, for Mr. J. Murton. Mr. John Hervey, architect:—

Smith	£380 0 0
Jerrett	354 0 0
Loss (accepted)	325 15 0

For erecting a house at East Sheen, for Mr. C. H. Sinclair. Mr. A. W. Blomfield, architect. Quantities supplied by Mr. J. A. Banker:—

Banker	£1,350 0 0
Turner & Sons	1,329 0 0
Sims	1,310 0 0

For roads and sewers on Mr. Partidge's estate at Plaistow, Essex. Mr. John M. Dean, surveyor:—

Cordery	£1,275 0 0
Biggs	1,150 0 0
Kent	840 0 0
Pizey	820 0 0
Harris (accepted)	797 0 0
Horn	722 0 0

For new church, Grove-road, Bow, for the Rev. Allan Curr. Mr. W. Wigginton, architect:—

Axford & Co.	£5,772 0 0
Love, Brother	5,625 0 0
Hill & Co.	5,482 0 0
Emor (accepted)	5,215 0 0

For repairing the exterior and tower of the parish church of St. Mary's, Whitechapel. Mr. John Hudson, architect:—

Mears	£630 0 0
Pritchard	620 0 0
F. & F. J. Wood	583 0 0
Hill & Keddell	559 0 0
Turner	528 0 0
Dudley	576 0 0

For new cast-iron bell-frame and rehanging peal of bells:—

Mears & Co.	£155 0 0
-------------	----------

For the erection of three warehouses, Gun-square, for Mr. L. Zimmerman. Mr. T. C. Clarke, architect:—

Bell	£3,252 14 0
Pritchard	2,435 0 0
Axford	2,800 0 0
Sargent	2,835 0 0
Brown & Robinson	2,824 0 0
King & Sons	2,780 0 0
Hack & Son	2,747 0 0
Conder	2,714 0 0
Turner	2,650 0 0
Anley	2,570 0 0

For the erection of four cottages, for Mr. James Baker, Hitchin. Mr. James Shillock, architect:—

Field	£272 10 0
Stapleton	260 0 0
Jeeves	232 0 0
Andrews (accepted)	250 0 0
<i>Carpenter and Joiner's Work.</i>	
Newton	£184 0 0
Poster	139 0 0
Anderson	138 0 0
Field (accepted)	132 10 0

For the erection and completion of houses in Culvercroft, Battersea Park, for Mr. Samuel Poupert. Mr. Charles Jones, architect:—

Godbois	£1,771 10 0
Baker	1,679 0 0
Lacy	1,657 0 0
Latney (Brothers)	1,641 0 0

For the erection of stables, &c., in Hampshire-grove, Torrington-avenue, Camden-road, for Mr. H. C. Newton, Mr. F. E. Holsworth, architect:—

Tracy & Son	£847 0 0
Dowson	770 0 0
L'Anso	740 0 0
Fish	680 0 0
Hall	651 10 0
Mansley & Rogers	577 0 0

For erecting two warehouses in Dantzic-street and Garden-street, Manchester, for Mr. John Bancroft. Mr. Henry Syam, architect. Pulling down old property and excavating by Mr. Leach not included in contracts:—

Collier	£1,454 0 0
Clay	1,440 0 0
Farrall	1,368 0 0
Brookthorpe	1,323 0 0
Burnell	1,315 0 0
Legger (accepted)	1,300 0 0
Neill	1,299 0 0

# The Builder.

VOL. XXIII.—No. 1155.

Peagee-property in London.

THE High Court of Parliament of Great Britain and Ireland assembled in Sir Charles Barry's most magnificent monument, consists, as every school-boy knows, or should know, of three estates of the realm: Queen, Lords, and Commons; and every school-boy midway in his

leons ought to know, or be made to know, that neither Queen nor Lords have any control over the exchequer, the budget of the year, or the estimates. Few or none, however,—and we include men of learning and rank,—are aware that nine English peers, of the Upper House, or second estate, have greater landed and house property in London, west and north-west of Temple Bar, than any ninety or more Commoners, of the Lower House, or the third estate. Here are the names of the nine lucky lords:—

1. The Duke of Bedford.
2. " " " " Portland.
3. The Marquis of Exeter.
4. " " " " Salisbury.
5. " " " " Northampton.
6. " " " " Westminster.
7. " " " " Camden.
8. Earl Craven.
9. Earl of Portman.

No other nine peers or M.P.s, or London citizens of "credit and renown," can be *peered*, we repeat, against these nine peers as owners of London property west of Temple Bar and without the jurisdiction of the Right Hon. the Lord Mayor and the oaken truncheons of the *Peelers* of city police.

Mark what follows:—

No. 1. His Grace William Russell, eighth Duke of Bedford and Marquis of Tavistock, owns Covent Garden Market-place (rated to the poor at 5,000*l.* a year, a prime minister's annual income), the whole of the parish of St. Paul's, Covent Garden, including Bedford, Russell, and Tavistock streets. Further still, to his Grace of Bedford belongs Bedford-square, Russell-square, Tavistock-square, and Woburn-square; Southampton-street and Bedford-street in the Strand; and then, as Cowley has it in his "Chronicle," a long *et cetera*.

No. 2. His Grace William John Cavendish Scott-Bentinck, fifth Duke of Portland, owns Cavendish-square, Portland-place, Bentinck-street, Welbeck-street, Harley-street, Cavendish-street, Vere-street, Holles-street, Bolsover-street, &c.: in truth, some two-thirds of Parliamentary Marylebone belong, through the families of Vere, Cavendish, and Harley, to his Grace of Portland.

No. 3. The Most Noble Brownlow-Cecil, Marquis of Exeter (topographically better known among Londoners as of Exeter Change, in the Strand), shares with

No. 4. The Most Noble James Brownlow William Gascoigne Cecil, Marquis of Salisbury, two-thirds of the Strand; indeed, the Strand may be safely called peagee property from No. 1, Charing Cross (or Northumberland House) to within a bowshot of Temple Bar. A Duke owns Northumberland House; an Earl owns the Craven-street property; a Cecil owns the Cecil and Salisbury-street property; the Savoy belongs to the Prince of Wales as Duke of Lancaster; the Crown owns Somerset House; Howard, Arundel, and Norfolk streets belong to Howard, Duke of Norfolk, &c.

No. 5. The Most Noble Charles Douglas Compton, Marquis of Northampton, owns more than a Dido bit of land, well covered with houses, in and about Clerkenwell and Islington.

No. 6. The Most Noble Richard Grosvenor, Marquis of Westminster, Earl Grosvenor, Viscount Belgrave, K.G., &c., owns Grosvenor-square, Belgrave-square, and about two-thirds of the City of Westminster, including Belgravia, Ebury, &c.

No. 7. The Most Noble George Charles Pratt, Marquis Camden; of Bayham Abbey, is the ground-landlord of Camden Town, with Pratt-street, Bayham-street, &c.

No. 8. The Right Hon. William Craven, Earl Craven, owns a thick and to be envied slice of the Strand, east of Northumberland House, with a little ring fence of improving roads and perches about Craven-yard, Drury-lane. My lord is the owner as well of a still more valuable property about Craven-hill, Bayswater.

No. 9. The Right Hon. Edward Berkeley, Baron Portman, of Bryanstone and Blandford, Dorsetshire, owns Blandford, Bryanstone, Dorset, and Portman squares, together with Portman Market and other land and brick rentals in and about Portman Market, yielding large and improving rentals.

Allow us, attentive reader, to indulge our topographical turn in relating, by way of episode, the results of some half-hours about peagee property, and heads of houses and owners and occupiers of houses in Great Britain and Ireland.

His Grace Walter Francis Montagu Douglas Scott, Duke of Buccleuch, K.G., &c. (a Scot by name and a Scot by birth), inhabits more houses in England and Scotland, and those his own, and fine ones withal, than any other man or woman in Great Britain and Ireland, her Most Gracious Majesty Queen Victoria not excepted. Her Majesty owns and inhabits—

1. Buckingham Palace.
2. St. James's Palace.
3. Windsor Castle.
4. Osborne.
5. Balmoral.

The "hold Buccleuch" owns and inhabits—

1. Montagu House, London.
2. Richmond, Surrey.
3. Boughton, Northamptonshire.
4. Dalkeith,
5. Drumlanrig, } in Scotland.
6. Bowhill.

With a Scott by name, and a Scot at heart—so firmly rooted in England—and a Scotland-yard of Metropolitan Police, the Thistle (*Nemo me, s'c.*) has taken a sturdy root in the garden of the English Rose. We cannot, however, say and sing with Allan Cunningham,

"The Thistle's grown above the Rose."

The Duke of Buccleuch was over-matched in the number of his houses in the three kingdoms by the late excellently accomplished William Cavendish, Duke of Devonshire, and K.G., who died in 1858. Here is a list of more houses than "Jack built," which the sculpture-loving duke

owned and kept up with very great taste and regal liberality:—

1. Devonshire House, London (Kent, architect). The finest site for a private house in London. The Piccadilly front, withdrawn by a court-yard from the rattle of Piccadilly, commands the Green Park, St. James's Park, Buckingham Palace, and the Surrey Hills.
2. Chiswick Villa, Middlesex, some six miles from London, the Palladian villa of the architect Earl of Burlington.
3. Chatsworth, Derbyshire (world-famous).
4. Hardwick Hall, in the same county, once Bess of Hardwick's, and a noble monument of Elizabethan architecture.
5. Bolton Abbey, Yorkshire, better known by Landseer's picture and Cousins's engraving.
6. Lonsdaleborough, Yorkshire; and
7. Lismore Castle, Ireland.

Chiswick is understood to have passed from the Dukes of Devonshire into the possession (for life or entirely, we know not which) of Harriet Duchess Dowager of Sutherland, a Carlisle Howard by birth, and one of the beauties and virtues of the court of Queen Victoria. Four "houses" are now the property of the Sutherland and Stafford Gowers:—

- Stafford House, St. James's.
- Trentham Hall, Staffordshire.
- Chiefden House, Maidenhead.
- Dunrobin Castle, Sutherlandshire.

All more than comfortable and pleasant to inhabit,—not too small to live in (like General Wade's London house), and certainly much too large (carrying out Lord Chesterfield's witicism) to "hang to your watch."

## UTILIZATION OF SEWAGE.

ALL the operations of nature are incomprehensibly marvellous. We do not call them "miracles," because they take place every day and every hour. But yet they are all as truly miraculous as those transcendent miracles by which the Divine Author of our religion showed His command over the laws of nature, and proved himself to be the God that had "made the worlds." For instance, a vine branch, in a few months, is enabled, by the laws of nature, to convert the colorless and tasteless raindrops into clusters of grapes, tinted to the eye, and flavoured to the taste; the juice of which, if merely left to itself, without any mixture, or any aid from man, becomes wine, not only grateful to the palate but gladdening to the heart. This yearly operation of Nature's laws is, to the thoughtful eye of faith, as great and divine a miracle as when the water mantled at once into wine, in the short interval between "Fill the water-pots with water," and "Draw out now."

But if that law of Nature is marvellous and divine which can develop such cherished qualities from the pure unflavoured raindrop, how still more evidently so is that law by which the fecid refuse of population, the excrementitious offscourings of man and beast, the poisonous cause of disease and death in the town, can become a source of life, of vigour, of fertility, and of beauty in the country, making the herb more grateful to cattle, the flower more fragrant, and the fruit more delicate and more rich. Had Paley written his "Theology" in these more scientific and more sanitary times, he might have done well to enlist among his instances of design, and his proofs of the power, wisdom, and goodness of God, this marvellous instance of a law of nature which can thus convert so fearful an evil into so beneficent a good.

We have been led into this train of thought by the title of this article, "The Utilization of Sewage," a subject in former times unjustly neglected, and even shunned, as though it were unfit for the consideration of delicate and refined minds. But we may remember that Dean Swift pointed out that a man may be "so nice as to be nasty," and a higher authority tells us that "to the pure all things are pure."

Lord Robert Montagu, as our readers know, has introduced a Bill into Parliament for better

enabling the inhabitants of towns to obey the laws of Nature which connect health with cleanliness, and disease with dirt.

The Bill is entitled, "A Bill for facilitating the more useful Application of Town Sewage in Great Britain and Ireland," and the preamble recites that "it is expedient to remove difficulties under which Local Boards and other bodies having the care of sewers in towns and populous places labour in disposing of the sewage of their districts, so as not to be a nuisance, and to give facilities to such authorities to make arrangements for the application of such sewage to land for agricultural purposes."

For this very desirable end a number of new powers are proposed to be given; the want of which has rendered it almost impracticable, in most instances, for towns to carry out the objects of this Bill.

All sewage and refuse are to be the property of the local authority, secured by penalties for their abstraction. Powers are given over the banks of rivers and the sea shore; and, with the sanction of the Secretary of State and after certain notices, compulsory powers of taking land for works are to be conferred. Powers, also, are proposed to be given of laying sewers and pipes under streets, &c., as in the Waterworks Clauses Act, 1847; of entering lands; of dealing with landowners and others; of forming for this purpose landowners' associations; of referring disputed arrangements to arbitration; of charging expenses on lands; of making by-laws; of selling the sewage to contractors for any period not exceeding ten years; and of borrowing money for carrying out works.

Considering that there is hardly a town in England, except Croydon and Worthing, where the town is systematically and thoroughly connected with the country by sewerage works and irrigating grounds, this Bill, if passed into a law, will occasion a very large circulation of capital, and very great employment for contractors and workmen for some years to come. Extensive brick culverts, innumerable pipe-sewers, and, in many cases, steam-engines, iron pipes, and other apparatus must be used.

But let us not regard this beneficial project merely as a measure of usefulness, which is its only pretension in the title of the Bill. Let us not merely consider whether the increased fertility of the land will repay in money the outlay in causing it; or even that preservation of the rivers of England and their fish requires such a measure. There is a far more valuable result than increase of crops or augmentation of riches, or the value of fisheries, namely, the improved health of those towns which shall in this mode fertilize their neighbouring fields. This result is beyond all money value. "Anything which a man has he will give for his life," and the intended Act cannot be properly applied to any town, built and formed and drained as towns are now, without a large saving of life in every case.

Croydon, for instance, is one of the towns that took the lead in this effort of sanitary progress. Every house is drained; no offensive refuse is retained in the town or parish; a farm of 300 acres, in the adjoining parish of Beddington, receives with benefit what the town is thankful to eject. The annual rent of this land has risen from 22s. to 5l. an acre, and if in hand would now let for even more; and the tenant, from land before yielding very small crops of grass, being a thin soil, on gravel, and soon burnt up, now cuts four heavy crops of grass in a year, each cutting yielding 13 tons to the acre. But the point to which we desire to direct our readers, is that before the sanitary arrangement was made (it began fourteen years ago) the average annual deaths in 1,000 persons, in the parish, for the preceding ten years, had been 22, whereas the average of the last ten years, ending Christmas last, was only 19; while that of Brighton, which ought to be the sanitarium of London, was 22. This improvement in the annual death-rate of Croydon, from 22 to 19 per 1,000 of its population of 40,000 persons, is a saving of 120 lives per annum; and if 120 persons every year are saved from death, how many more are relieved from deteriorated health and vigour? But this is not all; for besides this, the deaths that do happen are fewer than formerly at the useful ages between twenty-five and fifty, which is the interval in which death falls heaviest on a family, and indeed on the community. Compared with the state of health in the three great divisions of the kingdom which the Registrar General adopts, viz., "The Town Districts," "The Country Districts," and "All England," Croydon (being partly town and

partly country) ought to rank lower in the sanitary scale, that is, as less healthy than the country districts of the kingdom; but in the return of the Registrar General for the quarter ending Christmas last (which was an unhealthy one all over England) the average annual deaths per 1,000 are, in the town districts, 25.80; in all England, 23.85; in country districts, 21.16; but in Croydon, only 19.13.

Builders find the benefit of all this. They have no cesspools or sewers to construct; no wells to dig, or pumps to erect; water is supplied at only pumping price, without limit in quantity, and by a constant service, except during seven hours in the night; and as the result of this, houses are let before they are finished.

Whatever may be the benefit, in point of pecuniary result, in utilizing sewage by agriculture, the benefit of thus ridding the town of it is an advantage in point of health, which is beyond any money-value; and the proposed measure, therefore, is not so much one of utility as one of duty. At first the measure will be voluntary; but if any towns shall neglect to perform this duty of their own accord, then, as extramural burials are being now enforced upon populous places, there will be no hardship if a subsequent Act should enforce extramural utilization of sewage.

#### THE PEOPLE'S SHARE IN ART.

##### ARCHITECTURAL MUSEUM.

A MEETING of the members of the Architectural Museum was held on Tuesday evening last, at the Kensington Museum, for the distribution of prizes to art-workmen, and to hear an address "On the People's Share in Art," by Mr. Beresford Hope, president.

Mr. Hope said that, on previous occasions of a similar nature, he had been permitted to make some general remarks on questions of artistic interest, having reference especially to the objects to promote which the Architectural Museum was established. At the opening of the session of 1863, he had endeavoured to explain the peculiar phase of art which they were associated together to support,—not art simply nor architecture simply, but an intermediate something which they might call architectural art. Last year, having established what architectural art was the year before, he took up the art-workman's position—the position of the man who were the executive in the execution of architectural art—the art-producers, he now proposed to regard the whole question from another point of view, and to deal with it not so much as regarded the advancement or trade profit of the art-producer as from the point of view in which the interest and advantage of the art-consumer are concerned. He proposed to speak of the people's share in art; the share of those persons, some of whom might be able to practise more or less of art, but to do so for their own amusement and edification, and not as their calling in life. He desired to place before them, plainly and emphatically, a general test for a general qualification for art—as not one of those things to which they ought to be indifferent—one of those things which, as the world was now constituted, might or might not exist in a nation; but as a thing which ought to exist, if the nation meant adequately to fulfil its mission amongst the other peoples of the earth in a social, moral, intellectual, and material point of view. They should first inquire how far it was desirable or necessary to the well-being of a people that a general appreciation of art should be diffused; next, how far it was desirable towards this diffusion of taste in art that facilities for making acquaintance with art should be afforded to the general public.

How far, in other words, should they take steps, not only that persons should appreciate drawing, carving, and so on; but also to a certain extent be converted into carvers and draughtsmen, although carving and drawing might never be more to them than an amusement, or, at the outside, a very temporary and occasional employment. And, thirdly, he would apply the solution of the two questions to the peculiar circumstances of their own institution. First, how far ought a nation as a nation, and how far ought the individuals of that nation, to endeavour to make a general appreciation of art in all its branches—painting, sculpture, &c.—the general property of the people; not merely of the highly educated classes, but of those whose education and technical knowledge were comparatively limited;—in short, how far ought educa-

tion to be the education simply of the eye, and not so exclusively of the memory and the intellect. The question brought them back to principles of a deeper and wider character than mere consideration of artistic beauty. It resolved itself at once into that great first principle which the human mind in no narrow, or bigoted, or dry spirit, were united in asserting; namely, that for the healthy development of the mind, the imagination, no less than the reason, must be cultivated. This is an age in which science has made gigantic progress,—an age in which the machinery of literature, so to speak—printing, journals, public speaking—had attained a position and acquired a power such as no previous time furnished any instance of. All these were, in their way, antagonistic to the development of the imagination; but, on the other hand, they were good and right in themselves. How, then, was the imagination to be fostered? In former times more rude, and perhaps more stirring, the imagination and popular poetry and ballads. Heroic action, except in time of great refinement, threw itself into the form of lyric or ballad poetry.

The Homeric poems were the form in which the Greek mind treasured up for ages those gallant feats which it was fondly hoped were not altogether fabulous. The Romans had their ballads, such as those which Macaulay, in his "Lays of Ancient Rome," had attempted to revive. The Border forays, before England and Scotland, although they only concerned cattle-stealing cases, which a justice of the peace would dispose of now,—produced the ballad of "Chevy Chase" and its compeers. In Ireland the influence of ballad poetry upon the imagination of the Celtic race there was very great; and the treasures of the ancient poetry of Brittany had lately been displayed by the facile muse of Mr. Tom Taylor. Coming down to the middle of last century, they knew how amongst the Scotch half-civilized people in the Highlands of Scotland much stirring poetry contained in the land much stirring poetry contained in the land Jacobin ballads had been chanted. But take one more century and its heroic events—the great contest of right against wrong—the glorious, scientific, and successful feats of British arms; they only practically exist for us in the one ballad, "The Burial of Sir John Moore." Waterloo was unused; the Crimean War produced only Tennyson's "Charge of the Six Hundred;" the Indian Mutiny, although fruitful of incidents displaying the daring courage and heroism and devotion of the British soldier, was absolutely barren of verse; the war in America had produced a good deal of writing, but not one verse that could live. On the side of the people struggling for independence there was one touching ballad; on the side of those fighting for empire there was the dolorous ditty, "John Brown's Body is Mouldering, and his Soul is Marching on." Where, then, did the present generation stand? Were they given over, body and mind, to the steam empire? Had the iron of the railway entered into their souls? Where is the food on which the imagination might be nurtured? The answer was twofold. Amongst those who had the time and means of obtaining a classical education there was still the system, and he trusted it would long continue, of becoming acquainted with the classic authors. He might be asked, what had a classic education to do with Gothic art, of which they were admirers? Well, he was treating of art from an educational, and not from a technical, point of view; and next it was in the name of Gothic art that he claimed its pre-eminence in the literature of Greece and Rome. Gothic art had shown them the more excellent way, but they should confess that that more excellent way had its foundation in the streets of Athens and Rome. One reason why they studied Mediaeval art with more profit and elasticity, and less of mere pedantry than their contemporaries in France and Germany, was, that in those countries the rival Classic and Gothic schools were pitted against each other bitterly and unreasonably. Well, it being admitted that the study of ancient literature developed the imagination, expanded the sphere of thought, he asked what were the masses, who had not time, or means, or facilities of learning these things, to do? What equivalent was to be given for the knowledge of Classic literature? what compensation for the fresh stream of ballad and popular poetry which their rude ancestors called their own? His answer was a simple one, and it brought him to the point of the lecture,—for the masses, give freely, readily, and with an open hand the means of enjoying

art; give them plenty of opportunity of seeing art; give them the opportunity, too, of learning such simple principles of art as shall enable them to appreciate the merits or recognise the demerits of the specimens of art brought before them. It might also be asked, were they to take the rough sons of labour by the hand and hopefully to ask them to admire that which was so different from all that came within the ken of their ordinary life, and from the spirit of their ordinary pursuits? There might be difficulty in the way, but that ought not to deter them; for they should remember that the more the forms of beauty were strange to the ordinary life of the class to which he alluded, the more ought they to put them in the way of enjoying them when and as they could. One way in which they could do so was this, by giving them ample opportunity of studying copies, if they could not study the originals, of the masterpieces of art of a past time; and next, by keeping up a brisk supply of creditable art of modern production in and around and amongst them. If they banished ancient art, they would cut off a great connexion with the past and an important branch of art education; on the other hand, if they confined themselves to the reproduction, in casts and models, of old masterpieces, they would not infuse the breath of life into the existing body. Modern art might be inferior to ancient, but it was their own; it was the form and embodiment of the day in which they lived; and unless they fostered the school of art of their own time, unless they were forbearing and not too exacting, unless they encouraged it in its first tottering footsteps, they would fail to fulfil a duty they owed to the time in which they lived. In short, they should give the people museums and schools of art, and something more,—scattered up and down, in the highways and byways of their towns and villages they should have the forms of sculptured art; in their public buildings they should have specimens of painted art, so that the idea of painting and sculpture should become as household thoughts to the mass of the population. This was found to be the case on the Continent, and what was to lead to its being the case at home? Simply to go on boring with the thing until they made something like an impression;—to go on displaying before the eyes of the people a successive series of representations of forms, not merely graceful forms, but forms that would recall great historical events of a past time;—and, again, by taking every opportunity of giving instruction in art. The question of art-instruction for the multitude was last year, and might be again, matter of discussion in those high quarters where public affairs were seriously debated. It was, he held, the duty of a civilized commonwealth, as soon as it had appreciated the necessity and advantages of a movement towards general art-education, to foster that movement with no niggard hand, as a thing in which advancement must be made from above, even while the acknowledgment from below must, for a time, at least, hardly correspond with the zeal with which the missionaries of the movement stirred themselves up to their work. There was a great agitation now for industrial exhibitions. They had almost a plethora of art-complexions all over the country. What was required still was simply a regulating mind—a broad appreciation of art, not merely in its technical details, as good anatomical drawing, good foliage grouped in naturalistic or conventional forms, good adjustment of colour, and so forth,—all these were most essential,—but also as regarded its training directly with a view to its historical and poetical interest, and affording a rough-and-ready view of other times and countries. Take the great historical events of our own country. Where was the common Englishman, and how, to study them in pictures and sculpture? Such did not exist for the common man; and their not existing was he considered, a great disgrace and detriment to the country. How, then, might they exist? They might exist not only in frescoes and in sculpture, but in cheap lithographic prints, which could be circulated by the million. In the Houses of Parliament, which, with all the faults that had been so maliciously exaggerated, were still, he considered, a splendid monument, they might see this art for the people displayed. They might see it in the crypt of St. Stephen's, which had lately been so gorgeously and beautifully restored in the hall above, devoted to the statues of our worthies; in the painting of the grand old legend of Arthur; in the historical frescoes; they could also see it in the Assize Hall of Manchester,

which would shame many of the public buildings of London by its combined beauty and convenience; they could also see it in the new Orphanage at Birmingham, the donor of which had had a cloister underneath set apart as a play-ground for the children, the capitals of the columns of which were carved with fables, which were calculated to engage the minds of the children through the eye. Whether the walls of their churches would or would not be the vehicle of pictorial representations remained to be proved. Happily the idea that the Divine Being was dishonoured by representations of the great events of the Bible, that superstitious feeling, that idolatry of whitewash, was passing away, and the reasonable sense for representations of divine events was growing up. In Italy, in Germany, in Switzerland, they saw pictorial art,—of a very rude kind, no doubt,—ornamenting the walls of public buildings everywhere. Unhappily the same could not be said of Old England, with more opportunity for obtaining it now than ever before existed. And why? Partly from that superstitious dread of colouring which had been the Englishman's bugbear until now, and partly from the want of sufficient art-education in our governing classes, both of which causes were happily dying away. Again, if they wished to teach the people to appreciate art, they ought to teach them to do a little art themselves,—a little carving, a little drawing, and so forth. Drawing would give them a knowledge of proportion, which nothing else but a mathematical training could give them. Even children in village schools could be trained to a certain extent; they could have imparted to them instruction in the first principles of form and proportion which would be a valuable corrective to the irregularities of the mind in after-life. How it was to be done was not the place to discuss. He merely threw out that there was a necessity for affording to the people education in art which would stimulate and train the imaginative side of their mind, and also confirm and strengthen that harder and more practical element,—that which might be called the mathematical side of the intellect,—both of which were involved in art-training. But how did all this apply to the art-workman whom it was the privilege of the Architectural Museum to bring forward? It was a question of supply and demand. Once educate the people to know a little something of, and to have a taste for, art,—hold out before them grand types of artistic progress in ancient days, and good specimens of modern art, and they would create a demand for art-objects,—cheap and inferior, perhaps,—but for objects which should be supplied to meet the demand. Who were to furnish those art-objects? They might not be the venison of art, but the wholesome jerked beef at 3d. per lb.; and this jerked beef of art was especially what the art-workman should supply. The freccos, as they were called, of the old churches on the Continent, were run in three or four colours: why could not art-workmen be found here to fill the churches and public buildings and vestry-halls of England with similar paintings? Why could they not do the sign-painting, which was now so much neglected,—make statuettes for chimney-pieces, vases for flowers, and many other art-objects which an art-educated people would require and demand? All these the art-workman could produce if he steadfastly stuck to his last. The creation of a general art-feeling was quite possible, and it was called for especially in this day, when materialism must be counteracted by cultivated imagination. That feeling once diffused, then the erection of museums and art-schools, and the adornment of highways and public buildings, as he had suggested, would turn to the financial advantage of the art-workman or working artist; for they could be artists as truly as those who wrote "R.A." after their names. The former might produce art-objects for the million, as the latter did for the higher classes, and that was the people's share in art. They were all engaged in a great joint-stock company, of which those whom he addressed were the trustees. They might make it by their efforts, or mar it by their neglect. He asked them not to be thrown back by the fallacy that England was not an artistic nation. Those who held that idea might ask him, had he ever looked at Trafalgar-square? He had, and he admitted that there was necessity for manifesting a gigantic penitence. They might lead the way and carry the tapers in the penitential procession; and, having done so, show their repentance by their works. They might come forward and encourage a movement towards a

better state of things; not in a pedantic spirit, but with a generous appreciation of the art of all times terminating in that great art of Europe and England—the art of the Middle Ages,—of which they were the heirs, and destined, he believed, to be the promoters, the improvers, and the remitters to posterity.

The president then proceeded to distribute the following prizes:—

- For Silver Work.*  
Prize 1, 10l.—Henry Whitehoose, jun.  
Prize 2, 5l. 5s.—Stephenus Boreford.  
Extra Prize, 3l. 3s.—Geo. J. Langley.  
Ditto, 1l. 1s. and a Book.—Walter Harrison.  
*For Transparent Enamels.*  
Prize 1, 7l.—H. de Koningh.  
Prize 2, 3l.—Frederick Lowe.  
*For Opaque Enamels.*  
Prize of 10l.—Alfred Gray.  
*For Chinese Cloisonné Enamels.*  
Extra prize, a Book.—H. de Koningh.

#### "BLUE BOOKS MADE USEFUL."

FIVE years ago, on the opening of a session of Parliament, and under a similar heading to that prefixed, seeing the increasing importance of Parliamentary papers to our class of readers,—which was paralleled by that to each other class, or to the general public,—we devoted an article to the question whether the proper advantage was realized from the very costly system of so-called publication of these documents, and to the suggestion of means by which it might be.\* We endeavoured to show that elaborate machinery of the collection of evidence and the preparation of reports and returns, and charges for paper and printing, might be justified, but only on the supposition that a certain end was attained. Such object, we observed, was not the commercial one of profit from publication, or even the reimbursement of money. We showed that the amount realized from sale of these papers, was so little as not to deserve to be taken into an estimate; whilst that the price of them, nominally small, really helped to prevent the attainment of the object. The object primarily, as recognized by Mr. D'Israeli, was not the reduction of cost of printing and paper, but the dissemination of the information. We offered a suggestion of means by which the object might be attained, and even with a diminution possibly in the cost of paper and printing; and we concluded our article with an expression of hope that our observations might attract notice from Mr. Wm. Ewart, or some member of the committee of the House of Commons appointed to assist the Speaker in matters relating to printing.

From the date of our article in 1860, to the beginning of this month, we have looked for evidence of due attention to the subject, if not to our particular suggestion. But for the five years, excepting the proceedings of the Committee of 1862, we looked in vain; and what we understand is now to be brought before the House, though dictated by the feeling that advantage greater than there is, ought to be made to accrue from the Parliamentary Blue Books, and though desirable in itself, would only go a moderate distance towards the end, and not take away any of the arguments for our own proposition. Our suggestion, made after much consideration of the subject, and aiming at the diffusion of the information contained in Parliamentary papers, was to the effect that there should be a special public library, with a reading-room, for those documents. We supported the suggestion by arguments; and we are prepared with others.

The other suggestion is contained in a notice which we have learned was lately given by Mr. Wm. Ewart, for a motion in the House of Commons, or,—“To call the attention of the Government to the public advantage which would result and the saving which would accrue from the publication of an abridgment or digest, to be issued from time to time, of all the Parliamentary Blue Books, and similar documents, on the same plan as that of the ‘Statistical Abstract’ issued by the Board of Trade since the year 1854.” We have seen nothing in the reports of proceedings of the House, of the motion as having been actually made.

According to a lucid statement which we believe was originally compiled by Mr. Leone Levi, and which may be found in the *Journal of the Society of Arts* of 3rd of March, there are upwards of 1,000 documents, extending altogether

\* Vol. xviii., 1860, p. 81.

## ST. ANDREW'S CHURCH, HECKINGTON.

Sedilia in Chancel.

The Holy Sepulchre.

to not less than 50,000 pages, published annually under the general head, Parliamentary Papers. The cost of printing such papers for the Houses of Parliament, was given in 1864 at 67,500*l.*—this being independent of the printing for the several departments of Government, amounting in all to upwards of 300,000*l.* Volumes of 800 folio pages are quite common; the report, to which we referred in 1860, on the Endowed Schools (Ireland), had 1,881 pages. The statement then goes on almost in the same words as we used. The papers are not read by members, for want of time: they are not read by the public, for want of facilities for getting at them: the sale of single copies is very small; there is no means by which the public can consult the documents in a collective form,—no private gentleman and no public institution being able conveniently to afford the space to keep them; and the bulk of the copies go for sale as waste paper. Documents are printed again and again repeating the same facts or opinions, given in evidence or in returns. Particulars of the national finances appear to be printed in six different returns. But this statement is wanting in something which we think went to complete our own. We referred to instances of documents of the greatest value, now scarcely procurable at any price. Amongst them was the report of the Commission on Iron applied to railroad-structures, and that on the Stone for the Houses of Parliament. It has been said that a report on stone, probably a portion of the document connected with the Houses of Parliament, which originally was sold for 6*d.*, would now fetch a guinea.

Without the other impediments to the diffusion of the matter contained in Parliamentary Papers, there would be one comprised in the secrecy, as we cannot but call it, which is allowed to surround the publication. In the ordinary trade, were a publisher to refrain from letting the

public know of the publication of a book, he would fail to sell many copies of it; and he would be held to be rightly served in his eventual loss. The best hooks are in fact advertised the most extensively. The publisher does not trust to exposing them for sale, at his own place, or at the numerous shops of booksellers; but, for the Parliamentary papers, there is nothing of the nature of announcement of their publication, beyond a paragraph in a newspaper, when the subject concerns "the general reader," and the inclusion of the title in a printed list, of which the existence is known to few persons. This list however is reprinted regularly in the *Journal of the Society of Arts*.

The object of the expenditure in the compilation and printing of these documents, being to get them read by the public, or digested by those who form the public mind, it seems to us obvious that such object cannot be attained without the library. The money-*receipt* from the five persons once mentioned as making up the entire number of readers of a particular Blue-Book, would scarcely justify the publication; but the gain to the public, of useful information, through the fifty writers, journalists, or "publicists," who would resort to the library, and give forth the matter of their researches and conclusions, might be sufficient to afford justification for the largest amount of cost. One advantage, to which we alluded in our original article, of the library, would be, that in some cases printing would be avoided altogether, or where an attested manuscript copy of a return would suffice, as for the object of a single member of Parliament.

We have only to repeat what our idea of such a library would be. It should be a public library, devoted specially to all Parliamentary papers, but containing also all papers issuing from the Court of Common Council of the City of London, the Metropolitan Board of Works,

the District Boards, and the water and gas companies. In it, there should be found the documents of the Legislature of France, which are regularly sent to that of Great Britain, the *Moniteur*, and the reports of the municipality of Paris. The institution should be located in the vicinity of the Houses of Parliament: it should be open throughout the year, and be a lending-library to certain persons; and it should have several copies of each paper of late date, and one of each of the series from the commencement, or the first introduction of the system of publication or printing. In comfort and convenience, the reading-room should equal that of the British Museum; and the catalogues should be equal to those of the Patent Office Library. There should be atlases, statistical charts, commercial and geographical dictionaries, and space for the display of maps illustrative of schemes before Parliament.

Through the existence of such an institution as we have sketched the plan of, we should expect that the sale of Parliamentary papers would not be diminished, but increased,—that the diffusion of the papers would be the result of the concentration in the library. But whether this result or not, the object for which alone great cost of preparation and printing of Parliamentary papers is justifiable, would have the chance of being attained; the useful matter could be got at, and read; and its diffusion would follow. How much of such matter, important to ourselves and our readers, there is in Parliamentary papers, and how much is utterly lost, we need not now say.

MORSHAM CHURCH, SUSSEX.—Mr. Howes, who contracted and undertook to carry out the church restoration works, has called his creditors together, so that the restoration works are likely to be delayed.

ST. ANDREW'S, HECKINGTON,  
LINCOLNSHIRE.

HECKINGTON CHURCH is an exquisitely beautiful specimen of the Decorated period, and has fallen into a bad state, requiring the expenditure of a considerable sum of money. It needs re-roofing, re-seating, and other costly works to the extent of 5,000*l.*, and a committee has been formed to raise the necessary funds. More than 1,000*l.* have been subscribed by the parishioners, and an appeal is now justly made to the county, and indeed to the public generally, every Englishman being interested in keeping up for his country such a glorious monument of the skill and piety of his forefathers. We gladly assist in making public the appeal, and the engravings we insert\* will serve to show those who do not already know it what manner of church this is. The building took the place of one here at the time of the Conquest, and is thought to have been commenced about 1320, Richard de Potesgrave (buried in the chancel) being vicar, and completed about 1380.

The Easter Sepulchre, of which there is a cast in the Crystal Palace, and the Sedilia, are well-known features of the interior. Of these we give views.

The sedilia on the southern side of the sacrum consist of recesses worked in the wall, flanked by small shafts, and surmounted by richly crocketed canopies. Between these are pinnacles, foliated work, and six figures. Those in the centre represent our Lord and the Virgin Mary, crowned; the next, on either side, St. Barbara regarding the suggested Church Tower, held by an angel. On the right is St. Catherine, and on the left St. Margaret. The whole is finished with a carved cornice, adorned with figures of angels. The vaulting within the recesses that served as seats, and other details, are admirable.

Nearly opposite the sedilia is the Easter Sepulchre. In canopied recesses below are sculptured four of the sleeping Roman guardians, bearing shields of English soldiers of the fourteenth century. Above this is the tomb proper. Over its hood-moulding are figures of angels kneeling and censuring, and standing on the final of the hood-mould is a representation of our Lord freshly risen. On each side of this miniature representation of the sepulchre is a kneeling angel and a canopied niche, in one of which are figures of two of the Marys, and in the other the third Mary and the announcing angel. Above these niches is some beautiful foliated work, and the whole is finished with a cornice, displaying little figures blowing flutes.

Surely there should be no difficulty in raising funds to place such a building as this in a proper condition, to secure it for posterity.

MR. FERGUSON AND BIBLICAL  
ARCHITECTURE.

From the first broaching of Mr. Fergusson's views on the buildings of modern Jerusalem, I have maintained their soundness (*Builder*, vol. xix., p. 135) and still hold that architectural archeology would be a mere delusion if it did not suffice to settle that the "Dome of the Rock" is a Roman Christian work. But while firmly believing his discovery that this is no other than the church erected by Helena over what she mistook for the Sepulchre of Christ (which, of course, a cave within 50 yards of the Temple's most frequented gate could not possibly be), I would beg to point out the great fallacy, or series of fallacies, into which, in his late lecture, he was led by the gratuitous assumption that the first Temple reproduced, or, in his own words, "copied literally," the mystic measures or ratios of the Tabernacle; in short, that Solomon, entirely contrary to Mr. Fergusson's own commonsense principles, built, for the sake of symbolism, very bad and mock architecture, instead of, as I think it can be proved, very good, or at least as original and distinct from the Tabernacle, both in proportions and arrangement, as a rational stone monument ought to be from an equally rational tent.

Of the earlier structure, we probably have the means of knowing more than of any other past human work without contemporary drawings. The twice-repeated specification, first of every thing that was ordered to be made, and then of everything made, is so perfect, omitting, I

believe, no single necessary piece, either of wood, metal, cloth, or skin; so wondrously clear to even this distant age, in spite of one or two absurdly mistranslated words in every version; carries than any other document of the kind by three; and so distinguished from any half as old, and containing half so many figures, by the unique marvel of containing (*pace* Dr. Colenso) neither "anomalies in dimensions" nor a single discrepant numeral; that we might challenge the production of any modern architect's specification, telling us as much without one drawing, even for a present Bezael's own guidance. But now, with regard to the Temple, first or second, widely different is our information, whether in the histories, Ezekiel, or Josephus. Whatever each of those author's objects, it is plain that, to all who might never see the structures, their accounts leave them practically undescribed, and a restorer's imagination as absolutely free as if hardly a word beyond the three internal dimensions of the cell had been written. There is just enough, I submit, *totally to disprove* Mr. Fergusson's fancy that the Tabernacle, or anything thereof, was "copied literally," and that is all. If these antiquated accounts were (as well as those of Moses) "written for our learning," surely the chief we can learn from them is the utter spiritual unimportance of the details of Solomon's splendour (which have not even been kept from the corruption of contradictory statements), and that the former structure *alone* was inspired to prophecy by its dimensions, pieces, and numbers, which were not reproduced (their purpose being answered when once recorded in writing); but the human contrivers of the later building being left to follow in all things, as those of the former did in all but these mystic particulars, the best principles of design they could, with the simplest (or what would now be called most *Gothic*) reference to its physical uses and dignity, and no thought even in the former case, probably, where some details were prescribed, that they were overruled to be symbols and prophecies, unknown to any that served therein, in all the ages it stood, yet to be oracular afterward to the end of time.

Mr. Fergusson tells us "every dimension" of the Tabernacle, except the roof-slope, "was a multiple of 5 cubits," because those of the Temple were multiples of 10; and he has laid it down *a priori* that it was a copy with "every dimension doubled." Now, the Temple's interior was 60 cubits long, 20 cubits broad, 30 cubits high (1 Kings, vi. 2). The Tabernacle (Ex. xxvi. 16, 18, 20, 22—25) was 30 cubits long, twelve broad, only ten high to the eaves, but full twenty to the ridge of the equilateral-pitched roof I shall show it to have had. The breadth 12 (instead of "a multiple of 5") happens to be stated in just eight places!—the last (Ezek. xli. 1) being the only reference, I believe, to this structure by later prophets. Again, its Holy of Holies, Mr. Fergusson says, was "a cube of 10 cubits," and its Holy Place "a donkhe cube of 10." There is not a fact more plainly stated in the whole Bible than that these two apartments were equal, and neither less than twelve by fifteen! The veil dividing them was to be "under the taches" (Ex. xxvi. 33), which were buttons attaching the fifth of the ten breadths of tent-cloth (miscalled "curtains") to the sixth (ver. 3, 6), the reason for this seam alone being so buttoned being probably that one-half the covering might be carried and erected by common Levites, while only the Kohathites might touch what belonged, as the other half did, to the Holy of Holies (Numb. iii. 31). Now, how far any arrangement could shift this junction from the middle of the tent's length Mr. Fergusson has to show.

He next tells us "the porch" (being in the Temple, 20 by 10), was here "10 by 5." It may be clearly proved that, unless deformed by unequal intercolumns, its area was just 12 by 3. Five pillars are to bear a hanging before an aperture 12 cubits wide. If we place them in the aperture itself, "*in antis*," we make the six openings each less than 2 cubits, by a pillar's width, or too narrow for ingress. They, therefore must form a portico, either *prostyle* with all five in front, or *diptostyle* with only three in front. But the latter, having as many intercolumns on the flank as the front, would make the porch square, and the whole length of cell and porch, 42 cubits, while we have only 40 of tent-cloth to cover it. The only possible door arrangement

then was *mono-prostyle*, the front of four inter-columns, the flanks of one each, and the dimensions 12 by 3. There was no "verandah" anywhere of "5 cubits," and the only mention of such a dimension is for the height of the external court bangings.

Of course, the centre pillar of this porch bore the ridge-piece; but so, too, I believe did *all* the four internal pillars, the first standing in the centre of the Holy Place, the second at the middle of the veil, the third in the middle of the Holy of Holies, and the fourth close to the boards of its closed end. The expressions about the veil, "thou shalt hang it on four pillars" (xxvi. 32), and (xxvi. 36) "he made thereunto four pillars," do not imply they were all four to bear it *at once*. They were four identical or interchangeable pillars, any of which might serve for suspending the veil. That only one so served at a time, for they were all needed to bear the ridge (as in that honest New Zealanders' church, in the *Illustrated News*), is as plain to me as that the New Zealanders were better architects than Calmet or Palladio. Mr. Fergusson's next requirement of "nine" boards for the closed end is most unlucky. The statements about these (and therein of the Tabernacle's width) happen, as I have said to be seven:—

1. That the numbers ordered were six ordinary, and two stronger for the corners (xxvi. 22, 23).
2. That the whole number ordered was eight (ver. 25).
3. That two shoes under each would amount to sixteen (*Ibid.*).
4. That the boards made two six ordinary and two for the corners (xxvi. 27, 28).
5. That the whole number made was eight (ver. 30).
6. That sixteen shoes went under them, two to each (*Ibid.*).
7. That the shoes for four pillars, forty other boards, and these, amounted to 100 (xxxviii. 27).

Now, when Mr. Fergusson gets from these his "nine boards," none will even then avail to bear the ridge, for none were higher than the sides, the boards in general being all ordered to be but 10 cubits by 1½ (xxvi. 16; xxvi. 21). They could not extend, therefore, into the gable, which at this end (and therefore probably at the front also) remained open, forming the two sole hot inefficient windows, affording ventilation, and a sight to all without, of the cherm-embroidered roof-cloths.

The ridge-piece, the heaviest in the structure (as in the New Zealanders') is disguised in our version under the term "middle bar" (xxvi. 28; xxxvi. 33), and the latter reference should be translated, "He made the ridge-piece to overpass (or go beyond) the boards, both at one end and at the other." It had, I have shown, five supports, not by any "boards," and no longer bearing than 8 cubits; but its whole length was 38 or 39, according to how much we suppose the nine seams of the tent-pieces to overlap. These were stretched from the ridge by ten cords (that, by passing through the eyelets of their lapping selvages, would also serve to couple them) down to twenty pins or stakes in the ground; such being thrice mentioned in the brasswork, as needed not only for the court inclosure, but also the Tabernacle itself (xxvii. 19; xxxviii. 20, 31). Now it took cloths of 28 cubits to reach from eave to eave, across the ridge. This corresponds to a tent, of the pitch most common all the world over, the equilateral triangle, of 14 cubits base; and we have seen the room to be covered was 12 wide, leaving well-proportioned and necessary eave-projections. The two chambers then measuring together (for the porch was to all intents part of the first) 33 by 12, the roof covered 38 or 39 by 14, overhanging at the sides one cubit, but at the gables, *i.e.*, windows, 2½ or 3. Accordingly, the tent-covering next placed, of goats'-hair, is expressly said to have one cubit extra breadth to hang over each eave (xxvi. 13) as a valance, but half a breadth of stuff, or two cubits, over each gable (ver. 9, 12), the valance in each case about as deep as its projection.

This goats'-hair covering, though all visible, had no need to be weatherproof (at least where no rain drives from the east), for there was yet another double awning (xxvi. 14) of what we should call red morocco beneath, and badgerskins above, whose size is not given. Now I believe this to have been not less than 50 cubits or 60 cubits square, so that, hearing only on the ridge of the sacred cottage, which I have shown to stand (not "15 cubits, but) about 22 cubits above its silver bases, this awning would stretch, with quite enough slope for weathering, to the

heads, only 5 cubits high and 25 cubits distant, of the pillars of the outer court, the whole western half of which it would cover, and perhaps some verandah-like skirts even outside of it. The space sheltered was surely necessary for the Levites' services, and not so large as many a sheikh's leather tent covers now.

The Tabernacle, as a whole, presented then a white-curtained inclosure of some 80 ft. by 160 ft., and 8 ft. high, with the first half or square open to the sky, and the second celled with scarlet leather, upheld only by the ridge of the snow-white goats'-hair roof of the sacred cottage in its centre. The wood everywhere was "overlaid," i.e., copiously bound and filleted with metal; that of the court being, except its bases, silver; and that of the cottage, except its bases, gold. The entrance-curtains to both were of blue and red embroidery, and each filling four openings, between five pillars. Perhaps the corner and middle pillars of the court, and every fifth in its long lines, bore the standards of the twelve tribes. At least there were four lofty ensigns somewhere, perhaps at the corners of the surrounding Levites' camp, that regulated the alignment of all tents beyond (Numb. ii.). They were not allowed to cluster unlimitedly in all directions, but only in four, crosswise, making the utmost distance from any to the open no more than half the central square's width, instead of half the whole camp, as Dr. Colenso fancied. The males who had a right to encamp in the east arm of the cross were 188,000; in the south arm, 151,000; in the north, 157,000; and in the west, only 108,000; but to assume all availed themselves of this right for long together, or were habitually more concentrated than the largest tribes in the same desert now, is preposterous.

If I might now suggest anything as to the symbolism, I should say the central structure, guarded by the enclosure of sixty pillars, as by the sixty sub-tribes of Israel, stands both for the Word incarnate, and also, as other types of Him do mediately, for the word written. In the former view, of course its ground dimensions of 12 by 33 correspond to the ages of the Temple of flesh, beginning and finishing His Father's business; and as three years were public, so 3 cubits of the 33 are open porch. But leaving this for the less mystic meaning, as foreshadowing the written word, whose beginning the structure signified, the five pillars of entry are the Pentateuch, initiating us to that word. The forty boards of the sides answered one another, as those forty persons who thenceforward, through the ages of the Old Testament church, from Job and Moses, to Symeon and Anna, Elizabeth and the Baptist, were made to speak of Him who was to come. But the eight of the end are as the eight New Testament writers, closing in one generation the inspired word. The ridge-piece, overpassing all the boards "at one end and at the other," is of course the Alpha and Omega, the Branch, and "head stone of the corner." The ten cherub-embroidered cloths, upheld by this alone, and covering, embracing, but un-reached by all the rest, are the moral law. The four internal pillars, as the four mysterious living ones that are both "in the midst of the throne and round about the throne," are Divine perfections. As the ridge-piece, raised by them into the highest place, was yet unseen without, and perceived only by the plying of the eleven hair-cloths, so He that is above, entered within the veil, leaves eleven witnesses of His exaltation. Lastly, as on these came further coverings, without recorded measure, first of rams' skins and then of badgers', and the former dyed red; so has the Church unmeasured, of clean and unclean, and the former so by blood, been gathered upon the foundation of those eleven.

But much of all this would be falsified if we set aside the recorded specification to substitute figures deduced only, like Mr. Fergusson's, from a gratuitous and untenable theory.

E. L. GARRETT.

PARIAN CEMENT.—Sir: As a country builder of considerable experience, I can quite endorse the remarks of Messrs. Bellman & Ivey on Parian cement. I have hung the most delicate and expensive papers on Parian a few days after being finished; also pointed immediately on it, and never yet met with a disappointment. I, however, make sure of the proper material, as all sorts of rubbish are made and sold as Parian cement. I advise consumers to make inquiries before purchasing.—WILLIAM A. GOSS.

#### THE DRAINAGE OF LONDON. INSTITUTION OF CIVIL ENGINEERS.

ALTHOUGH we have from time to time fully informed our readers as to the metropolitan drainage works (our pages probably contain the most complete descriptions anywhere to be found), it may nevertheless be desirable that we should give a *resumé* of the accounts by Mr. Bazalgette, at the Institution of Civil Engineers, on the 14th inst.

In the year 1856 the present Metropolitan Board of Works was formed, being the first application, in the metropolis, of the system of local self-government. The author, having been appointed engineer to the Board, was instructed to prepare a plan for the Main Drainage, in which it was essential that ample means should be provided for the discharge of the increasing water-supply consequent on the universal adoption of closets, and of the ordinary rainfall and surface drainage at all times, except during extraordinary floods; and that it should afford to the low-lying districts a sufficiently deep outfall to allow of every house being effectually relieved of its fluid refuse. The objects sought to be attained by these works, now practically complete and in operation, were the interception, as far as practicable by gravitation, of the sewage, together with so much of the rainfall mixed with it as could be reasonably dealt with, so as to divert it from the river near London; the substitution of a constant near London; stagnant and tide-locked sewers, with their consequent accumulation of deposit; and the provision of deep and improved outfalls, for the extension of sewerage into districts previously, for want of such outfalls, imperfectly drained. Prior to these works being undertaken, the London main sewers fell into the valley of the Thames, and the sewage was discharged into the river at the time of low-water. In the system now adopted, it had been sought to remove the evils thus created by the construction of new lines of sewers, at right angles to the existing sewers, and a little below their levels, so as to intercept their contents, and convey them to an outfall fourteen miles below London Bridge. As large a proportion of the sewage as practicable was thus carried away by gravitation, and for the remainder a constant discharge was effected by pumping. At the outlets the sewage was delivered into reservoirs on the banks of the Thames, placed at such a level as would enable them to discharge into the river at or about the time of high-water. By this arrangement the sewage was not only at once diluted by the large volume of water at high-tide, but it was also carried by the ebb to a point twenty-six miles below London Bridge, and its return by the following flood-tide within the metropolitan area was effectually prevented. The points which required solution at the threshold of the inquiry, then successively noticed, were:—

- 1st. At what state of the tide could the sewage be discharged into the river so as not to return within the more densely inhabited portions of the metropolis.
- 2nd. What was the minimum fall which should be given to the intercepting sewers.
- 3rd. What was the quantity of sewage to be intercepted, and did it pass off in a uniform flow at all hours of the day and night, or in what manner.
- 4th. Was the rainfall to be mixed with the sewage; in what manner and quantities did it flow into the sewers; and was it also to be carried off into the intercepting sewers, or how was it to be provided for.

5th. Having regard to all these points, how were the sizes of the intercepting and main drainage sewers to be determined; and

6th. What description of pumping-engines and pumps were best suited for lifting the sewage of London at the pumping-stations.

As regarded the position of the outfalls and the time of discharge, an extract was given from the Report of the late Mr. Robert Stephenson and Sir William Cubitt, dated the 11th December, 1854, referring to a series of experiments made with a float, by the late Mr. Frank Forster, and subsequently repeated by Captain Burstal, R.N., and the author, which proved that it was essential to go as far as Barking Creek, and that the discharge should take place at or near to high water. These experiments also demonstrated, that "the delivery of the sewage at high water into the river at any point is equivalent to its discharge at low water at a

point twelve miles lower down the river; therefore the construction of twelve miles of sewer is saved by discharging the sewage at high instead of at low water."

With respect to the velocity of flow and the minimum fall, it was difficult to lay down any general rule, because the condition of the sewers, as to the quantity of deposit and the volume of sewage, varied considerably; but the results arrived at by Mr. Wicksteed, Mr. Beardmore, Mr. John Phillips, and Professor Robison were quoted, in confirmation of the author's own observations and experience, which lead him to regard a mean velocity of 1½ mile per hour, in a properly protected main sewer, when running half full, as sufficient, especially when the contents had previously passed through a pumping-station. Having thus determined the minimum velocity, it became necessary to ascertain the quantity of sewage to be carried off, before the full requisite to produce that velocity could be estimated. That quantity varied but little from the water supply; and as it was contemplated that 314 gallons per head per diem might be supplied to a district, of average density of population, containing 30,000 people to the square mile, except in outlying districts, where the number of inhabitants was reckoned at 20,000 per square mile; and as actual measurements showed that provision for one-half of the sewage to flow off within six hours of the day would be ample, the maximum quantity of sewage likely hereafter to enter the sewers at various parts of the metropolis had been arrived at.

It had been advocated, by theorists, that the rainfall should not be allowed to flow off with the sewage, but he dealt with by a separate system of sewers. This would have involved a double set of drains to every house, and the construction and maintenance of a second series of sewers in every street, at an expenditure of from ten to twelve millions sterling, at the least, besides the inconvenience. Observations of the quantity of rain falling on the metropolis within short periods showed that, on an average of several years, while there were about 155 days per annum on which rain fell, there were only about 23 days upon which the quantity amounted to ¼ of an inch in depth in 24 hours, or the 1-100th part of an inch per hour if spread over an entire day. Of such rainfalls a large proportion was evaporated or absorbed, and either did not pass through the sewers, or did not reach them until long after the rain had ceased; for it was shown, in the Report of Mr. Bidder, Mr. Hawksley, and the author, in 1858, that although the variations of atmospheric phenomena were too great to allow any philosophical proportions to be established between the rainfall and the sewer flow, yet, as a rule of averages, ¼ of an inch of rainfall would not contribute more than ½ of an inch to the sewers, nor a fall of ½ of an inch more than ¾ of an inch. There were, however, in almost every year, exceptional cases of heavy and violent rain-storms, which had measured 1 inch, and sometimes even 2 inches, in an hour. But it had been considered probable, that if the sewers were made capable of carrying off, during the six hours of the maximum flow of the sewage, a rainfall not exceeding ¼ of an inch in 24 hours on more than 25 days in a year, there would not be more than 12 days in a year on which the sewers would be overcharged, and then only for short periods during such days. The rare and excessive thunderstorms had been provided for by the construction of overflow sewers with the junctions of the intercepting sewers with the main valley lines, which would act as safety-valves in times of storm, when the surplus waters would be largely diluted, and, after the intercepting sewers were filled, would flow over the weirs, and by their original channels into the Thames.

Having thus ascertained the quantities of sewage and of rainfall to be carried off, and the rate of declivity of the sewer as limited only by considerations of the necessary velocity of flow, the sizes of the intercepting sewers were readily determined by the formulae of Prony, Eytelwein, and Du Buat, and the drainage sewers by the useful formula of Mr. Hawksley, which it was said, in the Report of the late Mr. R. Stephenson and Sir W. Cubitt, already referred to, were "applicable to almost every variety of condition which the complete drainage of large towns involves."

In regard to the sixth and last head of the inquiry, in 1859, numerous competing designs, involving the comparative advantages of Cornish or rotative engines, and the respective merits of centrifugal and screw pumps, chain pumps, lift-

ing bucket wheels, flash wheels, and every variety of suction or plunger pump and pump valve for raising the metropolitan sewage, were reported upon by Messrs. Stephenson, Field, Penn, Hawley, Bidder, and the author. Based upon the recommendations contained in that report, condensing double-acting rotative beam-engines, and plunger or ram pumps, had been adopted; the sewage being discharged from the pumps through a series of hanging valves. The contractors for the engines at Crossness and at Abbey Mills had guaranteed that they should, when working, raise 80 million pounds 1 ft. high, with 1 cwt. of Welsh coal.

It had already been stated, that a primary object sought to be attained by these works was, the removal of as much of the sewage as possible by gravitation, so as to reduce the amount of pumping to a minimum. To effect this, three lines of sewers had been constructed on each side of the river, termed respectively the High Level, the Middle Level, and the Low Level. The High and the Middle Level Sewers on both sides discharged by gravitation, but for the two Low-level Sewers the aid of pumping was necessary. The three lines of sewers north of the Thames converged to and were united at Abbey Mills, east of London, where the contents of the Low-level Sewer would be pumped into the Upper-level Sewer; the aggregate stream would thence flow through the Northern Outfall Sewer, which was carried in a concrete embankment across the marshes to Barking Creek, where the sewage was discharged into the river by gravitation. On the south side, the three intercepting lines united at Deptford Creek, and the contents of the Low-level Sewer were there pumped to the Upper Level, whence the three streams would flow in one channel through Woolwich to Crossness Point in Erith Marshes. Here the whole mass of the sewage could flow into the Thames at low water, but would ordinarily be raised by pumping into the reservoir.

As the intercepting sewers carried off only 1-100th part of an inch of rain in an hour, and the volume of sewage passing through them was at all times considerable, the flow through these sewers was more uniform than in drainage sewers constructed to carry off heavy rain storms. The form, therefore, generally adopted for the intercepting sewers was circular, as combining the greatest strength and capacity with the smallest amount of brickwork and the least cost. In the minor branches, for district drainage, the egg-shaped sewer, with the narrow part downwards, was preferable; because the dry weather flow of the sewage being very small, the greatest hydraulic mean depth, consequently the greatest velocity of flow and securing power, was obtained by that section in the bottom of the sewer, at the period when it was most required; and the broader section at the upper part allowed room for the passage of the storm waters, as also of the workmen engaged in repairing and cleansing these smaller sewers.

A more detailed description was then given of the several works, and of some of the peculiarities or difficulties met with during their construction.

On the north side of the Thames, the High-level Sewer varied in size from 4 ft. in diameter to 9 ft. 6 in. by 12 ft. Its fall was rapid, ranging at the upper end from 1 in 71 to 1 in 376, and at the lower end from 4 ft. to 5 ft. per mile. In its construction, much house property was successfully tunneled under at Hackney. Adjoining the railway station, a house was undermined and placed upon iron girders, and the sewer, being there 9 ft. 3 in. in diameter, was carried through the eclair. This sewer also passed close under Sir George Duckett's Canal; the distance between the soffit of the arch of the sewer and the water in the canal being only 24 in. The bottom of the canal and the top of the sewer were here formed of iron girders and plates with a thin coating of puddle, and no leakage had taken place. The Penstock and Weir Chamber, at the junction of the High and Middle Level Sewers at Old Ford, Bow, placed three-fourths of the northern sewage completely under command. It was built in brickwork, was 150 ft. in length by 40 ft. in breadth, and was, in places, 30 ft. in height. The principal difficulties in the prosecution of these works arose from combats and strikes amongst the workmen, and from a long-continued wet season, preventing the manufacture of bricks; as well as from the great increase in the prices of building materials and of labour.

The Middle-level Sewer was carried as near to the Thames as the contour of the ground would

permit, so as to limit the Low-level area, which was dependent upon pumping, to a minimum. The district intercepted by this sewer was 17½ square miles in extent, and was densely inhabited. The length of the main line was about 9½ miles, and of the Piccadilly branch 2 miles. The fall of the main line varied from 17½ ft. per mile at the upper end to 2 ft. per mile at the lower end. The sizes of this sewer ranged from 4 ft. 6 in. by 3 ft., to 10 ft. 6 in. in diameter, and lastly, to 9 ft. 6 in. by 12 ft. at the outlet. About 4 miles of the main line, and the whole of the Piccadilly branch, were constructed by tunnelling under the streets, at depths varying from 20 ft. to 60 ft. This sewer was formed mostly in the London clay; but to the east of Shore-ditch the ground was gravel. During the execution of the works under the Regent's Canal the water burst in; but by enclosing one-half of the width of the tunnel at a time within a coffer-dam, and then by open cutting, the sewer was subsequently completed. The Middle-level Sewer was carried over the Metropolitan Railway, by a wrought-iron aqueduct 150 ft. span, weighing 240 tons. The depth between the underside of the aqueduct and the inverts of the double line of sewers was only 2½ in.; and as the traffic of the railway could not be stopped during the construction of the aqueduct, which was designed to be only a few inches above the engine chimneys, the structure was built upon a stage at a height of 5 ft. above its intended level, and was afterwards lowered into its place by hydraulic rams. The sewers were here formed of wrought-iron plates, riveted together. The Middle-level Sewer was provided with weirs, or storm overflows, at its various junctions with all the main valley lines.

The length of the main line of the Low-level Sewer was 8½ miles, and its branches were about 4 miles in length. Its size varied from 6 ft. 9 in. to 10 ft. 3 in. in diameter, and its inclination ranged from 2 ft. to 3 ft. per mile: it was provided with storm overflows into the river. As well as being the intercepting sewer for the Low-level area, which contained 11 square miles, it was the main outlet for the drainage of the western suburb of London, a district of about 14½ square miles, which was so low, that its sewage had to be lifted at Chelsea, a height of 17½ ft., into the upper end of the Low-level Sewer. It was originally intended to deodorise or utilise the sewage of the western division in its own neighbourhood, rather than to incur the heavy cost of conveying it to Barking, and lifting it twice on its route to that place. But strong objections having been raised to this, the latter and more costly plan had been adopted. The works of this division were executed mainly through gravel, charged with such large volumes of water, that it was necessary to lay stoneware pipes under the inverts of the sewers, to lower the water in the ground, and to convey it to numerous steam pumps, before the sewers could be built.

The Northern Outfall Sewer was a work of peculiar construction; for, unlike ordinary sewers, it was raised above the level of the surrounding neighbourhood in an embankment, which was of sufficient strength to carry a roadway, or a railway, on the top, should it ever be required to do so, as was not improbable. Rivers, railways, streets, and roads, on the line of this sewer, were crossed by aqueducts. The North Woolwich and the Barking Railways were lowered to enable the sewer to pass over them; for the sewer, being reduced to a minimum uniform fall of 2 ft. per mile, could not be raised or depressed like a railway, to accommodate its levels to those of previously existing works. This constituted one of the chief difficulties in laying out the Outfall Sewer, for the district was already closely intersected by public works.

The Barking Reservoir had an average depth of 16½ ft., and was divided by partition walls, into four compartments, covering together an effective area of about 9½ acres. The ground over which it was built, being unfit to sustain the structure, the foundations of the piers and walls were carried down in concrete to a depth of nearly 20 ft. The external and partition walls were of brickwork, and the entire area was covered by brick arches supported upon brick piers, the floor being paved throughout with York stone.

The Abbey Mills Pumping Station,—the largest of the kind on the Main Drainage Works,—was furnished with engines of 1,140 collective horse power, for the purpose of lifting a maximum quantity of sewage and rainfall of 15,000 cubic feet per minute, a height of 36 ft. This station alone would consume about 9,700

tons of coal per annum; but the cost of pumping was not entirely in excess of former expenditure upon the drainage; for the removal of the deposit from the tide-locked and stagnant sewers in London previously led to an annual outlay of about 30,000*l.* The substitution of a constant flow through the sewers, now rendered possible, must necessarily largely reduce the deposit, and consequently the expense of cleansing.

On the south side of the Thames, the High-level Sewer and its southern branch, corresponding with the High and Middle Level Sewers on the north side of the river, together drained an area of about twenty square miles. Both lines were of sufficient capacity to carry off all the flood-waters, so that they might be entirely intercepted from the low and thickly-inhabited district, which was tide-locked and subject to floods. The Main Line varied in size from 4 ft. 6 in. by 3 ft. at the upper end, to a form 10 ft. 6 in. by 10 ft. 6 in. at the lower end, the latter having a circular crown and segmental sides and invert; its fall ranged from 53 ft., 26 ft., and 9 ft. per mile to the Effra, and thence to the outlet it was 2½ ft. per mile. The Branch Line was 4½ miles in length; its size varied from 7 ft. in diameter to 10 ft. 6 in. by 10 ft. 6 in., of the same form as the Main Line, by the side of which it was constructed. It had a fall of 30 ft. per mile at the upper end, and of 2½ ft. per mile at the lower end.

The Low-level Sewer drained a district of twenty square miles. The surface of this area was mostly below the level of high water, and was, in many places, 5 ft. or 6 ft. below it, having at one time been completely covered by the Thames. The sewers throughout the district had but little fall, and, excepting at the period of low water, were tide-locked and stagnant; consequently, after long-continued rain, they became overcharged, and were unable to empty themselves during the short period of low water. The want of flow, also caused large accumulations of deposit in the sewers, the removal of which was difficult and costly. These defects, added to the malarial arising from the stagnant sewage, contributed to render the district unhealthy; and it was with reference to its condition, that the late Mr. R. Stephenson and Sir W. Cubitt so forcibly described the effect of artificial drainage by pumping, as equivalent to raising the surface a height of 20 ft. The Low-level Sewer had rendered this district as dry and as healthy as any portion of the metropolis. Its length was about ten miles, and its size varied from a single sewer 4 ft. in diameter at the upper end, to two culverts each 7 ft. by 7 ft. at the lower end, their fall ranging from 4 ft. to 2 ft. per mile. The lift at the outlet of the sewer was 18 ft. Much difficulty was experienced in executing a portion of this work, close to and below the foundations of the arches of the Greenwich Railway and under Deptford Creek, owing to the immense volume of water there met with. This was, however, at last surmounted, by sinking two iron cylinders, each 10 ft. in diameter, through the sand to a depth of about 45 ft., the water being kept down by pumping at the rate of from 5,000 to 7,000 gallons per minute. The sewer was carried under Deptford Creek, and the navigation was kept open, by constructing a coffer-dam into the middle of the creek, and executing one-half of the work at a time.

The Deptford Pumping Station, where the sewage was lifted from the Low-level Sewer into the Outfall Sewer, was provided with four condensing, rotative beam engines, each of 125 horse-power, and capable together of raising 10,000 cubic feet of sewage per minute, a height of 18 ft.

The Southern Outfall Sewer conveyed the sewage which flowed into it from the High-level Sewer by gravitation, through four iron culverts laid under Deptford Creek, and that which was pumped into it from the Low-level Sewer, from Deptford through Greenwich and Woolwich to Crossness Point in the Erith Marshes. It was entirely underground for its whole length, 7½ miles; was 11 ft. 6 in. in diameter; and had a fall of 2 ft. per mile.

The Crossness Reservoir, which was 6½ acres in extent, was covered by brick arches supported on brick piers, and was furnished with overflow weirs and with a flushing culvert. Its height, level, and general construction were similar to that at Barking Creek. The ground upon which these works were constructed consisted of peat and sand, or soft silty clay, and afforded no sufficient foundation within 25 ft. of the surface. The outlet of the Southern Outfall

ST. ANDREW'S, HECKINGTON: SOUTH-EAST VIEW OF THE TOWER AND PORCH.

[See p. 205, ante.]

Sewer was ordinarily closed by a penstock, and its contents were raised by pumping into the reservoir, which stored the sewage except for the two hours of discharge after high water. The sewage was thus diverted from its direct course to the river into a side channel leading to the pump well, which formed part of the foundation for the engine-house. From this well it was lifted by four high-pressure condensing rotative beam engines, each of 125 horse-power, actuating, direct from the beam, two compound pumps, each having four plungers.

The bricks used in the works had been mostly picked stocks, frequently faced with gault clay bricks, and the inverters were occasionally faced with Staffordshire blue bricks. The brickwork was as a rule laid in blue lias lime mortar, mixed in the proportions of two of sand to one of lime, for two-thirds of the upper circumference of the sewers, and the lower third had been laid in Portland cement, mixed with an equal proportion of sand. A considerable length of sewer had been laid entirely in cement. A double test

of the quality of the cement had been employed, which had tended greatly to improve the manufacture of that material. The specifications provided that "the whole of the cement shall be Portland cement of the very best quality, ground extremely fine, weighing not less than 110 lb. to the bushel, and capable of maintaining a breaking weight of 500 lb. on 1½ square inch, seven days after being made in an iron mould, of the form and dimensions shown on a drawing, and immersed in water during the interval of seven days."

There were about 1,300 miles of sewers in London, and eighty-two miles of Main Inter-cepting Sewers. The total pumping power employed was 2,390 nominal horse-power, with an average estimated consumption of 20,000 tons of coal per annum. The sewage on the north side of the Thames at present amounted to 10 million cubic ft. per day, and on the south side to 4 million cubic ft. per day; but provision was made for an anticipated increase up to 11½ and 5½ million cubic ft. per day respectively, in addition to a rainfall of 28½ and 17½ million

cubic ft. per day respectively, or a total of 63 million cubic ft. per day.

The total cost of the Main Drainage Works would be about £1,100,000. The works had been executed under the immediate superintendence of the assistant engineers, Messrs. Lovick, Grant, & Cooper. The principal contractors had been Messrs. Brassy, Ogilvie, & Harrison, Mr. Webster, Mr. Furness, Messrs. Aird & Sons, Mr. Moxon, Messrs. James Watt & Co., Messrs. Slaughter, and Messrs. Rothwell & Co. The works were now completed, with the exception of the Low-level Sewer on the north side of the river, which was being formed in connexion with the Thames Embankment and the new street to the Mansion House, and would therefore, probably, not come into operation for a couple of years. The proportion of the area drained by that sewer was one-seventh of the whole. Some sections of the works had been in operation from two to four years, and the largest portion for more than one year; so that the principles upon which they were based had been fairly tested.

PROPOSED ROYAL ARCADE, BRIGHTON, SUSSEX.—MR JOHN ELLIS, ARCHITECT.

## ROYAL ARCADE, BRIGHTON.

An arcade on an improved system is about being erected in Brighton, on a plot of land running parallel with the Esplanade from West-street to Middle-street. It will be about 320 ft. in length, with a 25 ft. avenue, containing on both sides thirty shops; consisting each of kitchen, cellars, scullery, shop, show-room, over, and two bed-rooms, with all requisite conveniences. Each front, as may be seen in our engraving, is included within an arch, and will be formed of bronze, granite, and Serpentine. The decorations will be principally in Majolica ware, expressly designed for this building, and the whole will be covered with an ornamental iron roof, which will ventilate the entire arcade. The necessity for a building of this kind has long been felt in Brighton, and the applications for leases of the shops have been very numerous, and will all shortly be granted, we are told, to first-class tenants, who also have establishments in London and Brighton. The ground is freehold, and building operations will be commenced as soon as possession can be obtained. A good dividend is anticipated. The cost will be about 30,000*l.* The arcade has been designed, and the works are to be carried out, under the direction of Mr. John Ellis, architect, London.

## RATS.

THIS is an unpleasant subject; but in a sanitary point of view it must not be passed over without observation. The writer has often had opportunities of seeing the ravages of these vermin in large mansions, especially about thirty or forty years or so ago, when ill-constructed house-drains of brick were much in use, and when the trapping of closets was carelessly attended to, and in the servants' quarters left out altogether. In such cases the rats in many a stately dwelling insinuated in multitudes, and committed no end of havoc. Then the rat-catcher, with his traps, poison, and other means of destruction, went his regular periodical rounds; and, after one of these visits, we have often seen a stack of rats 6 ft. or 7 ft. in height, and about the same in length and breadth, piled up as a monument of the ratcatcher's skill, and for the purpose of adjusting the amount of payment for work done. The damage which those thousands of rats caused to premises must have been enormous. They got into the poultry-houses and destroyed young birds; they often even had the power to break the shells of eggs and devour the contents. In the stack-yards, barns, stables, and larders, the extent of their depredations could not be well estimated; but in connexion with the foundations of large structures, the destruction was perhaps of still greater money value. Besides, there were outbreaks of pestilence and deaths, which were to be attributed to rats in unsuspected places eating holes through drains, and admitting the poisonous atmosphere into suites of apartments which, in the thought of the tenants, were safe from such dangerous intrusion.

In one respect, it must be admitted that the rats have done some service, for in the sewers of the metropolis and the large towns they have done a deal of scavenging, and removed much impurity. In the Fleet stream, before it was covered from the daylight, especially when so much slaughtering of animals was done about Saffron-hill, in the dark sewers, we have seen shoals of rats busy with their work. In those parts the persons who provide rats for the amusement of a certain class of young gentlemen, of no great credit to the present age, find the animals which are, as in the days gone by, intended to test the activity of their dogs.

Sometimes—we can speak for five or six years ago—there might be seen in the streets of London a tall picturesque-looking man, with an illuminated belt across his shoulders, on which were shown several rats, done in gold, and the royal arms, together with the notification that the wearer was "Rat-catcher to Her Majesty;" two or three grave and well-connected looking dogs following closely behind. The royal rat-catcher also carried about with him bags of ferrets and other "properties" connected with his calling. It may be hoped, however, that at the present time, neither in connexion with the higher places in the realm nor elsewhere is the rat-catcher so important a functionary as he was a few reigns ago. Nevertheless, it is certain,

that far more has been done by the drain-maker in driving away rats from many important buildings, than by the operations of the rat-catcher; and in the metropolis, except in neglected places, the evil has been greatly mitigated. But still, as we know to our own cost, it too frequently happens, even in new districts, where the drainage is supposed to be properly cared for, that the inhabitant of one house has a predilection for home pets, fowls, rabbits, &c., which are cooped up in the back yard, whereby rats are enticed to find out the discrepancies in the sewerage, and the whole neighbourhood becomes a prey to their incursions. Kitchens and outhouses are undermined, and numerous inaccessible connexions with the drains open up the means of admitting the most poisonous gases; and though the owner of each house may incur great expense in endeavouring to stop the mischief, the seat of the disease is allowed to remain, the home pets increase, and the nuisance is unabated. The parish or Board of Health authorities should put a stop to all such encouragers of vermin, as well as the dust-bin accumulations, in the back yards of thickly-inhabited places.

Earthenware drain-pipes, trapped sinks and closets,—the traps at the points of communication with the main sewers,—are means of keeping many dwellings free from the unpleasant visitors; but independently of this, it is hoped that in the new main sewers no islands of sand or mud will be allowed to collect, to afford a standing or feeding place; if this be carefully seen to, the rats will be driven from the sewers altogether. On the banks of the canals, at the wharfs there, and along the sides of the Thames, in the docks, and elsewhere, these animals are still a source of mischief and annoyance; but as regards the Thames, there is hope that the evil will be abated when the impurities are intercepted which, by lying on the shores, attract and foster the rat tribe.

The disappearance of these pests is a sure sign of sanitary progress.

## THE ART-DEPARTMENT MINUTE AND THE ART MASTERS.

SIR,—As you have allowed Mr. D. W. Raimbach, one of the ancient masters of schools of design, to express to the public his opinion of this iniquitous Minute, which opinion is one of approbation, I ask the privilege also of replying to that opinion, and of showing what it is worth.

It may be inferred, because Mr. Raimbach is connected with the Birmingham School of Art, that he is an art-master who approves of the new Minute. I believe such a creature does not exist, and I think I can explain Mr. D. W. Raimbach's cause of delight. We have heard of the story of the fox and the grapes, and, remembering that Mr. Raimbach is master of the important school at Birmingham, whilst possessing only the elementary certificate of third grade, it may suit his purpose to make light of the advanced-figure certificates which he has never been able to obtain.

I would not have the public believe that the elementary or first certificate does require an overwhelming amount of art knowledge. In fact, it is the qualification which I require my junior assistants to hold after one year's probationship. But this is the A B C of an art-master's qualification: Mr. Raimbach's experience reaching only to the A B C, he says the whole alphabet is simple, and represents no great knowledge; and as he knows nothing about the rest of the alphabet, he is delighted that it is no longer necessary for men in similar positions to that which he holds. It is the old story: if you cannot reach the height attained by other men, try and pull them down to your own level.

When schools of design were pronounced a failure, Mr. Raimbach was a master of a school of design; and when schools of art, which have been pronounced successful by the Select Committee of Parliament, began to require a more highly-qualified set of teachers than ever were employed in the schools of design, it became a general question, "What is to become of the old masters?" Some said, "Hang them in the National Gallery;" and others, that Nature, in her beneficence, would gradually remove them, and that otherwise they need not be disturbed. And thus it has been: some have died, others have retired, one is in a lunatic asylum,

and Mr. Raimbach remains, I believe, the last of his race, to rise up and vilify the successful descendants of his class who are now attaining in art education what he and his fellows only attempted.

Mr. Raimbach's approval of the Minute must be valued at its true estimate. Art-masters and the committees of provincial schools generally disapprove of it, because it will rob them. It takes on an average three-fourths of all grants from the country schools and country masters. But does it affect Mr. Raimbach equally? No. He has an income of 75*l.* a year as an old master of a school of design, for doing nothing. And as this comes from the taxes of the country, art-masters and others, I leave you to judge of the good taste he displays by siding with the oppressors, and vilifying art-masters, when the latter make a stand for justice and fair play. If the Minute had abolished his pension, as it takes double his pension from me, we should have heard nothing of the fairness of the new regulations; but as it leaves him untouched, and only operates on every art-master, he thinks it quite just.

On the character and qualifications of the masters of schools of art,—the men who possess the certificates, whose value, artistically and educationally, Mr. Raimbach repudiates,—Sir Charles Eastlake, who may perhaps be recognised as even a higher authority than Mr. Raimbach, made this statement before the select committee of Parliament:—

3584. "Are there not throughout the schools of the United Kingdom many men of real ability, both as artists and teachers, conducting these schools?" "Yes; I have no doubt of it."

3585. "Do you, therefore, think that suggestions coming from them ought to be treated with respect?" "Yes; no doubt."

In opposition to Mr. Raimbach's opinion that "the Minute will displace bad art-masters," I assert that it will only displace the good ones, and leave the bad ones. The men whose abilities and experience will fetch a fair price in the educational market, will leave the schools and sell their labour among the upper and middle classes who will pay for it, and those only whose culture and abilities cannot command this market will remain in the schools for the pauper prices which they can get. Good educationalists could not afford to remain in the schools, unless the working men at the artisan prices, unless assisted, as previously, by Government grants, or unless bolstered up by a pension.

I will quote an instance: I myself give to the public work in Leeds, for a little over 100*l.* per year, the time per week for which middle-class schools would pay me 300*l.* per year. But, with the State assistance to the schools, this labour of mine is paid for. Now, when three-fourths, at least, of this assistance is withdrawn, is it a likely measure to keep me in the school? Yet, a man holding no certificate, and without experience, might be kept in the school, because out of it he would have no chance of employment.

The measure would then either cause the discontinuance of instruction to working men,—the very class for which all the schools were established,—and convert the schools into merely middle-class drawing studios, or shut up the majority of the schools by the withdrawal of the more highly qualified master, leaving only the very lowest class.

And Mr. Raimbach must not apply his argument, that, because we in Leeds will be displaced by the Minute, we are bad art-masters; because I shall in return remind him that the return of the Birmingham schools' success, in the last blue-book, credits the school with two national medals, thirty-three medals, and 403 successful students; and the last examination of the Leeds school credits it with four national medals, forty-one medals, and 983 successful students.

The idea that the effect of the Minute will be to cause a spread of drawing among night-classes and mechanics' institutions, is erroneous altogether. The Minute insists on three nights per week instruction in such institutions as a condition of the assistance given. Now, I think Yorkshire may be held to be a fair specimen of a county supporting mechanics' institutes; and as there are in the borough of Leeds ten of these institutes,—with the majority of which I have been at different times more or less connected,—I think you in Leeds have a right also to express an opinion on the point. Out of this number there is not one among them which ever has given, or could, by any possibility devote, any portion of its

premises for three nights per week to a drawing-class, or afford to pay for the lessons. The majority cannot even give room for one night per week, preferring to use their very limited class-accommodation for such subjects as reading, writing, and arithmetic. Nor will the inducement held out by the Minute make it worth their while to establish such classes.

If the Minute offered the same encouragement to the institutes for one night's instruction per week as it does for three provided the pupils passed the necessary examination, then real good would have been done. As it is, the scheme will be wholly inoperative.

With reference to the "irritating, harassing surveillance" experienced by the masters of schools, I can only say that there must have been something exceptionally wrong in Birmingham to make it necessary. I have held my appointment in this school for six years, during which it has been visited by four different inspectors and the secretary of the Art-Department, and I have never experienced any such surveillance, at the time of their visit or any other time. On the contrary, the visits of inspectors have been among the most pleasant and profitable events which have happened to me. You get the advice and experience of a highly-qualified man, who visits a large number of schools, and whose opinion on school management is valuable, and experience unquestioned; and I believe one of the very worst features of the Minute is that which dispenses with the services at examinations of these inspectors, and places the examinations of schools of art and elementary schools in the hands of an ever-changing agency, the committees, and whose qualifications for the office even courtesy itself would not be sponsor for.

In conclusion, I claim as much experience as an art-master as Mr. Raimbach, and regard the Minute as a wretched bungle, because it will destroy that which it proposes to foster.

*Leeds.* WALTER SMITH, Head Master.  
P.S. Since writing the above, I have heard that Mr. Raimbach did not obtain even the first elementary certificate, when I supposed he did; so that he actually does not hold any certificate of qualification whatever.

#### THE ORDINARY OF NEWGATE.

MANY who had the opportunity of knowing the active and kindly working of the gentleman who for a number of years held this important office, heard with regret of the very sudden death of the Rev. J. Davis. In connexion with the central metropolitan prison, the name of the deceased gentleman has been much before the public at times when notorious criminals have suffered at Newgate. On these occasions, which unfortunately have been of too frequent occurrence, Mr. Davis spared no exertions to do good. But it was not on those sad occurrences only that the ordinary was called upon to do work which was painful: he was the means of saving many who had been cast into prison on the suspicion of crime, and of leading others to better ways.

The duties of the conscientious chaplain of a large prison are of far more consequence than is generally supposed. Besides the regular religious services at which all the prisoners who are in a sufficient state of health attend, the attentive chaplain pays solitary visits; and if there be good in either man or boy, woman or girl, he is likely to find it out, and has opportunities of interfering with relations and in various ways helping to place those who have strayed into a wrong path into the right way again.

To fill with good effect the office of a prison chaplain requires that the person appointed should have some degree of knowledge of the class of people who are likely to come into his care, and he must earnestly, and without thought of personal convenience, devote himself to this duty; there are also books to be kept and reports to be prepared.

While lamenting the death of Mr. Davis, we are glad to learn that the Rev. Thomas Pugh, the evening lecturer at St. Sepulchre's, Skinner-street, has been provisionally appointed by the Court of Aldermen to fill the post of Ordinary of Newgate. For this office Mr. Pugh is well fitted. The writer had opportunities of noting, years ago, when the cholera was raging in parts of the London district, the exertions made by Mr. Pugh, who was then curate of the poor neighbourhood attached to Old St. Pancras

Church. Besides attending to the church duties, the curate found the means of establishing a district sanitary committee, and made a minute inspection of the poorer parts of his neighborhood. This led to much good in various ways; for, besides the sanitary improvements which were made, large numbers of children were sent to school and church. Afterwards Mr. Pugh undertook the duties of chaplain at the St. Pancras Workhouse, where there are usually about two thousand inmates; and here a very difficult task was satisfactorily performed, until a dispute chancing to take place between one of the medical officers and the guardians of the parish,—the medical attendant having confided a matter to Mr. Pugh in confidence,—the latter when called upon by the parish Board to give the particulars; declined to do so; and, in consequence, a rupture took place, and the parish lost an effective officer and the poor pent-up papers a sincere friend. Since then, this gentleman has worked hard in several ways, and has not been idle in the neglected slums of St. Sepulchre's. Believing that the experience which he has gathered, often with much pain, and the earnest efforts which he would use in connexion with any labours which he might undertake, would render him most useful as the religious instructor in the City Prison, we hope that the Court of Aldermen will avail themselves of the opportunity of obtaining Mr. Pugh's services permanently.

#### REWARDS TO RAILWAY SERVANTS.

WITH reference to the impending Exhibitions in Dublin and Paris, Mr. W. H. V. Sankey desires to suggest, through our pages, the desirability of "rewarding such railway servants as, by the nature of their employment, have to fill positions of combined responsibility and risk, and who have by cool judgment, steadiness of habits, long service, and irreplicable conduct, merited well of the community." "These men," he goes on to say, "have an immense responsibility cast upon them. They have to brave the stormy elements in the worst seasons of the year, and they must be constantly sober; they must be a painstaking, cleanly, obedient, energetic, active, intelligent set of men; and it is to the interest of every one that they should have some incentive for performing their duty honourably and efficiently."

We share the feeling and belief that prompt the suggestion, but, for all that, cannot recommend it. If we are to give prizes to engine-drivers, pointmen, signal-men, and others engaged on railways, for doing their duty, on what ground are we to pass over sea engineers, pilots, and others, from whom equal energy, activity, power of endurance, and clearheadedness to a like end, are required? The man of medicine risks his life in an infected atmosphere in the exercise of his profession, without hesitation or comment. It is his duty, and he does it. He looks for no medal from the public; and if he did do so, he certainly would not get it. The intelligent body of men employed on railways want no rewards for doing what they ought to do: they only want justice from their employers.

#### GUARDS' INDUSTRIAL HOME, WESTMINSTER.

UNDER this title a building has just been completed in Westminster, for the officers of the Brigade of Guards, from the design of Mr. H. A. Darbishire, architect.

It is intended for the education and maintenance of the daughters of non-commissioned officers and men of the Brigade of Guards. It will accommodate about forty girls, and is situated in Francis-street, Vauxhall Bridge-road, adjoining the Victoria Lodging House, which was built some years ago for the married soldiers of the brigade.

The basement story contains a large dining-room, kitchen, scullery, larder, and store-room, with vaults for coal-cellars, ash-pits, stores, &c. In the ground story are the brigade school, communicating with the Victoria Lodging House, with W.C., lavatory, &c.; an infants' nursery, where young children can be left with safety during the day while their mothers are occupied in washing or charring; a matron's room, lavatory, and separate porch entrance. The first-floor includes a large school-room, for the exclusive use of the house; a dormitory with four-

teen beds; a matron's parlour and bed-room, with lavatories and W.Cs. The second-floor contains two dormitories, each with sixteen beds; sub-matron's room, monitor's room, W.Cs., and lavatories. The third-floor has a sick-ward, with six beds, nurse's room, laundry, drying-room, ironing-room, clean and foul linen rooms, bath-room, W.C., and lavatory.

There is a good play-yard in the rear of the building; and the cost of the whole, exclusive of the site, will be about 3,000l.

#### THE ARCHITECTURAL ASSOCIATION.

THE usual meeting of members was held on Friday evening, the 17th instant, at the House in Conduit-street, Mr. Thomas Blashill in the chair.

Mr. R. P. Nottley, of Redcliffe-road, West Brompton, was elected a member of the Association.\*

The hon. secretary of the Voluntary Architectural Examination Class brought up the report for the year 1864, which stated that the number of members was twenty-one, and the average attendance ten.

The Chairman expressed his hope that the members of the Association would more generally avail themselves of the advantages to be derived from attending this class.

Mr. Paraire inquired whether the memorial to the Royal Institute of British Architects on the subject of architectural examination, referred to at the last meeting, had as yet been presented. From what he had been able to collect with reference to it, he fancied it was not of a sufficiently practical character to be acted upon by the Institute. In February, 1863, he had brought the subject under the notice of the Association, as he had always been of opinion that the charges of architects should be settled by some competent representative body, and that their authority to practise ought to be recognised by a certificate or diploma, to be issued by the Institute. If an architect had nothing to show that he was an architect, he was in no way superior to the builder or bricklayer who might assert his claim to be a member of the profession.

The Chairman said that no opportunity had yet occurred to present the memorial to the Council of the Institute, and that it would be premature to discuss the subject further at present.

Mr. R. O. Harris observed, that at the last meeting he had given notice of his intention to bring under the notice of the Association certain announcements issued by a publishing and lithographing firm in the neighbourhood of Lincoln's-inn-fields, offering to prepare competition drawings, architectural plans, &c. Since then he had been advised not to do so, the general impression being that no respectable architect would avail himself of such services as those offered.

A Member said, that he thought it would be very undignified of the Association to take any notice of the announcements of the company to whom Mr. Harris referred. As business was not a limited quantity, they had a perfect right to execute plans and drawings for any one who might employ them.

A paper was then read by Mr. J. Webber, on "Limes and Cements."

#### GAS.

Two important reports have been printed by the city authorities on the metropolitan gas question. One of these is the "Report of the Special Committee of the Commissioners of Sewers on Gas," and is dated 23rd February 1865. The other is a "Report to the Special Gas Committee on the Existing Conditions and Circumstances affecting the Gas Supply in the City of London," by W. Haywood, C.E., and H. Letheby, M.B., the one engineer and the other gas analyst for the city. This report is dated 10th December, 1864. The members of the Special Committee were Messrs. De Jersey, Farrar, Teulon, Chaplin, Bone, Green, and Elliott. They recommend

1. That an offer should again be made to the companies for the commission to undertake the lighting, extinguishing, cleansing, and the entire charge of the public lamps, affixing meters to every twenty lamps or thereabouts, and adopting such other precautions as will ensure a fair average consumption.
2. That the companies be requested to affix, at their expense, governors or regulators to the whole of the public lamps.
3. That the further assistance of the police be, if possible, obtained in the supervision of the public lighting.
4. That the application of Mr. Greenfield in respect of his carburetting apparatus be not complied with.
5. That all legal measures to secure to the citizens gas, equal to the Act of Parliament standard of illuminating power and chemical purity, should be resorted to.
6. That an application be made to the Secretary of State for the Home Department, to institute inquiry as to the capitals of the several companies, and for the purpose of securing to the consumers all the advantages contemplated by the Metropolis Gas Act, 1860.
7. That after mature consideration of the subjects referred to us, we are of opinion, that it is inexpedient at the present time to take measures with the view to the Commission manufacturing and selling gas, but that appli-

\* In notice of last meeting, amongst members elected for "G. Walsh" read "Geo. Welch."

cession be made to Parliament for a modification of the Metropolitan Gas Act, 1860, so far as it affects the City of London, and especially with the view of obtaining, for the citizens, gas of a higher illuminating power, of greater chemical purity, and at a cheaper price than that now supplied, and such other powers as may be beneficial to the ratepayers and gas consumers in the City.

If these, or suggestions, be carried out, we believe the citizens of London will be supplied with gas at less cost, than heretofore, and yet that the companies will continue to receive a 10 per cent. dividend on their capitals; but should the commission fall thus in its endeavours to benefit and to protect the public, we, unhesitatingly, advise that a respectful recommendation be made by your honourable court, to the Lord Mayor, aldermen, and common councilmen of the City, in common council assembled, to consider the propriety of its providing the means for constructing works, laying down distributing pipes, and undertaking the manufacture of gas for the citizens.

We are the less reluctant in recommending this course, because the commission possesses no funds from which to meet the cost, and would have to obtain additional powers of taxation for the purpose.\*

In a postscript the Special Committee say,—

"On the 14th day of February instant, when our labours were nearly at an end, and the preparation of the materials for this, our report, in hand, letters were received from the companies, stating that they intended reducing the price of gas to 4s. at Christmas next, although on the 28th of November last, the directors of the companies had declined to hold out to us hopes for any immediate reduction in the price. We therefore thought it our duty to your honourable court on this, the first step towards the attainment of the objects so much sought for by our fellow citizens."

It is an extraordinary and most absurd fact that the present price per lamp per annum of gas for the City streets is about 41 per cent. more than it was in 1823, when gas was at 15s. per 1,000 ft.

The private consumption of gas in the City is estimated to be about 1,000,000,000 cubic ft. per annum, so that excess of even 6d. per 1,000 ft. on that supply has cost the citizens 25,000l. per annum, or transferred that sum to the pockets of the companies.

A reprint of a series of articles on "The Gasworks of London,"\* by Mr. Zerah Colburn, C.E., from the *Engineer* journal of 1862, has been issued. The matter has been corrected and extended beyond its original scope. Mr. Colburn, in his introduction, acknowledges his obligations "to almost every gas engineer in London" for information on the subject of the London gas manufacture; and the treatise may, therefore, be regarded as reflecting the views of the gas engineers and the companies who employ such engineers; and accordingly, in the face of facts throughout the country which clearly prove the possibility of reaping the highest allowable profits from far lower prices than the metropolitan, under much less favourable circumstances, Mr. Colburn is of opinion that "after all the agitation created by a certain class [who are the certain class but the gas consumers in the mass as a class] the only hope of cheaper gas [than 4s. 6d., be it noted] lies in one or all of three contingencies,—first, in diminished leakage; second, in making a greater profit upon the residual products; and third, in a diminished profit upon the capital employed;" and that although "it is quite possible that all the ordinary gas burnt in the metropolis may yet be sold at 4s.," nevertheless "any diminution in price [from 4s. 6d.] must be the result of time." Now, the most significant comment which it is possible to make on this opinion is the fact that already, since this extended and corrected reprint of 1865 was issued, the companies are helping their own advocate, by announcing the reduction of their price from 4s. 6d. to 4s., without waiting the "result" of much "time" experience; and they are likely to be compelled, very shortly, to make a still further sacrifice of both time and price, if "a certain class," and certain authorities, persist in their determination to have really cheap and good gas, and not, as it is even yet, both dear and bad. Moreover, why should the present enormous and hurtful leakage be permitted?

#### THE LOCK-OUT IN THE IRON TRADE.

THE only point requiring our notice this week is that at a meeting of trades' delegates, held in London, a resolution was carried to the effect, that the North Staffordshire men be recommended to go in, and thus end the lock-out, submitting their case, at the same time, to arbitration. It is even said that the men on strike have unanimously agreed to submit their case to arbitration; and the masters, it is hoped, will also agree. Great misery and loss to all would thus be saved.

\* Spun, Bucklebury.

#### DYE-HOUSE ROOFS: STEREOGRAPHY.

At a recent meeting of the Manchester Literary and Philosophical Society, a paper, "On a New Form of Roof for Dye-houses," by Mr. John Thom, communicated by the President, was read. The object of the communication was to describe the construction of a roof for buildings in which there is a good deal of vapour, so as to produce the minimum amount of condensation of such vapour inside the buildings, and thus avoid the production of drops, as well as the minor evil of an obscure atmosphere. At the same meeting Mr. Dancer read a paper "On the Exhibition, Stereoscopically, of Photography on a Large Scale,"—a desideratum suggested in the *Builder* when stereographs first appeared. Stereoscopic transparencies were cut in two, and each half placed in its position in an oxygen-gas lantern mounted with achromatic objective-glasses. The half stereographs were then projected in juxtaposition on a long screen, and to realize the proper stereoscopic effect, the members were supplied with achromatised prismatic telescopes which had been prepared expressly for the purpose. Mr. Brothers exhibited a stereoscopic picture of the Blue John Mine in Derbyshire, which he had taken by the aid of the magnesium light, giving an exposure of five minutes. The negative was slightly fogged, owing to the lenses not having been wiped, and the dense fumes of magnesia caused by so long an exposure prevented another trial.

#### SEWAGE OF GREAT CROSBY DISTRICT, LIVERPOOL.

A GOVERNMENT inquiry has been made on this subject, Mr. Robert Morgan, C.E., being the commissioner sent down to examine into the projected scheme of the Local Board for sewerage the district by making the outfall on the shore. The sum required to be borrowed was 8,500l. Complaints of this scheme were made by the landowners adjoining the shore, the fouling of which, they urged, would ruin their property.

Amongst other witnesses examined was Mr. Tarbotton, C.E., surveyor to the corporation of Nottingham, who said that, after carefully examining the district and the plans, he thought the system proposed by Messrs. Reade & Goodison was, in point of outfall, superior to that proposed by the Local Board. On the ground of public propriety, decency, and health, and on engineering grounds, the outfall proposed by the Local Board was, he thought, calculated to do considerable mischief. He considered that the other scheme to which he referred was reasonably sufficient.

The commissioner afterwards proceeded to make an inspection of the district, and he will make his report to Sir George Grey in due course.

The plan of Messrs. Reade & Goodison has been reported on in a printed form. Its cost, they state, would only be 4,900l., and the outfall would be the natural outlet at Formby's Pool, which delivers at about high water of 16 ft. tides, and is consequently not liable to be locked up by the formation of shifting banks, fouling the shore, as the Local Board's scheme would be. The engineers require filtering tanks at the point of outlet in Dihh-lane. The plan suggested, they consider, would not only be the cheapest and least objectionable, but the most effectual,—pending the coming man!

#### SANITARY MATTERS.

*Silnsmouth*.—The local board have determined to construct a large outlet sewer into the sea, at low-water mark, so as to divert the present outlet from the river, and thereby prevent the accumulation of sewage matter at that point. The first part from the town drain will be a brick culvert of 130 ft., and the remainder 180 ft. by iron pipes of 2 ft. 6 in.: the increased fall of 4 ft. will enable the local board in future years, by reconstructing the town drains, to drain the whole of the town.

The neighboring towns of Badleigh Salterton, Exmouth, Dawlish, Teignmouth, and Torquay, have completed their outlet sewerage to the sea. Paignton and Brixham are about doing the same under the direction of Mr. Appleton, of Torquay.

*Whitehaven*.—It seems that there are 193 inhabited cellars in the town of Whitehaven, only

twenty of which come under the requirements of the Act as being fit for habitation. It is quite clear that there is a great want of accommodation for poor people in the town. It has been agreed by the Trustee Board that the closing of the cellars is very desirable, but that it is a move which ought to be made very gradually to avoid hardship. It is estimated that the population of the 193 habitations is not less than 562 persons.

*The Epidemic in Russia*.—It will have been noticed, that the contagious and epidemic fever which rages at present in St. Petersburg, carries off hundreds daily. The sanitary measures, prescribed by the Committee of Health, have been hitherto unsuccessous, and the authorities have been obliged to place the barracks of the guards at the disposal of the patients. In this building 2,000 beds have been prepared, the accommodation in the ordinary hospitals being insufficient; and the Prince of Oldenburg, president of the Council of Public Assistance, has ordered 600 beds for the sick in the Alexander manufactory buildings. The Minister of War is also to give up some buildings in his department for the same purpose. Some cases have already appeared in Moscow, and it is feared from the facility of communication between St. Petersburg and Warsaw, that it will also spread to the latter town, and thence, perhaps, to the rest of the Continent. Thirty surgeons have been sent from Moscow and Nijn-Novgorod, to assist in arresting the progress of the disease at St. Petersburg.

#### IRON-FOIL, TIN-FOIL, AND GOLD-FOIL.

THE thickness of tin-foil and gold-leaf, desiderated at page 209 of the *Builder*, I find, from art. 3 of "Manufactures in Metal" in Lardner's "Cabinet Cyclopaedia," pages 24 and 383, to be,—Tin-foil, the 1,000th of an inch; gold-leaf, the 252,000th of an inch.

Brother Jonathan perhaps considered that he had accomplished enough when he produced iron-foil as thin as tin-foil, not anticipating anything like the Swansea achievement of 4,800 leaves to the inch. JAS. WYLSON.

#### DECAY AND DEMOLITION OF ROOD SCREENS.

WRITING from the West of England, I regret that there is not kept in some central institution a record-book or folio, in which drawings of screens which have been destroyed or set aside as lumber, could be preserved.

Dulverton Church, Somerset, had remains of a very singular oak screen, with an ingeniously-contrived standard to mask its abutments on the piers. This, when the church was rebuilt, in 1853, from inability to renew it, was lost; so was Brompton Regis screen. Tiverton Church had a very rich example, with colored flowerets in the panels of the groining. The upper, the best part of this, was, in the rebuilding of the church, sacrificed. Holcombe Rogus, not far distant, had some fine illuminated panelling and stumps of standards, boarded over for concealment. Colnuppton screen was repaired and re-illuminated about fifteen years since. Here "the place of a skull" is well carved in a beam retaining the mortise for the rood. Kentisheare, near it, has a rich oak screen in good preservation; and Plymtree, a village in the same vicinity, a fine coloured example, with figures of saints. So has its neighbour, Bradninch Church; but here some liberties in paint have been taken.

Avilcombe has a Beer stone perpendicular screen, well preserved; a similar one seems to have been cut out in the neighbouring church of Gittisham, to make way for a classic composition. Honiton old church has a noble example.

In South Devon, Totnes has a grand Perpendicular coloured stone screen, encumbered with a gallery over it, and the bottom panels concealed by seats. It is of great height, 13 ft., and exhibits a variety in its carving, tracery, and groining. Dartmouth Church has a rich wood screen, of late date. There is a fine stone composition fencing off "the Kirkham Chantry," in Paignton Church, ruinous but not in danger; Churston Ferrers Church, near Paignton, has singular and rich examples: two of the screens are illuminated. It is feared that in a rearrangement of seating, these will not meet with the care and reverence which their value demands. I hope to describe others, existent or demolished, in another letter.

CONSERVATIVE.

## GOTHIC ARCHITECTURE IN SPAIN.

As my name is referred to in the *Builder* *critique* on Mr. Street's new work on Gothic Architecture in Spain, I am desirous of stating that I have published two works on Spain. The first, in conjunction with Mr. Macquoid, contains some of the best Renaissance bits, views, and detail in various parts of Spain; and this is the work apparently referred to by you. The other, consisting of over forty large lithographs, illustrates Burgos, Miraflores, and the neighbourhood. Mr. Street refers several times to this last; but, in describing the beautiful monument of Juan and Isabel at Miraflores, omits to state that it is fully illustrated in my work, and speaks only of "an illustration" of the tomb of Alfonso as being done by me, whereas this, also, is given in detail.

He then states that I call the small cloisters of Huelgas "Romanesque;" but, on reference to the letter-press, he will find the words "of a Romanesque character," they being, as he justly supposes, transitional. As regards San Pedro de Cardenas,—that old church still exists, but is of the plainest description, and well, or badly, whitewashed. It is curious that Mr. Fergusson, in the sketch of Spanish architecture in his "History of Architecture," omits any mention of either of my books on Spain, though both were published years ago; and, moreover, treats the public to copies of Villa-Amil's views, which, in the preface of each of my works, are expressly stated to be entirely untrustworthy.

Mr. Street has done excellently well in his new book, and leisure so employed he may well be proud of.

I may perhaps add, that in the *Builder* of 1852, several articles by me were given on Spanish Architecture, to the last of which, p. 197, I venture to ask Mr. Street's attention.

J. B. WARING.

## WANTED, A CARPET-GROUND.

WILL you kindly make known, through the medium of the *Builder*, the want now felt by most West-end carpenters and upholsters, of a carpet-ground, or place where carpets could be beaten, within a reasonable distance,—say two or three miles of Charing-cross, south or west.

Every year the houses, and, I suppose, the carpets, are increasing; and every year the places to beat carpets are getting fewer and further apart. One at Westminster, two at Chelsea, and one at Battersea, have been built upon or closed within the last year or so. I know of only one left now, and that is beyond the Brompton Cemetery, and which is generally so crowded in fine weather, that the time spent in going and coming and waiting for your turn makes carpet-beating very expensive, besides having to be so very civil to the now independent proprietor. This was at one time a good paying branch of our business, when the grounds were nearer; but it must be a good customer to tempt a master now to send a couple of men with one or two carpets to beat, at anything like the old prices. Surely some enterprising capitalist or limited liability company could find a vacant piece of ground to establish a ground. The capital required would be small. Some dozen or two of brooms, as many sticks, a few poles set up, a secure shed to store the carpets and keep the things in, and one man to look after them and take money, and let it be made known to those in the trade, and the thing is done. I am sure the investment would be a good one, as the season is coming on when there will be thousands of carpets to beat, and but little room to beat them in. F. II.

## THE FIRE AT STANCATE.

SIR,—Referring to the account of the fire which occurred on my works on Tuesday night (as reported in the morning papers), I beg to say the damage done is by no means so extensive as represented, as the stock in the different warehouses is unimpaired.

By large and early I have nearly cleared the factory of the debris; by twelve o'clock to-day I had the steam up again, and the brass-foundry, although without a roof (at present), is in full operation; and I expect in a few days' time to resume business as usual.

As the reports published might cause customers to withhold orders, I trust you will give insertion to this letter, which I cannot close without tendering my best thanks to Messrs. Henry Lee & Sons, Messrs. George Baker & Sons, Mr. William Higgs, Messrs. Thomas Lambert & Sons, Messrs. Burton, Sons, & Waller, Mr. S. Egan Rosser, Mr. Henry Benthall, and all other gentlemen who have offered me the use of their wharfs, premises, and machinery, to enable me to proceed with as little inconvenience as possible. GEORGE JENNINGS.

## ABSORBENT WELLS.

HAVING been sadly troubled myself in getting rid of sewage on a large scale in a country district, without detriment to the waters of a neighbouring brook, I read the description of the "absorbing well" completed some time back at New Barnet, Herts, an account of which is published in your columns of March 18, with great interest; but, it appears to me, a grave mistake has been committed, and one to which attention should be drawn. If I understand Mr. Blenkarn's plan, it was this,—that, finding it difficult to get rid of the storm-water and sewage of a building district through the natural channel, he resorted to the expedient of boring through the London clay into the subjacent or plastic clay formation, and into this poured the water and filtered sewage. It is, of course, a satisfactory process to achieve success, and Mr. Blenkarn seems to have been perfectly successful so far; but has that gentleman sufficiently considered that his effluent water, even granting he can thoroughly cleanse it by filtration of all organic matter held in suspension, which I doubt, remains charged with most of the poisonous components of his sewage, and that it will assuredly impregnate the water-bearing strata of the formation into which it enters, and taint the source of many a deep well?

In this one instance the danger may be slight; but let this principle, as from its convenience and apparent success I fear it may, be multiplied, and I cannot conceive anything more pregnant with mischief. PURE WATER.

## FROM SCOTLAND.

*Leith.*—The new wet dock at present in course of construction on the east sands has, during the past few months, been vigorously prosecuted by the contractor, and is already in a forward state of progress. About two-thirds of the embankment have passed through the preliminary stages of formation, the rough of the wall being nearly completed. The length of the embankment when finished will be 3,450 ft., and it will inclose an area of 36 acres of sands. Within this area will be constructed a wet dock of about 10½ acres in extent, the length of the dock being 1,100 ft., and the breadth 450 ft. There will be 3,040 ft. of quays, and the width of the wharfs will be about 200 ft. The lock for entering the dock will be 350 ft. long by 60 ft. wide, and will have a depth of 26 ft. 5 in. of water on the sill during the high water of spring tides, being 2 ft. deeper than the depth on the sill of the Victoria Dock. The lock will open from a large entrance-basin, as the outer pool is too narrow to allow it to open directly from the harbour.

*Hawick.*—The new contracts for erecting the Corn-exchange building have now been made. Mr. Steel, of Leith, is the contractor for the mason work; and the joiner work has been contracted for by Mr. Inglis, Deaubras.

*Abroath.*—At a meeting of shareholders and other persons interested in the movement for erecting a new public hall, the committee reported that the total amount subscribed was 2,457. Two sites were reported upon—one at Brothock Bridge and the other in the High-street; and plans for each had been prepared. The former scheme would cost 6,037l., and the revenue from the hall, shops, &c., was estimated at 2557. The cost of the High-street scheme was calculated at 4,003l., and the revenue at 1457. The committee recommended the adoption of this latter scheme. According to it, there would be provided a large public hall, 90 ft. long by 40 ft. broad, library and reading-rooms, a smaller hall or supper-room, and above the large hall a room 90 ft. long by 23 ft. broad, for the accommodation of the museum, for which 400l. would be paid. The plans have been prepared by Mr. James McLaren, architect, Dundee. The report was unanimously approved of. The Earl of Dalhousie has subscribed 100l. This would still leave 1,600l. to be raised. The meeting was adjourned for a fortnight, in order to afford an opportunity for additional subscriptions being received.

*Dumfries.*—In the town council, recently, the progress made in reference to the proposal to rebuild the New Church was considered. From the minutes of joint meetings of the Committee of Works and the committee from the congregation of the new church, it appeared that, on the 10th February, they agreed to advertise for

plans, and to offer a premium of 257. for the best plan of a new edifice, the cost not to exceed 4,000l., and to accommodate 1,000 sitters. On the 21st February, it was stated that the sub-committee appointed to meet with the clerk in reference to advertising for plans, were of opinion that 4,000l. was too large a sum to state as the amount which the church was to cost, as the architect competing would put that sum into the building alone, whereas it was understood or intended not only to build the church, but to cover the expense of purchasing the old buildings in front of the church, and paying the architect's fee, and the extra expenses incident upon the erection of a new building. It was remitted to the clerk to see the proprietors of the old buildings in front of the church, and ascertain what price they ask for them, and a resolution was passed, that the cost of the intended new building shall be limited to 4,000l., which sum shall include the architect's fee and that of the clerk of works. Mr. Fraser, architect, was appointed to prepare a plan of the ground, showing the position of the building.

*Peterhead.*—The Commercial Bank of Scotland has erected a building here in Broad-street, for bank office and residence of agents. The material of which it is constructed is Murrayshire sandstone. To have built one of the native granite, after the same design, and with the same amount of cutting and carving, would have considerably enhanced the cost. It is the only building in this town of imported material, and contrasts somewhat strangely with the sparkling granite of other buildings, looking, indeed, as if it had been translated from the good old city of Elgin. The contractor and builder of the new bank was a townsman, Mr. A. Stewart; and the carpenter work and office furnishings were done by Mr. B. Cowie. Mr. Ogilvie was inspector and superintendent of the work. Mr. J. Henderson, painter, had the decorating and painting of the interior.

## TOWN HALLS AND EXCHANGES.

*Manchester.*—The proprietors of the Manchester Royal Exchange have resolved to raise the capital required for the new exchange building,—firstly, by the creation of new stock, so as to raise the entire capital of 250,000l.; and secondly, by loans and debentures: the total sum borrowed not to exceed 125,000l. at any one time.

*Pendleton.*—It having been decided that a town-hall should be erected for the district of Pendleton, six architects of Manchester were invited by the finance and town-hall committee to furnish designs in competition for a building not exceeding 9,000l. in cost. After discussion, it was decided to adopt the design No. 1, in the Italian style, prepared by Mr. Darbishire, and that gentleman has been commissioned to proceed with the works, and the building is to be commenced forthwith under his superintendance. The building is to be erected on a plot of land situated at the corner of Broughton-road and Broad-street, with the principal front in Broughton-road looking to the church. The building will contain on the ground-floor the various committee-rooms and offices for the transaction of the district business, including the police department, the principal entrance being from Broughton-road, with another entrance in the Broad-street front, and both communicating with corridors leading to the grand staircase. The principal staircase is approached through a colonnade of arches, carried on polished Aberdeen granite columns, with carved capitals in Caen stone. This colonnade supports the landing above, leading into the large assembly-room. The staircase is constructed with a centre flight, and continued right and left. On the first-floor, the principal apartment is the assembly-room, 85 ft. by 39 ft. 6 in., and having a clear height of 30 ft. Near the platform is the ante-room for performers, lecturers, &c. Then follow the retiring-rooms for ladies and gentlemen, and the staircase leading to the second-floor at the back of the building, containing four large spare rooms, suitable for supper-rooms, refreshment-rooms, or offices. The whole of the basement is cellared, and provides a large kitchen, heating apparatus, lavatories, &c. The building will also contain a dwelling for the use of the hall-keeper. The style of the design is Italian, or rather a French treatment of the Italian, the chief feature being the assembly-room story, with its row of circular-headed windows, divided by pilasters, with carved caps supporting the main cornice, the frieze of which will be carved with

festoons of flowers and medallion heads. The apex of the pediment will be crowned by an allegorical figure carved in stone, and the acroteria will have vases also in stone. Over this pediment will rise a domical roof sustaining a clock turret, with balcony round. The roofs will be pitched high, and have turrets, surmounted with cresting at the three angles of the main streets. The principal entrance-doorway and portico will have corinthian columns on each side, and cornice with circular pediment over, filled with carving. The materials used will be stock bricks for the facing of the principal fronts, and all the dressings to windows, doors, &c., will be of stone, all the external stone being Yorkshire, polished and tooled according to its position in the elevations.

**Stockport.**—The subject of building a new town-hall in the borough of Stockport has been placed in the hands of the general purposes committee by the town council, for the purpose of making the necessary inquiries as to the probable cost and the possibility of obtaining a suitable site.

**Towcester (Northants).**—A committee has been formed from the shareholders of the town-hall and corn-exchange project, to consider the requirements of the town, and to meet the architect as to the plan of the proposed town-hall; the plan to be laid before a general meeting of the shareholders. A site at the southern end of the Market-place is to be purchased.

**Hull.**—The new town-hall, erected from the designs of Mr. Culbert Brodrick, is fast approaching completion. Alderman Hodge has resolved on presenting to the town a statue of Edward I., to whom the borough owes its charter of incorporation. The statue is to be placed in a niche in the grand hall of the new town-hall. Mr. Thomas Earle, of Brompton, has just completed the model from which the figure is to be carved in Sicilian marble. The king is represented wearing his cloak of state, his left hand resting on his sword-hilt, and the right holding out the charter of Hull's incorporation. The face is a portrait taken from old prints, and the costume has been copied from the records of the period. The statue is 7 ft. 3 in. high. A statue of Andrew Marvel might very properly fill another niche in the new town-hall.

#### PROVINCIAL NEWS.

**Ipswich.**—The project for a new Masonic Hall and Buildings, in Brook-street, Ipswich, has now assumed something like a definite shape. The hall will be erected at the back part of the premises, near St. Stephen's Church, and suitable buildings for shops will also be erected in that part facing Brook-street. The land was purchased by a member of the masonic body, and a scheme was proposed by him to raise 1,200l. by subscription of 1l. each. The sum required has been subscribed exclusively by members of "The Prince of Wales Lodge," and the plan of building already decided upon. The architects of the proposed hall are Messrs. Bacon & Bell. The hall and Masonic buildings will occupy a space of 102 ft. in length, and will comprise an entrance-hall and vestibule; robing, committee, and ante-rooms; banqueting-room, 40 ft. by 20 ft.; and hall, 45 ft. by 22 ft. 6 in., with a height of 22 ft. The hall, which will be used for masonic purposes only, will be decorated, fitted with sofa-cushioned seats, and lighted from the roof by the sun-light. There will be a gallery at the western end (where it is proposed to erect an organ), supported by two granite columns of appropriate architectural design. The building will be heated by hot-water apparatus. All suitable offices, such as kitchens, lavatories, regalia, and store-rooms, will be included in the internal arrangements. At the western end of the building, and facing the churchyard, will be erected a dwelling-house for the tyler, or hall-keeper. The exterior of the building will be plain, the great object of the promoters being directed to the interior as regards comfort, convenience, and appropriateness of arrangement. The approach to the hall will be by an ornamental doorway in St. Stephen's Church-lane. Upon the vacant space next Brook-street it is intended to erect three shops, having a depth of 54 ft. each by 20 ft. frontage.

**Sheffield.**—The Council have sanctioned the plans of Messrs. Flockton & Abbott for the erection of a new police station and offices in Castle-green, and the work will be commenced as speedily as possible. The leading feature of

the plan is the separation of the three distinct departments,—the offices of the chief constable and his official staff, warrant officer, clerks, &c.; the police force; and the prison.

#### PARIS.

At the point formed by the Boulevards Magenta and Saint Martin, the edifice for the Orpheic réunions of schools is to be erected, after the plans of M. Davion, architect of the Fontaine St. Michel, and the two theatres of the Châtelet. This place is to be decorated on the south and north-west sides with grass-plots and plantations, similar to those on the Faubourg du Temple and Boulevard des Amandiers, and the immense basin and fountain are to be displaced and transferred to the centre. When complete, this "square" will be a rectangle, 902 ft. 3 in. long, and 410 ft. broad, containing eight acres and a half.

The seventh public exhibition of the French Photographical Society is to be held at the Palais de l'Industrie, in Paris, from 1st of May next to 31st of July. The works of French and foreign photographers are invited, subject to the rules and conditions adopted by the committee of management. All objects are to be sent, free of carriage, addressed to "M. Martin Lanterie, Secrétaire-agent de la Société Française de Photographie, au Palais de l'Industrie, porte No. 1," from the 1st to the 10th of April.

The *Moniteur des Intérêts Matériels* states that M. Giraud, professor of physics at the Lyceum of Puy, has proposed a new method of preventing accidents from the explosion of fire-damp in mines. His plan consists in setting fire to the gas by means of the electric spark, before any of the men descend the shaft, and thus purging the mine from any inflammable air. In each drift, or particular portion of drift, where the gas may be supposed to accumulate, M. Giraud proposes to lay down a double conducting-wire, insulated with india-rubber or gutta-percha, and furnished at its extremity with a porcelain knob, traversed by two pieces of platinum wire, arranged so as to give a spark when the electric circuit is complete. This wire, or many of them, if it should be deemed advisable for the security of the mine, can be connected with a simple induction coil of Ruhmkoff, so that before the workmen descend a spark can be passed down the pit and through the drifts. If there be small accumulations of gas, explosions will take place partially; if the whole pit be full it will explode completely; but if no explosion takes place, the pit may be deemed safe for working.

#### THE THEATRES.

**The Haymarket.**—The scenery prepared for the new "Sensation," "The Woman in Mauve," is very picturesque and pretty, and does credit to Messrs. O'Connor & Morris, by whom it is painted. The disappearance of the first scene, a studio, and change to a garden sloping down to the Thames, with dilapidated sun-dial, pedestals, and garden-seats, is very well managed. The second act includes some mountain scenery at Chamouni and ruins, and the third ends with a view in the Colosseum, Rome, by sun-set. The piece itself has a great deal of fun in it, and, though it was misapprehended to a certain extent on the first night, it is now a good laugh from beginning to end. Mr. Buckstone as Mrs. Beetles, married to an *ex-Policeman*, Mr. Compton, and travelling to fit himself for a "restaurant" in Leicester-square, "opposite the beautiful statue of George II.," is inexpensively comic, and Mr. Southern is able to exhibit the ease and readiness that distinguish him, the haziness of mind which he assumes so well, and that contrast between mock heroics and the language and manner of every day, in which, as in "Bunkum," he seems to take delight. Mr. W. Farren, as an impetuous fire-acting *Russian Count*, and Miss Edith Sturt, new to the London stage, as the mysterious heroine, give force to their respective parts.

**The Princess's.**—"Arragh-na-Pogue," as represented here for the first time in London on Wednesday night last, includes an interesting and exciting story, excellent acting, great completeness in the minor parts, and some marvelously beautiful scenery. No wonder, then, that it achieved a great success, and that Mr. and Mrs. Boucicault, Mr. Dominick Murray, Miss M. Oliver, Mr. John Brongham, Mr. Seyton,—in fact, all concerned, received a succession of

honest plaudits. The piece may be described, without meaning anything invidious, as a cross between "Peep o' Day" and "The Colleen Bawn." The scene of the story is laid in Wicklow, and the period is 1798. An admirable view of Glendalough by Moonlight, with the ruins of St. Kevin's Abbey, painted by Mr. Telbin, opens the drama, and is succeeded by several other admirable works by the same artist. The great triumph, however, in this department belongs to Mr. F. Lloyds, for the last scene, where, from the battlements of the castle,—the watch-tower and walls built up on either side,—the sea, under a brilliant moon, stretches away almost to the top of the scene,—so that to be properly appreciated, it should, of course, be seen from the upper part of the theatre. A more beautiful effect we have never seen, and the artist was justly called on to bear evidence of the same opinion from a crowded audience.

**Royal Italian Opera.**—Mr. F. Gyo has issued a statement of his arrangements for the coming season, which is to commence on the 28th, giving good assurance that those who love good music, well rendered, will be able to find it for some months to come. Eleven first appearances are promised, including Madame Galletti, well spoken of abroad; but we look rather to the fact that Mesdames A. Patti, Michela Carvalho, Frisci, and Lucca, with Mario, Wachtel, Grzianzi, Schmid, and others, keep their places. Meyerheer's *Africaine* is promised, with great scenery.

#### Books Received.

*Vocabularies of Technical Terms, in Eight Languages.*—Civil and Ecclesiastical Architecture: Military Architecture and Fortification: Civil Engineering and Surveying. By Henry Hall, Assistant Surveyor, War Department. London: E. Stanford, 6, Charing-cross. 1865.

In the present day, when so many large public and other works are carried on in foreign countries by English capitalists and workmen, the want of concise polyglot vocabularies of the principal technical terms in architecture, engineering, and the different branches of construction, is much felt; and it is with the view of supplying this deficiency that these very useful vocabularies have been prepared by Mr. Hall, who during a long period of foreign service has met workmen of many nations, and has collected, at various times, from them, the terms of their different trades, many of which terms are not to be found in ordinary dictionaries; and, even though they were, would not be so trustworthy nor so convenient as a series of limited vocabularies prepared by a professional man of so much experience as Mr. Hall.

Our readers are already able to judge for themselves of their value from the specimen of them originally given in the *Builder*. To the vocabulary of technical terms on civil and ecclesiastical architecture, there are now added the two others named at the head of this notice; and the author intends, shortly, to extend the series to building and construction, mechanical engineering, and various other subjects.

There is reason to believe that these vocabularies will be received by the council for military education as a useful aid in the studies of the professional branches of the army.

*Scenes of Wonder and Curiosity in California:* illustrated. By JAMES M. HUTCHINS. London: Chapman & Hall. 1865.

The rough work of the diggings and the hush appear to be pretty well followed up in California already by the more civilizing processes which associate it on a rank of equality with other states or countries; and now we have here something like the ordinary guide-book, in a more enlarged and interesting shape than ordinary, with no less than 100 engravings, many of them very good indeed, and all executed in San Francisco, from photographs of the scenes, and under the author's own superintendence.

One of the chief wonders of California (besides its golden stores) is the gigantic trees, the cutting down of which as an Old World remnant, has been so much bewailed,—it now appears unnecessarily; inasmuch as many more have recently been discovered. The largest of hundreds which still exist is described as a fallen one (which has probably reached the close of its natural period of existence). It is estimated to have

been about 400 ft. high! and 40 ft. in diameter, or 120 ft. in circumference! Another, which lay also on the ground, was hollowed by fire into a tunnel, through which the author's party rode on horseback, a length of 153 ft.! This tree also must have been over 100 ft. in circumference, and was probably 350 ft. high. It seems the name "Wellingtonia," (or in the States "Washingtonia"), must be given up, as the tree has been found to be not a new genus, but a species of the old genus *Scoquia Gigantea* (*sempervirens*).

The volume is both well written and interesting, and, with its illustrations, gives a vivid idea of California.

#### VARIORUM.

"The Shops and Companies of London, and the Trade and Manufactories of Great Britain," edited by Mr. Henry Mayhew (The Strand Publishing Company), has for object, it is stated, "not only to exalt work and manufacturing skill, but to uphold the dignity of trade itself." The difficulty will be to make the public believe it has not puffing proclivities. There is a great deal for money in the first part, and some amusing and interesting papers; especially an account of Messrs. Beaufoy's Vinegar Works, Lambeth. The wrapper is very well drawn.—"Debrett's Illustrated Peerage," and "Debrett's Illustrated Baronetage and Knightage," are now in the hands of Messrs. Dean & Son, of Ludgate-hill, and have been issued by them for 1865 in a cheap form. These books having kept their position for a century, little recommendation to the public is now needed. Care seems to have been taken to correct them to the last moment; a specification of the church livings of which peers, baronets, &c., are patrons, is given, and a chapter on the Orders of State and Degrees of Honour is added.—"Odds and Ends," No. 2 (Edmonston & Douglas, Edinburgh), treats of Convicts; by a Practical Hand. The tract shows knowledge of the inside of a prison, and is interesting, but does not seem to have any practical intention or bearing. The writer, who considers the present system of management much better than the old, does not believe that an old thief can be made an honest man by reformatory influences.—"For and Against Tobacco," by Dr. Richardson (Clurehill & Son), appears to be the papers first published by the writer in the *Social Science Review*. Dr. Richardson must be placed amongst the defenders of smoking in moderation. The habit, good or bad, is not in need of defenders.—*The Social Science Review*; a quarterly journal of political economy and statistics. New York: Broadway. Vol. I. No. 1. January, 1865. It is almost a pity the Americans should have repeated a title already appropriated, although of course neither rivalry nor plagiarism need be charged against the New York proprietors and publishers. The present number is chiefly devoted to a critical dissection of the financial report of the Federal Treasury, under the title of "Mr. Fessenden's Report." The leading paper also is on "Government;" and there are others, on "Herbert Spencer," and "M. About's Progress."

#### Miscellaneous.

CAMBRIDGE HOUSE, PICCADILLY.—It is asserted that Cambridge House, the residence of Lord Palmerston, will be taken down to give a site for the talked-of Roman Catholic Cathedral in honour of the late Cardinal Wiseman. The story is that the lease is about to expire, and that the ground landlord, a Roman Catholic, has pledged himself to devote the site to religious purposes.

WOLSEY CHAPEL, WINDSOR CASTLE.—We understand that while Mr. Turnbull was accidentally examining a large window, with carved mullions, and with stone panes instead of glass, at the west end of the Wolsey Chapel, a piece fell out, and disclosed a portion of a painting. Three stone panes were then removed, and behind them were found full-length portraits of as many Knights of the Garter, painted on the wall, with strong iron bars before each picture. They were evidently inserted in the *blind* window, to give it the appearance of being filled with stained glass; and, should the rest of the stone slabs be removed (of which there must be upwards of twenty), the wall behind them will probably be found covered with the rest of the series of portraits.

CONSECRATION OF THE FIRST ENGLISH CHURCH IN NAPLES.—The newly-erected church for which a site was obtained from Garibaldi while he was dictator at Naples, by Mrs. Whyte, a resident, and of the design for which church we have already given engraved views in the *Builder*, has been consecrated by the Bishop of Gibraltar.

THE NEW GOVERNMENT ANNUITIES.—Mr. Gladstone's tables for granting annuities to the poor have been published. The main fact is this:—A working man, by paying a shilling a week from thirty to sixty, will secure himself an annuity from that date of 6s. a week for life; and with two shillings, of course twice that amount.

SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.—Dr. Charles Dresser delivered an interesting lecture "On Ornamental Manufacture, more particularly of Glass and Crockery Ware," before a numerous meeting. The lecturer based the principle of all ornamental art upon the double consideration of the particular requirement of the article manufactured and the materials available for its production, drawing ingenious deductions from the rudest contrivances of savage life to the costly utensils of art-production in the most civilised conditions of society. A discussion followed the lecture.

A MONUMENT FOR THE CITY.—The Estates Committee of St. Lawrence Jewry, and St. Mary Magdalen, Milk-street, are inviting designs for the erection of a memorial in the churchyard on the south side of the Guildhall of the City of London. The cost of it is not to exceed the sum of 500*l.*, and the design is to include a drinking-fountain. They require a guaranteed estimate of the cost, and yet will not pledge themselves to adopt or carry out any of the suggestions or designs, nor to award premiums or payments for them; but in the event of a design being selected, they will recommend to the vestry that the author of it be entrusted with the work "at such guaranteed amount."

ROYAL MASONIC INSTITUTION FOR BOYS.—The sixty-seventh anniversary festival of this Institution has been held at the Freemasons' Hall, the Duke of Manchester, R.W.P.G.M. for Northampton and Hunts, in the chair. More than ordinary interest was attached to the festival of this year, in consequence of a sum of nearly 10,000*l.* being required to complete the new building at Wood-green, and open it entirely free from debt on the 1st of July next. The whole cost of this structure will be 21,000*l.* Already the Institution educates and maintains seventy-two boys, which number is to be increased, in April, to eighty; but the new schools are capable of accommodating 150. The secretary read the list of subscriptions, amounting in the whole to about 4,500*l.* The lists which some of the stewards sent in were very heavy, Brother S. May's, of Bow-street, alone being nearly 400*l.* It is said that with one exception—that of the London Hospital a few years ago—so large a subscription list at a dinner as 4,500*l.* is unprecedented.

ARTISTS' BENEVOLENT FUND.—The annual general meeting of this Fund has been held in the Freemasons' Tavern, Great Queen-street, Lincoln's-inn-fields, Mr. Charles J. Dimond in the chair. The Report stated that since the formation of the Fund the sum of 26,310*l.* 18s. 3d. had been distributed in relieving widows and orphans of British artists, fifty-two widows having during the past year received annuities amounting to 751*l.* 5s., and ten orphans the sum of 43*l.* 11s. The total receipts during the year, including 251*l.* 7s. 1d. balance in hand commencing the year, was 1,367*l.* 12s. 7d.; total expenditure, 1,032*l.* 13s. 8d. The anniversary dinner of the institution is to take place on Saturday, the 27th May. It may not be interesting to re-state that the Artists' Benevolent Fund was established in the year 1810, and received from George IV. a royal charter of incorporation in 1827. It consists of two separate and distinct branches,—the Annuity Fund and the Benevolent Fund. The Artists' Annuity Fund is raised and wholly supported by the contributions of its members, for their own relief in sickness or superannuation: 300 artists are at present members of the Annuity Fund. All artists of merit in painting, sculpture, architecture, and engraving are eligible to become members. The Benevolent Fund is for the relief of the widows and orphans of the members of the Annuity Fund, and is supported by the donations and subscriptions of the patrons of the fine arts and artists, and the annual contributions of the members of the Annuity Fund.

A NEW PRISON.—The enlargement of Cold Bath Fields Prison, and the erection of a new one, are under the consideration of the Middlesex magistrates.

HERBERT HOSPITAL.—Sir: In reading your very interesting account of the Herbert Hospital, at Woolwich, it struck me that the general reader would have the impression that the water supply works on Shooter's Hill were included in the hospital contract, which is not the case: the contract has been carried out by me.

A. MATTHEWS.

THE NORWICH SURVEYORSHIP.—At a meeting of the Norwich Town Council, held last week, that body resolved itself into a board of health, and appointed Mr. Morant as surveyor to the board till the 9th of November next, at a salary of 250*l.* per annum, he finding thereon all competent assistance for the efficient discharge of his duties, and not to be permitted to take any private practice, nor to receive any fees or emoluments whatever. At the same meeting Mr. Benest was appointed surveyor to the Council till the 9th of November next, at a salary of 150*l.* per annum, with permission to take private practice.

INJURY TO TRADESMEN BY RAILWAY WORKS.—The tradesmen and inhabitants of the Euston, Tottenham Court, and Hampstead roads, have resolved to appeal to the House of Lords against a decision of the Court of Exchequer in the case of Ricket v. The Metropolitan Railway Company, which decides others, and whereby it is made to appear that however ruinous to a tradesman the adjoining works of a railway may be, he is not entitled to compensation. It may be useful for us to state that a full report of the Case in question will be found in the last number of *The Solicitors' Journal*.

THE HANGING OF FIELD-GATES.—Sir: The writer that you quoted in your last impression does not surmount the difficulty he describes; for on referring to the sketch it will be seen that the evil intended to be overcome would in fact be increased. The error is this. That the pivot on the top of the post is not directly over, but much beyond, the centre of the hinge below: the result is, that on opening the gate, it not only falls, but turns considerably out of the perpendicular; and besides this, the gate has a tendency to open instead of to shut. Permit me to suggest a slight improvement,—that the pivot be placed directly over the hinge (projecting from the post): this would not only remedy the evil, but make the counterbalance more effectual.—WALTER CHESTERTON.

WELSH MEMORIAL OF THE PRINCE CONSORT.—On the Castle Hill, at Tenby, workmen are engaged on the "cairn" which is to form the base of the monument to Prince Albert. This is about 75 ft. square at the base and 50 ft. on the top, in the centre of which a mass of solid masonry, grouted, 25 ft. square, has been built up from the solid rock to form the foundation on which the pedestal will be placed. The base of the pedestal will consist of three courses of large blocks of native marble, each course of which will form a step, 12 in. high, and upon the centre of the upper tier the pedestal will be placed. The pedestal will be also built of native marble, with the exception of the four panels: these will be of Sicilian marble; on one of which will be placed the arms of the Prince Consort, on another those of Wales, and the two remaining ones will be filled up with suitable inscriptions. The statue of the Prince, by Mr. Thomas, will be about 9 ft. high, so that the entire height of the memorial (not including the "cairn") will be 26 ft. There are now upwards of 1,000 subscribers to the fund.

FORTHCOMING ART EXHIBITION AT ALTON TOWERS.—The Earl of Shrewsbury and Talbot has placed Alton Towers at the disposal of the Wedgwood Memorial Committee, for the purpose of an art exhibition, to be held there in the ensuing autumn, in aid of the funds for the completion of the Wedgwood Institute, at Burslem; and the Committee of Council on Education have passed a minute, under the authority of which contributions will be furnished from the national collections at South Kensington. The Earl of Harrowby will contribute from the treasures of Sandon, and Mr. Beresford Hopo has promised his aid, while Mr. Joseph Mayer, of Liverpool, will furnish specimens from his museum. Mr. George Mely will send his collection of Shrewsbury pottery, and Mr. Benson rare old Wedgwood ware. Paintings, carvings, and illustrations of art workmanship are also promised.

# The Builder.

VOL. XXIII.—No. 1156.

## The Architecture of Asia Minor.\*

ENGLAND has contributed largely to the knowledge of Classic art; and the Society of Dilettanti, founded in 1734, continues its exertions to improve the public taste in architecture through the collection of information relative to the monuments of Grecian civilization in Eastern Europe and Western Asia.

Of recent years, Government aid has been afforded to exploration in different localities; and results are to be found in the British Museum. But of the researches by foreign nations, too little has been known. In our volume for 1862, in several articles, we gave particulars of some of the French researches that were then recent, yet did not notice all; nor did we do sufficient justice to those in Syria, that were under the direction of M. Renan. Of the published results of the researches in the last forty years, perhaps the most important are contained in the large work by M. Charles Texier on Asia Minor. M. Texier, in 1833, was commissioned by M. Guizot, then Minister of Public Instruction in France, to explore Asia Minor and Persia. He spent several years in those countries, passing through Bithynia and the central provinces, —as Galatia, the locality of the researches later, of M. Perrot, of which we gave particulars in 1862,—and through Mysia, Æolia, and Caria, on the west coast, and Lycia on the southern, and making careful drawings of the finest works he met with. His "*Asie Mineure*" was published at the cost of the French Government, in three folio volumes. In a second expedition, M. Texier removed the friezes of the Temple of Diana Leucophryno at Magnesia ad Mæandrum; and the vase from Pergamus; and fragments, including the frieze, of the Temple of Neptune at Assos, also were then obtained for the Louvre.

Important, however, as are the researches conducted by foreign governments, and worthy of British imitation, the manner and form of publication of the results, go to reduce considerably their value. The cost of the books, containing illustrations, published at the cost of the governments alluded to, is enormous. The size of volumes is not merely unnecessary for the actual size of plates, or for the explanatory matter in letterpress; the size and the weight,—the latter resulting, in fact, from an unnecessary thickness of paper,—are positively disadvantageous to the use of the volume, even not taking into consideration cost of purchasing it. Mr. C. W. Goodwin, a distinguished Egyptologist, recently, in a paper which he read at the Society of Antiquaries, mentioned that having to refer to the copy of a

papyrus given in a work of the class to which we allude, and where the transcript occupied only the centre of an atlas-folio page, he had found it necessary to have the copy recopied, in order that he might conveniently go through his labour. The Prussian works and the French, are much alike in this particular. The volumes, illustrative of M. Texier's researches are so expensive at least that they are not much consulted; and many of the buildings which they illustrate are less known to English architects than they should be.

With whatever the advantage derived from the exact delineation of the remains in Greece proper, in the islands, and in Magna Græcia and Sicily, much that is essential to the knowledge of Grecian architecture, has been left to be sought for in Asia. From the concentration of attention to the small number of examples,—of great excellence indeed,—which are to be found in Athens, the fertility of Grecian art has been underrated. The Society of Dilettanti did but touch the soil in those albeit valuable volumes commonly known as the "Ionian Antiquities;" however, portions of the interior and coast of Asia Minor continued to be explored by travellers, including Captain Beaufort and Mr. Cockerell, Colonel Leake, M. Texier, Mr. Hamilton, Sir Charles Fellows, Mr. Edward Falkener; Lieutenant Spratt, Professor Forbes and the Rev. J. Daniell; Mr. Ainsworth; and Mr. C. Newton, Lieutenant Smith, and Mr. R. P. Pullan. The importance of the researches by some of these travellers, to the history of architecture, is now even more apparent than it was. Since the Assyrian discoveries of Layard, and the commentary upon them by Mr. Fergusson, the fact of an Eastern influence upon Grecian architecture, such as may have helped to form the Ionic order, has been, we believe, generally admitted. In Galatia at least, as found by M. Perrot, there are remains of a description of art long anterior either to Gallo-Greek, or to the architecture of the Temple of Augustus at Ancyra. Different waves met to form the varied architecture of the peninsula. One, Assyro-Median, came from inland; others, from the coast, were the Egyptian, or Phœnician-Egyptian, and the Egypto-Greek, with the perfected Greek.

Whether we would understand the conditions under which styles of architecture are produced, or understand Greek art itself, study of the remains in Asia Minor may be deemed essential. It is true indeed that the number of the remains having a decorative character to be classed distinctly as Grecian, is small compared with the recorded names of the cities. Of the works of the early colonists from Greece, starting from the first settlement of the Æolians, Ionians, and Dorians, on the western coast, ten centuries before our era, the vestiges are few: for, Xerxes burnt most of the temples. He excepted the temple of Assos, as it belonged to the Persians. Generally the temples of Asia Minor date not earlier than Alexander; and in the majority of them there are features which are found in Roman works, and not in the Greek of the Periclean age; whilst the same examples are yet markedly Greek, compared with any recognised Roman works, as those in Rome, or Ba'albeck, or even compared with Roman works in Athens. The buildings of the true Greek period, which have disappeared, included temples the largest in their dimensions, which existed. Of these were the Temple of Diana at Ephesus, estimated to have been 425 ft. in length by 220 ft. in breadth; the Hermaeum of Samos, 346 ft. by 189 ft.; the Didymæon of Miletus, 295 ft. by 156 ft.; and the Temple of Cybele at Sardis, 261 ft. by 144 ft. Concerning them, or other structures which are represented only by heaps of stones, it is probable that much information would yet be disclosed by excavation; but the materials are found so convenient for modern building-purposes, that the

chance is rapidly passing away. Mr. Falkener's researches have not been forgotten by us.

Two aims are just now required of the lover of classic art,—the one, towards obtaining from foreign publications the information which has been collected in them,—and the other, the prosecution of those further researches which the extent of the still unworked field demands. To assist in these objects, Mr. Pullan was engaged, in 1861 and 1862, in an exploration of the western coast of Asia Minor, and in excavations and measurements of the Temple of Bacchus at Teos, for the Society of Dilettanti, and has now put together some of the illustrations from M. Texier's work, with abridged translations from its letterpress, and with some extracts from Hamilton, Beaufort, and others, and has prefixed a narrative of his journeys. The volume has therefore a composite character; and the matter that is quite new is rather topographical than architectural: but we are glad to have the particulars of the exploration, and the hope of the publication of details and a restoration of the temple at Teos, and likewise the selection from the "*Asie Mineure*." The illustrations from Texier relate to buildings at ten different localities, only four of which, namely Assos, Branchida, Pergamus, and Iassus, were visited by Mr. Pullan; but quotations from Texier and others are interspersed with the narrative. For the illustrations, impressions appear to have been transferred to stone from the original plates. The dimensions however are given in what seem to be feet and decimals; and there is a scale of feet and tenths at the foot of each plate. Some explanation of this matter of the notation or dimensions, should have been given in the preface; and Mr. Pullan's absence from England whilst the work was at press, has led to an awkward error or two, as in a name, or date.

Mr. Pullan devotes an Introduction to what is a very useful summary of the different researches in Asia Minor precedent to his own. The first traveller mentioned as having described and illustrated the ruins, is the Frenchman, Paul Lucas, who was at Rhodes about the year 1699, and who visited many parts of Asia Minor five years later. After this traveller, Spon and Wheeler, at the end of the seventeenth century; Tournfort, afterwards; Pococke in the beginning of the eighteenth century; and Corancez in 1809 to 1812, visited and described the country. Dr. Chandler, and Messrs. Revett and Pars, for the Dilettanti, left England in June 1764, and returned in September 1766; and results were published in 1769—1797, in folio, by the Society; and in 1775 in the quarto volume of Dr. Chandler. In 1811, a second expedition, consisting of Sir William Gell, and the architects, Gandy and Bedford, was sent to Asia Minor and to several places in Greece; and the results appeared in a third volume of the "Ionian Antiquities," and in the "Inedited Antiquities of Attica." Choiseul-Gouffier had visited the country in 1772. Views with architectural details, were published in 1782, in his "Voyage Pittoresque." Captain Beaufort, the late Professor Cockerell, and Colonel Leake have been mentioned, as also have travellers who came after M. Texier. Mr. Newton's researches commenced soon after his appointment to the vice-consulship of Mitylene, which was in 1852. In 1855, he visited Buzum, and finding traces of fine sculpture, he asked assistance from the Government. The *Gorgon* frigate was sent, and an officer of the Royal Engineers, Lieut. Smith, with a detachment of sappers. In January, 1857, Mr. Newton ascertained the site of the Mausoleum; and before the end of the year, he procured data for a plan of the monument, and brought to light the sculpture now in the British Museum. In December, 1857, he visited Chidus, and made excavations on the site of the Temple of Venus, at the Lion Tomb, the lower theatre, and the temples of Hecate. In 1857-58 Mr. Newton

\* "The Principal Ruins of Asia Minor, illustrated and described. By Charles Texier, Member of the Institute of France; Member of the Royal Academy of Science of Munich; Honorary Fellow of the Royal Institute of British Architects; formerly Inspector of the Fine Art Establishments in France; and Commissioner of Public Works in Algeria; and R. Poppellwell Pullan, F.R.I.B.A., Architect to the Bédouin Expedition; Agent for the Dilettanti Society in Asia Minor." London: Day & Son, 1865. Folio, pp. viii., & 66; Map, & 51 Plates.

and Lieut. Smith explored the whole of that part of Caria, from Lahranda and Euromns to the Bay of Marmorico, opposite Rhodes. The ruins of the Temple of Hecate at Lagina, with sculpture of the frieze in tolerable preservation, were discovered; the site of Labranda, where was the celebrated Temple of Jupiter, was identified; Mylasa, Myndus, and Bargalia were visited; and the island of Cos was explored. Mr. Newton also visited the ruins of the Temple of Apollo Branchidae, and brought from the Sacred Way the figures now in the British Museum. Mr. Pullan was sent, in 1857, to join the expedition; and he remained a year at Budrum and Cnidus, and exploring the island of Cos. Coming home, he visited the site of Troy, and Thessalonica.

In 1861, the Society of Dilettanti, desirous to obtain information as to the condition of the sites of certain temples, commissioned Mr. Pullan to visit them, and to report as to the desirability of excavation. The buildings were the Temple of Bacchus at Teos, the Temple of Apollo Sminthens in the Troad, the Temple of Minerva at Priene, and the Temple of Apollo Branchidae at Ierouda near Miletus. In the journeys which were necessary, he completed the archaeological survey of the greater part of the western coast to the Troad, from the point which had been reached by Mr. Newton. In 1862, as we infer, having received instructions, he conducted the excavations at Teos, and obtained the materials for illustration of the architecture of the Temple of Bacchus.

He left England in July, 1861, with his wife, who seems to have accompanied him in each of his excursions from Smyrna, the head-quarters. A tent was pitched, as the sleeping accommodation, during the summer months: in the colder weather, when quarters had to be procured somewhere under a roof, there appears to have been less danger from "bad men," yet little comfort. The Admiralty charts seem to have been of much service; but, the map which forms the frontispiece to the work, is not a very satisfactory production: not even all the places mentioned in the narrative are to be found in it. In his excursions, he passed by numerous ruins and fragments of which we regret not to have illustrations. Thus he speaks of a slab of frieze noticed amongst the ruins of the Temple of Diana Lencophryne, as finer than any of the work in the Louvre.

In his report to the Society of Dilettanti, on the ruins visited, and the probable expense of excavating, Mr. Pullan set down the Temple of Apollo Sminthens first, "since it afforded an entirely unique example of the Ionic order, its architectural details being at the same time of good style." He placed next, the Temple of Minerva at Priene, superior in the character of its architecture to any of the other buildings, but previously explored and illustrated in the Society's work. Thirdly, came the Temple of Bacchus at Teos, where no excavations had been made, and respecting which therefore little information had been obtained. The profiles of the mouldings are described as fine, though inferior to those of the temples already mentioned. Fourthly, was the Temple of Apollo Branchidae at Ierouda. The architecture there was fine in style; and excavations would probably bring to light sculpture of great value; but the size of the blocks of marble might make the excavation too expensive except for a government.

The excavations at Teos occupied about three months, inclusive of the week's holiday of the Bairam; and five-and-twenty Turks and six Greeks were employed as workmen. Great part of the frieze was discovered; but the sculpture was not of high character. Two slabs were sent to the British Museum. The Temple of Bacchus at Teos, was one of those of which Hecogenes of Alabanda was architect. The Temple of Diana Lencophryne at Magnesia ad Maeandrum was another.

The plates from M. Texier's work are illustrative of the Temple at Assos, the Temple of Apollo Branchidae at Ierouda, the Temple of Jupiter at Aizani, the Angustenum at Anycra, the Temple of Venns at Aphrodisias, the Theatre at Aspendus, the City of Iassus, the Theatre at Myra, a temple at Patara, and the Basilica at Pergamum. Of all the examples, none seems to be historically more important than the Temple at Assos, which was probably erected in the fifth century before the Christian era. It is remarked in the volume before us—"This temple is interesting as perhaps the earliest known example of the Greek Doric order," and the proportions, and the character of the architecture,

warrant the supposition. "In the Temple of Corinth, which was formerly considered the oldest example existing," it is continued, "the column is 4.065 diameters, and the capital has a considerable curve. At Assos, the column is 4.250 diameters, but the curve of the capital is the greatest of any known example; and the projection of the abacus is nearly equal to half the upper diameter." In later buildings, including the Parthenon, the column is more than  $5\frac{1}{2}$  diameters, the capital is shallow, the abacus has little projection; and the curve of the echinus is quite flat. These characteristics, including the height of the column in proportion to the diameter, are still more marked in edifices considered to be of the Macedonian period, such as the Portico of Philip in the island of Delos (Mr. Pullan says "at Athens"), and the portico at Budrum. In the order at Assos, the column has ten flutes. There are no guttae to the mutules. Not only the metopes are decorated with sculpture, but the architrave is; and this sculpture is of an extraordinary character. Some of it has an Egyptian appearance rather than Greek. The architrave is terminated at the foot, by a fillet. At the extremities of the architrave are two bulls in the attitude of combat; and in the centre are two sphinxes. Portions of the sculpture, and a capital, are in the Louvre. There are other remains of an interesting character at Assos. Lining the street of tombs are immense *sori* of red stone of the neighbourhood. From this stone, all tombs of the description and form of the *sori* derived their name. The stone was said to have the property of consuming bodies, with the exception of the teeth, in the period of forty years: hence the name *sarcophagus*. In the principal gateway of the town, the lintel, formed by two large stones placed side by side, is relieved by a *quasi*-arch on each side, or one built on the horizontal principle; and one of those arches, that on the exterior, is pointed, whilst the other is semicircular. In another gateway, having a semicircular arch, the construction is with voussoirs. The difference leads to the inference of difference of dates, or to that of the existence of a period when the arch with voussoirs was not known. Assos lies on the southern coast of the Troad, opposite the island of Lesbos or Mytileno.

The temples of Asia Minor appear to have been distinguished from these in Greece of the age of Pericles, by their accessories, the peristyles, and the Sacred Way. Those of the age of Alexander, of chief importance, and of the Greco-Roman period generally, have the peristyle enclosing a large area of ground, and the wall internally enriched with columns. The same feature was produced by the Romans with their temples, as of Ba'alhek, and received a large amount of decoration. Amongst the remains of late Greek works in Asia Minor are those of the Temple of Apollo Branchidae. It is described as the largest of all temples; but it was never roofed in. As the site of the most celebrated oracle of Asia, and the most renowned after Delphi, it was a great place of resort. Ierouda, near which the remains are, is south of Miletus, in Caria, and opposite the peninsula in which are situated Myndus and Budrum. The architects of the building were Daphnis of Miletus, and Peonius of Ephesus, the latter of whom was chosen to complete the Temple of Diana at Ephesus. The peristyle was of great extent, and was filled with fine trees. There are no traces of its wall; but the whole course of the Sacred Way from the port, a distance of two miles, is distinctly visible. It was lined by seated figures and sphinxes in a very archaic style of art. Several of these, as before referred to, are now in the British Museum. The exact site is on the promontory of Poseidon; and the temple must have been seen on either side, from the sea, at several leagues' distance. Three columns are standing, one of them, unfinished, or not fluted, and still serve as landmarks. The facility of obtaining stones has led to the formation of a village on one side of the temple. The full length of the building is given in the text of the volume before us, as 306 ft. 6 in., and the breadth as 161 ft. 5 in.; but we cannot make these dimensions quite agree with those on the plan of M. Texier; and it is noted by Mr. Pullan that there is a discrepancy between this plan, and that of the "Ionian Antiquities." The temple was decastyle, and dipteral, and is considered to have been hypæthral. Even in the present state, the ruins are spoken of by Mr. Pullan as "the most imposing of their kind to be seen," and as giving a better idea "of the grandeur of Greek archi-

ture than any other existing ruins, even than those of the Temple of Jupiter Olympias at Athens." Notwithstanding the destruction by the villagers, exploration would doubtless lead to important discoveries. The blocks average 6 ft. by 3 ft. by 2 ft.; so that better appliances than are at hand are needed for the removal. The order may be considered as a good representative example of the Ionic of Asia Minor, and of late Greek date, differing from the Athenian Ionics of the Periclean period, and agreeing with the Roman, in the straight-lined arrangement of that part of the capital which is between the volutes,—or where in the Athenian examples, the hem of the volutes is carried across in a descending curve,—and also differing from the Athenian and agreeing with the Roman practice, by the introduction of the square plinth as the lower member of the base. In the forms of the oves, and elsewhere, the character is Greek. The pilaster-capitals from the interior, known from previous illustrations, and from copies of them in some modern buildings, are of fine character. The ends of the abacus are carried by small volutes terminating a band, with leaf-enrichment, which encloses a panel or space variously decorated, as with anthemions and scrolls, or chimæra,—the return ends below the volutes being also enriched with scrolls. Amongst the ruins lies a block, which has sculptured upon it, a genius with outspread wings, and scrolls. This fragment is of the finest character of Greek art.

The remains of the Temple of Jupiter at Aizani, at the period of M. Texier's researches, were even more important than those of the example last described. The site is in Phrygia, and was not visited by Mr. Pullan. The evidence on the spot, enabled M. Texier to make a satisfactory restoration. The *temenos*, or sacred enclosure was of great extent, the dimensions given by the terrace-walls being 520 ft. by 485 ft. For within this was the peristyle proper, a double colonnade enclosing the paved area surrounding the actual temple. The terrace of the principal front was carried by arches, the line being broken in the centre by the first broad flight of steps. Having ascended these, and crossed the outer ground of the *temenos*,—which was no doubt planted with trees, interspersed with *cedres* and *bricinia*,—the great porch of the *stoa* or *peristyle* was passed through; and the temple itself, with its surrounding peristyle, appeared. The columns and pediment of this, however, seen from a distance, towered above the surrounding features of the plan. It may be noticed now, how essential to the knowledge of Grecian architecture is the study of something more than the temples of Athens, as well as how much light may be thrown upon the descriptions of the Jewish temple by remains of the temples of the Greeks and Romans. The temple at Aizani is thought to belong to about the second century of the Christian era. Beneath the cella of the temple proper, is a large chamber with a semicircular *niche*. It was approached by a staircase in the *posticum*, and lighted by two openings in the surface of the cella-wall. Eighteen columns with the entablature of the order, and with the *locunaria* and cross-beams in a singularly perfect state, and a considerable portion of the cella, were standing in M. Texier's time. The architecture was of the Greco-Roman period; and the order is Ionic. The enrichment of the frieze, with volutes boldly projecting and carried by acanthus leaves, is very peculiar, but graceful. The cornice has modillions as well as dentils. The baluster-ends of the capitals are elaborate in their leaf-work enrichment. The arrangement of the volutes of the capital resembles generally that which we have characterized as Roman. In each flute, at the top of it, is an ornament in the form of a small vase with handles. The capitals of the *antæ* are Composite in their general character; and the columns between the *antæ* of the *posticum* have Composite capitals, and have no plinths. The order of the peristyle was Corinthian.

At Aizani are considerable remains of the theatre. It was Greek in plan; that is to say, the side-wall of the *cavea* is at an angle with the face of the scene, instead of being parallel with it, as in the Roman theatres. The Greek plan however is preserved in theatres known to be Greco-Roman. M. Texier's plates include a plan and details of the proscenium. A peculiar Ionic capital, considered as unique, is employed. The volutes face four ways, or are placed angle-wise, as in the later Italian practice. There is an obliquely-set modillion at the angle of the cornice; and the lower portions of the flutes are

filled in with cabling. All these are characteristics of late Roman works; and amongst others are the forms of the oves in the cornice; whilst the oves to the architrave, and the filets throughout, may be called Greek.

Of the Augustæum at Ancyra in Galatia, illustrations, additional to those of M. Texier, should be now about being published from the measurements by M. Guillaume, the architect who was attached to the expedition conducted by M. Perrot. All that was visible at the time of M. Texier's exploration, comprised the two side walls of the cella, the ante terminating them, and the doorway, of Greek character. The blocks of marble, are put together with bronze cramps. The capitals of the ante have winged figures of Victory in the midst of foliage; and from them an acanthus-scroll extends round the cella-walls to form a frieze. The order of the peristyle of this building was Corinthian. The date corresponds as nearly as possible with the commencement of the Christian era. The remains of the *naos* are valuable as showing the decorative character of the interior of a temple. Rusticated work is carried up to the height of 15 ft.,—but the vertical sunk-fillets are not kept regularly over one another; above this is a cornice-moulding with festoons; and the remainder of the height is now plain space, but was probably once decorated with paintings. On the external face before mentioned, of the pronos-wall, the Greek character is found in the palm-leaf ornamentation, and the froth, which are in the base and surbase mouldings.

In the Temple of Venus at Aphrodisias, near Mount Cadmus, in Caria, we have again an example of the Asiatic-Greek arrangement of accessories in plan, and a very fine cue of the Ionic, Asiatic, or of Greco-Roman date. Upon the shaft of each column is a tablet with an inscription; but the inscriptions give no clue to the date, except in showing that the building was erected in Roman times. The temple proper stood in a large peribolus, which had coupled columns of the Corinthian order, projecting from the wall, the two columns carrying a pediment. Between these salient features, were small square-headed niches, similarly decorated with pilasters and pediments, but the pediments alternately curved and triangular. Within the peribolus, and in front of the temple proper, stood a double row or screen, of small Corinthian columns. Coming to this from the entrance of the peribolus, the way was flanked by two recumbent lions, and two large basins or piscine. The ornamentation of the Ionic capitals is equal to the best in Asia Minor. The Corinthian of the peribolus-wall has much more of the Roman character. The frieze, for example, is convex or pulvinated; and the dentils are small; there are no modillions to the cornice; and there are none to that of the small order of the screen, also Corinthian. Probably the screen and the peribolus are as late as Trajan.

The site of Aspendus, on a mountain at the extremity of the plain of Perga, has the finest and best-preserved theatre in Asia Minor. The view of the interior forms one of the most striking subjects in the book. The building was erected in the time of Antoninus and Lucius Verus. An inscription in the interior records,—“The senate and the people have honoured Zeo, the architect of the theatre and of the works in the town, by erecting a statue in the theatre, and by giving him a garden situated near the Hippodrome.” The columns of the proscenium; and the roof of the scene,—for the timbers of which the holes however are apparent; and the *velarium*, or awning,—for the masts of which, the perforated consoles are *in situ*,—comprise nearly all that is wanting. A theatre which is well preserved, is indicated on the plan of Iassus. At Myra, in Lycia, also is a fine Greek theatre, illustrated in the “*Asia Mineure*” and in the volume before us, and remaining in an almost perfect state. The order, Composite, and the other decorative features, are of very superior character. The most remarkable remains, however, are the tombs cut in the rock, and which seem to have been designed to imitate wooden buildings. M. Texier made a view of the well-known example which has the sculptured representation of a combat of a lion and a bull in the pediment, a common subject in Asia, and no doubt symbolic. Beaufort, as quoted by Mr. Pullan, says of Myra,—“My time would not permit me to examine this great emporium of precious relics; but Mr. Cockrell, a gentleman well known to the literary world by his

interesting discoveries in Greece, and who visited Myra the following year, found there the ruins of a considerable city. . . . The inhabitants are chiefly Turks, and he described them as more than ordinarily jealous and ferocious. While examining some statues, one of the mob exclaimed, “If the infidels are attracted here by these blasphemous figures, the temptation shall soon cease; for, when that dog is gone, I will destroy them.” From Patara, in Lycia, where also there is a theatre (its proscenium being well preserved), M. Texier's illustrations include a peculiar capital, bearing a resemblance to that in the Temple of the Winds at Athens, but some time known, and details of the doorway of a tomb, “one of the most elegant doorways of the Greco-Roman period existing in Asia Minor.” The volume is terminated by illustrations of a building at Pergamus, which was probably a basilica.

Those who have access to the original volumes of M. Texier, may do well to prefer them to the abridgment. Those who have not them at hand, will find the present publication a convenient substitute. For the researches which Mr. Pullan himself has made, we offer him our thanks; and we look forward with interest to the publication of the work on the Temple of Bacchus at Teos.

#### CONDITION OF OUR TOWNS: PERTH.\*

In our previous article on the fair city of Perth we exhausted, as far as we could in connexion with its extraordinary mortality, the physical conditions of the surrounding soil, the climate, and those meteorological phenomena with respect to the influence of which on the public health we held the inhabitants, or rather their local government, to be clearly exonerated. We now proceed to take up the general sanitary condition of the town itself, the consequences of which will be easier related to those who are the responsible agents.

We shall begin with the water-supply. The Perth Water Company obtain their supply by pumping from a well dug in the bed of the River Tay. When it was originally proposed to bring this water from the river, a curious difficulty arose, which is worth recording here. They began by digging pits close to the river, the object of which was to get the water filtered through the gravel of which the bed of the Tay is composed. But, however close to the river they dug these pits, the river-water was never obtained; it was always water impregnated with mineral salts—the same, in fact, as that which was found in the *hard* wells of the upper levels of the town. At length it occurred to Dr. Anderson, an eminent Perth academician (under whose superintendence the works were successfully constructed) to attempt the excavation *within* the course of the river, and so obtain the superincumbent pressure of the river-water itself. Accordingly a well was dug at the northern extremity of that large island which divides the stream immediately below the town; and into this well the river-water flowed freely, filtered and purified at the same time in its passage through the gravel. From this well the water is pumped in pipes laid under the bed of the river to a small ornamental reservoir on its western bank, containing a large circular iron tank, from which the town was, during some years, supplied. But there has recently been constructed a new reservoir at Dovecot Land, a small hamlet on the rising grounds to the west of the town, which is better calculated to supply the higher levels. To this point the water is forced up by the same engine that draws the supply from the river; which engine, we were told, works night and day.

The supply of water thus obtained is more than ample; and the service constant and uninterrupted. Even very poor houses have a separate supply; that is to say, houses which possess an annual rental of 5*l.* and upwards. But, besides this, Perth is more profusely supplied with public wells than any other town in Scotland. These Perth wells, which are of an exceedingly simple but tasteful design, are, we understand, being extensively adopted throughout the country. We may add here, that the plumber-work done in Perth is of a very high order. In the better class of houses, such as in some of the best mansions in the neighbourhood, there is hot and cold water laid on in every room; and the baths, waterclosets, and wash-band basins,

with their complicated fittings and apparatus, might teach some of our Londoners a lesson in the art of hydraulic engineering. As a whole, the arrangement for the water supply of Perth is extremely creditable to the town; and we shall see the result, after all, may not be so; as we shall see.

For it is written that man shall not live on bread alone; neither can the economy of human health be wholly sustained by water, however pure and abundant. A thorough system of drainage must always accompany a system of water supply. But when we come to investigate the *drainage* of Perth, we are sorry to say that our report in the one case must consist of a violent contrast to the other. Indeed, it is clear that the facilities for the one matter do not imply equal facilities in the other; that is, a town may be favourably situated with respect to water-supply, and most unfavourably with respect to drainage. Such, in point of fact, is the case at Perth. Up till within the last two or three years, Perth does not seem to have had any thorough system of drainage at all. Since that period, two main drains have been carried through High-street and South-street; where their contents are discharged at right angles into the river, just immediately above the point at which the water is pumped up for supply of the town. Now, we must point out that a sewage outfall in this position is a very serious mistake. Although the water is doubtless filtered in its passage through the gravel of the bed of the river, it must be remembered that the process of filtering can only separate mechanical impurities; it is quite useless with respect to the separation of the chemical impurities which all sewage matter contains. It may be said that the large volume of water and the rapid flow of the river are sufficient precautions against this contamination. We are far from sure of that. The Tay is a tidal river like the Thames; and we all know how the Thames has its putrid and offensive matters carried up and down by the tide. Besides, there is always the greater risk of contamination during hot weather, in the height of the summer season, when the stream diminishes in volume and the bed of the river becomes contracted. It is also during this season that the greatest risk may be apprehended from the dyo works and bleachfields which are situated higher up the river. But the outfall is not the worst of these main drains. The river rises at full tide far above the lower levels, and consequently dams up and carries back their noxious contents. There is no scientific provision made for this well-known contingency, such as boxes and sluice-valves, as we have had to make in the case of the under level sewers which intersect the Thames Embankment; and it does not seem to have struck the Engineer that there was any necessity for such provision.

And after all these two main sewers drain only a very small fraction of the area of the town. The Mill-lade of which we have spoken, or rather the canal or town aqueduct, which is supplied from the River Almond, and which constituted at one time the regular water supply of the ancient city, also serves the purpose of a sewer, if we may judge from its appearance after traversing the town.\* But, with these exceptions, Perth seems to be utterly destitute of main sewers; and of course all the most densely-populated districts are absolutely undrained. The consequences of this are very apparent even on a cursory inspection of the town. We have already spoken of the excessively dirty condition of the streets and the depth of mud on the roads. At the time of our visit, we observed two old men feebly endeavouring, about the hour of noon, to remove the tons of sludge and filth which reposed in peace on the road-way of the High-street. But the High-street is a perfect paradise compared with some of the closes and lanes which branch from it. In the mill-wynd, for instance, which closely adjoins the Mill-lade, the roadway seems to be used as a common convenience, particularly by the junior portion of the population. In a town of 27,000 inhabitants, there are only four public conveniences. One of these, pointed out to us, was of rather a remarkable character and construction. The principal apartment was situated on the *upper floor* of a two-story building somewhat of the model of a coach-

\* Speaking from recollection we may possibly be mixing up two separate channels in this statement. What we mean is, that open ditch which passes through the margin of the South Inch on our way to the railway station from South-street.

\* See p. 132, ante.

house and hayloft. The seats were arranged along one side of this room, and the trough was partially filled with tanner's bark,—we presume as a sort of disinfectant, or deodoriser, or perhaps as both. When the trough was completely filled and the bark thoroughly saturated, this manure was scooped down through an orifice to a dung-cart which had backed into the apartment below, and was at once transported to the central depot. Near this arrangement was an equally curious dust-bin, which consisted of a square pit dug in the ground, covered with a trap-door. On the centre of this trap-door was constructed a sort of sheet-iron funnel, about 3 ft. high, through which the neighbouring inhabitants are supposed to shunt their ashes and other solid refuse. Generally speaking, the closes or "vennels" between South-street and Canal-street, and those between High-street and South-street, are unspenkably filthy. One, we remember, was full of slaughter-houses; another was crowded with cows (Shuttlefield close), the milk from which animals, we thought, could not be very wholesome or pure. But, at any rate, their proximity to such crowded sleeping-rooms is most pernicious.

These districts are all situated in the oldest parts of the town; but some of the outskirts are quite as bad in their sanitary condition. A sort of "claeham," or collection of weavers' houses, exists at the upper extremity of the High-street, near Claypot's-wynd, which, as far as we could judge, had reached the worst stages of neglect. The few we had time to inspect were low, mean, red-tiled cottages, of two floors (one sunk) and attics. In the best room the ceilings did not exceed 7 ft. in height; and window-openings of about 2 ft. square, with fixed sashes. The area in front was spanned by a series of rickety and dilapidated-looking stairs, the timbers of which were very far gone in decay. In these houses there was no water laid on, neither was there any other provision of a sanitary description. In the little plots of ground at the back of the houses we discovered a few privies and pigsties in intimate contact; but the state of the green-sward in too many instances showed still greater necessity for increased accommodation. The whole state of these houses we can only characterize as disgusting; yet they were all crowded with population, of which the majority, of course, were children.

We must remark here, with whatever reluctance, that the manner in which soil, ashes, refuse-matter, and surface filth of every description, are strewn about the streets and thoroughfares of Perth, is a great disgrace to the authorities; for they seem to regard their sanitary delinquencies as a lucrative source of revenue. Perth being situated in the very centre of a fertile agricultural country, where the farms are chiefly wrought under a system of very high tillage, its surface manure is unquestionably at a premium.\* But we are just afraid that this common sewage has a greater value than common decency. The public health suffers in competition with the public manure!

Perth having thus polluted its surface to an extent which almost surpasses belief, has also made considerable progress in poisoning the subsoil. Some of the most populous and densely-crowded parts of the city, as we have said, are absolutely untrained. But this is not the greatest evil. Some of the most fashionable quarters, such as Marshall-place, in the South Inch, and Athole-crescent, in the North Inch, are only drained by cesspools. These cesspools, we must explain, are generally huge receptacles about 20 ft. or 30 ft. deep, in many cases the shafts of the former draw-wells which existed previously to the introduction of water to the town. The accumulation in these horrible pits will better be conceived than described, when we add that they are only emptied once in two, or sometimes three, years. They are generally emptied, too, during the night; just as if atmospheric poison were not more pernicious and fatal at night than it is during the day! It is in the highest degree fortunate for our argument, and for the cause which we have at heart, that we can adduce some local authority in support of our statement regarding these plague-spots;

\* "Sale of Public Manure.—On Friday last, the whole dunghills within the manure depot at Tullylamb were exposed to sale, by public roup. It being market-day there was a large attendance of farmers, and consequently the competition was very keen. There were in all 140 lots, which realised an average of 3l. 7s. each. The sale was conducted by Mr. Duncan Macintosh, and the business-like manner in which he performed his duties was the subject of general remark."—Perth Reporter, January 30, 1865.

because we are perfectly conscious that many people conceive we have a tendency in these papers to make out a case. In the month of September last year, the commissioners of police had their attention directed to the subject, and Mr. Walsh, the inspector of nuisances (who is also the superintendent of police) submitted a report, from which we will make one or two quotations.

With reference to Marshall-place, it is stated that it consists of twenty-eight inhabited houses, to each of which there is a cesspool, and to the greater number two. These cesspools are situated at a greater or less distance from the houses, the furthest off being about 20 yards. Nearly all of the cesspools, although not found belching up, were full to the cover: in consequence of this the walls in some of the houses were damp, and in the back courts and areas the green moss and fungi were growing by the wall-sides and edges of the paving-stones,—evident symptoms that the sewage had found its way through the whole ground. Indeed, the whole background lying between the Dundee Railway and the houses is saturated and discoloured with sewage, and no one can go into the area without being sensibly affected by the offensive atmosphere. After adverting to the state of King-street and King's-place, which were nearly as bad, the report concludes by expressing an opinion, that before the inhabitants can expect to escape the diseases which spring from poisonous gases, a main drain must be laid down, of sufficient capacity to carry away the night-soil and sewage.

Mr. John Young, C.E., of Perth, supplemented this report by a plan and estimate of cost. He proposed to construct a main drain along King-street, King's-place, and Marshall-place, to the Tay, which would likewise be capable of receiving all the sewage from the upper western parts of the town. He estimated the cost of the works at 1,248l.; and as there were seventy proprietors along the route, the average cost to each would be 18l.

The above reports, we understand, were "laid on the table of the Commissioners of Police in the mean time;" and we have not heard anything of them since. But our readers may possibly divine what the commissioners are about from another local report just issued, viz., the report of the registrar (to which we were indebted for the vital statistics), who, in presenting his "mournful sheet," as he most justly calls it, to the town council, thus speaks:—"It would be presumption in me to go into any discussion as to the sanitary state of the town. The inspector of nuisances has already reported on the open pestiferous ditches and obstructive sewage on the west side of the town, and scores of obnoxious cesspools on the south. Can these account partly for the great mortality which has occurred? [The town council or the commissioners ought to answer this important question.] I beg also to call attention to the statistics kindly furnished to me by the Registrar-General of Scotland, from which it appears that the number of deaths in Perth bears a larger proportion to the number of births than it does in any other of the large towns in Scotland. Perth is the smallest of the districts which make such returns. We are not, therefore, pent in a populous city where sewers need annoy and vitiate the air. We have the finest river in Britain rolling past and washing our very walls; we have an ample supply of water in our Mill-lade, from which streams sweep all impurities from drains into the Tay; and thus we possess every means of making Perth the cleanest town in Scotland. I enter not here into the loss which some may argue is sustained from not saving our sewage. But what is that compared with the health of our inhabitants?" This is another most proper inquiry which the commissioners are bound to take up and dispose of. We must be permitted to share in the hope with which the registrar concludes his report, that Perth will one day be known as the healthy city as well as the fair city.

Where such an earnest disposition to reform prevails on the part of the burgh officials, it would be alike ungenerous and unnecessary for us to prolong the case. But we have still a few remarks to make. One singular and melancholy fact we are bound to report as it reached us; and our readers will probably not feel surprised to hear it. Last year an addition had to be made to the Perth Infirmary for the purpose of accommodating the increase of fever patients! We need not recur to the death-rate of the town, particularly to the infantile death-rate, nor will we dwell on the medical reports. Dr. Bramwell, an intelligent physician of the city, showed last

year that the mortality of Perth would bear comparison with that of other towns during a visitation of cholera. Scarletina, typhus, typhoid, and gastric fevers, are all, in fact, constant visitors: in one word, the diseases which spring from foul and noxious emanations joined to those which result from overcrowding in uninhabitable rooms, are those which support the high mortality.

We have now, we suspect, done enough to show that Perth is suffering mortally from causes which are well known to be more or less preventable. The first question that occurs, therefore, is, what must be done? It is not so much our business in this inquiry to suggest practical remedies as to point out radical errors. Our presumption is that the local authorities are always equal to the emergency and necessities of reform. Yet, as we cannot but regard Perth as a sadly neglected case; and as we are sure anything we do suggest will be kindly received, we venture to point out the following measures as alike urgent and imperative.

In the first place, there must be a system of thorough drainage for the entire burghal area. Cesspools must be abolished.

Secondly, the sewage outfall should be changed, so as to avoid contaminating the river at the source of the water supply.

Thirdly, there ought to be a public slaughter-house.

Fourthly, a system of periodical slushing might be advantageously employed not only for their drains, but for the surface of their streets and closes. There is plenty of water for the purpose.

Fifthly, Better scavenging is much needed. Finally, a thorough investigation and reform of the poorer class of dwellings are absolutely necessary. It is there the mortality bills find their most numerous supporters.

We make no suggestion as to the manner in which these improvements ought to be carried out. With regard to the mechanical difficulties, if there be any, the engineers of the Tay can surely solve them. And as to the legal difficulties, if there be any, an Act of Parliament is soon passed when life is in danger. But it will be strange if, among the multiplicity of Scottish Acts and Public Health Bills respecting Scotland, which every year pass through the Legislature, the lawyers of "bonnie Saint Johnstone" cannot discover a method of evading tailzies and teinds, fens and enfeoffments, and other quips and quodlibets which stand in the way and impede their progress. There was, we may state, an application made by Sir George Grey of certain clauses in the General Police Bill for Scotland some time ago; but its practical operation, we suppose, has not yet commenced.

One word as to the municipal government of the town. We are somewhat at sea, we must own, with regard to its constitution. First of all we have the Lord Provost and magistrates, then the town-council, and then the police commissioners. Are these bodies fashioned according to the principle of *trio in uno*, or do they each possess a separate and independent jurisdiction? What is the Tay District Fishery Board? Has it any interest in the conservation of the river? and would it object to any system of thorough drainage? Who is the local authority under the Nuisances Removal Act? What powers have the Parochial Boards in the matter of epidemics? Who exercises the power of levying assessments? We are very glad to hear that the "Craigie Nuisance" has been arranged between the incorporation of glovers and the hospital managers. But which of the two bodies made the obstruction? It seems to be the fashion in Perth for magistrates and bailies to contract for the town's work, in open defiance of the 10th clause of the Burgh Financial Act.\* Could some of them not contract to clean out the closes properly? Again, the superintendent of police is inspector of nuisances and master of the fire brigade; he is also, we believe, the procurator fiscal. These duties are surely not cognate; could they not be divided with good effect? There appear to be two city clerks in the town: this is surely one too many; could not one be exchanged for a medical officer of health?

The old proverb about too many cooks would seem to be very applicable to the condition of Perth at this moment. But, after all, we understand these are not the proper sort of cooks. There are a great many shopkeepers in the Perth Town Council; there are also a great many lawyers.

\* See Bailie Jamieson's speech at the ordinary monthly meeting of the town council, September, 1863.

There is not a single builder, architect, or engineer. There is not, we were told, a blacksmith or a brassfounder. Even the amiable Sir David Ross follows the peaceful and useful occupation of a grocer. It is no disgrace to these burghesses to say that though they may know something of the simple yet inevitable laws which govern the public health, they may at the same time be somewhat ignorant of the method of carrying those laws into effect. But we must not dwell over such circumstances. Our business is to tell the Town Council of Perth, which, from old services in the cause of liberty, has a just claim to popular esteem, that it must take heed and amend its ways. The time is rapidly coming when antiquated systems of government will be judged of by their practical usefulness; and if thus tried in the balance and found wanting, they will run a strong chance of being abrogated and swept away.

When we began these notes we soon saw that we should necessarily fall into violent collision with the novelist and the poet. Our readers will now judge who has the best of it. Perth, under different circumstances, would be one of the most desirable residences in all Scotland. But who, in his proper senses, would at present think of going there to pay scot and lot. We cannot but think that in a sanitary point of view it rather does a town damage to be continually flattered for its beauty. The local guide-books are had enough; but even the staid old literary men who compile gazetteers are carried off their feet when they come to treat of this picturesque glory of Scotland, and write in the poetical language of the arcadians, or with the glowing metaphors of the troubadours. We beg to remind these gentlemen of the mortality tables. In future, while writing about the beauty, they must not forget the filth. A higher philosophy must teach them that there is no romance in bad drainage, and no chivalry in a high infantile death-rate.

#### ARCHÆOLOGIC ITEMS FROM ROME.

The first impression of Rome received by the traveller who approaches by the new railway-lines that sweep round the southern circuit of walls from the Tiber to the breach made in those battlemented structures for the railway-ingress near the Diocletian Thermae, is striking, and in some degree novel, even for those familiar with the local aspects. So contrasted indeed is this city with other Italian capitals,—in some respects so inferior as to refinement, comforts, civilization, in others so uniquely and nobly distinguished,—that one feels her outward physiognomy to be exceptional, strangely individualized as is her political destiny.

The resources of the Papal Government are, even with the unflinching auxiliary of the "Peter Pence," reduced to lamentable insufficiency; yet the vigour with which public works, and restorations of the Antique, have been carried on during the years ensuing since the dismemberment of these states, has been beyond the expectations even of friends, if not quite up to the level of deserts infernal from reports that always, in this quarter, partake of the grandiloquent, and almost always exaggerate. One result of the absolute denial of liberty to the press is, that its official organs cannot be trusted in regard to any claims on the gratitude or approval which may, or may not, be merited by authorities from a public only informed within certain limits of truth. The report lately published by the Ministry of Commerce, Fine Arts, and Public Works respecting restorations of monuments and civic improvements, from the beginning of 1850 to the end of 1864, though on the whole satisfactory, indeed honourable to this Government, is of a nature to raise ideas beyond realities, and is drawn up with details that are not all to be easily verified; some (we cannot but suspect) open to quasi refutation. We read of repairs effected in the fortifications of Servius Tullius, as well as in the *Agger* called after that king (that rampart having been, in part, broken and levelled with the ground, for railway purposes, within the period contemplated); repairs of the Pyramid of Cestius (its apex restored after the ancient one had been struck off by lightning); of the Tabularium, the Circus Maximus, the Pantheon, the Tomb of the Scipios, the Colosseum, the Forum of Augustus, the Arches of Constantine and Septimius Severus, the Column of Trajan, the Circus of Caracalla, the Portico of Octavia, the Aqueducts of Nero and Trajan, the Villa of Hadrian, the Thermae of

Titus and Caracalla, the Etruscan Tombs of Corneto (Tarquinii); and, moreover, the restorations of ancient ways,—the Latin, Prænestine, Appian, Claudian, besides the uninterrupted continuance of excavations in Ostia, in the Palatine, and at Prima Porta, and site of the Villa of Libia. Fourteen churches restored, and nineteen embellished with new paintings, evince the activity in the interests of those monuments naturally most precious in the eyes of this Government; and in order to display the movement of commerce in art-objects within this period, tables were supplied, from which we learn, besides particulars referring to earlier date, that in 1863 the ancient paintings exported from these states represented the value of 116,427 scudi; the ancient sculptures, that of 213,130 scudi; the entire amount of these exportations in the Fine-art Department, during six years, more than 8,000,000 francs. High-sounding and imposing is the above list; but if we confront it with realities, we shall find many of its items refer to things so trivial, many of the assumed "public works" confined to details so insignificant as to justify the charge against the ministerial report, of almost fallacious wording. Nothing has been restored at the Thermae of Titus or Caracalla, the Augustan Forum, or the triumphal arches, that can meet or declare itself to the eyes, without express particularization of every stone renewed or polished, every letter fresh cut in the epigraph. At the Column of Trajan, as at the Arch of Constantine, the only undertaking effected has been the execution of casts from the historic sculptures, at the same time ordered by this Government for Rome, as by the French for Paris; and one may be amazed at the archæologic science of this report, in reference to the "Circus of Caracalla"—the ruins implied having been long known to every eye since the distinct refutation of such misnomer, as the Circus of Maxentius, on the Appian Way. We visited that impressive scene, so picturesque in the Campagna solitude, a few days ago, for the first time after long absence, for perhaps the fortieth time since we first saw those interesting ruins, and certainly no perceptible traces of the restoring labours could we detect in any portion of the encircling walls, the extant *arcades*, the triumphal arch, or once-buried *spina*.

The discovery of an antique art-production pertaining to the highest order, is naturally an event to excite all attention, to become the subject of all talk and conjecture in this city, where other interests can be discussed so little at freedom; but it is long since any incident of the kind has made such sensation here as the exhuming, under the Pio Palace, of the magnificent Hercules statue, one of the priceless adornments of Pompey's Theatre, which has lately been removed from its original site for the requisite restoration (little more than one foot being wanted), by Tenerani, after which it is to have its place in the Vatican; we are not exactly informed in what locality that museum. The Academicians of St. Liko, invited by the Pope to pronounce *ex cathedra* upon the merits and assignable value of this colossal work, dwelt some time on the rather subtle question, whether it should be described of the *highest* or the *best* period in Greek art, the former definition having been (we understand) suggested by Mr. Gilson, but the latter unanimously adopted in the result. That theatre, connected with the curia of Pompey, which passed through such strange Medieval vicissitudes, and became eventually, with the curia, temple, and portico belonging to the same aggregate, completely buried underground beneath a labyrinth of obscure streets, near the present Campo de' Fiori, has from time to time yielded wealth, even from its hidden recesses, to enrich the Roman museums with some of their most prized contents. The *Bolvedere Torso* (also a Hercules); the Hercules with the infant Ajax, a *Melpomene*, a *Enterpe* (all statues at the Vatican), besides the celebrated colossus of Pompey, at the base of which "great Cosar fell," were alike found on the site once occupied by those splendid Pompeian buildings. In that Pio Palace, the fortunate discoverer of the new antique, Cav. Righetti, is having the works of excavation continued, whilst the Government is carrying on similar researches under the houses adjacent, with a view to laying open the ruins of the curia and portico. An inner court, presenting the scene of neglect and decay common to Roman palaces, is the area where labourers are now employed under Righetti's directions; and here we look down, at considerable depth, on remains of walls and pavement,

from amidst which had been raised, just before our last visit, a female figure, headless, and, indeed, little more than a torso, in fine marble, and beautifully draped; turning from which spot to enter a chamber off this court, we see a multitude of marble fragments, some most precious in material, giallo and verde antico, porphyry, *fior di Perseo*, Phrygian pamaazetto, &c., from the same local where the Hercules was found; a variety of architectonic ornaments, antefixa, and others very rich in character; masses of bronze in state of fusion (the evidence of injury suffered by fire), several terra cotta drinking-vessels of the coarser kind, probably from some *popina* near Pompey's Theatre, and a few busts of not common character, one supposed, from its deathlike aspect, to be a mask taken from the human original after decease; another a female remarkable for the head-dress, with hair gathered behind in a net, like some of the Italian fashions still to be seen in rural districts.

In the excavations in the Palatine the most important of late discoveries among the buildings of imperial origin is a massive substructure, reduced to but a few courses of square-hewn lithard tufa, isolated by its elevation on a quadrangular platform, referred by Signor Rosa to the Temple of *Jupiter Propagator*, and to all appearance an edifice of republican antiquity. The last-discovered work of art noticeable for high merit, is a torso of a man with a leopard-skin thrown over one shoulder, so grandly treated and firmly characterised in form as to have suggested the idea that this may be the veritable original by Praxiteles, often copied, and reproduced with more or less variation in several statues classed with the most valuable antiques of Rome's museums.

A remnant of the Servian walls in eight courses, at different lengths, of square-hewn stone blocks, brought to light in works for levelling the uneven space before the Quirinal Palace,—this structure belonging to a buttress that supported the slope above,—is among late discoveries to notice; but condemned, we believe, to demolition for improvement of the approach to the papal residence. In levelling for a new street to reach the central railway-station, opposite the Diocletian Thermae, have been opened several chambers in the inferior brickwork of those ruins, a more conspicuous hemicycle, and a larger hall containing hats, with verde antico pavement; but these, it appears, must share the fate of many antiques brought to light in the course of works for utilitarian purposes during recent years, by being sooner or later destroyed.

#### SOCIETY OF BRITISH ARTISTS.

There is little to distinguish this, the forty-second exhibition of the Society of British Artists, from those that have recurred from year to year for a long time past. Accepting it in its integrity, and looking for no novel feature to enhance its interest, it will be found to include the average amount of attractiveness the members have been wont to offer their several admirers; and if it afford no justification for congratulation to them for any advanced position or promise of fresh vitality, such as might be obtained from young and able members of the profession joining their ranks, it at least testifies to the ordnung qualities of whatever claims they may have to attention and consideration now potent to them.

The present collection is an unusually large one, comprising oil pictures, water-colour drawings, and sculpture, to the number of 1,042 works. The multiplicity of performances that will now shortly be in evidence before the public, will help by-and-by to raise an inquiry as to what becomes of this incessant and increasing supply of these not indispensable adjuncts to existence? And perhaps as soon as something like a satisfactory elucidation of the mystery attached to the ultimate fate of pins has been arrived at, it might be allowed to replace that puzzling question as one nearly equal to it, involving as much conjecture, and far more important consequences for statistical result, to any who would wish to see the influences of fine art spread with the generous breadth of sunshine over a wider radius than it yet has reached.

It must be evident to those who are at all inquisitive about the matter, that but a comparatively small proportion of most people's acquaintance, extensive as it may be, are in possession of pictures painted within the last

ten or twenty years, unless they happen to be fortunate Art Union prize-holders, and whilst they are well aware of the great demand for ready good, and also in some cases really had emanations from well-known and popular names, and the vast absorption of the best class of pictures by wealthy collectors, must wonder sometimes—making allowances for a fair distribution of taste and discretion,—where at least one-half the mass that most exhibitions consist of finds a market and a destiny—and think it almost a cause for regret that nearly all that is most desirable should become part and parcel of gathered numbers, when, if more widely distributed, each item would do more towards encouraging and improving that taste than all the most elaborate and exhaustive essays ever written on the subject, however much they may assist in directing it.

Tastes are known to differ; otherwise it would be easy to reduce the hypothesis of half the doubts that surround it, at least. Perhaps it is occasionally more necessary to ask for the exercise of discretion than that of taste; if it be not a discerning one: however ungracious the remark may be, and though it applies elsewhere as well as here, it too often happens that the favourable opportunities for comparison are by no means strong or frequent enough to mark the degrees of what is the reverse where there is such a preponderance of it.

In the absence of any material assistance such as their invitation to general contributors at times procures for them, the character of the annual display in Suffolk-street varies so little, and the specialities of the best known members have now become so thoroughly to be identified with their names, that it is supererogatory to say much more of the present collection than that the weight of it is evenly divided amongst them.

Mr. F. Y. Hurlstone, the President, still devotes his resources to the representations of Italian beggar-boys so happy in their vagabondism and picturesque in their dirt. These "Descendants of Marius and the Gracchi amidst the ruins of the Roman Empire" (385) are the degenerate scions of hero ancestors easily recognised by northern appreciators of burly-gurdy music, who do not object to being reminded of a familiar association with monkeys and have no dread of fleas, though here they are to be seen at home with only some of such belongings—the least likely to inconvenience them—as they lie stretched in classic drape and all the glory of a temporary independence, sucking grapes; or sit curling their knees in abject repose. Very different from Mr. Hurlstone's sun-burnt types are Mr. Baxter's specimens of complexion "The Sisters" (47), one with the blue eyes and the other with the brown; how impossible it would be to decide upon a preference if the artist did not assist in some measure by throwing one into shade: so creamy, so delicately rosy and waxen soft are these ineffable beauties of Mr. Baxter's that it is absolute cruelty on his part to send them out of doors without veils, unless he would like to see them tamed a little, which to some would appear to be a very laudable desire; or, perhaps, he knows that his cutaneous preparations are warranted to withstand all atmospheric or other uncertainties; for even in "Winter" (511) the possibility of a red nose (and no veil again!) is never so slightly hinted at. Mr. J. J. Hill adopts some of his precepts: "Innocence" (198) will show to what extent.

Mr. Salter contributes an illustration from English History, "Queen Elizabeth reproving Dean Nowell in the vestry of St. Paul's" (131) for presenting her with an illuminated service book by way of a new year's gift. It may be remembered that her majestic lived considerably before our time, and had some strict notions with regard to idolatry.

Mr. Woolmer is more dreamy and enigmatical than ever, though often suggestive in his perfectly imaginative creations. "Miranda Sleeping" (417), in an enchanted and enchanting attitude, and a graceful figure of a young girl disrobing, "Returned from the Ball" (664), are more satisfactory than another selection from "The Tempest," "Prospero's Isle—Ferdinand and Miranda playing at Chess" (266), where too much is left to be understood by the spectator.

Mr. E. J. Cobbett's conspicuous group of peasant children, entitled "The Thorn" (108), is less pleasing than some of his numerous too similar treatments of too similar models. Mr. G. A. Holmes has a sweet little study of childhood. "The Blackbird's Song," "Oh, Blackbird, sing

me something well" (168), is one of the most complete pictures in the rooms, notwithstanding its small size and rather excessive prevalence of pink in the flesh-colour. Mr. W. Hensley's "Grace before Meat" (58), is unaffectionately simple in its homeliness and well painted; and the same should be said of Mr. James Collinson's domestic incident, "The Bird's Nest" (67), for the conscientious pains that have been bestowed in both cases are also deserving of the acknowledgment earned by either.

Mr. T. Roberts chooses his actors of everyday social life from a higher grade, and is none the less natural for the refinement that distinguishes his agreeable method of depicting them than those who ignore such aid; "The Family Pew" (64), though the family of family pews may be growing somewhat too large, is a very pleasing and companionable picture.

To note others, Miss E. Osborn's courtship of German lovers, "Of course she said Yes" (46), though the very tall fair one is in a very awkward position—physical as well as mental—deserves a better place; "The Pangs of Poverty" (176), by Mr. E. C. Barnes; "Sunday Afternoon" (185), by Mr. G. Pope, curiously and thoroughly indicative of quietude and repose; Miss Kato Swift's pretty little French girl with "A Lesson to Learn" (69), intent on getting it by heart—which she certainly and speedily will do; so bright is she by nature, and standing for further enlightenment still in a flood of bathing sunshine, she looks the refection of reflexion, and a charming little emblem of progress and knowledge besides.

Mr. G. Bonavia's "Child of the Country" (422) is arch and pretty, and, with Mr. C. Rossiter's "Gentle Help" (633), Mr. W. Bromley's "Grace" (666), and others of cognate merits, are sure to secure their share of praise.

There is something excessively good in Mr. F. Holl's "Knitting" (343); it shows close observation, and a power of investing trifles with art value quite rare enough to be remarkable; Mr. A. B. Donaldson's fine sense for colour condones the fault of affecting a mannerism all too prevalent. "The Empty Fountain" (307) is but a title to what may prove to be a source of promise; and Mr. W. Holyoake's love-lorn damsel, "Love Not; the Thing you love may change" (369), is too well painted to be overlooked.

The landscape department, including so many professors of established notoriety, has always been the more important section; and if there are no signalising instances of exceptional worth and interest, there are many that will help to support this old claim to superiority, although it is very reasonable to expect that if no recruits are forthcoming, each successive season will make it more apparent that the members have been too independent of natural consequences and too reliant on their own endurance, for it can never be concealed that time is inexorable to all of us, and shows little favour at the last.

Mr. J. B. Pym's stately composition, embracing "The Roman Aqueducts, from the Palace and Church of St. John Lateran, with the Alban Hills, &c." (205), has afforded him ample opportunity for indulging in those glowing lines he delights in: this, with "The Church of San Giorgio Maggiore, with the Dogana, Venice" (495), well sustains his high reputation.

Mr. G. Cole is very forcibly represented. His brilliantly-illuminated landscapes dazzle the eyes, and leave them blind to anything that is uninteresting enough to be in their neighbourhood. "Returning from the Harvest Field—Autumn Evening" (88) vies in the intensity of its effect with a real approach of sunset. Mr. H. J. Boddington, Mr. Alfred Clint, Mr. J. P. Pettit, and Mr. J. J. Wilson are all announced in numerous examples of that particular forte that has long ago been accorded to them; and Mr. J. Syer, less remarkable for the number than the quality of his works, has provided one of the leaders, "A Mountain Rill" (511); Mr. W. S. Rose's cleverly-painted triptych, "Morning, Noon, and Night" (194), and "The Shower is Over" (262), by Mr. H. Shirley, are assistant items.

There are more water-colour drawings than the society habitually find room for, and so many of them are meritorious, that it was a wise step to provide the extra accommodation of a screen. We have room but to mention Mr. W. W. Gosling's "Flew-netting on the Thames" (749); Mr. T. F. Wainwright's carefully-drawn studies of sheep in "Winter on the Thames"

(780); "The Reculvers, Kent," painted on the spot (795), by Mr. J. V. De Fleury; Mr. G. Wolfe's very suggestive and imposing drawing, "A Message from the Sea" (812); Mr. H. Corbould's cattle subject entitled "Lords of the Isles," (825); "On the Thames, near Wargrave" (826), by Miss S. S. Warren; Mr. G. Pope's "Rebecca admiring the Armlit" (867); Mr. Wyke Bayliss's "Westminster Abbey, view from the Chancel" (906); Mr. J. Hardy's capially drawn and coloured study of dead partridges and pheasants, in "October" (913); "The Outskirts of the Forest, Sherwood" (945), by Mr. H. A. Harper; "An Abyssinian Negro" (967) by Mr. A. Haesam; "In the Woods at Ardencaple, Dumbartonshire" (987), by Mr. T. Fairbairn; "The Cottage Door" (989) by Mr. H. Webb; "The Gamekeeper's Cottage" (990) by Mr. H. T. Green; "Late Autumn" (995) by Mr. H. C. Warren, and "Le Maltraite" (1002) by Mr. S. T. Whitford.\*

#### OUR SUGGESTION FOR THE LIBRARY OF PARLIAMENTARY PAPERS.

On Friday evening in last week, or subsequent to the publication of our number containing the article headed "Blue Books made Useful" wherein we suggested the establishment of a public and special library for Parliamentary Papers, Mr. William Ewart brought on his motion for a digest or abridgment of the papers of each session; when after some discussion, and in the absence of support from the Government, the motion had to be withdrawn. We need only observe that the arguments which secured the rejection of the particular proposal of Mr. Ewart, were insufficient; but that they cannot be regarded as the strongest arguments for the library. The digest would not render unnecessary, reference to the documents themselves: the library would permit of this reference; which now cannot be made at all, in a large number of cases. Mr. Y. R. Yorke, in the course of the discussion, having mentioned that last year 50,000 pages were issued at a cost of 67,000*l.*, said,— "It was lamentable to reflect what a large proportion of this expenditure might be said to be entirely thrown away. He would suggest that the large number of copies now printed *in extenso* were not necessary, and that if a small number were printed and so placed as to be readily accessible for reference, that would be quite sufficient for all public purposes." Clearly however as this pointed to the library, that mode of attaining the object was not referred to by any speaker.

#### THE MACADAM ROAD-WAY OF PICCADILLY.

The efficacy of the macadam roadway to sustain the traffic of a great metropolitan thoroughfare will shortly be tested in the above-named great line of communication. The success attending the Regent-street roadway in its highly-improved condition,—as maintained under the contract system, as distinguished from that of parish work,—has, by reason of its smoothness and consequent noiselessness under the traffic, been found so great a benefit to the traders of this street as to induce the St. James's vestry to yield to the earnest solicitations of the traders of Piccadilly and Coventry-street to have the boon extended to them. The resolution of the vestry for this was come to in the early part of last year, but the vestry, seeing that there was another good year's service in the existing pavement, deferred the immediate execution of the order. The work of laying down the new roadway has, however, now been commenced, and is to be completed by Easter; and no interruption, in the meantime, to the free passage of the street is to take place.

The contract is taken by Mr. Browne (who also holds the Regent-street contract) for seven years, at 1,480*l.* per annum for maintenance, inclusive of scavenging and watering, with 870*l.* and the old stones for the conversion. The line of way thus to be treated commences at a point in Coventry-street a few paces west of Leicester-square, and terminates at the corner of St. James's-street; the part of Piccadilly lying west of the latter point being in the parish of St. George, Hanover-square.

\* At the meeting of this society held for the election of members, on the 27th of March, Messrs. Wyke Bayliss, E. C. Barnes, and E. Hayes were elected members.

## THE PROJECTED POLAR EXPLORATION.

The hopeless and absurd attempt to discover a practicable "north-west passage" for ships into the Pacific Ocean, by way of the ice-bound regions of the extreme north of America, has been finally given up; and it is to be hoped that future explorations of the Arctic regions (for there must and will be further attempts to reach the pole) will cease to follow the old routes westward, or to allow the old impracticable notions of a north-west passage for shipping to have any such adverse influence as it has heretofore had in leading explorers away from the more interesting scientific object of arctic voyages,—the discovery of the north pole.

The warm gulf-stream runs north-eastward from the tropics by the British isles and Spitzbergen; then circulates round the pole; and then returns—as a cold current—chiefly through the north-westward regions about Baffin's Bay and Greenland, southwards by Nova Scotia and Newfoundland, where so many icebergs hence occur in summer. Thus, and from the stretching of land (which is always much colder than water) so far north towards the pole in America, the north-western region is pre-eminently the frozen region; and yet it has always been with the ostensible view of discovering a passage in this direction for ships, that our sailors have been sent into the arctic regions. Now, however, that the real, as well as the ostensible, reason for further explorations will henceforth be the actual discovery of the north pole, I hope that the suggestion made by me in the *Builder*, many years ago, that to follow the warm gulf-stream must be the most hopeful route to the pole, will be adopted. Some years since, Dr. Petermann claimed this suggestion; but I pointed out in the *Builder* at the time that it had previously been publicly suggested in its columns. Whether Dr. Petermann or the *Builder* were the first to publish the suggestion, however, does not much matter. It is of far more importance now for me to note that the suggested route has obtained the approval of such authorities as Sir Edward Belcher, Admiral Ommanney, Admiral Fitzroy, and Admiral Maury, all of whom have expressed their preference for that route, while discussing the subject, on Monday last, as you would observe, at a meeting of the Geographical Society, where a letter of Dr. Petermann, advocating the Spitzbergen route, was read.

In course of the discussion, Admiral Fitzroy referred to the records of the voyages of Dutch sailors in the fifteenth and sixteenth centuries, which stated that they had sailed as far north as 88 deg. and he thought that these records were quite reliable. He entered into a consideration of the circumstances which might form a barrier of ice round the north pole, and leave an open sea within. He conceived that the action of centrifugal force would tend to impel the masses of floating ice towards the equator; and that, arresting a wind blowing in a contrary direction, the ice would be confined within a certain zone surrounding the pole, like an icy ring, but not extending to the pole itself. He stated that it had been observed, both in arctic and antarctic regions, that the mercury in the barometer falls on approaching the poles, thus indicating that the pressure of the atmosphere is less at the poles than at the equator.

In Dr. Petermann's letter, it was remarked that the argument in favour of finding an open sea near the north pole was greatly strengthened by the known condition of the ice in antarctic regions. It was an ascertained fact that there was much more ice near the south pole than there was towards the north, and that icebergs and masses of ice approached much nearer the equator in the south; nevertheless, Sir James Ross had succeeded in penetrating through a barrier of ice many miles in extent, and reached an open sea, and came in sight of an antarctic island or continent, with mountains 10,000 ft. high. If this could be accomplished near the south pole, where the ice was so much more abundant, it was contended that there would be little difficulty in penetrating to the north pole, where the ice is in summer broken up, and generally less abundant.

That an open sea does exist beyond the icy rampart which surrounds the north pole, and that land there also exists, as at the south pole, have already been proved by Dr. Kane and his party, who penetrated through the northern barrier, *viz.* Baffin's Bay to latitude 81°22', in 1853-4, and "came to open water (I quote from my own notes, made at the time of the return of the

expedition), 81 miles north of the coast of Greenland, where the temperature rose to 56°, from an intense cold farther south, which produced lockjaw, and killed two men and fifty-seven dogs. Numerous animals, birds, &c., were seen at the open water, and a mountain was discerned at 82°30' N., and called *Perry*." Here there was evidence not only of an open sea beyond the icy barrier, but of polar land like the antarctic, in that open sea, although Dr. Petermann maintains the probability that there is nothing but open sea within the northern ice barrier.

In adjoining the discussion, Sir Roderick Murchison said that at the next meeting a paper would be read, in which the author would undertake to prove, by reasoning from physical causes, that the temperature is warmer at the north pole than at a distance of several degrees from it. It was an opinion which had received the sanction of Sir John Herschel; and, on the discussion of that paper, the subject of the north polar exploration might be resumed.

It is to be hoped that in this promised paper it will not be forgotten that Dr. Kane has already attested the fact that it is warmer beyond the icy barrier, and that an open sea does there exist, with mountainous land in it polewards; and, with the warm gulf-stream constantly circulating through it, carrying in heat and bringing out cold, like a warming apparatus, how can it be otherwise?

Can it be possible that this polar sea-girt land, and its milder region beyond the icy barrier of the north, were known in ancient times? We have seen, from Admiral Fitzroy's remarks, that the Dutch voyagers of the fifteenth and sixteenth centuries seem to have got as far north as 88°; but my question relates to far more ancient times, and to a land "beyond the cold north wind,"—a hyperborean land, in short, of which there are records, or fancies, in heathen mythology; but if merely fancies, they are certainly startling in their curious coincidence with our most advanced scientific ideas of the polar region.

Thus, we now find it reasonable to believe, without any reference to such traditional, or even to its merely mythological, notions, that the icy region of the north only surrounds, with its barrier, the stronghold of the mountain-studded oceanic polar basin, and does not extend into its mild and "open sea," which is full of animal life. Therefore, "the cold north wind" must originate in the icy ring or rampart around the milder polar region, and not extend to, or come from, or include, that polar region itself, which must hence be actually beyond these boreal blasts, or truly hyperborean,—an idea till now quite unintelligible; and seemingly in all respects, or to all appearance, impossible. Yet this is now, as I have said, the most advanced scientific idea that we have of the north polar region!

"The Hyperborei," says "Smith's Geographical Dictionary," "were believed to occupy the remote regions of the north, beyond boreas or the north wind. They never felt the cold north wind, but had their lot fixed in a happy clime, where, like an alpine summit, rising above [or beyond] the storms, they were surrounded by an atmosphere of calm and undisturbed serenity." They were a pious people, "living in perpetual serenity, in the service of their God for a thousand years!" There was "no doom of sickness or disease for this sacred race: they lived apart from toil and battles, undisturbed by exacting Nemesis. But, at length, tired out with this easy life, between the sun and the shade [six months in the light and six months in the shade], they leaped, crowned with garlands, from a rock, into the sea,"—the open hyperborean sea.\* It is with allusion to the mythical Hyperborei that the Arimaspi are spoken of, who "steal the gold from the griffins," whatever that may mean; and who "live in a country where the men sleep half the year, and the air is filled with feathers." The myth, or tradition, as to the Hyperborei, was an Eastern no less than a Western one. Colonel Franklin, in noting the connexion between the mythoses of the East and those of the West, says of the Eastern:—"The gods are

\* That the arctic region was "once upon a time" tropical, or even ultra-tropical, and hence capable of yielding "garlands," there can be no doubt; although that was certainly "a long time ago." Bally points attention to the fact, too, that the polar region must have been the first habitable part of the globe, as it cooled. But still, that must have also been a very long time ago. It is just worth noting, however, in connexion with the text, and from the curiosity of the whole series of coincidences.

Merupa—Meropes of Homer,—signifying, in Sanscrit, Lords of Mount Meru, the north pole, of the Hindus, which is a circular spot, and the stronghold of the gods: it is called *Ila*; or, in the derivative form, *Ileyam*, or *Ilium*."

Now, what I maintain is, that, making all allowance for mere mythological fancies, there is something very remarkable about these fancies and their coincidences with our most advanced ideas as to the north pole. The very notion that the polar mountainous land, in the open sea, beyond the cold region of the north, is "a circular spot," must itself be highly probable, if there be any land at all there, as Dr. Kane's observation of a mountain appears to indicate that there is; for the gulf-stream evidently circulates round the pole, and any land there must naturally have assumed the form of "a circular spot." Whether it ever was, or still is, "the stronghold of the gods," whose barrier walls or ramparts and fortifications are assuredly godlike in their magnitude and strength if not impregnable, we had better leave it to Captain Osborn to ascertain for us. But I sincerely trust that the gulf-stream may prove to be the clue of Ariadne, which shall lead him within those godlike barriers of eternal ice, and into that mild and serene hyperborean region of modern science, which is known to teem with animal life at least, if not with spiritual.

JOHN E. DOVE.

## ON THE BETTER SUPPLY OF ANIMAL FOOD FOR THE PEOPLE.

OWING to various causes, there has been for some time past, and there is just now, a continued rise in the price of animal food; and the great masses of the industrious and poorer classes of the community are deprived of the means of providing a quantity of such food sufficient for the preservation of a proper duration of life, and insuring a right amount of that health and strength upon which the welfare of the country in so many ways depends.

While, at home, the price of butchers' meat is so high that its use has become an occasional luxury instead of a matter of daily consumption, in foreign lands there are immense quantities of the most nutritious food which is yearly allowed to be wasted, in a manner not only wicked, but also foolish. In Australia, for long, great flocks of sheep were slaughtered, and only the hides and the fat preserved. In that country there is now a greater demand for this kind of meat; but there are comparatively boundless expanses of land on which sheep and cattle only require to be placed, and a little care for, in order to insure a supply of this important necessary sufficient for the need of a large part of Europe.

In South America almost countless herds of wild cattle are killed for the sake of their hides, hoofs, and horns, and no doubt, if needful, the number of cattle produced in these regions might be increased to an extraordinary extent. In the Crimea and other parts of the Russian territories, and elsewhere, there are either already in existence, or there might soon be provided, great quantities of nutritious food; but it has unfortunately been the case that the distance of those extensive grazing grounds has rendered it impossible to bring this food to the populous parts of Europe in a fit condition, or at a cost which would render it serviceable. New means are now, however, being brought into use, and exertions made, which give promise of future good results. For instance, in parts of the prairies of South America, plans on a large scale have been adopted for the purpose of preparing the prime parts of the animals which abound there, so that they may be carried in a wholesome state by shipping to distant parts. And now we have accounts of the importation of considerable quantities of South American meat,—into London, Glasgow, Liverpool, and some other large towns,—which can be sold at 3d. a pound. It is said that this meat, which is prepared by a simple process of curing, and drying in the sun (which gives it, by the way, a not very inviting appearance, except to such, perhaps, as are familiar with the appearance of good dried fish, and prefer it to the soaked and lime-whitened rubbish which the Londoners prefer), is of excellent quality when brought to market, and medical and other authorities state that it is good and fit for the purpose of food. In cooking, it requires to be soaked in luke-warm water for three or four hours, and then it can be used in the ordinary ways. It makes very good soup, or, cut into

pieces and boiled with vegetables, a wholesome Irish stew, and is soon ready. Satisfactory pieces may be selected, rolled, stuffed with herbs, and well boiled. In many other ways a managing housewife will provide palatable and healthful dinners for families with this meat at the price of 3d. a pound. Properly managed on a sufficiently large scale, the American beef will be most valuable in soup-kitchens, &c. In providing food at a very moderate cost for the poor, and in most families of the industrious classes, it may be made to serve a valuable purpose; but it seems that there is likely to be a difficulty for some time to come in getting a sufficient supply of the article into the proper market. In London alone, an enormous quantity of this beef would be likely to be consumed; but it will be necessary that people should have the means of seeing and purchasing small quantities of it, in order to judge properly of its quality. In London, few persons would know where to buy this meat, and it would be an advantage if those who are promoting this importation were to open, in the populous parts of the metropolis, depôts for the sale of the commodity, in connexion with which we believe that there is an extensive trade to be done; but, in the first instance, it is doubtful if this will be properly managed by the regular butchers, who are slow to recognise the introduction of any new commodities into their business. It would, therefore, be of advantage to establish agencies for the sale of this meat, at which quantities of from three to four or five pounds might be purchased, and where there may be no chance of disguising bad kinds of English beef in something of the same shape as that imported.

In Ireland, there has been a considerable decline in the number of cattle yearly produced; and there is no doubt that there, as well as in large portions of Scotland, England, and Wales, there are opportunities for the production of animal food which are at present neglected. The utilization of the sewage may be a means of remedying this defect to a considerable extent, and the foreign traffic in live sheep and oxen, and stann and other carriage, is largely increasing. Notwithstanding this, however, as we have stated, the price continues to increase also, and it becomes, therefore, a matter of vast national importance to avail ourselves of new articles of food. And it should also be borne in mind that the extension of the culture of various kinds of poultry, fish, and even some descriptions of game, may be made a means of cheapening the price of butcher's meat and improving the food of the people.

Baron Liebig has recently communicated the particulars of a new extract of beef to the *Annalen der Chemie und Pharmacie*. Since the introduction of this extract of flesh, the *Lancet* reports on its great efficacy in numerous cases of debility, indigestion, &c. It appears that large quantities of this preparation are made in Uruguay, for use in Europe. To a certain extent the extract is used for domestic purposes: its present price is 2s. per ounce, and it is said that even poor persons who have once experienced its beneficial effects return to its use. Liebig says, that for the last fifteen years he has recommended the use of this preparation of meat to the dwellers in Buenos Ayres. On reading his account of this extract, Herr Geibert, an engineer of Hamburg, who had spent several years in South America and Uruguay, came to Munich to learn the process of making the extract, and afterwards proceeded to South America for the purpose of undertaking its manufacture on a large scale. As is usually the case in connection with all new introductions, numerous difficulties were thrown in the way of this gentleman, who was desirous of proving a benefactor, not only to the people of those distant countries, but to the world at large. Eventually Herr Geibert got Baron Liebig's conditional permission to use his name as patron of the extract. Recently 50lb. of the extract of beef, and 30lb. of extract of mutton have been sent from South America to Milan, and it is said that both quality and price are most satisfactory.

A few words on our metropolitan fish-markets will not be out of place here. For many years past we have had, in this great population of nearly three millions of people, only one fish-market which really deserves the name. At Hungerford, and one or two other localities, there were, and, to a certain extent, still are, places for the sale of fish; but Billingsgate is the great emporium where one of the most important articles of human food is bought and sold,

notwithstanding that most important changes have taken place in the manner of the transit of fish and other commodities. Not more than about a quarter of a century ago, the deep-sea and coast fish, the oysters, crabs, lobsters, periwinkles, and other shellfish, were brought for the use of the Londoners by water, in vessels of different descriptions: now enormous quantities of fish are brought from the coasts and rivers of Scotland, Ireland, and England, by railway. In the meanwhile the metropolis has branched off in every direction, and the demand has been increased in consequence of the advance of the population. The distance to which fish has to be carried has also materially increased. Still, Billingsgate continues to be the chief—indeed, almost the only mart, to which there is perhaps so much fish taken in waggons and other carriages, from the various railway termini, as is landed from the vessels, and in consequence the land-approaches to this celebrated but insufficient market present a scene of confusion during several hours of each day, which only those who have had the means of personal experience can appreciate.

With the greatest difficulty the goods are got into the hands of the salesman in their limited space; and, amid noise and tumult, the packages of fish are disposed of and taken by conveyances of many kinds, to the market at the New-cut, the Bill, and other well-known spots; and to the fish-shops in Bond-street and other aristocratic neighbourhoods, as well as to those of more humble pretensions. By these means there is frequently as much time spent in taking the fish from one of the railway termini to Billingsgate, and from thence to the distant places of sale, as there has been in the passage from the coast to the metropolis.

In regard to the wholesale dealing in fruit and vegetables, there is a similar just cause of complaint; and the price of potatoes and of some other articles which are in constant use, is increased by the distances to which they have to be removed. In order partly to obviate this inconvenience, so far as the Great Northern Railway is concerned, the managers of the line have recently opened a market for the sale of potatoes on a part of their premises in the York-road, near King's-Cross; and this has proved to be of so much benefit to the potato dealers and to all concerned, that it is contemplated to open a fish-market here also; and it is suggested that if this be carried out, not only here but also at other railway-stations, it will lessen the expense of the consignors and consignees, and will also be the means in certain districts of causing the fish to be delivered in better condition, and reducing the number of carts, vans, and costermongers' barrows, which block up Lower Thames-street and the adjoining thoroughfares.

When we take up the modern map of London, and glance at the immense space which within a very short time has been covered with human habitations, and by reference to the census reports learn the extent of the population, and take that of St. Pancras, Islington, Marylebone, &c., and compare these with the great English towns, such as Manchester, Liverpool, Birmingham, &c., as regards the extent of the market-places for provisions, it will be seen how much improvement is needed in London in this way; but as we have often before said, although this need of change is evident to all who have given thought to such matters, it is most difficult to get a movement made in the right direction. We hope, however, that the Great Northern Railway Company will persevere as regards the fish-market, believing that it will be so successful, that other railway companies may be induced by the results to imitate the example.

In further connexion with the subject of food-supply, we may here remark, before concluding, that in the *Veterinarian*, a lady correspondent, under the signature of "Humanitas," suggests that cows' milk might be made much more suitable to the tastes and stomachs of infants were the cows fed upon provender containing more of the elements of sugar, and of carbon and alkali, than is usual; the purpose being to make the milk (with water) more to resemble the food proper for infants. Experiments might be tried to this end, for which "Humanitas" suggests beetroot, or carrots, corn, bran mashes, and grains, or hay, in fitting proportions; but it may be that no modification of feeding would much alter the quality of the milk proper to calves; and even were it so altered, would such customers as the Londoners prefer it to the milk of which "Humanitas" complains that they use so little?

Perhaps not. Even as it is, they are said to prefer impure milk to pure, from being so accustomed to it in an impure state; and we are persuaded there is some truth in the anecdote as to a new milkman who provided purer milk than his predecessor, and was only grumbled at for giving his customers stuff which soon got "a nasty smon on it," such as they had never seen before in his regretted predecessor's time.

Since the preceding remarks were prepared, a paper "On the Preservation of Food, especially Fresh Meat and Fish, and the Best Form for Import and Provisioning Armies, Ships, and Expeditions," by Mr. G. C. Street, F.R.C.S., has been read at the Society of Arts, Adelphi. Mr. Street well appreciates the vast sources of animal food in South America and elsewhere, but expresses an unfavorable opinion on the mode as yet adopted in South America for preserving beef by drying it. Though the meat, *per se*, is of good quality, there is a nasty flavoured about it, he has found, which renders it by no means likely to be saleable in this country. \* It is not necessary to describe the processes for preserving meat, such as Mr. Morgan's method of injecting a whole carcass at once if need be, through the blood-vessels, with a saline liquid or brine; the method of preserving cooked meat in cases; and the inclosure of raw meat in an artificial atmosphere free of oxygen. Of this last method he says:—

"This process appears to be exceedingly applicable for the import of fresh raw provisions from countries where they can be obtained at small cost. It is available for putting up meat cut into joints suited for the consumer, which it is not necessary to separate the meat from the bone, so that the shape and natural appearance of the joint are well preserved. The cases might be received in this country by the same means as the tin cases for joints; them and dealt with as if just purchased at the carcass butchers, or, while in the cases, it might be transferred from town to town, as occasion might require; or, on the other hand, the meat would be in a ready and safe form for victualling armies or supplying ships. Indeed, whole carcasses might be packed singly or in numbers in tanks or in casks furnished with tapers, these might be treated in exactly the same manner as the tin cases for joints; instead of soldering on the cap it could be made air-tight, by means of binding screws, washers, &c. Suppose, for the sake of illustration, that a factory was established in any district where animal food might be found in great plenty, all the best portions of the animals, the joints, might be preserved and put up raw by the atmospheric process, while the parts not available for that procedure could be made into steaks, curries, soups, ragouts, &c. These cases, both of raw and cooked food, might be then transferred hither and thither where most needed. Such a plan is about to be carried out by a company recently established, who will have a factory or factories abroad, and who are just starting a like business at home. They propose to purchase the cattle, pigs, poultry, fish, game, &c., at first hand, to slaughter and dress the cattle, and, after preserving the finest joints by the raw-meat process, to put up the remainder by the cooking method. This will insure all portions used not only to be fresh and free from taint, but to be obtained from healthy animals, and therefore most fit for human food, and conveying into the system the largest relative amount of nutrition."

It becomes a matter of necessity that this plan, or something like this, should be adopted, for we cannot shut our eyes to the growing wants of our population, and the increasing dearthness of animal food. Not only the South American prairies, but our own Australian and other colonies, might be thus made most useful to us; and even nearer home an immense supply of fresh butcher meat might be had from Russia, through the Mediterranean and the Baltic, as now we have it, and of the finest of all qualities, too, from the North of Scotland by railway, without any artificial process of preservation.

#### FRANCE.

A CERTAIN number of the departments of France, such as the Haut and Bas Rhin, Les Vosges, La Sarthe, Le Lot, &c., are actively engaged in transforming a portion of their great roads of communication into railways for vicinal traffic. The Bas Rhin led the way, and has given good results for the first three months of working.

A company has been just formed, in Paris, for the establishment of a Halle aux Cuirs, or Leather Market in Paris. Its capital is to be 130,000*l.*, divided into 6,500 shares of 20*l.*, and the intention is, 1st, to construct a *halle* and general warehouses and sale-rooms, to open an isolating thoroughfare all round of 49 ft. wide, and to execute all the works dependent upon the construction and carrying on of the establishment, appropriation of old buildings and lands, &c.; second, to carry on the exploitation of the *halle* and two sale-rooms for public sales of skins

\* Dr. Lethely states that he has examined various samples of the charqui, and has always found that the fat was rancid, but the lean, of which he has partaken, quite wholesome.

and leathers of all sorts; third, to purchase all lands necessary for the present construction or for further requirements of these *halles*; fourth, to have the power of issuing warrants negotiable by the Bank of France or any other bank. The works are to be commenced at once, so that the establishment may be opened at the end of the year.

The water-supply of Paris,\* furnished by the Seine, the Ourcq, the sources of Belleville and Arcueil, and the artesian well of Grenelle, and about to be increased by the waters of the Dhuie, the Marne, and the two artesian wells of La Chapelle and La Butte-aux-Cailles, is, it is stated, to receive a further addition, by a supply from the Vanne, a tributary of the Yonne. This water-course, fed by the streams of Moulin de Noé, Cbigny, Thiel, Malhortie, Saint Philibert, and Armentières, can furnish 22,000,000 gallons of fresh water, but only at a height of 230 ft. above sea-level, and can be brought to a reservoir at Montrouge, whence the lower quarters of the town can be supplied up to the highest stories. Starting from the Vanne, near the Armentière Farm, in the department of the Aube, this canal can, if required, receive at a future period tributaries from the sources of Lunain, Orvanne, l'Abime, Villemer, Fontaine-Carrée, Chaintreuveville, and the Gouffre de la Prairie.

The new reservoir at Meuilmontant is expected to be finished in the month of May next, and will contain 22,000,000 gallons of spring-water, at a height of 354 ft. above the sea, and 7,700,000 gallons of water of the Marne, raised by the St. Maurice machines to a height of 328 ft. above the sea. The first half of the Telegraph Reservoir, at Belleville, is nearly completed also; this is to receive 33,000,000 gallons of spring-water at a height of 440-95 ft., and 5,500,000 gallons of water of the Marne, at a level of 430-12 ft. above sea-level. Already one of the compartments is supplied with Seine water by the pumps at Charonne. The works for the supply from the Dhuie are well advanced; in 1863 about 10 miles of aqueduct or syphons had been completed. In 1864 there were 59½ miles, so that only about 10 miles remain to be executed, and these are expected to be finished for service in May next.

A subscription has been opened at Clâteau-Thierry for a monument commemorative of the battles of Champaubert, Montmirail, Clâteau-Thierry, and Vauchamps, fought on the 10th, 11th, 12th, and 14th February, 1814. The monument, consisting of a single column, of the Corinthian order, is to be erected on the boundary line between the two departments of L'Aisne and La Marne, in sight of Montmirail and Marchais, on the very spot occupied by Napoleon I. at the most decisive moment of the battle. The Emperor Napoleon III. has subscribed the sum of 4,000 £. (160*l.*) for this monument.

#### THE PARIS BRIDGES.

In the whole length of Paris as it now stands, *i.e.*, between the fortifications, about 7½ miles, there are eighteen communications between the north and south sides of the Seine; these, on account of the islands of the city proper and of Saint Louis consist of twenty-five independent bridges. Of this number, all except seven have been either altogether newly constructed, or have been rebuilt or repaired during the past few years.

The new Pont de Bercy has just been rebuilt of stone, in place of the suspension-bridge erected in 1835, so that no example of this sort of structure remains in Paris except the *passerelle*, or foot-bridge of Constantine, leading from the Halle aux Vins to the Ile St. Louis. The Pont d'Austerlitz, an iron bridge built in 1807 only, has been replaced by one with arches of masonry. Considerable repairs have been made to the Pont de la Tonnelie, already enlarged in 1851. Pont Marie, built in 1635 by a contractor of that name, had its approaches and inclines ameliorated in 1851. Pont Louis Philippe, a suspension-bridge like that of Bercy, demolished, and a stone bridge erected in its place. Pont Rouge, or Pont de la Cité, also the Pont d'Arcole, suspension-bridges, removed, and iron bridges substituted. Pont Notre Dame, restored in 1659 under Louis XIV., reconstructed in 1853, and put on a level with the adjoining streets. Pont au Change,†

was formerly, like the Pont Notre Dame, a *dos d'âne* with steep ascents; this bridge was rebuilt in 1859 on another site, in a line and on a level with the new boulevard. During the years 1852 and 1853 the Pont Neuf was completely restored, and the gradients improved, without for a moment interrupting the traffic. The Petit-Pont, leading from the Cité to the Rue St. Jacques, was entirely demolished in 1853, and rebuilt of one arch. Pont St. Michel, rebuilt in 1616; was again constructed a few years since. Pont des Invalides, suspension-bridge, built in 1825, removed in 1854, and a stone one substituted. Ponts de Solferino and Alma,—these are altogether new constructions. Pont de Grenelle,—this is the bridge whose style of architecture the capital has least reason to be proud of, and the only toll-bridge. In the neighbourhood of Paris new bridges are to be built, next season; one at Pantin, over the Ourcq Canal; another between the Ile de la Grande-Jatte and the territory of Courhevois over the large arm of the Seine in a line with that already existing between the island and the territory of Neuilly, and opposite the end of the Boulevard Bineau; lastly, at Clichy, over the Seine, to open a communication with the peninsula of Gennevilliers.

#### DRAWINGS OF ANCIENT PAINTED GLASS.

UNDER the auspices of the Archeological Institute, an exhibition of drawings of ancient painted glass, by the late Mr. Chas. Winston, is now open, in the rooms of the Arundel Society, Old Bond-street. There are no fewer than 772 drawings, which are arranged, approximately under the heads,—(1) Early English, from (circa) A.D. 1150 to 1280; (2) Decorated, from 1280 to 1380; (3) Perpendicular, from 1380 to 1500; (4) Cinque-cento, from 1500 to 1550; and (5) Italian, styled by Mr. Winston Intermediate, from 1550 to the close of the seventeenth century. Mr. J. B. Waring, in a sensible preface attached to the catalogue, says,—“This classification is in a measure arbitrary, and applies mainly to England. The first period is distinguished by the use of coloured glass (pot metal), chiefly applied so as to form a mosaic work, and is characterized by great depth and splendour of colour, with figure subjects on a small scale, principally in medallions, the ornament being of a modified conventional Romanesque character. The second period presents a preponderating element in figures and architectural accessories, the ornament consisting mainly of foliage naturally treated. In the third period the colouring is less rich and powerful; the architectural and figure accessories become even still more important; the natural foliage of the second period is retained and conventionalized; heraldic ornaments abound, and the practice of *stippling* shadows, instead of smearing them, came into general use. In the fourth period, the early part of which Mr. Winston describes as “the golden age of glass-painting,” the pictorial treatment predominates; the colouring is of a most rich and splendid nature; perfect brilliancy and effect are aimed at and obtained; the figures and draperies are well drawn; the architecture and ornament become of secondary consideration, and the whole subject is distinguished by a profuse employment of rich yellow glass of varied tints; the accessories are of the Renaissance school. In the fifth period, enamel painting on glass mainly supersedes the use of the pot metal, and the general style follows the decline of most of the arts connected with architecture; but even in this period, and up to the close of the seventeenth century, Holland, South Germany, and Switzerland produced works in enamel colours of great power and brilliancy, especially for small subjects applicable to civic and domestic buildings. This last gleam of light, however, was of short duration, and the art, whether as a mosaic or painted process, became obscured and almost entirely lost by the first half of the eighteenth century.”

Mr. Waring's statement of his own view of the subject may be usefully quoted:—

“It is our own belief,” says the preface, “after having seen and duly appreciated most of the great examples of stained glass in Europe, from the noble but too confused and sombre works of the thirteenth century downwards, that none are more worthy of study and noticeable as models of style than the pieces left by the Italian artists of the fifteenth and sixteenth centuries, whether for colour, composition, or proper architectural effect. For colour, too, the Swiss and German

glass of the sixteenth and seventeenth centuries may be studied with advantage. We do not, however, pretend to lay down rules in matters of taste; there is nothing cast-iron about art: it is infinite in its plasticity and resources, and that is good which serves its particular purpose, and produces on the mind and imagination the desired effect. But we would make one remark, which is, that, until this present age in which we live, all art has been distinguished by the artist bringing to bear on such particular branch of it as he happened to be engaged on, the greatest powers he possessed. *He did his best*; and we see, in all the noblest works of the past, the highest point to which the architectural, sculptural, and pictorial genius of the period had advanced. It is to be greatly regretted that such is not the case at the present day, but that artists are too frequently found attempting, with much care and perverted talent, to imitate their predecessors in the infancy of those arts the progress of which they profess to advance, but which they thus in reality retard. The writer has the satisfaction of knowing that Mr. Winston's ideas on this subject were entirely in unison with his own, and that of late years so acutely did he feel how little his counsels were followed, as regards style, while his scientific researches were made use of, in the carrying out of principles entirely opposed to his own ideas of true art, that he retired very much from public notice in this department, and contented himself with practical studies in connexion with the material itself. In this respect his labours have indeed been invaluable; and to his experiments made, in common with a friend of great chemical knowledge (Mr. C. Harwood Clarke), may fairly be attributed the great excellence of the glass now obtainable in this country, which gives to its “*pot metal*” a superiority over the manufacture of any other country.”

The collection of drawings now on view is a remarkable one, and affords a striking evidence of the devotion with which Mr. Winston applied himself to the study of the art.

#### MAXWELL CHURCH, GLASGOW.

THIS church, which was opened on Sunday last, is situated at the junction of Pollok-street and Ardgowan-street. The style is Geometric, the principal front being to Pollok-street. The tower, which rises to the height of 140 ft., is to the side, at the immediate corner of the two above-named streets. The main feature in the front elevation is the four-light centre window over the principal doorway. The front doorway arch is supported by columns with carved caps and bases. The ridge to roof is surmounted by a cresting. The church inside is divided into nave and aisles by iron pillars on each side. These pillars support the galleries, and also the roof. They have moulded caps, from which spring arches of perforated woodwork. There are five doors of exit. The ceiling being partly ceiled, it was deemed necessary to relieve it with colour. In the centre, between the main comles, are pierced centre flowers, designed in character with the building. These will be used as ventilating outlets. The walls are tinted of a light salmon colour. The front of the galleries is of an ornamental design, and the panels are decorated. The principal features internally are the two windows, the one over the main door and the other over the pulpit. The pulpit, or rather platform, is of stained woodwork, the panels diapered in gold, on a crimson ground. The small carved caps and other carvings are hatched in gold. The arcade at the back of the platform is to be filled in with illuminated texts and the ten commandments. The organ will be placed in the end gallery, and will be divided half on each side of the large window, and so designed as to be an ornament to the church. The doors are to be covered with crimson cloth and ornamental brass hinges. The Maxwell Church is from the designs of Mr. G. H. O'Donoghue, of Glasgow, architect, under whose superintendence it has been erected. The contractors were—Messrs. Coghill, mason; Connell, wright; Brown, plasterer; Morrison, slater; and Barbour, plumber, all of Glasgow. Messrs. Fyfe, painters, and Messrs. Keir, were intrusted with the order for the coloured windows. Messrs. Combe furnished the heating apparatus, which works by means of hot water.

The interior measures 81 ft. from gable to gable, and 52 ft. within the side walls. The church holds nearly a thousand sittings. The cost is about 4,000*l.*

\* See *Builder*, vol. xxii., p. 642.

† See a description of this old bridge in a previous volume of the *Builder*.

ST. ANDREW'S, HECKINGTON. — NORTH-EAST VIEW.

#### PROPOSED RESTORATION OF HECKINGTON CHURCH.

The notice and illustrations in our last issue having excited interest on the part of some of our readers, we are led to add a view of the church from the north-east. This gives a good idea of the great window at the east end of the chancel, and of the adjacent building now used as a vestry. Beneath it is a vault or chamber lighted at the east end by what was originally a window, but has since been covered into a doorway. Beyond are seen one of the fine pinnacles of the nave, and the eastern elevation of the north transept, which in part of 1840 is the earliest and plainest portion of the building.

#### THE HILTON AND DE WINT MONUMENT IN LINCOLN CATHEDRAL.

This monument, erected to the memory of two artists, is about 8 ft. long by 4 ft. wide, and is 4 ft. 6 in. in height. It is executed in Caen stone, alabaster, and marble, in the style of the middle of the fourteenth century. The panels in front contain copies in low relief, from three of the most important works by the late Mr. Hilton. The first is, "Mary anointing the feet of our Lord," after a painting in St. Michael's church, College-hill, London. The second is after the large painting of the "Crucifixion," at Liverpool, of which an engraving was issued some years ago by the Art-Union of London. The third, the "Raising of Lazarus," is after a very large painting in the church of Newark. The west-end panel contains a sculptured representation of the west front of the cathedral, including the tower and the west window of the west transept. This order, connecting the heads of the artists in one memorial has been selected as a reference of their own works, and the most appropriate being brothers-in-law, and much attached to each other. All these panels are executed in the purest white alabaster. The panels at the top are fitted with white marble, on which are the following inscriptions:—

"In memory of William Hilton, esq., R.A., one of the most eminent historical painters this country has produced. He was for many years keeper of the Royal Academy, in which office he was distinguished as well by his private worth, as the honourable and efficient discharge of his public duties. Born at Lincoln, 3rd of June, 1786. Died in London, 30th December, 1839. Buried in the Chapel Royal of the Savoy. Also of Peter De Wint, esq. He was one of the earliest members of the Society of Painters in Water Colours, founded in 1804, to whose exhibitions he was throughout life one of the most distinguished and popular contributors. In private life he was much and deservedly respected for his upright and honourable conduct, and sincerity of character. Born in Stafford-

THE HILTON AND DE WINT MONUMENT, LINCOLN CATHEDRAL.—MR. EDWARD BLORE, ARCHITECT. MR. J. FORSYTH, SCULPTOR.

Main body of text, consisting of several paragraphs of faint, illegible script. The text appears to be organized into sections, possibly separated by horizontal lines or headings, but the specific content is unreadable due to the low contrast and blurriness of the image.

shire, 21st January, 1784. Died in London, 30th June, 1849. Buried in the Chapel Royal of the Savoy."

The single hutchesses are surmounted by angels, representing Hope, Resignation, and Adoration. The monument has been erected by Mrs. De Wint, who was Mr. Hilton's sister, and Mr. De Wint's widow; and Lincoln's magnificent cathedral has been selected as the most appropriate locality, where it is placed on the south side, and under the east window of the presbytery, forming a pendant to some fine old monuments on the opposite side. Mr. Hilton was a native of the city, and the family have long resided there.

The monument is executed by Mr. James Forsyth, sculptor, after the design of Mr. Edward Blore, for many years the intimate friend and companion of the two distinguished artists to whose memory it has been erected. It is right further to record the liberality of the Dean and Chapter, who have allowed it a place in their cathedral without requiring the fees which are usual on such occasions, and have shown other acts of kindness and courtesy.

#### MODERN WARFARE.\*

AMONG other kinds of knowledge formerly the domains of a privileged few, the art of warfare may also be said to be undergoing a kind of popularizing. The Volunteer movement in England has, to some extent, popularized the profession of arms, while the application of the modern resources of engineering to modern warfare, both at land and at sea, has been mainly carried out by civilians; and the annual list of patents for warlike inventions occasionally shows that shoemakers may sometimes leave their lasts with profit.

The work before us is an extremely interesting attempt by a military man to produce a book equally readable by military men and by civilians. Merely as a matter of pleasant reading, the work ought to get into many hands, and it gives another instance of the sensationalism of truth being more vivid than that of fiction. There are not many people, for instance, who are aware that Napoleon, when desirous "of remaining at Moscow, to the last possible moment, in the hope that proposals of peace by Russia would extricate him from his alarming position," employed the great mathematician Laplace to calculate, by his famous theory of probabilities, how long the army might remain at Moscow while yet leaving sufficient time to retreat in case of failure in the negotiations.

"The philosopher ascertained that the chances were more than a hundred to one, calculated on the data of past seasons, that the extreme cold would not commence before the 25th November." The hundredth to one chance did however occur, and the winter set in on the 6th of November with more than usual severity, and with the result of upsetting the power of the then Dictator of Europe. But there are, besides, several portions of this book of a special technical interest. Amongst these is Colonel MacDougall's description of a form of floating breakwater, proposed by Captain Adleyerleigh, a naval officer, "whose original object was to supersede the ruinously costly structures raised from the bottom of the sea for the protection of harbours." The proposed plan certainly seems worthy of some attention. The structure, as here described, appears to consist of a kind of hollow pontoon, probably made of iron plate, having a certain amount of free movement in the water backwards and forwards. This free movement is obtained in connexion with permanency of position, by attaching, at certain distances, along both the front and rear of the structure, very heavy chain cables, having a great deal of slack, which are fastened at the other end to permanent moorings, laid down at the bottom of the sea." In order to divert the force of the waves, the front surface of the sea-wall, instead of being vertical, is made with a slope of about 15° with the horizon,—a somewhat similar inclination as that "which a sea-beach naturally assumes under the action of the waves." In order to avoid the dangerous action on a cable from the vertical motion of floating structures, the breakwater is made some 17 ft. below the surface of the sea, or a depth where the water is always still,—at least, in the English Channel.

The chapter on street fighting is also of much interest, and we may here find more or less ex-

planation of the success and no success of the street battles and barricades which, within the last twenty years, have desolated almost all the capitals of the Continent. The abdication of Louis Philippe, and the consequent outburst of the revolutions of 1848, were due to the unskilful handling of the French troops against the Parisian barricades. "They were led to the attack of barricade after barricade, through high and narrow streets, the houses of which were swarming with foes, without any attempt being made to fight the insurgents with their own weapons." Instead of this direct system, the royal troops should have been directed to break into "the enclosing houses on both sides of a street, at the farther end of which a barricade existed, and push their way from one house to another, until the barricade was turned." The superior means at the disposal of regular troops, and their discipline, would thus have been made available instead of their being brought down to the level of the insurgents by fighting man to man at the barricades. Both the first and the second Napoleon have proved that regular troops, when well handled, can always defeat a street insurrection. It is, indeed, very questionable whether an insurrection of the kind is now possible in Paris, at least if it have to encounter ordinary management. The paving stones, so easily pulled up for barricades, are now replaced by asphalt, and the now wide and straight streets could be easily swept by cannon.

#### THE BATH-FORUM COMPETITION, BATH.

At the last meeting of the Bath town council, held on the 21st ultimo, the committee brought up a report in which they said,—

"The committee resolved to hear from Messrs. Wilson & Willcox, in the presence of Mr. Clark, the referee, on what grounds their estimate differed so widely from his; their chief reason was that Mr. Clark had cubed the work at 51d. per foot, whereas they could show that they had erected buildings of the same style of work as that required by the Corporation for 4d. per foot, and they represented that this difference would bring the building proposed by them within the requisite limits. They also stated that if the corporation, approving generally of their plan, wished the principal rooms to be more lofty, the additional height could be gained by subtracting from the upper rooms without either altering the entire cost or producing any disadvantage.

It was obvious to the committee that, having heard this statement from Messrs. Wilson & Willcox, they were bound to give Mr. Davis an opportunity of submitting his case likewise. Accordingly they requested him to meet them for this purpose also, in the presence of the referee. Mr. Davis complied with the request, and expressed his opinion that the estimate of Mr. Clark should have been 4d. rather than 51d. per cubic foot, and that if his plan were estimated at the lower sum the cost would be reduced very nearly to the sum named by the council. Mr. Davis's views, as well as those of Messrs. Wilson & Willcox, may be best presented in their own letters, from which the council can form an opinion as to the course recommended by the committee.

Taking into consideration all the facts of the case, the committee have come to the conclusion that the premiums ought now to be awarded as originally proposed—the first to Mr. Davis, the second to Messrs. Wilson & Willcox.

The mayor moved the adoption of the report and a long discussion followed. Alderman Gore moved as an amendment, "That the report of the committee be adopted, except so far as it related to the adjudication of the premiums, and that the first premium be awarded to Messrs. Wilson & Willcox."

Alderman Hunt said, he thought at their last meeting they would have been justified in deciding that none of the competitors had complied with the instructions, but their decision would have been in the face of some of the usages of the profession, and also of the press; for the *Builder*, in an article on the subject, had stated that if the council did not award the premiums, they would be acting the part of swindlers. The council were prepared to do what was right and just to all parties, and they had put themselves into the position to do so. He quoted the price per foot of the design of Mr. Davis (as set forth in his letter to the mayor), the total cost of which would be 15,624*l.*, and contended that so far from evading calculation, Mr. Davis went into it, and showed in what respects he demurred to Mr. Clark's calculation.

Ultimately, the amendment, awarding the first premium of 200*l.* to Messrs. Wilson & Willcox, was carried by 23 to 10.

The adjudication of the second premium was deferred until the next meeting of the council.

OPERATIVE COACHMAKERS' EXHIBITION.—The distribution of prizes of the first Operative Coachmakers' Industrial Exhibition will be made by Lord Truro in the Great Room of the Society of Arts, on Monday, April the 3rd.

#### BRISTOL.

THE arrangements for the forthcoming Industrial Exhibition in Bristol are progressing favourably. The list of vice-presidents and supporters is influential, and intending exhibitors are preparing to contribute ingenious and skilful specimens of handicraft.—It is asserted that the tower of the Cathedral is in a dangerous state. The Ecclesiastical Commissioners sent an architect to report on it. We are told that he states there is no immediate danger; but that its safety would be much greater if—as the pressure upon the piers and arches is from the east side—there was a nave to support (in fact, to hutchess) the building on the west. The discussion on the subject seems to have awakened a disposition on the part of some portion of the public, to begin a movement towards completing the collegiate church.—We understand that it has been arranged between the corporation and the dean and chapter that the road between St. Augustine's Church and College-street is to be lowered to the level of the floor of the Cathedral, and that the piece of ground to the west of the building is to be similarly dealt with. This would give increased architectural effect to the cathedral.—Clifton suspension-bridge has been rated to the relief of the poor of Clifton parish at 1,400*l.* This is for one-half the bridge, the portion supposed to belong to Gloucestershire, and a similar rating will be applied to the other of Somerset side.—The increase of large and costly houses observable at Clifton is remarkable.

#### MANCHESTER ARCHITECTURAL ASSOCIATION.

AFTER experiencing some difficulties, a new session has been opened by the Manchester Architectural Association, and the members are looking forward to a satisfactory future.

At the first meeting, Mr. J. Blackwell in the chair,—

The President, Mr. L. Booth, read an opening address. He said they were met for the purpose of forwarding the interests of an Association whose object was the advancement of its members in the study and practice of architecture; and the importance of the few remarks he had to offer would depend more upon the spirit in which they would be received by the members than upon any interests particularly of their own. It was to be feared that many of them were absorbed in the pursuit of individual gain and professional success to the exclusion of proper attention to the more general interests of the profession.

After referring to the various questions which were every day more and more pressing for a solution, and deprecating the spirit of mutual distrust and the unprofessional conduct at times exhibited by some of the local architects, he continued,—“There are those who contend that Associations like this are powerless for good, but here we see abuses which assuredly can never be rectified by isolated individual efforts, and which could not possibly exist to anything like the same extent in a body of men associated together and brought into personal contact for any common object.”

A discussion followed. After a vote of thanks to the reader, the hon. secretary, Mr. Darbyshire, gave notice that the paper for the next meeting would be read by Mr. H. Fisher, on "Strikes in the Building Trades."

#### THE VALUE OF STONE UNDER FIRE.

THE superintendent of the London Fire-engine Establishment, in his last report, to which we have already alluded, comments on the errors and omissions of the Building Act. In the course of these observations he quotes,—

"Sec. 22. The lobbies, stairs, &c., of a certain class of buildings must be made of 'stone or other fire-proof material,' and says,—“This enactment involves an error, inasmuch as stone is in no sense fire-proof; on the contrary, it yields to fire sooner than almost any other building material, and much more rapidly than wood. It is true that it does not, like wood, add fuel to the fire, but it does worse, as its known tendency to split off from the walls, and fall down altogether, prevents the firemen from availing themselves of the best positions for their work, which they can almost always occupy where there are wooden staircases. For a staircase on

\* "Modern Warfare, as influenced by Modern Artillery." By Colonel MacDougall, London: John Murray, 1864.

the outside of a building stone may be safely used, but its brittleness, when exposed to different degrees of heat in different parts, makes it an unsafe material for inside staircases or lobbies, which are liable in case of fire to undergo a sudden expansion in the tread or exposed part, while the support or part resting inside the wall is scarcely raised in temperature; or, if they escape this danger, and get hot so slowly as not to break, the water from the engines, or even in some cases the draught of cold air caused by opening a door or window, is quite sufficient to contract and split the stone. In both cases the fracture occurs in the same place, close in to the wall."

The reporter goes on to say,—"No staircase can be considered really fire-proof, unless constructed either of fire-bricks laid in fire-cement, which would be both costly and cumbersome, or of wrought iron, which, for appearance, comfort, or convenience, might be covered with slabs of slate, stone, or wood. In this latter case the real strength would consist, not in the stone or other covering, but in the wrought-iron framing; and such stairs, particularly if protected by plaster, which could be easily done, might safely be relied on in all ordinary fires, as the heat near a staircase being tempered with the cold draught from the outside is rarely sufficient to weaken wrought iron, which only fuses at about 3,000° Fahrenheit, and retains a considerable portion of its strength almost to the melting point. That paragraph, which asserts that stone is a fire-proof material suited for lobbies, stairs, &c., has done incalculable injury, as may be observed at the scene of any fire in a building so constructed, particularly if there have been both wooden and stone stairs, in which case it almost invariably happens that some portion of the wooden stairs is saved, while the stone is completely destroyed, and generally discovered afterwards among the ruins in the basement. It seems therefore, wrong, to continue any longer a compulsory law based on a grave error, and certain always to do, as it already has done, most serious injury to life and property. The only way in which a stone staircase can be saved in a building on fire is to flood it with water at an early stage, and this must always occupy the careful attention of the firemen at the very time when their efforts would otherwise be exerted in a totally different direction."

Of course, the experience of the superintendent in this direction has been considerable, but we should be glad, nevertheless, to have some additional evidence as to the behaviour of all stone staircases under fire.

#### THE MAGNESIUM LIGHT IN ST. STEPHEN'S CRYPT.

READERS of the *Builder* know that St. Stephen's crypt, in the Palace of Westminster, has been completely restored and decorated, under the direction of Mr. E. M. Barry. Every portion of the stone work is covered with colour and gilding, the columns are of Polished Purbeck marble, the lower part of the walls is lined with alabaster and mosaic work, the window openings are filled with stained glass, and the panels in the east wall, seen in the view of the crypt, published in our last year's volume (when we also gave some descriptive particulars), now contain paintings, not unsatisfactory, of St. Peter, St. Stephen, St. Edward the Confessor, and others. On Monday last, under the auspices of the Chief Commissioner of Works, the Hon. William Cowper, this gorgeous monument was lighted for a time by means of the magnesium lamp, and every detail was brought so into view as it has not before been seen, and was gazed at admiringly by a considerable gathering of members of Parliament, with a sprinkling of her Majesty's ministers, and ladies. The elaborate beauty of the moulded and carved doorways, and of the bosses in the groining, was specially observable.

As respects the management of the light itself, improvement in the arrangements is still necessary. The lamp used on this occasion was fitted with simple clockwork, to force forward the wires, three in number, and was understood to provide for half an hour's continuous burning. For reasons, however, not at present fully understood, though a guess may be made as to them, the wire sometimes suddenly ceased to burn; resulting of course in darkness. The possibility

of this, as the wire is at present made, is a risk that would prevent the general use of the light. Every man, however, was once a baby, and we may expect before long to see the new light able to run alone. As one mode of obviating the difficulty we are speaking of, the introduction of a small spirit-lamp has been suggested, into the flame of which the wire would be continuously forced, so as to relight it in the event of occasional failure.

It is stated that Mr. Nadar is now photographing the interior of the Paris Catacombs by means of this light: and we shall soon hear of its use in other places and for other purposes.

#### THE SPIRE OF ST. ALDATE'S CHURCH, OXFORD.

A CORRESPONDENT writes,—"Seeing in your last impression a note of the operations of Mr. Burns, 'Steeple Jack,' at Oxford, you will excuse my informing you that, at the same time, there was another 'Steeple-Jack' operation going on in the town. The work I am speaking of was not only to take off the weathercock of a spire, but to take the spire down to the level of the tower. This was performed by Messrs. Young & Co., builders, of this town, on the spire of St. Aldate's Church, which had become considerably out of the perpendicular and dangerous, and was effected without a scaffold and without accident: not even a slate was broken on the roofs of the church below. The spire was built of stone, on a tower about 56 ft. high, and the spire to weathercock 50 ft., and the top of the spire, which was solid about 10 ft. down, was all removed from ladders; and below that point the men could work and lower the stuff inside. A trough or spout was formed from the top of the tower to the top of the churchyard wall, and all materials were shot completely off the premises.

I may as well state my ideas as regards the construction of the spire, and the cause of its failure. There was a 12-inch iron bar, copped at the angles, inserted in the first course of stone at base of spire, the stone being 7 in. thick. The rusting of this bar (which was in some places literally rusted through) had burst the stone away both inside and out; and had it not been for the pinnacles or angles of the tower, the spire must have fallen years ago."

#### THE HOMES OF THE LONDON OPERATIVE BAKERS.

NOTWITHSTANDING the exertions of this numerous body of workmen, assisted by influential portions of the press, and backed by such men as the Duke of Argyll, Lord Dunsley, Mr. A. H. Layard, the Hon. W. Cowper, the Bishop of Oxford, the Dean of Westminster, and a host of others too numerous to mention, the operative bakers are still obliged to fight a hard battle with the prejudices of a considerable number of the masters. This is a matter to be regretted; but we hope that what has transpired so far may be a means of inducing the men to continue their exertions with increased vigour. At a recent meeting of bakers, held in the great hall of the Whittington Chnl, over which the Duke of Argyll presided, his grace regretted that the general attendance of the public was so scanty. After referring to those long hours of labour,—the particulars of which have been before brought to the notice of our readers,—the duke mentioned the effects of bad ventilation in bake-houses upon health, expressing an opinion that the duration of the hours of labour should be a matter of combination of voluntary associations of the men, who would work out their wishes by conferences with employers, rather than by making this a matter for parliamentary interference; and an object of the meeting was to organize homes and reading-rooms for journey men bakers; an object which would, if successful, be a means of strengthening the men in any desirable movement. In London alone, there are upwards of 14,000 journey men bakers: many of these men are constantly arriving in the metropolis from Scotland, Germany, and some of the provincial towns of England, &c.; and while in search of employment, the only places of resort are the "call-houses," which are generally public-houses, and, to a considerable extent, supported by the drinking-money expended by the men. Instead of this very bad plan, it is proposed that in those homes

the journeymen shall meet, and in them a register of all situations vacant shall be kept; and where the men,—those employed and those unemployed,—may meet for conversation, without the necessity of going to a public-house. The Duke of Argyll hoped that the general public would assist this movement, but reminded the meeting that the real and ultimate success of the institution depended upon the amount of the support afforded by the journeymen bakers themselves, and the masters.

The secretary announced a general improvement in the condition of the bakers; and he considered that since 1860 their state had improved to the extent of twenty-five per cent. Wages had increased. Some masters had abolished night-work altogether, and a few had closed their shops on Sundays; and thus done away with labour on the Sunday altogether. Already a home and reading-room had been established in Rolls-buildings, Fetter-lane, and fitted up with a certain amount of useful accommodation; but some 250l. were required to complete the whole, and put the place in thorough and practical working order. They had a library of 140 volumes; and the assistance of both journeymen and masters might be usefully employed in providing what is needful in the commencement of this establishment, and making it a model which might be imitated in other districts.

Mr. Layard moved, "That the journeymen bakers are justified in using all the moral, legal, and constitutional means within their power to abolish the pernicious system of night-work and unlimited hours, in order that they may have a better opportunity of improving their intellectual capabilities, and to afford time for a little rational recreation and amusement." In reviewing the operation of the recent Act of Parliament, he said that one objection to the Act was, that it was not compulsory; and he would be glad if some means could be devised for making the exercise of the power for visiting bakehouses compulsory, and the appointment of a bakehouse inspector in a parish as compulsory as that of a sanitary inspector.

#### THE POSITION OF THE INSTITUTE OF ARCHITECTS.

MR. EDITOR,—If it would be any satisfaction to you to hear that the counsels that have turned the Institute into a Freemasons' Lodge, in spite of your well-founded objections, are fast leading it into a state of schism and disruption, you might now find it.\*

The meeting of members on last Monday night gave pretty strong evidence of it. As you know, the council lately, on a division, recommended Mr. Butterfield for the Royal Medal. "Stuff and nonsense," said a general meeting, held to confirm the recommendation. "You are passing over better known men,—men who have done more work, men of more catholic views;" and so they voted the medal to Mr. Pennehorne. The meeting on Monday night was called by those who felt aggrieved by this, ostensibly "to consider the manner in which the recommendation of the council as to the award of the Royal Gold Medal has been set aside, and also the steps which it is desirable to take with regard to its award for the future." Some very hard words were bandied, and it was easy to see that if care be not taken a split will take place. "Let us adjourn," said one wisely. "If you do, without fully discussing the question now before us," exclaimed a leading Gothic architect, "I quit the Institute for ever." A Fellow who had taken some part in the reversal of the council's recommendation, was reprimanded by one of the Gothic party (my party) for sending round a private letter, inviting the Fellows not to absent themselves. "Why should you object?" says one of the other side, "when you yourselves are at this moment sending round a private letter to secure the election, in May next, of a certain gentleman as president?" The meeting afterwards became pretty unanimous in passing a resolution calculated to prevent the unexpected reversal of the council's recommendation as to the Royal Medal; but it seems pretty clear to me that unless some of the wiser and wider-viewed members of the Institute lend their aid to prevent it, we shall fall into anarchy. Oh! for a session of the steady management of the Nelson-Lewis secretaryship, and of earlier days!

A GOTH.

\* We should find no satisfaction in any such thing: quite the reverse. It would be subject for deepest regret.—Ed.

## VOLUNTARY ARCHITECTURAL EXAMINATIONS.

SIR,—The Class of Proficiency I believe to be the only one to which the Institute can look for present success. That of Distinction now gives a title to which its possessor, according to current examinations, cannot be held to possess. Let the Class of Distinction bide its time, and when the examination in proficiency is compulsory, I think the Institute might, with some degree of reverence for our calling, establish a voluntary examination for distinction which shall be really in accordance with its title, and which will sit "gracefully" on the heads of the profession.

The suggestions which have been prepared by the Architectural Association, and which will be laid before the council of the Institute on the first day of its meeting, contains that which, if adopted, will probably establish the examination in proficiency on a basis of success. The ridiculously small space of time—three hours—given at the last examination for preparing plan, elevation, and sections of a vaulted library, with a private chapel over, ought to be regarded as a monstrosity. I am glad to find that additional time is now allowed. Again: the Examination Papers say, "Give an outline of the principal styles of European architecture." I know on authority that three-quarters of an hour was the time available for that purpose at the last examination, and I defy 90 out of every 100 of the Royal Institute of British Architects to sit down and perform the operation, satisfactorily, so as to possess any value as a test, in that time. The work to be done throughout is not too hard, but the time for doing it too short. The suggestion of the Association, that the examination should be held on alternate days, possesses advantages for town students; but those from the country might, perhaps, feel it to be a waste of time, and prolong their stay in town unnecessarily. Certainly the examination must not extend over a longer period than will be occupied by alternate days.

The question of architectural examination—"to be or not to be,"—is now virtually before us. If the Institute, at their next examination, adopt a system possessing the means of arriving at a fair and reasonable test of ability, it will, I hope, regain the confidence of students. On one point there is a strong feeling, viz., that some written recognition, but not a diploma, of having passed the examination should be given.

A MEMBER OF THE ARCHITECTURAL ASSOCIATION.

## PEERAGE PROPERTY IN LONDON.

SIR,—As a subscriber to the *Builder*, which I have taken in for some time, I wish to point out to you two inaccuracies, which you may wish to correct on some future occasion. On the first page, in the list of noblemen possessing London property, you mention, at No. 9, *Earl of Portman*, and soon after, *Baron Portman*, which he is. The other is the omission of *Lilleshall*, in Shropshire, one of the country houses of the Duke of Sutherland. A. W. J. CLIFFORD.  
*House of Lords.*

## SURREY THEATRE.

LIEUT.-COL. TEMPLE WEST, to whom the greater portion of the land in the neighbourhood belongs, has entrusted all the details and rebuilding of the new theatre to Mr. John Ellis, architect, Austin-friars. The works are to be immediately commenced, and carried out in the best manner, so that the building may be perfect by the 29th of September next.

## EAST LONDON INDUSTRIAL EXHIBITION.

SOME of our readers may be glad to be told that the East London Working Classes' Industrial Exhibition, 1865, will be held at the St. Mary's Schools, Whitechapel. It will be opened on the 12th of July next, under the patronage of the Earl of Shaftesbury, the Earl of Maclesfield, Lord Ebury, the Chancellor of the Exchequer, Viscount Enfield, M.P., and others, who have become guarantors to the amount of 200l., if required, to defray the expenses. The committee meet on Monday evenings at the Christ Church Schools, Cannon-street-road, E. The chairman is the Rev. G. H. McGill. Applications for space should be made to the secretary, Mr. John Webb, at the schools.

## THE TEMPERATURE OF WESTMINSTER ABBEY.

SIR,—Your correspondent "C," in your impression of the 18th March, speaks of the desirability of warming Westminster Abbey, and alludes to the perfect way in which St. Paul's Cathedral has been treated.

As the engineer who accomplished the latter work, perhaps you will allow me to state that since its completion we have successfully warmed York, Lincoln, Ripon, Gloucester, Worcester, and various other Cathedrals, to say nothing of many hundreds of churches and other buildings; that there is no difficulty whatever to contend with in the case of Westminster Abbey; that the work could be done certainly, effectually, inexpensively, without detriment to the architecture (as the apparatus would be unseen); that an agreeable temperature would be secured throughout the whole building, involving no possible risk from fire; and that the interior of the edifice, together with the monuments contained therein, would be greatly preserved by the process.

Wm. WOODCOCK,  
*London Warming Company.*

## "GRINDING MONEY"

SIR,—Knowing how deep an interest you take in all that relates to builders and their men, we send you the following case, which was tried at the Cumberwell County Court, March 21st. The plaintiff, a carpenter, was in our employ. Not requiring his services any longer, we dismissed him. When he received his wages at one o'clock on February 25th, 1865, he asked for "grinding money." We refused to pay it, he receiving 7d. per hour. He then took out a summons to recover not only "grinding money," but also loss of time in fetching away his tools. The Judge, on hearing his statement, at once dismissed the case, "he having no claim." This may be useful to our trade.

J. & J. GOODMAN.

## THE NEIGHBOURHOOD OF THE POST OFFICE.

MAY I take the liberty of drawing your attention to the Postmaster General's application to the Legislature for power to purchase a large area now covered with houses, extending from Angel-street to Newgate-street, on the west side of St. Martin's-le-Grand, upon which it is proposed to erect buildings in extension of the General Post-office opposite?

It is not my present purpose to offer any remarks upon this proposal in itself, as I take it for granted that such an extension is considered indispensably necessary in connexion with the vastly-increased business and new functions of the Post-office; but simply to invoke your aid in converting the present awkward and somewhat chance-medley junction of several great thoroughfares into something befitting their importance and the dignity of the neighbouring buildings of St. Paul's and the Post-office. The proposed clearance affords an admirable opportunity for the formation of a central place, from which would radiate the several great thoroughfares, as well as opening up a new and grand view of what is generally admitted to be the *chef-d'œuvre* of English architects, St. Paul's.

The value of land in this vicinity is so great, that anything much beyond the present space is not to be looked for; but even that, somewhat augmented by a liberal rounding of corners and a re-arrangement, would give one of the noblest architectural views in the metropolis.

Let St. Martin's-le-Grand be continued into St. Paul's Church-yard by a gentle curve beginning at Angel-street, and having for its central point the great dome, with a liberal rounding of the corners east and west into the Churchyard. The street itself should be 80 ft. in width. This would necessitate the reconstruction of all the houses east of the new street to the present junction of Newgate-street and Cheapside, and would cause the prolongation of Cheapside at the expense of Paternoster-row. The block between the row and the churchyard would require to be reconstructed, on a site to be purchased of the dean and chapter, somewhat southward of its present site; and the roadway would encroach on the railed space of the churchyard. It would also follow that Sir Robert Peel's statue would have to be removed to the centre of the new place, that is, to a point not far from the junction of Paternoster-alley with the Row. And this brings

me to a matter that is, perhaps, of more importance than even the present proposal.

When Newgate Market is removed to Smithfield, there will be a great motive in utilising its site by continuing Cheapside through it to Warwick-square, and thence westward between the Court-boulevard and the prison across the Old Bailey and Farringdon-street to Carey-street, and again from that street, by a double curve, to the eastern end of Long-acre. The enormous value of the new frontage would go a long way in recompensing the body who would have the management of such an improvement, which would be a noble undertaking for the Metropolitan Board of Works when they have got the Embankment and Main Drainage well out of hand. In the meantime, a slight concession from the Post-office would prepare the way without much, if any, sacrifice of land, as they would gain on the east side of the street the same space as they gave up on the west.

I venture to suggest the whole improvement to a joint-stock company (limited), in connexion with an underground railway in the street, which appears to be the only way in London of getting any comprehensive improvement. J. W.

## THE BUILDING TRADES.

WHILE the Birmingham and other workmen are doing their best to come to a permanent good understanding with the masters, by means of arbitration of trade questions, the Manchester masons are flying in the face of all such means of arrangement, although they had agreed to it in 1862. They now inform the Masters' Association, that "no just arbitrator, apart from the employers and employed, can settle the difference between us in a just and equitable manner." It is evident their notions are not very clear on the subject. They have resolved that they "cannot entertain the principle of arbitration in any shape whatever." They threaten a strike, through which upwards of 600 men will throw themselves out of work, if a demand of an increase of wages, from 30s. to 33s. in summer, and from 27s. to 30s. in winter, be not agreed to by the masters. There is therefore no hope of any "just arbitrator" settling this question. The masters will not agree to the demand; but they have offered to meet the men half-way, to which offer the men refuse to listen.

Meanwhile, however, the principle of just arbitration which the Manchester masons repudiate is spreading elsewhere throughout the country. The masters and men of Wolverhampton have agreed to the principle, and have appointed the following delegates for the settlement of future disputes by means of arbitration:—For the joiners and carpenters, Messrs. Thomas Whittle, Joseph Humphries, Thomas Skett, John Jeavons, Walter Parry, and Thomas Crumpton; for the masters, Messrs. George Higham, Lovatt, Heveningham, Burditt, Elliott, and John Cockrill. The following resolution was then agreed to:—"That the employers and operatives mutually and severally agree to conform to and fulfil all rules agreed to by the majority of the delegates, or settled by the casting vote of the chairman or umpire appointed." At this point, says the report of the proceedings, the delegates from the men joined the masters on the platform, amidst the applause of the meeting. One of the delegates from the carpenters and joiners, Mr. Whittle, in seconding a vote of thanks to the mayor, remarked that he hoped a new era was now about to commence. He was much pleased to say that at the interviews they had had with the masters they had been most courteously and civilly received. It was not as dog meeting man—the former evincing a desire to bite the latter's nose off,—but as man meeting man.

At Derby the bricklayers and labourers struck work recently, the former for an advance of 3s. per week, and the latter for 2s. 6d. The masters had offered the bricklayers, joiners, plasterers, and labourers, 2s. for nine months in the year, the wages remaining as before during the winter months. The offer was declined, and the masters then proposed arbitration, which was also refused; but it is said those on strike are now willing to adopt the principle of arbitration.

At a meeting held in Leeds, of deputations from the masters and the operative carpenters and joiners, an advance of a farthing per hour on the present rate of wages was offered and refused, the men holding out for an advance of a halfpenny on the present rate of 5½d. per hour.

A "strike" is not improbable on the 6th of May next, unless the men accede to the masters' proposal as to wages. The Leeds working painters have also had a meeting to consider a proposal of the employers with respect to wages. The men resolved not to accept less than 26s. per week during the summer, and 22s. during the winter months. A year ago the summer wages were increased from 25s. to 26s.

The Worcester operative carpenters and joiners have requested an advance of 2s. a week by the 1st of July next.

The Falmouth and Penryn carpenters and joiners seek an advance of 6d. a day.

The painters of Glasgow, in connexion with the Operative Painters' Association, are out on strike, or have been locked out, the cause of dispute being a demand for an increase of wages to the extent of a halfpenny per hour, or from 5d. to 5½d. About fifty painters, in the employment of Mr. Ramage, were the first to strike, while engaged in painting a large steamer, and without it has been said, any warning. A number of the masters then entered into an agreement, by which they became bound to support one another, and they have now dispensed with the services of the whole of their men connected with the union. They have also arranged among themselves that they should personally work at the ship, twelve at a time, till the painting shall be finished. They are also, it is understood, prepared to act on the same principle in the case of any job of a very pressing nature. The number of men at present on strike or locked out is said to be from 150 to 200.

The carpenters of Nairn are at present out on strike. They demand 18s. for fifty-seven hours' work.

#### METROPOLIS SEWAGE AND ESSEX RECLAMATION BILL.

THE report of the referees on the petition of the mayor, aldermen, and commoners of the City of London, says:—

"The company who are the promoters of the Bill propose to convey the sewage now collected in the main sewers of the Metropolitan Board of Works on the northern side of the river Thames, for the fertilisation of lands lying to the east of London, and the surplus to be conveyed into the sea near to the Foulness (or Maplin) and Dengie Sands, in the county of Essex, a distance of forty miles from the metropolis; and the said company also propose to reclaim certain parts of the Maplin and Dengie Sands.

The petitioners objected that the estimate was insufficient, and especially that the Maplin and Dengie Sands were so loose and unstable that the embankments could not be constructed upon them, unless at a much greater cost than the estimate would provide for, while they would neither be able to resist the sea on so exposed a coast, nor to prevent the filtration of the sea-water under them.

They also objected that there was not sufficient fall in the conduits for the proper flow of the sewage.

As the pumping stations on the main conduit will raise the sewage 42 ft. (20 ft. and 32 ft. respectively), while the distance the sewage is to be conveyed in a direct line is forty-four miles, there will be a fall of about 1 ft. per mile to the points of discharge, which will give a velocity of about 1½ mile per hour.

The fall and velocity are sufficient for the proper flow of the sewage.

On the Maplin Sands it is proposed to inclose an area of 5,000 acres by an embankment twelve miles in length, and on the Dengie Sands it is proposed to inclose an area of 3,000 acres by a similar embankment of nine miles in length.

These embankments are to be placed from one end a half to two miles seaward of the present coast line.

They will be 15 ft. in height towards the sea, and will vary at the ends from that height to 6 ft., where they join the present sea-walls.

There will be 9 ft. of water on the embankment at spring-tides.

Those areas, containing 8,000 acres, it is proposed to reclaim and cultivate by means of the sewage.

The sand is of the same description at both places, and it was proved that it was solid and tenacious, having a considerable admixture of clay and other substances in it, which render it sufficiently firm for the construction of the embankments upon it.

There are no quicksands, and it is not likely there will be filtration from the sea under the embankments to any great extent.

The estimate is 2,100,000*l.*

The referees are of opinion there are no objections, in an engineering point of view, to the proposed works, and that the estimate is sufficient."

#### THE THAMES EMBANKMENT.

COPIES have been issued of the correspondence between the Board of Trade and the Metropolitan Board of Works, relative to the material used for filling in the Thames Embankment, and of the report of Messrs. Coode and Rawlinson to the Board of Trade. It appears that these gentlemen are of opinion that the materials dredged from the river are, if properly used, perfectly good materials for the embankment, with the exception, perhaps, of the filling in for 20 ft.

behind the wall; that the quantity needed for the embankment can, with proper arrangement, be obtained in ample time for the fulfilment of the contracts; and further, that if all the materials to be used henceforward for filling in the embankment are taken from the bed of the river; the quantity of water thus gained will not compensate the river for the water displaced by the embankment. [Is it not overlooked here that the embankment, by narrowing the stream, will itself help to deepen it, by increasing its force, thereby flushing its channel, as it were, continually, at the ebbs?]

"Looking to the intentions of Parliament," writes the secretary to the Board of Trade to the chairman of the Metropolitan Board of Works, "in passing the Thames Embankment Act, with respect to the river and to the report, the Board of Trade cannot doubt but that the Metropolitan Board of Works will at once give directions that for the future the material to be used in filling in the embankment shall be taken by the contractors from the river, and not from the land. As the matter is one which admits of no delay, my lords will be glad to hear at once what steps the Board of Works propose to take."

The clerk to the Metropolitan Board replies, that they have referred the report made by Messrs. Coode and Rawlinson to the Thames Embankment Committee for consideration and report.

Mr. Bazalgette has made the following return of the quantity of filling-in materials supplied respectively from the land and river to the embankment, from the time of the first return being made, on the 9th of December last, to 15th March, the quantity being stated in cube yards: No. 1 contract—from land, 30,453; from river, 22,881. No. 2 contract—from land, 6,864; from river, 7,023. Total—from land, 37,317; from river, 29,904.

#### ACCIDENTS.

AN accident has occurred at the passenger station, in Ludgate-hill, of the London, Chatham, and Dover Railway, which happily has been unattended with serious consequences. At that part of the line northward beyond the present temporary station there were nine girders resting a dead weight upon the walls which were to support the iron roof intended to be placed there; but, it being considered advisable to have a lighter roof, that portion which had been fitted was removed and a derrick put up to support the girders in the unfinished state of the roof. An iron band went the whole length of the roof, and the derrick supported that band which held the girders. It is supposed that the high wind which prevailed must have acted on the face of the girders and shaken the derrick, which slipped and fell, the band of course giving way, and the girders coming down. The girders fell on to the line, and no further damage ensued. The superintendent of the line was soon on the spot, and went over the works with Mr. Thomas, the principal assistant to Mr. Cubitt, the engineer of the company; and the foreman to Mr. Lucas, the contractor, was also present. A very small portion merely of the scaffolding gave way, and no bricks were displaced from the external walls. The portion of the line where the accident happened was beyond the traffic part of the station.

At Croydon, for some time past, a number of men have been engaged in forming a new branch in the Epsom and Leatherhead line of the London, Brighton, and South Coast Railway, and for that purpose they had to remove a passenger bridge that crossed the Wellesley-road close to the Croydon station. The men had just proceeded to the bridge in order to pull it down before the trains commenced running, which would be one o'clock, as it was Sunday. They had a powerful steam-engine at work, and they were going to bore a hole through the centre of the bridge for the purpose of adjusting a chain, which they intended to fix to the engine and so to pull the bridge to pieces. Scarcely had the men, fourteen in number, begun to make the hole, before the whole mass fell down, burying beneath it five of the unfortunate men, two of whom were killed on the spot and one afterwards died at the hospital.

At Rochdale, during the late boisterous winds, the chimney belonging to the works of Mr. George Hume, machinist, of George-street and Norreys-street, Rochdale, was blown down to the ground. The debris fell upon the roof of one portion of the workshop, smashing it in and doing considerable damage to machinery. Two or three persons sustained injuries, but not of a serious nature.

#### SCHOOLS OF ART.

*The School for Oxford.*—A public meeting on behalf of the school proposed for Oxford has been held in the Town-hall, the Dean of Christ Church in the chair. A large number of drawings and designs, executed by pupils of Schools of Art, were hung round the hall. The chairman, in his address, said that, in the school which he hoped would shortly be established, he expected to see classes formed comprehending every rank of society, and thus both producers and patrons would reap an advantage. Some years ago an attempt was made, when the number of professorships was increased, to induce the University to found a Professorship of Art, but from a want of sympathy in the matter it failed. A School of Art was also set on foot by citizens, but its basis seemed to have been ill considered, and it fell to the ground. The present scheme was in connexion with the Educational Department of the Privy Council; and, though he knew there was some feeling against a central authority and the somewhat minute regulations supposed to be enforced, he understood that, by the recent minute of Council, the interference with local schools was considerably diminished, while at the same time the grants were also renewed. This, however, he did not consider to be of much consequence, as they might fairly expect sufficient support to set the school well afloat; and it would speedily become self-supporting,—an indispensable qualification in the minds of the promoters. The report of the Provisional Committee stated that they believed there was every reason to expect that a School of Art would succeed as well in Oxford as in the many towns where such an institution had been established. They had obtained the use of an apartment from the Curators of the Taylor Institution for the school. Mr. Holman Hunt and various other gentlemen addressed the meeting, and appropriate resolutions were passed, and office-bearers appointed. The Duke of Marlborough has been named as president of the school.

#### THE CENSUS.

THE registration of the people, the account of the births, marriages, and deaths of the population of Great Britain, the periodical numbering of the population, and other statistics of health, life, and death, which are prepared under the Registrar-General, at Somerset House, are of the greatest value, provided that the figures can be perfectly relied upon; but without this, the very large sums which are granted by the Government for a most important purpose must be viewed as in a great measure wasted.

We believe that most praiseworthy care is taken in respect of the general registration of life and death, by not only the district, but the sub-district registrars; and we know of cases, in London, of ignorance or neglect, in which the registrar has proceeded from his office with book, pen, and inkhorn, to poor homes, and then himself made out the returns. Still, there are many persons (children especially), who do not find a record in the vital statistics of the nation, and additional care is requisite in this respect.

As regards the taking of the census, we hope that in the metropolis and the large towns especially, measures will be adopted to test the accuracy of the enumerators. If a supervision of this kind were extensively carried out, it would be the means of causing a more strict inquiry to be made in connexion with the numbers of persons in thickly populated houses. We have before us hints that there was a want of exactness on this point in 1861; but although knowing this, we have felt surprise at a statement which has appeared in most of the leading papers, that in Liverpool, 3,200 inhabited places, for which the corporation rates were paid at the time, were omitted from the census returns of 1861, making, it is calculated, a difference of 20,000 in the population of the borough.

If this be not true, it should be at once contradicted, or explained by the Registrar-General; and if it be a fact, we ought to know how such an error could possibly be allowed; if inquiry be made, it would be well to ascertain the exact population of this corporation property, and obtain the exact death-rate.

It is just worth while to notice, that the ink used for the registration of Great Britain, not only at Somerset House, but also in the offices of all the registrars throughout the kingdom, is of the same quality, so that a uniform and unmistakable distinctness may pervade all the

reports throughout. We do not know who the maker of this ink is, but it is of an excellent description. The black colour of entries which were made with it several years ago is fully retained.

#### PROVINCIAL NEWS.

**Cheltenham.**—A further enlargement of Cheltenham College has been determined upon by the council, who have resolved upon the erection of three additional schoolrooms for the junior department. The new rooms will be built on to the present quadrangle in the rear of the large room of the classical department.

**Chester.**—Five tenders have been sent in for the proposed new town-hall. The town-hall committee opened them, but deferred consideration of them.

**Cottingley.**—The new town-hall for this village has been formally opened by Mr. John Crossley, of Halifax. The hall is in the Italian style. It comprises a large hall, to be used as a lecture-room, schoolroom, and mechanics' institute. Entering from the front door on the left side is a room for a library and reading and club room. On the right side is a room to be used as a vestry. The lecture-hall is further in the passage. The hall is estimated to hold 700 persons. The room on the left of the passage is so constructed that, by the opening of a sliding door, it can immediately be thrown into a part of the hall when required. The school-room is one large room, nearly square, and is estimated to seat as many as the lecture-room. The design of the building was provided by Mr. Samuel Jackson, of Bradford, and the following were the contractors:—Masons, Messrs. Denbigh & Johnson, 414, 48, 10d.; joiner, W. Whitley, Bingley, 303, 15s. 6d.; slater, T. Thornton, Bingley, 581, 10s.; plumbers, Walton & Bear, Bradford, 251.; plasterer, J. Murgatroyd, 251.; warming apparatus, J. Longbottom, 401.

#### CHURCH-BUILDING NEWS.

**Rusper (Sussex).**—The chancel of the new church, built by the Rev. J. Broadwood, of Lync, only ten years ago, had been sinking for some time past, and the walls beginning to show wide cracks, the top ornament at the end getting much out of place, it was resolved to attempt to get a new foundation. Many workmen were employed for a considerable time in doing it, but it is now completed.

**Reading.**—St. Stephen's Church, which has been erected in New Town, as a chapel-of-ease to the parish church of St. Giles, has been consecrated. The church consists of a chancel nearly 30 ft. long, and a nave nearly twice that length, with aisles to the chancel and nave on the north side, and a north porch. It is built of red bricks, with a few buff and black bricks introduced in patterns. The window-tracery is of Bath stone. The jambs and labels of the arches and windows are of bricks moulded for the purpose. The style is after the manner of the early part of the fourteenth century. There is a western bell-gable consisting of two arched openings, surmounted by a high-pitched gable; beneath this, between the two buttresses supporting it, is a four-light window with pierced tracery; the east window is of five graduated lights. The area of the church is fitted with light open benches, standing on a floor of wood blocks, laid berring-bone fashion, solid on concrete. The timber roofs are open, of somewhat light construction. The roofs generally are covered with plain red tiles and crimped ridges; but the north aisle, which is nearly flat, is covered with lead in order to give a greater height of wall. The building was designed by Mr. White, of London, architect. The cost of the structure is rather more than 2,000l. Messrs. Wheeler were the builders, and Mr. J. Matthews carried out the carpenter's work.

**Taplow (Bucks).**—The parish church, which for ten months past has undergone alterations and improvements of an extensive character, has been re-opened. The principal portion of the work has been the erection of a new chancel in the Gothic style, in accordance with a design by Mr. Scott. The structure affords increased accommodation. The seats for the choir, the pulpit, reading-desk, and other fittings in the chancel, are of oak, and carved. A recess for an organ has been formed in the rear of the choir's seats, and Mr. Walker, of London, is building the instrument. The gallery has been removed, and open seats have been substituted for the old pews. The roof has been altered,

imparting to the edifice a more lofty aspect. Two new windows have been opened on either side of the chancel, and other improvements effected. The contractor for the erection of the chancel was Mr. Snowball; and Mr. James Rutland undertook the work in the body of the church.

**Saul (Gloucestershire).**—Saul Parish Church has been re-opened. The old church had fallen very much out of repair. The only parts of the original building that remain are the tower, the south wall, and the nave roof. This latter, with its network of old oaken beams, contrasts with the stained roof of the other parts. The old brick chancel has been taken down and rebuilt of stone. The north aisle is new. A north transept has been built. The arcade dividing the nave from the aisle is new. The old box pews, some of them 5 ft. high, have been replaced by open sittings, made after the model of about a dozen seats found in the old chancel. The bench-ends are oak, and the seats elm. The style of the chancel is very Early Decorated. The moulding of the chancel-arch rests on columns of polished Devonshire marble, and the corbels are carved with figures of angels. The floors, both of the chancel and of the nave, are paved with Godwin's tiles. The window of the chancel is a memorial to the late Captain Clegram. The cost has been about 70l. The window comprises three long lights, separated by mullions and the tracery under the arch; these have been filled with painted glass. Being an altar and a memorial window, the principal subject is that of our Lord's Resurrection, shown in the centre light. The space on the right and left of the picture is occupied by the angel sitting over against the open tomb, and the three crosses on Calvary. The subject in the first compartment of the window is the Nativity. The third light has for its subject the Adoration of the Wise Men. The three groups are depicted under architectural canopies, the shafts of which extend down the sides of the lights and rest upon pedestals or bases. The panels in the tracery are filled with stained glass. The cinquefoil at the apex is occupied by a figure of our Lord seated in majesty, surrounded by a halo of rays in a vesiciform form, outside of which are angels in adoration. The whole is encompassed by a border of ruby and emerald glass. The artist was Mr. Waller, of Newcastle. Beneath the tower there is a small new stained-glass window. Outside the building is all new, with the exception of the tower and the south side, which have been repaired. The bell-framing of the tower has been repaired. The building has been well-nigh re-roofed. The church is warmed by one of Gurney's stoves. About a rood and twelve perches have been added to the old burial-ground. The architect of the restoration was Mr. Fulljames, and the builder Mr. Estcourt, both of Gloucester. The carving has been done by Mr. Parlay. The cost has been upwards of 1,000l.

**Nottingham.**—The vane has been affixed to the spire of the new church of All Saints, which Mr. W. Windley has given to the town. The vane stands 8 ft. 2 in. from the masonry of the spire, and the cock is at a height of 177 ft. 9 in. from the surface of the ground. Mr. Speed, the clerk of the works, under Messrs. Hine & Evans, the architects, adjusted the vane, assisted by the representative of Messrs. A. & R. Dennett, the contractors. The church is now complete with the exception of the organ and peal of bells. A new peal of eight bells has been cast for the church by Messrs. Taylor & Co., of Loughborough. The bells are in the key of E natural, the tenor weighing 17 cwt. 11 lb. It is thought they will most probably be placed in the tower by Easter.

**Colwick (Notts).**—It is the intention of the rector of Colwick, to restore, re-seat, and otherwise improve the parish church of that village. The plans have already been prepared by Mr. S. D. Walker. They comprise the addition of a new aisle, priests' and choristers' vestries, the opening of the tower arch so as to allow the ground story of the tower to be used as a baptistry, new eastern window enriched with stained glass, low chancel screen, organ chamber, &c.

**Ardivick (Lancashire).**—St. Matthew's School Church, Ardivick, has been opened for divine service. The plan consists of a nave (to be used in the week for a school-room) and shallow chancel, with a transept for children. The nave is 61 ft. long and 30 ft. wide. At the west end is an infants' school, 33 ft. by 16 ft. There is a vestry and a kitchen, or boiler-room, at the opposite end of the building. The edifice has an

open-timbered roof of stained deal. Low open benches, with hacks, are provided for the service on Sundays. The chancel is fitted with a simple moulded altar-rail, communion-table standing on a footpace, and prayer desk and sedilia. The east window is of stone, and is filled with tinted glass arranged in geometrical patterns. The chancel floor is laid with Broseley tiles. The material is chiefly red brick, handed with blue. Over the chancel arch is a slated bell turret of simple design, in which a bell is hung. The cost is about 430l., and the large room will seat about 346 persons. The building has been erected by Messrs. Barnes & Howe, of Ardivick, builders, from the design of the architect, Mr. J. Medland Taylor.

**Barton-on-Irwell (Lancashire).**—The reported erection of a church at Barton-on-Irwell by Sir H. de Trafford, at a cost of 20,000l., is so far in error that the building, we hear, is intended for Roman Catholics.

**Reddish.**—A church, recently erected at Reddish, near Stockport, has been consecrated by the Bishop of Manchester. The edifice has cost about 2,000l., which has been obtained principally by subscriptions in the neighbourhood, assisted by a grant from the Manchester Diocesan Society of 100l. There is likewise an endowment of 1,000l., and 200l. have been invested for the sustentation of the fabric. The church is intended to accommodate 400 persons, 154 free. The building, which is of stone, is in the Early Geometric style; and the architects are Messrs. Shellard & Brown, of Manchester.

#### DISSENTING CHURCH-BUILDING NEWS.

**Peckham.**—The new Wesleyan Chapel at Peckham has been opened. The style is Early Decorated, from a design by Mr. W. F. Ponton, of Reading. A view and description appeared in the *Builder* of 30th April, 1864; but we may here briefly note a few particulars of the edifice as completed. The chapel stands at the junction of the Hadders-road with the Queen's-road. The tower and spire are at the angle adjoining on the Queen's-road, and are, together, 120 ft. in height. The main front of the chapel contains a large five-light tracered window, and the elevation is flanked by a turret 54 ft. high, on the Hadders-road side. The materials used for the external walls are Kentish rag, with Bath stone dressings, and Bath stone bands are introduced at intervals on the rag stones. The spire is constructed entirely of Bath stone. The roofs of the chapel and turret are slated, in both cases rows of blue and red slates being alternated. The chapel, a parallelogram in shape, is 81 ft. in internal length, and 43 ft. 8 in. wide. An apse at the back of the chapel, 11 ft. 6 in. deep, while adding to the apparent length of the building, provides a space for the erection of an organ, and for the use of the choir. On the side of the apse, next the Queen's-road, is a vestry 10 ft. by 14 ft. 6 in. There are galleries both to the sides and ends of the chapel. The gallery front is inclosed half-way up, and the upper half is filled with ornamental iron. The ceiling is of a slightly arched form, the height in the centre being 37 ft., and at the sides 24 ft., and is throughout divided into panels by wooden ribs. The roof principals are partly visible below the ceiling line, the form of which they follow, and terminate in an arched outline on stone corbels let into the wall some distance below the plate level. The apse ceiling is groined over, and the groining, walls, and ceiling panels, are throughout relieved with enrichments in distemper. All visible woodwork and pew fittings are stained and varnished. The total accommodation is for 1,000 persons. There is ample room left on the site for the future erection of schools and class-rooms. The contract for the building (exclusive of lighting, by Hart & Son, and heating, by Haden & Son, Trowbridge) was taken by Mr. Sawyer, of Dulwich, at the sum of 4,427l.; but the total cost, including land, fencing, and every other expense, is expected to be about 7,000l.

**Bedford.**—The new Moravian chapel, St. Peter's Green, has been consecrated. The plans and specifications were prepared by Mr. James Horsford, of this town. The style of architecture is Roman, and the building is of brick, with stone quoins and window frames. The arrangements of the interior are simple: a gallery occupies the south end, the pulpit is placed in a position at the extreme north, and there is a recess for the organ about midway in the western wall. Pews occupy a portion of the space beneath the gallery, the remainder of the available space being

reserved for free and other sittings in accordance with the plans usually adopted by the Moravian. Messrs. James Francis & Son were the principal contractors; Mr. S. Joy executed the carpentry; Mr. S. Jarvis the masonry; and Mr. G. Small the painting.

**Ringwood (Hampshire).**—The memorial stone for a new Congregational Church at Ringwood has been laid. The building will be erected after the Early English style of architecture, built of white brick, with Bath stone dressings. Two spires will be carried up 65 ft. high, and at each of the front angles will be a pinnacle. The church will be lighted by five lancet windows on either side, and a large four-light tracery window in the front. The seating will be by open benches, the pulpit will be of cement, and the communion pew, the two aisles, and the entrances will be paved with tessellated tiles. At the end of the church is a minister's vestry, and adjoining it the appliances for heating the building. Over the vestry and the apparatus-room will be an organ-loft. There will be a roof proper and a masked roof. The entire length of the church, exclusive of the vestry, will be 60 ft., and 37 ft. wide, and the edifice will accommodate about 450 persons. It will be lighted with gas. The contract for the building has been taken at 1,000 guineas, but this does not include the conversion of the old chapel into school-rooms, nor the heating appliances of the new chapel, and other *à-retener*. The land has been given by Messrs. A. Carter & Co. When the work is finished the church premises will cost, it is estimated, nearly 2,000l. The architect is Mr. H. T. Hellyer, of Ryde; and the contractors are Messrs. Tuck & Carley.

#### STAINED GLASS.

**Albury Church, Herts.**—A west window has been presented to this church by Mr. A. Gibbs, of Bedford-square. It represents Christ's charge to St. Peter. The upper part of the light is filled with foliage.

**Pill Church, near Bristol.**—A memorial window late Mrs. Moore, wife of the Rev. P. Moore, incumbent of Pill, has just been placed in the south side of the chancel of Pill Church. The window is a single lancet, the subject, "The Resurrection," below which, and in a medallion, is an angel bearing a scroll. The artists are Messrs. Horwood, of Mells, near Frome.

**St. Mary's Church, Leicester.**—A three-light window has recently been erected in Dr. Noble's Chapel, in this church, the gift of Miss E. A. Nohle. The subjects are as follow:—The Holy Women at the Tomb, the Adoration of the Magi, and our Lord appearing to St. Mary Magdalene after the Resurrection. The window was supplied from the works of Mr. Preddy, of London.

**Oldham Church.**—The nave of this church has recently been enriched by the insertion of two more memorial stained glass windows, being the design and execution of the Messrs. O'Connor, of London, the artists who prepared the "Rowntree" window in the same church. Both the windows are on the south side, and are composed of three main lights, each of considerable dimensions. The window which is nearest to the east has been erected to the memory of three sons of the late Mr. Barker, of Frank-hill,—whose monumental tablet is close adjacent,—and the subject of it is the "Atonement" or "Passion" of the Saviour; the groupings (six in number) being so contrived as to form one picture in effect, though separately enshrined in forms composed of the vine foliage. The outer groups of the lower part represent on one side the birth of the Saviour, and on the other his body laid in the sepulchre. At the base of the centre is a group consisting of Mary Magdalene, the Virgin Mary, and St. John, weeping at the foot of the cross, while the whole upper portion of the three lights shows our Lord upon the cross, surrounded by weeping angels; all these upper figures being depicted on a ground-work of rays of glory. Along the three lights at the base of these groups are the words "He suffered for our salvation." The other window is at the west end, and has been erected to the memory of the late Mr. Bellot and two deceased sons. It has for its subject "The Resurrection of the Just," and is also arranged in a grouping of six, the whole forming one complete picture. The base of the centre lights has groups of figures ascending from open sepulchres, and borne by guardian angels towards the Saviour, who appears seated in the upper part of the window, and attended by angels on either

side. The light on the left hand represents the raising of the widow's son (Luke vii.), and that on the right hand the raising of Lazarus (John xi.), each light forming a separate picture. Along the base of the whole is the text, "I am the Resurrection and the Life."

**York Guildhall.**—Mr. R. Farrer, who a few years since filled the office of Sheriff of York, has, we understand, intimated his willingness to present a window for the Guildhall. Besides that which has already been placed in this edifice in memory of the late Mr. Ald. Meek, five others had been promised; thus, with Mr. Farrer's, seven of the windows will shortly be filled up. The whole of these are to form a series historical in their design of past events connected with the city.

**Wigton Church.**—The parish church of Wigton has been enriched by the presentation of a stained-glass window, which is placed in the chancel. It is the gift of Mr. Banks, of Highmore House, and is intended to commemorate the coming of age of his eldest son. The window is formed of a large central opening, with semicircular head and rectangular openings on each side. In the main opening is a representation of Our Saviour Blessing Little Children. In a circular panel above the subject, our Saviour is seated in his sovereignty, surrounded with cherubim of many-coloured wings; the interspaces are filled with foliated ornament, and the sacred monograms I.H.S. and X.P.C. The whole is banded with a border, and above the window, in the wall, is written, "Glory to God in the Highest." The side-openings contain respectively representations of the Last Supper and the Baptism, and in medallions, busts of the four evangelists, with their suitable emblems. These are placed on a ground-work of mosaic. The artists were Messrs. R. Edmundson & Son, of Manchester.

#### SCHOOL-BUILDING NEWS.

**Witley (Surrey).**—The foundation stone of King Edward's School, at Witley, has been laid. The schools are in connexion with the Bridewell Hospital, London. The site is on the summit of the hill, a few hundred yards from the railway station at Witley. The design was furnished by Mr. Sidney Smirke. The style is based upon the Elizabethan, but partakes largely of a more modern character. The carrying out of the plans has been entrusted to Messrs. Mansfield & Sons, of London. The building will be of three stories. The material used is red brick, with Bath-stone facings. The school itself will cover two acres of ground, and with two lodges and a lawn in front, and an extensive play-ground behind, some three acres and a half will be used in all. The principal front faces the turnpike road leading to Witley and Milford, and is 269 ft. long. The height to the top of the bell-turret, which will rise above the principal entrance in the front of the building, will be 73 ft. The frontage includes chaplain's house at the left corner, board-room, waiting-room, storekeeper's rooms, offices, and master's house at the right corner. The arrangements on the ground floor include four large school-rooms, each measuring 45 ft. by 24 ft.; a large dining-room, measuring 45 ft. by 40 ft.; a day-room, 70 ft. by 24 ft.; two plunge-baths, &c.; and the dormitories above will be of ample dimensions to correspond. The cost of the whole will be, we are informed, some 30,000l.

**Cheveston (Northants).**—The new schools have been opened. The total cost will be about 800l. The site and stones of the building were given by Mr. H. C. Wice, of Woodcote Hall, Warwickshire, and Miss Desborough, of Walton Hall, Derbyshire. The school-room, in plan, is in the form of a T, and is capable of accommodating 120 children. The master's house adjoins the school. The whole is built of native lime-stone, with Bath-stone dressings. It is in the Old English style, with good pointed gables, square-headed mullioned windows, with label or hood mouldings over them. The architects were Messrs. E. F. Law & Sons, of Northampton; and the builder, Mr. Ball, of Wellingborough. The cost of the whole, exclusive of site and the building stone, but including the architect's commission, is 800l.

**Nottingham.**—The chief stone of St. Paul's Schools, Nottingham, has been laid. The building is of two stories, of an English Gothic character, and formed of stone and coloured brick-work. The north elevation, fronting Plat-street and Cross-street, presents a gable of two triple lancet windows, the upper one with a

deeply-pointed arch and simple tracery, the lower being a mullion transom window, with a flat arch head. Between the gable and doorway to the upper school is a bell-turret, in which there is another entrance to the school-rooms. This also forms the lobby, and contains three tiers of windows. There will be accommodation for 300 children, and the room on the ground-floor measures 56 ft. by 20 ft. There is other accommodation on both stories, and the building has two elevations, one to the north, the other to the west, both ornamental. The architects are Messrs. Jackson & Heazell, of Nottingham; and Mr. White, of Keyworth, is the general contractor.

**Birkenhead.**—The Albert Memorial Industrial Ragged Schools, which are situated in Corporation-road, near St. James's Church and the Dock Cottages, at Birkenhead, are approaching completion. The schools are being erected at the sole cost of Mr. William Jackson, M.P., and are intended to accommodate 200 children, 100 of which number will be residents. The basement floor contains the large dining-hall and kitchen offices, with work-rooms for industrial pursuits, plunge baths, lavatories, laundries, and other conveniences requisite for establishments of this class, special attention having been paid to light and ventilation. The ground-floor comprises large school and class rooms for boys and girls, teachers' apartments, offices, and board-room, with central as well as separate stone staircases to each wing, in direct communication with the main corridor. The superintendent's apartments are placed on intercal floor over the main entrance, being equi-distant from all parts of the building, so as to insure perfect supervision. The first and second floors contain the children's dormitories, which are placed immediately over school-rooms in each wing, the front being occupied by the superintendent's and teachers' bed-rooms, sick-wards, store-rooms, &c. The classification of sexes has received special care, the staircases and entrances being so arranged that they cannot intermix. Large play-grounds, with covered play-sheds, are obtained in the rear of the building. The style adopted has been termed Victorian, and is dependent for its effect mainly upon its breadth of proportion and broken skyline, rather than closeness of the material with which it is erected. The architect is Mr. David Walker, of Liverpool; the contractor being Mr. Neill, of Chester, and Mr. Laycock the clerk of the works. The workmen employed in its erection have been recently entertained at the usual "rearing" dinner, when about ninety persons sat down.

**Rhyl.**—The New British Schools in Vale-road have been opened. There are two schools, mixed and an infants' school. The mixed school consists of two rooms opening into each other, the length being about 39 ft. by 18 ft. wide each. The infants' school is 27 ft. long by 18 ft. wide. There are also class-rooms, lobbies, cloak-room, and lavatories. They are built to accommodate 230 children, say 60 infants and 170 boys and girls. The land was given by Mr. W. Shipley Cony, and the cost of erection is about 7500l. Mr. F. D. Johnson, of Birmingham, was the architect; Mr. J. Rhyddwen Jones, of Rhyl, was the builder.

**York.**—The chief stone of the new Primitive Methodist Sunday School, in York, has been laid in Nuncey-lane, in the suburbs of this city. The new school-room will cost nearly 700l. The land on which the school is to be erected has a frontage of 110 ft., and a depth of 50 ft. The building is arranged in the centre of the plot, and the school-room will be 60 ft. long and 30 ft. wide. Separate entrances will be provided for the boys and girls, together with lobbies and other conveniences. There will be two class-rooms at the back of the building, each 15 ft. by 12 ft. Iron palisading will extend along the frontage. The walls of the school will be faced with white brick, and the arches and strings will be built of red pressed bricks. Each side of the school-room inside will form a series of arches, and the ceiling will be a flat one, divided into compartments, with a cornice round. The room will be about 18 ft. 6 in. high. Special means of ventilation will be adopted, and accommodation provided for 400 children. The school-room will be lighted by four two-light windows in the front, and two behind. The architect employed to superintend the work is Mr. H. Pippard, of this city, and the contractors for the work, who all reside in York, are the following:—Mr. Shatto, for brick and stone; Mr. Dennison, of Marygate, for joiner's work; Messrs. Shonk-smith, for plumber and smiths' work; Mr. H.

Young, plasterer; Mr. B. Baynes, slater; and Mr. Westgarth, painter.

**Bradford.**—New Ragged Schools have been erected on ground adjoining upon Vauban-street and Rebecca-street, in Westgate, and formally opened. The schools have been built from the designs of Messrs. Knowles & Wilcock, architects. The following shows the arrangement of the ground and building:—Basement-floor: cooking kitchen, 17 ft. by 16 ft.; dining-room, 33 ft. by 24 ft.; bath-room, 18 ft. by 13 ft.; girls' playground; boys' playground; committee-room, 14 ft. by 12½ ft.; parlour, 15 ft. by 14 ft.; living-room, 15 ft. by 14 ft.; wash-kitchen, 14 ft. by 10 ft.; masters' yard and conveniences. First-floor: girls' school, 30 ft. by 24 ft.; infants' school, 24 ft. by 21 ft.; boys' school, 41 ft. by 24 ft.; class-room, 17 ft. by 16 ft.; bed-room, 14 ft. by 12½ ft.; bed-room, 14 ft. by 14 ft.; and bed-room, 15 ft. by 14 ft. Top-floor: bed-room, 29 ft. by 14 ft.; bed-room, 24 ft. by 15 ft.; and bed-room, 17 ft. by 15 ft. Such architectural features as the buildings possess are of a simple Gothic character, and based on the construction of the various parts. The site slopes considerably, and presented at first view difficulties and disadvantages. The cost of the schools and land has been 2,700l. The following were the contractors:—Messrs. Kershaw & Co., masons; Mr. Wm. Brunton, joiner; Mr. J. Schofield, plumber; Mr. E. Thornton, slater; Mr. Wm. Sugden, plasterer; Mr. Wm. Hird, painter; and Messrs. Byrne & Co., ironmongers. The clerk of the works was Mr. J. Craven, of Bingley.

### Books Received.

*Contributions to English Literature by the Civil Servants of the Crown and East-India Company, From 1794 to 1863. With Occasional Biographical Notes.* By LEOPOLD CHARLES MARTIN, of Her Majesty's Stationery Office. Longman, Green, & Co. 1865.

This son of one of whom England has reason to be proud,—John Martin,—seeks by this little book to show the important services rendered to the State by the civil servants of the Crown and the East-India Company, independently of their duties and exertions in an official capacity, and that "so far from being overpaid and underworked, some of the noblest names in every branch of English literature, and some of our most laborious authors, have been in the official employment of the Government." The catalogue is confined to the works of those who have been officially employed since 1794, and nevertheless contains the names of 207 authors. Looking through the list it strikes us that many of these are rather civil servants obtained from the profession of literature than literary men produced by the Civil Service. Nevertheless Mr. Leopold Martin, who is himself of her Majesty's Stationery Office, has made a good case, and is especially entitled to the thanks of the Civil Servants of the Crown.

### Miscellaneous.

**CAMBRIDGE HOUSE.**—We find the following in the *Record*.—"It is said that Lord Palmerston's attention was recently called to a paragraph in the *Builder* stating that Cambridge House was to be pulled down to make way for a Roman Catholic Cathedral. 'Well,' said his lordship, 'I can't tell what may be done with it when my time is up, but I am happy to tell you that I have a lease for fifteen years.'" We mentioned the statement as "a story" that was going about.

**ANOTHER "STREET THEATRE" BURNED DOWN.**—At Sheffield, on Saturday morning last, the "Surrey Theatre," the property of Mr. T. Youdan, of Westbar, was rapidly destroyed by fire. The sensational representation of a fire in "The Streets of London" is believed to have been the cause of the fire, although it was not observed till two a.m., when it suddenly blazed out, and in less than half an hour reduced the theatre to a mere wreck. From the first there was not the slightest chance of saving it, and the engines could only play upon adjoining buildings, to prevent extension of the fire. The theatre and its contents had cost from 25,000l. to 30,000l. They were insured for 13,000l.

**THE WELLINGTON MONUMENT FOR ST. PAUL'S.** London complaints again being heard, Mr. Cowper was forced to state in the House of Commons, the other night, that Mr. Stephens had not completed the model which he had been commissioned to prepare. He had addressed frequent remonstrances to him, but was not able at present to say when the model would be ready. We are amongst the last who would hurry an artist, but surely, in the present case, it is now time something should be ready.

**MODEL HOUSES INDUSTRIAL EXHIBITION.**—Not to be behind hand, "The Society for Improving the Condition of the Labouring Classes" have organized an Exhibition seeking to promote the useful employment of leisure time amongst the tenants of the Society's houses, and an interchange of kind feelings between landlord and tenant. Prizes, varying in amount from 10l. to 1l. for adults, and from 2l. to 10s. for children under the age of fourteen, have been offered to the producers of useful articles or ingenious designs. The Exhibition will be opened upon Tuesday, April 4th, in St. Martin's Hall, and will continue open for a fortnight.

**"THE BRITISH WORKMAN."**—The new number of *The British Workman*, full of excellent engravings as usual (a famous pennyworth), includes a good word for Cabmen, by Mrs. S. C. Hall, in the shape of an account of the "Cabman's Cat at the Pelham Crescent Stand," told with that lady's usual taste and feeling. The original cat fostered by the men is dead, it seems, but they have adopted another. The London Cabmen, as a body, are a better set of fellows than some people think. We have had a fight for them ourselves before now, and showed with what difficulty it is they earn enough to live on after paying the hire of their horse and vehicle. They live a hard life, and deserve consideration at the hands of the public.

**THE THAMES AND ITS NAVIGATION.**—The general committee of the up-stream navigation, beyond Staines, have memorialized Parliament on the almost hopeless state of decay into which the locks and embarkment are falling since railways in a great measure superseded this route. The revenue has declined from 14,000l. in 1845, to 3,097l. in 1864. They pray for an inquiry by committee of the House, or by Royal Commission. Mr. Milner Gibson, on the part of the Government, said they had no objection to the appointment of a committee, or even the advance of public money by way of loan; but he had been informed that the construction of the locks was bad, and that the charges were too high. Reductions of tolls had greatly increased the tonnage below Staines; but the old tolls were still charged above Staines.

**NEW WAREHOUSES AT THE TYNE DOCKS.**—The new large warehouses at these docks are expected to be opened shortly. They are six stories high, the ground floor being intended to be used for general merchandise, and the five upper stories for grain, of which they will contain between 20,000 and 30,000 quarters. The lines of rail are carried through the ground floor of the warehouse from one end to the other, and each ascending floor or warehouse is provided with a trap-door and hoist; and on the side of the warehouse facing the docks each floor is provided with a covered-in platform, where also will be fixed a hoist. Other warehouses are to be built on the west side of the dock. The North-Eastern Railway Company, it is said, purpose building about eighty new houses, in the vicinity of the Tyne Docks, as residences for their workmen.

**IMPROVEMENT IN ORGANS AND HARMONIUMS.**—An important invention has just been patented by Mr. Dawes, of Leeds, engineer. The principle is this, that the highest note of any chord played on the key-board is made to predominate with greater power than the harmony. Thus the melody always stands out prominently, as if produced by another instrument. The effect, it is said, is sometimes marvellous, converting a comparatively dull and toneless instrument into a brilliant and enjoyable one. It is said to be the one essential improvement which will make harmoniums fit for places of worship as well as for the home circle. The invention is already patented in England, France, and Belgium. The patentee has given the name of "Melodie Céleste" to his invention, which is exceedingly simple, and can be applied, it is said, to any instrument for about 5l. Could he not be contented with some English words?

**HEALTH OF LONDON.**—In the week that ended Saturday before last, the births in London and nine other cities or boroughs of the United Kingdom were 4,368; the deaths, 2,982. The annual rate of mortality in the week in those ten large towns was 28 per 1,000 persons living, and was less than in the previous week, when it was 29.

**BUILDERS' CLERKS.**—A correspondent wishes to be informed "if there is a society in existence calculated to benefit builders' clerks in regulating their hours of labour, &c.," as he thinks the hours insisted on by many firms excessive, viz., from eight till eight, or other hours making twelve, while the pay is often not so much as that of a mechanic, and the responsibility and labour both of head and of hand are much greater.

**MONUMENTAL.**—The formal inauguration of the statues of Allan Ramsay and Professor Wilson, at Edinburgh, has taken place, amidst much rejoicing. The statue of Wilson is in bronze, and about 11 ft. 8 in. in height. It occupies a position near the western entrance to the East Princes-street Gardens. The Ramsay memorial is in white marble, 10 ft. 8 in. in height, and is placed at the eastern entrance to the West Princes-street Gardens—the two statues being thus placed one at each side of the Royal Institution. Both statues have been executed by Mr. John Steell, R.S.A., the well-known sculptor. We may say something about them next week.

**DOMESTIC ACCOMPLISHMENTS OF THE SPINNING-WHEEL ORDER REVIVED.**—An elegant loom, with all the necessary properties, has been constructed by Messrs. Stewart, of Kilmarnock, for the Countess of Eglinton, who intends to manufacture her own dresses. The frame is of yellow pine, highly polished, of convenient dimensions, and completely isolated, so that it can be set down and lifted at pleasure. It works either twilled or plain; and the apparatus has "a self-acting motion," and therefore requires small care. A printed lace web has been put in, and some specimens of work shot on for her ladyship's guidance.

**GAS.**—In consequence of a determined opposition by the town authorities of Leamington to a new Bill promoted by the Leamington Priors Gaslight and Coko Company, in Parliament, before a committee of the House of Lords, the maximum price of gas at Leamington, from the 31st March, will be reduced from 5s. 5d. to 4s. The company had for a period of nearly thirty years leased their works, although they had no power so to do under their Act of Parliament, for which the Lords Committee said they were "certainly liable to censure." The illuminating power has also been increased from twelve to fourteen sperm candles. The company have given notice that much further reduction in the price will from time to time be made, as the future consumption and the increase of profits will warrant.

**THE PROFITS OF GAS.**—The shareholders in the Phoenix Gas Company had a return last year, in the shape of dividend, bonus, &c., of no less than 38 per cent. The ordinary dividend was 10 per cent.; back dividend (1858) 1 per cent.; a share of the value of 16l. bearing 5 per cent. interest, was allotted to every holder of an original share of 60l.; and to each of whom was also given the opportunity of taking 40l. of a new stock at 7½ per cent. interest; the total result being, as we have stated, a profit of 38 per cent. in the year.—*City Press.*

**THE STRIKE AND LOCK-OUT IN THE IRON TRADE.** A meeting of the North Staffordshire iron-workers and their masters, in the presence of Lord Lichfield, took place, on Wednesday, at Stoke. It seems to have ended abortively. The masters insisted, as a *sine qua non*, that the men should go to work at the reduced rate of wages, and that then the differences between them should be referred to arbitration. To this the men declined to agree. They would not go to work at the wages the South Staffordshire men had accepted, and the quarrel seems now as far from being healed as ever. The London trades' delegates, too, met again on Wednesday, and passed resolutions approving of the conduct of the North Staffordshire men, and promising them support; so that their former resolution, advising the men to submit their case to arbitration, was somewhat equivocal, and hence was generally misunderstood. Nevertheless we have hopes the lock-out will not last long.

FIRE-PROOFING.—At the Philharmonic Hall, Islington, Professor Sylvester has delivered a lecture on this subject, illustrating it with fire-proofed materials, in the shape of beams, curtains, ballet-dresses, and a live ballet-girl, whose gauzy drapery was set fire to by a lighted torch, which only caused the dress to smoulder slowly away. The lecturer does not appear to have described the fire-proofing processes he used, but we suppose he does not claim any originality in that respect.

METROPOLITAN BOARD OF WORKS; TENDERS FOR JOBBING AND OTHER WORKS.—At the last weekly meeting of the Metropolitan Board of Works, the tender of Mr. William Detrick, for the execution of the day, jobbing, and measured works to be executed by the Board, comprising the eastern portion of the metropolis north of the Thames, for three years, at 12½ per cent. under the prices enumerated in the schedule, was conditionally accepted; as also was the tender of Messrs. Hill & Keddell for the execution of the works south of the Thames, for three years, at 10½ per cent. under the prices enumerated in the schedule.

THE DESTRUCTION OF ANCIENT IRISH REMAINS. It is much to be regretted that the Government do not take some effectual measures for the preservation of ancient Irish remains. They are gradually disappearing, and in a few years not a trace of some of them will be left. In other instances they have already long since disappeared; but the traces even of those might be re-discovered, like many of our own Romano-British and other stone records. The round tower of Devinish, in Lougherna, has been cared for, but others are in the last stages of decay. The Glendalough tower is becoming dilapidated at the apex, and nothing is being done to preserve it. Two or three of the Seven Churches are levelled to the ground, and all the carvings which Ledwick described in his day as "quite unique in Ireland," have disappeared. Many other instances might be given. The Government do not quite allow every trace of the archaeological history of England and Scotland to go to wreck: why should they do so in Ireland?

"MAGNETIC PAINTS."—A new species of paint powders, under this perhaps more attractive than chemically correct title, is now in the market. It does not seem to be intended for fine work, but is deemed suitable for iron and wooden bridges and girders, gasometers, railings and facings, boilers, and such like; and it is said to be composed of iron. The colours are mainly black (as the magnetic oxide of iron is), browns, and greens, slate and lead colours, purple, red, and blue. Whatever may be thought of their alleged "magnetic" properties, these paints seem, from testimonials in their favor, to be very economical colours. Thus, in a report, signed "James Edward Ransome," and addressed to Messrs. Ransome & Sims, of Ipswich, we find it said,—"We took ½ lb. of mixture of white lead and lamp black, and thinned this down with ½ pint of oil. We took ½ lb. of [Palford's] magnetic slate-colour, and thinned this down with ½ pint of oil. The two colours thus made were of the same consistency and fit for use, and they both covered the same quantity of work. As the magnetic paint is about half the price, in the first instance, and takes only half the oil, in the second, to thin it down, and will then cover as much surface, its cost is just one-half." As to the effect of weather on the paint, the report does not testify.

TENDERS

Table with 2 columns: Name and Amount. Includes Ashby & Sons (£3,176 0 0), Conder (£3,134 0 0), Riddle (£3,036 0 0), Williams (£2,987 0 0), Henshaw (£2,682 0 0), Brown & Robinson (£2,375 0 0), Kilby (£2,292 0 0), Macers (£2,800 0 0), Pritchard (£2,789 0 0), Eaton & Chapman (£2,745 0 0).

For taking down and rebuilding No. 10, Paddington-street, St. Marylebone, and premises in rear thereof, for Mr. Klein. Mr. Charles Bradley, architect. Quantities supplied:—

Table with 2 columns: Name and Amount. Includes Stabelford (£2,140 0 0), Hingett (£1,948 0 0), Hesour (£1,877 0 0), Howard & Son (£1,857 0 0), Mills & Son (£1,848 0 0), Longmire & Burge (£1,835 0 0), Brown (£1,798 0 0), Tracey & Co. (£1,772 0 0), Simpson & Son (£1,675 0 0).

For works at the Greenwich Station of the Phoenix Gas Company:—

Table with 2 columns: Name and Amount. Includes Smith & Son (£18,547 0 0), Moxon (£7,293 0 0), Pearson (£4,600 0 0), Dowra & Son (£15,400 0 0), Mann (£14,600 0 0), Aird & Sons (£15,338 0 0), Dowra & Son (£4,283 0 0), Pearson (£3,700 0 0), Aird & Sons (£3,604 0 0), Smith & Son (£3,603 0 0), Mann (£3,300 0 0), Moxon (£3,100 0 0).

Retort House complete.

Table with 4 columns: Name, Outside Framing, Cast-iron of Guide Framing, Wrt-iron of Guide Framing. Includes Challinor & Inskip (£961 9 0), Matthews (£890 0 0), Odden (£867 0 0), Steele (£832 0 0), Woodridge (£825 0 0), Hammersley (£725 0 0).

For two dwelling-houses, situated in Birch-terrace, Hanley, for Mr. Harrop. Messrs. Scrivenor & Son, architects. Quantities supplied:—

Table with 2 columns: Name and Amount. Includes Chaliner & Inskip (£961 9 0), Matthews (£890 0 0), Odden (£867 0 0), Steele (£832 0 0), Woodridge (£825 0 0), Hammersley (£725 0 0).

For two dwelling-houses, Cannon-square, Hanley, for Mr. Ephraim Woodridge. Messrs. Scrivenor & Son, architects. Quantities supplied:—

Table with 2 columns: Name and Amount. Includes Chaliner & Inskip (£961 9 0), Matthews (£890 0 0), Odden (£867 0 0), Steele (£832 0 0), Woodridge (£825 0 0), Hammersley (£725 0 0).

For alterations at spirit vaults, Market-square, Brnslem. Messrs. Scrivenor & Son, architects. Quantities supplied:—

Table with 2 columns: Name and Amount. Includes Bailey & Trevor (£2,505 0 0), Woodridge (£499 0 0), Aleock & Yates (£465 0 0), Steele (£458 0 0).

For Ide Hill New Church, Kent. Mr. C. H. Cooke, architect:—

Table with 2 columns: Name and Amount. Includes Piper & Wheeler (£3,327 0 0), Mansfield & Son (£3,320 0 0), Myers (£3,265 0 0), Carter & Son (£3,155 0 0), Matthews (£2,727 0 0), Constable (£2,260 0 0), Warren (£2,255 0 0), Kirk (£2,230 0 0).

For rebuilding Nos. 94 and 95, Middlesex-street, White-chapel, for Mr. B. Grainger. Messrs. Wimbly & Taylor, architects:—

Table with 2 columns: Name and Amount. Includes Barratt (£1,285 0 0), Tarratt (£1,255 0 0), Brighton (£1,250 0 0), Wills (£1,234 0 0), Messrs (£1,137 0 0), Kilby (£1,119 0 0).

For the erection of a new chapel at Fendrayton, Cambridgeshire:—

Table with 2 columns: Name and Amount. Includes Bennett (£1,175 0 0), Smith (£1,091 0 0), Thackeray & Son (£1,089 0 0), Sainsbury (£1,070 0 0), Branting & Son (£967 0 0), Allen & Smith (£962 3 6).

Tender for two pairs and one single villa, at Ealing, for Mr. White:—

Table with 2 columns: Name and Amount. Includes Brunnden (£1,115 0 0), Myram (£1,109 0 0), Adamson & Son (£867 0 0), Strudwick (£830 0 0), Lacey (£735 0 0).

For erecting two semi-detached houses at Barnes. Mr. Dural, architect. Quantities supplied by Mr. F. G. Widows:—

Table with 2 columns: Name and Amount. Includes Wood (£1,963 0 0), Daley (£1,700 0 0), Emsor (£1,490 0 0), Sale (£1,529 0 0), Scadown (£1,478 0 0).

For three houses for Mr. H. Tilley, Walton-on-Thames. Mr. J. Scott, architect. Quantities not supplied:—

Table with 2 columns: Name and Amount. Includes Farley (£1,123 0 0), Brown (£1,097 0 0), Messrs. Alderton (£1,007 8 0).

For a residence, at Mettingham, Suffolk, for Mr. J. P. Tallent. Mr. E. Boardman, architect. Quantities supplied:—

Table with 2 columns: Name and Amount. Includes Fells (£1,498 0 0), Darby (£1,387 0 0), Blunderfield (£1,351 12 0), Botwright (£1,320 10 0), Balls (£1,290 0 0).

For taking down and rebuilding eight-roomed house, with three stories of workshops in rear, at No. 8, Wilson-street. Mr. Bush, architect. Quantities not supplied:—

Table with 2 columns: Name and Amount. Includes Callow (£797 0 0), Green (£779 0 0), Harrison (£463 0 0).

For two semi-detached residences, in Glossop-road, Sheffield, for Mr. J. H. Sales. Messrs. Blackmoor & Withers, architects. Quantities supplied:—

Table with 2 columns: Name and Amount. Includes Crayn (£2,288 0 0), Wade (£2,260 0 0), Oakey (£2,145 0 0), Wilson (£2,094 0 0), Reynolds (£2,088 0 0), Ditto using ground mortar (£2,079 0 0).

Accepted for dining-hall and dormitories, Millland Counties Proprietary School. Mr. George Bidlake, architect:—

Table with 2 columns: Name and Amount. Includes Messrs. Barseley (£1,288 0 0).

Accepted for new class-rooms, re-paving, and altering Wesley Chapel, Westbromwich. Mr. G. Bidlake, architect:—

Table with 2 columns: Name and Amount. Includes Trow & Sons (£1,200 0 0).

Accepted for alterations and additions Evelth Manor, Shiffnal. Mr. G. Bidlake, architect:—

Table with 2 columns: Name and Amount. Includes Clarke (£751 0 0).

Accepted for chapel class-rooms, retaining halls, &c., Tipton. Mr. G. Bidlake, architect:—

Table with 2 columns: Name and Amount. Includes Trow & Sons (£4,737 0 0).

Accepted for shop, residence, and outbuildings, at Oaken Gates, Shropshire. Mr. G. Bidlake, architect:—

Table with 2 columns: Name and Amount. Includes Bowler (£1,455 0 0).

Table with 2 columns: Name and Amount. Includes Trow & Sons (£1,200 0 0), Clarke (£751 0 0), Trow & Sons (£4,737 0 0), Bowler (£1,455 0 0).

TO CORRESPONDENTS.

C. B. L. E. J. W. A. N. J. R. W. C. H. W. H. C. M. O'D. C. F. C. O. F. C. T. O. D. B. R. E. W. E. R. J. M. R. J. K. W. D. H. L. W. J. W. F. C. H. C. H. C. J. H. C. F. R. W. L. W. D. R. C. E. T. W. C. C. J. H. (shall hear as to last communication).—A. A. J. must use his own means to make known his Carpet-beating ground. We simply announced the wash-ink (beyond our control).—A. E. G. do not announce orders (done, without knowledge).—G. W. D. (cash has been sent).—J. O. N. R. (we shall be very glad to receive the paper).—Art-Lover (thanks). But we usually prefer to let our correspondents of the press go to their own way.—A. W. R. (we are glad to hear of your success). We are compelled to decline pointing out books and giving addresses. All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender; not necessarily for publication.

[ADVERTISEMENT.]

CHURCH, TURRET, and STABLE CLOCKS. J. W. BENSON, having erected steam-power and improved machinery for clock-making, at the manufactory, Ludgate-hill, will be glad to furnish to clergymen, architects, and committees, Estimates and Specifications of every description of Horological Machine, especially cathedral and public clocks, chiming tunes on any number of bells. A descriptive pamphlet on Church Clocks post free for one stamp. Watch and Clock Maker by Warrant of Appointment to H.R.H. the Prince of Wales, and maker of the great clock for the Exhibition, 1862. 33 & 34, Ludgate-hill, E.C. Established 1749.

ADVERTISEMENTS.

TO ARCHITECTS, ARCHÆOLOGISTS, and ANTIQVARIANS.—Messrs. COX & WYMAN, Printers of "The Builder," having had great experience in the production of their various works, and being supplied with the most extensive and the finest Arts, their Establishment affords superior facilities for the execution of the above description of PRINTING, whether illustrated or otherwise, at the best possible terms, and at moderate prices. COX & WYMAN, Fine-Print and Classical Printers, 74, 75, Great Queen-street, London, W.

BANKRUPTCY.—PUBLIC NOTICE.—JOHN McDOWALL, SON'S, Engineers, of Wood-Cutting Machinery, Walkinshaw Foundry, Johnston (established upwards of forty years), feel it necessary to announce that they have NO CONNECTION whatever with the recent firm of JOHN McDOWALL & SONS, Engineers, Dimsy-street, Johnston, whose acquisition appeared in the Edinburgh Gazette of the 14th instant. They continue their Business of Manufacturing every description of Wood-Cutting Machinery, for which they have been so long eminent. Walkinshaw Foundry, Johnston, near Glasgow. 17th March, 1865.

GALBRAITH and HAUGHTON'S SCIENTIFIC MANUALS. Now ready, in 6p. 3s. price 3s. sewed, or 3s. 6d. cloth.

MANUAL OF ARITHMETIC; Revised Edition, containing nearly 3,000 Examples. By the Rev. J. A. GALBRAITH, M.A. and Rev. S. HAUGHTON, M.D. F.R.S. Professors at the University of Dublin. Also improved Editions of the following Manuals by the same Author:—

Table with 2 columns: Title and Price. Includes Mechanics (£2), Algebra (£2), Euclid & Trigonometry (£2), Hydrostatics (£2), Euclid & Parts, each (£2), Oceanic (£2), Mathematical Tables (£2), Scales and their Curves (£2), or Sixpence more each Manual in cloth lettered.

MISS ACTON'S MODERN COOKERY.—8000, price 7s. 6d. Seventy-sixth Thousand, revised and enlarged. "The best book of its class yet published."—Illustrated London News. London: LONGMAN, GREEN, & Co. Paternoster-row.

Second edition, revised and enlarged, in part 8vo. with 27 Figures on Wood, price 6s. 6d. cloth.

THE ELEMENTS OF MECHANISM, designed for Students of Applied Mechanics. By T. M. GOODEVE, M.A. Prof. of Mechanics at the Royal Military Academy, Woolwich. London: LONGMAN, GREEN, & Co. Paternoster-row.

NEW EDITION OF PROFESSOR TYNDALL'S WORKS ON HEAT. In 10 vols. with Fifty and 100 Woodcuts, price 15s. 6d.

HEAT considered as a MODE OF MOTION. By JOHN TYNDALL, F.R.S. Professor of Natural Philosophy in the Royal Institution of Great Britain and in the Royal School of Mines. Second Edition, with Additional Illustrations. London: LONGMAN, GREEN, & Co. Paternoster-row.

[NOTE.—Has latter omitted the house or workshops?]

# The Builder.

VOL. XXIII.—No. 1157.

Woman's Work in the Art-world.

It scarcely seems fair to discuss the subject of female influence on art without admitting reference to the fair sisterhood of the present day. There has been such a wonderful stride made in this matter in the lifetime of this generation that thousands of eyes must flash fire and thousands of lips curl scornfully at an exclusion that so materially affects the facts of the case. It is as though we were to treat of musketry and bring our subject to an end with an account of the capabilities of Brown Bess, leaving all the improvements of the modern war-smiths out of the question. In art, as in arms, the work of the day tells of the hursting of bounds, the breaking up of barriers, the opening out of floodgates, and of new lights and new powers starting up in every direction. There is, moreover, so strong a tendency to suffer the ashes of forgetfulness to collect on the memory of those who have passed from us that we may be sure it is but a very small proportion of the names of great workers in their generations that have come down to us. We have proof of the truth of this conclusion in our possession of ancient works of art whose authors are unknown; and what applies to men applies to women. The exigencies of living interests—the mighty waters of to-day—carry most things before them, wash away traces of the great, fill up places left by the good, and reduce to insignificance much that was once esteemed of consequence. We must hear this tendency in mind when we attempt to compute the influence of the female sex in the art-world.

Granting, however, no reference to living talent, we may see, if we like to give the matter thought, that art has benefited more by woman than we are generally disposed to allow. As far as we can see back into the history of the human race, there appear to have always been channels of taste, or grooves, in which the aspirations of intellect were directed, not, as in our own day, of fleeting fashion, but of long endurance, the result ripening, and ultimately rotting, in the suns of centuries; and in all these successions of intellectual endeavour, woman has taken due part. In the days of the prophets there were prophetesses of equal sanctity and esteem; in the mythological era there were the sibyls, whose *god-counsel* was obeyed by trembling Trojans and by the awe-struck Roman senate; temples were served by priestesses and vestals, as well as priests. In the early days of Christianity there were holy women teaching with as much vigour and practising as much austerity as any convert of the stronger sex; and in the steadfast declaration of Christianity, in the face and in the fulfilment of martyrdom, women bore their full part. In fine, since the world began, we find women have occupied governing points and wielded great influences, instead of having been slaves in the first instance, and housekeepers and

nurses in the second, as some are apt unctuously to assert, with complacent comparison with the present state of things.

If we cannot trace to woman the genesis of song,—the triumphant utterance of Lamoch on seeing the sword his son had forged being conceded to be the first on record,—we must acknowledge the early evidence of her power of song in that of Deborah. This gifted woman sang with a majesty and power scarcely exceeded; her vigorous cadences ring again like trumpet-calls, and depict many "great thoughts of heart." Although Barak is accredited with a share of the authorship of this poem, some of the best passages in it are incontestably hers,—as, for instance, the proud boast of being a mother in Israel, and the tender transition from the tent in which Jael set the "lordly dish" before the fugitive Sisera and killed him while he slept after his repast, to his longing mother watching at the window and crying at the lattice for his return. That this outpouring was not a solitary example we may conclude from the solemn and spiritual song of Hannah. We will look, however, more especially at those names lighted up by the phosphorescence of genius among the hurried nameless myriads of Mediæval times. Many of these irradiated names are feminine. They first appear in Italy, France, Spain, and ultimately in England and North Europe, marking thereby woman's active participation in the gradual enlargement of the regions owning the impalpable but elevating sway of the fine arts. In the cluster of Italian poetesses Vittoria Colonna shines apart as having executed the most and the best work. Nor were her pearls cast before swine. She was almost idolised by her contemporaries, who bestowed upon her by acclamation the title of *Divina*; Michelangelo, Galeazzo di Tarsia, and others addressed many of their sonnets to her, princes offered her their hands in marriage, and four editions of her poems were issued in her lifetime (1490—1547). French literature may not yield so dazzling an example, but it contains several instances of very early poetesses possessing more than average ability; and it is delightful to find that the possessors of these talents were as pious and pure—in ages of great laxity—as Vittoria Colonna. Birds of gaudy plumage and flapping mien in those days were as songless as their modern representatives. Doctro de Troies mentioned in the "Ehile Guyot de Provins," as in the court of the Emperor Conrad, at Mentz,—

"De Troye la bele Doctro  
Y chantaient cettie chazouette,  
Quant venait la saison  
Que l'herbe reverdoie,"

is an example of a French poetess in the days of *trouvères*, jongleurs, and *trouhadours*. The work of Barbe de Verrue, of about the same date, must always be quoted in any attempt to illustrate the literature of those days, and is pithy and pointed among productions that are 500 years newer. In the first half of the thirteenth century Beatrix de Savoie, la Comtesse de Provence, sang songs in praise of wedded love, and was herself much praised by her contemporaries. Claire d'Andazo wrote verses still in esteem. Clotilde de Surville, when quite young, translated an ode of Petarch with so much grace of diction that Christine de Pisanee declared that he must yield to her all his right to the sceptre of Parnassus. Being left a widow, by the death of her husband at the siege of Orleans, only seven years after her marriage in 1421, she devoted herself to the education of young women who possessed poetical talents. Margaret of Scotland, wife of Louis the Dauphin, sent Clotilde a crown of artificial laurel surmounted by twelve pearls with golden studs and silver leaves, with the device, "Margaret of Scotland to the Marguerite (pearl) of Helicon," proving that female talents enjoyed feminine admiration and recognition. Clemence Isaura, known as the Sappho of

Toulouse, still appeals to us out of this long-ago past. Her life was identified with flowers, for, having lost her father when young, she was brought up in seclusion, and allowed to spend much of her time in her garden. A *trouhadour*, Raoul, lived near, and becoming intensely in love with her, acquainted her with his passion in song. She replied with flowers; and when her lover fell in battle, she devoted her fortune to the revival of the floral games, once esteemed by the *trouhadours*, but which had fallen into disregard. Her ode to Spring is perfumed with roses. Louise Lahé was a later light. Her works, consisting of a "Dispute between Love and Folly," three elegies, and twenty-four sonnets, first appeared in 1556. Her character was of a different cast from that of the gentle Isaura. She excelled in physical feats; and under the name of Captain Lois was present at the siege of Perpignan; but her accomplishments and conversation were none the less charming, for her house was the centre of cultivated society in Lyons: the street in which she lived was called by her name.

Two queens in the sixteenth century gave the world specimens of considerable literary ability. Marguerite de Valois, queen of Navarre, prepared mysteries for representation; wrote the "Mirror of the Sinful Soul," a collection of stories called "*Heptameron, ou Sept Journales de la Reine de Navarre*," and a number of poems published in 1547, as the "*Marguerites de la Marguerite des Princesses*." The second royal poetess was Mary Stuart, Queen of Scots, who wrote both Latin and French poetry with elegance. Nearer our own time the works of Meslames Sévigné, Staël, and de Genlis will bear examination. Mary Stuart brings to mind the equally unfortunate and more to be regretted Lady Jane Grey, who would have left a larger legacy to the art-world if her life had been prolonged. The sister of Sir Philip Sydney, Countess Pembroke, was a genius of the first water. The four daughters of Sir Anthony Cooke—Lady Burleigh, Lady Bacon, Lady Russell, and Lady Killigrew—are celebrated instances in which the genius of a family ran in the approved channel of taste. These ladies were all good Greek and Latin scholars,—Lady Burleigh adding Hebrew to her list of accomplishments; the mother of the illustrious Bacon translated twenty-five sermons from the Italian of Barnardine Ochine, and the "Apology for the Church of England," from the Latin of Bishop Jewel; Lady Russell was especially clever at epitaphs and elegies in Greek, Latin, and English verse; and the youngest was a good *Holraist*, and wrote in Greek and Latin.

Queen Elizabeth's intellect was cultivated in the same direction, we know. The taste prevailed into Stuart times. Evelyn mentions many ladies much accomplished in these Classic tongues, and describes his own little son to have had a passion for Greek when he was but five years old. These word-studies died out of sight as fiction dawned upon the art-world; and we find the feminine intellect adapting itself to the creation of heroes and heroines quite as easily as that of the other sex. The literary work of Jane Porter, that once spanned all Britain with sympathy for the woes of Poland; of Mrs. Anne Radcliffe, that thrilled all nerves after dark, and peopled every corridor with phantom forms; of Miss Burney, enjoyed by George III., his Queen, and the Royal children, besides Johnson, Reynolds, Burke, and all the *beau monde* of that day; of Anna Seward, incorporated by Sir Walter Scott in his choicest collections; of Hannah More, Mary Wollstonecraft, Miss Edgeworth, Miss Austen, Miss Mitford, Miss Opie, Mrs. Barbauld, and Miss Brontë, is independent of any allowance for the sex of the writers. And here, in connexion with the last-mentioned name, we cannot but note a practice induced by our assumption of superiority of workmanship. Several of the most able and spirited of modern writers, French

as well as English, have challenged criticism disguised in masculine *noms-de-plume*, a defiant, ironical *coup de main* we can scarcely condemn as long as we have two degrees of comparison and criticism for the work of the respective sexes. Our string of pearls would not be complete without mention of the following poetesses.—Charlotte Smith, Mrs. Grant, Johanna Baillie, Caroline Bowles (whose work is the concentrated essence of pathos); Felicia Hemans and Elizabeth Barrett Browning, both winners of the world's highest sympathies; Letitia Elizabeth Landon, who stands out conspicuously from the more numerous smaller beads, amongst which there are still such names as Mrs. Hunter, Mrs. Tighe, Jane Taylor, Maria Jewsbury, Charlotte and Emily Brontë, excluding the bright galaxy of the day.

It cannot be denied that woman has ennobled and enriched dramatic art most bountifully in the two centuries that have elapsed since she set her foot upon the stage. Consider what Shakspeare's heroines have received at her hands. How much of the beauty of Desdemona and Ophelia would be lost by their impersonation by youths, even supposing that they were all as handsome as Kynaston, the young man who represented them in Colley Cibber's remembrance. In this department of art, at least, there are no names that glitter so extinguishably as those of Mrs. Braegerle, Mrs. Oldfield, Miss O'Neill, and Mrs. Siddons: in comparison with these stars, the fame of the male actors of the same periods is but the sheen of a spangle on Harlequin's scaly coat.

But not only as a performer has woman dignified the stage. The "Busy Body" of Mrs. Centlivre was a brilliant success, when Congreve's "Way of the World" was a failure. Garrick took his farewell in one of her plays; and the London managers, notwithstanding all their press of canvas from rising authors, have not yet shelved some two or three out of the score she wrote. The association of the stage with the name and memory of Mrs. Inchbald, actress, dramatist, and authoress of the "Simple Story," gives it more attraction to minds admiring diligent virtue in the constant exercise of self-denying charity than all its scenic wonders; but regarding only the art-phase of her life, it was beautiful. Her first production was the *Mogul* tale. This was so successful in drawing the town, as the phrase went, that Colman assured her she might earn any money as a dramatist. Like Mrs. Centlivre, she wrote about a score of plays, one of which, "Every Man has his Fault," brought her 700*l.*; and another, "To Marry or not to Marry," 600*l.*; and this only a short time before Coleridge was writing for Cottle, the Bristol bookseller, at the rate of a guinea and a half for every 150 lines of poetry, and but a short time after poor Chatterton wrote as many as sixteen songs for half a guinea. Theatricals appear to have occupied the throne of fashion between the setting of the taste for Greek and Latin compositions among intellectually-gifted people, and the rise of novels and romances. Mrs. Inchbald could turn from one to the other, her "Nature and Art" and "Simple Story" having as much fascination as her histrionic abilities.

We contend that if music had occupied the same place in public esteem as poetry, classic scholarship, theatrical performances, and novel writing have done, successively, there would have been as bright a galaxy of female musicians to point to as there are artists in those departments; and of this we have corroborative assurance in the fact, that when a prize was offered for a new part-song, it was carried off by Miss Elizabeth Stirling's startlingly original, "All among the harley." And so, too, with painting and sculpture. If Maria Angélica Kaufmann be almost a solitary example of a last century painter attaining excellence of workmanship, it is because female talent was turning its attention to a very different subject. But we have undergone another change of taste, and painting and sculpture are now the popular forms of expressing creative power and artistic feeling; consequently woman is dividing the laurels with us in these fields as she did with our fathers in those formerly frequented. Thus it is why it seems scarcely fair that we should discuss the subject at all, without reference to living artists. There died, however, in 1830, broken hearted, it is believed, a female sculptor, who has special claims on our regard for devoting her gifted labour to the decoration of architecture. This was Propertina Rossi. She fitted herself for the task by studying architecture and perspective; and her chief

work, the angels on the façade of the church of St. Petronia, is of admitted excellence. French studios have given the art-world three female sculptors, Madame Julien Charpentier, Madame Antoinette G. Desfontaines, and Madame Milot. And among her English contemporaries Miss C. Adams is generally allotted a recognised position.

At the sale of the Pompadour Collection, a few days ago, a marble monument, by Mlle. Felicia de Feanvean, on which was represented the history of Francesca de Rimini and Paolo, was sold for 2,920 francs.

A more lengthy examination of the quality and quantity of woman's work in the art-world would, doubtless, reveal more that should be placed to her account. We have aimed, however, only at breaching a lance in honour of violet memories likely to be passed over unheeded, but for some such effort.

#### COMPLETION OF THE SOUTHERN METROPOLITAN SEWERAGE.

The works of the outfall of the London sewerage, south of the Thames, being complete, the ceremony of their inauguration took place on Tuesday last, when the pumping-engines were started by the Prince of Wales, in presence of many members of the two Houses of Parliament, the Lord Mayor, and numerous other visitors. Though one important division of the system, namely the Low-level Sewer of the northern side of the river, is only commenced,—and though there are even left to be settled, questions, affecting the whole of London, which are no less than those of first principles of town-sewerage,—the occasion of last week was an appropriate one for the celebration of a successful termination of what has, from the first acceptance of the system, or throughout the progress of the works, been most skilfully directed and supervised. During the first inception of the schemes that, by arrangements similar in principle to those which Mr. Bazalgette has at length carried into effect, sought an adjustment of the Metropolitan Sewerage difficulty, we watched the progress of the question; and since the principle was decided upon, and the commencement of the works made in the Northern High-level sewer, we have minutely described all the divisions of the work completed, with but one important exception, the Crossness Outfall itself; and that one has so often had its relation to the general system of the southern side mentioned, and has so often been referred to when speaking of the Northern Outfall, that our readers cannot be unacquainted with its general features. The details of contrivance for the placing the sewage in the reservoir, and for ejecting it into the river, indeed, are such as we have felt could not be explained without diagrams; but, these we hope shortly to publish, when minute description of the arrangements and construction can be given best for being understood. Of the reservoir alone, but omitting a certain peculiarity of its foundations, some idea may be formed from the description in our last volume, of that of the Northern Outfall,—though there is considerable difference in dimensions. Each reservoir is divided into four compartments; and the two reservoirs have the same method of construction of piers and arches, and covering, culverts and sluices for flushing, and weir-walls for the overflow when a compartment is fully charged. The differences which there are between the Northern Outfall and the Southern, result from the difference of level of the sewage at the place of arrival in the two cases. On the north side, the sewage, arrived at the river-bank, is at such a level that it can all pass into the river by gravitation, the storage having for object only the interception of flow into the river during the time of rising tide, or when it would have been carried up to the metropolis. On the south side, the sewage arrives at such a low level that it has to be, the whole of it, pumped into the reservoir; from which it has to flow into the river. The Northern Low-level sewage is pumped at Abbey-Mills to the level which is that of the High and Middle-level lines or culverts,—the three being continued parallel with one another. On the south side, the Low-level sewage is pumped into the High-level at Deptford; whence the whole sewage of the High and Low Levels continues, joined in its course by that of Woolwich, and finally arrives at Crossness, at the level which has been referred to,—9 ft. below low-water level, or stating the level of invert of the sewer, about

28 ft. 6 in. below high-water. Whilst there are three culverts to the outfall on the north side, on the south side there is but one, or from Deptford to Crossness.

The culverts serving for the passage of the sewage between the Outfall-Sewer and the pumps, between the pumps and the reservoir, and between the reservoir and the river, are, for the most part, built together in three stages or stories; so that expense in foundations is saved. The low-level culvert of the three, passes the sewage to the pumps; then the high-level culvert distributes it and allows it to flow through penstocks, or sluices, into the reservoir; and lastly, the middle-level culvert allows it to pass to two low-water outlets in the river, or to the deep outlet; which last is furnished with twelve iron pipes, and is so placed in prolongation of the Outfall Sewer, that in case of emergency, such as an accident to all the pumps, the sewer could discharge into the river direct, that is on the old system. It should be observed that the arrangement of the conduction of the sewage of the north side of the Thames, from Abbey Mills to the outfall, in three channels or culverts, allows of the diversion from any one of them into the others when repairs are required; whilst the arrangement on the south side, below Deptford, where there is only one channel, would seem to involve a prospect of difficulty.

So much in the way of description and comparison was required for the sake of those who may not be able instantly to refer to what has already appeared in our pages.

The outfall into the Thames at Crossness, without the reservoir and pumping machinery, has been in use imperfectly, for some time approaching a year. It has been used subject to the old evils of tide-locked sewerage. The invert of the sewer being 9 ft. below low-water, there was always sewage, or water, in the sewer, up to a length of four miles from the outlet; and on the rise of the tide, a penstock had to be let down; or the low-lands, and perhaps inhabited districts, would have been flooded through the openings of ventilators and gullies. This provisional use of the Outfall Sewer can hardly have been beneficial to Woolwich; though to Bermondsey it may have been.

The Crossness reservoir has an area of about 61 acres,—the northern reservoir having an area of about 10 acres. It is 17 ft. deep; and the four compartments into which it is divided, each measuring 560 ft. by 130 ft. 6 in., or 132 ft. 6 in., are together capable of holding 4,340,000 cubic feet, or 27,000,000 gallons of sewage. The entire area of the works, including adjoining and reclaimed land, is about 36 acres.

Even Mr. Bazalgette's own description in the *resumé* which we lately gave of the paper read at the Institution of Civil Engineers, omits mention of most of the structural details, and all of the decorative,—for, there are the latter. Particulars of the whole would be interesting to our readers, or useful for purposes of comparison; but we must reserve most of them. We may state here that the engines, four in number, double-acting condensing, make up a nominal power of 500 horses. Each engine works two single-acting ram-pumps or sets of plungers. The cylinder of each engine is 4 ft. in diameter and 9 ft. stroke; and the plungers (eight to each engine) are 4 ft. 6 in. diameter, half of them with 4 ft. 6 in. stroke, and the remainder with 2 ft. 3 in. stroke. The pump-cases are 12 ft. diameter. The two delivery-troughs, or outlets from the pumps, are each 32 ft. long, 11 ft. 6 in. wide, and 10 ft. high. Substances that might get into the valves of the pumps are intercepted by a grating, and are lifted by scrapers and combs attached to an endless chain, working vertically. There are twelve hoilers; and they are each 30 feet in length and 6 ft. in diameter. The engine-house is about 154 ft. in length and 53 ft. in width. There is an amount of decoration in carved stone to the doorways and other parts, that may be deemed great, considering the situation of the building. The general character is Medieval with Byzantine and Norman features. The boiler-house, adjoining the engine-house on the south, or between it and the reservoir, is about 112 ft. by 64 ft. The decorative chimney-shaft is about 200 ft. in height. Coal-sheds extend along one side of the reservoir for a length of about 530 ft., and are 43 ft. in width. The contract-price for the reservoir and buildings was 360,000*l.*; and the engines, by Messrs. Wain & Co., were contracted for at 44,900*l.*

The statements which have appeared as to the proportion of sewage of the metropolis, yet

remaining to be intercepted, one-seventh, are doubtless correct; but the amount and importance of the work of the Northern Low-level Sewer, seem to us to have been underrated. The eastern portion of the line is well advanced; but of the lengths reaching to the embankment where Mr. Ritson's contract commences, at Whitefriars, we have heard nothing. The progress of the embankment, for a great part of its length, is not satisfactory; and this portion of the line includes, as our description showed, a large amount of work in connexion with storm-water outfalls of the sewage of the Middle and High Level districts. Westward of Westminster Bridge to a spot near Cremorne Gardens, and including a pumping-station, nothing had been decided upon when we last looked into the matter. The western sewerage has been efficiently accomplished; but, pending the completion of the works lower down, it discharges into the river.

Since the construction of the aqueduct over the Metropolitan Railway, however, the Northern Middle-level sewage in its entire volume passes on with the High-level to Barking Creek; so that the bulk of the accumulation in the low-levels, from the tide-locked mouths of the original outfalls in the river, is prevented. Along with this measure of improvement, and the completion of the southern division, and with the use of pumping, a regular flow is kept up, being substituted for the intermittent one which produced deposit, and entailed the enormous cost and other evils of manual cleansing. The gain must be immense, unless counterbalanced by evil such as might be compensated by the abstraction of water from the river, or the substitution for the Thames, of a smaller but concentrated stream of sewage. As regards tributaries to the stream, the intercepting system, in place of restoring the original brooks, has kept them as sewers, and has also diverted them, excepting at times of great rainfall. Contemporaneously with this, the intake from the Thames, of the water-companies, has become such apparently as to not only injure the navigation, but to add to the sewage-nuisance itself. The quantity intercepted may be less important than has sometimes been assumed; but the question, what is going on in the case of London, is important not entirely for the sake of the metropolis, but for the case of other towns wherein the intercepting system may be adopted. As to the capability of the new channels for giving off deleterious effluvia through ventilators and gullies, we believe that Mr. Bazalgette claims to have accomplished his design, which was to produce such a flow as, preventing deposit, would not allow the time for decomposition. According to one theory, that has been supported by experience, it is possible by sufficient fall, and by proper form of section of a sewer, for the solids to be passed through a considerable length of sewerage, without maceration, or decomposition, that is without deposit or deleterious effluvia. It is claimed for the new sewers that they have accomplished the desired objects referred to. In the account of the Northern Outfall-sewer in our last volume, we looked to the evidence on some of these points, both at the outfall, and in the sewer, but found it rather contradictory. In the sewer, the middle of the invert was perfectly clean; whilst the remainder of the invert, and a portion of the height of the curved sides, had some deposit; though the time since the sewer had first been in use had not allowed the deposit to become great.

When the scheme of the Metropolitan Board of Works, for the sewerage of London, was put forth, we said that it could not be regarded as the solution of the difficulty. We have had to repeat this since; and, now, towards the completion of the works, we see no reason to alter our view. Mr. Bazalgette may have accomplished his design, as he has most efficiently perfected the details of it: but the question for the inland towns like Manchester and Birmingham is not much helped; and the issue, so far, of what was commenced for London, may be due to having attempted little, comparatively speaking.

Regarding the question as Londoners should, he observed that the proper horizon extends farther than the boundary of the jurisdiction of the Metropolitan Board. For the purification of the Thames, it is not sufficient that the sewage of the Board's London should be intercepted; the sewage of the farther metropolis which includes Richmond and Kingston must be intercepted, or dealt with, likewise. And the same measure, or aim, must be extended to the sewage of all the towns up the river, towns

whose sewage we actually drink. And similarly for the Lea. As we foresaw years ago, the question, at last, is between a sewer for all the towns to the sea, and the discovery of some outfall other than into rivers. The point which logically regarded, stood first, was staved off to the last: there may have been no help for that; but the sewage-utilization question forces itself uppermost, and will make a costly levy against the arrears of attention to it.

The scheme of the Metropolitan Board comprised an area less than that of the plan of the Referees, Capt. Galton, and Messrs. Simpson & Blackwell, and much less than would seem to be necessary if intercepting sewerage is to be combined with the proposed jurisdiction of a Board over an entire water-shed. But the complaints as to pollution of the river above the jurisdiction of the Metropolitan Board, show there is something lacking in the constitution of such a Board as the latter, or in the principles of sewerage that should be recognised. In designing a system of sewerage, the first question is—Outfall, where or how shall it be? The Board's scheme did not supply the solution of that question. It still kept to an outfall on the river, to the prejudice, we should think, of Erith and Gravesend; and it did not extend its line of sewer to the sea, or the mouth of the river, as did the scheme of the Referees. But it has joined with a scheme, which both adopts utilization, and proposes an outfall-sewer of even greater length than that of the Referees. This sewer would start from Abbey Mills; so that if the new scheme be successful, the line thence to the Thames, and the reservoir near Barking Creek would seem to be useless.

The course we have taken since Mr. Bazalgette commenced his work, is sufficiently known to prevent any idea that we are now finding fault with the Board or their engineer. We remarked at the outset of the scheme, that a costly experiment might be necessary; and no one now is in a position to show, with sufficient precision, what else could have been done. The case of London was not that of a new town, but of a vast metropolis previously sewered. During the progress of the works of the Metropolitan Board, the question of sewerage-utilization has, it seems to us, advanced somewhat; but even now, there is room for doubt whether the Board, representing the rate-payers, could have rightly promoted any undertaking, less clear of accomplishment than that which has still preserved outfall into the river. Amongst the questions that experience will now test, is the question of the return of the sewage on the rising tide, one which is not so clear as it should be. That the Board has been admirably served by Mr. Bazalgette, and all the engineering staff, we need not say: the fact is shown by structural work that is the admiration of all who have seen it.

#### THE PRESIDENCY OF THE INSTITUTE OF ARCHITECTS.

A PAPER WAR appears to have commenced. In reply to the circular touching the presidentship, to which reference was made by a correspondent last week, Professor Donaldson, the president, has written a letter, and circulated it amongst the members. In this the Professor expresses his astonishment that members of the Institute should take upon themselves to anticipate the council, to whom, for many years, the Institute has given the right of recommendation; and goes on to say—"The Institute has, by its votes, for successive years declared the expediency of having a professional man as president, and since the death of the Earl de Grey has acted upon this principle, which you would now set aside. In this assumption I see an attempt to override the feelings of the great body of the members, and to establish a rule of government in this Institute of an intolerable nature, that would elevate one class at the expense of the other, and be intolerant to all else. I think it, therefore, time for the members to rally round this fundamental rule of action and high feeling for true art in the most general sense; to elect a leading member of the profession as president, irrespective of his personal predilections (which he may fairly and honourably entertain, whether Medievalist or Classicist), under the recognised obligation that he shall be impartial,—not a party man,—ready to further the study of architecture in whatever style,—to promote good fellowship and forbearance; and not to make the Institute a platform for party strife and oppression of one class of art over the other."

To this Mr. Street replies, and prints his letter, in which he thinks it worth while to say, that sixteen years ago the Professor considered it advantageous to have a non-professional president. He is stronger, however, in pointing out that,—“When the charter was granted to the Institute, it was with the permission, if not with the intention, that the president should be a non-professional man; for which purpose the class of honorary fellows seems to have been expressly created.” He goes on to say,—“I reply to you therefore in your own words, and say openly, that in this letter of yours, just as in the award of the gold medal the other day, all unprejudiced men may see ‘an attempt to override the feelings of the great body of the members, and to establish a rule of government in this Institute of an intolerable nature, that would elevate one class at the expense of the other, and be intolerant to all else;’ and ‘I think it, therefore, time for the members to rally’ in support of the ‘fundamental rules’ of the Institute, and to select their president with a ‘high feeling for true art in the most general sense,’ i. e. with a view to the fitness of the person proposed, and not with regard to the persons who propose him, or the nature of his legal qualification for the office.”

Afterwards, comes out a letter from Mr. Scott, assuming that Mr. Hoop will be among the candidates to be considered by the council, and asking permission to lay before the members the reasons why he thinks all might unite in this choice; first and foremost amongst which is, of course, the provision in the laws already referred to, that the president may be elected from among the honorary fellows. He goes on to say,—“Secondly. Though it is, no doubt, desirable that our presidents should, in a majority of instances, be professional architects, I feel it to be equally the case that it is desirable to establish a community of feeling between the professional and non-professional promoters of our art by, from time to time, doing honour to those who, without professional impulse, devote themselves to the same study with ourselves. We have now elected three professional presidents in succession, and I cannot but feel that it would be a graceful act now to give a fair turn to our lay members, and to show them that their privileges are not a name only but a reality.”

In conclusion, Mr. Scott writes,—“I am strongly convinced that nothing would so much tend to the harmony and good working of our Institute as the unopposed acceptance, on this occasion, of Mr. Hoop as our president; and I am equally convinced that he would accept the honour as a pledge of harmony and good feeling, and would fill the position with the strictest impartiality, and as the representative of our art in its unity and integrity, and in no degree of one individual branch of it; while those who are anxious that he should on this occasion preside over our Institute, would view the withdrawal of opposition to his election as the best pledge of future harmony and mutual good-feeling.”

Years ago we urged zealously, and we have reason to believe not without effect, that the president of the Institute should be one of its professional members; and the successive election of the late Professor Cockerell, Mr. Tite, and Professor Donaldson, since the death of Earl de Grey, would seem to show that the principle has been accepted by the body. We are not able to change our opinion. What we believed then we believe now. We have the greatest regard for Mr. Hoop personally, the fullest appreciation of his services to art, which, indeed, place him in an almost exceptional position; but we still think that a member of the profession should fill the presidential chair. At the present moment, when a competition for a great national building looms in the distance, on the jury for which the president of the Institute would doubtless be placed *ex officio*, it is even specially desirable.

Mr. Scott unites in himself many qualifications for the office; and, moreover, would probably sufficiently meet the views of even those members of the Institute who seem to think that, unless an architect ridiculo and despite all other styles, he can have no knowledge or love of Gothic architecture. We shall be glad to find him a candidate, or willing to be put up as one. Professor Smirke, R.A., has been spoken of; and it has been stated that, should both these gentlemen decline, Mr. Tite, if requested, might probably be induced to serve again. The question at present, as we understand it, is simply as between a professional and non-professional president.

THE MISUNDERSTANDING AT THE  
INSTITUTE OF ARCHITECTS.

SIR,—It is not advisable that any paper war should be set on foot about this matter; but the remark of your very sensible correspondent, "A Goth," that a split seems impending, must be contradicted. Matters will soon right themselves now; as it is impossible to believe that the annual election next month can pass over without a definite settlement. The dispute is not between Classic and Gothic, but between a handful of revolutionists and the entire remainder of peaceful, practical men of business,—between, at the utmost, five-and-twenty on the one hand, and, at the least, five times as many on the other. Let any person tell down the list of Fellows, and he cannot come to any other conclusion. The majority is composed of men of all shades of opinion, whose motto is, *The common weal*. The minority is formed, to say the least, on some different motive. That this minority, insignificant as it is, should obtain temporary power in the council, is an accident easily understood; but it is a thing quite as easily remedied. COMMON SENSE.

WESTMINSTER ABBEY.

The condition of this edifice, as observed by a correspondent in the *Builder*, p. 195, is certainly most deplorable as to its arrangement for congregational worship; for, during the winter months, to remain two hours within the precincts is a service of danger; and, despite the attractions of the fine choir, the pealing organ, the accumulated sacred relics with characteristic statuary, and the college of dignitaries who represent our grandest metropolitan dean and chapter, it is positively deserted, or frequented chiefly by visitors through curiosity rather than by residents for worship. It may be said that the defaults of proper ventilation and warmth may be easily corrected; and so they may; although this enormous and massive fabric stands on a level with the adjacent causeway—*not having a basement story, like St. Paul's*; but there are other shortcomings and defects in this great national shrine, which in the present day of metropolitan improvements become more flagrant and inexorable, since a citizen of a sister metropolis has expended out of his private fortune 150,000*l.* to restore and embellish the ancient cathedral of St. Patrick.

The dean and chapter of Westminster have an immense income, and, besides that, most valuable patronage,—quite enough to subsidize all their canons, dignitaries, and officers, as well as to sustain the structure in a condition worthy of its dedication. How do we find it?—chill and dank as the Church of Corinth,—neglected and rude as the tombs of Egypt. On one side, the north, it is open to St. Margaret's Church-yard, and to the fine, though as yet unfinished thoroughfare, of the Broad Sanctuary and Victoria-street. On the east—Henry VII.'s Chapel, fronting Old Palace Yard and House of Parliament; there is an open space, which is suitable in all respects; but on the south, only separated by a narrow footway, some small antiquated houses in the August pile, which is again allowed to be desecrated by the temporal rhodes of vergers and officers, in close and compact connexion with the venerable fane! Whilst, again, in Palace Yard, confronting the House of Lords, six odd mansions screen off the view! Were these mean erections, with their entanglements, the malleable property of their freeholders, it might be expected that the guild spiritual of the Abbey should purchase them out, for the purpose of clearing away all secular contaminations, and to isolate the building, with the view of bestowing upon it unity of aspect, and an elevation on all sides worthy the principal cathedral of reformed England; but all the precincts, including Dean's-yard, the Cloisters, and the two intrusive stacks of architects' offices, are the estate and property of the dean and chapter! The very fact that they are so accounts for the decaying and forlorn condition of the whole vicinage; for Church lands and possessions, wheresoever found, are the most notable exceptions, if not actually obstacles, in the way of improvement and amelioration. Property to a great extent on this side, extending nearly to Vincent-square, belongs also to the Capitular Estate; and now that the most important improvements of London meet just at this glorious site, where

Barry's splendid achievement of St. Stephen's Palace had pre-determined the grand centre of State intercourse, surely it is time that so great a blot as those mean parasite buildings which cluster about the Abbey should be cleared away, and that its complete integrity be effectuated.

On the north range, which, with Henry VII.'s Chapel, measures about 165 yards, the open space of St. Margaret's Churchyard and the Broad Sanctuary, confer upon the grand entrance facade a fair aspect. On the east, Palace-yard equally favours by its ample width the pleasing contrast exhibited by the two best examples that we possess of ancient and modern art. On the west the opening from Victoria-street reveals about two third parts of the elevation, including the two restored towers; the other portion being screened off by a block of six houses of recent erection, which back Dean's-yard, and are occupied by professional men, or as chambers. This stack is certainly finished in a style not very discordant with the Abbey; but, being on the estate of the dean and chapter, it was let as all Church lands are let, to a speculating builder, and thus, from that aspect, the view of the cathedral is scaled up and shut out. On the south side, however, there is still scope enough left for opening out and exhibiting the building in a becoming way; and, considering the present onward march of improvements and renovations which are to connect the City by the river embankment with the West-End, the time has arrived to necessitate the demolition and clearance of the old parlous and closes that in its origin circumscribed the Abbey, and which now block in and conceal the finest portion of its elevation. On this side the open spaces and buildings all belong to the Capitular Estate, as also the whole extent of house property between Dean-street and Palace-yard from east to west, and between the Abbey and College-street from north to south.

Within these boundaries we find Dean's-yard, an open square surrounded by houses,—seventeen of them occupied by externs, and four or five by members of the Capitular establishment, measuring clear of the buildings about 130 yards by 90 yards,—as large as Cavendish or Manover square; next the dean's garden, an open turfed expanse of about 280 ft. square; then three open squares surrounded by venerable and not unpleasing cloisters, which are surmounted by a most incongruous series of heterogeneous buildings, arranged as domiciles for a dozen canons and officers of the cathedral; some are of brick, some of plaster,—modern and ancient mixed; the doors of access in the cloisters, with names on brass plates, as also tablets and inscriptions of the departed functionaries and worthies who were interred in the adjacent spaces,—these are all in squares along the cloistered galleries.

The far-famed and justly celebrated school, nesting close to the foundation, occupies an old and misshapen structure, the only merit whereof as a fit place for the studies of 150 pupils is its registered prestige, and the inscriptions chiselled by thousands of departed and living pupils of their names in simple Roman character,—as chambers appropriate for study, or for continued occupation during six or eight hours daily,—no other foundation in London is worse provided; for, despite the hot-ir-pipes, and the gas-light throughout a winter's day, it is gloomy, dank, and most inconvenient. Again, an *Infirmiry* of decent architecture and large proportions, now a school, occupies a considerable space about the central position, near College-street; and herein we find lecture-rooms on the ground-floor, and chambers for forty boys over. But the greatest hemish on these wide possessions, is the too close proximity of houses under the shadow of the august pile, and within 15 ft. of Henry VII.'s Chapel in Poets' Corner. Here, too, the range of houses in Palace-yard commences, cutting off the view of the whole cathedral and grounds, and screening off the Houses of Parliament. This range bounds the quadrangle on the east side, as does Dean-street on the west, and College-street on the south; the whole interval being in possession of the dean and chapter, what a glorious opportunity is afforded to them to open out, improve, and remodel their cathedral!—to pull away unsightly gables and masses, but to preserve ancient cloisters and arcades, and all that is venerable or suitable to the sacred precincts. There is ample space for schools, for an infirmiry, ay, for domiciles to lodge the whole chapter and its adherents; but away with the rubbish. By judicious planning and outlaying of these central, but now inscrutable lairs, a noble site for man-

sions or public establishments might be secured with profit in this "juste milieu" of intercourse—central, easily accessible, and germane to palaces, marts of commerce, and aristocratic quarters.

This is not an ecclesiastical; it is a national question. In Italy, in France, as well as in Ireland, not only the erection of new churches, but, most of all, the reconstruction and embellishment of old cathedrals, is being actively pursued; and where the church estates are of regal proportions, some enterprise and fair liberality ought to be devoted to the work by churchmen, without waiting for a princely deodand.

An opening is now offered for the resuscitation from a long sleep of these venerable reliques. Let the whole block of houses in Poets' Corner, Palace-yard, and Abingdon-street, together with the back *Stable-lane* be swept away, and a proper iron fence substituted, with suitable entrances. This will reveal, from the Houses of Parliament to Dean-street, a space exceeding twelve acres. Widened throughout its length Great College-street in a direct line; this, if continued, will fructify from Victoria-street, at the junction of Strutton ground, opposite Christchurch-yard, passing along Pye-street, the worst and meanest slum of Westminster,—a block of inferior houses, for about 100 ft., between Smith-street and Dean-street will have to be cut through. Thence the line will pass at the back of Dean's-yard houses, forming one side of a delta terminating close to the Victoria Tower.

Here, built upon the Alhdy grounds along a causeway 80 ft. wide, a range of modern houses will accommodate the dean, all the masters, and the canons residentiary; while ample space will remain for an appropriate school foundation, and, if need be, for a hospital. All these will then build, and not obstruct, a *hallowed campo santo*—preserving all that is valuable for its antiquity, remove or restore all that is unsightly; open walks throughout, with grass and shrub where available; have the cloistered walks of celibate monks relieved of their superincumbent deformities; in fine, let the chapter take a lesson from the Marquis of Westminster in his *gairances*. A little worldly wisdom may be gained therefrom, showing how to make the estate pay. This, together with the clearances and new routes now about inception, would at once double the value of the whole property in houses, extending to Vincent-square, and wherever modernization is carried out.

If, however, the opening out of College-street and Pye-street, in the direct line of Victoria-street, is ever to be effectuated, there is not a moment to be lost; for all the building frontages are let, save only that one which is requisite at the corner of Strutton-ground; and should the new street now in progress, and opening into Orchard-street, be completed and built in, it may then be too late.

The Chapter House, once a chapel, its enormous windows and flying buttresses built in with rude brickwork, leans against the south transept: having been used as a record repository, it is now vacant; the external masonry wasting and smouldering to ruin. Another votive shrine, built against the south wall of the aisle, is now a kitchen and "trattorio," where forty Queen's scholars daily dine. These and the cloisters are the most ancient relics of the monastery, much impaired by time, but more by ruthless Gothism: to restore them would be a new consecration.

Such is the condition of the exterior, which, except in these instances, and also where concealed and built in by *household habitations*, has been fairly restored and eased up with block-stone and ashlar. But for the interior, what has been done? Here we possess a sacred treasury of art,—a sanctuary of antique relics, the embodiment of a nation's devotional history. It is humiliating to compare its aspect with that of any other great metropolitan shrine: the stupendous routes, the tracery, the whole superficies are left to time and chance: nothing has been done to illustrate or illuminate the sacred temple that we may "enter these courts with praise,"—sheltered only from the external elements: time, smoke, and damp vapours are suffered to waste and obfuscate all that is remarkable and graceful in ecclesiastical architecture!

What, then, is easier than to preserve the whole fabric by a proper system of ventilation and warmth, as has been done at St. Paul's, York, and other cathedrals, and in numerous churches? Free entrance may be given to all; but until a genial atmosphere is secured through-

out the gorgeous dome, the permission favours only the curious, and not those who would "go their way into these gates with thanksgiving," QUONDAM.

#### CHURCH BELLS: THEIR ANTIQUITIES AND CONNEXION WITH ARCHITECTURE.\*

So much has been said and written of late years on Church Bells, that, notwithstanding this is the first time the subject has been brought before the Architectural Institute in the shape of a lecture, it is by no means easy to discourse upon it with any charm of novelty to the scientific audience which I now have the honour to address, many of you being probably as well up in the subject as your lecturer. Campanology, however, is a science (I use this term advisedly) which most appropriately holds a place in an association like our own, whose object is to develop and enunciate the close and inseparable connexion of high art with the Catholic faith, for no musical instrument has ever exercised so great an influence upon architecture as the church bell. To it we owe the most striking external features of our churches, whether in the varied groups of the many-towered city, or the country spire pointing amidst the trees to the skies, or rearing itself heavenward like a ladder of fire, as seen in the horizontal rays of the rising or setting sun against the same horizon of the fen country of East Anglia. Then, again, there are the hundred different forms of cot and gable which crest the humble village church.

Sometimes we find large towers standing altogether detached from the churches to which they belong; the campanile at Chichester is a well-known example to most of us. Canterbury and Salisbury also yielded similar examples, the latter having been wantonly destroyed almost within the memory of those still living. Beccles, in Suffolk, is another notable example; so is Ledbury, in Herefordshire, and West Walton, in Norfolk, the latter forming a noble entrance gateway to the churchyard. I might name a dozen smaller ones. Now these towers were not built for mere fancy or picturesque effect, but to contain heavy bells, the vibration of which would have a gradually ruinous effect upon the general fabric of the churches to which they belonged; were they an integral portion of them. For the same reason the central towers of minsters and other large churches were intended to be lanterns proper, and not campaniles. The experiment was tried in a few instances, and great was the ruin that followed where the bells were at all heavy, as at Winchester and Ely. Bell-towers proper were invariably as little connected as possible with their churches. With the exception of Hereford, which fell down; Ely, which never had a large bell; Winton (Minster); and two or three other examples, we never see a minster proper even with a *bona fide* west tower; and yet we may be sure that their architects would most gladly have had them could it have been possible, for the greater space allowed for fenestration permitted by their absence is no equivalent (viewed internally at least) for the noble western arch which their existence would have afforded. The same internal western perspectives of Winchester or Norwich will hardly bear comparison with the western tower churches, even of the smaller type of Boston or Wymondham. Bell-towers were placed either westward of the aisles or on one side of them, as at Exeter, on purpose to lessen their connexion with the building, and guard against the ruinous shake of vibration. A virtue may, indeed, be said to have arisen out of the necessity, and an elegance and dignity to have been conveyed externally, by the double western tower; but this, I think, is viewed as an effect necessitated by a cause rather than as an original creation unfettered by circumstances.

Whether you agree to this theory about western towers or not, we shall all, I think, concur in this, that our forefathers did not build towers and spires only to put into them the very small and ill-sounding article, the eliek of which is a standing nuisance to the western half of the metropolis. Most old churches were furnished with such bells over and above the chiming bells; they occupied either the eastern gable of the nave as a sanctus bell, or they hung in some picturesque little lanvre, outside the tower or spire. Specimens of this latter treatment may be

seen at Hadleigh in Suffolk, Ichleton, and Hinxton in Cambridgeshire. Sometimes they hung in the weather-boarding of the belfry windows; but this latter arrangement is much more common on the Continent than in England, whole chiming being thus exposed to view in the hellicies of the south of France, Italy, &c. Though no larger than the modern call-bell of a London district church, their tone was sweet and silvery. Neither, again, did our ancestors build their towers as a very convenient smoke-flue, as was so common twenty years since, till we were bold enough to venture upon the good, open, honest, undisguised chimney. I would urge upon all connected with church building that the object of towers is to contain bells, spires being merely their ornamental capping; and that, unless there is a good and reasonable prospect of more bells than one, the money would be far better expended in adding height and dignity to the interior, which in a town church, where we have now to contend with the rapidly-increasing bulk of secular architecture, is becoming more than ever a vital point.

However, we must fall back upon the bell itself. In the first place, it is a satisfaction to be able to claim an unmistakably Christian origin for an instrument which has laid so mightily a hold upon ecclesiastical architecture. The earliest names for bells—"nola" and "campana"—would seem to point to Nola, in Campania, as their birthplace, and the fifth and sixth century as their earliest date. A favourite and expressive Medieval name for a church bell was "signum." I not long ago read in one of the newly-printed Record publications, but I have unfortunately mislaid the extract giving names and dates; but the fact is this, a certain Irish bishop, who was also suffragan to the see of Worcester, was sent over to Tewkesbury to consecrate two new bells for the abbey church in that town, and the legal term employed for them is "duo magna signa."

The very earliest bells were probably mere sheets of metal curled into a circular shape, and riveted together at their junction, the top being flattened in. These were struck on the outside by a hammer, having no connexion with the bell itself. This, of course, produced no very exquisite tone. Once started, bells soon developed into shape and size somewhat analogous to those now in use. The art of working and fusing metals together was a very early invention; and the sister one of melting and casting not long in following. We know that both tin and copper ore were worked in Britain during the Roman occupation of the island, probably still earlier in more civilised Europe. There is no reasonable doubt that a bell, or even bells, in important places, formed a portion of the furniture of every church before the Norman Conquest. Judging from the vast size of Norman towers, I think it highly probable that church bells had at that time reached their largest dimensions in this country, and also attained a perfection not since surpassed. The fact of no bells of ascertained Norman date remaining at the present day, when we consider the 101 different accidents to which such an instrument is subject, is no proof in the case whatever. Considering the bell as an instrument of percussion, it is only a cause of wonder that so many examples, even of the thirteenth, fourteenth, and fifteenth centuries, have come down to us unimpaired. Then, again, there are other causes for change besides breakage, fashions as to shape and size, and number changed also, just as churches themselves were always more or less under alteration and supposed improvement.

The lecturer here read a short MS. account of the bells in Canterbury Cathedral (Canterbury, vol. i. p. 91, No. 453) as one example out of many of this constant change; and though perhaps churches of less note and smaller revenues were favourable exceptions, still this rule of change remained in a very large percentage. From this account you will see, amongst other things, that bells, as I said before, attained very large dimensions in the eleventh and twelfth centuries. They so continued till the Reformation; soon after which, the art of change-ringing coming in, completely overturned the existing order of things. Under the old system bells were few and heavy, dignity of tone and solemnity being the main desideratum, and, as they were only chimed, lightness was not an object. Cathedral churches were not allowed to possess more than five or seven bells, and these often not placed together for simultaneous use; collegiate and parish churches not more than three besides the sanctus bell. There is a curious

injunction extant relative to the village churches on the coast of Kent and Sussex, to the effect that they should not possess more than one bell each, lest they should present an object of plunder to opposite neighbours; church bells not being readily movable like plate, vestments, and lighter articles. It is curious that to this day the same rule seems in force, for in no other district in England are there so many one-bell churches as along that coast, while directly we get a few miles inland, peals of three and five are the prevailing number.

The oldest bells that have come down to us bear simply the names of the saints to whom they are dedicated—the tenor, or heaviest bell, usually representing the patron saint of the church; the others, for the most part, the names of those saints who had altars below; and I very strongly suspect that each bell was tolled for mass at the altar of its own dedication. This is a point I should much like to have cleared up by some one learned in Medieval ritual. At present I would only throw it out as a probability, from the fact that out of a number of such cases which I have examined, I have found a considerable balance in favour of the connexion between the names of bells and the records of altars so dedicated. At Durham, for instance, there were four great bells in the Galilee tower, and three smaller ones in the lantern-tower, dedicated, the largest to St. Cuthbert, another to Christ and the Blessed Virgin, a third to St. Margaret, another to St. Benedict, another to St. Michael, another to St. Oswald, another to the Venerable Bede; all of whom were commemorated either in the nine altars or elsewhere in the church. I will take one other example. At the church of St. Bartholomew-the-Great, Smithfield, now undergoing its interesting restoration, is a little peal of five bells, dating from the close of the fifteenth century. Here the treble is dedicated to the patron saint, the others to St. Katherine, St. Anne, St. John the Baptist, and St. Peter, each dedication ending, as was usual at that period, with an "*ora pro nobis*." Possibly there may be documents yet remaining which may connect this peal with some subsidiary altars in that church. If some of you do not mind doing a little chimney-sweep's work, you will be rewarded for your trouble by personally inspecting these bells; also a similar peal of three in the adjoining church of St. Bartholomew-the-Less. These are almost the only ancient bells remaining in London. I would recommend you, however, to send a man up two or three hours beforehand with a broom to remove the soot from their crosses. The bells at St. Bartholomew-the-Less are dedicated to St. Augustine, St. Vincent, and St. Michael, the legends being in full—1. "Vox Augustini sonat in aure Dei;" 2. "Vincentus revocat in casta patria tollat;" 3. "Intonat do celis vox campana Michaelis." The two smaller ones are by a well-known Medieval manufacturer, William the Founder, and have his arms on them, a  $\Delta$  between three evers. The tenor, about the same date, has the initials S. O., with a cross between them on a shield. It has not yet been identified.

While upon London bells, I may mention that King Edward III. erected a clocher, or bell-tower, and placed in it three bells for the use of St. Stephen's Chapel, at Westminster. On the tenor was inscribed,—

"King Ed. made me thirty thousand weight and 3,  
Take me down and wey me and more you will find me."

This, by the way, if true, is the earliest example known of an inscription in English. They were taken down in the reign of Henry VIII., when some one wrote underneath, in chalk,—

"But Henry the Eight  
Will batt me of my weight."

Stow tells the story explaining that Sir Miles Partridge staked 100*l.*, and won them of Henry VIII. at a east of dice. He, however, affixes it to a clocher standing on the site of the present St. Paul's School, and says that there were four bells, the greatest in England, and called the Jesus Bells.

It is exceedingly difficult to guess the exact date of the oldest bells that have come down to our times. Dates there are none at that early period, rarely even the founder's mark, or lettering, which may give the exact era. In bells of the fourteenth and fifteenth centuries there is not this difficulty; for, though they are rarely dated, they invariably bear shields, lettering, and other architectural devices, which enable us to form a tolerably correct guess at their date. These marks, however, are by no means infallible guides to the uninitiated in such matters; for

\* By the Rev. John H. Sperling, M.A. Read at the Architectural Museum.

foundries often went on for generations, and marks and stamps were handed down from father to son often for a century or more. A little close inspection, however, will usually afford some slight addition, either in the stopping or moulding, which decides against the hoped-for antiquity. I have myself several times seen Medieval shields and lettering upon bells only dating early in the seventeenth century; a date in Arabic numerals often unravels the mystery. Dates came in about 1570 in England, and have been continued ever since. In foreign countries they are met with much earlier. The earliest known dated bell is at Freyburgh. Its diameter at the mouth, according to Mr. Tyssen, is 57 in.; height, 5 ft. 5 in.; weight, about 2 tons. The inscription is, " + O Rex Glorie veal cum pace, — me resonante pia populo sueuero Maria, — A. D. 1258." At Duneton, in Sussex, is a bell which Mr. Tyssen supposes to be the earliest dated bell in England. The date on this is 1319. This also is of foreign manufacture. At All Hallows, Staining, London, is another, with an inscription in honour of St. Martin, dated 1458.

We come now to the prolific subject of inscriptions. The oldest known bells, as I have already said, bear the simple name of the saint to whom they were dedicated. After this came "ad laudem" or "in honorem" St. So-and-so. Then set in the overlasting "Ora pro nobis," which was the stereotype of the fourteenth century and very common even up to the Reformation. There were, during the fifteenth century, two celebrated foundries in East Anglia, one at Norwich, another at Bury St. Edmund's. Both of them, I believe, were more or less connected with monasteries, and they issued a much superior style of inscription, usually cast into the form of a Latin hexameter, laudatory or imprecatory of the saint to whom the bell was dedicated, and often commemorated one of his or her supposed attributes. Some of these are so good that I will read you a selection from them:—

"To our Saviour:—

1. { Placet tibi chorus iste.
2. { Filius Virginis Marie
- Det nobis gaudia vite.

To the Blessed Virgin:—

- Sum Rosa pulsat Mundi Maria vocata.  
Virgine egregie vocat campana Maria.  
Stella Maria Maria succurre piissimis nobis.  
Virgo coronata duc nos ad regna beata.

St. Mary Magd. { Dona repende pia

- { Rogo Magdalena Maria,  
Subveniat digna,  
Donatus habet Esterina,  
{ Celesti manna tua proles

St. Katharine { Nos cibet Anna.

- { Vox Margarite  
{ Nobis hec munera leta,  
{ Hec nova campana,  
{ Margarite est nominata.

St. Margaret { Intonsa de celis

- { Vox campana Michaelis.  
{ Dulcis sicut melis  
{ Campana vocat Michaelis.

St. Michael { Hac in conclave

- { Nunc pango maus  
{ Gabriel are.  
{ Mitem de celis  
{ Nomen habes Gabrielis.

St. Giles..... { Sonitus Egilii

- { Ascendit ad culmina celli.  
{ Meritis Edmundi  
{ Semper a crinitis mundi.

St. Edmund { Munere Baptiste

- { Benedictus sit chorus iste,  
{ Nos Thome meritis  
{ Mereamur gaudia vite.

St. Peter..... { Petrus ad eterna

- { Ducat nos pascha vite,  
{ Nos societ sanctis  
{ Semper Nicolans in altis.

St. Nicholas { Johannes XII caris

- { Dignus pro nobis orare,  
{ Hoc mihi jam retro  
{ Nomen de Simone Petro.

St. Peter... { Antonius monet

- { Ut campana bene sonet.\*

The two most common inscriptions of the age, common to all parts of England, are "Sit nomen Domini hincletum," and "In multis annis resonet campana Johanna." These, however, were not used by the Norwich or Bury foundries. At Elsenham, in Essex, is a very pretty bell of this date, bearing the letter S, thrice repeated in beautifully illuminated character, and crowned.

This is, no doubt, an ancient sanctus bell. I have never seen a similar example. During the latter part of the sixteenth century, and up to 1630, we find some very good inscriptions also in Latin; many of these would well bear reproducing at the present day. At Cherry Hinton, near Cambridge, the two heaviest bells have legends from the "Venite," the remaining three were probably once similarly treated. On those that remain, are—

"Cum populus terre placidit Domino,  
Omnis psalmis venite ad Dominum."

At Oshury, Norfolk, we find legends from the

"To Deum" similarly employed. Other pleasing inscriptions of this period are—

"Non clamor sed amor cantat in eure Dei,  
Sonoro sono meo sono Deo.  
Cantabo laudes tuas Domine,  
Domini laudes non verbo sed voce resonabo.  
Jubilante Deo salutare nostro,  
Cantate Domino canticum novum.  
Merorem mortis, letis sic leta sonabo.  
Domine dirige nos."

To this period belongs the well-known legend,

{ "Laudo Deum verum  
Populum voco; congreo clerum."

In the eastern counties, the stronghold of Puritans, we find the following—

{ "Non sono animabus mortuorum  
Sed auribus viventium."

by way of a fling at the old faith.

Also the following, which I have never heard satisfactorily translated—

"Cano trista mori  
Cum pulpetta vivere dest."

Another is very good—

{ "Vocem ego do vobis, } 1638. St. Brinda,  
{ Vos date verba Deo. } Cornwall."

At Norwich, All Saints', is the curious inscription—

{ "Gallus vocor,  
Super omnia sono."

The English legend, though it peeped out as an exceptional thing in the fifteenth century—instance the beautiful tenor at Minster, Thanet, "Holy, pray for us," and another at Long Sutton, Hants, "Hail! Mary full of gras!"—did not come into general use till quite late in the sixteenth century. In the next fifty years English and Latin were used pretty equally, some foundries supplying one, the others the other. The English ones are usually very short and simple, as—

"Jesus be our speede,  
God save His church,  
God save the King,  
Laud the Lord alwaies,  
Fear God, &c."

But sometimes more extensive. At Attleboro', Norfolk, cast by Wm. Brend, of Norwich, in 1617, we find on the three heaviest—

- 1 { "It iojeth me much  
To go to God's church."
- 2 { "Do not slack thee  
To repeat thee."

Tenor 3 { "I wish to die  
To live heavenlie."

To this date belong the tenor inscriptions,—

{ "I sweetly tolling me do call  
To taste of meats that feed the soul."

And { "My ringing sound doth notes give,  
That men cannot here alwaies live."

Also { "God save the church,  
Our Queen, and realme,  
And send us peace in Xt. Amen. 1601."

And { "I sound to bid the sick repent,  
In hope of life when breath is spent."

{ "First I call you to God's word,  
And at last unto the Lord."

These examples might be multiplied to any amount.

After 1660 nearly all interest in inscriptions ceases. We find little more than the founder's name and date of casting, added to which, on the tenor, are usually the names of the rector and churchwardens. Those that do occur are usually vulgar, as,—

"Fall on, brave boys, I am metal to the backbone. I'll be hanged before I'll crack."

"My sound is good, my shape is neat,  
So-and-so made me all complete."

"I sound aloud from day to day,  
My sound hath praise, and well it may."

"All ye who hear my solemn sound,  
Thank Lady Hopton's hundred pound."

Bath Abbey.

"I ring to sermon with a lusty boom,  
That all may come and none may stay at home."

A founder, early in the last century, named Pleasant, was for ever punning upon his own name. Another, named Penn, of Peterborough, of the same date, was much more successful. Some of his Latin verses are very well turned; he also occasionally condescended to English, as at St. Ives's, Hunts.

"Sometimes joy, sometimes sorrow,  
Marriage to-day, and death to-morrow."

"When backward rang I tell of fire,  
Think how the world shall thus expire."

"When sons are from their bodies torn,  
'Tis not to die, but to be born."

These, perhaps, led to the writing of the well-known verses for the Whitechapel foundry, about 1750, which they have placed upon most of their bells since. I will only give two other examples—one from St. Helen, Worcester, where a peal of eight was cast in 1706, and dedicated

in honour of the Duke of Marlborough's victories; the other example is from Masham, Yorkshire, cast by Harrison, of Barrow, in 1766, and containing a set of rules for singing (vol. 1, p. 136, No. 676). It is very desirable that some verses should be taken to ensure decent inscriptions on church bells in the present day. With a few notable exceptions, as St. Gabriel, Pimlico, Sussex, where the clergy have taken the matter up, either nothing but founder's name and date, and those of the parochial authorities, or else such rubbish as was allowed to be put up at Sherborne only a few years since, was found. I should very much like to print a few dozen suitable inscriptions, short and to the point. As from 4d. to 6d. per letter is charged for the casting, a very long inscription is both expensive and tedious.

Having rung so many changes upon the inscriptions of the last five centuries, I must hasten on to some other notabilia connected with ancient bells.\*

#### EXAMPLES OF BRIDGE AND VIADUCT CONSTRUCTION.†

This work consists of a number of very excellent lithographs of different bridges and viaducts erected in England for some of the railway lines, in masonry, timber, and iron. The editor, and presumably the designer, of most of these Examples, is Mr. Haskoll, whose book, on "Railways in the East," we favourably noticed at some length last year. As examples of masonry work, we have the Etherow and the Hoghton Viaducts; the Maunbury Bridge, on the Wilts, Somerset, and Weymouth Railway; two elliptical arched viaducts on the South Wales Railway; and, amongst others, several small bridges of the same material. In timber there are the viaducts of forty bays on the Wilts, Somerset, and Weymouth Railway; a somewhat similar one on the South Wales line; a timber bridge, of 46 ft. opening, on the Lynn and Ely Railway; a timber bridge, of 34 ft. bays, on the same line; a timber arch, of 24 ft. opening, over the Newport and Pontypool Railway; and three smaller timber bridges on other lines. In cast and wrought iron, Mr. Haskoll shows us two ornamental cast-iron arch bridges, on the Newport and Pontypool Railway; a cast-iron girder bridge, on the East Lancashire line; a similar erection on the Birmingham, Shrewsbury, and Shropshire Iron Railway; as also a number of patterns, with plans and elevations, of east-iron girders, of different spans; ending with three sheets of some wrought-iron girders, on the Swansea Harbour Railway.

This enumeration, while it shows the scope of the work, also to a great extent formulates at the same time its condemnation. It is seen, that not a single work of great importance is presented to the purchaser of this sheet of drawings. We do not mean to deny all value to these excellent lithographs, furnished with details on a large scale, and more or less supplemented with dimensions. But when it is considered that a large number of really important engineering undertakings of the kind are being constructed, or have just been constructed, it is difficult to look upon Mr. Haskoll's productions without some surprise. When a man ventures into print, he is expected to come with something new and not easily attainable by any other means than by publishing the book in question. In this case, however, we see nothing but very ordinary examples of bridges and viaducts, and Mr. Haskoll has no doubt confined himself to drawings of works he has himself carried out, or to drawings of works to which he had direct access. A number of very remarkable stone viaducts have been lately erected in England, and more especially in Switzerland and France, presenting considerable engineering problems, and yet Mr. Haskoll has confined himself to constructions little more than 130 ft. above the foundations, and within 100 ft. span. Exactly the same thing has to be observed with respect to Mr. Haskoll's examples of iron bridges, which are remarkable neither in an engineering nor an architectural sense. The lithographer, however, has done his part well, and has rendered this work good of its kind, though its kind is certainly not great.

\* To be continued.

† Examples of Bridge and Viaduct Construction of Masonry, Timber, and Iron from the Contract Drawings and Aliments of Select Works. By W. Davis Haskoll, C.E. London: Lockwood & Co. 1864.

## STARVED TO DEATH.

It is time that an important problem in connection with London society was solved, and that we should know whether it is to the way in which the poor-rates are managed by the parochial authorities, or to what other causes we are to attribute the terrible instances of destitution which are constantly making themselves heard of in the eastern districts of the metropolis. There is no doubt whatever of the existence of a great evil, and we trust that the present session of Parliament will not be brought to a close before some members, who will take the trouble to make themselves acquainted with the subject, bring the matter in an effective way into notice. More especially it should be the duty of the metropolitan members to attend to this. Certain local peculiarities especially affect large masses of the poorer classes, particularly those who have been driven into a most abject condition of poverty, often by changes in our manufacturing industry, or by other causes over which they have no control.

Take up the newspapers when you may, it is rare to find one without some account of death happening from actual starvation, and in nine instances out of ten, these occur in Bethnal-green, St. George's-in-the-East, and other parts of the eastern region of London. Certainly the news reporters in these parts are not more active than those in Clerkenwell, Islington, St. Pancras, and elsewhere: yet the deaths from destitution, of which we read accounts in other districts besides the east, are few and far between. It is not that poverty of the worst kind does not exist, but we believe that the hardness of this is rendered more tolerable by the liberal and kindly spirit in which an often painful duty is performed by the guardians and others who have charge of the poor.

We take up by chance a weekly paper, and find, under the heading "Death of a Needlewoman," which occurred in St. George's in the East, that the deceased earned a scanty livelihood by needlework (the stitching of waterproof capes for a warehouse). She lived with another woman, and the average earnings of the two were about 4s. a week. They paid 2s. a week for the rent of a room in which they lived, or, rather, started, together. Their chief support was one pound of bread and a cup of tea daily. About once a month they had meat, which consisted of bullock's cheek. They never applied to the parish for relief, and slept on some straw on the floor: and here it is to be noticed that we find the common objection to make any application for help at the workhouse. To this cause we attribute many deaths. On a Wednesday morning the deceased went to a pawnbroker's to endeavour to pledge a petticoat for sixpence; but the pawnbroker would not make the desired advance; she then, on attempting to leave the shop, fell down in a state of insensibility, was removed home, and a surgeon was called in, who found her in an exhausted state: he ordered wine and other stimulants, but the poor woman never rallied, and died on the following morning. The medical testimony,—to which the jury agreed, and gave a verdict accordingly,—was, that death was caused by effusion of blood into the ventricles of the brain, brought on by want and long privation.

In the same paper an account is given of another death,—this one in Bethnal-green. The deceased had been many months under the care of Dr. Gayton, one of the medical officers of the parish, who attended him three times, but did not visit him again, but requested the deceased to come to him. This it appears, he was not able to do, and never had any further out-door relief. The deceased was removed, by an order, to the workhouse, in a very weak state, and died on the following morning. The wife supported the deceased and herself by her earnings of 6s. 6d. a week. Mr. Moore, surgeon, said that he was called in, and found the deceased in a very low condition: he died on the next morning. He had since made a *post-mortem* examination, and externally the body was much emaciated. There were other signs of disease, but the cause of death was no doubt accelerated by the absence of nourishment and want of sufficient warmth during the inclement weather. Dr. Gayton had also seen the deceased, and desired him to call at his surgery; and, not having done so, thought he had gone to work; but Mrs. Hyams, the man's wife, said that, when she called upon Dr. Gayton, and when that gentleman visited her husband for the last time, he said that he was sinking, but after that he

never came near her husband. She then applied to the relieving officer, when the deceased was removed by an order of the Board. In reply to a question by the foreman of the jury, the wife said she did not remove the deceased to the workhouse in consequence of the objection which he had to go into this workhouse. The jury were of opinion that Mrs. Hyams was to blame for having so long delayed getting her husband admitted into the workhouse. The coroner, however, expressed an opinion, in which we quite agree, that the wife had done the best she could, according to her earnings as a shoehinder, but deceased did not get sufficient nourishment. In answer to a question by the coroner, the wife replied that she had obtained an order for out-door relief, which only lasted a fortnight; and, at the expiration of that time, the deceased was ordered into the workhouse, but he refused to go.

The verdict of the jury was that the deceased died from disease of the lungs, accelerated by want of proper nourishment and warmth.

## THE RAILWAY AND BUILDING MOVEMENT, AND THE DEMOLITION OF DWELLINGS.

THE Earl of Shaftesbury has more than once brought this subject before the notice of the House of Lords, and on a recent occasion he particularly dwelt upon the extensive demolition of labourers' dwellings by the making of metropolitan railways and other great works. His lordship stated that the number of persons who had been displaced in the present year by the Railway and other Acts was no less than 20,000, and the number of houses to be pulled down was about 3,500. The persons thus affected consisted chiefly of skilled artisans and day-labourers; and no provision had been made or existed either in the model lodging-houses or in the old kind of houses, suitable to such persons, or within their means, as domiciles. "Judged," continued Lord Shaftesbury, "such houses as are at present to be let would not accommodate a hundredth part of the numbers displaced. In fact, the places fit for the poor working class to live in were actually overcrowded already, and the result was injurious both to the pockets of this class and to their health, and no doubt increased pauperism. The suddenness of some displacements, too, acted with great severity, and not unfrequently drove them to take shelter in the common lodging-houses, and places where they had to pay higher for worse accommodation than in their former homes. Numbers had thus been brought down from a condition of honest livelihood to a state of pauperism and vagrancy, and that by no fault of their own, but by this most unjust and abominable system of demolition."

Lord Shaftesbury told the peers that he had visited a room which, in many respects, resembles certain "pleasant lodgings" in the west part of London, described by us some time ago.\* The room visited by the noble earl was inhabited by a young couple and their baby. The walls were full of holes: the place was exactly over the main-drain; and the wife told Lord Shaftesbury that she and her husband, Jack, sat up all night alternately, because such swarms of rats infested the place that they were afraid they would eat up the baby. On complaining to the landlord, he had told them that *they might go if they liked, for he could get plenty of other tenants immediately.*

Lord Shaftesbury again asked the important question "What is the remedy?" It was easy to reply,—"*Build more model lodging-houses.*" But where were the 600,000*l.* to come from which would be necessary to build such houses for 20,000 people? Besides, model lodging-houses were for a superior class to many turned out of their homes, and such houses were by no means remunerative, seldom paying so much as 5 per cent., and never exceeding it. "Suburban villages at a cheap rate had been proposed; but his inquiries showed him that they were not in a position to build such villages. Cheap trains were still an experiment; but he was happy to learn that it was likely to be a successful one, and would turn out ultimately to the advantage of the working classes, but it would scarcely mitigate the evil in the present generation." This lordship concluded by moving a new stand-

\* It is satisfactory to notice that since our account was written, the dwellers in that neglected tenement have, much to their astonishment and satisfaction, been visited by the landlord, and useful and very necessary repairs made.

ing order on the subject, requiring that notice be given to Parliament before the end of December, by the promoters of any bill to take fifteen or more houses inhabited by the working classes; that notice to be given eight weeks before taking the houses, to the heads of families inhabiting the same, and by placard and hand-bill displayed in the vicinity; and also, that no house should be so taken until a justice of the peace should have certified that the provisions of the order had been complied with.

To a certain extent, the proposition of Lord Shaftesbury would be an advantage; but it would be but a very small instalment indeed of what is due and requisite. Even this, however, as is the case with most of the well-intentioned propositions of his lordship, met with opposition; and when matters are brought under notice in the House of Peers which materially affect large masses of the poorer part of the community, lords who have liberal opinions, as many have, are not in their places to support Lord Shaftesbury, who has carefully studied and made himself acquainted with this painful but most important subject.

## LOCAL ART AND PORTRAIT GALLERIES.

WE are well pleased to notice that an idea, at which we have often hinted, is likely to a certain extent to be carried out in the busy and important town of Birmingham. The *Birmingham Gazette* expresses a belief that, at the Midland Institute *soirée*, there would be a proposition made which, if carried out in a spirited manner, will not only be of great importance to the inhabitants, but will tend to raise the artistic character of the town itself in the opinion of all who love and can appreciate true art. The proposition is to decorate the various panels of the ceiling of the new art gallery with portraits of a series of Birmingham and Warwickshire men, whose memory has been made dear by noble works done or noble words written. There are twenty-eight of such panels; and, fortunately for the history of the town and country, there will be no lack of fitting subjects to furnish them all. In order to test the effect of the proposed plan of decoration, a cartoon, by Mr. S. E. Evans, commemorative of Shakspeare, is to be placed in one of the panels. So says our authority; and we can only hope that this appropriate plan of decorating part of an art gallery will be well and tastefully carried out. But it should not be forgotten that ceiling decorations in apartments are of a very perishable and frail nature in this country; and that although it was the practice, especially in the reigns of Charles I. and II., and Queen Anne, to paint the ceilings with allegorical and other figures, it cannot be said that portraits painted on ceilings in panels had a good effect. Some of the reasons for this are, that the light upon the ceiling of a room is seldom good; that it is uncomfortable to look directly overhead at any object of interest which requires much examination; also the mass of white on a ceiling, however much it may be enriched by mouldings, diaper, and other patterns, is in most instances used as a means of improving the lighting by the power of reflection; and on the ceiling of a picture-gallery especially, there should be breadth and simplicity, instead of violent colour, or light and shadow. In the present state of our information on this matter, it is but too likely that right principles will be deviated from; but we hope that the proposed plan of decorating this institute ceiling with portraits may be a step in the right direction, which will lead to the establishment of a far more permanent portrait gallery of Warwickshire men in Birmingham than this will be. We want to see authentic pictures of the famous poets, historians, artists, and men of science, the most eminent workers who have been instrumental in making the great hive of industry, now known throughout the civilized world as Birmingham, so famous as it is; and instead of the effigies of those worthies exalted to the ceilings, we would like to see them face to face, in such a position, and in such artistic skill in execution, that they would be likely, with care, to last for some centuries yet to come. In combination with the portrait gallery,\* there might also be arranged a local picture gallery, and we hope that Bir-

\* We have before suggested that the town halls of provincial cities, &c., and the vestry-halls of the metropolitan parishes, are the right places for the formation of portrait galleries, in those places where there is no permanent place for the exhibition of local and other pictures.

tingham will ere long set an example in this way to other towns.

We have long thought of this subject, which is of more importance than many people at present believe, and which, as time rolls on and intelligence advances, will increase in interest; and we have a clear conviction that it only requires a movement to be made in this direction in two or three of our chief towns, to cause galleries of this kind to be generally brought into fashion.

Will Birmingham, Manchester, Liverpool, Newcastle-on-Tyne, or some other town lead the way?

#### THE ART EXHIBITION AT WINDSOR.

ON Monday evening the Art Exhibition in connexion with the Windsor and Eton Literary Institution was opened by Mr. R. W. Harris, the mayor, at the Town-hall, Windsor. The exhibition consists of a choice collection of articles of *virtu*, and works of art of a highly interesting description. Among the articles contributed by the Queen were a group of Indian gods and goddesses, carved in ivory, a case containing a number of silver busts of Continental sovereigns, and two panels, each containing four curiously painted subjects, from the "History of St. George and the Dragon," The Prince and Princess of Wales exhibited their costly wedding caskets, together with the gifts presented by the Corporation of the City of London, the Fishmongers' and Mercers' Companies, the ladies of York, Edinburgh, and New South Wales.

The opening of the exhibition was celebrated by a *conversazione*.

#### CHRIST CHURCH, MAYFAIR.

THE new church recently erected in Dacre-street, Piccadilly, was consecrated on Monday, the 27th ult., by the Bishop of London. Only a portion of the church has yet been built, as the whole of the site cannot at present be acquired. The church will accommodate about 800 persons when it is completed: at present there are seats for 420.

The style is Flowing Middle Pointed, with details drawn from Continental examples. The site is very limited and peculiar in form, necessitating an exceptional mode of treatment in the plan.

The nave is 50 ft. long and 34 ft. wide. There is a north transept, 28 ft. long and 22 ft. wide; and transept aisle, 28 ft. long by 16 ft. wide.

The church is of lofty proportions, the nave being 35 ft. high to the roof-plate, and 66 ft. 6 in. to the ridge. The roof is of Memel timber, stained, covered with boarding laid diagonally. The east window is of seven lights, with geometric tracery; and the windows on south side are of nave are of three lights, thrown into dormers for the sake of greater altitude. The endeavour has been, by a bold treatment of the several parts, to rescue the church from being dwarfed by the houses in the immediate vicinity. The tower and spire at the north-east angle will, when finished, be about 130 ft. in height, the spire being covered with slate worked in pattern, and saddle-back in form, and terminated by an ornamental iron cresting and vane. The building is faced externally with Kentish rag-stone, and Bath stone dressings; and, internally, with red, black, and white bricks, worked in pattern, the window-jamb, arches, &c., being of Bath stone. The piers to transept are of Portland stone, with detached shafts in red Mansfield. It is proposed to insert encaustic tiles in the walls as bands, when funds permit, the brickwork having been set back for this purpose. The chief enrichments at present in the church are the stained-glass window at the east end, with the stone screen or *recedos* underneath, both of which have been presented by Mrs. Hope, of Piccadilly, to the memory of her late husband, Mr. H. T. Hope, of Deepdene. The window has been executed by Messrs. Clayton & Bell, and represents the Crucifixion and Last Supper, with rich canopies, angels, and emblems, occupying the tracery above. The screen is of Caen stone, and consists of a series of arched panels, deeply recessed, with angels bearing scrolls in the spandrels; carved crockets of the passion-flower, lily, &c.; with shields bearing suitable emblems and devices, supported on shafts of Devonshire marble. The six compartments immediately over the altar are filled with carved representations of the six acts of mercy.

This work has been executed from the designs of the architects by Mr. F. G. Anstey, of Lissongrove.

The builder of the church was Mr. Charles Fish, of Pimlico: the architects were Messrs. F. & H. Francis.

#### NEW POLYTECHNIC INSTITUTION AT STUTTGART.

##### ARCHITECTURAL EDUCATION ABROAD.

A NEW and very extensive Polytechnic Institution has recently been completed and inaugurated in Stuttgart. The title has not the same meaning that we are accustomed to attach to it as a place of entertainment; or, as in the case of the Ecole Polytechnique, at Paris, a college for military education only; but is given in Germany to colleges, where, under the supervision of Government, young men are educated as architects, civil engineers, analytical chemists, machine engineers, and in kindred arts and sciences are taught. There are several very large establishments of this kind in various parts of Germany, some with from 400 to 700 students, the chief being those of Berlin, Hanover, Carlsruhe, Munich, Zurich, and Stuttgart. A young man, intended for one of the professions above enumerated, is generally sent direct to one or other of these institutes directly he leaves school, and there enters the "mathematical" or preparatory department, in which he remains, on an average, for two years. After passing a rather severe examination in the higher branches of mathematics, including geometry and conic sections, he then enters a three years' course of studies, either as an architect, civil engineer, &c., as the case may be, and is then again subjected to a second examination, should he wish to become a candidate for Government employment. To the architect, intending to acquire a private practice, such an examination is, however, voluntary. A few words on the method of instruction may here be interesting, although the writer would confine himself to the "architectural" department, being able to speak from personal experience. This department generally consists of three, sometimes of four classes; the first being all but elementary, and confined almost entirely to the first initiatory mysteries of wielding the pencil, the pen, or the brush, with any degree of neatness. But that the mind may profit as well as the fingers, the student has to copy the series of sheets illustrating details of construction in wood, stone, brick, and iron. The walls and ceiling of the large room occupied by these students at Carlsruhe are "finished," or rather left partially unfinished, to show such constructions by ocular demonstration. The walls, divided into panels by plain slightly projecting pilasters, show various modes of external stone constructions: ashlar, flint, even and uneven courses, all are there; as also the various kinds of "bonds" employed in brickwork. The ceiling is divided into panels also, one panel showing the joists, another the struts, a third the ceiling-joists, a fourth the laths, &c. In the second class the student takes up statics, and attends lectures on the properties of the various building materials, and the process of their manufacture; archaeology, and the principles of designing; and illustrates his "Notes," which he is *obliged* to take, partly from dictation, by sketches made on the black board. The third and fourth classes are similar, the lectures being of a higher and more difficult kind; but one system holds good in all classes, that of leaving the entire afternoon free for drawing, no lecture being later than twelve o'clock. The hours from five to seven are employed in winter with modelling in wood, clay, or plaster of Paris; in summer, with figure-drawing (cast and life), and in constructing complicated and simple brick arches on piers in a yard especially set apart for this purpose, the students having to make their own centreings. At Whitsuntide a fortnight is usually set apart for an excursion, when some twenty students start by train or otherwise under the guidance of one of the professors, who points out the various objects interesting either from a constructive or archaeological point of view, and assists them in selecting points for their sketches, most of which are coloured in on the spot.

In social respects the young men are entirely their own masters, living dispersed in families or lodgings; and as living in most of these cities is cheap, except, perhaps, at Berlin, the education, including college fees and living, need not exceed 60*l.* per annum.

But we have wandered from the description of the new Polytechnic Institute of Stuttgart, which has now been completed under the direction of Mr. Spindler. The building is 285 ft. long, 90 ft. projection of wings, and 65 ft. wide in its narrowest part. The height from pavement to top cornice is 62 ft., the top of the observatory dome being 46 ft. higher, or 108 ft. from the pavement. The chief façade faces the north-west, and along it are ranged the drawing-rooms, whilst the lecture-rooms face the south. The whole building covers about 25,000 square feet of ground, and contains in its basement, ground-floor, and two stories, about twenty-five drawing and lecture rooms, most of them having an area of 1,200 to 1,600 square feet. Besides these, there are some forty rooms for professors, masters, committees, examinations, &c.; a theatre, and three laboratories; a large meeting-hall, a library, an observatory, and three wide stone staircases. The corridors are 11 ft. 6 in. wide, lighted from above by a series of flat domes, which give borrowed, but ample, light from the large dome-covered wells of the staircases. The principal feature of the interior arrangement is the great meeting-hall, which contains an area of 2,500 square feet, by a height of 33 ft. The niches in this hall, as also on the staircases, will in time be filled with statues and portraits of men who have been famous in arts and sciences, and the panels will have frescoes illustrating scientific discoveries, &c. The style throughout is a free treatment of Italian Renaissance. The exterior is treated with two rows of arcades and pilasters upon a massive plinth, which forms the basement floor; and the field of the central pediment is filled with a finely-executed composition in high relief, by Professor Ploek, representing the tutelary deity of the kingdom descending from her throne in order to deliver a charter to a number of youths carrying building, engineering, and other implements. Medallions in the central building contain the heads of Fr. Gansz, Frannhofer, Redtenbacher, &c., as an encouragement to active activity; whilst in the medallions in the wings we find Michelangelo, Gaspare Monge, Isaac Newton, and George Stephenson. Lavoisier, Watt, Kepler, and Albert Durer are shortly to be added.

Two female figures, representing "Science" and "Art," flank the chief entrance. The materials used in this building are sandstone; that of the basement and ground floor being red, whilst the rest is of a yellowish green colour. The costs of the whole were about 34,000*l.*

#### THE MEMORIAL OF THE LATE SIR TATTON SYKES, BART., FOR DRIFFIELD, YORKSHIRE.

PREPARATIONS are being made to have the first stone of this memorial set during the present month. The accompanying engraving represents the design, which was selected from one hundred and fifty-six competitive drawings sent in. The total height of the memorial will be 120 ft. by 28 ft. at the base. The material proposed is Box ground stone, with Whitley and Mansfield, the columns and strings being of the latter stone. The chief stage is devoted to sculpture, in which will be represented characteristically the late Baronet. Coats-of-arms, various devices, and sundry pieces of foliage in caps, cornices, and strings, with some ornamental ironwork, gilt, form the decorative parts of the design. In other respects the memorial is plain and bold. A staircase is provided, at the top of which is a room lighted by four oval windows, commanding views of the extensive and picturesque country around, including the residence of the late Sir Tatton. The committee anticipate the completion of the erection by the end of September; and, at the proposed inauguration, a great "meet" of the friends and admirers of the late Baronet will no doubt take place. The architect is Mr. John Gibbs, of Oxford.

THE LOCK-OUT IN THE IRON TRADE.—The lock-out is withdrawn to a certain extent. The South Staffordshire masters have passed a resolution to the effect that they will open their works on the men giving a pledge that they will neither directly nor indirectly support the North Staffordshire men who are on strike. The Glasgow ironworkers have wisely resolved to settle their dispute with the masters by arbitration. They recommend their brethren throughout the country to adopt the same course.

PROPOSED MEMORIAL OF THE LATE SIR TATTON SYKES; DRIFFIELD, YORKSHIRE.  
MR. JOHN GIBBS, ARCHITECT.

FROM EDINBURGH.

It is merely a truism that "the architecture of any period exhibits the peculiarity of thought prevalent at the time," for architecture and the other arts are, like literature, an outcome and expression of that thought. The classical mania took firmer hold in Edinburgh than perhaps in any city of the kingdom. She was delighted to be called "the modern Athens," and her architects vied with each other in reproducing classical temples and quadrangles. The picturesque character of the Old Town suffered greatly at this period; ancient and interesting relics were ruthlessly swept away to give place to structures quite out of keeping with their surroundings. This spirit survived until very lately, and the last instance of it was the construction of a Corn Exchange in the style of an Italian Palazzo amidst the gables and turrets of the Grass-market, the scene of some of the most remarkable events in Scottish history. The more recent additions to the architecture of the Old Town are, in most instances, in accord with their position; and the reaction has been so great that the Gothicists have begun the invasion of the New Town, where, hitherto, no specimen of Gothic was to be seen in the street architecture. The daring innovator is Mr. George Beattie, and the scene of his operations is in West Register-street. The building upon which he has exercised his skill is a warehouse for the Messrs. Cowan, paper manufacturers, and the style he has adopted is late Venetian Gothic. The building is four stories in height, and has elevations to the east, south, and west; and the last although it only fronts a lane of about 6 ft. broad, is as richly treated as the others. The ground floor is occupied by shops having circular arched doorways and windows, the spandrels being carved; and above the shops is a horizontal band of blank arcading. The second story consists of ogee pointed and cusped windows, with the characteristic fillet mouldings. The windows of the third story are also ogee pointed, without the cusps. Pilasters are run up between these two rows of windows, and united by pointed arches. The fourth story has trefoil-headed windows; and the elevation is finished by a rich cornice and pierced parapet. The second elevation has in the centre a circular-headed archway leading to a central court, and above it a three-light window, with a circular arch above, contained under a pointed arch. Upon the impost of the gateway are medallion portraits, and a feeble attempt at the introduction of colour has been made at this point: the angles are cut off, and doorways and two light windows introduced. The whole structure is profusely decorated with carving of natural foliage, animals, &c., and the general effect is pleasing. There are some parts of the detail to which exception might be taken,—such as the blank arcading, which is not in good keeping with the style, and the windows of the third story, which would have been much better with cusps; but, as a first attempt in a new direction, these blemishes may be overlooked.

Two statues, both of them the work of Mr. John Steel, were inaugurated lately in this city, as we have already briefly mentioned; one of Professor Wilson (Christopher North), and the other of Allan Ramsay, the poet. They are placed in the Princes-street Gardens, flanking the Royal Institution,—that of Ramsay to the west of that building, and that of Wilson to the east. The situation is well chosen and the figures group advantageously with the surrounding buildings in almost every point of view. It is seldom that perfect harmony can be obtained, and the colossal bronze figure of Wilson, when looked at in a line with the Scott Monument, is hardly in unison with the fretted Gothic work of that structure. It is, however, a remarkably fine work of its kind. No sculptor could have had a better model than John Wilson, whose tall athletic figure, fine leonine head, and careless easy style of dress rendered him the most remarkable man in the city, "the observed of all observers." Mr. Steel has therefore wisely represented the man in his every-day costume, a loose frock-coat, and flowing plaid thrown negligently over his shoulders, bare neck and ample lying-down collar: the right hand is grasping the plaid, and the left holding a loose manuscript: a palm-tree trunk, indicative of his principal poem, supports the figure. The whole form is full of animation, and the position graceful, but not stiff; altogether, it presents one of the best instances of the adaptation of modern every-day costume to statuary in this country. The pedestal con-

sists of a square block of freestone, with base and cornice, having attached shafts at the angles.

The statue of Allan Ramsay, the gift of his descendant, the late Lord Murray, has been executed in Carrara marble, and is upwards of 10 ft. in height. The poet is represented in the quaint costume of the period in which he flourished,—a round cap (similar to that in the well-known portrait of Hogarth), large square-cut coat with huge pocket flaps and turned-up cuffs, ruffles at the wrists, deep vest to match, knee breeches, tight-fitting hose, with shoe and knee buckles. The position of the figure of Ramsay does not appear to us to be so successful as that of Wilson. The pose of the figure is rather constrained and leans backward, producing an effect as if he were supporting himself against the mass of drapery which falls from his left shoulder; and this flowing drapery we think a mistake, as it detracts from the quaintness that should have been the characteristic of a figure so costumed. The terrace of the west garden being much narrower than that of the east one, it was necessary, in order to bring the statues into line, to erect a platform upon which to place that of Ramsay; and this part of the work has been entrusted to Mr. David Bryce, architect. The dip of the ground is sudden and deep, and it was found necessary to make the foundations at a depth of 40 ft. below the level of Princes-street. Upon this foundation a square structure has been raised, which is corbelled out near the top, decorated with a roof-moulding and gargoyles, and formed into a flat platform for the pedestal, having a walk of 3 ft. in breadth all round, surrounded by a low stone balustrade. This platform is joined to the terrace by a narrow stone bridge. The effect of this arrangement is quaint and unique, and might have been still better had the whole structure been larger. The pedestal is exactly the same as that for Professor Wilson, with the addition of medallion portraits of Ramsay's most distinguished relatives, including one of Lord Murray.

PROPOSED TESTIMONIAL TO PROFESSOR DONALDSON.

In accordance with the movement we mentioned, 145 gentlemen have expressed their concurrence in the proposal. A meeting was held on the 25th ult., when a communication from Dr. Donaldson was read, expressing his high appreciation of the kind mark of approval of his services; stating, however, that he felt averse to any personal testimonial, but at the same time he freely offered the use of his name for any act that might benefit the profession and the art. It was ultimately,—

Resolved,—“That the meeting, conscious of the eminent services rendered to his colleagues in art on all occasions by Professor Donaldson (President of the Royal Institute of British Architects), and desirous to do him honour, considers it expedient that on his retirement from the Professorial Chair of Architecture in University College, London, a medal be struck bearing his portrait, and that such medal be entrusted to the Royal Institute of British Architects, to be given to students in architecture annually, or at such other intervals of time as may be hereafter determined.”

Subscriptions continue to be received.

CHESTER NEW TOWN-HALL.

The tenders received for erecting the new Town-hall were as under:—

	With stone fronts, but without tower.	With stone fronts, including tower.	With brick fronts, and including tower.
	£ s. d.	£ s. d.	£ s. d.
Clarke .....	21,610 0 0	23,590 0 0	22,588 0 0
Horsman .....	23,097 15 6	24,886 10 3	23,109 8 8
Roberts .....	23,329 19 3	25,438 6 0	23,688 11 4

Hughes .....	22,535 0 0	24,611 0 0	22,735 0 0

Messrs. Clarke reside at Denhigh; Mr. Horsman, Wolverhampton; Mr. J. Roberts, Chester; Messrs. Owen, Chester; Mr. T. Hughes, Aldford. Mr. T. M. Lockwood, of Chester, architect, in a letter to the local *Chronicle*, says:—"Instead of the successful plan costing only 16,000*l.*, as it ought to do according to conditions Nos. 5 and 12 issued by the Council, the lowest tender now handed in amounts to 22,590*l.*, showing nearly 50 per cent. of partiality or advantage over its rivals, granted to it for some reason or other by the town-council of this city. . . . As Mr. Wyatt, the professional gentleman whom they called in to advise them, unfortunately jumbled up together the two questions of which design

ought to receive the premium and which would best suit the purpose of the city, the town council fell rather helplessly into a flagrant act of injustice. They awarded the premium to a design which evaded the chief difficulties of the conditions; and they cannot get a complete building unless they spend 7,500*l.* beyond the legitimate sum at their disposal. . . . The building as projected, if built in its entirety, would be most appropriate in arrangement and style to the requirements of the city; but I do not for a moment admit that the design should have won the premium in the competition."

THE LIVERPOOL HEALTH REPORT.

DR. TRENCH, the medical officer of health for the borough of Liverpool, has made his annual report for 1864 to the local authorities, on the health of the borough, and the report has, as usual, been printed.

As was to be expected from what we have already recorded, the report, in respect to health, is by no means a favourable one. The sickness characterising the years 1862 and 1863 continued without intermission during the whole period of 1864, when the deaths in the borough amounted to 16,836, or to 1,626 above the corrected average of the preceding ten years, making its death-rate equal to 36 in every 1,000 of the inhabitants; that of the parish being 39.4 and of the out townships 30.9 in the 1,000. Typhus, or what is regarded by some medical men, but not by all, as typhoid and not typhoid fever, was the most extensively prevalent and fatal of the zymotic class of diseases; and indeed became a destructive epidemic in the last quarter of 1864. It will be remembered by our readers that in commenting on a special report on the health of Liverpool lately, in which it was said of this epidemic that no distinct cause could be adduced to account for its origin; overcrowding, and dirt, want of ventilation, and starvation, or the usual causes of typhus fever not having become in any way suddenly aggravated in course of last year; we drew attention to the fact that we had predicted an access of fever at the close of the year from the want of sufficient rain for natural cleansing purposes throughout the summer, as we had on more than one occasion noted such a sequence; and its contrary, an increase of health after wet summers; and indeed had therefore on previous occasions ventured to make the same prediction, the force and truth of which the daily press were not slow in appreciating. When, therefore, it was reported that the epidemic at Liverpool was mainly typhus, and not typhoid in its nature, we expressed an opinion that it must at least have been complicated or aggravated by the typhoid cause, namely, the prevalence of decomposing matter, as in drains, from the want of rain during the summer. Had we been medical, perhaps we might have even ventured to question the assertion that the fever was exclusively or chiefly typhus, our conviction of the probability of its having been at least aggravated by a typhoid cause being so clear and decided. And we now find, accordingly, that medical men themselves are not by any means unanimous in their opinion that it was purely typhus. On the contrary, although Dr. Trench is of that opinion, he very fairly points out the differences of opinion which, to some extent, exist among the Liverpool medical men on this question: indeed, he himself admits, that under the term typhus "our nosology includes every variety of continued fever." That, at all events, a typhoid cause has had something to do with the conversion of the fever into "a destructive epidemic" we cannot doubt.

The progress of the fever is indicated by the series of annual deaths since 1860, which is taken as a period of average healthiness previously to the aggravation of the more normal state of the fever by such causes as want and overcrowding arising from the cotton famine. The deaths from typhus rose from 390 in 1860, consecutively, in the three following years, to 482, 730, and 1,304, while, in 1864, they reached to 1,774. Contagion, poverty, overcrowding, and filth are regarded in the report as the great causes of the fever in Liverpool as elsewhere.

In regard to overcrowding, the conductor of this journal is glad to have Dr. Trench's "hearty adherence" to his proposal "that houses which are unlet should be registered, and the landlords obliged to comply with some simple requirements for proper ventilation, such as windows opening up and down, and zinc pierced panes where there are no chimneys."

A great want is to provide more available accommodation for the poor, and an endeavour to meet this, as our readers know, is being made in Liverpool; nevertheless there will always exist the overcrowding of indigence, and hence unfortunately there will always be need of some such regulations as we have suggested.

#### A WORKSHOP NEAR KING'S CROSS.

SOME time since, an engraving appeared in the *Builder*, showing the condition of a workshop in the neighbourhood of King's-Cross. This poisonous place, much as it was crowded, was above the surface; but, in another house, not far from the same locality, there is an even worse arrangement; for, in this instance, in a small room, the floor of which is upwards of 6 ft. below the surface of the roadway, from twenty-three to twenty-five (generally the latter) young women and girls are employed during many hours of each day in the making of artificial flowers. The house is only one room in depth, and, with the exception of a back door, which at the top of a flight of steps leads to a yard, there are no openings at the back; in fact, there can be few places more unwholesome than this is, in which so many people are for so long a time pent up. Besides the work-people, there are in the same house nine other persons.

In the work-room, which is as bad in sanitary arrangements as some of the cellar dwellings in Bethnal-green, there is a width of 9 ft., a length of 12 ft., and a height of 8 ft. This gives a cubic space of 864 ft. for the breathing of twenty-five people—a space not sufficient for two persons, even if a fair amount of care were taken respecting the ventilation. As it is, however, there are not 35 ft. of breathing space for each living person who is here in critical years of life confined. How can we, under such circumstances, wonder

A Workshop: Making and Destroying.

at the pale, cadaverous, and anxious-looking faces of those who are here engaged in sedentary work during twelve or fifteen hours a day? It is in this way that consumption, fever, and other diseases are generated. In this instance the evil effects have in several ways been made evident. Recently six of the work-girls were ill at the same time at their homes, or at the Fever Hospital, suffering from a malignant attack.

In another place, in an overcrowded house, twelve children were removed, all ill of fever, in the course of one week. We have heard of several similar cases which have occurred lately, and show the need of that kind of inspection to which we have so often referred. That twenty-five young girls should be placed in such a space as has been mentioned is a monstrous abuse, and arrangements as bad and even worse may be met with in far too many places. No proper effectual change will be made until all workshops and rooms in which more than a certain number of people, particularly those of tender age, are engaged, are subject to inspection; and those who employ labour, as in millinery establishments, in cigar manufactories, artificial flower rooms, even in printing-houses, hakehouses, &c., are forced to obtain a certificate of the fitness of the premises for carrying on their works. Cahmen require their special licence; taverns must also be made fit for the intended uses; and, when it is considered how many valuable lives depend on the sanitary state of workshops, there seems to be no reason why proper restrictions should not be insisted on in that direction.

At present there is no way to discover the evils which are shown in the engraving. The clergymen of the district do not know that in this particular house there is a concentrated poison both for the body and the mind; and it may be a question, as to whether or not the district surgeon is aware of the evil. Thousands of casual wayfarers might pass by this underground kitchen or cellar, and little dream that under

the influence of an ignorant and driving mistress, there were so many hands at work without air.

When we read accounts of the raging of pestilence, although the distance may be many thousands of miles, and we should be separated from the infected spots by immense tracts of water and land, we do not let the matter pass unheeded; for the plague of terrible and sudden death and the spread of diseases which in a great measure defy even the advanced skill of our present medical practitioners, are passed along by the breeze from country to country, in each of which it travels from town to town and from village to village, spreading death and terror along rivers and other water-courses, and marking with sure and fatal visitations the scenes of sanitary neglect. For many centuries back the origin of some of the most dreadful and most scourging plagues has been attributed to the eastern regions of the world; but respecting this question, on which there is much difference of opinion, we will not just now add to what we have said on former occasions, except to note that in a well-known cholera district there has appeared a malignant and most fatal disorder—a sort of plague, in fact, although it is called at present the "Siberian pestilence." According to the accounts received, this terrible sickness has appeared at Chanew, on the Waldaj circle, and for a time did not seem of a very fatal character. Some medical men were sent from St. Petersburg, but on their arrival the epidemic assumed such a fatal form that the medical men who had been sent fell victims to it in the course of a few days: soon after other doctors were sent, who speedily shared the same fate. The next news which reached St. Petersburg by telegraph was, that the entire district of Chanew was depopulated, and great consternation prevails in St. Petersburg in consequence of several cases having appeared which bear a striking resem-

blance to the Siberian disorder. In order to calm the alarm in the public mind, these attacks have been attributed to fever of a typhoid kind; but reports which come through Germany state, that the public mind in the Russian capital is by no means appeased, especially as "this typhus having declared itself in the Oboukov hospital, in a very few days carried off, not only the greater part of the patients, but the whole of the sanitary and medical staff." It is stated that the Government of Russia have taken steps to invite to the metropolis several medical men of note, from Germany, France, and England, in order that the benefit of their counsels may be had.

In the face of the advent of such a pestilence elsewhere, we should see that all proper precautions are taken to ensure healthy conditions in our own country. Amongst other steps we should prevent the crowding together of poor women in such a workshop as that we have here illustrated, by means of which disease and death are caused, even without the existence of an epidemic.

exhibition had met with a success that excelled the most sanguine expectations of the committee. The prizes for artistic merit were twenty-one; for mechanical contrivance, thirteen; and for manual skill, seventeen.

*West London Working Classes' Industrial Exhibition.*—A public meeting was held on Tuesday night at the St. James's Vestry Hall, Piccadilly, with the view of originating an industrial exhibition, to be held at the Floral Hall, Covent Garden, in the ensuing months of May, June, and July. The Hon. F. Byng occupied the chair. It is proposed that the exhibition should be kept open from the 1st of May to the end of July. The Prince of Wales, being a resident in the West of London, is to be solicited to preside at the opening ceremony on the 1st of May.

#### ARCHITECTURAL EXHIBITION.

THE annual report, just published, announces that last year's deficit in the cash account has been somewhat reduced; but the reduction is so small as to be scarcely worth mentioning. The receipts from admissions and other sources are a little more than last year's, and the expenses have been reduced: it may be hoped that the balance still due to the honorary secretaries, as shown in the accompanying balance-sheet, will be repaid entirely by the proceeds of the forthcoming Exhibition. The committee urge that employers would materially assist the interests of the Exhibition by distributing the season tickets, the price of which has been purposely fixed at the very small sum of half-a-crown, in order to obtain a very extended circulation. The drawings, photographs, models, &c., must be delivered on Monday, the 10th of April next, before six o'clock p.m.

The receipts at the doors, including receipts connected with the department of materials, &c., were 304l. 1s.; by season tickets, 28l. 15s.; and the annual subscriptions and donations, 112l. 6s. 6d. The expenses, including rent (200l.) are met by these sums, and there remains due to the honorary secretaries, 41l. 19s. 11d. The committee, however, hold shares in the Architectural Union Company to the extent of 100l., the gift of the late Earl de Grey and others.

#### CROPS ON THE CROYDON FARM.

INCREDULITY having been expressed as to the assertion in a recent article in our pages of the weight of the cutting of grass on the Croydon Board's Farm per acre, namely, thirteen tons, we have made further inquiry, and have the confirmation of the engineer that, as stated in our article, thirteen tons to the acre at one cutting in some places are produced. This, however, is a maximum; it is not so much as that on each cutting throughout: about ten tons per acre at each cutting is the average. The Italian rye-grass is 3 ft. long in the growth, and stands heading, 2 ft. 6 in.; and, while neighbouring fields are whitened with daisies, or yellowed with buttercups, or reddened with sorrel, in the Italian rye-grass there is not one of those weeds, but the whole field is a bluish green. The tenant cuts it and carries it off green to London for horses and cows.

#### THE REGULATION OF THEATRES AND OTHER PLACES OF AMUSEMENT.

THE draft of a bill to amend the laws relating to theatres and other places of public amusement, which was brought in by Mr. Locke, on the 10th of last month, has just been published. Appended to the bill is a schedule of rules, intended to insure the safety of the public in theatres. One of them is left incomplete and unintelligible through an error of the press. The others provide: 1. That, with the exception of private box lobbies, to which the public have not free access, every hall or corridor shall be at least 5 ft. wide, and 1 ft. more in width for each hundred persons over five hundred who are to be accommodated in the part of the building to which it leads. 2. That in each part of the building there shall be doorway access of 6 ft. in width at least for each five hundred persons to be accommodated in that part, and 1 ft. more for each additional hundred; and that no box or internal doorway shall be less than 3 ft. wide. 3. That all doors shall be hung so as to open outwards,—that is, towards

#### INDUSTRIAL EXHIBITIONS.

*South London Industrial Exhibition.*—The prizes have been distributed by Lord Palmerston, who took "the Speaker's chair of the old House of Commons" on the occasion. The following is a summary of the awards:—First class, 35; second, 85; third, 123; honourable mention, 129—total, 372. Out of 120 first and second class prizeholders, 110 elected that a portion of their prize should consist of a medal, 77 choosing silver and 33 bronze mementoes of the exhibition.

*The Operatives' Coachmakers' Industrial Exhibition.*—The prizes awarded by the judges to the exhibitors in the above exhibition were delivered on Monday night to the different recipients by the Right Hon. Lord Truro, at the Society of Arts. Mr. Hooper stated that the

the way of egress. 5. That all alleys and gangways in the audience part of the house shall be kept free from seats and every other obstruction to the free ingress and egress of the public. 6. That all gaslights in any part of the building which are, or may be at any time, within 2 ft. of any inflammable substance, shall be efficiently guarded, with wire-work or otherwise.

#### THE PRODUCTION OF SKILLED ARTISANS.

SIR,—It has been lately stated that many of our employers are compelled, by the scarcity of skilled artisans, to send some of their best work to the Continent to have it executed. The obvious inconvenience of this is exciting considerable inquiry amongst the parties interested, and they are anxiously casting about for information upon this undesirable state of things to be remedied.

Perhaps a few remarks on the subject, by a plain working man, may not be out of place, or deemed undeserving of attention.

It is well known that our continental neighbours are indebted to their paternal government for encouragement and assistance in the articulation of the industrial classes. Every means that experience could suggest towards improving the taste and skill of the workers has been, and still, employed in such a way that the poorest *ouvrier* and his family have within their reach means for acquiring facility of design, skill essential to their calling, and of cultivating the love of the beautiful. The ranks of the continental artisans are thus replenished from their own children, specially trained for their future vocations. In England the case is very different. comparatively little has been done in cultivating the higher tastes of the people. That something has been done in this direction is very creditable to our rulers; and for small mercies there have been many things to be thankful for. But it is not enough. What has been done by Government should be followed up by employers. Hitherto the latter have trusted to mere chance, or fortuitous circumstances, for their supply of skilled artisans. No regular organised efforts have been made in this country to train up a superior class of workmen in those trades their natural tastes and capacities fit them for. Skilled labour is like everything else: if you want a superior quality it must be cultivated. It is not enough to say there is a demand for it: steps must be taken to produce it.

To this many large employers are indifferent: some are even opposed to it. The former will not be troubled with apprentices; the latter would abolish them altogether, and solely rely upon the spirit of competition, or an ambition to rise, for throwing up a supply of skilled workmen equal to the demand. I do not believe in the latter formula. Free, open competition is, no doubt, a healthy stimulus; but it will not, in this case, according to my belief, supersede regular systematic training. The one could be a slow unsatisfactory process, the other is rapid and certain. Now I beg respectfully to submit a suggestion to large employers of skilled labour. Let them offer to take a certain number of apprentices *without premium*. These apprenticeships to be competed for solely by the sons of working men (labourers or mechanics). We should establish a system of examinations on a fair principle than that instituted by the Society of Arts. Lads passing this examination should be selected to learn such trades as their acquirements and natural tastes they are best fitted for. Scores of lads are put to school for which they are not fitted either by nature or education: the result is a batch of different workmen. We want to remedy this; and I hold that a first step is a careful selection, such as is proposed. When apprenticed, I could not make them the drudges they too often are now for the first year or two of their time. We would place them under the care of the cleverest and most intelligent man in the factory or workshop to instruct them in the use of tools, and the best and readiest modes of working; one-half or two-thirds of each day to be devoted to this duty: the remainder should be occupied in improving themselves in drawing, geometry, &c., &c., under the care of first-class instructors. With one or two years' special training of this kind, a youth of sixteen years of age would take his place in the workshop of the brightest of prospects; and I venture to think it would be strange, indeed, if such a system did not turn out some first-class skilled

artisans, fully equal to the requirements of the most fastidious or exacting employer.

Independently of the gain, I believe employers (and through them the public) would find, by adopting a plan of this kind, it would stimulate the general education of the industrial classes.

WILL JACKPLANE.

#### REVOLVING LIGHTS.

"Honour to whom honour is due."

THE saving of human life was the purpose of my late father, Adam Walker (lecturer on experimental philosophy), in the invention of the revolving lights now so familiar to us on every coast, and that purpose his invention has, under Divine providence, happily accomplished. Of his invention he gives the following account in his own manuscript:—

"About the year 1789 or 1790, I was applied to by the Corporation of the Trinity House to contrive a light that might be distinguished from all others, for a tower on St. Mary's Isle (one of the Scilly Islands), off the coast of Cornwall, as the Eddystone lighthouse, and several others, were in its neighbourhood, and were by East and West India ships often mistaken or confounded with one another. It was necessary that the light generally first made should have a character by which it could not be mistaken. Large lenses of different coloured glass, and several other devices, had been tried without effect. Coloured light, I found, was lost at a distance, and had no colour. I thought a large volume of intermittent light the most likely to answer the twofold purpose of being seen at a greater distance, and be unlike all others by revolving, and showing its light and dark sides alternately. I drew out the design. It was approved, and I was engaged to put it in immediate execution. I knew that reflected light would answer better than transmitted, so I had seven mirrors of copper silvered, each 22 in. diameter, formed parabolic, with each an Argand's lamp in the centre, so that the rays were sent out parallel from the mirrors. These mirrors were all fixed in a frame in a lantern of thick glass on the top of the tower, and communicated with the machine below by a stem. I calculated the size of each wheel, the number of teeth in each wheel, the weight to make the machine go sixteen hours (the length of the longest night), and to turn the above frame once round every two minutes. So there was a body of intense light, above 5 ft. in diameter, met the distant ship in full blaze, and then the light began gradually to diminish for one minute, when the light totally disappeared. This was only for two or three seconds, when a glimpse of light again appeared, and kept increasing, so that in another minute the full blaze again saluted the ship. Thus, the seaman had only to take out his watch, and observe that the light revolved once every two minutes, to be assured that it was the Scilly Light, for at that time there was no other light with that property. For this invention, and inspecting its execution, the Corporation of the Trinity House paid me 100*l.*; indeed, it was all I demanded, not doubting, if it succeeded, that a further remuneration would take place."

No further remuneration, however, was asked for or received, but wheresoever the revolving light is seen shining, it should be recognised as the best monument to his memory. There are many ways to fame, but few can compete with those which have for their object the public good.

DEANE F. WALKER.

#### RAIN-WATER PIPES.

Your correspondent "Octavius," in your number for March, 1865, page 159, has very truly described some of the causes for the stoppage and overflow of rain-water pipes; but I do not observe that he has referred to three conditions which are the most ordinary reasons for the injuries he refers to. The first is, that the rain-water pipes now generally used are much too small. Our old rain-water pipes were, so far as my experience extends, never less than 3 in. diameter net inside measure, and more commonly 3½ in. and 4 in.; while lead, being a malleable substance, would yield on pressure: now they are usually of iron, a hard and brittle material, and often not more than 2 in. or 2½ in. clear bore. I require mine always to be 4 in. at least, clear bore, and I find no stoppages. I am often told,—"Oh, so little water runs down this

pipe, that a 2-in. will carry all that is wanted." My reply is, "The less water carried down, the larger" (in reason) "the pipe should be, since a small quantity of water has not force enough to clear a small pipe, which therefore soon gets choked up."

The second is, that it is not uncommon to see a larger (old) pipe at top, and a smaller (new one) at bottom; this is often the case when the old pipe at top is lead, and the new one at bottom is iron: the iron metal being thicker than the lead, the pipe looks externally as large, though, in fact, much smaller inside. I always make my lower cast-iron pipes ½ in. or more larger clear internal bore than the upper lead pipe. And the third is, the defective plan of making the rain-water pipe in bends, elbows, and knees, to follow the projections of moldings, strings, plinths, &c.: these ought always to be avoided if possible, but if not possible, the rain-water pipe ought to be made larger at these bends, and the bends be made as gradual as possible, so as to present as small and sloping a ledge as possible, and too sloping for any dirt or rubbish to remain on. These precautions will prevent much of the injury complained of.

DECIMUS.

#### A CASE OF DRY ROT.

SIR,—I have a case of dry rot which I consider rather an extraordinary one. I have lately built a villa adjoining the town of Trowbridge. The situation is a very dry one, being on the side of a hill, and elevated above the lawn some 8 ft. The soil for the first 2 ft. is gravel, and underneath is about 3 ft. of hard rock. The turf, and about 6 in. of mould, were removed over the whole area upon which the house stands, this forming the level of the cellar. The walls were then built to the height of about 5½ ft., leaving the floors of the principal rooms 2½ ft. clear above this level. From the nature of the soil, and its being on a gentle slope, everything drained away from the house, so that there was not a damp corner even, in either of the cellars; but, strange to say, before the house was scarcely finished, the dry-rot appeared in the casements of the drawing-room, and in the course of a twelvemonth they have entirely perished for 2 ft. above the floor. I must here state that great care was taken to obtain good and well-seasoned timber for these particular casements. It was cut out two years before used, and was of the very first quality, crown Melem, without either knots or sap, and, in appearance, next in durability to oak. As the house has been beautifully finished, and being afraid that (except quickly stopped) it will spread throughout the house, I have written, thinking you, or some of your experienced subscribers, may give me a hint on the subject, as I have been in business for nearly twenty years and nothing of the sort has occurred in my experience before. W. S.

#### ABSORBING WELLS.

It is not my intention to continue a profligate controversy with your anonymous correspondent, "Pure Water." I am as much interested in the subject of pure water as he is, but bare assertions and doubts must not be allowed to pass for proofs and facts. Although we are in possession of materials and data in abundance relative to the secondary formations, this is by no means the case with the Tertiary, or is likely to be: difficulties arise when inquiry has to be made, as to the area of the outcrop, the lithological structure, or the water-bearing capacity. It was thought formerly that the lower Tertiaries supplied most of the water of the deep wells, but this idea has been again and again refuted in cases where accurate accounts have been kept of the borings made into the chalk. Analysis has proved that the water from the Tertiaries is seldom or never so pure as that obtained from the chalk, and in many cases unfit for use.\* It is often chalybeate to a degree perceptible to the taste, and it evolves sulphuretted hydrogen. The tertiary sands are not available

\* It is a pity that chemists are not always geologists, for in many instances the water of the sands under the plastic clay takes the credit due to that from the chalk. Thus in the analysis of the water at Colney Hatch Lunatic Asylum (Shaw & Sons, publishers, 1851), it is gravely stated by the eminent analytical chemist, "And, in common with all the artesian wells on the London and plastic clay, the water is," &c. Now, the water supplying the asylum is from the chalk, and sand water is tubed out and prevented from entering the well. This is by no means a solitary instance of such mistakes.—J. B.

where a large quantity of water is required, and few deep wells depend on a supply from that source, but are sunk into the chalk.

With reference to the question of poisoning wells by the admission of filtered sewage into the strata, I take great care that the water shall be as perfectly filtered as possible, and a little reflection will show that such poisoning could never take place unless the wells were in very close proximity indeed, as the water must be purified and filtered in its passage through the sands, or whatever the strata may be, just as it is filtered as it is first received on the outcrop. It may be objected that this first infiltration is a process requiring much time, but we have no proof that it is so. We know that the outcrop of the Tertiaries forms a zone covered with rich vegetation, highly farmed land, decaying vegetable and animal matters, cesspools, and foul ponds occurring everywhere on the surface. We also know that the level at which the water stands in the wells is gradually lowered in dry seasons, and that after continuous snow or rain, it is found to rise, proving that the surface water is not so long descending as we should suppose, with all its nasty compounds along with it. It is a fact known to every well-borer and all engineers, that the water in the lower Tertiary sands, when first reached by boring or sinking, is very often so bad in quality, that it cannot be used; but that after continuous pumping it improves and becomes fit for domestic use. We can only understand this condition by assuming that the water as it is set free by pumping instead of being in a stagnant state, is filtered through the sands to the bore-hole, and that the more it is used the farther it is moved, and more perfect the filtration. In conclusion, let me observe that there is little or no communication between the dark grey sands of the low Tertiary formations and the chalk.

J. BLENKARN.

#### CONTINENTAL NEWS.

**Paris.**—The tower of the church of St. Germain l'Auxerrois is about to receive a very perfect chime, consisting of no less than forty bells, which will play twice every day; and the machinery setting them in motion is so arranged that any number of tunes may be played upon them. The well-known mechanic, Collin, has constructed a gas-engine, in which the air is condensed to twenty-one atmospheres, and thus sets in motion a number of small cylinders, which act upon the bells on the musical-box principle. M. Collin is now engaged upon a series of experiments in which electricity forms the motive power.—A new method of obtaining brilliant effects for stained-glass windows is being tried by M. Marschal at Nancy. Pieces of differently-coloured glass are placed one behind another, and thus shades and half tones are produced which are said to be very effective. Several windows in the Cathedral of Metz are to be filled in this manner.

**The French Book Post.**—The director-general of the French Post-office, lately consulted as to his interpretation of the law of June, 1856, relative to the postage of manuscripts, has given the following decision, useful to be known by our correspondents. It is decided that literary or scientific manuscripts sent alone can be transmitted through the post at the ordinary rates of circulars or commercial papers. The rule generally adopted by the administration is this: except the case come under some formal restrictions prescribed by the instructions, nothing should be excluded from packets of commercial notes or papers of business, but those having the character or purport of personal correspondence.

**Vienna.**—The restorations now being carried on in the interior of the Dom have proved the fact that the walls were originally covered with frescoes, and those which have as yet been found are curious and worthy the attention of the connoisseur. Unfortunately, however, they have suffered so much by the repeated coatings of whitewash and distemper that their preservation is thought hardly advisable.—The execution of the new buildings for the Imperial Society of Musicians has been entrusted to Mr. Hansen, and the works will be begun next autumn. The site chosen is next to the "Künstler Haas," or Imperial Academy.—A public competition, which however

\* Thus Mr. Mylne observes,—"Under these circumstances, either by continuous pumping, or after lengthened use, a progressive improvement in the quality of the water invariably takes place."

is confined to Austrian architects only, is announced for plans for the new "Rathhaus," or Hôtel de Ville. No less than ten premiums are offered, namely, three of 3,000 florins (250*l.*), three of 2,000 florins (166*l.*), and four of 1,000 florins (83*l.*) each. The author of the first of these ten premeditated designs is to carry out the buildings, and the time for sending in is fixed for the 31st March, 1866.—Several denotations are announced for the purpose of restoring the cathedral church of St. Martin, at Pesth, the ancient place of coronation of the kings of Hungary. Amongst these are the Emperor, with 1,000 florins; the Dowager Empress Caroline Augusta, with 4,000 florins; Archduke Charles, 500 florins, &c.

#### PROVINCIAL NEWS.

**Dorking.**—The tenders for three cottages, near the railway-station, Mr. F. J. Dillie, architect, quantities supplied, were as follows:—

Lynn & Dudley .....	£264 10 0
Inkpen .....	550 0 0
Hamblin .....	520 0 0

**Warwick.**—The additional buildings, at the rear of the Crown court, County-hall, comprising three rooms, are now nearly complete, the work having been performed by Mr. W. Gascoyne, builder, Leamington. One of these rooms, fitted up with a small lavatory and closets, will be set apart specially for the juries, and the other two are open for witnesses and the general public.

**Bristol.**—The proposal for erecting the new Assize Courts, Bristol, in the space (arched over) between the Stone Bridge and Draw Bridge, was carried by a majority of four over the Queen-square and ten over the Small-street sites. The opponents of the first-named plan contend it cannot be carried out without an Act of Parliament.

**Doncaster.**—The committee appointed by the inhabitants of Doncaster to decide as to the site, &c., of a public infirmary in that town, have agreed to accept the tender of Messrs. Anelay, of Doncaster, to erect the building for 3,803*l.* 9*s.* The highest tender was for 5,280*l.*

**Whitehaven.**—The following tenders have been received for the construction of the intended new dock at Whitehaven, on the north side of the harbour there:—Messrs. Rawlley & Dacwra, 159,000*l.*; Nelson & Co., Carlisle, 175,000*l.*; Ritson & Co., 179,000*l.* There is a question whether the tender of Messrs. Rawlley & Dacwra includes the engineer's commission. If not, it will be, like the other two, above Mr. Rendell's estimate.

#### THE BUILDING TRADES.

At Leeds, a deputation of the master painters have met a like body of the Operative House Painters Association, and the dispute existing in the trade with respect to wages has been amicably settled. It is said that while the committee of the operative carpenters and joiners suggested that their difference with the masters should be put to arbitration, this was declined by the employers.

In Blackburn, a strike of operative plumbers has taken place, owing to one of the master plumbers and glaziers having refused to comply with the resolution to increase the wages of the operative plumbers 2*s.* per week. All the other master plumbers concurred the increase.

The joiners of Gainsborough are to have a half-holiday on Saturdays. The cabinet-makers are to work till four o'clock on that day, with an increase of wages.

At Derby, after notice given to the operatives, six master builders, representing the association of master builders in Derby, held a meeting at the Bell Hotel, to meet six operative bricklayers appointed as a deputation by their body to fix upon a chairman to arbitrate the matters in dispute between the masters and men. The bricklayers, however, having no power to refer the matter to arbitration, the matter rests just where it was, and with the labourers by the same rule.

Some months since the Droitwich bricklayers formed a branch of the Operative Bricklayers' Society, and subsequently issued a notice to their masters, the purport of which was, that after the 20th of March they should require an advance in wages of 8*d.* per day and a decrease in the number of hours for labour. In accordance with this notice, the whole of the bricklayers (those in the employ of the Salt Company excepted) ceased work, and they afterwards

waited on the masters with the view of ascertaining their intentions, but the latter have expressed their determination not to comply in the slightest degree with the terms contained in the document. The average wages given in the place has been 1*l.* to a guinea per week.

At a meeting of Dundee master plasterers and other master tradesmen, for the purpose of considering the present movement among the journeymen plasterers, to reduce the hours of labour from fifty-seven to fifty-one hours per week there was a large attendance—the different building trades being pretty well represented, and it was unanimously resolved that the hour of labour be as formerly, that the nine hours movement of the journeymen plasterers be resisted, and that the building trades generally support the master plasterers in their determination to withstand that movement.

#### WINDOW HORTICULTURE AND CITY GARDENS.

This is a subject which the *Builder* has occasionally treated of when it was less thought of, and we are glad to see that it is making progress. A paper by Mr. John Bell was read last week at the Society of Arts, "On Window Horticulture and the Cultivation of Plants in Flowers in Cities and Crowded Localities." A Mr. Bell remarks,—

"This whole subject of the treatment of flowers and plants in and about great cities is one fertile of ideas; and it does not appear of small interest even in respect to London itself, when we ask ourselves the question, 'Of its three millions of inhabitants, how large or how small a proportion love flowers, more especially?' I believe the proportion is very large, that delight in flowers, ranging from infancy to age. I conceive, indeed, that we may be as yet but on the threshold of the treatment of facilities for domestic household gardening in cities, and I have little doubt that a few years will see us much advanced in this respect."

Amongst the revelations of the railways are those which we look down upon the tops of houses in some of the poorer parts of London, and those inhabited much by the artisan and workman. As the train moves slowly in respect to London itself, when we ask ourselves the question, 'Of its three millions of inhabitants, how large or how small a proportion love flowers, more especially?' I believe the proportion is very large, that delight in flowers, ranging from infancy to age. I conceive, indeed, that we may be as yet but on the threshold of the treatment of facilities for domestic household gardening in cities, and I have little doubt that a few years will see us much advanced in this respect."

Will the pigeons and canaries, on the present occasion, we have nothing to do: but as regards the accommodation of flowers and plants, we may well remark the variety of expedients to which the love of Nature, and at the same time the narrowness of space and means, drive the enthusiastic. Tubs, pails, baskets, crockery of many kinds, troughs, glasses, bottles, and almost every kind of receptacle here, are the love of birds and the love of flowers; and in more than one ambitious instance I have seen the top of some small out-building, covered with a layer of earth, for the accommodation of flowers and shrubs, and fenced round with boards and slates on end, to keep them in their place within their narrow bounds."

Promotive of information to window gardeners, and of a desire to grow such gardens where it does not exist, two little penny pamphlets have been published by Partridge, of Paternoster-row, one "How to Grow a Plant and Win a Prize," by the Rev. S. H. Parkes, M.A., incumbent of St. Leonard's-on-Sea, and author of "Window Gardens for the People," and the other titled "Illustrated Penny Readings: Cried by Jenny; or, the Voices of Flowers."

#### GAS.

SEVERAL hundred pounds' worth of Reading gas stock has just been sold by auction, the 5 per cent. stock at par; the 7 per cent. at 12*l.* 10*s.* per cent. premium; and the 8 per cent. at 30*l.* to 35*l.* per cent. premium.—The Tyne-mouth Gas Company have declared a dividend of 7½ per cent. upon original shares, with a bonus of 3*s.* per share, and have resolved to divide among themselves, in shares, an increase of their capital to 80,000*l.* by the issue of 4,000 half-shares of 2*l.* 10*s.* each, on which, so far as called up, a dividend of 5 per cent. is to be paid. The works, including a new coal depot, new gasometer for 210,000*cu.* ft. of gas, new purifiers, &c., have been completed at a cost of 7,005*l.* and paid for. The mains have been extended to Preston.—The Midhurst Gas Company have resolved on a reduction in price from 8*s.* 4*d.* to 7*s.* 6*d.* per thousand feet.—A contract for the formation of gas works for Earls Colne has been signed with Messrs. Holmes & Co., engineers and gas contractors, of Huddersfield, to erect the entire of the works for the Earls Colne Gas Company (limited), for 1,015*l.*, and Messrs.

Colmes & Co. shortly afterwards concluded a sub-contract with Mr. Rogers, builder, Earls Colne, to complete the buildings for 255l. 10s. — movement is also in progress for the lighting of St. Oeyth. — The Stockport Advertiser states that Mr. Leslie, the gas engineer, is about to leave Stockport for a more lucrative situation at Wydenham, and pays a high compliment to him in the occasion.

A PUBLIC COMPANY AND ITS ARCHITECT.

ONE of the special-jury causes at the late Manchester Assizes was Green v. The Todmorden Town-hall Company, Limited. Mr. Attorney-General James, Q.C., and Mr. T. Jones appeared for the plaintiff, and Mr. Temple, Q.C., and Mr. Bain appeared for the defendants. The following were the particulars of the plaintiff's claim:—

Table with 2 columns: Description of work and Amount. Includes items like 'Superintending repairs of Odd Fellows Bridge, caused by flood', 'Making sketches, designs, plans, drawings, and specifications, &c., complete, and final town-hall, as per agreement, and superintending of works', 'Paid for builder's quantities and lithographing the same', 'Drawings and superintendence of works under County Bridge', 'Drawings and superintendence of works under Odd Fellows Bridge', 'Cr. Cash on account', 'Paid into Court'.

The plaintiff, Mr. James Green, architect for many public and private buildings, including the Accrington town-hall, the Craven Bank, Burnley, the Burnley Technical School, &c., &c., being examined, said, that towards the end of 1860 it was considered desirable to erect in Todmorden a building for public purposes. A meeting was held, and eventually a company was formed. The directors consulted him. He was asked to prepare sketches and designs. He exhibited some, and without having made a detailed estimate, stated that he thought such a building as was then proposed could be carried out for 10,000l. It was afterwards proposed that a part of basement of hall and a space of land adjoining should be made into a public market, which would have increased the expense. In February, 1861, plans of the whole were submitted to, and approved by, the directors, who passed a vote of thanks to the plaintiff for preparing plans and sketches for proposed buildings; and on the 6th of April the shareholders passed a resolution approving of general plans, and requested the committee to proceed with the works as early as possible. In the 2nd of May, 1861, the first meeting after the registration of the company, the directors resolved, on the motion of Mr. Lord, seconded by Mr. Joshua Fielden, — "That Mr. Green be engaged as architect of the company, on the following terms, viz., to be paid the sum of 2,500l. if the whole of the buildings, including foundations, and the arching of the water-course, cost 10,000l. or more; but in case the cost is less than 10,000l., then to be paid 5l. per cent. on the cost, this remuneration not to include the expense of the works, but to include the cost of all plans preliminary and subsequent to his appointment."

A large portion of the site of the town-hall was occupied by the remains of a river, which required to be bridged over. It was estimated that the work could be done for 1,000l. or 1,200l., but, owing to the unusual and uncertain nature of the ground, and the depth of gravel and strata which had been deposited, when the arching was completed, and the foundation walls raised to the level of the streets, it was found that 2,500l. had been expended. This formed no part of the original estimate of 10,000l. During the progress of the arching and foundation works, the plans of the main superstructure were being prepared, and they were submitted to the directors, who approved them, and authorized the plaintiff to advertise. He told the defendants that builders' quantities would have to be taken out before any tenders could be obtained; and the advertisement stated that quantities would be supplied to the parties who applied for them. At the time he advertised he handed over the plans and specifications to Mr. Bradley, surveyor, Liverpool, with instructions to take out the quantities, and to deliver as many as possible, the arrangement being that the charge for such quantities, exclusive of lithographic copies, should not exceed 1 1/2 per cent. on the amount of each trade. The fact that a surveyor was employed to take out quantities was repeatedly brought to the express notice of the directors. The lowest tender was 13,855l., greatly in excess of the amount at the disposal of the company, if all the shares taken had been put in. The directors, on the 19th of June, about the time the plaintiff offered to revise the design, diminish the ornament, and reduce the cost, but the directors refused; and on June 19, they passed the following resolution:—

"Tenders having been presented for the erection of the whole building, the lowest of which amounts to the sum of 13,855l., and the whole available funds (supposing all the shares taken were paid up), amounting only about 2,000l., resolved,—1. That the directors do not feel justified in letting the whole of the works. 2. That in the opinion of the directors, it is desirable to recommend to the shareholders the advisability of erecting the shops in the basement of the market-house, butchers' shambles in Bridge-street, and the base course of main building, to be built of stone, and such temporary covering as may be adopted as may be found most advisable for

the purpose; and, 3. That Mr. Green be empowered to obtain tenders for carrying out the works mentioned in the above resolution."

At an extraordinary general meeting of the shareholders, on the 3rd of July, the resolutions of the directors were confirmed. And it was also resolved that each shareholder should have a lithographed copy of the proposed building presented to him; and the plaintiff was directed to "prepare a specification for the works proposed to be done; and to write to Thornton, Brothers, for a detailed tender, and also request their attendance at the next meeting." On the 10th it was resolved:—

"That the portion of the building proposed to be erected be let to Thornton, Brothers, for the sum of 1,331l., provided they will complete it according to the specification submitted by Mr. Green."

Other contracts accepted were those of Dobson, for the timber work (110l.); and Hellewell, for the plumbers' work (72l.). The reason assigned for executing only portions of the works was that, by the time they were completed, trade might be improved and money cheaper; and it was supposed that when the building was started more capital would be subscribed.

Eventually it was agreed that the company should be wound up, and liquidators were appointed. When he sent in his account, in compliance with the request of the directors, exception was taken to the 186l. paid for quantities. Correspondence ensued, and arbitration, which he proposed, had been declined. He would have had very little more labour if the whole design had been carried out. His labour had been working the plans and preparing the tenders.

The Judge interposing, said that the resolutions which had been read seemed to establish a contract in writing; but it would be prudent, if possible, to avoid further litigation; and it was a case in which compromise might fairly be made.

Mr. James was prepared to refer it to a barrister at once to assess the amount due.

The Judge thought it would be better to take a moderate sum of the claim, and to settle the matter without reference at all. He wished to save expense, which would only add to the difficulty.

After considerable discussion, it was proposed to refer the matter to Mr. Waterhouse, the architect of the Assize Courts. He was to hear Mr. Green's statement, and the statement of one person on the other side, to examine the building, and to say what ought to be done.

The Judge said he did not think a better conclusion could be come to.

Mr. Green said he offered that proposition to the directors long since.

The Judge said he had seen nothing to impeach the professional skill or reputation of the plaintiff.

A verdict was then taken for the plaintiff, subject to the award or certificate of Mr. Waterhouse.

Books Received.

The printed Proceedings of the Institute of Engineers in Scotland for 15th February, 1865, contain a full account of Low's patent boring machines, &c., in a paper by Mr. John Downing read before the Institute on that date. The paper is illustrated by engravings.—"History of the Steam Hammer: a Lecture, with illustrations, by Mr. T. S. Rowlandson. Eccles, Shuttleworth. 1864." This is a reprint from a local paper of a lecture delivered at the mechanics' institution, Patricroft, in December last. The following statement, made by Mr. Rowlandson after the reading of the paper, rather surprises us:—"Although it is an unquestioned fact that Mr. Wilson was the sole inventor of the self-acting motion,—which motion was, in the first instance, the cause of the steam hammer's great success,—yet in 1843, Mr. Nasmyth secured a patent for it, in his own name, and as his own invention,—a fact only accidentally discovered by Mr. Wilson within the last few weeks."

Miscellaneous.

NON-ABSORBENT BRICKS.—A correspondent is anxious to hear of an impervious or non-absorbent brick, at moderate price. The want is so often expressed, that we print his inquiry in the hope of eliciting some useful information on the subject.

TATTERSALL'S.—The new buildings erected at Knightsbridge-green, for Messrs. Tattersall, under the direction of Mr. C. Freeman, architect, were opened on Wednesday evening last. Some time ago we gave a few particulars of the edifice and arrangements, and we may supplement these on a future occasion. Messrs. Holland were the builders.

ROYAL HIBERNIAN ACADEMY.—The thirty-seventh annual exhibition of paintings, sculpture, &c., of the Royal Hibernian Academy has been opened, in the Academy House, Lower Abbey-street, Dublin. The opening day was, as usual, confined to the holders of season tickets, of whom there were a good number present. The Lord Lieutenant and Lady Wodehouse visited the Academy. The exhibition is not so large as that of last year, and it is especially remarkable for the very limited display of Irish art.

THE LEEDS SURVEYORSHIP.—At the last meeting of the town council, a letter was read from Mr. Filitier, the borough surveyor, resigning his office, because he was informed the Improvement Act required that an independent engineer must be appointed to carry out the sewerage works in certain proposed new districts.

ROYAL ITALIAN OPERA HOUSE.—Seldom has so much satisfactory variety been afforded to the subscribers and the public, at the opening of the season, as they have found on the present occasion. "Faust," the "Trovatore," and "Guglielmo Tell" have alternated; and the "Prophete," with Mlle. de Edelsberg as Fides,—Mario, who is in good voice, sustaining his old part,—is underlined for Tuesday next. In the "Trovatore," Signor Wachtel has considerably improved his position. Mlle. Honoré, a new singer, has scarcely sufficient weight for the Gipsy mother, and pleased the house much better as Siebel, in "Faust."

LONDON AND MIDDLESEX ARCHÆOLOGICAL SOCIETY.—At the ordinary monthly evening meeting of this Society, to be held at 22, Hart-street, Bloomsbury, on Monday next, the 10th inst., there will be exhibited, by the kind permission of the Dean and Chapter, the original drawings made by Sir Christopher Wren for St. Paul's Cathedral. Some remarks on these interesting works of the celebrated architect will be made by Mr. F. C. Penrose, the cathedral surveyor; and a series of drawings of Sir Christopher's first model, which was not carried out, will be exhibited by Mr. J. E. Goodchild, Mr. Arthur Aschapel, V.P., will preside, and the Rev. Thomas Hngo, M.A. F.S.A., Mr. C. J. Shoppee, Mr. Charles Baily, Mr. George R. French, Mr. John Whiteford, F.S.A., John Young, jun., F.S.A., and other members are expected to take part in the proceedings. The chair will be taken at eight o'clock precisely.

ROYAL HORTICULTURAL SOCIETY.—The love of flowers, inherent in all classes of the community, is clearly shown by the response made to last year's offer of medals by the Royal Horticultural Society for the best collections of plants from the various counties of Britain. A large number of collections made during last summer have been forwarded in answer; and so uniformly excellent are they in displaying, not only a love of flowers, but a good scientific knowledge of the plants, that the Society has been induced to award no less than forty-two medals,—twenty-six being silver, five gold, and the rest bronze. Nineteen ladies are among the recipients, fourteen receiving silver and one a gold medal. The other gold medals are awarded for the best of the county collections,—one being given to Mr. J. Clarke, of Saffron Walden, for the discovery of a wild plant entirely new to Britain; and an extra gold medal to Mr. W. G. Smith, whose name often appears to drawings in our pages, for "two volumes of beautifully executed drawings of fungi and pflanzerogamous plants."

LECTURE ON DOMESTIC ARCHITECTURE.—Mr. G. E. Street has been lecturing at Cambridge Town-hall, on "The Application of Gothic Architecture to Modern Domestic Buildings." The chair was occupied by Mr. F. S. Powell, M.P. The lecturer commenced by stating that our present architecture is unsatisfactory, and the question that first arises is this, viz., if there is to be a renewal of good architecture, is it to be a Classic or a Gothic revival? He was prepared to prove that Gothic can be revived with the best results. It is our indigenous and national style: it is most suited for our climate and for our local materials: it is at once the most truthful and the cheapest. For works of a high class, it admits sculpture in any amount of richness or profusion; it demands no iron rigid uniformity, but is essentially free in its conception, and its practice is that of common sense; whereas Classic architecture is generally little better than a uniformity. The lecturer gave amusing instances in proof of his allegations, such as are to be found in "Pugin's Contrasts," and advocated the formation of our buildings, utensils, furniture, paper-hangings, carpets, and dress, upon the principles of design that obtained favour in the Mediæval period, and is now to be found in the East. He showed that there was much to be avoided in modern Gothic work when it had been executed without a due appreciation of true principles, and that many old houses were more agreeable to dwell in than many modern ones.

THE METROPOLITAN HOUSELESS POOR BILL.— This bill has been read a second time in the House of Commons on the motion of Mr. Villiers, who then stated his intention to propose that the police be authorised to take all persons to those refuges whom they saw simulating misery in the streets at night. Mr. Bromley proposed to make the police relieving officers in the various districts. In St. Paul's, Covent-garden, the practice was in force and worked most effectively. Mr. Villiers's proposal was adopted in committee.

TOWERS AND SPIRES.— A lecture was delivered last week, to the students of the Cambridge School of Art, by the Rev. Mackenzie E. C. Walcott, upon "Towers and Spires." The Rev. Dr. Bateson presided, and exhibited to the meeting the drawings of the new tower now in course of construction at the west end of the new chapel St. John's College: the cost of its erection is about 10,000l., and will be defrayed by Mr. Henry Hoare, to whom a serious accident has recently happened. Its highest point will be 156 ft. from the ground, or about 20 ft. more than the summit of King's Chapel pinnacles.

THE CARTOONS AT HAMPTON COURT.— Lord St. Leonards has presented a petition to the House of Lords from inhabitants of Kingston-on-Thames, &c., praying that the cartoons might remain in Hampton Court Palace, but Earl Granville stated that applications had been made to permit the cartoons to be exhibited at Kensington as a loan, and when the public had had an opportunity of seeing them there it would be a very proper subject of inquiry where they should be permanently placed. The real question was in which place would they be most available for the inspection of the general public.

MASTERS AND MEN IN FRANCE.— A lock-out seemed likely to be the result of the strike among the workmen of the Government tobacco works at Bordeaux. A great number of the workmen have already gone to work, the number being 600 at present in full labour. A notice was posted in the manufactory, a few days ago, announcing that orders had been received from Paris, if 500 workmen would not join the works on that day, to shut the building up for a month. Later accounts state that 900 entered at once, and that the strike may be considered as terminated.

LIVERPOOL ARCHITECTURAL SOCIETY.— At the last fortnightly meeting, Mr. Joseph Bout presiding, the paper for the evening was read by Mr. Hermann, on the "Construction of Theatres." Alluding to the liability of theatres to accidents from fire, he observed that the risk would be materially lessened if the whole of the fly gangways and carpentry, wing ladders, &c., were highly constructed of iron, leaving nothing but the draperies to burn; and even the risk from the ignition of the house appropriated to the audience were entirely shut off, as others have suggested, by an iron drop-scene. He had no doubt the proprietor would find the small additional cost fully compensated for by the additional security, which would probably reduce the insurance rates.

LECTURE ON ART AT ROYAL INSTITUTION.— Mr. Westmacott has been lecturing at the Royal Institution on "How Works of Art should be Looked at." His chief object was to show the importance of cultivating and improving a taste for art generally. That there is a taste for art in this country, the numbers of exhibitions and of the persons who visit them were adduced as evidence. The money collected in "dirty shillings" at the annual exhibitions of the Royal Academy alone was stated to amount to nearly 10,000l., for which sum Mr. Westmacott said the Royal Academy had no need to be thankful, for it was the only assistance they received from the public, with the exception of the use of the building, and for each shilling were given about 2,000 works of art. Mr. Westmacott expressed himself strongly against that style of art in which minuteness of detail is carried to such an extent that a rock represents its mineralogical structure, and a dead leaf on the ground is so well defined as to indicate the kind of tree from which it fell. Many of those who now set themselves up as judges of art, he maintained, were ignorant of its first principles; and artists, seeing that their judges were incapable of appreciating what is really beautiful and excellent, wanted the stimulus to exertion, and what was really good in them could not be "dug out."

AUGUSTE HYACINTHE DEBAY, a few years ago the Nestor of sculpture in France, has just died. Born at Nantes in 1804, he won the grand prize at Rome while he was only twenty years of age, and subsequently painted several large pictures for the Versailles Gallery. As a sculptor, his best work is the group called the "Berceau primitif," representing Eve nursing on her knees two sleeping infants.

LIQUID GLUE.— A French receipt says, — A kilogramme, 2½ lb. avoidupois, of good glue of Cologne, or Givet, is dissolved in a litre of water in an earthen pot plunged in hot water, the water lost by evaporation being replaced. When the glue is completely dissolved, one-fifth of a kilogramme of nitric acid at 30 deg. centigrado is added. When quiescent it should be well stirred, set aside to cool, and afterwards placed in well-stopped vessels for future use.

THE NEW MINUTE OF THE DEPARTMENT OF ART.— The Committee of the Dundee School of Art say,—"The Minute of January will have the effect of reducing the already insufficient aid to less than one-third of the present amount—will abolish all assistance to the master in teaching the classes—will deprive the classes for working men's children of that superintendence by the School of Art which has hitherto worked so well—and will oblige numbers of the Schools of Art to close their doors;" and they fear that this will be their own case, so far as the teaching of the industrial classes is concerned. The total annual receipts from Government, under the proposed regulations, would not likely reach 40l., and out of that sum it would be necessary to pay one or two assistants, leaving a balance totally inadequate to maintain the classes on their present footing. They assert that viewing the school as now attended, under the certificate system, the aid would have been 226l. 17s.; under the present system it is 167l. 6s. 4d.; and that under the proposed system it would be 37l. 15s.

TENDERS

For new London and County Bank, Faruham Branch, Surrey. Messrs. Egger & Sisley, architects:— Birch (accepted)..... £1,370 0 0

For the erection of a villa residence near the London-road, Devizes, for Mr. W. Brown. Mr. Weaver, architect:— Long..... £1,095 0 0 Plank & Ash..... 1,089 14 0 Russell..... 1,085 0 0 Mullings (accepted)..... 1,090 0 0

For new Congregational Church, Sunningdale, Berks. Mr. W. F. Poulton, Reading, architect:— Hooker..... £1,335 0 0 Norris..... 1,236 17 0 Sawyer..... 1,151 0 0 Simpson..... 1,135 0 0 Oades (accepted)..... 1,016 0 0

For two villas at Wood-green, for Mr. H. Friend. Mr. Samuel Hill, architect:— Coscock..... £1,335 0 0 Comber..... 1,320 0 0 Abbott & Hopwood..... 1,285 0 0 Bradley & Pegg..... 1,250 0 0 Warr..... 1,177 0 0 Brooks..... 1,045 0 0

For additions to a house on the Newmarket-road, Norwich, for Mr. J. Hignin. Mr. J. S. Benest, architect. Quantities supplied:— Balls..... £379 0 0 Wales..... 573 0 0 Poyson..... 569 0 0 Taylor..... 545 0 0 Browne & Bailey..... 538 15 0 Hocking (accepted)..... 622 0 0

For alterations to Mr. Snelling's premises, Rampant Horse-street, Norwich. Mr. James S. Benest, architect:— Ling & Aimes..... £249 0 0 Gilbert..... 157 0 0 Plummer & Bloom (accepted)..... 310 0 0

For an orphanage and other buildings, at the Convent of the Sacred Heart, Southampton. Quantities supplied by Mr. D. J. Brown. Messrs. M. E. Haddfield & Son, Sheffield, architects:— Haward..... £688 0 0 Gammon..... 679 0 0 Brass..... 626 0 0 Sewell & Sois..... 624 0 0 Hill & Keddell..... 577 0 0 Longmire & Burge (accepted)..... 627 0 0

For practising-school, chapel, and other buildings, for the Training-school, Mount Pleasant, Liverpool. Quantities by Mr. Brown. Messrs. M. E. Haddfield & Son, architects:— Bucknall..... £980 0 0 Haigh & Co..... 930 0 0 Tomkinson..... 915 0 0 Beteman..... 869 0 0 Brinall..... 823 0 0 Hughes..... 807 0 0 Robinson..... 800 0 0 Farrell (accepted, with certain deductions)..... 825 0 0

For alteration of the music-hall, Sheffield. Quantities by Mr. C. J. Innocent. Messrs. M. E. Haddfield & Son, architects:— Wade..... £4,900 0 0 Carr..... 4,300 0 0 Besselt..... 4,250 0 0 Robinson..... 3,950 0 0

For a further contract for the Spital Hill Works, Sheffield. Quantities by Mr. C. J. Innocent. Messrs. M. E. Haddfield & Son, architects:— Carr..... £2,805 0 0

For villa in the Tapwood-road, Caterham, Surrey. Mr. J. T. Jackman, architect:— Macey..... £5,077 0 0 Gills & Son..... 4,245 0 0 West..... 4,088 0 0 Cowland..... 3,992 0 0 Adamson & Sons..... 3,797 0 0 Willis..... 3,763 0 0

For villa at the Rock, Reigate, Surrey. Mr. J. T. Jackman, architect:— Cowland..... £1,059 0 0 Adamson & Sons..... 3,697 0 0 Sharpington & Cole..... 3,555 0 0

For erecting a warehouse, Bridge-row, Cannon-street City, for Mr. Thomas Wrigley. Mr. Alexander Pecklen architect. Quantities supplied:— Braxton..... £3,651 0 0 Macey..... 3,633 0 0 Ennor..... 3,445 0 0 Myers..... 3,360 0 0 And for Rib-wire endless rope:— Lawrence, Brothers..... £139 0 0 Clark & Co..... 95 0 0

For residence at Haling Park, Croydon, for Mr. C. Wise. Mr. John Berney, architect:— Hollidge..... £2,200 0 0 Loose..... 1,867 0 0 Jarrett (accepted)..... 1,864 0 0

For two villas at New Waudsworth. Mr. C. W. Horne architect:— Langmead & Way..... £1,607 0 0 Heath..... 1,695 9 7 Adamson & Sons..... 1,677 0 0 Widgery..... 1,645 0 0

For the erection of four houses, Nelson-terrace, Lucy-road, Bermondsey, for Mr. S. Smith:— West & Morse (accepted)..... £1,160 0 0

For house, Brunswick-square, Gloucester, for Mr. N. C. Fluck. Mr. James, architect:— Cullis (accepted)..... £554 0 0

For iron fence, Marine-parade, Brighton. Mr. Philip C. Lockwood, C.E., borough surveyor:— Bennett..... £1,370 0 0 Jones & Blaxton..... 1,259 0 0 Taylor..... 1,157 0 0 Wiliusburst..... 1,157 0 0 Hammond & Parrett..... 1,171 10 0 Costam & Co..... 1,155 0 0 Rayner..... 1,134 0 0 Drury & Biggleston..... 1,110 0 0 St. Pancras Iron Company..... 1,089 0 0 Hill & Smith..... 1,073 0 0 Reading Iron Company..... 1,020 0 0 Newton & Chambers..... 1,000 0 0 Packham & Son..... 965 0 0 Head & Ashby..... 920 0 0 Hernleowicz..... 850 0 0 Reed & Co. (accepted)..... 725 0 0

For new Baptist chapel, Harlow, Essex. Messrs. Crofts & Smith, architects:— Hitch..... £2,170 0 0 Glasscock..... 2,040 0 0 Burton..... 1,940 0 0 Nicholls (accepted)..... 1,927 0 0

For villa at Tulse Hill, for Mr. Thomas Cree. Mr. Charles Hanbridge, architect. Quantities by Mr. J. W. Dennison:— Piper & Wheeler..... £4,993 0 0 Myers & Sons..... 4,885 0 0 Ashby & Horner..... 4,749 0 0 Bishop..... 4,326 10 0 Hill & Keddell..... 4,350 0 0 Brown & Robinson..... 4,223 0 0

For additions to Wimpole Hall, for the Right Hon. the Earl of Hardwicke. Mr. Erant, architect. Quantities not supplied:— Bell & Sons..... £2,885 0 0 Thoday & Clayton (accepted)..... 6,730 0 0

TO CORRESPONDENTS.

R. A. B.—J. Y.—G. E.—W. S.—C. E. T.—G. W.—H. & Son.—W. R. C.—W. W.—W. P.—A. Galt.—T. A. M.—W. S. G.—W. E. H.—J. E. P.—D. F. W. (to the Editor). B. P.—G. F. (under our name).—Jenifer (State of the Month-ster Anne's Courts have already been given in our pages).—J. K. (there are special cases where the delectating earth closets may be usefully applied; but that is all that can be said).—A. P.—J. H.—J. W.—J. P. We are compelled to decline pointing out books and giving addresses. All statements of fact, lists of tenders, &c., must be accompanied by the names and address of the sender; but not necessarily for publication.

NOTICE.—GOOD FRIDAY.—"The Builder" for the Week ending April 15th will be published at TWO O'CLOCK, p.m., on THURSDAY, the 13th Instant.

Advertisements intended for insertion in that issue must therefore reach the Office before FIVE O'CLOCK, p.m., on WEDNESDAY, the 12th Instant.

# The Builder.

VOL. XXIII.—No. 1158.

A Budget of Books and Papers.

**URING** the last few weeks, books, pamphlets, and journals, have accumulated; for truly, as the Book says, "of making many books there is no end." He who mastered them all might be disposed to add, completing the quotation, "And much study is a weariness of the flesh." Leaving some of the heavier and more important,—such, for example, as "Reynolds and his Times," and Mr. Murray's interesting "New Testament illustrated,"—for early special notice, we must make a dash at the heap, and endeavour to bring the contents of some of them to the knowledge of our readers.\*

First comes to hand "A Proposal for diminishing Crime, Misery, and Poverty, in Liverpool," by M. J. Whitty. The condition of Liverpool has been for some time forcing itself on the minds of its more thoughtful citizens. Foremost amongst these is Mr. M. J. Whitty, who, in connexion with the *Daily Post*, and in his high position, has long sought to make this condition known, and to obtain remedies. Under the title we have given, he prints three letters, one describing "A street in a dark district;" the second asking, "Why are streets the abode of vice, crime, and misery?" and the third offering a "Remedy." Public opinion and the public eye, says he, are the two most potent powers in the world. On the denizens of those streets these powers have no bearing. Bring them to bear, that is my remedy. "My plan is the ancient one in principle—responsibility of neighbour for neighbour." What he proposes is, that the densely populated and the less opulent parts of the town be divided into districts, and that each district shall be presided over by a "local committee of safety," the members of these committees to be elected by the householders, ten householders electing one member from among themselves. Ten electors, he thinks, will be numerous enough, because small streets should have at least one representative, and large streets more than one. A district should not be too large, and for this reason, a committee should belong to the district, in order that members should know the inhabitants and be known to them. The proposed "local committee of safety" should present themselves as Government officials; and, in order that they may do this, it will be

absolutely essential that they proceed under the sanction of an Act of Parliament. The Act must of course be general, and, being a Government measure, will cost nothing. When properly appointed, what are the committees to do? By virtue of their office they will have authority to get information, to remonstrate, to advise, to hear complaints. Like the medical officer and the sanitary officers of the Corporation, they may enter any house without being charged with trespass, and, being sworn in as constables, they may demand the assistance of the force and give aid to the force when required. Their business, however, will be mainly to counsel and reprimand; to be kind even when they address the worst offenders, and, when counsel and remonstrance fail, to appeal to those whose especial duty it is to put the law, criminal or repressive, in force. "Warning must precede action, and the act will be the communication of facts to Major Greig, the health committee, the watch committee, the select vestry, Mr. Raffles, and the mayor."

Would such an organisation effect great good? We have not the least doubt about it. It is to be feared, however, that there are sufficient difficulties in the way to render it unlikely that it will be brought about. Even an approach to it would be advantageous: the appointment of district committees without the authority of an Act of Parliament.—While Liverpool has its Whitty, Trench, and others, Salisbury is all the better for Mr. Middleton, who puts forth, in the shape of a pamphlet entitled "The Benefits of Sanitary Reform, as shown by Salisbury, in nine years' experience thereof," the paper he read at Bath. Salisbury must date its movement towards improvement from the last visitation of cholera there. It had long been noted as unhealthy. In that wonderful book, the "Anatomy of Melancholy," there is an allusion to Salisbury quoted by Mr. Middleton. Burton there writes, "The worst is a thick, cloudy, misty, foggy air, such as comes from fens, moorish grounds, lakes, muck-hills, draughts, sinks, where any carcases or carrion lies, or from whence any stinking, fulsome smell comes. Galen, Avicenna, Mercurialis, new and old physicians, hold that such an air is unwholesome, and engenders melancholy, plagues, and what not." After naming several towns abroad, "Salisbury with us, Hull and Lynn" are mentioned; and he goes on to say: "But let the site of places be as it may, how can they be excused that have a delicious seat, or pleasant air, and all that nature can afford, and yet, through their own nastiness, and sluttishness, immodest and sordid manner of life, suffer their air to putrefy and themselves to be choked." Old Burton was evidently a worshipper of Hygeia. In the history of Salisbury, Hatcher records no less than five visitations of plague within ninety years. That more recent cholera time to which we have referred we well remember. The Archeological Institute was holding its congress there, and the then Bishop struck dismay into many hearts by his sermon, preached during the proceedings. Sorrow overspread the city. Invited on one morning by a leading citizen to dine that day, we found the inviter dead at the hour appointed! A sad time: but let that pass. It enabled the clearer heads of the city, including the writer of the pamphlet before us, afterwards to obtain better water supply and sewerage, and Mr. Middleton now tells of the gratifying result. He shows, for example, that while in nine consecutive years before the drainage the births were 244 in number more than the deaths, in nine consecutive years after it they were 929 more than the deaths; that while the average mortality, in the period named, before drainage was about 27 in the thousand, for the nine years since it was 20 in the thousand;—the cholera year not being included. The Close of Salisbury,

with a population not varying much over a long series of years, presents the following facts as to mortality. For many years that mortality was at the rate of nearly 20 in 1,000; for the last nine years, since drainage, it has been only about 14 in 1,000, thus showing a death-rate lower than that of the Isle of Wight, which is 17; of Gumberland, Westmoreland, and other rural districts, the most healthy in the kingdom; for the death-rate of seventy of the districts, selected as the most healthy in England, is 17 in 1,000. This writer properly says,—

"I do not claim that drainage and water-works saved all the 331 lives, being quite aware that so many concomitant physical and moral causes exist to produce effects upon vitality—so many ways to the gates of death—that to make such claim would be as rash as to put the hand upon each of 331 persons and say, 'You and you were saved.' But, holding the strong opinions which I do about the fostering causes of many diseases being removable, and seeing what I do see in Salisbury, it would be affliction on my part not to say that I believe the works done to have been one cause, and that the main cause, of the diminution of mortality; and although it may be objected that assertion is easy, proof difficult, in vital statistics, in this case I do not think it would be easy, if possible, to suggest another even plausible cause of such a great alteration having continued for so many as nine years."

If any of our readers can suggest a more obvious reason, we shall be glad to hear it. We are unable to do so ourselves.—The admirable *Times* occasionally reminds us, by some of its leaders, of a large grand old dog, who, anxious to show his friendly feeling, bounds in amongst his friends, and begins by knocking them all over. Thus in a recent article on the sanitary condition of Calcutta, the writer starts with what might almost be considered a laugh at the sanitary reformer. "A social censor," says he,—

"Satirizing the follies and vices of the age has often been taken for one steeped to the lips in wrong-doing, who, as a last resort, is earning money for future sin by detailing the experiences of the past. But of all who take upon themselves the task of exposing the evils of the world, the sanitary reformer is surely the man who most enjoys the evil he denounces. His delight in impure water is so great that he might be supposed to be always taking 'headers' in it; he wades through filth, and whenever he comes across anything which is particularly nasty, he stirs it up for the benefit of the bystanders; and whoever has been misguided enough to attend a sanitary conference knows that his enjoyment of bad air is most practical and lasting."

But then the writer goes off into quite the right line, a denunciation of the infamous filthiness of Calcutta. Will it be believed that up to a year ago 5,000 human corpses had been thrown every year into the river which supplies the greater part of the inhabitants with water for all domestic purposes, and which, moreover, for several miles is covered with shipping as thickly as almost any river in the world? What is, however, more astounding, is the statement that more than 1,500 corpses have been thrown into the river in one year from the Government hospitals alone. Measures were taken by the Bengal Government last March to stop the casting of corpses into the river, and to introduce the practice of incineration, which are said to have been successful; but up to that time the veneration of the native for the sacred stream had been too powerful to be thwarted by the Government. "But those bodies thrown into the river as we see dogs thrown into the Thames, only under a hotter sun, form but one of the nuisances of Calcutta. There does not exist a properly constructed drain in the city!" Fire away, *O Times!* In no direction can thy power be more usefully applied than in obtaining improvements which will enable the peoples to live, and not die,—before their time.—Liebig's Reports, communicated to the Corporation of the City of London, on the agricultural value and economic disposal of the sewage of great towns, have been published in a complete form, by W. H. Collingridge, with the numerical quantities reduced to ordinary English standards. These documents will, we have no doubt, be sought for by many, who will be glad to find them in this accessible form. The report of the Coal and Corn Committee of the Court of Common Council forms part of the pamphlet. Our own opinion of Liebig's letters, less commendatory than some writers have expressed, is already known. A

*Fraser's Magazine*.  
*Railway News*.  
Day & Son's "First Folio Shakespeare."  
*Giornale dell' Ingegnere*, &c., Milan.

spark of spite unworthy of a philosopher, makes itself visible in them here and there.—“The Present State of the Town Sewage Question,” by G. W. Child, M.D. (Oxford and London: J. H. & J. Parker), formed the substance of a communication made to the Ashmolean Society of Oxford in February last. The author, Dr. Child, is physician to the Radcliffe Infirmary at Oxford. It is not intended to advocate any particular scheme for the utilization of sewage as of universal application, but rather to show the present position of the question in the author's estimation, especially as he would wish it to be viewed in Oxford, where the subject presses urgently for a solution, as it elsewhere does.—No. 2 of “The Shops and Companies of London and the Trades and Manufactures of Great Britain,” edited by Mr. Henry Mayhew, gives one an amusing as well as instructive insight into such matters, and promises a volume of very pleasant reading. The present part treats of the late jewel robberies in the City; the shops of America; Pickford's; the odd shops of London; Searle the boat-builder's; more curiosities of advertising; crinoline; the Hamman or Turkish bath; the percentage evil of West-end trade; the Falcon Glass-works; experiences of a town traveller; the Times Office; advice to young men from the country; and various other subjects.

“Hardwicke's Science Gossip,” for April, seems to be chiefly of interest to naturalists. A small section of it is devoted to window gardens and aquaria.—The Rev. J. G. Wood's “Homes without Hands” has reached Part 16. Parasitic insects of various kinds, including that terrible pest the chigoe, are described in it.—“Let's Monthly Postal Almanac” seems to be a useful penny publication, full of information as to mails, postages, and post hours, inland, colonial, and foreign despatches, and other intelligence of a like order.—And then we get “Meteorological Diagrams for 1864.” Stanford, Charing-Cross. The temperature, rainfall, and atmospheric pressure during each day and night of the past year are given in this very useful diagrammatic map.—“The Popular Science Review for April” contains, as usual, a great variety of interesting matter, including papers on train signalling, by C. V. Walker; extract of meat; physical phenomena of other worlds, by R. Hunt; on the oldest known fossil, and various others; besides the scientific summary of the month and reviews of books.—A volume entitled “The Applications of Geology to the Arts and Manufactures,” by Professor D. T. Ansted, F.R.S. (Hardwicke), consists of the series of Cantor lectures on geology, delivered at the Society of Arts in the session 1864-5. The lectures may be said to be merely sketches in broad outline, as each subject, if entered upon in detail, would demand a separate course of lectures, and one or more volumes to itself; but a great deal of useful and reliable matter is nevertheless embodied in these pages, which treat of such practical subjects as springs and water supply; sands, clays, cements, and artificial stones; stones used in construction; ironstone and coal; and so on.—However, we must get on another tack. In the current *Art Journal* (it has a very good engraving *inter alia* after F. Goodall), Mr. Ruskin continues his papers titled “The Cestus of Aeglia,” eloquent, but, we must take the liberty of saying, to some extent misty. We will quote a piece that is least so. He is speaking of *patience* in art, and the necessity for it:—

“For one instance only; has the reader ever reflected on the patience, and deliberate subtlety, and unostentatious will, involved in the ordinary process of steel engraving; that process, which engravers themselves now with doleful voices deplore the decline, and with sorrowful hearts expect the extinction, after their own days.

By the way, my friends of the field of steel, you need fear nothing of the kind. What there is of mechanical in your work, of habitual and thoughtless, of vulgar or servile—for that, indeed, the time has come; the sun will burn it up for you, very meticulously; but what there is of human liberty and of sanguine life, in finger and fancy, is kindred of the sun, and quite inexhaustible by him. He is the very last of divinities who would wish to extinguish it. With his red right hand, though full of lightning coruscation, he will faithfully and tenderly clasp yours, warm hooded; you will see the vermilion in the flesh shadows all the way; but your hand will not be withered. I tell you (dogmatically, if you like to call it so, knowing it well) a square inch of man's engraving is worth all the photographs that ever were dipped in acid (or left half-washed afterwards, which is saying much), only it must be man's engraving, not machine's engraving. You have founded a school on patience and labour only. That school must soon be extinct. You will have to found one on thought, which is Phœnician in immortality, and fears no fire. Believe me, photography can do against line-engraving just what Madame Tussaud's wax-work can do against sculpture,—that, and no more.”

The Editor in his “Memoirs of Authors” this time sets forth strikingly Theodore Hook, the man with two lives,—brilliant abroad, wretched at home. We heard Hook make his last public speech; heard him say *nearly* his last clever thing; but we have not space now to indulge in the look-back.—The *Art-Student* denies the rumour of its termination; and the number for the month is an agreeable and instructive one.—The *Church Builder* publishes a method of Warming Churches, which should rather be described as a method of burning and vitiating the air about to be used in a church. The fire is made to play on a stack of iron tubes through which the air for the church is conducted. We are not likely to recommend the system.—The current *Fraser* has a brief article on “The Embankment of the Thames,” treating chiefly of the evidence before the Parliamentary Committee of 1860. A paper in it on “British Sea-fish and Fisheries” is more valuable. Many will learn from it, with surprise, the extent of the Scottish pearl fisheries. The fish yielding the British pearl is a species of mussel, rather small than otherwise.—From the *Railway News*, we get a notice of the work that is going on at Clapham Junction, and the preparation there making for a “tarnal smash” one of these days. “A day's traffic,” says the writer,—

“In and out of this Clapham Junction, is represented by nearly seven hundred trains, or a number which would give about one in every two minutes throughout the twenty-four hours. There is no moment of the day, from six in the morning till six at night, when there is not a train actually on one or other of the lines at Clapham; and during a large part of the day the traveller will seldom see the place without three or four trains entering, standing, or leaving the Junction. There are times when this enormous aggregation of traffic is so great that the engines passed through the station, and on an Ascot day the number is nearly as large.”

It is to be hoped the signals are well looked after here; or the smash will not be long delayed.—And what have we under the yellow cover of foolscap size? Parts 7, 8, and 9, of the Sun and Stone printed first folio edition of “Spik-speare,” now past its half, since sixteen parts are to complete it. The last page printed brings us up to the beginning of the 5th act of the Second Part of King Henry the Fourth, and we take from it a pregnant sentence out of the mouth of Falstaff:—“It is certain that either wise bearing or ignorant carriage is caught, as men take diseases, one of another; and therefore, let men take heed of their company.”—And now a publication from Italy, *Giornale dell' Ingegnere*—*Architetto ed Agronomo*, carried on with ability by Signor Raffaele Pareto. The March number contains a full description of the Cathedral of Parma, with a large view of the entrance-front, lithographed from a photograph. Here, however, we must wipe the pen, though not half through the packet.

#### CHURCH BELLS: THEIR ANTIQUITIES AND CONNEXION WITH ARCHITECTURE.\*

BELLS in the Mediæval period, like most other productions of that age, are well deserving of study as works of art. A vast field of beautiful lettering and diapered ornamentation may be gleaned from the helms of East Anglia. I have not made very extensive researches in the northern and western districts of England, but from what I have seen they must yield the palm to Norfolk, Suffolk, and Lincolnshire. The same must be said for the southern counties.

I think we may safely point to Lynn, in Norfolk, for the earliest specimens of these beautiful castings, many of which are, in their way, fully equal to what have come down to us in illuminated MSS. We find the names of Thomas and William de Lynn, of Johannes Godyng de Lynn, of the Wambis and Schep families connected with this art during the fourteenth century, all more or less diffused over East Anglia, and using lettering and stamps and diaper nearly identical. One could heartily wish that more specimens of their work remained, but the custom of augmenting bells for ringing purposes during the eighteenth century in all the larger parishes has made terrible havoc amongst them; the chances of a successful find being now much greater in the inaccessible village bell-cot than in the stately well-newelled tower. The inscriptions on the bells of this period are invariably in single capitals, each capital highly adorned,

the initial ones especially so, with diapered ornament. Often the human figure is combined in various attitudes to suit the shape of the letter, usually in ecclesiastical costume. Many of the initial capitals are besides beautifully crowned. The inscription always begins with a flourished cross, more or less elaborate; and between each word is a stop, usually a *fleur-de-lis*, or sprig of some pattern. The canons are often besides elaborately moulded.

Bells with ornamentation of this particular character are not found in the fifteenth century. Whether the Lynn foundry died out, or whether it was absorbed in, or removed to, Norwich, I have not yet been able to discover. All we know is, that with the fifteenth century arose a very flourishing foundry in Norwich, conducted for some generations by the Brazier family. They seem to have founded largely, as their bells are still very numerous throughout Norfolk. With them came in a totally different kind of ornamentation. Black letter was now used exclusively, and of a very superior character. The capitals were still remarkably beautiful, and, as before, often crowned. A new class of initial cross and stops were also produced. The bells from the Norwich foundry may be readily recognised by the presence of a shield upon their crown. This shield is of three sizes, and somewhat different in detail, on each of them a dual crown between three bells, arranged heraldically. The earliest shield had a simply diapered field. This was afterwards replaced by an ermine ground in two sizes. This foundry was carried on by various hands till nearly the middle of the last century. After the Reformation they made an attempt to return to the characters of the Lynn foundry; but whether they had preserved the original stamps, or had copies made from them, I cannot say. I am inclined, however, to the latter opinion.

Contemporaneously with the Norwich foundry was another at Bury, probably connected with the Abbey. They had a good business in Suffolk and Essex, and a little in Norfolk; their castings, however, are rough and inferior to those of the Norwich foundry. Their bells may be easily recognized by a shield, consisting of a bell pierced by two keys in saltire, a chief with a dual crown between two pairs of arrows compounded from the arms of Bury St. Edmund's, together with a rude representation of some of their tools. This foundry came into great note under Stephen Tonne, towards the end of the sixteenth century, many of the largest and best bells in Essex and Suffolk being of his manufacture. It was afterwards removed to Thetford, in Norfolk, and either died out in the middle of the last century, or was revived again at Downham under Thomas Osborn.

The above foundries were confined to East Anglia, as was also the Sudbury foundry, of some note in the last century. Much information concerning them, particularly during the early period of their existence, has been gathered by Mr. Lestrange, of Norwich, which he hopes shortly to print. The book will be fully illustrated with specimens of the crosses, stamps, and letterings used in the fourteenth and fifteenth centuries. Other ornaments were also common besides the stamps, crosses, and lettering. I have several times met with the Evangelistic symbols used as stops between the words of the inscription; also the various emblems of saints, sometimes figures of the saints themselves, sometimes a rood with attendant figures of SS. Mary and John. On the tenor at Minster, in Thaxet, the inscription begins with a good demi-figure of a priest in eucharistic vestments. Flowers were also largely used as borders. I have met with a beautiful border of daisies on a bell dedicated to St. Margaret.

Leaving East Anglia we find other foundries of early date in other parts of England; but having but scanty information concerning them, I will not detain you upon them. There are, however, certain founder's marks which were used pretty generally over England, for which a home has not yet been found—possibly they were itinerants. In the sixteenth and seventeenth centuries there was hardly a large town in England without its foundry. Many of them turned out beautiful bells so far as sound is concerned, but as works of art there is little to say concerning them. The most celebrated founder in the seventeenth century was Miles Gray. His head-quarters were at Colchester, but he itinerated considerably; the number of his bells yet remaining is marvellous, and not the less remarkable is the exceeding beauty of their tone. There are some twenty or thirty of his tenors yet in

\* By the Rev. John H. Spering. See p. 241, *ante*.

Suffolk, and that at Lavenham, though in no way better than several others, has been often moulded by bell-founders. So great was Gray's reputation that the great bell at St. Nicholas, Newcastle-on-Tyne, called the Mayor's Bell, weighing over two tons, was sent all the way to Colchester to be re-cast by him. Richard Oldfield cast some very fine bells about the same period, or a trifle earlier; his remaining works are but few—only, so far as I am aware of, to be found in Essex and Hert. A kind of lettering was adopted by him in very good imitation of fourteenth century work; his mark was an arrow on a shield between his initials, in chief and quarter, and *fleur-de-lis*. The only other founder of this age that I shall mention is Richard Chandler; of his whereabouts I am uncertain, and I have only seen some dozen of his bells, in Bucks, Hert., and Cambridgeshire, but his tenor bell at Melbourn, near Cambridge, is one of the finest bells in existence for its weight.

The last century saw the extinction of most of the smaller foundries, or rather their absorption into the two great establishments at Gloucester and Whitechapel. The Gloucester foundry had existed for many centuries. John of Gloucester was a bell-founder there in the thirteenth century; but under the Rudhall family it chiefly came into note during the last century, upon the decline of the Salishury trade. Its turn came at last for amalgamation with Whitechapel, which foundry, at the beginning of the present century, may have been said to have been the foundry for England; Market Downham, in Norfolk, the last of the East Anglian foundries, being also sucked into it. There was again a considerable establishment in Reading during the sixteenth and seventeenth centuries: this was removed by the Knights to Southwark, in 1750, or thereabouts; and that again flowed into Whitechapel. At the present time we have three foundries in England: the old-established house of Meares; the Messrs. Warner, of Cripplelegate, who are now getting into a large business in this department; and the Taylors, of Loughton, of whose bells I can also speak very highly, having had several orders executed by them.

So much in a very cursory way for the history of bells and bell-founding in England. I will now push on to the practical part of the subject, with which we are more particularly concerned. With all thanks to our three worthy founders of the present day for what they have done and are doing for us, I will still say, and I know that if any of them read this they will feel that I am only speaking the truth when I say, that the art of bell-founding in the present day is not what it ought to be, or what it might be. I lay very little blame, however, on their shoulders, for I am sorry to say that no art has met with so little encouragement as the art of bell-founding, or has been more crippled by the fatal mistake of expecting great results from very little money. And, believe me, nothing is more easily starved than a church bell. People now expect to get a peal of six for no more than the cost of a proper tenor. Everything in a bell is the quality of the tone; the note is a mere result of certain dimensions, and may, I believe, be reached by metal little thicker than paper. Tone depends on the material, the shape, and the thickness of the metal. Consequently, bell-founders are sorely tempted to do the best they can for very inadequate sums of money, and with a result that pleases no one. And so many a tower is only furnished with the odious ting-tang that might have had a peal had there been reasonable hope of securing the grand and mellow tones of former days.

Again, as to the lettering, stopping, and ornamentation of bells.—Why are these now altogether abandoned? It is true our founders have a black lettering, which can be used if asked for; but something better than any of them have yet is easily attainable; and, when once the moulds are made, a good design costs no more than a bad one. It may be said bells are out of sight, and so what is put on them does not very much matter. I think it does. A bell is a sacred instrument dedicated to the service of God, and religious art may be brought to bear upon it just as rightly as upon other sacred vessels. The fact of its being seen but by few does not appear to me to affect the question; for we have got beyond the notion prevalent some fifty years since, that that only need be decent which meets the eye of man. The same rule applies to the careful selection of dedicatory inscriptions. Now in the nature of the case it cannot be expected that each architect should

provide the bell-founder with designs for the bells of any given church; but I think it should be the care of this Institute to provide each founder with legitimate forms of lettering and stops.

The next suggestion I would offer is this. We either find nothing but our little enemy the ting-tang, or an ambitious scheme for a peal of six or eight, too often realized only in skeleton by the tenor, its third and fifth forming what may be called a hop, skip, and jump style of music, the constant repetition of which is far from pleasing to the ear; and but too often the further development of the peal is unrealized. The Marylebone churches, early in the present century, were furnished with these skeletons of peals of six, and they have hopped, skipped, and jumped for the last forty years without the least sign of filling up their gaps. I am sorry to find they have even had the contrary effect of inducing other steeples to follow in their frolics, for St. Paul's, Knightsbridge; All Saints, Margaret-street; and some others have begun a similar skirmish. Now instead of this unsatisfactory music, why not be content with a really good tenor and one bell next above it? Nothing can be grander than two good bells chiming thus together. Such music is far preferable to three or four light bells at odd intervals. I am, of course, only alluding to those churches where peal-ringing is not contemplated. You are all of you probably familiar with the grand and pleasing effect of the two heaviest of the Abbey bells at Westminster chiming thus together for daily prayer. It is a return to ancient usage, besides being most dignified in itself, and satisfactory to the ear. Then, by degrees, perhaps, a third bell, also in succession, may be obtained. Three such bells would leave nothing to be desired.

The third suggestion I have to make refers only to peals of five bells and upwards. It is that there is no necessity whatever for the universal adoption of the modern major scale, which, for the last half-century or more, has been the undeviating practice. By so doing, the harmonic combinations are very much limited, and many very pleasing scales in the minor mode altogether ignored. Now, minor intervals were great favourites in the sixteenth and seventeenth centuries, from their peculiar plaintiveness and expression. This fact was forced upon my notice some few years since, when in charge of a Suffolk parish. The church tower nearly adjoined the rectory; and the peal of five was a very light one, the tenor only 8 cwt. I was for some weeks puzzled to account for its pleasing effect. Suddenly the fact dawned upon me that it was in the key of A minor. I at once took the hint, and tested the keys of all the peals in the neighbourhood; the result was the discovery of several other examples. I have tried a great many peals of the present century, but I do not yet discovered one in the minor mode. I speak under correction when I say that I do not believe there is one in all England. Now, accepting the major and minor modes as equally legitimate, see what an increase of harmonies we have. Taking D natural as the correct tenor note, and A natural as the highest for any peal, we get eight different keys for our peals; and by flattening the third, to bring them into the minor mode, the number is doubled.

After all, however, we must remember that, so far as bells are concerned, an exact scale, in present received musical expression, is of no moment whatever. So long as a peal of bells is in harmony with itself, and satisfies the ear, it matters not in what key it is, or whether in no describable key whatever. It is a great mistake to tie a founder down to any exact key or scale; it is sure to involve that evil instrument, the tuning-lathe, to reduce them to the appointed standard of pitch; when most probably they were much better when first broken out of the moulds, and even more pleasing to the ear. No bell is ever cast thicker in the sound-bow than it ought to be. The thickness of the sound-bow should be one-thirtieth of diameter; that of the waist, one-thirty-sixth of the diameter of the mouth. Many are cast far below this standard, for economy's sake. When, therefore, the tuning-lathe is brought to bear upon a bell, we may be certain that the tone is being sacrificed to the note; and, if this is bad in modern bells, what shall we say to paring them to the shallow tones of modern additions to the peal? It is, I fully believe, to facilitate this tuning process that the proportion of copper to tin in present use is so much greater than it

ought to be. The modern practice is to make the proportions three parts copper to one of tin. Now, as tin wastes considerably in the fusing, this is far too small. The proportions ought to be in thirds,—two of copper to one of tin. Bell-founders say that such a proportion is liable to render the metal somewhat brittle; and this, coupled with the thinness of the bells in the present generation, greatly increases the risk of a fracture. There is a remedy for this, however: there is no reason why the metal should not be reduced to a state of fusion twice before being allowed to run into the mould. Then, again, in the present day, the melting process is a rapid one in a roaring furnace. In former times it was slower, mostly with timber fires, and cross had opportunity of escape, which now is all fused into the bell.

I need hardly tell you that the prevalent idea of silver entering largely into the composition of ancient bells is a pure myth. So far as sound goes, silver is little better than lead, and would spoil any bell where largely used. The idea has, no doubt, arisen from the much larger quantity of tin formerly used. Mr. Lukis relates in his little work on Wiltshire bells, that when the peal of Great Bedwyn Church was taken down to be re-stocked, the cacons were found to have become white in places where there had been friction, and nothing would persuade the work-people that it was tin, not silver, that they saw. The old bell of St. Laurence Chapel, Warmminster, in which tin had been largely used, was also traditionally said to be rich in silver. When it was re-cast in a field adjoining the chapel in 1657, a good deal of additional silver was thrown in by the inhabitants, as they thought to improve its tone still further. An old foreign bell at St. John's College, Cambridge, from its sweet tone is popularly called the silver bell; this, of course, being a similar delusion. The same may be said of another very pretty bell at Acton, Middlesex, called the Acton Nightingale.

Another great difference between bells, ancient and modern, is in their shape. The most ancient bells were very long in the waist, and high in the shoulder, many of them to an exaggerated degree; we now run into the opposite extreme of short waists and flat shoulders. The reason of this change is obviously connected with the art of ringing, short bells being much easier to raise, and taking up less room than bells of the old proportions. The modern founders are all in favour of this change, asserting that the note is identical in both cases, and that metal lying in the waist is useless. If they would be content with saying that it is a more convenient form, both for the pockets of the customers, the ringers, and their own moulds, I should agree with them; but there is no denying that though the note may be identical, the quality of tone is very different, and this is evident on acoustic principles. The waist of a bell is, so to speak, its sound-board. The scientific view of a bell is that of an elastic instrument composed of an infinite number of rings or circles, varying in tone according to their several dimensions, the sound arising from the vibratory motion of all of them when set in motion by the clapper. A bell properly and truly cast, will give the notes of a common chord more or less blended into one, and major or minor according to its height. This fact is easily ascertainable by striking the bell with the hand, or with a stick, in three different places: the note of the bell will form the base where the clapper strikes, and its third and fifth will be given at certain distances above. This flat bell-founding is, I fear, on the increase, and the lips are now so extended that a section of the bell would almost describe an ogee arch; hence we get the same notes at about half the weight of metal employed by our ancestors. I believe this system was first brought out at Downham, late in the last century. It was certainly adopted with Dobson into the White-chapel foundry, for their earlier bells were of a more pleasing shape. Where money, however, is not a very pressing consideration, we still see the use of earlier and more graceful forms.

As regards weights of tenors, I think some fixed rule should be adopted; for instance, a tenor to a peal, say of ten or twelve in D, should range from 40 cwt. to 50 cwt.; and for a peal of eight, not less than 35 cwt. A tenor in E ought not to carry a peal of more than eight, and should range from 20 cwt. to 35 cwt.; but no one should attempt in E under 20 cwt.; now we sometimes see one as low as 15 cwt. F is the usual tenor for peals of six, and should range from 16 cwt. to 25 cwt.; and G, also available

for six, but better for five, should never be under 13 cwt. No higher note should be allowed for the tenor of any peal; nor should any treble be of a higher note than F natural, all the higher ones being harsh and unpleasant. And as we must not go higher than F, neither need we go lower than D. The tone of very heavy bells in the notes of A, B, and C, may be very grand as a sort of baritone, but they are destitute of a musical effect, besides being impossible to raise for the purpose of ringing. No note is so pleasing to the ear, or so desirable for a tenor as E; even D is inferior to it, though the cost is greatly augmented.

With all care, however, and attention to these suggestions, and others also known only to the bellfounder, another great agency is necessary to perfect one bell. It is a fact, of which there is no gaining, that no bell, be it made ever so carefully and skillfully, sounds so well at first as it does after it has been hung some years. There is an atmospheric effect, a process of oxidation, very gradual, which goes on improving and mellowing the quality of tone as years advance. I have noticed this in several instances, and believe it to be an unvarying process. The colour of a bell changes in a few months: a greenish tint and crust come upon it; and after a long course of years the surface becomes slightly uneven, just as we are accustomed to note the process of de-vegetation in ancient painted glass. I believe it is in this process that the peculiarly quaint tone of the most ancient bells may be attributed.

Having thus pointed out the limits of a peal, I must add a word or two on the origin of change-ringing. As before stated, it was introduced early in the seventeenth century, and led to a complete revolution in the art of the bellfounder as well as of the hanger. From that time all the heavy chimes of three and four and five were reduced in weight, and multiplied in number, forming peals of six, eight, ten, and twelve. Whole wheels were necessitated in place of the old three-quarter arrangements, and often the still simpler one of leverage only. King's College, Cambridge, has the honour of having possessed the first ringing peal of five in the kingdom. According to one tradition they were a present from Pope Calixtus III. to the college; and, according to another, they were taken by Henry V. from some church in France after the battle of Agincourt, and by him presented to the college: possibly the archives of the college may be able to clear up the matter; at any rate, they were only chimed like other bells in that generation, though it is highly probable that they were the first peal on which the art of change-ringing was tried. They were heavy bells, the tenor being as much as 57 cwt.; whereas the tenor of the present famous peal of the University Church in that town is only 30 cwt., or half the weight. These bells were hung in a wooden tower westward of the present chapel, and are alluded to by Mr. Major, the historian, who, writing about 1518, states that whilst he was of Christ's College, he frequently lay in bed to hear the melody of these bells, which were rung early in the morning on festivals; and, being near the river, was heightened by the reverberation of the water. On the taking down of the bell-tower the bells were suffered for many years to remain unused in the ante-chapel, but were sold about the year 1750 to Phelps, the bell-founder of Whitechapel, who melted them down. I suspect their sale had something to do with the erection of some new college buildings.

Peals of eight were hung in a few churches early in the seventeenth century. In 1677 came out the first book on ringing; and soon after the number of peals was increased to ten, and then to twelve. The first peal of twelve was hung in York Minster in 1681, tenor 63 cwt.; Oxford, in Gloucestershire, followed next, then St. Bride's, London, in 1718; St. Martin-in-the-Fields, 1726; St. Michael's, Cornhill, 1728; St. Saviour's, Southwark, 1735.

The honour of the invention of change-ringing is said to belong to a Mr. Benjamin Anable, who died at an advanced age in 1755. His methods were much improved and enlarged by Mr. Holt. These, together with a Mr. Patrick, have produced some of the most celebrated peals.

In conclusion, this lecture has been for the most part but in outline; time has not allowed me to fill in many a detail which I could have wished. My object, however, has been rather to suggest than to satisfy,—to give you the starting-points from which to prosecute your own researches, as opportunity or inclination

may offer; I trust, therefore, it may not fall of so practical effect. Taken as works of art, our bells need a re-infusion of ancient taste; there is no reason why they should not be made as comely in shape and ornamentation as they were in the fourteenth and fifteenth centuries. There is no want of appreciation amongst our bell-founders of the beautiful lettering, stops, and crosses on many a bell which comes to them, alas! only to be melted down. I have been favoured with the loan of a very beautiful volume, belonging to the Messrs. Mears, containing *fac-similes* of many of the best ancient bells that have been sent to them for recasting, and with only some encouragement from the patrons of art, we should see our bells once again such as we might be proud to own; and not only in the matter of decoration, but still more in shape, in composition, and consequently in quality of tone, should we push on for improvement. With the scientific knowledge and applications of the present century we ought even to surpass the bell-founding of previous centuries, though we may learn of them to advantage in many things. We have seen great progress in the minor details of art, both sacred and secular, within the last few years; it has arisen in great measure from carefully tracing its sources and investigating first principles. There is much yet to be learned on the subject of bells, much to be done before we can hope to arrive at the perfection which was attained even three centuries ago, when the following inscription could be honestly written:—

"Me melior vere  
Non est campana sub ere."

#### STREET ARCHITECTURE OF THE OLD TOWN OF EDINBURGH.

IN this paper we purpose noticing some of the distinguishing features or characteristics of the architecture of the Old Town of Edinburgh. No one can have visited the northern metropolis and have failed, as he walked along its noble Princes-street or North Bridge, to be struck by the picturesque effect produced by the lofty range of houses which, crowning the back-bone of the city, as it were, and stretching from the Palace of Holyrood to the Castle Rock, rise to a height of from seven to a dozen stories, and break the sky-line by their crown-stepped gables and high chimney-stalks. Involuntarily he finds himself repeating Sir Walter Scott's enthusiastic apostrophe:—

"The height,  
Where the huge castle holds its state,  
And all the steep slope down,  
Whose ridgy back heaves to the sky,  
Piled deep and massy, close and high,  
Mine own romantic town."

There is a large class of visitors, however, who make no nearer acquaintance with this same Old Town, or are contented with such glimpses as they obtain of it in traversing the bridges on their way to visit the University and the Industrial Museum, or in proceeding from the Council-chambers up the Lawn-market, to view the Scotch regalia which are preserved in the castle. These are lions which must be done; but the tontor but seldom proposes or is requested to guide the stranger to any of the numerous *wynds* or closes which debouch off the main thoroughfares, or to the courts they lead to. Strange apathy! for these were once the abodes of the chivalrons and the fair, of the *ancienne noblesse* of Scotland, of eminent statesmen and dignified ecclesiastics, of the highest ornaments of the bench and bar, of philosophers and poets. The noble families of Gordon, Lauderdale, Hopetoun, Argyll, Sutherland, Moray, Guise, London, Lindores, and others, dwelt in those wynds. There, from that window, did John Knox thunder forth his biting denunciations of Popery; from the balcony of that other, forgetful alike of lady-like dignity and of the forbearance due to a fallen foe, did the newly-married Marchioness of Argyll stand in the midst of her wedding guests, and spit at the gallant Montrose, as he was led into Edinburgh, in humiliation and contumely, to abide his execution. From that staircase, in the Grassmarket, did a determined and resolute mob, not yet a century and a half ago, taking justice into their own hands, hang Porteous, the obnoxious captain of the Old City Guard, from a dyer's pole. Down the Bow there, if you will believe tradition, thundered Satan himself in a carriage, drawn by six headless horses, to pick up for a midnight drive his friend, the infamous Major Weir, who in

1670 had been strangled and buried at the foot of the Calton Hill, on the spot where now stands Lady Glenorchy's church.\* The inn where Dr. Johnson and Boswell lodged, and where the former, as Lord Stowell informs us, got into so violent a passion at the waiter for sweetening his lemonade with his fingers; the house where the author of "Humphrey Clinker" resided; and that other where David Hume first saw the light,—surely those ought to attract the steps of many a pilgrim. What a galaxy of legal talent, too, has dwelt in this Old Town! Sir George Mackenzie, the bloody Lord Advocate, as his detractors termed him; that other Mackenzie, known from his principal work as "the Man of Feeling;" the Earl of Stair (author of the "Institutes"); Lords Fountainhall, Glenleck, Corhouse, Bankton, and Braxfield,—these are but a few of the celebrated juriconsults who were denizens of Auld Reekie. Indisissolubly associated, too, with these old wynds, around which they have thrown a halo of poetry, are Allan Ramsay, Robert Ferguson, Robert Burns, and Sir Walter Scott.

In Sebastian Munster's "Cosmography," published at Basle, in 1550, there occurs this passage in a descriptive notice of Edinburgh:—"From the High-street (*Vicus Regius*), there extend both to the north and south many alleys, all of which are replenished with lofty houses; as is also the Cowgate (*Vicus Vaccarua*), in which dwell the patricians and senators of the city, and in which are the palaces of the magnates of the kingdom, where nothing is humble or rustic, but all is magnificent (*ubi nihil est humile aut rusticum, sed omnia magnificentia*). Hear another witness writing seventy years later—John Taylor, the Water-poet of London, in his "Pennyless Pilgrimage," thus speaks of the Canongate:—"Herein are gentlemen's houses, much finer than the buildings in the High-street, for in the High-street the merchants and tradesmen doe dwell, but the gentlemen's mansions and goodliest houses are obscurely founded in the aforesaid lanes: the walles are 8 or 10 foote thick, exceeding strong; not built for a day, a weeke, a month, or a yeere, but from antiquity to posterity for many ages."

The glory of these old buildings or *lands* has indeed faded. No longer inhabited by the noble and the wealthy, many of them have been abandoned to the very lowest dregs of the population,—a hungry "half-fed, half-sarkit" race of low Irish and Scotch being the tenants. "Decay's effacing fingers" have been busy in earnest,—

"Fire, time, and modern taste, the worst of all,  
Have swept in ruthless zeal across the scene."

Enough, however, still remains to interest the antiquary and the architect.

The different progressive stages of the Old Town architecture are well defined, and afford a good test of the different ages in which each building has been erected, which again can be verified by the numerous armorial bearings, inscriptions, and dates carved upon them, as well as by documentary evidence.

In what may be termed the first stage of the domestic architecture of Edinburgh, or that prior to the commencement of the sixteenth century, the *tenements* or houses of the better class consisted of a substantial ground flat, surmounted by a second story of wood, access to which was obtained by an outside stair. The roofs, which were very highly pitched and pierced by storm-windows, were covered with thatch. Specimens of houses of this period are still to be met with in the Grassmarket, the Cowgate, and the Pleasance; slates, however, having been substituted for the thatch. Sometimes the

\* An' then there's the Major, shir' less winsa ser' him,  
His servitude hauls o'er the Crook o' the Bow,  
Wi' his titte, shir' better folk wuona gaun near him,  
Come thundering at midnight in glaurour a' low;  
The Deil for their coochman's a whup wi' some  
medium.  
As needs manna wha drive wi' Auld Cloddy to lead 'em,  
Hurrying down, stolerin' an' stamblin',  
The glegger ye gaug hetter luck against tumblin'!  
Or bejaye, for a change, just as twal' is a bangin',  
Whir, cool frae the pond, in a whirwind o' flame,  
Dik eloot, wi' a low frae the causey it's a clangin',  
The headless hell-charger gaugs gallopin' hame,  
I'll luck to the loon says gude 'en as he's gangin',  
He were better gaug down the West Tow to his languin'.  
Hurrying down, &c.

† A tenement often contains a number of houses. "Tenement," as a word for house, is used everywhere in Scotland in reference to any species of street building; but *land* from its being so long applied exclusively to the tall houses of the Old Town, which were invariably divided into flats, is only at this day applicable to that description of mansion, and is confined to Edinburgh.—"Introduction to Chambers's Reekians," xvi.

second story projects over the first, and, resting upon wooden beams, forms a kind of piazza. An example of this is to be seen immediately to the east of Baron Grant's Close, in the High-street, although the piazza has been blocked by windows in such a way as to seem at first sight to form a basement story running flush with that above it. Better examples, although of a later date, are the timber-fronted tenement at the Bow-head, and another at the head of the High School Wynd. Merchandise was exposed for sale in these piazzas.

The year 1508 saw the dawn of another stage in the domestic architecture of the capital. In that year King James IV. passed an edict, giving permission to the citizens to extend their houses 7 ft. farther into the street by means of wooden projections. As an inducement, they were allowed to cut down and remove, without any charge, the oak and other timber which then covered the Burgh Muir. The burghers rapidly availed themselves of the privilege thus granted to them; and the result is those grotesque piles of gable-fronted houses with each succeeding story overhanging the one beneath it, which seem to the astonished tourist more likely to topple over than even the leaning Tower of Pisa. Go into the closes, too, and the opposite lands have approached one another so as almost to touch. The denizens of these "timber-fronted lands" may shake hands across the common street without leaving their respective homes to any further extent than putting their arms out at their windows. This style of building continued more or less in vogue until 1677, when, on account of the danger to which the inhabitants were exposed from fire, a law was passed prohibiting the erection of wooden buildiings within the burgh.

Another peculiarity arising from the permission to project the upper flats into the street, consisted in the position of the gates which defended the mouths of the wynds. These having been placed there at the first erection of the buildings, came to occupy a position 7 ft. behind the front of the street. The gates have indeed been removed, but the heavy iron hooks on which they were swung and the gateways still remain.

An outer or fore stair led up to a gallery in the second story in the wooden houses, or to a doorway in those of stone. An instance of the former arrangement may be seen in the house below Baron Grant's Close, already adverted to, and in the Lawmarket, especially noticeable from its having the apse-like LAYS DEO, and the date 1591,\* wrought in antique iron letters and figures on its front, presents an example of a later. Another very common arrangement, though of somewhat later date, was to have the staircase placed in a circular or octagonal tower situated at the back of the building and running up its entire height. Access to the doors of these towers is obtained by an archway communicating with the front of the street. As the door is almost invariably placed at an oblique angle to the passago or archway, it is probable that this was done more for security than convenience of access, the opposite wall preventing the use of a bastering-ram against the door. These staircases are generally well lighted by large square windows, crossed by parallel slips or bars of wood; and the stairs, which are called *tumpikes* in Scotland, ascending in corkscrew fashion round a newel, are broad and of easy ascent. Good examples of this species of staircase tower may be seen by passing through the Old Playhouse Close or Coopers' Entry, both of which are situated on the south side of the Canongate.

Sometimes where the site of the staircase is necessarily cramped by neighbouring buildings, the doorway enters under a boldly corbelled out angle. An excellent example of this may be seen in the first court in Riddle's Close in the Lawmarket. Near John Knox's house there is a curious hanging tumpike stair, supported on corbels, which are formed by the projection of the stone steps on the first floor beyond the wall. There is a very beautiful staircase tower surmounted by a dormer window, which occupies the right angle formed by two buildings on the south side of the Grassmarket, and is corbelled out, so as not to impede the entrance to a close, which, running flush with the wall of the one house, passes underneath the end of the other. Upon

entering any of these staircases, the visitor may possibly discover a square hole in the wall, the purpose of which he is not likely readily to discover. One end of a thick wooden beam used to be slipped into this, and the other resting against the closed door, afforded great security against any attempt made to force it. Sometimes, as in the case with Sir Archibald Acheson's house in the Canongate, the bar was slid into two holes, one at either side of, and behind the, door.

The stone lands are generally very lofty, rising to a height of seven and eight stories towards the street; while, in consequence of the precipitous character of the hill on which they stand, their back façades have as many as ten, eleven, and twelve flats. The gables are ordinarily surmounted by a tall chimney stalk, or stack of chimneys. Sometimes they terminate in a finial, as in the case with one of the gables in the Abbot of Melrose's mansion in Dickson's Close—the finial being in the form of a curious *fleur-de-lis*. A *fleur-de-lis* also crowns the very lofty stone gable of the house second from the Bow-head; and there is a very large and beautiful Scotch thistle surmounting a gable on the south side of the Grassmarket. Most frequently the gables face the street, and their different heights and angles add much to the picturesque appearance of the streets of the Old Town.

Occasionally we find a lofty gable crow-stepped, and terminating in a half chimney-stalk. There is an excellent example of this in Milne's-court, which, irregularly studded with glistening oyster-shells, presents a very picturesque effect, as seen from the Monnd towering over and behind the Free Church College. The stone gables are almost invariably crow-stepped; and the earlier examples present a series of pediments surmounting the steps. An excellent example of these pedimented crow-steps may be seen on the gables of the Cunzie House, or Mint, which stands in the Cowgate, and the principal entrance to which bears the date 1574. A little timber-fronted building in the Candlemaker-row, and at the south-east entrance to the Grassmarket, known as the *Cunzie Nook*, shows a series of lofty French-like crow-steps surmounted by pediments. The pediments are frequently richly decorated. At a later period, when the plain square crow-step was adopted, the lowest of them generally bore the arms or initials of the founder or the date of the erection. In Dickson's Close, a stone tenement, dating from the early part of the sixteenth century, has the Habburton arms sculptured on the lowest crow-step. The monogram I. H. S. occupies the same position on a building in the College-wynd, which at one time was a *collegium sacerdotum* in connexion with the Church of St. Mary-in-the-Fields, and the tailor's device of three balls of thread is similarly situated on their fine old hall in the Cowgate, memorable from the fact of from 200 to 300 of the reformed clergy having met there in 1638, to consider the Covenant before presenting it to the multitude for signature. Several ranges of crow-steps run up the centres of the roofs of the palatial hospital of George Heriot, built in the beginning of the seventeenth century.

The roofs of the sixteenth and seventeenth centuries are often ornamented with cannon-shaped or grotesque gurgoyles, which serve the purpose of gutters. Good examples of the former kind may be seen on an old grim-looking tenement on the south side of the Castle Hill, which belonged to the ducal family of Gordon, and on the fine tower of St. Magdalen's Chapel in the Cowgate; and on the roof of the Abbot of Melrose's mansion, in Dickson's Close, there is a very curious gargoyle of antique form.

Dormer windows, with gablets running into the roof, are very common in houses of the sixteenth and seventeenth centuries. They have generally triangular pediments, more commonly of stone than of wood. The pediment is sometimes crow-stepped—more frequently surmounted by a finial. These finials vary very much in design—the thistle, rose, *fleur-de-lis*, crescent, scallop shell, and Templars' Cross being the more frequent devices. Within the pediment are sometimes found sculptured the arms, initials, or monogram of the original owner, or of himself and wife. On the east wing of the Tailors' Hall there is a pediment over a window, with *fleurs-de-lis* at the two sides and the apex, and a pair of shears, and the date 1621 sculptured within. The pediment of one of the windows of Sir Archibald Acheson, of Glencairney, in the Canongate, contains the initials of himself and wife. In some cases, where the dormer windows are half above and half below the level of the wall,

a bold string-course is carried round their lower halves, and immediately beneath the roof.

In buildings of the time of James VI. and Charles I., the highly-pitched roof has occasionally a second tier of dormer or storm windows, presenting the picturesque appearance of the steep old Flemish roofs. The ancient hostelry in the White Horse Close, the front land through which runs the Playhouse Close, Lord Dirleton's house in the Canongate, the tenement immediately behind the Old Corn Exchange in the Grassmarket, and another in St. Mary's Wynd, are favourable examples of houses with two ranges of dormer windows. A more particular description of the two first-mentioned buildings may interest the reader. The White Horse Close has been said, but on no very reliable authority, to owe its name to Queen Mary's having kept a white palfrey at stables there. It possesses the additional fictitious interest of being the quarters assigned by Sir Walter Scott to Captain Waverley, after he had joined Prince Charles Edward's standard in 1745. The hostelry, to which most antiquaries assign the beginning of the seventeenth century as the period of its erection, presents, when viewed from the north back of the Canongate, an imposing and uniform range of buildings resting upon a series of low-browed arches, now all blocked, with the exception of one which gives entrance to the inner court. The basement story, which is strongly arched, was, according to a very common arrangement in the seventeenth century, fitted up as stables. The gables are crow-stepped, and the roof, which is very steep, has two ranges of dormer windows, nine in the first row and three in the other. Passing under the open archway, the visitor ascends a steep pend, and finds himself in a large open court of an oblong form, where he has an opportunity of examining the south façade, less regular, but perhaps on that account more picturesque than the northern. A broad flight of stone stairs, flanked by substantial sloping walls, leads up to the first landing, and, diverging to the right and left, gives access to two very picturesque wooden porches overhanging the basement story. They are surmounted by triangular pediments, now made to serve as dove-cots. On one of the dormer windows of this front is incised the date 1623, which is probably that of the erection. The court, on the east and west sides of which there are several antique houses with outside stairs, communicates with the Canongate by another archway, which passes underneath an old tenement known as Bishop Paterson's house.

The land, the centre of which is pierced by the Old Playhouse Close, is a substantial four-storied house of polished ashlar, and stands a little back from the other houses in the Canongate. The first row of dormer windows, five in number, have plain triangular stone pediments, crowned by finials representing a thistle, rose, *fleur-de-lis*, shamrock, and star respectively. The windows of the second tier are the same in number, but are considerably smaller, and are surmounted by wooden pediments. I have already taken notice of the staircase tower at the back of the building. Over the entrance to the stair there is an ornamental tablet with a Latin inscription, which is now so much defaced and obscured by white-wash as to be all but illegible. The gables have plain square crow-steps. This house, the lower portion of which is at the present day a tavern, was built in Charles I.'s reign. Nearly opposite it a radiated arrangement of the canopy indicates the original site of St. John's Cross, which now stands against the wall of the Canongate Tol-booth. The spot marks the ancient ecclesiastical boundary of the city. The lion heralds still read the Royal proclamations at this spot.

Many houses belonging to the sixteenth and seventeenth centuries have hartzianed roofs and ornamental copings. The house referred to as standing on the south side of the Castle Hill is thus hartzianed, and another excellent example was lately pulled down to make room for the erection of the new corn exchange in the Grassmarket. Upon these hartzians and the fore-stairs the citizens were wont to assemble to view processions, pageants, and other sights of interest. "A historian of Queen Mary's time tells us, that when that unfortunate lady was brought along the street, after being taken into the keeping of the Confederated lords at Carberry, the women stood on these stairs, and reviled her with vulgar abuse, in reference to her late infamous marriage."\* The fact of the Grass-

\* This land is undoubtedly much older than this date, which it is probable was placed on the ashlar front after removing the wooden front.

\* Introduction to Chambers's "Reekiana," p. xxv.

market having been from Charles II.'s time till 1784 the common place of execution may account for the prevalence of bartizaned roofs on its buildings.

In the better class of the older mansions the windows were divided by stone mullions, and were furnished with leaden casements. Occasionally they were also divided by stone transoms. There is a fine old tenement in Chalmers's Close, reasonably presumed to be the mansion of John de Hope, who came from France in 1537, and was the founder of the noble family of Hopetoun, in which the principal windows have clearly been divided by stone mullions and transoms, and are ornamented with rich mouldings at the sides. In another old building on the west side of Blackfriars Wynd, which has a timber front, there are moulded windows which present traces of having been divided by stone mullions, on the original ashlar *façade*. The same is true of the neatly-moulded windows which adorn an old stone *land* in Baxter's Close in the Lawnmarket, interesting, it may be mentioned, *en passant*, as having been the house in which Burns first lodged in Edinburgh.

Another description of window was divided by a wooden transom, the upper half being glazed and the lower filled in with wooden shutters, often very finely carved on the exterior. Good examples of this kind of window are to be seen on the square turret of the Canizie House in the Cowgate, in Riddle's Close, Lawnmarket, and on a projecting staircase on the north side of the Grassmarket. There are a good many such windows in the older houses in Leith. The shutters are generally made of oak, and the most common ornaments are the *egg and arrow* and the *linen pattern*.

In Baxter's Close, in the Lawnmarket, there is a very curious succession of windows, one above another, divided by such narrow lintels or transoms as to present the strange appearance of one single window from top to bottom of the building. The same peculiarity is observable in Heriot's Hospital, where the segment of an octagonal tower in the south *façade* is lighted through its whole extent by a succession of Gothic windows, filled with stained glass, and separated only by transoms, which thus form one lofty oriel.

Occasionally the window is boldly corbelled out from the wall. There is a beautiful double window corbelled out in this way in an old stone tenement of the early part of the sixteenth century in Dickson's Close; and Heriot's Hospital presents several examples, the most noticeable being over the entrance from the quadrangle to the chapel.

The lintels of the windows not infrequently have carved upon them, in bold relief, armorial bearings, inscriptions, and dates. There is a stone tenement in Baillie Fife's Close with a window on which are carved two stars in chief, and a crescent in base—the family arms of the Trotters—with the initials T. T. and J. M., and the date 1612. Sometimes in the older houses, while the Gothic style was yet predominant, the windows are found ogee-arched. In a projecting staircase on the east side of the College Wynd, there is a window so shaped. It is fitted with the antique oaken transom and oaken shutter beneath.

Pediments are common over windows belonging to the seventeenth century, and frequently contain inscriptions. In the house in Trunk's Close, built by Sir John Scot, of Ancrum, in 1670, there is a window, the pediment of which contains this aphorism:—"Hodie · Mihi · Cras · Tibi," boldly carved in Roman letters. The pediment over one of the windows of the Tailors' Hall has sculptured within its tympanum a pair of shears (the badge of the trade), the date 1621, and this inscription:—"God · Give · The · Blessing · To · The · Tailor · Craft · In · The · Good · Town · Of · Edinburgh." It may be mentioned in this place that Heriot's Hospital, founded in 1628, has no less than two hundred pedimented windows. The pediments are triangular, semicircular, and open in the middle, the design being exactly alike in no two of the whole number.

During the seventeenth century, when the Gothic forms began to give place in Scotland to the unbroken lines of Italian composition, instead of the dormer windows breaking the line of the roof, we find the pedimented window appearing as a panel in the wall face beneath. A very good example of this is to be seen in Aberdon House. Ornamental string-courses, often very irregular, ornament the better class of the old

ashlar-fronted buildings. In houses of the seventeenth century, the eaves string-course is often carried round the windows, giving the latter the appearance of projecting from the wall.

Many of the houses built prior to the Reformation have decorated niches often let into abrupt corners, which doubtless once contained statues of the Holy Virgin and lamps to arrest the attention of the passers by. Over the gateway of the *Collegium Sacerdotum* in the College Wynd, previously adverted to, there originally stood, although it has since been transferred to another part of the building, a highly decorated Gothic niche with an ogee arch, above a lintel, on which is beautifully sculptured this pious wish,—"*Ave Maria, Gratia plena, Dominus tecum.*" Niches are also to be found on buildings of a date later than the establishment of the reformed religion, which were probably occupied by the busts or effigies of the founders or of eminent persons. Over what was the principal entrance to the Canizie House there is an ornamental niche now empty, and beneath it, on the lintel of the door, is the inscription in Roman letters, "Be · Merciful · To · Me · O · God · 1574." The south *façade* of the Morocco Land in the Canongate has a curious effigy of the Emperor of Morocco in Oriental costume occupying a pulpit, which projects from a niche over the second story. This effigy was placed there in the year 1574. On the picturesque old house in the High-street, for long the residence of John Knox, one of the angles has a small effigy of the Reformer occupying a pulpit. His right hand points to a carved stone or tablet, on which is carved the name of the Deity in Greek, Latin, and English.

Ornamental stone tablets, with armorial bearings, devices, and inscriptions, carved upon them are very common, and are to be found on all parts of the exterior, although the most common position is over the principal doorway. The Shoemakers' land, in the Canongate, has a tablet of this kind over the main entrance. It is highly ornamented with *cherubs' heads*, and contains the Shoemakers' arms and the date, 1677, while on the pages of an open book is carved the first verse of the 133rd Psalm. A tablet over the door of a lofty stone tenement in the Cowgate has a sculptured representation of two men carrying a barrel, *sting and ting* fashion,—that is suspended to a pole resting on the shoulder of each.

A great variety of design is observable in the principal doorways. Pointed arches are to be met with, but they are rare. There are many beautiful Gothic doorways, with ogee arches and sculptured tympana, dating chiefly from the beginning of the sixteenth century. In Blair's Close, a turnpike stair, which forms the original main entrance to the whole building (that already mentioned as the residence of the Duke of Gordon), is entered by a handsome Gothic doorway, surmounted by a sculptured tympanum, which, unfortunately, is greatly disfigured by whitewash. The arch is ogee, and in the tympanum are sculptured a coronet, and two deer-hounds as supporters. The Earl of Morton's residence, on the west side of Blackfriars Wynd, has a similar doorway, the tympanum containing a coronet supported by unicorns.

In houses of the sixteenth and seventeenth centuries the doorways are generally square-headed and richly moulded. Their architraves and lintels are in general decorated with sculptured coats of arms, the names and initials of the owners or founders, and inscriptions chiefly of a pious character, others being terse and epigrammatical. On the east side of the Fountain Close there is a highly-ornamental entrance, consisting of two doorways, on each side of which narrow pilasters support the architrave. Above the pilasters are sculptured the words and date, "Vincit Veritas, 1573;" while the architrave bears the names of the proprietor, Adam Fullerton, a zealous friend of the Reformation, and of his wife, and the inscriptions, "Only · Be · Cryst" and "Aryis · O · Lord." On the architrave over the principal door of an ancient mansion in Blackfriars Wynd, there are sculptured a shield with armorial bearings, and the date 1619 above, and a hand beneath, the index finger of which points to these inscriptions:—

"In · To · Domine · Speravi,  
Et · Non · Erubescit · Me ·  
Salus · Eminentibus."

Over the doorway which gives access to the curious hanging turnpike stair in Society's Close, already mentioned, is the following inscription:—

"R.H. Hodie · Mihi · Cras · Tibi · Cur · igitur · Curas."

The date is effaced. Over the entrance to Rae's Close there is sculptured the following beautiful prayer, unfortunately partly concealed by a modern shop-front:—

"Misere Mei Domine; A Peccato, Probo, Debito,  
Et Morte subita, me libera · 1 · 6 · 1 · 8."

Similar inscriptions in Latin and in Scotch, many of the latter being quotations from the Psalms of David, are to be found in great abundance, both on the architraves of the doorways and in the ornamental stone panels which are of so frequent occurrence on the *façades* of houses of the seventeenth century. We shall only add one or two more examples of the "proverbial philosophy" of the period. On the Marquis of Huntley's house occur these two inscriptions:—

"Constanti · Pectori · Res · Mortalium · Umbra;"  
and  
"Ut tu lingue tue, sic ego mear: anrium Magister sum."

The Canongate Tolbooth exhibits the following:

"J · R · 6 · Justitia et Pietas Valde sunt principis arcus."

and this piece of doubtful consolation to those incarcerated within its walls:—

"Sic itur ad astra."

The letters of these inscriptions are sometimes variously coloured, and the coats of arms embazoned, as is the case with the burgh arms upon the Canongate Tolbooth.

It is not easy to understand how so few of the doors themselves remain. They were generally made of oak, and studded with iron nails or knobs. There is a fine oak door, ornamented with fine carving, to be seen in what has been the principal entrance to a large mansion in South Foulis's Close.

The doors of the older houses were furnished with risps or tirling-pins in lieu of knockers. These consist of a notched or rasped iron rod, up and down which the applicant for admission draws an iron ring. The London reader may see a couple of these tirling-pins in the British Museum, and when he visits Edinburgh he will find one on the door of an old tenement in the College Wynd and another in Toddrick's Wynd. A very handsome one was removed, a few years ago, from an old door of the Canizie House. Allusion is made to the risp in this verse of an old Scotch ballad:—

"There came a ghost to Margaret's door  
Why many a grievous groan;  
And aye he tried at the pin,  
But answer made she none."

#### DESTRUCTION OF BUILDINGS BY FIRE.

The reference made in our recent article on the destruction of Saville House,\* to the fact of the great length of time that elapsed before the fire was communicated to the top story, notwithstanding extraordinary fury of the fire in the story next below, led soon afterwards to inquiry into the structural formation of the flooring; which last, we had remarked, could not have been of the ordinary description, or as in the common kind of London house. Upon an investigation of the circumstances by Mr. T. Haxter Lewis, who is surveyor to the Union Insurance Office, and holds a similar position under the committee of the London Fire Brigade, it was found that the flooring between the two stories had been constructed very nearly after the manner, and with the features, to which we alluded as capable of affording a considerable amount of fire-resistance. Mr. Lewis, in writing to us, says,—"There was a good plastered ceiling; and the space between ceiling and floor was filled in, to a considerable extent, with small sea-shells (bivalves); one of which I send you with this. They had been put in loose, and not cemented or concreted together in any way." He also says that the floor-boards were tongued, in great part at least. The shell is a common cockle-shell.

This explanation affords to our mind proof that the value of a plaster-ceiling, well laid, and of the best constructed floor, with pugging, is considerably greater than has been lately estimated, judging from practice, and from the use of the term *fire-proof flooring* for methods of construction which may be inferior,—or rather, probably are so by very much. But, that the entire impression of this should be felt, it would be necessary to have witnessed the fury of the flames to which we alluded. The valuable

\* Page 167, "Saville House: Why was it Burnt?"

lesson to be learned for improved construction of that class of buildings in which fire peculiarly involves danger to life, is that vacancies between timbers, and behind skirtings and similar finishings, should be avoided, and that special attention should be given to the plasterers' work, as well as to strength of joists.

In the article mentioned, we referred also to the necessity for greater attention than seemed to be given to the gas arrangements in many buildings. On the occasion of the inquest on the fire of Covent Garden Theatre, we remember that Mr. Braidwood mentioned some important facts as to the danger from gaslights placed at what might seem to be a sufficient distance below woodwork. It would be well that the results of any experience on this subject were now published. The recent destruction of theatres may be due to this cause, operating after long continuance of the desecration which buildings of this kind undergo nightly.

It seems that there is considerable misunderstanding as to the circumstances under which destruction of a building by fire may be due to an explosion of gas. Explosion does not occur except there be a mixture of the gas and air; and it will not occur if the air or the gas be greatly in excess, one of the other. The gases generated during an explosion of coal-gas (the gas of gas-lighting), and on or during combustion of the gas, are not only not capable in themselves of burning, but would if present to any large extent, extinguish fire. This is taken advantage of in the principle of Phillips's Fire Annihilator. But there is flame when a mixture of the gas and air is exploded; and such flame may ignite inflammable material with which it comes in contact. It would probably ignite any gas escaping from a pipe. Should the escape have been taking place near to any easily-combustible object, we may imagine how the latter might be set fire to; or, we may see how the same result could occur from the flame of the explosion merely.

#### THE ALBERT BRIDGE: FROM CHELSEA TO BATTERSEA.

In forming an opinion as to the relative merits of the systems of engineering practised in our own and in earlier times, there is at hand, perhaps, no readier means of enabling us to effect a comparison of this kind than by bringing into view the various styles and methods employed in the construction of bridges.

Dating from the times of the erection of the old and unsightly wooden structures, of which Battersea and Putney bridges yet remain as examples, we have, in the successive undertakings of this character, a sort of permanent record of the progress made in static science. Nor is it unimportant, perhaps, to observe along this pathway of architectural study which these numerous structures may be said to form, those points where art and science seem more to have approached one another, until at last, following up this observation to our own time, we may soon hope to see them blending, as it were, into the mass and design of the structure itself with such harmony that their points of contact will altogether disappear.

The most striking departure from any recognised model in the construction of bridges is more strongly suggested, perhaps, at that period when their openings or spans began to diminish in number and consequently to increase in size, thus requiring a smaller number of piers or supports. Prior to this time, the weight of such structures was upheld with a safety apparently proportionate to the number of openings of which they were formed, so that their foundations were not very wide apart. But this modification in the length of span gradually prepared the way for the introduction of the suspension system, which had for its object the removal of all the intermediate piers between those nearest the shore at either side; and it was considered at one time as likely to become extensively employed in practical engineering.

The application of some such means for effecting communication between the opposite shores of rivers, as well as in cases where shorter junctions were required, had for a long time occupied the attention of scientific engineers. The experiments carried out by Stephenson as to the erection of the tubular bridge between Anglesey and Carnarvonshire, were, upon these grounds, followed up with much interest. The incautious use of iron for purposes of this kind then began to be discussed abroad, and perhaps

somewhat opportunely, as an opinion seemed to have taken a pretty general hold that there were few laws or limits to its application. The conclusions therefore arrived at, at this time, marked an important era in constructive science.

The suspension system underwent innumerable and severe trials, and it resulted in the proof of its unfitness for structures of this class, where they were required of unusual magnitude, or to support heavy loads; although it was adopted upon a lesser scale, and where a comparatively small moving load, at slow speed, had to be sustained.

In the course of his experiments, it does not seem to have been largely considered by Stephenson or by Brunel, who sought to render it popular and useful, that the principle of suspension itself was amenable to modification and improvement. Owing to various and successive attempts brought to bear in this direction since their time, we now begin to see most of the more serious objections to its extended use disappearing one by one.

Some idea of its utility may be inferred from the fact, that notwithstanding the many drawbacks which had hitherto excluded it in so large a measure from the attention of the practical engineer, it, nevertheless, was attempted to be employed,—in many cases with great want of judgment, and in some, not without absolute danger. It had much in its favour, always on account of its comparative economy with the systems it was intended to supersede, but it could not easily escape being considered untrustworthy wherever a firm structure was required. Its cheapness alone, however, formed a recommendation which led to its being subjected to numerous trials; for at the time when it was first sought to be introduced, the cost of the construction of bridges was very great. London Bridge, for instance, which was begun in 1824, and finished in 1831, designed and built by Rennie, of granite, cost, with approaches, not less than 2,566,268*l.*; and Southwark Bridge, chiefly constructed of iron, was erected by the same engineer, at a cost of 660,000*l.* The approximate cost of the first suspension-bridge over the Thames, that erected by Brunel at Hungerford, was 90,000*l.*; the approaches, in this case, being of course less than in the others already named; but however great the saving in this as compared with the cost of other bridges, it still wanted that essential feature which could alone bring it into general use, by reconciling the public to freely adopt it. So great was the fear to employ this bridge for any other purpose besides passenger traffic, on account of its excessive oscillation, that while in London it seldom went by the name of the locality in which it was placed, as the other bridges along the Thames commonly do; but, up to the time of its removal, it was almost invariably known by the principle employed in its construction, which never failed to be associated with a certain sense of danger.

This feeling was no doubt exaggerated from the novelty of the thing, though from some points of view it was justified and acknowledged to be not altogether without foundation.

For some purposes such a class of structure was evidently impracticable; and, where anything beyond passenger and ordinary vehicle traffic had to be provided for, it was seldom employed. The suspension system accordingly appeared to have sunk into disuse, as compared with what was expected of it, only a limited number of structures of the kind came to be erected.

The Albert Bridge, which, perhaps before this, we should have stated, is designed by Mr. Rowland Mason Ordish, of the firm of Ordish & Le Feuvre, engineers to the Amsterdam and Dublin Exhibitions, does not appear to resemble in its construction the ordinary and generally-known structures of its class. Its chief distinction, however, seems only to be, that it is secured from oscillation, or movement, it being virtually rigid in those parts which are moveable in the suspension-bridges already in use.

The want of stability formed, as is, perhaps, well known, one of the great difficulties, apparently, to overcome with regard to this class of structure.

The Albert Bridge is intended to be so constructed that it will support moving and stationary loads with a safety equalling that of any of the bridges at present used for purposes of railway traffic over the Thames; while it is said to be more adapted for this purpose where wider spans have to be bridged over, so that it is capable of being used where other structures

could not be erected with facility for purposes of railway accommodation.

The Albert Bridge will be erected over the Thames uniting Oakley-street, Chelsea, to the Albert-road, Battersea Park; and has already been commenced at the Albert-road abutment.

We give a general view of the intended bridge. The piers, as shown on the opposite page, will be formed of cast-iron cylinders filled in with concrete and masonry. The diameter of the cylinders above high-water is 16 ft., and beneath the bed of the river 22 ft. On the tops of the cylinders a series of ornamental cast-iron brackets are arranged, forming, as it were, a sort of capital to the cylinders, and supporting the footway where it is necessary for it to pass round the base of the towers without interfering with the uniform width of the roadway. The two columns forming each tower are connected at the top by an ornamental lattice girder, under which an arch is formed of ornamental cast-iron spandrels, which terminate about half-way down the length of the columns at either side. The engraving at top of page shows where the Catenarian chain is suspended at the extreme height of the towers, and immediately beneath the portion which incloses the saddles of the main chains. The engraving at the bottom shows the anchorage of the main chains and general outline of the abutments. The other details explain themselves. The bridge will have three spans, the middle one being 453 ft. 6 in., and the side openings each 152 ft. 3 in., which, with the diameters of the piers, will bring the total length of the bridge, exclusive of the length of the abutments, to 790 ft. The width of the bridge will be 40 ft., forming a roadway of 26 ft. 6 in., and two footpaths, each 6 ft. 9 in. wide. The platform will be supported by iron chains, extending in straight lines from the abutments to the tops of the towers, and thence to the required points of the roadway, forming a series of hold triangles with the longitudinal girders and towers. The main chains will be kept straight by means of an auxiliary curved chain suspended above them along their entire length. This is permitted to slacken until it assumes a deflection corresponding with the inclination of the main chains to the roadway, and then, when "set," vertical tie-rods will connect it to the main chains.

As the Catenarian chain acquires its maximum deflection where the major angles intersect, the rods which unite it to the main chains do not reach any undue length.

Thus there is apparently altogether attained a reciprocal or combined rigidity, as far as this word may be used with reference to structures of the kind, between the ties, the Catenarian, and the main chains,—a combination which is, perhaps, worthy of being regarded as a very interesting result of science as applied to modern engineering.

The Albert Bridge appears to possess many new features as compared with existing bridges. For instance, whereas in Chelsea and Hammer-smith bridges a girder runs at either side along the entire length of the roadway dividing the carriage-way from the footways, and separating the width of the bridge into three comparatively narrow channels in the Albert Bridge, both these are done away with. In most of the suspension-bridges at present erected, also, the roadway, where it passes through the uprights forming the towers, becomes contracted, and afterwards enlarges to its original width again. This, also, is obviated in the Albert Bridge, the roadway of which remains the same right throughout until it enters upon or blends with the approaches at either side, where it assumes their width.

The introduction of this modification of the principle of suspension structures will probably form a new starting-point in some of the wider paths of practical engineering.

It is already introduced on the Continent; a bridge similar in construction to the one from which our illustrations are taken, being likely soon to be commenced over the Moldau at Prague, by the well-known Austrian contractors Messrs. Klein, Brothers.

FALL OF A NEW PIER.—On Sunday last a new pier in course of construction at New Brighton, Cheshire, gave way, and upwards of forty people were precipitated on to the shore. Fortunately the tide was out, and beyond the shock caused by the fall, no person was severely injured.

ALBERT BRIDGE, ON THE THAMES. DETAILS.

VIEW OF PROPOSED ALBERT BRIDGE, TO CROSS THE THAMES FROM GREENWICH TO BATTERSEA.—Messrs. OUBIN & DE FONVILLÉ, ENGINEERS.

J. H. B. 1865

## A REGULATING THERMOMETER.

A THERMOMETER that will control the temperature of the surrounding medium and maintain it at any required degree of heat must be invaluable for hospitals, greenhouses, laboratories, for the hatching of eggs, silkworms, and for any case in which a uniformity of heat is necessary. A new instrument, invented by M. Jules Maistre, has perfectly succeeded in accomplishing this object, and it is thus described. A mercurial thermometer is provided with two pieces of platinum wire, one dipping into the mercury in the bulb, and another entering a certain distance into the stem. These wires are connected with the poles of a galvanic battery, so that when by the application of heat the dilation of the mercury causes it to touch the upper wire the electric circuit will be complete. The valve by which heated air is admitted to an apartment is made to open and shut by means of a lever attached to an electro-magnet, also in communication with the wires of the thermometer. Supposing that it is required to admit a supply of hot air so as to maintain a temperature not exceeding 86°, the upper platinum wire is let down as far as the given degree and the tube closed hermetically. When the expansion of the mercury has reached 86° the circuit is rendered complete, and the electro-magnet raising the lever shuts the valve for admitting the heated air. On the temperature falling below 86° the current is intercepted again by the mercury retreating, the lever falls, and the valve admits more hot air.

This apparatus can be usefully applied to some cases not mentioned by the inventor. The thermometer may be readily connected with an alarm-bell, or series of alarm-bells, in the event of undue heat taking place, or spontaneous combustion, or accident from fire occurring in any dwelling-house, shop, warehouse, store, or in the hold of a ship.

## A NOTE ON THE PRESERVATION OF BRITISH ANTIQUITIES.

To many persons the opportunity of showing to others rare works of art, antique rarities, or places of picturesque beauty, noted for historical and other associations, is a source of even more pleasure than the possession of them. The spirit is commendable, and this good disposition has, doubtless, led to the advance of antiquarian knowledge, and to the improvement of artistic taste. It is, therefore, very desirable to afford every encouragement to those who have a desire in this way to please and benefit the public.

In many instances the keeping up of extensive ruins is a cause not only of considerable expense, but also of anxiety and trouble. There are fitting custodians to be provided, and regulations made for the admission of those who may feel interested. Care must be taken that no damage shall be committed by thoughtless persons to objects of old date and curiosity, which, if destroyed, could not be again replaced; and it is the case with some who have possession of valuable antiquities, that while they have no objection, under certain restrictions, to admit visitors, they do not desire to incur expenses to any large extent. The fees for admission to view parts of Westminster Abbey, St. Paul's Cathedral, and many of our other cathedrals and churches throughout the country, have long been, and still continue to be, a cause of anger and vexation; but then the deans and chapters of the metropolitan cathedrals, and those in charge of some other important ecclesiastical structures, will say that a want of pecuniary means for safely exhibiting those holdings, forces them to resort to a charge of so much a head for admission.

In the course of long and varied pilgrimages in most parts of Great Britain, we have in mansions stored with the choicest objects of interest, met with impediments and sources of annoyance, which were as vexations to the visitor as we believe the account of them would be to the proprietors. Feeling the wrong and inconvenience of leaving picture galleries and collections in the charge of avaricious, and too often ignorant housekeepers, several of the nobility and others have devised plans of admission by means of tickets, which can be easily obtained from the shopkeepers of the metropolis and the provincial towns. In some instances a charge varying from 1s. is made, and in certain cases the proceeds are devoted to

the assistance of some charitable or useful institution.

The main points to be considered in connexion with this subject are, to make scenes of interest as accessible to the public as can be done without interfering too much with the convenience of the proprietors or risking the safety of the treasures which have been collected. In all religious institutions there should, whenever it is possible, be free admission. All ruins and other vestiges of antiquity which are in the possession of the Government should be placed in the charge of competent persons.

The remains of many extensive fabrics, of rare and picturesque beauty, have been allowed to fall into entire wreck in consequence of the want of a little timely care. Under peculiar circumstances this might be afforded by the Government, especially when the ruins have a historic interest. In some cases help might, at a small outlay, be afforded by a local rate. There may be some difference of opinion on this point; but we think there will be none respecting the following arrangements, which have been a chief means of inducing us to make the preceding observations. They are reported in the Newport paper, and are to the effect that the Assessment Committee of the County of Monmouth have rated the ruins of Raglan Castle, as "a beneficial residence," at 40*l.* a year! The Duke of Beaufort has consequently closed the Castle to the public, thereby depriving tourists of a sight of one of the most interesting scenes in the country, and inflicting a severe loss upon the trade-people of the neighbourhood.

Many who read the account of this wrong step will hope that it may be speedily retraced, and that the strong opinions which have been expressed on the subject may prevent the example being followed in other directions.

## THE POLAR LAND AND THE HYPERBOREANS.

YOUR ingenious correspondent, Mr. Dove<sup>1</sup> seems to have been misled by his love of mythology in suggesting that the mythical Hyperboreans had their dwelling in a polar sea-girt land, beyond the icy barrier of the north, and "beyond the cold north wind." He quotes the account given in Smith's "Geographical Dictionary," and says,—"It is with allusion to the mythical Hyperborei that the Arimaspi are spoken of, who steal the gold from the Griffins, whatever that may mean, and who live in a country where men sleep half the year, and the air is filled with feathers!" [snow].

Now, notwithstanding the story of the Arimaspi has no more to do with the north pole than with the equator, it is worth looking at, although the pages of the *Builder* are hardly appropriate for its discussion; unless, indeed, for the statement that this mysterious nation built temples, in the top of which was preserved the sacred fire. My object in writing this letter is to point out that a theory which would connect the Hyperboreans, of whom the ancients had heard, with those, of whom the ancients had heard, is untenable, and merely fanciful; and to remind your correspondent that the Hyperboreans, the Arimaspians, and the Scythians are represented as contiguous nations, between whom and the people of the Isle of Delos there was frequent communication.

Herodotus (book iv. 13) mentions that Aristæus, the poet, came to a people called the Issedones, beyond whom he found the Arimaspi, a nation who have but one eye; further on were the Gryphins, the guardians of the gold; and beyond these, the Hyperboreans, who possess the whole country quite to the sea. It would appear that Aristæus (if there ever was such a person) had given this account in a fragment known as the Arimaspians Verse, and that the Arimaspi had been made known in Greece by this Aristæus. Elsewhere (book iv. 27) Herodotus says:—"The Issedones" (whom he had previously described as a remote Scythian nation occupying the northern part of the tract now in possession of the Eastern horde of the Kirghis) "themselves affirm that the country beyond them is inhabited by a race of men who have but one eye, and by Gryphins, who are guardians of the gold. Such" (adds Herodotus) "is the information which the Scythians have from the Issedones, and from the Scythians; in the Scythian tongue they are called Arimaspians, from *Arimas*, the Scythian word for *one*, and *spes*, an eye." And (in section 32) he continues:

"Of the Hyperboreans, neither the Scythians nor any of the neighbouring people,—the Issedones alone excepted,—have any knowledge."

It is not surprising, therefore, that fables should have been invented about the Arimaspi and the Griffins. "It is affirmed," says Herodotus (book iii. 116), "that the Arimaspi take this gold" (he is speaking of the gold found in the North-western regions of Asia) "away violently from the Gryphins." The same fable is related by Pliny (Nat. Hist., lib. vii. c. 2); and Eschylus says:—

"Thus the Gryphins,

Those dumb and ravenous dogs of Jove, avoid  
The Arimaspians troops, whose frowning foreheads  
Gleam with one blinding eye; along the banks  
Where Pluto rolls his streams of gold, they rein  
Their foaming steeds."

In many places the sands of the Scythian river Arimaspi are said to have been golden. And the dwellers on its banks are mentioned by Lucan as a people who ornamented their hair with gold.

"Auroque ligatus  
Substringens Arimaspe comas."

The Gryphins are fabled to be monsters resembling lions, with the wings and beaks of eagles. They appear to have been of Egyptian invention; the Scythians, it is to be remembered, are supposed to have been of Babylonian origin. Possibly the powers of nature with which the Arimaspi had to contend in order to obtain the gold were thus personified.

The Arimaspians were fire-worshippers, and *charis*, the name of their temples, is a suggestive word, as the reader may see in Miller's "Science of Language," vol. ii., p. 371. By the poets of the Veda, the *Havis*, "the Bright ones" were fabled to be horses of the sun and the dawn; they had come to be yoked to the car of the dawn. In one passage, they are represented with beautiful wings. In the Greek mythology (which, like Sanskrit, is but another dialect of the common Aryan mythology), the name appears under the form *Charis* and *Charites*, retaining its etymological meaning of the lustrous brightness, or the dawn.

Can the dwellers in the Arimaspias have derived the attribute of Cyclopean monstrosity from wearing in warfare a frontlet or helmet with a golden star?

As to the Hyperboreans, it is well known that the ancients do not appear to have had any precise ideas as to the country they inhabited. According to the Scholiast on Pindar, the Greeks called even the Thracians Boreans; they may well, therefore, have called the people beyond them Hyperboreans. But this is not a fitting place to discuss the subject. W. S. G.

Having shown these observations to Mr. Dove, we append his reply:—

The title of "W. S. G.'s" very courteous but not very correct letter, lies not in the main body of it, which, as he puts it, is rather irrelevant; but chiefly in the last paragraph, to which, therefore, I shall first advert, by simply asking him what country north of Thrace, south of polar land, could be said to be "beyond boreas or the cold north wind," as is said of that of the true Hyperboreans (Smith's Geog. Dic.), who lived "betwixt the sun and the shade," where "the sun was said to rise and set to them but once a year" (Lemprière); a country, moreover, which lay still further north than another (the Arimaspians), "where the men sleep half the year, and the air is filled with feathers," and which, therefore, does seem to have, itself, something less to do with the equator than with the pole, notwithstanding what "W. S. G." thinks to the contrary. These ideas as to the Hyperboreans, be it here noted, are not mine, as "W. S. G." incorrectly asserts; and no man's love of mythology could have induced me to suggest them as my own. By quoting them I purposely disclaimed them by inference, and they all the more enforced my argument of that account. They are no other, in fact, than the ideas long and popularly entertained by probably one and all of the best modern authorities, who have had no special theory such as mine to support; and who merely based their idea of the Hyperboreans fairly and unbiassedly on the fragmentary allusions of the ancients,—allusions which induced even the lesser ancients (if I may so call them), such as Virgil, to place the Hyperboreans under the north pole, where the Hindus also placed the "stronghold of the gods," and where alone such a country as is described either could or can exist.

As for those looser expressions of the ancient Greeks whereby they indicated merely unknown

countries to the north of Thrace, I am quite well aware that such expressions were also in use, and they are carefully contradistinguished by the authorities from those which can only refer to a polar land as the true land of the Hyperboreans. Thus one author (Macbean), after alluding to the Hyperborean mountainous land as being "almost under the pole," goes on to speak of the "Hyperborei, the people the inhabitants of Scythia, in a looser sense (Strabo) and, in a looser still, those to the north of the Euxine, the Ister, and the Adriatic." Others, such as Lemprère, make a similar distinction.

Without going into the question, therefore, as to what the various ancient writers themselves, either directly or indirectly, did say of the Hyperboreans in a stricter sense, which cannot be properly done in the *Builder*, it is quite clear that such are these various allusions that our modern authorities have been thereby led to place the long-lived Hyperborean men-gods, or perfected men, in a polar land, beyond the cold north wind, with a mild and equable climate, an open sea, and a sun which rose and set to them but once a year—in short, in just such a land as the polar must be, according to our most advanced modern ideas.

That these Hyperboreans may have had regular communication, through intervening countries, with the sacred and Apollo-hearing Delos, where, as with the Hyperboreans and the "deathless" and Apollo-worshipping Druids, disease and death were (theoretically) unknown, is quite possible, although the latter part of "W. S. G.'s" own quotation from Herodotus is scarcely consistent with that idea; but it was said of the Hyperboreans that, "whenever they made offerings, they always sent them towards the south, and the people of Dodona were the first of the Greeks who received them." That a polar people could do so was perfectly possible without much navigation, if the warm gulf stream really produces an open sea within the ice-bound stronghold of the arctic region; for that stream, running northwards, and carrying with it the rotary movement of the earth from west to east, into slower regions, naturally and inevitably takes a north-eastward course, between Spitzbergen and Nova Zembla; and the same possibility which enables our own vessels now-a-days to carry on traffic occasionally with Archangel, in the White Sea, might enable the Hyperboreans to reach that sea, where the ancient Arimaphi resided; to the east of which were their neighbours the Ripheci of the Ural (gold-bearing) mountains; and from either of whom, to the Issedones of Scythia, or the Balk district, was but a very short journey. To Greece they might have had a much shorter route at one time than this would have been.

What "W. S. G." says, therefore, of the Issedones, even apart from all he says of the more northern Arimaphi, and Giphians, only seems to strengthen the probabilities in favour of the idea that the ancient allusions to the Hyperboreans were not mere mythical fancies, as I myself have said they might be.

The Issedones inhabited a district which is believed to have been the most anciently inhabited, by mankind, in all Asia. It lies north of the Hindoo Koosh and the Bolor mountains; the latter, as it were, of the great plateaux of Tibet and of Iran or Persia; and it is from some such source that even the Chinese and the Hindus traditionally trace their origin. Indeed, it was from the fire-worshipping biglanders of Upper Asia that the Aryan and other emigrations of antiquity probably originally emanated. A little to the north-west of the Issedones were the *Aspisii* mountains of antiquity, and a little further north were the *Arimaphi* of the White Sea and the Polar Circle, already alluded to; either of these, or both, may have been the *Arimaphi* of Hyper-Scythia, "where the men kept half the year, and the air was filled with feathers;" and adjoining both were the *Giphians* of the Ural mountains, which run north and south like a continuation from Nova Zembla to the Polar Ocean; these *Ripheci* were probably the *Giphians* who guarded the (Ural) gold, which the Arimaphi stole from them; their lineage and angle qualifications being perhaps metaphorical; and the name of the *Finnis* may be a remnant of the same local name.

Thus even the association of the names of the countries of the Issedones and the more northern Arimaphi and Giphians, with that of the Hyperboreans of the still remoter north, only point all the more distinctly and clearly to the north pole as

the true and only possible Hyperborean region, to which these other countries south of it were the most direct route of the initiated from the most ancient heart of the old world of civilized humanity, and the shortest and best possible sea route, viz the White Sea and the gulf-stream as it flows north eastward, between Nova Zembla and Spitzbergen.

That even the longer route to the "deathless" Hyperborean men-gods by the gulf-stream viz the British Isles may have also been known at some former time, not only to that "deathless brotherhood," the Druidical "twice-born" men-gods, or godly men, but to kindred continental initiates, or co-religionists, who regarded these Apollo-worshipping Druidical magi, as they did the priests of Delos, with great veneration, would seem to be indicated by the ancient idea that the British or Irish Isles also had something to do with the Hyperboreans.

Before concluding, I would wish to remark that from a fuller report than I at first had of the meeting of the Geographical Society at which Dr. Petermann's letter was read, it appears that his present idea can scarcely be identified with mine, inasmuch as he does not propose the arctic voyagers to follow the route of the gulf-stream north-eastward between Spitzbergen and Nova Zembla, but to go on once to the north of Spitzbergen, and hence out of the direct course of that stream, north-eastward.

MASONIC MUSINGS.

THE CRAFTSMEN-ARCHITECTS OF ROME.

"A ROMAN legion was always accompanied by builders, sculptors, painters, and other artists and workmen, and it has been observed the marks of their footsteps are visible wherever they trod, and that a map of the Roman roads in Britain alone is a magnificent monument of their greatness."

Traced on sculptured frieze and panel,  
Testimonies still outlast  
Of those minds who grooved a channel  
For the record of their art.  
Enraptured skill in curve and conic,  
In every maze it seem'd at home,  
With those grand and old Masonic  
Craftsmen-Architects of Rome.

How they plant'd and how they ponder'd,  
Are the themes we read to-day;  
How they wrought, and where they wander'd,  
Which old legion led the way.

In the Doric and Ionic  
Column, arch, or duct, or dome,  
Live those grand and old Masonic  
Craftsmen-Architects of Rome.

First to span with pier and centre,  
Dron the keystone, dress, to groin,  
Sound and sink, explore and enter  
Tunnel, pile, embank, and groin,  
Human love of labour chronic,  
Forming one great epic poem  
Of those grand and great Masonic  
Craftsmen-Architects of Rome.

In their contact with the Briton,  
Whom they conquer'd, whom they taught,  
Much of what is still unwritten,  
In each wide domain they wrought;  
Genius glowing, souls harmonious,  
Exiled artists from their home,  
Told'd those roving old Masonic  
Craftsmen-Architects of Rome.

Vandal might and despot malice  
Wreak'd their fury all in vain;  
Brilliant wreck of shrine and palace  
Deck the city still, and plain,  
Homes and haunts, and halls baroniac,  
Archives fill'd with many a tome  
Of those glorious old Masonic  
Craftsmen-Architects of Rome.

Gone the sunshine, dried the river,  
Genius gushes forth in pain;  
Man ignores the primal Giver,  
Dies atheist in soul and brain;  
Gone, those brave and bright laconic  
Workmen, to their kindred home;  
Gone, the great and grand Masonic  
Craftsmen-Architects of Rome.

CLAYTON HOPE.

THE PRESIDENCY OF THE INSTITUTE.

SIR,—In the *Builder* of the 8th inst., I observe that you do me the honour to say that I am one of those who have been named in reference to the Presidency of the Institute. As whatever tends to simplify a complication aids in the solution of it, I hasten to assure any member whose friendly feelings may induce him to contemplate nominating me, that my failing strength compels me to forego all hope of that high honour; and that, therefore, a vote in my favour could not possibly be productive of any good result.

STONEY SMIRKE.

OPENING OF A NEW FERRY AT LIVERPOOL.

THE want of a direct ferry between the south end of Liverpool and the Cheshire side of the Mersey has long been felt and complained of, and this cause of complaint has been at last removed, the works having been completed, and the ferry formally opened. On the Liverpool side the permanent structure consists of a floating-landing-stage, which measures 120 ft. in length by 30 ft. in breadth, and moored in the river, near the Harrington Dock wall, with which it is connected by a wrought-iron bridge, of 150 ft. in length, and which weighs about 60 tons. The stage, which floats on a wrought-iron pontoon, was constructed by Messrs. Bowdler, Cbaffers, & Co., iron shipbuilders, Seacombe. The bridge was made by Messrs. H. Grayson & Son, from designs by and under the superintendence of Mr. D. Henson, engineer. The pier on the Cheshire side of the Mersey, at New Ferry, has been constructed from the designs of Mr. J. Brunlees, of Westminster, as we have recorded in a former notice of this ferry. The piers now about to be erected at New Brighton and Rhyl are also from designs by the same engineer. The New Ferry Pier commences from the land end with three rows of wrought-iron lattice-girders, 60 ft. in length, and 4 ft. 6 in. in depth, supported by cast-iron columns, 12 in. external diameter, braced with angle irons, the platform, of 4-in. planking, being laid on the bottom flange of the girders. A centre girder divides the whole width of the roadway into two, each of which is 9 ft. wide. The pier proper is 550 ft. in length, consisting of fourteen bays or spans, each 60 ft. in length; at the end of this is a cluster of piles to form a steady point of attachment for the top of the movable bridge, the end of which is connected with a floating pontoon. The bridge itself is 158 ft. long, and 9 ft. wide. The pontoon forming the landing-stage is 100 ft. long, and 22 ft. wide. This fabric was erected by Messrs. William Galloway & Sons, of Manchester, under the management of Mr. H. Hooper, who, as resident engineer, superintended and carried out the work. The pier and its landing-stage have been erected at the expense of Mr. R. A. Macfie.

THE ARCHITECTURAL ASSOCIATION.

THE usual meeting of members was held on Friday evening, the 31st ult., at the House in Conduit-street.

The chair was occupied by the president, Mr. J. H. Christian.

Mr. James Throppe, 4, Stockport-terrace, Holloway, and Mr. Thomas Ray, 16, Thayer-street, Manchester-square, were elected members of the Association.

Mr. J. D. Mathews (hon. secretary) announced that it was intended to resume the visits of inspection to interesting metropolitan buildings, and that Mr. Edward Barry had kindly consented to accompany the members over the new Hotel at the South-Eastern Railway Terminus at Charing Cross, which was now so near completion as to admit of full examination. Members were, therefore, requested to assemble on Saturday afternoon, the 8th inst., at three o'clock, in the first-class waiting-room of the railway-station adjoining.

With reference to the paper read on a previous evening, on "Limes and Cements," a wish was expressed, as some of the writer's views were questioned, that he would attend some evening which might be appointed for the discussion of it.

The Chairman said he thought that, in the absence of Mr. Wehler, it would not be desirable to discuss any question raised in his paper.

After some conversation, it was arranged that the subject should stand over.

Mr. Mathews directed attention to a communication addressed to the Association on the subject of a memorial to be erected in the City, but with what end was not described. It stated (as we have already mentioned in the *Builder*) that the charity and estates committee of the united parishes of St. Lawrence, Jewry, and St. Mary Magdalen, Milk-street, were desirous of receiving suggestions and proposals, together with drawings and designs or models, for the erection of a memorial in the churchyard on the south side of the Guildhall, at a cost not exceeding 500*l.*, a drinking-fountain to form a feature.

A member inquired what was the object of bringing such a communication under the notice of the Association.

Mr. Mathews said, he had not the most remote idea unless for publicity's sake.

Mr. Blashill said that, in some places, possibly in the City of London, the object and uses of a memorial appeared to be unknown. He had himself spoken to a civic authority on the subject of a proposed memorial which was required, and ventured to ask what it was that was wanted, and all the answer he got was "A memorial—we want a memorial!"

A Member said, he hoped that as a drinking-fountain was to form "a feature" in the proposed memorial, no member of the Association would have the hardihood to suggest another abomination similar to those to be found in the streets of the metropolis, which were absolutely a disgrace to a civilized community. He referred more especially to the iron tea-urns, with threads of intermittent water, a notable example of which was to be found in the Regent-circus, Oxford-street. These caricatures on street fountains made us the laughing-stock of foreigners.

In reply to questions as to the object of the memorial which the united parishes of St. Lawrence, Jewry, and St. Mary Magdalen, desired to erect, it was suggested that it could not be to the memory of the late City architect (Mr. Bunning), as the corporation were about to "put up something" in the Guildhall, for that purpose. This, however, was subsequently contradicted.

The Chairman said, he regretted to announce that Mr. Wells, who had promised to read a paper "On the Influence of Eastern and Western Art," had been summoned by telegraph to Chatham, and consequently could not be present.

Mr. Paraire then volunteered some remarks upon perspective, which he illustrated with the aid of the drawing-board.

It was announced that the next drawing in the class of design would be an embroidered altar frontal.

#### THE BUILDING TRADES.

The Stockport brick-setters' labourers have struck for an advance of wages. They demand an addition of 2s. per week to their present rate, or an advance from 18s. to 20s. per week. It is considered doubtful if the demand will be conceded while the market is so overstocked with unemployed out-door labourers.

A strike of the operative joiners of Blackburn seems to be likely to follow that of the plumbers. A meeting of masters is to be held, to decide what shall be done in the matter.

The masons of Barnsley have struck for an increase of wages and a diminution of working hours. The men state, that some time since they informed their employers that they should require their wages to be raised to 28s. per week, and the working hours reduced from ten to nine per day. The masters not having responded to the notice given, all the works were abandoned by the men.

The dispute at Halifax between the master and operative joiners is yet unsettled. The men seek to have the hours of labour reduced from 57½ hours to 52½ hours per week. The masters have held a meeting, and offered a settlement by the men working 54 hours a week.

At a meeting of the joiners of Newcastle and Gateshead, in order to arrive at some determination respecting the nine-hours movement, which they had asked the masters to concede, about 200 men were present, nearly all the workshops on both sides of the river being represented. A motion was unanimously adopted, to the effect, that if the masters did not concede the terms asked by the men, namely, nine hours per day, they will cease work as soon as the notice expires.

At Carlisle the strike of the bricklayers has terminated by a compromise. The masters withdrew the hour system, which had been the immediate cause of the strike. The men are to receive 26s. a week in summer, and 24s. in winter. Instead of leaving off work at one on Saturday and commencing at seven on Monday, the hours will be twelve o'clock on Saturday and six o'clock on Monday morning. Walking time to be allowed to all jobs outside the city, but within a mile of the Market-cross work is to commence at six a.m. With regard to non-interference, the masters are to employ any bricklayers they may think proper, and the men may work for whom they may think proper; the master to have the power of conducting his own business in any way he may think most advantageous

in the matter of letting piecework and in all details of management not interfering with the individual liberty of the men. The masons were offered the same terms, but declined to accept them, and they still remain on strike. The master painters have agreed to give the Saturday half-holiday without change of wages, but will not give the hour asked for on Monday mornings. The men stand out for that hour, which is now all that is in dispute between them. The joiners have reduced the difference to the same question, and some have consented to give the hour,—that is to say, let the men start work at seven o'clock instead of six.

In the Commons, on the motion of Lord Elcho, who moved for Mr. Cobbett, a select committee has been appointed to inquire into the state of the law as regards contracts of service between master and servant, and as to the expediency of amending the same.

#### COMPETITIONS.

*Swansea Infirmary.*—A design by Mr. Graham, London, has been selected: the proposed expenditure is 12,000*l.* Tenders are to be applied for: and on obtaining subscriptions to the amount of 6,000*l.*, the works are to be proceeded with.

*Chester Town-hall.*—The whole affair has come to a standstill for the present; the lowest estimate, without the tower, being 21,600*l.*, instead of 15,000*l.* stipulated, and the town council refusing to go on.

#### CAST-LEAD TRAPS.

The importance of good stretch-traps and the value of improvements tending to perfect and cheapen them are not to be over-rated. The invention by means of which lead traps may be cast whole, patented by Messrs. Beard & Dent, and advertised by them with diagrams in our pages for some weeks past, deserves immediate attention. Hitherto syphon traps have been made by hand, as it was impossible to cast them on loam cores with profit. They were made by beating up two half-pipes from sheet lead and soldering the edges together with soft solder. Under the new system the cores are formed of gun-metal or of east iron, according to an invention patented by Mr. Lowe, an American, some four years since; and while, in old times, to make four of these traps occupied a plumber and labourer a whole day, with two sets of the newly-invented cores four men can make eighteen of the 4-inch traps in an hour. The patentees claim:—

1. That the traps are considerably cheaper than hand-made traps.
2. That they are of pure and solid lead, without solder or seam of any kind, and as smooth and clear inside and out as pipe made by hydraulic pressure.
3. That they are of perfectly regular substance throughout; and, being composed of one metal, are not subject to injurious expansion from hot water, nor are they liable to be affected by the generation of gases which almost invariably destroy the ordinary trap.

As these assertions seem to us perfectly correct, we can scarcely doubt that the new traps will be extensively used.

#### STONE STAIRS UNDER FIRE.

THE experience of architects and builders in Glasgow with respect to the behaviour of stone stairs there in conflagrations, might be usefully educed in the question (*vide p. 229*) raised by the superintendent of the London Fire-engine establishment. There, while many of the stone staircases entirely project from the buildings to which they appertain, fully as many are comprised within the main walls of the building; yet in no instance have I known any failure at all in the stairs, of the kind referred to. When the combustible parts of a large and substantial structure have been consumed, there along with the walls stands the staircase intact, from the landings of which the ruins can be surveyed, and the levels, for the restoration, be determined. Usually, the staircase is bounded on one side by a main wall of the building; but the other sides, say three in number, are equally fire-proof, consisting either of 9 in. brickwork, or a similar thickness of ashlar stonework, rubbed (or, as they express it, polished) on the side next the stairs, while in the centre is an open well-hole with iron railings or an ashlar newel-wall, which is often not more than 6 in. or 6 in. thick. I think, while about the metro-

polis the stone used is mostly limestone or oolite, that used in Glasgow is generally sandstone,—a difference which may have much to do with the failure in question.

I hope Glaswegians and others, accustomed to stone staircases, will throw light on this subject; and that any sudden disposition to discard solid stone as a material for fire-proof stairs may be arrested.

JAMES WYLSON.

#### A FEW WORDS ABOUT WORKING MEN'S CLOTHES.

I VERY much wish that you would allow me to communicate, through the *Builder*, to the world at large, the particulars of a little trick which I have practised for some years with great comfort. I must state that I have as tidy and industrious a wife at home as any man could desire, and it is to her I am indebted for the idea, and the carrying of it out. I never wear the same suit of clothes, or under-clothing, or boots, two days running. I am only a working man, engaged in a dirty, foul employment, and the clothes of all my fellow-workmen fairly stink: they call me "the gentleman" because I appear comparatively respectable. Now, I have two clean shirts a week (my whole stock of shirts is four; not of a very grand sort, but they do for me), and I put on one clean shirt on Sunday morning, and one clean one on Monday morning. Then the Sunday one goes on again on Tuesday, Thursday, and Saturday, and the Monday one goes on again on Wednesday and Friday. The days they are left at home my wife looks to them, sees to any tears, &c., which my work has caused: on fine days she hangs them out in the wind, and so on. The same with my stockings and outer clothes. My boots also she dries and tidies up. Before I got home a night from work, she has laid out on my chair, a bedside, all my toggery for next day; and, when I get up in the morning, I have no trouble whatever with my clothes. I give myself a good wash, and start a king! Why, sir, cannot a working man, with wives at home,—I mean men who earn a fair week's wages,—do the same thing whether they are carpenters, or masons, or smiths, or what not? I can assure them that it does not cost me one penny more a year for clothes than it does my mates; indeed, less than some. Any kind of two sets of clothes answer and the good comes directly. I did not like my wife to have so much trouble with me at first, but she was determined to do it, and I was obliged to give way. She is a good one, sir. God bless her!

A WORKING MAN.

#### DRY ROT.

No remedy is known to perfectly and effectually stop the ravages of dry-rot, although many experiments have been made with more or less success, and made public at various times. Few persons now require telling that the dry-rot is fungus, known to science as *Merulius lacrymans*. In its mature state the fungus and the surrounding wood frequently drip with moisture, hence its specific name. To be seen in perfection should be sought for during wet weather, in the autumn, when it is common on the stumps and in the hollow trunks of dying trees. In addition to this form, common on firs, there are many other species found in this country, nearly all to it, and sometimes mistaken for it. The dry rot of oak timber, though bearing the same popular name, is a totally distinct thing.

It must be obvious to all, that with dry-rot prevention is better than cure; for where the timber of a house is reduced to powder, where care can there be other than cutting the infected wood away, and replacing it with new; but such is the rapid growth of this plant, when once it has found a fitting habitat, that in a couple of years it has been known to utterly destroy a large house, not only reducing the timber to powder, but by insinuating its between the interstices of the brickwork, and growing through the plaster of the walls, it so ruined the building as to cause its complete destruction.

However sound the timber may look, or however dry the situation may appear, the fungus cannot exist without moisture; unless it can find various favourable conditions necessary for the growth of its seeds or spores, it can never manifest its appearance; these seeds being microscopic objects, are wafted by the slightest agitation

the air from one locality to another, and from one end of the land to the other, and just in those places where the conditions are fitting for its growth, will those seeds germinate and produce the dry-rot (this is considering the mycelium, or spore, or roots are not already in the timber). Experiments have often been tried with wood cut in summer and wood cut in winter, when the sap is down; but although preference has been given to the latter, sapwood of great age is constantly found as free from fungoid growth, and as sound as the very best summer-felled timber: so little or nothing can be said for it.

In open situations, where the air is dry, and where there is plenty of ventilation, the fungus certainly will not grow. This is partly proved by the fact of the dry-rot attacking the timber of one house in a certain neighbourhood, and not appearing elsewhere in the same locality.

If the following precautions be taken, they will reduce the chance of an attack of dry rot to the minimum. In the first place, great care should be taken that the timber used has been felled a reasonable time, and that it is perfectly dry and dead. It is of the first importance to have a free circulation of air wherever wood is used, as the disease usually appears where the air is confined and damp. If possible, to more certainly prevent its appearance, a saturation of the timber, before it is used, with creosote, is perhaps the best means, although the various metallic salts have been mentioned as effectual,—a solution of copper, iron, or zinc; of corrosive sublimate; or washing with gas-tar; or the application of albumen.

W. G. S.

#### LESSONS FOR STUDENTS.

THERE can be no doubt of the great value of the study of details by the student of decorative art, with the power of drawing and modelling, and skill in adapting natural and beautiful forms to ornamental purposes. It is desirable however, that together with the study of details there should also be afforded the means of inspecting various kinds of work when they are fixed in the right positions and form parts of a whole.

It may be said that the general arrangement of the ornamentation of a building comes within the province of the architect, and not that of the skilled workman. This, to a certain extent, is true; but it must also be acknowledged that in some instances the decorator must act without especial dependence on the architect. It is therefore of consequence, that together with the teaching of the details, the student of architectural decoration\* should have lessons of a more comprehensive and general kind; and there are many such to be had within the bounds of the metropolis. Amongst these Somerset House may be mentioned, as a remarkable instance of the elegant application of highly artistic details to parts which are of graceful and good proportions. In this fine building, not only on the exterior, but also in the interior parts, there are decorations of good design and most excellent workmanship. The railings of the staircases, the colouring and gilding of the columns and capitals on the principal landings, the panelling of doors and walls, the foliated brass-work attached to the locks and door-handles, but above all the ceilings of apartments are especially worthy of attention. It is said that the chief part of this work was executed by Jean-Baptiste. During the reigns of Charles II., Queen Anne, William and Mary, and the first and second Georges, there were numerous most elaborate and well-designed ceilings executed by our own countrymen, and it is worth while to notice how very similar the style of the ornamentation of the Somerset House ceilings is to the wood carvings by Grinling Gibbons, and those who in this walk of art succeeded him; and we cannot think that although this appropriate and pleasing style of decoration fell for a number of years almost entirely into disuse, it will fail one day to be revived in a worthy manner; but it is said that there is a difficulty in obtaining workmen of sufficient skill to compete successfully with the older plaster workers. There is, however, no lack in London of lessons in this style of ornamentation still to be found in the dwellings of the nobility; but especially in some of Sir Christopher Wren's, Gibbs's, and other

churches. In the state apartments of St. James's Palace, and in Buckingham Palace, there is much which is worthy of study, with other matters which are in their way useful as instances of what should be avoided.

In connexion with the subject at which we have briefly hinted, it would be desirable that a class for this kind of study should be formed by those of the South Kensington establishment who are engaged in the study of the various branches connected with building and architectural decoration. Then it would become a question how the students could obtain admission into the buildings which it is necessary to see. As regards the churches, Houses of Parliament, &c., there would be no difficulty. Parts of Somerset House, too, are accessible, such as the apartments of the Antiquarian Society. Other portions, occupied as Government offices, are for the most part unoccupied after four o'clock in the afternoon, and on Saturdays at a much earlier hour. St. James's Palace is visited during the chief part of the year, and we should think that, for a purpose such as this, access could be easily obtained to Buckingham Palace. In fact, it would be a great boon to those engaged in all the departments of art, decoration, and manufacture, and to the tasteful portion of the public, if, at stated times, certain of the apartments of this royal palace, when it is not occupied by her Majesty, were rendered accessible. In this palace there are rare treasures of art, the study of which would delight and improve many.

AN ARTIST.

#### ABSORBING WELLS.

I HAVE read the letters in your paper on this subject with great interest, and some alarm.

I think the proceedings at New Barnet to be of such a serious nature, that if the system is likely to be carried out in other places, the interference of the Legislature will be necessary to protect the main springs in the Thanet sands from being charged with organic matter.

I agree entirely with the letter signed "Pure Water," and am sure that Mr. Blenkarn is in error when he states that the water arising from the sand stratum under the blue clay is impure.

I have had several artesian wells sunk into this stratum in Essex, and found the water rising from it both softer and purer than that coming from the fissures in the chalk. The Croydon water which rises in the chalk contains not less than 18 grains of carbonate of lime in a gallon; and, although a good anti-cholera water, it coats the vessels in which it is boiled with chalk, and will not agree with many constitutions.

I thought that, after the report of the Committee of the House of Commons in favour of the successful irrigation system carried out under my directions at Croydon, none of these attempts to waste the fertilizing matter contained in the sewer-water would have been repeated, and am sorry that such an influential association as the British Land Company should have allowed such an interference with the main spring.

I know the situation of the absorbing well at New Barnet, and can state that it is within a short distance of the artesian well that supplies that place with water. It will, no doubt, be said that the sand spring is shut out there; but, from my own experience, I can state that this is next to impossible, as the fissures in the chalk below will prevent this being done excepting in the well itself.

With regard to the system of purifying the water in tanks, I need only state that, some years since, the Croydon Local Board, acting under the pressure of an injunction of the Court of Chancery, attempted, with the advice of that eminent chemist, Mr. Way, to cleanse the sewer water there. The matter held in suspension was soon extracted, but the noxious matter held in solution still remained; and I am at a loss to perceive how water loaded with ammonia can be called purified because it has been merely clarified. Nothing but passing the water over growing crops will effect this. I have before me the analysis of the Croydon sewer water taken before and after it has passed over the irrigation fields; and I am sure that the result will convince the most sceptical that this system is the only effectual mode of cleansing the sewer water.

JAMES FENTON.

\*\* We quite agree with those of our correspondents who regard the idea of Absorbing Wells with disfavour. In France, special legislation prevents their formation.—Ed.

#### WINDOW GARDENS.

THE idea of "window gardens" is now become general in London, and, as it undoubtedly contributes to the cheerful aspect of the exterior of our dull, dreary-looking houses, and also to the healthy state of the rooms within, it is well to afford every possible facility for this plan. The impediment generally is, want of width of the window-sill on which to place the flower-pots; also want of some protection to prevent the wind from blowing them down into the street. If builders of houses for all classes, whether rich or poor, would make a wide window-cill, with an iron rail, it would be all that is required for a window-garden; and, moreover, it would enable many a poor family to have the benefit of fresh air from an open window without fear of the little children falling out, which is often a reason for not opening the window.

#### FOREIGN.

**St. Nazaire.**—From its admirable position the town of Saint-Nazaire is likely to become the great maritime metropolis of French Transatlantic commerce, as Marseilles is of that of the Mediterranean. Thirty years ago this poor village, at the mouth of the River Loire, contained only 1,200 inhabitants, and few expected that it would in a few years enjoy, as it does now, the position it occupies, with a population of 150,000. In 1858 the Government built in the port a floating basin of 32 acres, the result being, in a few years, a maritime traffic representing half a million tons, without taking into account that of the fleet of Transatlantic packets, now numbering fourteen, and of the united capacity of 27,600 tons, and 8,000 horse power. The insufficiency of this basin was soon manifested, and it was determined to construct a second basin, of 52 acres, now in course of completion. In presence of these works, and the ever-increasing population consequent upon the traffic of the port, a new town is absolutely required, and a company has been formed to carry out the project. Here everything has to be created,—a complete town, with docks, warehouses, depôts, custom-houses, exchange-rooms, chamber of commerce, halls and markets, slaughter-houses, public lavatories, bath establishments, water and gas supply, churches, municipal buildings, schools, theatres, &c. The founders of this society are Messrs. Alph. Cezard, J. Cezard, Ls. Cezard, Count de Loppinot, Colechester, and Thos. Lucasen.

**Local Railways.**—The French Government is at this moment considering a new project of organization of railways of local interest, constructed at the expense of the departments. This organization will be placed under the direction of the prefects, and annexed to the service of the public highways. Moreover, these local railways can be subventioned by the State, and become assimilated to departmental roads.

**Puy.**—The town of Puy has just organized two free public courses, one of chemistry and another of literature. In this instance the municipal council has marked the interest with which it regards this step by subventions.

**The Russian Epidemic.**—M. F. V. Raspail, in a letter addressed to the *Siccle*, thus speaks of the Russian epidemic. This disease bears the general character of the plague which ravaged Marseilles every fifty years, when the port of that town was a vast cloaca,—a plague which is in permanence, at certain seasons, in the ports of the Gulf of Mexico—that vast sewer of the Atlantic Ocean, and in permanence even in countries nearer to us, in the barren and wasted steppes of La Campine (Flanders), the depôt of the infiltrations of the Escant and other channels. In his opinion the pest at St. Petersburg is nothing but a miasmatic affection of the air arising from the putrid emanations of a soil permeable to and soaked with the *immondities* of the city and the mud for years accumulated by the inundations of the Neva and the Baltic. The time at last comes when the organic matter with which the earth is impregnated arrives at such a state of decomposition that the terrestrial elements suffice no longer either to contain them or to preserve the atmosphere from their effects. The remedy for such an evil lies not in drugs; an atmospheric infection requires an atmospheric antidote. To effect this he urges the use of large fires on the public places of the town, and in the large thoroughfares, and even to burn the dead; to fumigate with acetic vapour not only the houses, but the

\* This embraces a wide field, and the laborers in it consist of workers in stone, wood, and various kinds of metal, glass staining, painting, glazing, the making of mosaic floors, plastering, paper designing and hanging, furniture making, gilding, and many other processes.

streets; to cover the infected ground with charcoal, dust, ashes, or chloride of lime; and enjoining all persons to carry a pail of acetate of ammonia, and to frequently inhale it. In order to prevent the return of the calamities, he urges the abolition of cesspools, and the immediate transformation of the refuse of the city into an inoffensive and fertilizing ingredient of cultivation, by the removal of it into the open fields, and by proper treatment there.

#### PROVINCIAL NEWS.

**Parshore.**—At the county sessions the court voted 1,700l. for the erection of a police-station in this town, and an additional 300l. for a magistrates' room, to form part of the same building. It is to be erected at the entrance of the Worcester-road, the work to be commenced at once. The building will consist of two stories, the material being brick, faced with freestone, and will be built from the plans of Mr. Rowe, county architect, the builder being Mr. O. Wilson. In front, there are to be two entrances for the public business, and one for the magistrates; and at each side the superintendent and constable will have an entrance to their dwellings respectively. On the ground-floor are a charge-room, waiting-room, three cells, corridor, residences for the aforesaid officers, with drill-yard, airing-place, stabling, and outbuildings; and in the upper story, a petty sessions room, 28 ft. by 18 ft. 6 in., retiring-room, and six bed-rooms for the officers, &c. The station will be slate-roofed, and the area of the premises is to be surrounded with a dwarf wall and fence.

**Wells.**—Within the next twelve months, Wells will be considerably improved in appearance by the erection of several new buildings in the outskirts, and re-modelling of others in the city. Of the former, the foundations for the erection of a hotel and several dwelling-houses are now being excavated, the site for them being in an orchard adjoining Prince's-road, and close to the new market-place. Mr. T. Charles, of London, who is the owner of a great deal of house-property in this city, is having the same greatly improved by the introduction of plate-glass fronts, &c. Good houses for the middle and working classes are in great demand and much wanted.

#### CHURCH-BUILDING NEWS.

**Sutton Courtney (Berks).**—A new porch has recently been erected on the north side of the church in this village, corresponding in style with the original north doorway. It is of Box stone, with red Mansfield stone columns, on which are carved caps. The cost was defrayed by the Rev. H. Rice, rector of the parish, assisted by some few private friends. The architect of the new porch was Mr. J. Gibbs, of Oxford; and the builder Mr. Howse, of Sutton Courtney.

**Masey.**—A font has just been placed in Maxcy Church. The First Pointed period of Mediaeval art has been chosen in designing it. The bowl is of Ketton stone, and supported on a centre shaft of rouge royal marble. There are also four minor shaft supports, executed in Alpine green and white marble. These small shafts have carved capitals of conventional foliage, and the foliage of these capitals is continued round the bowl. The upper and outer rim of the bowl is ornamented with the nail-head ornament. This font is the gift of Mrs. Argles, and was designed by Mr. Browning, of Stamford. The carving and wrought stonework were by Mr. Hilliam, of Stamford; and the masonry by Messrs. Burke, of London.

**Burton-on-Trent (Staffordshire).**—Mr. Bass, M.P., has offered 12,000l. to be spent as follows:—5,000l. to build a church in the town; 500l. for the parsonage; and the remaining 6,500l. to be the endowment.

**Leckhampton (Gloucestershire).**—The parishioners, vicar, and churchwardens of Leckhampton are engaged in providing funds for the restoration of their ancient parish church. At a meeting it has been determined to proceed at once with the repairs and enlargement of the structure. The committee state that they intend to provide 200 additional sittings. In all 1,800l. will be required.

**Sidmouth (Devon).**—The warming of the parish church has been carried out under the plan of Messrs. Haden, of Trowbridge, at a cost of about 160l. The outward air from the roof has been excluded by the closing up of about 3 in.

all round, that had been left open by order of the architect, who was employed when the church was repaired and enlarged three years since. At that time another plan of warming was tried by his direction, with a furnace and flues, and underneath the aisles, the heat from which never warmed the church.

**Brilley.**—The parish church of Brilley, a village about sixteen miles from Hereford, and near Whitney, has been re-opened, after undergoing a renovation. The church was in a sad state of dilapidation. It was decided, however, to restore, and not to rebuild, so as to enable the architect to preserve the peculiar arrangement of the chancel. The restoration work includes the rebuilding of the timber porch after its ancient type, and adapting therein such of the old woodwork as was available. The old windows have been replaced by others of a more modern design, and finished with stone internally as well as externally. The flat ceilings have been removed, opening to view the timber framework of the roof. There are now low open seats, all free and unappropriated. The roof has been covered with green Pembrokeshire slates, and the peaks of the gables finished with stone crests, with metal crosses. The walls have been stripped of the plaster which before covered them, and the joints pointed. The defective drainage of the building has been remedied, and the windows have been glazed with thick cathedral glass, a painted subject being inserted in the east window. There remains one thing to be done, viz., the restoration of the tower, which is of a characteristic type. The plans for the restoration were designed by, and carried out under the supervision of, the diocesan architect, Mr. T. Nicholson, of Hereford.

**Wiston (Pembrokeshire).**—The parish church of Wiston, situated near to Haverfordwest, has been re-opened for Divine service, after having been closed for a year and a half, during which time the old and dilapidated roofs over the nave, chancel, and tower have been replaced with new open timbered roofs; the nave and chancel seated; and the stonework of the church internally and externally cleared of whitewash, and restored where practicable. The cost of the works has been defrayed by the Earl of Cadwor, this being the seventh church which has been restored upon his property in Pembrokeshire and Carmarthenshire within the last few years; in addition to which restored churches a new one has been built at Penloy, in Cardiganshire. The parishioners of Wiston have raised a subscription for the purpose of placing a stained-glass window in the chancel, in memory of the late Earl of Cadwor. The church is one of the usual type of Pembrokeshire churches, with few exceptions, being of an early period, with a characteristic square tower at the western end, diminishing in size from the base upwards. The edifice will accommodate 350 adults and 40 children. The works have been carried out by Mr. James Rogers, builder, of Tenby, from the design of Mr. D. Brandon.

**Kimberworth.**—The church here has been reopened. It is in a plain Gothic style, and the original dimensions of the nave were 42 ft. square, with vestries and small recesses for a chancel at the east end. Across the west end was a gallery appropriated to the choir and school children. The improvements that have been effected consist of the removal of the gallery and the erection of a tower 71 ft. high. The nave has thus been lengthened 11 ft., and considerable additional accommodation has been gained. On the one side of the tower is an organ chamber, and on the other side a porch. The cost has been about 400l. The architects were Messrs. Blackmoor & Withers; and the builder, Mr. Ripley, Masbro'.

**Kilnwick Percy (Pocklington, Yorkshire).**—The church here is about to be rebuilt, with the exception of the chancel. It is of Norman character, and the restoration will be in that style. It will consist of new nave, 42 ft. by 21½ ft.; north porch, vestry on the south side, and the present chancel, 18 ft. by 15½ ft. The present ornamental porch, in the existing south wall (closed) will be restored and rebuilt into the north porch, and a part of the west doorway will be inserted into the inner door of the porch. The roofs will be open and varnished, boarded and felted, and covered with slate. The windows are to be filled with stained and cathedral glass. The nave will be entirely refitted with open seats, and those in the chancel, as well as the pulpit and desk, will be reinstated and re-formed out of the oak carving, which was previously in the church. The entire work is being carried out

at the expense of the Hon. Admiral Duncombe M.P., of Kilnwick Percy, from designs prepared by Messrs. J. B. & Wm. Atkinson, of York, architects; and the works are being executed by Mr. Aid. Weatherley, of York.

**Pickering (Yorkshire).**—The church of Thornton is to be restored. The chancel will be renewed, the old pewing removed, and new seats substituted, and the whole of the interior will be renovated. Several memorial windows will be put up, viz.,—one at the east end, in memory of the late Mr. R. Hill, of Thornton; at the west end, in memory of the late Mr. Champley, of Scarborough; and another in memory of the late Mrs. Heslop, wife of the present rector. The exterior will also be improved by a new roof, as the probable addition of a spire to the present steeple, as well as the repair of the whole of the exterior fabric. The whole work, with the exception of the spire, is computed to cost about 1,200l., and of this sum upwards of 900l. have already been sacrificed. Mr. Scott has been employed in the work, which will be commenced forthwith.

**Rotherham.**—A font has just been placed in the parish church of All Saints, Rotherham, the gift of Mr. John Shaw, of this town, architect. It is in the Perpendicular style, and in a great measure a *fac-simile* of the old font, copied from an old sketch of it in the possession of the donor.

#### STAINED GLASS.

**Thatcham Church.**—A new memorial window has been placed in the west end of the south aisle of Thatcham Church, by the vicar and his family, in memory of some of their deceased relatives. The glass is by Powell, of London. The subject is that of the Nativity, exhibited in three compartments. The centre one contains the figures of the Virgin Mary, with the infant Jesus, attended by St. Joseph and adoring angels. In the compartments on either side are the Shepherds and the kindly Magi, in the act of worshipping; while the beams from the Star in the East, falling alike on the Divine infant and His worshippers, give unity to the subject.

**Hope Church, Hanley.**—A memorial window to the late Rev. J. Eastwood, incumbent, has been placed in this church. The window consists of two medallion groups on a foliage ground and border, representing the Walk to Emmaus and our Lord making himself known by the Breaking of Bread. One window has been executed by Mr. Wailes, of Newcastle.

**Gloucester.**—Three painted glass windows have lately been erected in this city, according to the local *Chronicle*,—two at the cathedral, and third in St. Mark's Church; a memorial window in Dean Rice has been placed in the east cloister of the cathedral; and the large memorial window to Dr. Jenner and the late Mr. John Elliott, Gloucester, will probably be erected in the course of a few weeks. Mrs. Claxson, widow of the late Rev. Dr. Claxson, is about to place a memorial window in the cathedral to Hooper, the martyr-bishop of Gloucester. Messrs. Clayton & Bevers were engaged, and the artist under whose direction the window has been executed is Mr. Kemp, a nephew of Mrs. Claxson. The window selected for the reception of the glass is the third from the east entrance to the cloisters in the north aisle. The window is a Norman one, and the introduction of Perpendicular tracery rendered the carrying out of any broad design difficult, not impossible. The mullions divide the main portion of the window into three lights, and the semicircular part into two lights, and there are two smaller side lights. The subject represented in the first light is the torture of St. John the Evangelist in the cauldron of boiling oil at Rome,—an ordeal through which we are told he passed unhurt. The subject in the centre is the martyrdom of Bishop Hooper. The subject of the third light is the martyrdom of St. Lawrence, who was roasted to death on a gridiron. There are canopies over the figures. The window is inscribed in memory of Richard Hooper, sometime Bishop of Gloucester and Worcester. The bishop's name was John, not Richard; and he is represented in Roman vestments, which is scarcely consistent with his own aversion to the ceremonial religion of Rome. The second window is a memorial to Archbishop Wetherell, and is placed in the east cloister. The artist was Hardman, of Birmingham. The window is divided into four tiers, the two lower ones each containing eight lights, the third floor with two main lights in the top. The subject

selected is "The Temptation of Our Lord," which is depicted in the second tier, the lower spaces being filled with decorated quarries. Each space is occupied by one figure, and, of course, two lights are devoted to the representation of each incident. The tracery lights are decorated with foliage, of the German Gothic leaf; and the main pictures are represented on an enriched blue ground, which affords a contrast to the window to Dean Laxmore, which is next to it. The colouring of this is necessarily light, and the subject is rather meagre, the artist being confined to two figures, but the incidents are clearly delineated. A stained glass window has been put up in the east end of the south chancel aisle of St. Mark's Church, by Mr. A. C. Wheeler, of Kingsholme, to the memory of his father. The window is a double lancet, with a quatrefoil over. The general plan of the subject refers to the infant life of the Saviour and his treatment of children. The artists were Messrs. Heaton, Butler, & Bayne, of London. With the exception of the east window at St. Aldate's Church, this is the only specimen of their art in Manchester.

**St. Peter's, Newcastle.**—A stained-glass window has just been placed in the chancel of St. Peter's Church, Newcastle, to the memory of the late Captain Woods, by his widow and daughter. The subject introduced is that of "The Good Centurion." The window was executed by Messrs. Herdman, of Birmingham.

Miscellaneous.

**NATIONAL GALLERY.**—It is understood that the Government plan for enlarging the National Gallery will be presented to Parliament after the recess.

**PROPOSED NEW EXCHANGE FOR MANCHESTER.** It is now suggested to carry the Exchange, like the post-office, to Brown-street, and the plot selected is one bounded by that street on one side, by Spring Gardens on the other, and running back from King-street to the Clarence Hotel. The plot can be obtained without an Act of Parliament, and is said to afford space for a building double the size of the present Exchange, and one-third larger than that the Exchange Committee propose to build. It contains 4,280 yards of available building land after allowing nearly 100 yards for street improvements. The estimated cost of land and buildings is 200,000*l.* and it is calculated that a net revenue of 200,000*l.* might be obtained from subscribers. The party of this scheme is a very influential one.

**MEMORIAL OF THE LATE DUKE OF NORTHUMBRLAND.**—A public meeting has been held at Newcastle-upon-Tyne for the purpose of opening subscription to provide funds for erecting at the sea-side, in the county of Northumberland, a suitable building, to be called "The Prudhoe Waralescent Home," for discharged or convalescent infirm patients, and others, "as a memorial of the admiration in which the memory of the late Duke of Northumberland is held by all classes of his countrymen." The meeting is under the presidency of the Mayor of Newcastle, and was attended by most of the leading gentry of the town and neighbourhood. The company included a large number of ladies. Appropriate resolutions were passed, a subscription-list opened, and a committee appointed. Mr. William Armstrong subscribes 1,000*l.*, and Mr. High Taylor 500*l.* The subscriptions at the close of the meeting amounted to 3,011*l.*

**MAGNESIUM AND ITS LIGHT.**—A Putney correspondent, "William White," who states that he has made many experiments with magnesium, writes, in a communication to us on the subject, "suggesting that the wire should be passed through a spirit flame, you indicate an efficient remedy for the annoyance. A lamp in which the wire was so treated was devised by Mr. William Mather, of the Salford Iron Works. The wire was paid out by hand from a roller, and passed through the flame of a spirit-lamp, and so on, with no risk of extinction. I find the ribbon is with greater certainty, as well as brilliancy, than the wire. The wholesale price of magnesium wire and ribbon has been reduced half, or to 10s. an ounce. There are about 1*l.* of wire or ribbon to the ounce, and so, I calculate, it will be retailed in the shops at 1*l.* 6*s.* I find the ribbon burns at the rate of a minute, so one might have a magnesium illumination for two hours at the cost of 10*s.*"

**FALL OF FLOORS.**—Four floors in a wall corner of the corn-mills in the occupation of Messrs. James Ellis & Co., Bradford, suddenly fell, precipitating about 192 sacks of flour, about 200 quarters of wheat, and several workmen, to the ground floor. The accident arose from the giving way in the third story of a brick wall, on which rested an iron pillar which supported the three floors above. A joiner was rather severely bruised.

**THE FITTINGS FOR THE WEST LONDON EXHIBITION.**—Tenders have been obtained for the erection of counter space in the Floral Hall, Covent Garden, for the West London Industrial Exhibition at per superficial foot. The following is a list:—Mr. Tackley, 9*d.* per ft.; Mr. French, 6*d.* per ft.; Mr. Warwick, 6*d.* per ft.; Mr. Bradbeer, 5*d.* per ft.; Mr. Carpenter, 3*d.* per ft.; Mr. W. H. Thompson, 3*d.* per ft.; and the last has been accepted. Mr. S. S. Brown is the architect.

**THE LANDED ESTATES COMPANY.**—By the Report read at the first annual meeting of this company, it appeared that 31,743*l.* had been received in respect of allotted shares, while the gross profit on the year's transactions equalled 12,856*l.* 13*s.* 4*d.* After payment of all outgoings the net profit amounted to 11,301*l.* 6*s.* 6*d.*, which would enable the directors, after declaring a dividend of 15 per cent., to carry forward over 10,000*l.* The first estate the company had purchased was the Worcester Park Estate, near Kingston and Ewell. The company had nothing to do with bricks and mortar, further than assisting builders in the erection of first-class houses upon the estate, which comprised about 300 acres, and from the sale of 64 acres only, a profit of more than 11,000*l.* had been realised, after deducting the expenses of roads, sewers, &c.

**STATUE OF THE PREMIER.**—At Lady Palmerton's receptions the model of an intended marble statue of the Prime Minister has excited attention. This statue, about to be executed by Cavaliere Giovanni Pandiani, of Milan, is the third of a series which he is engaged upon, and which are to form the nucleus of a collection of European celebrities for Mr. Ernesto Zuccani, a gentleman of considerable mercantile standing long resident in London. The first of these statues, a life-size one of Garibaldi, appeared in the Exhibition of 1862. For the second one, that of the late Comte Cavour, Signor Pandiani received the honour of knighthood from the King of Italy.

**GAS LIGHTING OF MOSCOW.**—We announced on the 17th of December last, that a Hague gentleman had got a concession from the Russian Government for lighting Moscow with gas. This concession, we now learn, has been assigned to a new limited company, to be called "The City of Moscow Gas Company," among the directors of which are some substantially good names. The capital will be 875,000*l.*, in 35,000 shares of 25*l.* each. Deposit, 1*l.* on application, and 4*l.* on allotment; 7 per cent. per annum allowed during construction. Moscow is a great city, with 17,032 shops, 700 factories, &c., 200 hotels, 4,841 inns, cafes, &c., and numerous universities, schools, hospitals, public offices, and buildings devoted to public amusement. It is, in fact, the winter capital of Russia, and an exclusive right to supply such a city with gas ought to be a fine thing for the shareholders. The population is about 500,000. The city is situated at the centre of the commerce of the country, with six railways converging within its walls. The Kremlin (which covers 250 acres, and includes the Emperor's Palace, the Senate, the Arsenal and Government Offices), the great Universities, and the public schools, will all have to be lighted by gas. There are upwards of 100 police posts and stations, and 102 printing-offices. The Government pays annually 13,600*l.* for the lighting of the Opera House and the Russian Theatre alone, and 12,000*l.* for the Barracks. Private houses also will, doubtless, be lighted with gas. A provisional contract has been entered into with Smith, Knight, & Co. for works capable of supplying 120,000 lights, together with the whole of the mains of the city (upwards of 140 miles in length). The net profits upon the capital required for this purpose are calculated to exceed 20 per cent. per annum, and in this estimate no profit is assumed on the public lights. Sufficient plant will be erected for the supply of 50,000 lights, by the end of August in next year. We are not surprised to hear that the chief part of the capital is already subscribed.

**NON-ABSORBENT BRICKS.**—With reference to the inquiry after non-absorbent bricks noted in your last, I think the perforated bricks that come up by the Great Northern Railway from Arley are as nearly non-absorbent as any material I know of which is obtainable at a moderate price. They make a good, clean, uniform face, though rather pale; but they stand well. The only drawbacks I have found to their use are, that cutting them is almost impossible, and that they generally run larger than ordinary bricks; so that a little extra care is needed where they are used along with others to keep the mortar-joints of the facing very fine.—R. S.

**METROPOLITAN OPEN SPACES.**—The first report of the select committee appointed to inquire into the best means of preserving for the public use the forests, commons, and open spaces in and around the metropolis, have made progress in the matters referred to them, and have agreed—"That it is not expedient that the Wimbledon Common should be fenced round or enclosed, or that the existing common rights should be extinguished. That it is not necessary, and would be undesirable, that any part of the common should be sold. That the 20 Hen. 3. c. 4, commonly called the Statute of Merton, by which a lord of the manor can enclose without either the assent of the commons or the sanction of Parliament, ought immediately to be repealed."

**THE DISPLACEMENT OF THE LONDON POOL.**—In the House of Lords, last week, the Lord Chancellor stated that to insure the return of the actual dwellers of the houses to be taken for demolition he proposed an amendment in the Standing Order No. 191, of the words "inhabited by the labouring classes," to "occupied either altogether or partly as tenants or lodgers by persons belonging to the labouring classes;" and that another alteration should be made rendering it obligatory on companies to give notice, by placards and handbills exhibited in the vicinity, of the houses about to be pulled down, the certificate of a magistrate being made necessary to show that the order had been complied with. The Order, thus amended, was then agreed to.

**INAUGURATION OF A GYMNASIUM AT EDINBURGH.**—The new Royal Gymnasium, in connexion with Pitt-street swimming-baths, has been publicly inaugurated in presence of the Lord Provost, magistrates, and town council of Edinburgh. The new gymnasium has been constructed at the expense and under the immediate supervision of Mr. John Cox, Gorgie House. The patent rotatory "boat" is one of its features. This "boat" in the form of a circle, is 471 ft. in circumference, and 6 ft. wide. It is placed in a large circular artificial pond, and is designed to rotate with rapid motion when the means of propulsion are applied. To preserve it in an undeviating course, and prevent it coming into collision with the sides of the pond, it is stayed with wire ropes, which are attached to an iron pivot fixed in the centre of the water. It is like a merry-go-round rotating in a pond. The boat is constructed to carry 600 "passengers," and when unladen draws 4 in. of water. The guests got into the rotatory boat, and had a sail round the artificial pond, Miss Cox having christened it, oddly, the "Great Sea Serpent." The next invention tested was the "Merry-go-round" itself, in which a large number of the guests took seats, and to all appearance, they enjoyed the sport.

**RAILWAY BRIDGES OVER STREETS.**—The London, Chatham, and Dover Railway Company have been charged, at the home circuit assizes, with a nuisance, by contravening their Act in the mode of building their Newington bridges, thereby endangering the public safety. The company pleaded not guilty to the indictment. The local vestry were the prosecutors, in the name of the Queen. It was argued on their part that the bridges complained of were not water-tight, and from want of deadening arrangements the noise of trains passing startled horses, so that accidents had happened and lives were lost. In other and similar bridges these defects had been obviated with the greatest ease, and the defendants were bound to do all in their power to prevent their bridges being a public nuisance. They were not asked to destroy the bridges, but simply to alter or improve them a little. The Lord Chief Baron, at the close of the prosecutors' case, suggested that the matter should be referred to some competent person to examine the bridges, and decide what should be done; and this was finally agreed to, the defendants to pay the costs of the suit, if found in the wrong.

**SUBSTITUTE FOR BLASTING POWDER.**—At Stockholm several experiments have been made with nitro-glycerine, in order to test its application as a substitute for blasting powder in mining operations. They were considered very successful, the new compound being found to be superior in its effects to the ancient method, and the price considerably less. Among other trials, a hole bored near the summit of a rock to a depth of 23 ft., was charged with 5 lb. of nitro-glycerine. Five minutes after the fuse had been lighted a dull report was heard, and enormous blocks were detached from the rock. Several other mines were fired with blasting powder, but their effects were inferior to those of the nitro-glycerine.

**"SUSPENDED BETWEEN HEAVEN AND EARTH, LIKE MAHOMET'S COFFIN."**—There is a good deal of "see-saw" in Science. First it is pointed out that the idea of Mahomet's Coffin, suspended between heaven and earth, is a strictly scientific one, which indicates a possible effect of magnetism. Then it is proved that such a suspension is not scientifically possible. Then again, we find Prof. Tyndall, in one of his recent lectures "On Electricity," at the Royal Institution, showing the idea to be, after all, a strictly scientific one. A piece of gold leaf, 2½ in. long and 1¼ in. wide, is cut into the form of a kite or fish, placed on a piece of paper, and presented to the knob of a large Leyden jar charged with electricity. When detached by a knife, the leaf springs towards the knob, but stops within 2 in., and remains hovering in the air, the tail waving like that of a fish. When the jar is moved, the gold leaf follows, and continues to float for nearly an hour. The experiment may be made with a smaller jar and with smaller pieces of gold leaf.

**IRISH RAILWAYS.**—In the House of Commons, last week, Mr. Monsell moved that an address be presented to her Majesty, praying that the commissioners appointed to inquire into the railway system of the United Kingdom may be instructed to direct their inquiries, in the first instance, to the Irish railway system, with a view of ascertaining such facts as may enable the House to determine whether the provisions of the second clause of the General Railway Act of 1844 should be applied to such Irish railways as are subject to its provisions. He contended that the application of the Act of 1844, by which the Government would take possession of the railways of Ireland, would immediately benefit that country and stimulate industry and enterprise. Mr. Whiteside supported the motion. If the motion were carried, he said, it would be regarded in Ireland as a proof of the kindly feeling of the House. Mr. Stenoel also strongly supported the proposition. Mr. Ennis thought the Chancellor of the Exchequer would be an exceedingly bold man if he attempted to carry out the change proposed. There could be no doubt that railways in Ireland were at present comparatively failures; but that arose from the wretched condition of the country. The Chancellor of the Exchequer said he could give the assurance that measures should be taken to ensure the fullest investigation into the affairs of Irish railways. If it were desired to confer any special boon on Ireland, he did not believe there was any method so comprehensive as the Government taking the railways into their control, with a view to the reduction of the fares; but he could not pledge himself to what would be done by the Government in the matter at some future time. Mr. Monsell then withdrew his motion.

**TENDERS**

For alterations to the rifle range for the Norwich Volunteer Rifle Corps. Mr. James S. Benet, architect.—Newman & Hussey (accepted) ... £107 5 0

For rebuilding a house, in Lawrence-street, Chelsea, for Mr. Auguste Smith. Mr. Charles Bowes, architect.—Field ..... £250 0 0  
Pitts ..... 55 0 0  
Godbold (accepted) ..... 47 12 0

Accepted for new national school, Mexboro', exclusive of fittings. Messrs. Blackmore & Wither, architects.—*Mason's Work.*

Harper	Carpenter and Joiner's Work	£258 0 0
Pearson	Plasterer's Work	145 0 0
Bendall	Plumber and Glazier's Work	31 0 0
Hirst	Slater's Work	45 0 0
Kemp	Painter's Work	78 0 0
Briggs		14 0 0

Accepted for school, at Brightside, near Sheffield. Mr. C. J. Innocent, architect. Quantities supplied:—

Greenwood (mason)	320 0 0
Bradbury (joiner)	320 0 0
Stanford (later)	42 12 0
Harrison & Chadwick (plasterers)	29 0 0
Saule (plumber and glazier)	105 10 0
Langton (painter)	8 0 0

For collar dam and river wall, Norwich. Mr. James S. Benet, architect.—

Coe & Hobrough	£118 6 0
Spinks	148 0 0
Hobrough & Moore	133 0 0
Baile (accepted)	125 0 0

For the enlargement of Christ Church, Milton. Mr. S. Parr, architect.—

Gould	£333 0 0
Stump	506 0 0
Cobham	477 14 0
Lillystone	472 0 0
Blake (accepted)	447 0 0

For a house, in the Upper Richmond-road, Putney, for Mr. Hewitt. Mr. Livock, architect. Quantities supplied by Mr. Hain:—

Colls & Son	£1,145 0 0
Jennings	1,143 0 0
Sharrington & Cole	1,483 0 0
Howard	1,045 0 0
Avis & Son	1,622 0 0
Adams & Sons	885 0 0

For the erection of a new chapel, at Beeston, in Bedfordshire.—

Williams	£295 13 4
Joy	499 0 0
Field	489 0 0
Dainham (accepted)	475 0 0

For alterations, 309, Camberwell-road, for Mr. R. Knight. Credit allowed for old materials. Mr. John Scott, architect. Quantities supplied by Mr. C. W. Epply:—

Acock & Son	£370 0 0
Westrop	349 10 0
Closser, Brothers	205 0 0
Humphries, Brothers	250 0 0
Ring & Wannan	239 0 0

**TO CORRESPONDENTS.**

A. G. J. C. F. J. W. E. T. S. & W. S. D. W. M. C. A. R. B. S. R. H. P. H. C. R. W. W. (in type).—O. & P. W. S. R. S. R. L. (not looked to). A. F. X. (premium desired entirely on the office selected and the capability of the youth).—H. R. H. (small see a prof.)—W. R. C. (in type).

We are compelled to decline pointing out books and giving addresses. All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessary for publication.

Advertisements cannot be received for the current week's issue later than FIVE o'clock, p.m., on Thursday.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

**[ADVERTISEMENT.]**

**CHURCH, TURRET, and STABLE CLOCKS.** J. W. BENSON, having erected steam-power and improved machinery for clock-making at the manufactory, Ludgate-hill, will be glad to furnish to clergymen, architects, and committees, Estimates and Specifications of every description of Horological Machine, especially cathedral and public clocks, chiming tunes on an number of bells. A descriptive pamphlet on Church Clocks sent free for one stamp. Watch and Clock Maker by Warrant of Appointment to H. R. H. the Prince of Wales, and maker of the great clock for the Exhibition, 1862, 33 & 34, Ludgate-hill, E.C. Established 1749.

**ADVERTISEMENTS.**

**CITY PROPERTY.**—First-class investment in King William-street. **MESSRS. BEADLE** are instructed to **SELL** BY AUCTION, at the GUILDHALL HOTEL, Oresbam-street, on WEDNESDAY, the 18th APRIL next (unless previously disposed of by Private Contract) the commanding PREMISES, known as No. 39 King William-street, built on an lease for a term of 80 years from Michaelmas, 1838, at the market value of £600 per annum. The premises are a building of 18 feet, with an average depth of 45 feet, and contains about 510 square feet. In the basement are convenient domestic offices. On the ground floor, elegant shop with private room in the rear; also an office which, with the first and upper floors of the house, is appropriated by a separate entrance from the street. The one, two, and three pair-rooms are used as offices, and on the roof, which is sub-let to Mr. Henderson for 14 years from Midsummer, 1862, at 2s. 6d. the lease being determinable by the vendor at Midsummer, 1875, thus enabling a purchaser to obtain early possession of these important premises, when, from their situation, are capable of producing a return of at least 500 per annum. Further particulars will shortly be published and may in the meantime be obtained of Messrs. CREW & LEST, Solicitors, 10, Gray's Inn-square, W.C.; Messrs. NEWBY, RICHMOND, & WATSON, Solicitors, Stockton-on-Tees; and of Messrs. BEADLE, 25, Green-abchurch, E.C.

**TO CONTRACTORS, BUILDERS, and OTHERS.**—IMPORTANT SALE of RAILWAY PLANS.—To be sold by Public Auction, on MONDAY, the 11th day of APRIL next, and before the close of the remaining extensive PLANT employed in the construction of the Government. New York and Fenwick Railway, a leading Contractor, Bank and other Low-motive Engines; a large number of earth wagons, yard wagons, double cars, quarry and detour cars, and other machinery, including and between, and temporary sleepers, bolts, chairs, blocks, tools, &c.—Printed descriptive Catalogue will be ready seven days prior to the day of sale, and may be had gratis on application to the Auctioneer, Mr. JOHN JACKSON, Fenwick; or at the Offices of Messrs. GEORGE BOUTON & SON, in Fenwick, Newcastle, or Cockermouth.

**To Timber Merchants and Government Contractors.**—Extensive Sale of Large Navy Oak, with top, top, and bark; also Larch and Spruce Timber, standing on the Kirby Estate, Inskip, and on the Fenwick Estate, Fenwick, near Newcastle. **MESSRS. ALEX. DAVIS & T. PALMER** are honored with instructions from Captain Butler, to Sell, by Auction, the above Timber, at the Rooms of Messrs. Messrs. ALEX. DAVIS & T. PALMER, 77, N. B. OAKS, standing on Midden Court Farm, near Fenwick. The above timber is subject to good orders. That at Kirby being near the Kintyre Wharf and Station, most convenient for water or railway carriage, ship builders, and timber merchants, to the above Sale, the timber being of large yard measure, of superior quality, and is admirably adapted for government and shipping purposes.—Catalogue, with full particulars, reservations, and conditions of sale, may be had on application, of the Clerk of the Gardner at Kirby House, and JAMES GREEN, East Moor, DAVIS & PALMER, Auctioneers, Fenwick, Lands and Timber surveyors, and Estate Agents, Market Place, Newbury, Berks.

**To Paper-stainers, Decorators, Builders, and Others.** **MR. J. HONISS** has been favoured with instructions from the Inspector in the Office of Mr. J. M. Gairdner, to Sell, by PUBLIC AUCTION, on the PREMISES, on TUESDAY, APRIL 15, and following days, at TWELVE o'clock, P.M., the whole of the stock of French and English PAPER, including all the stock of the first manufacturers in Paris; and also 50,000 pieces of Raglin paper, borders, &c., all of which are of the best quality, and of various sizes, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press, printing, and metal-pressing machinery, and all the necessary tools, and a great number of which are quite new; and all the metal and valuable tools, such as galleys, rollers, and other printing and book-binding machinery, with all the necessary books, letter-press,

# The Builder.

VOL. XXIII.—No. 1159.

A Note of Warning.—Plague in a Pit Village.

THE practical way to prevent the dreaded Russian fever fastening on any portion of Great Britain and spreading amongst the inhabitants, will be for the several State and local authorities to take time by the forelock. "A stitch-in-time" policy will be better than "waiting until something turns up." What are the officials at the Local Government Act Office doing? The reply may be "Nothing; because Government has transferred the power of action to the Privy Council." Doctors may visit the seats of the disease in Russia, and write most ably on the appearances of the fever and means of cure adopted or recommended in that country; but such expenditure of public money will do nothing to prevent the seeds of disease developing in this country, if wafted over by any means into fitting

localities in some of our dirty sea-port towns. Preventive works may now be commenced and carried out to the greatest advantage, and an expenditure of public money for that purpose will be true economy under any contingencies. Town councils, boards of guardians, town committees, local boards of health, and others should, at once, cause inspection to be made, and then immediately remove accumulations of foul matter from the vicinity of human dwellings. Cesspits should be emptied and disinfected; yards behind slaughter-houses cleansed; refuse-heaps in lanes, yards, courts, and waste grounds disinfected and removed; stagnant water drained; foul ditches disinfected, cleansed, deepened, and, if practicable, sewered or drained. Dirty courts and houses should be cleansed and lime-washed; ventilation be provided; overcrowding prevented; and an immediate removal of fever cases to hospitals be insisted upon. Dead bodies should be buried under such regulations as prevail in France. Fever, plague, or other form of pestilence may then be kept under, if all previous experience in this direction do not prove fallacious, which we have no reason to anticipate. Boards of guardians and local boards of health ought to remember that sickness, in excess, is the heaviest form of rate a poor man can suffer under. Now is the time for action,—now, before the heat of summer is added to other exciting causes of pestilence. Those who have read the pages of the *Builder* know that the crowded parts of our cities, towns, and villages do require this immediate attention and cleansing.

Let us give another instance recently brought

under our observation. This is a case of a pit-village containing about 140 back-to-back dwelling-houses, planted down close to a colliery, when first started by a company, without pathways, drains, privies, water provision, or any sanitary forethought whatever; and beyond the limits of the jurisdiction of the nearest local Board of Health. The site of this pit-village is flat, and it has a clay subsoil: it lies about a mile west from the bracing seashore on the Northumbrian coast, in the township of Haxley, near Warkworth. With the exception of a very few double-roomed houses near the pit, these dwellings consist of but one room on the ground-floor, 8 ft. 6 in. high, and about 16 ft. square, a tiny pantry, and a low attic: about 25 ft. or 30 ft. from every door is an ash or ordure heap; and at about 40 yards' distance a row of piggeries in corresponding number. The houses are built back-to-back, he it remembered, in two long rows running at rough right-angles with one another; and, besides these principal rows, there are two much smaller blocks at some distance from them.\* This village is now inhabited by a population of 633 persons, among whom typhus and small-pox have been working their will during the last twelve months, to an extent of 194 cases, 21 of which have been fatal. The absence of paving and draining causes the whole village to be a sheet of mud in wet weather, a state of things which has called into use a set of stepping-stones, or a cinder ridgeway at every door. One house near the pit has a privy: the rest of the inhabitants, 700 in number, are destitute of that convenience. We are forced to speak plainly. Nice people must skip it. The water used by some of the residents is a stream running in a mddy-bottomed open ditch, which goes altogether dry in summer; a dirty pool by the roadside is the resource of others; and those families nearest the pumping-engine use what they call steam-water, from a jet for condensing the steam.

The difficulty of this case is, that the expenditure required to place the village on a sanitary basis would exhaust, figuratively, the resources of the pit itself; and that it is scarcely fair to expect the present lessee to repair every omission of his predecessors, more especially as an endeavour has been shown to effect as much good as could be realized by the erection of a school-house, now duly attended by 157 children, and of a library. Without, however, a pecuniary sacrifice is made in some quarter or other, the human sacrifice will continue to recur with Dahomeyan persistency.

The only local authority to which this fever-breeding centre is amenable is that of the guardians of the Alnwick Union. On the occurrence of a former visitation, the lamentable state of the place was brought to the notice of this Board by the district overseer, on account of the increase of parochial relief required by the sick families. An inspector of nuisances, the local police inspector, under the direction of Major Brown, chief constable of the police, was deputed to inquire more particularly into the matter, and ordered to make a report. When this was furnished, detailing the facts mentioned above, with the addition that the trackways before the houses were higher than the floors, causing them to be constantly damp and flooded in wet weather, it was forwarded to the lessee, with an order for him to attend to the requirements of the case. No notice was taken of this communication. The Board then applied to the justices for an order empowering them to execute the necessary work and charge the lessee with the cost, if he did not take it in hand immediately. When this order was served upon the lessee he appeared before the Board with a deprecatory answer, to the effect that it was beyond his means to cleanse, pave, drain, privy, and water the place; but he

\* A sketch of a similar pit-row will be found in our vol. xii. p. 721.

agreed to do what he could towards it, and asked the guardians to appoint one of their own body to overlook the sanitary requisites he intended to effect, the most particular of which was understood to be the removal of the enormous mass of offal, ordure, and cinders which raised the trackways before the doors higher than the floors. The Board complied with this proposition, and placed the supervision in the hands of a gentleman residing near the spot, with instructions to him to report progress. No more was heard of the matter till the startling fact came to light of the mortality and disease given above. It was then found that the removal of the accumulated soil and cinders from before the doors had left a substratum of retentive clay exposed, which, far from improving the cleanliness of the place, had made it worse; that the 157 children at school were unprovided with a privy; and, with one exception, that there was not such a convenience in the settlement; that the water used was either ditch water or pool water, contaminated by ordure, or the pumping-engine water; and that the whole place was in a disastrous condition.

The guardians, having no surveyor of their own, obtained the services of the surveyor of the Alnwick Local Board of Health, and despatched him to make a practical and faithful report. This officer condemned the partial measures taken by the lessee as totally inadequate to meet the seriousness of the responsibility. After detailing the inefficiency of the slight drainage that has been attempted at one place, he remarks:—"The water is very bad. Some use water got from the pumping-engine (I understand it is from the jet for condensing the steam—they call it steam-water), and it is worth notice that fever has not been so prevalent among the families using steam-water as others; but most of the people get water from a brook or open ditch, which rises somewhere about Togston and runs past on the south side of the village, and thence on to the sea near Bonny Car. This ditch goes dry during the summer months, has little fall, a muddy bottom, and altogether a dirty appearance. About one-third of the people get their water from a pool above where the road leading to Morpeth crosses. About half-way down, and on the east side of the lane leading from the houses to the ditch, there is a conduit discharging dark-coloured water, which falls into the ditch. . . . We saw night-soil in different places in the ditch, and close to the water's edge; and during easterly winds the sewage waters will be blown upwards and mix with the water in the pool that is taken away for use. . . . There is a house near the pit which has a privy attached: with this exception there is not a water-closet or privy in the place, and the *fit* is a necessity. One woman, who has a husband and four children, had a remarkably clean house: on being asked how they managed to preserve decency without a privy, she pointed significantly to the pantry, saying, 'There we do all, and empty at night.' . . . I asked the schoolmaster how the children do to preserve decency when they have to go out. He replied that he did not know what they did nor where they went to. . . There have been nearly 200 fever cases during the last twelve months, out of which number about twenty died. . . . Mr. Robson states that the place is never free from fever and kindred diseases. Dr. West states that there are some cases of typhus fever just now, and considers the inefficient drainage and bad water the chief causes of disease. Thomas Redpath states, that during the last winter the mud was ankle-deep in front of the cottages. . . . Fever and diarrhoea prevail to an alarming extent; the place as we now see it is a hotbed for disease and the cause of death. Something should be done without delay to remedy this state of things, or the neglect may entail serious consequence

both to the inhabitants and also, by contagion, to the people of the surrounding districts."

We enter thus fully into this case as an instance of the difficulties sanitary reform has to combat. If a legislative enactment existed which prohibited lessees from running up such plague-generating hovels upon the surface of the spot of green earth they intend to hore into for mining purposes, the evil would not be created. But as this prevention is not in force, we must look to the best mode of care. Some extra authority is evidently required.

A significant fact has been ascertained, which is in accordance with experience. It consists in the circumstance that the families avoiding the ditch and pool water escaped. This would appear to furnish a key to some of the misery, and at the same time to suggest a cure that would not be of ruinous cost. Let the whole village have the privilege of using the water that has not the property of injuring the health of those who partake of it. The pumping-engine lifts 600 gallons of water per minute from the pit. Let this be filtered and conveyed by pipe to places convenient for all.

It very often happens that a task is unattempted because it has too herculean an aspect. In the present instance, it is apparent that the simple step here recommended and disentangled from less pressing requirements would not cost a king's ransom. The auxiliary accommodations may require some little effort; but the health-destroying waters should be abandoned at once.

Once more we say, let England be warned in time.

#### LESLIE AND TAYLOR'S SIR JOSHUA REYNOLDS.\*

Of the twin or compound authors of these long-looked-for and really welcome volumes, a few words seem necessary by way of introduction. Mr. Leslie was one of five painters born in America and settling in London, who acquired academic honours in the Royal Academy of Arts in London. Benjamin West was the first to cross the Atlantic and make London his home. West became the second President of the Royal Academy. His "well-balanced" "Death of Wolfe"—parly through Woollett's inimitable graver—more than preserves his name. Copley followed West; and two pictures of glorious deaths—those of Chatham and Major Penrose—perpetuate his excellence in his art. West and Copley were followed to a trio of clever men, Newton, and Allston—a trio of clever men, Newton and Allston died young. Leslie lived to paint many pictures of great excellence, known and admired by all who are acquainted with the noble request and gifts of Robert Vernon and John Sheepshanks to London—i.e., the world.

Of these five American artists who made England the country of their adoption, and loved the country they sought, West was illiterate; Copley (not so illiterate) was the father of the great Lord Chancellor Lyndhurst; Newton (with a very fine eye for colour) was more than a tuft-hunter; Allston was an accomplished poet; and Leslie, besides some printed lectures on art (marked with good sense), was the author of a quarto Life of his friend John Constable, the painter, in which the merits of that painter, and they were many,—are cleverly, and, as some think, unduly extolled; why, when, and wherefore (unless Washington Irving betrayed and misled him), Leslie (we drop Misteralbera a great name) thought he was fit for a "Life of Sir Joshua" it would be idle to inquire. A literary reputation seems to have been always dear to a painter; Reynolds sought it and obtained it; and his reputation as an author stands deservedly high in English literature. He knew, as all very great men know, wherein his weaknesses lay; and he knew, no man knew better, how to make good what he had not. To hope to have the whole of a full-length, robes and ermine, seals and naces, finished by a great painter, is as hopeless to ask or look for as a Laocoon or an Apollo—quarried, rough-bewed, chiselled, tooled, filed, coloured, and paid for—à la Gibson.

What Reynolds has obtained and will retain (seemingly absolutely and without dispute), Benjamin West, who in a letter to Chantrey called him "a sculpture," did not seek,—Lawrence, with Wiltshire wisdom, did not seek. Sir Martin Shee (his Sir Thomas Munro will preserve

his name) was an accomplished gentleman—half a poet and half a wit. Sir Charles Eastlake, it has been said (with some sarcasm and with greater truth), brought more than Fuseli literature,—into a wing at least of Somerset House and the east end of Trafalgar-square.

There are several "Lives" of Sir Joshua. That by Northcote, his pupil, is the most ambitious; that by Allan Cunningham (who was a boy of eight at Reynolds's death) is the most able and, to our thinking, still the most truthful; Chantrey-touched here and there, perhaps, with a little asperity, for the sake of what artists would call light and shade, but bearing throughout a skill in composition and in observation of life and character that commanded and called forth the admiration of Southey. In one hundred and fourteen pages of a pocket volume, Mr. Cunningham managed, and with ease, to present a miniature full-length of Sir Joshua, both as a painter and a man.

The desperate hooks, slashing Bentley hooks," meant to distinguish Mr. Leslie's labours from Mr. Tom Taylor's labours in the bulky volumes before us, are not always, we are sorry to say, distinguishable, and remind us of the hooks with which Mr. Wilson Croker, in the first edition of his "Boswell," puzzled and perplexed and provoked the eyes of so many critics, quarterly and weekly, from Lord Macaulay upwards to Mr. Anonymous downwards. In what we have to say, we shall labour to keep our twin authors apart, and we trust successfully.

We wish we could have seen from an author too little appreciated by Mr. Leslie and Mr. Taylor this fine passage in these volumes:—

"How painting has rekindled from its embers, the works of many living artists demonstrate. The prints after the works of Sir Joshua Reynolds have spread his fame to Italy, where they have not at present a single painter that can pretend to rival an imagination so fertile, that the attitudes of his portraits are as various as those of history. In what age were paternal despair and the horrors of death pronounced with more expressive accents than in his picture of Count Ugolino? Where infantine loveliness, or emphyrio passions touched with sweeter truth than in his portraits of Miss Price and the baby Jupiter?"—*Horace Walpole.*

Sixteen pages of commemorative quotations from "Poets and Prosemen" might have heralded in these volumes with great advantage.

Mr. Taylor tells us (perhaps it is Mr. Leslie) that of hachelor Sir Joshua's two nieces,—in whose honours they found a Martha and Theresa Bonlatasyon,—"Offy Palmer" was the favourite. They were charming Devonshire girls, we read and have heard, who knew good London society through their uncle Sir Joshua, and who were not unremembered by dear uncle in his "will." Read this hitherto unprinted (Mr. Taylor tells us) letter from the president painter of the Waldegrave girls (a 5,000,—not 800!—picture any day), and a "letter" (congratulatory), far above, in simplicity and feeling, that which Alexander Pope, of the "Rape of the Lock," wrote to Arabella Fermor on her marriage:—

"To Miss Palmer, at Mrs. Bunsbury's, Borton."

My dear Office,—I set out to-morrow for Blenheim. I had some thoughts of bringing you to town, as it coincided with a very pressing invitation which I had from Lord Granby to pass some days at Chiveley; but, receiving at the same time a letter that I was expected at Blenheim, that scheme is at an end; and how you will come to town the Lord knows. In regard to our separation, I feel exactly as you have expressed yourself. You say you are perfectly happy where you are, from the kindness and civility of your hostess and Miss Horneck, and only wish to see us. We wish likewise to see you, at the same time that we are perfectly well contented with your absence, when it is in a family which will somewhat contribute to confirm by habit those principles in which you have been educated, those principles in which you thought are infinitely beyond all precepts, which go into one ear and out at the other. I never was so great friend to the efficacy of precept, nor a great professor of love and affection, and therefore I never told you how much I loved you, for fear you should grow saucy upon it.

I have got a ring and a bracelet of my own picture; don't you tell your sister that I have given you your choice.

My compliments to all the family, and remain, Dear Office, your affectionate uncle,  
J. REYNOLDS.

The pictures of Sir Joshua—and there are a thousand and odd genuine (at least)—are known

so well to all who love art, and have means to travel; and so much "Correggio and stuff" have been talked-and-written about them (these volumes have a rag-tag and bob-tail about them), that we shall not be expected to discourse or lecture, or waste our readers' time upon Sir Joshua's position in art. Words cannot compare him with his great predecessors, Titian, Velasquez, and Vandyck; it would be waste of time to contrast him with his little successors, Lawrence and Hopper, Owen and Phillips, Raeburn and Gordon, and Shee and—Albemarle-street catalogues can alone tell us who.

Mr. Tom Taylor, Mr. Leslie's adopted executor, and literary executor in these volumes, is deservedly known to the public as the editor of erratic, enthusiastic "Haydon's Journals,"—better still as a skilled contributor to the stage, and as a critic on pictures,—quick to see and point out merit, prompt to perceive and to condemn defects. A "Life of Sir Joshua" in such "company" pens was sure to prove not a Sternhold & Hopkins affair, but a Deamont & Fletcher performance, and such, we are pleased to say, we find it.

That Reynolds, in his "Discourses" was under obligations to Johnson (up to 1784, when Johnson died), and to Burke finally, is a noble proof of his discernment in seeking and obtaining assistance where assistance should be sought and was gained. The real or supposed "secrecy" of the Royal Academy has done much to injure the great name of the founder of the Academy: would Sir Joshua's "hero" Johnson (the more to be admired, therefore, have submitted his "Vanities of Human Wishes" or his "Lives" to "forty" poets in his "Essex Street," or fifty prosemen in his "Gerard Street," Clubs? No! not he.

The reputation of Reynolds in art is accepted, his position in literature is different.

What his pupils did for his Pencil is utterly inimitable. There was no head-work—merely hand-work in what they did. What his friends did for his inimitable "Discourses" is a different matter, has caused much controversy, and is little understood.

We will attempt to throw a light on the subject, in a little way assisted by thirty years, we can after a careful inquiry of thirty years, we can throw some upon it. Reynolds (more to his honour than to his credit, who does not?—his "Discourses," and could "a Royal Academy" examination in them) made memoranda wherever he went: his "Elanders Tour Notes" are examples for all who travel with Sir Henry Wotton's advice to Milton—"Thoughts close and looks loose" in their way they are unequalled: connoisseurs abide by them; picture-dealers "bid" by them.

We appeal confidently to Messrs. Christie & Manson, and to Mr. Henry Farrer (those "invaluable" men), in proof of what we state. Mr. Murray's many-handed "Handbookers" quote them, with skill and taste; and they are supreme above all the Academy has ever given us, or seems likely to give.

The question of Reynolds's skill with the pen may, perhaps, be tested by examining the famous Sir Joshua letter of resignation (vol. 1, p. 167), Mr. Sandby's recent "History of the Royal Academy" with the version of the same letter which Messrs. Leslie & Taylor give us (vol. ii, p. 555). How in a copy of a "notelet" so many discrepancies could or can occur we are utterly at a loss to know. Perhaps the Professor of Ancient or Modern (if there is such an office) literature, in Trafalgar-square, will tell us.

Careful commentator and annotator, read Messrs. Leslie & Taylor's copy of Sir Joshua's farewell letter to Michelangelo at Somerset House, with Mr. Sandby's previously printed variations from it. The Sandby variations are here in brackets.

"To the Secretary of the Royal Academy of Arts. Leicester-fields, February 23 [22], 1790.

Sir,—I beg you would [will] inform the council, which I understand meet this evening, with my fixed resolution of resigning the Presidency of the Royal Academy, and consequently my seat as an Academician. As I can no longer be of any use [service] to the Academy as President, it would be still less in my power in a subordinate situation. I therefore [now] take my [final] leave of the Academy, with my sincere good wishes for its prosperity, and with all due respect to its members.

I am, Sir, your most humble servant,  
JOSHUA REYNOLDS.

Sandby's version final is determined, and is doubtless, correct. We shall return to those volumes in a suggestive and congratulatory mood.

\* "Life and Times of Sir Joshua Reynolds: with Notices of some of his Contemporaries." Commenced by Charles Robert Leslie, R.A.; continued and concluded by Tom Taylor, M.A. 2 vols. Murray.

**THE IMPROVEMENTS IN PARIS: THE QUESTION OF THEIR IMPORTANCE IN THE VIEW OF THE INCREASING MORTALITY OF LONDON.**

At different times during the last few years, we have drawn our readers' attention to the statistics of the mortality of London and Paris placed in comparison, believing that the figures so viewed would be found to deserve attention, and possibly to suggest particular measures to be taken for the diminution of the mortality of London. In our last volume, under the same heading as that which is here prefixed, we gave the mortality of Paris during each of the years, 1850, 1861, and 1862, per thousand of the living, as calculated upon data of the population which do not admit of dispute, and upon the positive returns of the number of deaths, and compared it with the mortality of London as stated by the Registrar-General; and we also compared the mean mortality of the three years, of the one capital with that of the other.\* As our readers are aware, statistics have been presented from time to time by the municipality of Paris, showing a considerable amelioration in the sanitary condition of that capital in the course of several years past, and demonstrating that the chief gain has been contemporaneous with the formation of the many wide streets and the aeration of the different quarters. But such a comparative statement as we gave had not been made, previously to our own. We found that although in 1860 the rate of mortality of Paris exceeded the London rate by 2.25 (here omitting one of our figures of decimals) per thousand persons living, and though the excess rose to the figure 2.47 in 1861,—a year which was marked by an increase in each capital,—the rate in 1862 became so greatly reduced in the former capital, whilst it was actually increased in the latter, that the excess of Paris over London was reduced to 0.77, or little more than three-fourths of one in the thousand. It is true that the comparison of the mean of the three years in the two capitals, showed an excess of the rate of Paris over the London rate, amounting to 1.83, or somewhat less than two in the thousand; but this result was very different to what the English public had been led to conclude from statements, some of them then recent, which had been based upon inadequate knowledge of facts. At the same time we hinted our opinion that in the comparison of the statistics of the year 1863, corroboration might be looked for of a prediction which we had previously ventured to make, that the sanitary condition of Paris would here long transcend that of our metropolis. Those who remember the mortality of our chief towns will not require to be told that these have long been much less healthy than Paris.

We have now before us the statement of the number of deaths in Paris during the year 1863, given in the "Annuaire" for the present year, published by the "Bureau des Longitudes." The statement for 1864 is not published. We can make, therefore, no comparison for the year 1864; and it is the more important that we should say, as we shall shortly, what are the data that exist for the calculations in each year, since, in the French journals themselves, or at least *La Presse*, a statement of conclusions as established in a "Mémoire" drawn up by M. Deville for the Inspectors of the Verification of Deaths, and lately presented to the Prefect, contained errors, or inasmuch as for 1862 the population manifestly was taken at that of the census of the previous year, whilst the deaths were those of 1862; and the mortality must have been less than the stated one death in forty inhabitants,—not to mention what we shall show to have been probably the facts in 1863. The statement from the French press was inadvertently allowed to appear, without a note, in our number of the 4th of March; but, since the figures of the census of 1861 are, by decree, required to be recognised as solely authentic during five years from the 1st of January, 1862, we are by no means certain that the errors as resulting from that requirement, are not to be found in the original "Mémoire." However, we may here remind our readers that our calculations are based upon an estimate of the population of Paris as increasing each year only one-fifth of the increase in the previous quinquennial period. A similar assumed basis was originally suggested to us by the secretary of the "Bureau de la Statistique" of the Hôtel de Ville, for an estimate of the population in

each year of the last quinquennial period; and, having made use of it prior to 1861, the census of that year showed to us that the facts and the assumption were in remarkable accordance, or from 1856 to 1861 at least. As in England the population in one year of a period from census to census would exceed that of a year of the previous census period, we might fairly suppose the population of Paris to have been subject similarly to the law of progression, especially when we have to take into the account the constant influx of persons of foreign birth. We prefer, however, to take the estimate at the very lowest, for the present; but we ought at the same time to point out that the figures of the number of deaths being those of positive returns, the proportion of deaths is likely to be found less, rather than at all greater, than we have made it.

Though statements of the mortality of Paris are carried back not only to 1856, and to the date of the commencement of the improvements, but to a much earlier period, and may be taken as presenting facts of importance, we prefer not to attempt any comparison for the years prior to 1860, the year of the establishment of the limits of the city as they now exist. It would have been very desirable to compare the mortalities of the two capitals during more years than four, and to take the average of a greater number of years; but to get the population of the *banlieue* of Paris, and its number of deaths, or to get merely figures for the city as before 1860, would require references which in this country, we are not able to make. The population in 1856 of the entire area which now constitutes Paris, as taken in the census, we have in a distinct document to which we referred last year; when we stated that the population of 1856, was 1,525,942, inclusive of the garrison, and that the number in 1861 was 1,696,141,—these figures showing an increase during the five years, of 170,199. Taking one-fifth of this increase, we may say that the increase since 1861 has been 34,039.8 in each year. Thus far as to our data; and the reader will probably conclude that there is no margin of error capable of effecting the substantial accuracy of our comparison, or perhaps deserving the attention which nevertheless we have here given to it.

Subsequently to the publication of the comparison in our last volume, Mr. Tite (some of whose previous assertions had induced us to make the statement of figures) read before the Statistical Section of the British Association, an interesting paper on the mortality of London and Paris; wherein, though he estimated the mortality of the French capital as greater than that of London for the period of ten years from 1853 to 1862, he so far modified his original expression of opinion as to say that there had been a great and marked decrease since 1853, or shortly after the Emperor began to urge upon the City the necessity of making better provision for sewerage, water-supply, street-aeration, and other improvements, and that the difference in the rates of mortality of late years had been very slight. We do not question the accuracy of Mr. Tite's conclusion as to his period of ten years; though we should have been glad to be informed of his data,—since he confesses to similar difficulties to those we have experienced. But the facts which will be brought out by a comparison of the mortality of Paris and London, during the period of only four years to which we have alluded, and those of the present mortality of London, are such as require to be stated; for, they tend to show that in the latter capital progress is not just now being made in the amelioration of public health, similar to that in Paris, and to substantiate our view that on the expiration of a period of ten years hence, a better position sanitarily will be found reached in the capital of France, than in that of Great Britain.

Our anticipation that the mortality of Paris of 1863, would be found below that of London in the same year, is now shown to have been correct; and in 1864 (for which year, as already stated, we have not the deaths for Paris) the mortality of London had increased about two in the thousand beyond that of 1863, or so as to make it greater than it has been for ten years. In fact, during the last five years, the mortality of London has been steadily increasing; and the greatest increase in any year is that which took place in 1864, when the deaths were 26.45 in the thousand; having been in the previous year, 1863, 24.47.

After the paper "On the Municipal Organization of Paris, particularly with regard to the

Public Works," read by Mr. G. R. Burnell at the Society of Arts, on the 22nd of February, the Chairman, Mr. W. Hawes, in the course of his speech, made some remarks (reported in the Society's Journal, but not in our pages) which embody expression of the common view of the immense superiority of London in sanitary matters, one which will be here shown to require qualification. Mr. Hawes is reported to have said,—

"There was one observation in the paper which he did not think the facts brought before them justified. It was to the effect that Paris had gained in everything, that tends 'to make life valuable' in large towns. What had Paris gained? Some very remarkable streets and a great deal of elegant architecture. But let them see also what it had lost. Notwithstanding all the improvements in Paris, the sanitary condition of that city was inferior to that of London. How was that to be accounted for if London deserved the amount of abuse heaped on it? The real fact was that the health of the poorer classes was cared for in a higher degree in London than in Paris."

The reader has already been placed in a position for judging how far such general assertions of the superiority of the sanitary condition of London are to be relied on. We need not repeat the comparison for the two capitals, for 1860, 1861, or 1862,—that is, separating the years; it will be found in the article in our last volume; and the conclusions are stated above. But we will give the comparison for 1863 separately. The population of Paris, in the year, is to be estimated as that of 1861 (or the number 1,696,141), plus the number 68,060 for the years 1862 and 1863 together,—this latter number being two-fifths of the increase from 1856 to 1861. The sum, 1,764,221, is the population of Paris on the 31st December, 1863, as estimated, but in a manner which is based on previous facts. The deaths are taken as given in the "Annuaire" of the "Bureau des Longitudes," where they are stated as 42,582. The mortality for London is quoted from the Registrar-General's Summary of Weekly Returns, dated the 18th of February last, only altering the position of the decimal point to obtain the comparison per thousand. The figures differ slightly from those in our last year's article, obtained from the former Summary; and, annually, the latest figures undergo correction. The result then is as under:—

In 1863 —	Per Thousand.
In London, the deaths were at the rate of .....	24.47
In Paris (including the garrison, which appears to be very healthy), they were .....	24.13
Thus the rate of London mortality exceeded the Paris rate .....	0.34

Of the Paris rate in 1864, as we have said, we have no knowledge; but the London rate is shown by the "Summary" to have increased from 24.47 to 26.45 as already mentioned; and it is known that this year there has been a large increase in cases of zymotic disease, as typhus fever.

Assuming that it be considered unsafe to judge by single years,—though there is yet considerable importance in the facts as at present, of the progression of Paris, and the contrary tendency of London,—we append the comparison of the averages of four years. The comparison which we made in our last volume, for three years, showed an excess of mortality of Paris over London, of 1.836 in a thousand.

In 1860, 1861, 1862, 1863 —	Per Thousand.
In Paris:—	1860 = 21.745
1861 = 23.694	
1862 = 24.938	
1863 = 24.136	
98.575 ÷ 4 = 24.718	mean of the four years.
In London:—	Per Thousand.
1860 = 22.490	
1861 = 23.189	
1862 = 23.300	
1863 = 24.470	
93.700 ÷ 4 = 23.425	do.
Excess of the rate of mortality of Paris, per thousand, over the London rate .....	1.293 do.

Either way of making the comparison, there has been a reduction in the mortality of Paris, and an increase in that of London; and neither present circumstances, nor the actual prospect, are such as should satisfy us.

The improved water-supply, for which the works are now in active progress, will tend vastly to ameliorate the sanitary condition of the French capital. The supply for purposes of ablution is by no means so defective as has been represented; whilst a large quantity of water is used for street-cleansing; but there is no question

\* Vol. xxii., 1864, March 5th, page 161.

that the absence of a high-service by pipes in the houses, is a serious evil. The deficiency causes stench within the houses, and similar stench during some months of the year in the streets, from house-drains crossing the footways. But not to mention the now extensive aëration of every quarter of Paris, the street-cleansing, contrasting so much with the flagrant neglect in London, the air not so much impregnated with "carbonaceous particles," and even better light, must be largely operative in diminished mortality. The report of the Registrar-General, written whilst Londoners were wallowing through what was called a "mud-ocean," adverted to one form of dirty streets, affecting mortality; but another has come in with the hot weather. During the last fortnight, the stench from triturated horse-dung and other offensive matter, has been worse than any of the stenches of the streets of Paris. Washing the streets, as in the French capital, there is none; and it would be hard to say that there is any scavenging. The inattention to street-cleansing must be one cause of the mortality of which mention has been made. Also, it may be observed, the retention of refuse for long periods, in back-yards and cellars, which is the London practice, must have much to do with the rate of mortality. The Paris system, of depositing such refuse at night-time in the streets, may be attended with inconvenience to those who are out at late hours, and who stumble over a heap of broken crockery; but the streets, each morning, are divested of every straw and speck, and presented clear and clean as we never see the streets of this metropolis. Both the eyes and the nose get used to various abominations; but it is probable that those in London are no less injurious than the sights and smells elsewhere, which are offensive because they are new.

#### DECORATION AS A HANDMAID TO ARCHITECTURE.

##### THE ARCHITECTURAL MUSEUM.

A LECTURE was delivered on Tuesday evening last before the members of the Architectural Museum, in the theatre of the South Kensington Museum, by the very Rev. Canon Rock, D.D., subject, "Decoration as a Handmaid to Architecture."

The lecturer said, he presumed that those who heard him had occasionally met some individual who had an odd custom of talking to himself,—of thinking aloud, and not unfrequently upon subjects with which he was not very conversant, and regardless of the persons near him, and forgetful of the place in which he was. He was very much in that position there, being, so to say, a mere layman in architecture and decoration; but, if the parallel went some way, it very soon ceased. He was perfectly conscious of the presence in which he was, and he knew the place on which he stood. There were persons present to whom it would be a pleasure and a profit to him to listen, persons distinguished in constructive architecture and in decorative art. And he was conscious of the place from which he spoke. Often had he listened to instructive lectures delivered from that tribune, by their excellent and worthy president and by other eminent men. He could not forget one circumstance, which made him feel forcibly the place which he occupied. It was but a bare year since his dear friend and old schoolfellow, his Eminence Cardinal Wiseman stood there, and never should he forget the cordial welcome he had received, or the delightful lecture he delivered. He (Dr. Rock) had been invited to deliver a lecture upon ornamentation as a handmaid to architecture. He believed it was Cicero who, speaking of what should constitute a perfect orator, said that oratory required its professor to be a man of great acquisition and vast learning; not only to be conversant with all the ramifications of the twelve tables of the Roman law, but to be thoroughly acquainted with international law, and able to declaim upon any subject that might be proposed to him. The well-informed architect should be something like Cicero's orator. Man in every clime in which his lot is cast, whether in Siberia or in the torrid zone, must have some refuge by day and by night, some place more or less suitable to his own builder, but let a number of men come together, and one would be found to be superior, and he would become a professor of the great art, for such it was, of raising habitations for the others to

reside in. In a great community, magnificent cathedrals, spacious churches, stately palaces, temples of justice, great public buildings, institutions for the poor; jails, unfortunately, and, fortunately for humanity, hospitals; as well as town houses and country houses for the nobility and gentry, and abodes for the poorer classes, were required. The true professor of the great art must not only be acquainted with constructive science, but he must be more or less versed in geology;—whether the soil was or was not wholesome, whether water could be found, whether the climate would admit of the use of certain materials,—and with all this he must be a man of taste. The best architecture was nothing less nor more than ornamented utility. The first thing was to make a building useful so as to meet the material wants of man; but there was more in man than matter: he was a thinking creature, capable of being impressed and influenced by surrounding objects; and the building, along with being useful, should be so constructed and completed as to appeal to the better feelings of man, to make him more joyful when he is joyous, and to soothe his sorrow when in grief. As Christian men they required churches to worship in. Few men were called upon to build cathedrals, and still fewer lived to carry out the commission; but many men were called upon to restore cathedrals. He had some time since had an opportunity of visiting Peterborough Cathedral, and he was happy to say that its restoration, so far as it went, was all that he could desire. One other thing gratified him during his visit. They knew that the vergers of cathedrals, like other men, liked palm oil, and they sometimes followed the visitor about, so that he could not stop opposite a tomb without having to listen to their assistance was impossible. At Peterborough it was different. The vergers were there, no doubt, to afford information when required; but he did not in the least put himself forward, and there were no gates locked, so that a visitor might go through the cathedral, and examine each part of it, without interruption. That was as it should be. Well, if it was not the good fortune of architects to have many cathedrals to build, they had to erect a great many churches. Now, he thought that a church, of all buildings, afforded the greatest field for displaying the capability of uniting the requisite with the ornamental. Pre-eminently the architect should make a church decorated utility. The roofs of churches were capable of being very much improved. Many of them were overlaid with lead; but the great majority were constructed of slate, or the prepared stone called, in the country, "slat." Now, he regarded the use of slate as a very ugly object indeed. A roof of glazed glass which might be sturred, would be far preferable, and, after a shower of rain, would present a beautiful appearance. Then, as to the windows. Frequently architects were allowed to make the windows of a church ornamental by means of small columns, and they used stone for the columns. Why was not marble used? Polished marble would not only be highly ornamental, but would bear the severity of winter and of summer, and be still beautiful after years and years had rolled away. He believed that many kinds of marble might be obtained with facility. There were quarries in Derbyshire and in Devonshire; and a beautiful green marble might be obtained from Connemara. Colour was to be seen everywhere in Nature: why was it not more used for architectural purposes? Inside, churches were usually open-roofed, and in many cases well ornamented. But sometimes there were long ugly pipes to be seen, for hot air and for cold air, which had anything but a pleasing effect. Now, to remedy that, the architect should know a little of natural philosophy. If he went to the Serpentine on a frosty day, he would see how it could be done. There he would see swans breasting the water, and the ice broken to allow them to do so; and yet the breast of a swan was very tender. The secret was that the down held atmospheric air, which was a non-conductor of heat and of cold. How could they apply that principle to the churches? By having two roofs, by which means they would leave a stratum of air between the two; or, in other words, they would have above the congregation that which the swan had on its breast as a protection. And they should remember that for the same reason that the church is too cold in winter, it is too warm in summer, and especially if the blue slates were on it. The remedy he suggested would be a guard against too much heat at one season, and against too much cold

at another. He begged his architectural friends to bear in mind that throughout these suggestions he was only thinking aloud. Now, let them come down a little further into the church. Many of their churches were exceedingly stuffy, and required the windows to be frequently opened, and they were opened by means of cords, which were unsightly affairs. Now, the suggestion he had to offer to get rid of that state of things would not involve much cost, and it would make the architecture of the church be decorated utility. He would have beneath the windows a moulding of such breadth that, though it would not give footing to a Banting, it would admit of a slim youth passing to and fro to open the windows in summer, and to close them effectually in winter, which cords could not do. Another use could be made of it also. He loved to see churches decorated with flowers in the manner he suggested, and he wished that, as of old, times of rejoicing, and he wished that, as of old, the great mysteries of Christianity could be depicted in tapestry, and hung round the church at appropriate seasons. There would then be a celebration of the church's festivals to the eye; not only would the people bear from their preacher that was Christmas or Easter, but the eyes would tell them of it also. This could be easily done, and no doubt there would be willing hearts and kind hands to bring it about. When the festival was over the tapestry could be removed, and facility would be afforded for doing so in the manner he suggested. In another respect the interior of churches could be decorated, and that was by the architect practically showing that he understood the symbols of colours—green the emblem of hope here; blue the emblem of hope of heaven hereafter; red the emblem of burning charity towards the Maker and all mankind. Why were not marbles of these tints used? Then, instead of whitewashed walls, the eye would be arrested by the beauty and harmony of colour. In the heavens above, in the fields, in the woods, on the hills, there is colour: why was it not to be found more than it is now in the House of God? So much for churches. He would now say a word as to buildings for civil employments, and for the purposes of residence. What was said as to cathedrals applied also to palaces: it fell to the lot of very few to build them; but some had been built in their own day, and others would yet be built. There was, for instance, the glorious palace of Westminster, which he was delighted to say was in the Pointed style; for his love was for the Pointed, not for the Classic. It was a very critical and difficult thing for an architect to have to deal with one style in a building, and with another in the decoration,—called upon to do so by his clients. Now, an architect should be not only able to build a house, but to instruct the proprietor of it as to the suitable decorations for it, and as to the furniture and the laying out of the grounds, so that all would correspond with the style. Windsor Castle was built in the Pointed style by the man whose motto was, "Manners make the man;" but he regretted to say that some of the interior restoration, the decorations, and furniture were in the style of the Grand Monarch, and not in that of the building. The decorations to which he alluded were admirably executed, and by English hands, he was thankful to say; but he regretted the style of the building. Speaking of Windsor, he could not forget the exquisite taste of the latest evidences of the Princes Consort. He had a small room fitted up as a surprise for the Queen, in which her Majesty now receives her ministers, and everything was designed by himself, and all in keeping and harmony, even to the hinges and keyholes of the doors. That principle should be more borne in mind by those who had the construction of houses entrusted to them. According to the present rule, if you went into one house in a street, and looked at the ceilings, you would find an ornament in the centre and a moulding all round: go into the next house, and you would find it exactly similar. Then, again, look at the roofs of London houses. Could anything be more ugly than the chimney-pots, with which their eyes were all too familiar? But it might be said, "They draw well." That he denied. If they did, there would be no occasion for the tallboys, which made ugliness still more ugly. Was it to be said that these architects could invent nothing better than the present chimney-pots? He hoped not. What did the men of former days do? Let them go to Eton and see. They would find beautiful chimney-pots there. Even in the old farm-houses of Sussex they would come across chimneys that would

shame the palace chimneys of London. Concerning elevation, he regretted to see our houses so very bald. There was a large surface of wall, but it was left as bald as possible. Then there were segments of circles or bands placed over the windows; but he regarded them as direct architectural falsehoods, as they in effect stated that they went through into the apartment, which was not the fact. They might have mouldings or use glazed tiles to keep the rain from the windows, and in that way arrive again at decorated utility. An architect ought not to think that building a great thing would be the establishing of his fame. He might show his power and his refined and cultivated taste in the artistic treatment of a small building. He never went down Piccadilly without contrasting a very large and a very small building. The one was Buckingham Palace, the other a house of about 20 ft. clear, of two windows in breadth, with small balconies, the front being decorated with two little columns and some nice iron-work. He could not look at it without admiring it. For himself, he would rather be the architect of the small house than of the great palace; there were more talent, more elegance, more taste, more science displayed in the former than in the latter. But in the general run of houses, there seemed to be but one general and-dry rule of ornamentation: the dining-room, for instance, was hung with a dark-red paper, and the chimney-piece was black. Why were dining-rooms made thus dull? He would be told it was the fashion. Why was black marble used? The room was not meant to be a sepulchre; and London fogs were sufficiently darkening and depressing without the aid of dark paper that quenched the light. He should have thought that men on returning home from business would like something cheerful about the apartment in which they took their meal. For his part, he would be for making dining-rooms light and cheerful. He was delighted to observe the love of flowers that was manifested in London. Why, he might be permitted to ask, do not architects avail themselves of that taste? A window-sill was provided for flower-pots, and nothing more; so that, as he knew to his cost,—a gust of wind might blow down a tall geranium, and cause the loss of your plant, your patience, and your money. He believed that little appliances could be furnished for flowers, not only in dining-rooms and drawing-rooms, but higher still; and that in that way the elevation might be relieved of a great deal of its baldness. It was much to be regretted that the houses in which men who had been famous in their day and generation as authors, as artists, as statesmen, as lovers of their kind,—practical philanthropists,—were not so marked that their names would be had in perpetual remembrance. This would have an effect for good upon succeeding generations, and he thought that provision for such things ought to be made by architects in the construction of houses. Great architects did not always, in their own case, carry out the principles which they practised in the case of others. Pugin, hearing of a great robbery in the neighbourhood in which he was about to reside, constructed the windows of his house too narrow, and the doors so low that you had to stoop to get in. The architects of the present day, however, should rejoice that they had such a man to go before them. When he (Dr. Rock) first knew Pugin, Painted architecture was little better than Carpenters' Gothic. The country was overrun with frightful specimens of the Painted style. Pugin had to encounter great difficulties; but he overcame them all; and he was not only able to advise his clients with respect to the decoration and garnishing of every part of the decoration and the furniture, and even as to the plate that would best suit it. He did a great and a good work, and they might well say,

"Lie softly on him, Earth, for he  
Laid many a fair and holy pile on thee!"

He (Dr. Rock) hoped the day was not far distant when they would witness a great revolution in their street architecture. Let them imagine a sick man coming, depressed in spirit, out of a dark dining-room, walking out for recreation, and turning down Harley-street! There was nothing there to appeal to the inner man; nothing was to be seen but walls of bricks, with holes for windows and holes for doors. How different it was in the olden time, when, if they had not stately houses in profusion, they had houses which were picturesque and pleasant to

look upon. That was not the case now. A man buys a piece of ground, and he studs it over with house after house, all of the same pattern, and with a total disregard of the first lesson of beauty,—a beautiful sky-line. Each house ought to be a little gem of architecture, and the houses in our squares ought to be noble edifices. This might yet be brought about; and such a society as the Architectural Museum was calculated to give great aid in the good movement. It would create and spread a taste for something better, something more beautiful; and taste worked downwards as well as upwards. He believed that a better spirit was abroad,—a spirit that gave them reason to hope that the day of indifference to art was passing away, and that the time was approaching when decorated utility would be the rule, and not the exception.

#### THE PRESIDENCY OF THE INSTITUTE.

A GREAT deal of anxiety is expressed on all hands as to the results of the present disputes. It is held very strongly by a numerous body of the members, irrespective of party, as by us, that a professional president ought to be appointed; and it is understood that Mr. Tite has in the press a powerful appeal in favour of this view, and urging the election of Mr. Scott, or, if he declines, Mr. Salvin. It is impossible to question the disinterestedness of such an appeal, if it is to be recognised as the act of what we may call the Eclectic party. We are informed, moreover, that overtures have been made towards the negotiation of some friendly basis of compromise; and all true friends of the profession and the Institute would, no doubt, be glad to learn that such a measure had been successful.

Of all professions at the present day, architects surely require to remember the trite maxim that "union is strength" and nothing can be more fatal to the common good than anything like partisan violence. A fair competition of rival opinions for public favour is not to be discouraged; but the moment this ripens into unfriendly discord, it is time for all wise men to pause and reflect. Like a goodly house, the Institute has taken many years to build and decorate and finish; but if the foundation give way, what then? A few ill-advised friends have certainly made an ugly dig or two at it lately.

#### THE PRESIDENCY OF THE INSTITUTE.

##### THE POSITION OF ARCHITECTURE.

SIR,—I am not, and never have been, at all interested in professional differences; but the great question now before the Institute is, I think, so important, and involves so vital a principle, that I cannot forbear to trouble you with a very few lines about it. What I have to say does not appear to have occurred to any one of those engaged in this momentous difference. If I mistake not, your own view will be found to be, in the long run, the wisest. I cannot help, too, feeling a little personal interest in it, as I have been all my life dreaming of art-principles, which, if those who think in opposition to yourself are right, must be entirely and wholly wrong.

I think myself that art generally, and architecture more particularly, has just now sunk to the very lowest possible point it ever has or can sink to; for must it not strike every one, whatever style he may practise, with astonishment, if he but consider it a moment thoughtfully, that the Institute, as the body above all others representative of architecture as a fine art, does not in any way afford to the public evidence of the personal art power, whether in kind or degree, of its members who compose it? If any one should be curious as to the special art faculty and method of work and "style of stone painting" of any particular member of that body, he could not get it, for it does not exist; he must refer to the work of some outside body,—to the assistants or draughtsmen,—for actual specimens of such art-work. In short, in the place of individual and personal art power and architectural fine art, he can get only architectural manufacture. I think this has never before; for, consequent on this complete change in the method of architectural art-production, architecture as a fine art,—as a personal, mental, and hand-and-foot equal to painting,—is now simply extinct. Cockerell was the last of

his race. The headship of such a profession has now no real and true meaning in fine art, for it is the headship of a system of manufacture, not of art. The art signatures are false, and the actual handwriting that of others, whether good or bad, rough or delicate. Is not this a very extraordinary thing? Pugin, Barry, and Cockerell are all gone, and have no successor!

I would, in passing, here ask whether some of us who are not blind to this, would not be fully justified,—indeed, are we not called on,—to attempt the formation of a new Art-Society, which shall demand of its members, individually, some evidence of their personal art-producing powers, as the painters—and the painters only—of the Academy are compelled to afford, and that their art-power as artists should be made evident to the public mind, and should personally work out its own ideas; to exhibit, in short, that same power seen in such works as the details of the Bridgewater House and the Sun Fire Office. If architecture be nothing but a mere manufacture, which any one, learned or ignorant, may practise at will through others, then, I say, it is not worth a further thought; and is, in reality, no fine art at all, but a business.

But, that I may not lengthen this letter, suppose that the Institute were now to ask, as one of its absolute requirements of membership, constant evidence, in future buildings, recognised by it, of this personal impression of architectural power, first in drawing and then in material. I ask, would it be possible for such a body of men as such architectural artists must be, to get anything from what is called the lay element? Would not such a body regard lay talking as presumptuous impertinence? It can never teach, for it knows nothing; it cannot appreciate or select; it can only listen. It cannot even learn, for to learn architecture, as we were lately told by Mr. Scott,—the head of the profession,—requires now an amount of practice, skill, and time, and acquired accomplishments, which the greatest artists of the past never could have dreamed of. Mr. Scott says, "Let us have the lay element for this once." So I say; a better time could not have been chosen; for the real natural and life-giving power being given up to assistants, and consequently extinct, it can matter but little who it is that heads such a body, doing its work in the way it does. But I would respectfully ask any one here, is not such a system in the long run absolutely destructive? Does it not, not only destroy professional capacity, but the very fine art itself? Is it not to destroy the Institute as the embodiment of a great professional and art idea? I think myself that the time will come when, what has been said by Professor Donaldson and yourself will be found to come literally true, and that the wisest policy in these days is and must be a liberal and fair one, and one of fine art and professional knowledge and acumen; and that no greater calamity can happen to any Society, an Art-Society particularly, than to abandon wilfully, or even to forget, its true vocation, its professional work, and to cease to ask for guidance, and to accept patronage of whatever kind in the place of it.

I cannot, too, help feeling grateful to the Institute for some past favours, and should be sorry to see it all narrowed down to a little sectarian fancy, utterly worthless in itself; for no greater delusion can be entertained than that of supposing that Gothic architecture and art, as now practised, will or can be accepted by the public as the art idea of the future. Nature never repeats herself: the Gothic of Medievalism is dead and cannot be revived; its attempted—possible—copying, is all that is now or can be possible—and that only in churches, the result of accident. When the Gothic died the thread broke, and it cannot be again tied. The real strength with the public lies in what may be termed, for convenience sake, *Modern Renaissance*, and for which the line has not been broken; thin and weak it may be, and is, but it is still an unbroken thread, acknowledged by the public and made use of and already accepted by the public mind. It is its direction only that needs a master mind and hand. The Classic side have nothing to fear; a single sentence would seal the fate as a principle of modern Gothic.

I will add but one more word, shortly and simply. I think the lay presidency will sink architecture to the lowest point it can possibly go to. I hope it will rouse up a new effort and idea in art and architecture, as I cannot help thinking it will. In these darkest days of art action, abandoned as it is to underlings, it will cause us to look more gratefully than ever to the

Royal Academy for the truly wonderful and manifold it has made against this final art attack. It has, as all know, for ever rejected the lay element,—will not accept paintings by the hands of assistants, with the names only of its members in their corners; and thus has it bridged over, as it were, the art quagmire the world is now in, and will at least convey to the future the fact, that the need of *art signature and knowledge* has not, even in these days, been wholly abandoned as needless and foolish. The future of architecture in its very commencement will and must date from the appearance in material of the handwriting of the artist architect himself, and such a one can receive guidance and help only from some power equal or superior to his own, and such power must be the result of professional toil and long acquired knowledge, for in no other way can it be attained.

Whatever, therefore may be the result of the coming contest, as between a wide and generous policy, and a narrow and restricted one, of this I am certain, that no long time can elapse before a thorough and radical reform in fine art action must of necessity be commenced. Never before was it so needful, for when once an institution representative of an idea sinks below that idea, by leaving it, its next and last step is to use it as a mere advertisement, and that done, all real and faithful talent abandons it to cluster in a new form round the principle which gave form to the Society at its birth. It is impossible to perpetuate error and stupidity.

C. BRUCE ALLEN.

#### EXHIBITION OF FRENCH AND FLEMISH PICTURES.

THE twelfth annual exhibition of foreign pictures improves a now established acquaintance with the peculiar merits that distinguish the Flemish and French schools, and, as usual, under such advantageous conditions as will afford the best opportunities for deriving instruction, from judiciously-selected examples, in what respects their superiority subsists generally, and in what particulars they may differ one from the other; for with the system very wisely adopted of including none but what may be accepted as choice specimens, fair comparison must be confined within the walls and between the immediate representatives of these, rather than in a wider field that would include our own school with those so partially represented.

Pre-eminent for its size and force of descriptive fact, a *replica* in oil, or perhaps the finished study of one of the series of mural paintings Baron Henri Leys has been commissioned to execute for the town-hall of Antwerp, defies all comparison, and secures for Belgium a precedence this time unquestioned by any similar production emanating from France; indeed, to those who would be most desirous of paying our nearer continental neighbors all the honour due to them, it would not occur to cite this as an occasion for denouncing a just opinion of French art, though there may be sufficient evidence of those distinctive qualities that always characterize the least pretentious performances of such as are at all capable of really representing it. On the other hand, with such exceptional exponents as Baron Henri Leys and M. Louis Gallait to uphold contemporary art in their country, the Flemish school is greatly in the ascendant when accounting for the interest attached to the present collection.

It may be almost as reasonable to congratulate M. Leys on the chances afforded him for so completely proving his great ability as a painter, and the resources his genius and carefully-acquired knowledge have placed at his command, as to applaud his fellow townsmen for their discrimination in employing them to such good purpose. Such acknowledgment is not always the certain reward of excellence, however well deserved. The style of this eminent artist is admirably applicable to such service as in the instance offered here (90) it is intended to fulfil. Many of the subjects illustrated in the series have more than a local historical interest attached to them: loyalty and bravery are common to all climes, and admiration for any extra display of their possession has a current circulation changeable into the coin of anywhere. Those pleasant sentiments so encouraging of self-reliance and independence that a scene like this may be supposed to inspire, wherein "Lancelot Van Urseel, burgomaster of Antwerp, addresses the armed guilds, in front of the town-hall, invests Town-councillor Van

Spanghen with the command, and confides to their care the safety of Antwerp, attacked by the Guelders, under Martin Van Rosken, in 1542" must be shared by all who admire patriotism as a principle and the Voltateers, as an institution; for, though these honest, stolid, and earnest members of corps are not quite so good-looking as some the other day, they look as terribly determined not to run under any less provocation than that thirst for the beer proper to the entire trust and confidence reposed in them as their modern emulators would be. A thorough appreciation of such aid as literal truth in the study of costume and architecture, and the elaborate finish of detail, are to giving reality to a picture, has contributed to the worth of this, and was all the more necessary, as, in the absence of excuse for introducing diversified action, the painter had but little else to depend on for giving vitality to the composition beyond whatever different aspects with which the same expression could be marked—that of absorbed attention—amongst the throngs of soldiers eagerly listening to the directions of the burgomaster, whose national type of features gives him with them a decidedly family likeness.

This fine work is at once to be identified with its author, as much by the mannerism of its execution,—now proverbial, but which is a splendid one after all,—as by the perfect fitness of every accessory to the period and circumstances of the historical incident recorded.

The influence of M. Leys's acceptance of precedent and observance of tradition as a rule, extends beyond the circle of those who may be supposed to be necessarily affected by it.

M. Layge, his pupil, affords a striking example of its direct effect, and his faithful adherence to such tutelage, in (75), "A Christening at Antwerp—fifteenth century;" and in "Marguerite in the Chapel of Our Lady of Sorrow" (76); though in the latter case there are more grace and closer approach to female beauty than would directly indicate it,—the fine colour and strict realism exacted by such imitation leave in neither a doubt of it. The same may be said of M. Alma-Tadema, another disciple, who has aptly made in a valuable investment of these peculiarities in elaborating Egyptian ornament and reconstituting antiquity, in a very quiet representation of "An Evening Party at Nineveh" (1), of which it may be said—slightly to reflect on the habits and customs of the era—that the ladies, at all events, wear no gloves! and offer an authority for very low dresses indeed. In an "Egyptian Game" (2), of chess, apparently during the twelfth dynasty, he has been still more successful in breathing the Promethean spark into the mummies of the past.

The works of M. Joseph Lies have a charm of their own beyond the merits to be accorded to a school; his (88), "Children playing by the Riverside (Antwerp)," is delightfully natural, and very beautiful in tone; and with his group of fugitives, "A Netherland Protestant Family, under the Duke of Alva" (97), will help to keep his name in lasting recollection.

M. Koller's single contribution presents the often repeated "First Interview of Faust and Marguerite" (73). It has admirably solid painting to recommend it, with a sweet and innocent heroine, but a very cold and unimpassioned Faust.

M. Louis Gallait, who divides with M. Leys the honour of supremacy amongst Belgian artists, and is as cordially acknowledged abroad as at home, is quite opposed in practice to the principles of his rival luminary: with him, poetry and imagination are indispensable adjuncts to art creation; and, actuated by this right conviction, he sometimes errs on virtue's side in the amount of dramatic force with which he depicts the images of his conception, and is carried beyond poetical suggestiveness to the verge of a stage demonstration, by the fervour with which he pursues his aim. This may be urged to some degree as an objection to his very impressive study, "Désillusion" (51), showing Columbus, aged and imprisoned, grasping his chains, and glaring with blood-shot eyes into vacancy, as, lost in retrospection of that which promised such different results to a devoted but wasted gigantic energy, he typifies the disenchantment of age. A pendant to this is "Illusion" (50), a handsome youth, in the full enjoyment of that conceit common to young genius, that would encourage the belief of the world's being all his own, and that its fairest and broadest prospects were opened only for

him to select his own pleasant pathway. Enthusiast! go and look at Columbus.

Of the French pictures, where all are remarkable, or nearly all, for that inexpressible something which can only be denominated as "French," there are three, by M. Meissonnier, as imitably brilliant and minute as ever, and marvellous for that resemblance to the living which his small figures always retain, whether they be "Soldiers playing at Cards in the Guard-room" (103-4), or indulging in more refined amusement, like "The Guitar Player" (105). A slightly-painted but exquisite study of "Deer in the Forest of Fontainebleau" (17), by Mlle. Rosa Bonheur; more soldiers "Playing at Cards" (120), by M. Ruiperez, pupil of Meissonnier; and one who follows him very closely in this and other departments,—witness "The Bull-tion Dealer" and "The Smoker" (121, 122). There are two, by M. Edouard Frere, of simple domestic incident,—"Good Morning, Baby," and "Bed-time," with cottager-children kneeling by the side of their grandmother, and saying their prayers (146, 147); but this year M. Frere is not well represented, to the advantage of M. Duverger, whose illustration of one of La Fontaine's fables, "The Hidden Treasure" (34), gains from such excellence being undispensed, as he shares in common with Frere.

Whatever M. Gerome may produce hereafter, or may have produced antecedent to it, his name will always be associated with "The Duel in the Snow." He is another evidence of the enduring influences the teacher acquires over the taught, for his manipulative method has a curious affinity to that of Delaroché; though "Muezzin calling the Hour of Prayer (Evening-Cairo)" (55) is to be noted more for the completeness with which the subject is made out, than for any claims it has to interest as a picture.

For mastery of expression in a most difficult phase of it, M. F. Heilbuth is unrivalled. His "Cardinals meeting on Monte Pincio" (57), and exchanging courtesies, is really wonderful in its genial apprehensiveness of character, and only inferior to this in his "Interior of a Cardinal's Carriage." It is scarcely necessary, however, to enumerate any further the several items of this choice collection, and very much more to a useful purpose to advise all who may wish to become familiar with contemporary foreign art and cultivate a catholic taste, not to miss such opportunities as these recurring exhibitions offer them. Under such auspices as the good judgment on the part of the management of those who bring them together have hitherto manifested, a knowledge of foreign art is safe to be beneficial to the progress of art at home.

#### HULL CORPORATION WATERWORKS.

At a meeting of the Hull town council, held on the 13th instant, a gratuity of 500l. was granted to Mr. Thomas Dale, the resident engineer of the Corporation Waterworks, for his extraordinary services in having designed and carried out the new waterworks and artesian well, at Springhead, whence the town now obtains a supply of water from the chalk; and they also, without any application from Mr. Dale, made an addition to his salary, of 50l. per annum.

#### ST. MICHAEL'S CHURCH IN ST. ALBAN'S.

THE inhabitants of the ancient town of St. Alban's have given Mr. Scott something to do. The church of St. Stephen, in St. Alban's, what he has done to St. Alban's Abbey, and his report on the ancient Clock Tower of St. Alban's, and what should be done to restore it, are evidences. He has now reported on the present condition, &c., of St. Michael's Church, in St. Alban's, the church in which the great Lord Chancellor Bacon is buried, and where his "Sic se debet" statue (sculptor unhappily unknown) has been, is, and will continue to be an object of the highest attraction. The report shows that it is in a very bad state.

That the restoration of this most interesting church will be done, and well done, there cannot be a doubt. The lord of Lord Bacon's much-loved Goshamery, and the patron of the living of St. Michael's, heads the subscription with five hundred pounds. The owners of the Four Inns of Court—Bacon's own Grays Inn especially,—should open their hearts and purses in aid of the restoration of the church which holds all that is mortal of Francis Bacon.

CREEDS AND TEMPLES: THEIR RELATION TO ONE ANOTHER, IN PAST AND PRESENT TIMES.\*

In considering some of the relations between different religious creeds and the buildings to which they gave rise, I do not of course mean to go into a detailed history of temples and rituals. But it may be worth while to take a glance, successively, at the religions which have left the most remarkable architectural monuments of their existence (considering them, of course, from a purely speculative, not from a theological point of view), and to observe how the requirements or spirit of the religion were represented in the plan or style of the building; not merely for the interest of the subject, but in order also to obtain standing ground from whence to view our own position, and to consider what are the legitimate demands of Christian worship upon architecture in the present century.

Modern ethnologists, it is well known, have divided mankind into three great families, generally known as the *Aryan* or *Indo-Germanic*, the *Semitic*, and the *Turanian* or *Uraltauric* races, emerging successively from the same quarter of the globe, the region about the Euphrates, and the north-west of India; the Turanians being the earliest developed, the Aryans the latest and most intellectual; and in early historic times each of these races had its own peculiar class of religious belief, the influence of which may be traced even to the present day. What may be called the *Theistic* faith, recognising the existence of an omnipresent yet personal Deity, was the peculiar property of the Semitic race, represented by the Jews, and in later times by the Arabians. The primitive Aryans, the earliest representatives of whom are the ancient Persians or Magi, were the high priests of Pantheism, or the worship of external nature; while among the ancient Egyptians, the earliest Turanian people we are acquainted with, we find ourselves in the midst of the wildest and most fanciful Polytheism. And here we at once notice a remarkable fact, of which we find additional evidence in later times, that it is to the various forms of Polytheism that we are indebted for the grandest and most impressive sacred buildings. The Jews, as we know, were not required by their religion to erect more than one temple; and even that, though richly adorned, was always too small in dimensions to be taken into any account by the side of such piles as Karnac and Luxor, Cologne and Amiens; while to the early Persians, holding a faith in which the elements were the ministers, and the sun the chief object of worship, a temple could only have been an incongruous structure. The extraordinary contrast between the Aryan and Turanian races in these points, is very well put before us in the words of an eminent ethnologist, Dr. Prichard, who remarks that "the metaphysical belief and religious sentiments and practices of the two nations were equally diverse; the one adoring an invisible and eternal spirit, at whose word the universe started into existence, and the morning stars sang together; the other," the Turanian, "adorning splendid temples with costly magnificence, in which, with mysterious and grotesque rites, they paid a strange and portentous worship to some foul and revolting object—a snake, a tortoise, a crocodile, or an ape." It is, then, to the banks of the Nile, under the influence of such a worship as this, that we turn to find the first development of ecclesiastical architecture.

Sir Gardner Wilkinson considers the germ of the Egyptian temple to have been a simple *cella*, with a porch, which always remained of nearly the same size and form, though, in process of time, surrounded with one adjunct after another, till it assumed the form represented in the plan of the temple of Rhamess the Great, which is a pretty fair type of the great Theban temples. The whole arrangement of these temples is clearly indicative both of the mysterious and superstitious character of the worship for which they were erected, and of the splendour of the ceremonial by which a powerful priesthood sought to invest the religion with dignity and solemnity in the eyes of the common people. And it may here be remarked that, both in this and in all subsequent temple styles, the extent and magnificence of the plan are in almost direct proportion to the power and influence of the priesthood. In ancient Egypt the priestly caste was predominant over every other, and never, certainly, has there been a more suc-

cessful attempt to give an outward sublimity to a worship essentially contemptible, than in these temples of the Theban dynasty. The long avenues of sphinxes, sometimes stretching for nearly a mile from the gateway; the entrance, with its great propylons towering on each side, and leading into a wide court-yard surrounded by the deep shadow of a covered colonnade; the second court, with its rows of seated colossi; the hypostyle hall of assembly, with its forest of columns, dimly lighted from above,—all these must have combined to produce an effect scarcely equalled since, and well calculated to suggest how awful must be the sanctity of those three dark cells to which all this grandeur formed only a vestibule. Into that sanctity, however, the people were wisely never permitted to examine, the king alone being occasionally introduced, a priest leading him by the hand, into the presence of the Deity (a ceremony frequently represented in the Egyptian paintings), the mass of the people always remaining without, and participating in the sacrifice only through their priestly vicars. The triple arrangement of cells which seems to have generally prevailed resulted from the belief in a triad of deities presiding over each of the principal cities, and generally supposed to consist of a god, a goddess, and their son or daughter; and this belief (which is also to be traced among the Etruscans and Pelasgi) gave rise to the small temples called *naumenes*, so remarkably resembling the Greek temples in plan, and which appear to have been considered as the typical halls of the deities. The most important ceremonies next to the sacrifices, were the processions of the deities, who were occasionally borne in state, under a canopy, either round the courts of the temple or outside its inclosure; and we can easily imagine how important a part the avenues of sphinxes must have played in these probably gorgeous processions, and may perhaps trace to them the origin of the covered colonnade in the first court, as a provision for the spectators of the procession within the boundaries of the temple.

Altogether, the Egyptian temple may be viewed as the most complete outward expression of a religion, in which the idea of the beautiful was almost entirely subordinate to that of the religious expression; no high order of æsthetic beauty being observable in the details of the building, even the lotus capital owing its prominent position as much to the sacred character of the flower as to its outward beauty; the statues deriving their importance less from their artistic merits than from their significance as representations of Osiris; every part of the building being constructed to subserve the purpose of enhancing the ideas of mystery which pervade the whole of the Egyptian mythology—the whole representing, indeed, the *apothéosis* of superstition, in the awful and imposing forms into which it had been, as it were, consolidated, during the lapse of centuries, by a people eminently conservative, and moving very slowly down the stream of history.

Breaking for a moment the chronological order of styles, and turning to Hindustan, the temple style of which arose as that of Egypt became extinct, we see the same phenomenon presented of the rise of temple architecture coinciding with that of priestcraft and superstition. For the earlier Sanscrit writings, the Vedas, which contain the original precepts of Hinduism, and which were long anterior to the rise of Hindu architecture, are essentially Pantheistic, and are said to show symptoms of derivation from the ancient Persians, having been, most probably, introduced into India by the portion of the Aryan tribe who penetrated there.

Long before this introduction, however, India was already occupied by a people of Turanian origin, and nearly connected with the Egyptians; and under the influence of these, as they advanced in civilization, the pure faith became gradually corrupted; the priesthood became a caste, continually increasing in power, and the original pantheism merged into a polytheism far more gross and degrading than that of the Egyptians. Hence was developed a form of temple which, as it arose under similar circumstances as did those of Egypt, so it bore to the latter a striking resemblance in several points. We find the same dignity given to the entrances by pyramidal gate-towers, the same pillared courts within courts; the same extraordinary hithos in plan by which a whole array of entrance-gates, court-yards, columns, &c., presenting a gorgeous and striking exterior, but becom-

ing smaller and meaner as they are penetrated, *culminate* at length (if one may use the word) in the one little insignificant chamber, lighted only through the door, and additionally darkened by a covered porch, which was perhaps the fittest kind of shrine for such deities as have been conjured up by the Hindus. Such a plan as this could only have originated from a religion in which a priestly caste stood completely between the people and the deity, and in which the imaginary deity partook not of the higher nature, but of all the baser and more degrading passions of humanity.

Going back in our chronology, and starting again from Egypt, we cross over to Greece, and here we are at once in a purer atmosphere, for we have got quit of the exclusive influence of the Turanian race. The ancient Pelasgi, indeed, the earliest known inhabitants of Greece, were of Turanian origin; but the Greeks, *par excellence*, were the offspring of the union between these aboriginal inhabitants and the great Aryan race, represented by the Dorian colonists, who joined their high intellectual capabilities and common sense to the brilliant artistic capabilities of the Pelasgi. Hence their religion, though a polytheism, was of a bright and beautiful kind, being, in fact, a deification of the various attributes of nature, closely allied to the pure Aryan pantheism, and possessing few elements of mystery or superstition. No caste of priests here combined to blind and stultify the worshippers; the priests were the officers of the temple merely; the sacrifices and the worship of the deity were witnessed and joined in by the people. Accordingly we find here no labyrinth of courts within courts, no solemn vistas of statues, none of that expression of gloomy grandeur which we met with on the banks of the Nile; all that was required on plan was a simple rectangular chamber, with the statue and altar of the deity at the further end of it, where sacrifices could be witnessed by all assembled in the temple. These peristylar temples seem to have been developed from a simple *cella*, in much the same manner as the Egyptian; though whether the original form came from Pelasgic or Egyptian sources appears to be a vexed question. The one exception to the simple character of the Greek form of worship is the celebration of the Eleusian mysteries, which, however, are known to have been borrowed directly from the Egyptians, and which, as we might have expected, gave rise to a special plan of temple at Eleusis: a nearly square building, with columns equally spaced over the greater part of the area, and this plan, so different in proportion and arrangement from the ordinary Greek temple, has been supposed, I think with great probability, to have been suggested by the hypostyle halls of the Egyptians.

It seems probable, from various passages in later Greek and Roman writers, that these mysteries consisted mainly in scenic representations of the most significant passages in the Greek mythology, particularly in relation to a future state. In such a case it is easy to see that a plan like this, with the view partially intercepted in every direction by columns, and lighted from above by windows which could be darkened at pleasure, might greatly aid the effect of such exhibitions.

We know how amply the Greek temples compensated for their comparatively small size by the exquisitely artistic and finished character of their decorations, and in this way they present a remarkable contrast to the Egyptian temples, in two points not unconnected with the opposite character of the two religions. The first is, that the Greek ornamentation did not, like the Egyptian, owe its interest to its sacred or symbolic meaning; of this it possessed nothing, for the Greeks were far too intellectual to descend to material symbolism; all their decoration was placed there solely for its artistic effect; and if, as before said, the Egyptian style was the *apothéosis* of superstition, the Greek was certainly that of æsthetic beauty. Secondly, the phonic art introduced into the Egyptian temples, the endless wall-paintings of nearly every possible subject, had no relation to any previously compiled and well-known histories of things either sacred or profane; they were themselves the book; and, like the painted windows and sculptures of the Medieval cathedrals, were probably the chief sources of instruction to the mass of the people. The Greek sculptures, on the other hand, were only the illustrations of the most beautiful Pagan mythology, and the most splendid literature, Pagan or Christian, that ever existed; the heroes and gods of Homer

\* Read before the Liverpool Architectural Society, April 5th.

lived again in the friezes and tympana of the temples:—

"Nor these alone, but every legend fair,  
Which the supreme Caucasian mind  
Carved out of nature for itself, was there,  
Not less than life, design'd."

The Romans contributed but little to the temple-styles of the world; they were an Aryan race, displaying in excess the matter-of-fact character and comparative indifference to religious art which has always belonged to this division of the human family. Their temples and religious rites were chiefly borrowed from the Greeks, as those of the Greeks in many cases from the Egyptians; but while the latter merely borrowed, and vastly improved on their models, the Romans started with copying, and soon spoiled and vulgarised all the details in the process. One form of temple, however, possesses an interest for us, as being the model on which the Christian baptisteries were afterwards built; I refer to the circular form, which was borrowed from the Etruscans, a Turanian race nearly allied to the Pelasgi, and holding the same place in ancient Italy as the latter in ancient Greece; with this distinction, that the Roman colonists did not, like the Dorian, fuse themselves with this aboriginal race, but overpowered and superseded it. Originally these circular buildings were probably tombs, for the Etruscans were essentially a tomb-building race, owing to the reverence in which they held their ancestors; and though the Romans used them as temples (always dedicating them, however, to deities of an Etruscan and not of a Roman origin), the traditional use of them showed itself again in the Christian era, in such buildings as the tomb of Theodoric and the circular church erected by Charlemagne at Aix, to form his own sepulchre; and even in the Christian baptisteries the same feeling may be traced, inasmuch as these buildings were commonly erected over spots consecrated by the entombment or martyrdom of a saint.

On a first view of the subject, it would appear that under no circumstances might we be so well justified in looking for an entirely new style of temple architecture as under the rise and spread of a religion so new in character, so completely in contrast to all the existing faiths of the then civilized world, as the Christian. But the absence of such a style is the most striking exemplification of the fact, which meets us elsewhere in history, that the rise of a purer religion, or the reformation of an old and corrupted one, is always accompanied by a corresponding neglect of temple architecture. This was commented upon as early as the fifth century, by Isidore, who remarks "that in the time of the apostles, when spiritual gifts abounded, there were no temples; but now the buildings are adorned more than necessary, while the church has fallen into disgrace." During the first years of Christianity, of course, the persecution to which it was subjected would have prevented the erection of any public places of worship; but, though during great part of the third century the Christians enjoyed great toleration, and their numbers rapidly increased; and though even in the second century we find evidence of an organised church government represented by bishops and presbyters, there is nothing to show that there were at this time any buildings specially erected and set apart for purposes of worship. And when, at the commencement of the fourth century, the empire under Constantine became nominally a Christian one, and the church emerged from its obscurity into comparative power and honour, the necessity for some public place of meeting was supplied neither by a new style of temple nor by the adaptation of former ones; but by the most convenient buildings that came to hand, the disused basilicæ or halls of justice of the extinct heathen empire.

There was more than one reason for this choice. The early Christians regarded with horror everything connected with the old religion; the gods were to them demons, the temples polluted by Pagan associations. The basilicæ, besides that they were free from this objection, were in fact so admirably adapted for the purposes of the Christians, that the new churches, when built, were for a long time on exactly the same model. They presented in the great hall an admirable area for a large assembly, while the seat in the centre of the apse, from which the pastor had administered justice, formed a dignified throne for the bishop, and the presbyters occupied the semicircular seats formerly appropriated to judges and lawyers. This simplicity of arrangement,

however, did not long continue, for church government was already in a much more advanced state than church building; and so early as the beginning of the fourth century the idea had developed itself of a peculiar sanctity residing in the clergy, and of the necessity of their separating from the laity, who were already beginning to be ruled with a rod of iron. And though down to the ninth or tenth century the basilicæ remained the principal type of church, the actual halls themselves were not very long retained as places of worship, owing to a feeling which led the people to seek out sites consecrated by the martyrdom of saints. There is a somewhat detailed account given by Eusebius (about A.D. 330) of the arrangement of a new church built in his time at Tyre, which, taken in connexion with the plan of the old Basilican church of St. Peter's at Rome, gives a good idea of the general arrangements of the churches of this period, and the motives which governed them. Eusebius describes how the bishop "raised a stately portico against the rays of the rising sun" (for the orientation of churches was not all universal at this time, and in Italy never became a rule). "After you have come within the gates he has not permitted you to enter into the holy place with unshod feet, but having left a large vacancy between the portico and the temple, he beautified the vacant space, having enclosed it as a quadrangle, with four opposite cloisters, supported on every side with pillars. Here also he placed the mysterious symbols of the sacred purgations; to wit, fountains built opposite to the front of the church, which afforded water for those who entered the sacred precincts to wash in. . . . And this place yielded a very commodious mansion for those who wanted instruction in the first principles of religion." After speaking of the decorations, he proceeds,—"Having thus finished the temple, and adorned it with the highest thrones in honour of the prelates of the churches, and with benches placed in order all over the church, he placed the holy of holies, the altar, in the midst; and that the multitude might not come within these holy places, he enclosed it with wooden rails resembling net-work, which were curiously and artificially framed and carved." This last passage has given rise to some pretty sharp paper warfare, as to whether the altar was placed in the chancel or not. I believe the explanation is, that Eusebius, when he says "all over the church," means, by a carelessness of expression, "all over the chancel"—the part raised off, and appropriated to the clergy; for we know from contemporary church historians that the congregation was not allowed to sit at all, but that benches were always placed within the *chancel* for the inferior clergy; and in this case the expression "in the midst" applied to the altar would indicate that it was within what we should now call the "chancel." The different parts of the church were carefully partitioned off for different classes of worshippers. The atrium was, as Eusebius indicates, appropriated to the untaught converts, while the side of it next the church, called the *vestibule*, was the place for penitents who were under temporary excommunication; an arrangement occasionally revived in Mediaeval times in what are termed the Galilee porches of our cathedrals. The lower end of the church, next the entrance, was partitioned off by a barrier about one-third the distance up the nave, and was appropriated to the catechumens, who were still under instruction, and were only allowed to hear the reading and preaching, not to join in the prayers or sacraments; hence this was called the *locus auditivus*. Beyond this barrier was the *locus fidei*, the place of the faithful, who alone were permitted to join in the more solemn parts of the service. The men were always stationed on the right side (what would with us be the south) of the church, and the women opposite, a barrier dividing the two; an arrangement which the wisdom of certain modern ecclesiologists has revived. The altar was shrouded from the people by a curtain, which was withdrawn during the celebration of the Eucharist. On each side of the chancel was a small chamber; that on the south side, called the *diaconicum*, being for the reception of the vestments and other furniture of the church, which was under the care of the deacons; that on the north, the *prothesis*, for the keeping of the sacred vessels and elements, which were set out in order there previously to the celebration of the Communion. These two small chambers, generally built out on each side of the church, form, I suspect, the real origin of the transepts and of the cross form,

which had a symbolism tacked on to it afterwards, with which it had originally nothing whatever to do. The small size of the apse indicates that the clerical body were not at this period very numerous, but we cannot go much further without finding decided evidence of their increase. Custom and precedent led to the retention of the simple apsidal termination for some time after; but as the clerical ranks were swelled, and a new order of chorists founded among them by Pope Gregory in the sixth century, we find that, in order to give room for them, the chancel was continued out into the church, and divided off from the people by a screen all round it; and into it the reading-desk, or *ambo*, was conveyed from its original position on the *bema*. The true *chancel*, as we understand the term, did not in reality develop itself till about the eleventh century, and owed its importance to a liturgical cause. It was the outward expression of the dogma of transubstantiation, which began to make itself felt at the beginning of that century, and gradually became a received faith, till it was formally confirmed by a general council in the year 1215. The belief in this miraculous change of the elements invested the priesthood who performed it with an additional sanctity, both in their own estimation, and still more in that of the people; and, accompanied as it was by the elevation and adoration of the host, it naturally demanded that the priests, in the performance of this rite, should be separated more decidedly than ever from the people, and that the simple apse should be expanded and beautified to form a fitting arena for the celebration of so great a mystery. The rise of the chancel in the eleventh, and its progressive importance up to the thirteenth century, as exhibited in the French churches, keeps pace almost exactly with the development of this doctrine, forming one more evidence of the coincident growth of religious architecture and religious superstition. In France, however, the chancel took a peculiar form, modified by the influence of circular churches, about which something must be said.\*

H. H. STATHAM, JUN.

#### THE SCULPTURED ROCKS OF NORTHUMBERLAND.

MR. TATE has reprinted his memoir from the "Proceedings of the Berwickshire Naturalists' Club," apparently with emendations, after the paper, as "a report that embodied the labour of years," was read on 25th August last, and reviewed in the *Builder* of 3rd September, with occasional references to and comparisons with the theoretical views of our correspondent, Mr. Dove, which had previously appeared (on 2nd July, in the *Builder*). The influence of these peculiar views on Mr. Tate's endeavours to explain the meaning and purpose of these mysterious symbols has been already alluded to in the *Builder*, and is here pretty obvious; although, from what Mr. Tate says of "those who are not content unless every mystery is fully explained," it would rather seem as if he regretted that any endeavour should have been made, at least by others, to unravel the mystery, and so to diminish its sensational effect on the public mind, on its first presentation by him, in all its native darkness, to their notice. Nevertheless, as we have said, the influence on Mr. Tate's own mind of the only endeavour yet made to really explain that mystery is pretty obvious in this memoir. For example, in speaking of the probable purpose of the rock sculptures in connexion with the dead, and after mentioning that there were "only four distinct cases in Northumberland of their being used in sepulchral chambers, though there are others not far distant from interments;" Mr. Tate says,—

"Their use for the dead was, therefore, I think, only partial and secondary; and arose out of the sacred import of the symbols. The Mediaeval Christian, as he was dying, gazed with hopeful earnestness on the cross as the symbol of his salvation, and had it placed over his tomb; and he was sometimes buried in earth brought from the Holy Land. And so, as the ancient Briton was laid in his tomb, with his weapon and his earthen cup at his side, he might be supposed to gaze on the sacred concentric circles, as symbolizing his hope of immortality."

Mr. Tate, however, acknowledges that these symbols had a far more obvious reference to the life than to the death—to the camps and circles

\* To be continued.

\* "The Ancient British Sculptured Rocks of Northumberland and the Eastern Borders," with Notices of the Remains associated with these Sculptures." By George Tate, F.G.S., &c., Alnwick, 1865.

than to the graves—of the ancient Britons; but this he does not attempt to explain.

The idea of the glazed eyes of the dead earnestly "gazing" on the concentric circled symbol is just about as near an approximation to Mr. Dove's previous suggestion of their use for the contemplative eyes of the living initiates of the Druidical mysteries to be concentrated and fixed upon, in their religious services, while dying the mystical and holy death of entrancement, as was possible without positively and entirely appropriating that suggestion without acknowledgment; as in the case of other suggestions, such as the indication of a transition from a lower to a higher—a concentrative to a radiative (or entranced)—state of life, in these concentric-circled and radial-grooved symbols of the concentro-radiative and celestial "spheres above the Head [or Soul-centre] of the diviner," as our correspondent conceived them to have originally been.

Now, with ideas so much akin to those referred to, and especially as the author claims in this memoir to have himself suggested (in a very vague and general way), so long ago as 1853 (in one place he calls it 1852), that the rock sculptures "were symbolical figures representing religious thoughts," is it not odd that Mr. Tate should have carefully avoided even the slightest reference, either to the *Builder*, or to the only theoretical endeavour (published only in the *Builder*), to show what those "religious thoughts" really were on which his rock symbols seemed to have been based? If that endeavour could have been easily shown to be improbable or erroneous, would it, in that case, and the *Builder* which contained it, have been altogether ignored?

Having already, at some length, reviewed the paper forming the reprint under notice, and inserted other communications bearing on it in the *Builder*, we cannot re-count on the subject here; and we need now only say that all who feel interested in the very curious rock symbols of Northumberland will find here, and only here, a detailed and authentic account of them, illustrated by numerous engraved examples.

There are a few errors and inconsistencies, however, some of which indicate haste in composition, and all of which should be corrected in any future edition. Thus, for example, the author alludes to fig. 2 of plate 8th as presenting, at Old Bewick, the only example of anything like a spiral among the Northumbrian sculptures, and which likeness to a spiral he attributes to the action of the weather on a concentric circular symbol; whereas in plate 11th, fig. 3, he illustrates one at Coldmartin, close upon the Cheviots, which is obviously a spiral with several coils, and with a "radial groove," as it is called, or centre-pointer. If this be not a spiral the illustrations must be worthless. Mr. Tate, however, distinctly states that it is a figure of four incomplete concentric circles, with the cup and radial line. The likeness of this, as a spiral symbol, by the way, to one from a rock temple in Malta, illustrated on page 34, is remarkable, both ends being seemingly cupped in both cases: the "radial groove," or centre-pointer, however, is wanting in the Maltese symbol.

Again, it will be found that the references to the plates are not always correct. On page 43, for example (where another and similar error occurs), reference is made to plate 12th, fig. 2, for certain "strange figures on Cuddy's Cove," resembling alphabetical characters, and which Mr. Tate regards as archaic and similar to others on sepulchres in Brittany which, he thinks, are undoubtedly of great antiquity. There are no such characters marked fig. 2; those obviously referred to being marked fig. 3. One of these singular characters (see page 13, below that like the Medieval letter "H") has already been referred to in the *Builder* as resembling one illustrated by Governor Pownall, in the "Archæologia," as of a Phœnician character; and forming an example of those sculptures in the Sorcery Hall at New Grange which certain Irish archaeologists seem to have since mistaken for palm-leaves! Another consists of a cross (which is the plan of the New Grange Sorcery Hall itself, by the way), and has, in the centre of the cross, two concentric circles, with the central point, hollow, or cup, as in so many of the other rock symbols.

While referring to quasi-alphabetical characters we may remark that Mr. Tate illustrates one symbol, as a characteristic or typical one amongst the Border rock sculptures, with "lines similar to an ogham." It has "nine straight lines, appearing like rays, incised above

the outer circle," and was seen at Ronting Linn. This symbol reminds us very much of what Mr. Dove says of the concentric-circled symbol called the Jewish Sephiroth, or Splendors, the outer circle of which was called "the crown,"—that is, the crown of splendor, crown of glory, or radiate crown, and the central space "the kingdom." In the Ronting Linn symbol the nine radiating lines on the outermost circle (see p. 7, or plate 11th, fig. 10—not 12, as Mr. Tate gives it on page 43) much more resemble a crown than an ogham.

Mr. Tate, we observe, does not now say that our antiquities "have no relation" to the Hebrew, Egyptian, or Assyrian symbolization, relation "since 'no relation' into 'but little' assertion appeared in the *Builder*. Even still, however, the concentric circles of the Jews, and the centre-and-circle symbol of the Egyptians, Hindus, and almost all other nations, have not the true Northumbrian ring and burr; and Mr. Tate will have nothing to do with them. In short, there never were and never will be such wonderful symbols in existence as the Northumbrian are in the eyes of Northumbrian archaeologists: not even the Irish—not even the Scottish—are quite the thing; and it seems almost to insult the Northumbrians to compare their incomparable symbols with any others on the face of the earth, however analogous, however identical, they may essentially be in the eyes of outsiders.

Before concluding, there is one notable circumstance as to the rock symbols, mentioned by Mr. Tate, to which we desire to draw special attention. "When found *in situ*, they are always in high grounds, generally on lofty hills, some of which are nearly 800 ft. above the sea level." No doubt their connexion with the sites of ancient forts and camps may have had something to do with this; but it is also just what would have occurred if the symbols were so exceedingly ancient as to have at least approximated to the close of the glacial era, when the low lands of this country were covered by the sea, and the glacial drift had the flint weapons of the ancient people enclosed in it. Some such symbols occur on glaciated blocks, as in Ireland, at New Grange, as mentioned by Professor King in the *Builder* of 19th November last,—or since the discussion on the rock symbols in our mention by Professor King in the *Builder*, has been intercalated (without any allusion to the *Builder*, though), on page 32 of Mr. Tate's paper, where he (no doubt unconsciously) unites with Mr. Dove in calling New Grange a "Sorcery hall,"—or rather, for variety's sake, we suppose, a "Sorcery chamber." Several of the standing stones of Siennis in Orkney, also, (one of which,—the stone of Odin,—is perforated with a hole through which sexual and other compacts were made between two persons, by joining hands through the hole,) have still traces of glacial action. From such traces Mr. Tate concludes that these Orcaidian stones must have been cut or set up long after the era of glacial action,—which is not so very clear; for the glacial era was undoubtedly an era of summer floods no less than of winter freezings, and glaciated blocks might have been made use of by men (if in existence) during the glacial era. However, even though we should regard these blocks as only an evidence of subsequent handling by man, that handling may also date from an approximation to the close of the glacial era, in the drift of which era so many flint weapons of the ancient Britons have been discovered. At that period many of our high lands or hills must have been islands, and our Celtic highlanders islanders, as they still are in the western isles of Scotland. The connexion of the rock sculptures of Britain with those of the high land of Brittany would thus be significant.

#### THE DWELLINGS OF THE LABOURING CLASSES IN BAVARIA.

THE Society of Arts, desirous of extending to some parts of the Continent its inquiry into the statistics of model dwellings, addressed, in 1863, to Dr. Von Hermand, a privy councillor and a member of the Bavarian Government, a request to be favoured with some account of what steps had been taken in that country towards the improvement of the dwellings of the labouring classes; and the Minister of the Interior sent out a form (consisting of a series of questions) to the Government officials in all the districts of

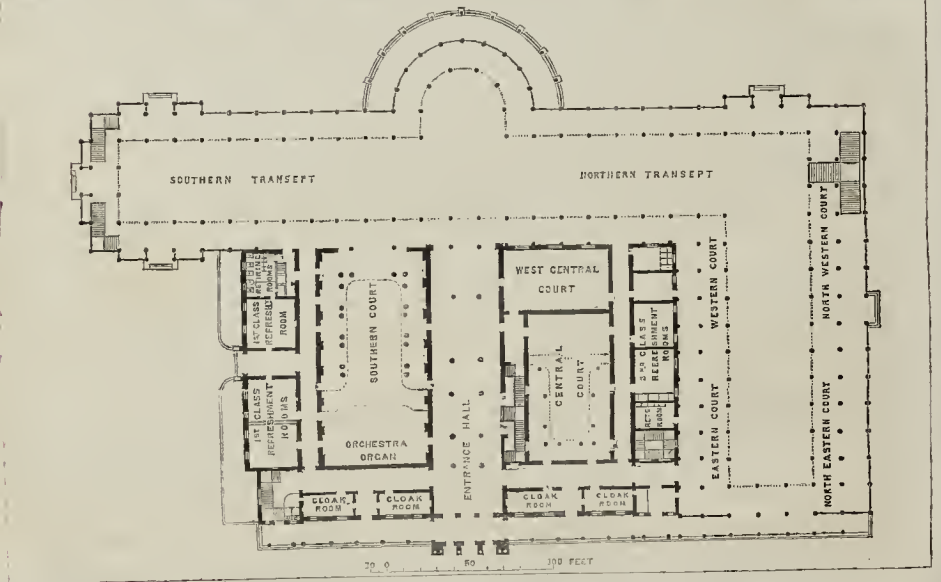

that country. In consequence, a number of documents and plans have been forwarded to the council, a *resumé* of which has been prepared by Mr. Gilbert Redgrave.

The buildings described have mostly been erected by the owners of factories for the accommodation of their workmen. In two or three cases, however, these dwellings belong to building societies, who have erected them rather from pecuniary than from philanthropic views. These buildings are invariably grouped either in rows or blocks, and offer no example of single or double cottages as in England. They have sprung up either in manufacturing or mining districts, and in towns where manufactures are carried on. In Munich, where no manufactures of any importance exist, all attempts which have hitherto been made on a speculative footing have failed, partly for that reason, and partly perhaps because the laws relating to mortgage enable the possessor of a moderate capital to obtain the requisite building funds without the interposition of any company. There is, however, in the suburbs of Munich, a class of buildings unknown in England, parts of which may be bought by different families. Bavarian manufacturers finding, as a rule, that their workmen were badly lodged, and on that account unhealthy, and that the paucity of dwellings created a scarcity of workmen, have from time to time built, in the vicinity of their factories, blocks of dwellings generally offering different degrees of accommodation, and varying considerably as to rent. The reports prove that the construction of these dwellings has brought about the most favourable results. The workmen and their families have improved in health and appearance. Mortality and diseases of the chest, arising from their former ill-ventilated and badly-warmed cottages, have decreased, and a better feeling has sprung up among the men, leading to the formation of benefit societies, reading clubs, and the like.

The rough average cost of some of the buildings, amounts to 106l. 6s., with a maximum of 136l., and a minimum of 68l. per dwelling. Many of the blocks contain from twelve to twenty families. The area which each dwelling occupies varies considerably, ranging approximately from 700 to 1,000 square ft. Most of the tenements have yards, and sometimes small gardens. The houses are generally built of brick, though a few are of wood, and they are roofed with tiles or slates. The dwellings are in many instances under the supervision of the proprietor or manufacturer, who causes a weekly or monthly inspection to be made by a superintendent appointed for this purpose. The buildings are, as has been stated, mainly inhabited by the workpeople of the factories to which they are attached. The average number of a family seems to be seven. In houses of this class in towns the inmates are either small tradesmen, mechanics, or the employes of railways, post-offices, &c. In a building of this kind in Nuremberg, eighteen families inhabit three blocks. There are seven artisans, seven labourers, and the remaining four are employes at the railway or the post-office. The wages of the artisan, among whom there are three joiners, two shoemakers, one turner, and one locksmith, range from 16s. 8d. to 25s. weekly. The labourers earn from 11s. 8d. to 16s. 8d. weekly; and the men employed at the railway and post, from 50s. to 84s. per month. In another return from the town of Fûrth, it is stated that among twelve families there are five joiners, two turners, three metal-workers, and two belt-makers. Many of the buildings have been so recently opened, that an estimate of the annual rate of mortality is impossible; but in one instance, among a manufacturing population of 600 workmen, there has been a daily average of 2½ sick persons; and in Nuremberg, among ninety-eight inhabitants of a building for workmen, only one death is recorded for the year 1863. The great difficulty in planning sets of dwellings in several stories is to insure privacy to each family; but it does not appear that the German manufacturers have in any instance adopted the external gallery system. It is pleasing to see the friendly relations which exist in Germany between the families inhabiting the same house, resulting in clubs and savings-banks of the same character as our benefit societies in England.

PRIZES FOR ART WORKMEN.—The Council of the Society of Arts have offered prizes for workmanship. The list of subjects is published. It is not very different from that last year.

THE DUBLIN EXHIBITION PALACE. — Plan and Section of Iron Building.

THE DUBLIN EXHIBITION PALACE.—MR. ALFRED G. JONES, ARCHITECT.

## DUBLIN EXHIBITION PALACE AND WINTER GARDEN.

The permanent buildings may be classified under two heads, viz., the main building and the winter garden; the former of which is a stone structure, the latter of iron and glass construction. The main building contains a grand central entrance-hall, with two rows of Caen stone columns, and a principal staircase leading to the gallery above. The lower hall is intended for sculpture, and the upper as a picture gallery, having a carved ceiling, divided into compartments by cast-iron arched ribs. Round the gallery railing pedestals are placed, to receive groups of statuary.

The large concert-hall, on the left hand of the entrance-hall, provides accommodation for 3,000, the end of which opens into the winter-garden building, and thereby greatly increasing that number, and on ordinary occasions enables the hall to be speedily emptied. This hall is also surrounded by two main corridors, with doors leading into the same; and off the corridors are cloak-rooms and rooms for the orchestra use. The orchestra will accommodate about 1,000, and underneath are large rooms for the band, and the double staircases leading to the same. On the right hand of the entrance-hall is the small concert-hall, intended to accommodate 1,500, floored over on the level of the gallery for the purpose of obtaining an additional large picture gallery. This concert-hall is arranged so as to admit of private theatricals. At the end of the hall is a large practice-room. This hall is also surrounded by corridors and cloak-rooms, together with orchestra accommodation. All the main corridors lead into the winter garden, both on the ground-floor and upper floor.

There is in the main building on the upper floor a large dining-hall, 30 ft. wide by 107 ft. long, capable of being divided by a partition, the full width of the room lowered with a double partition by means of crab winches. On the upper floor there are also provided off the corridors cloak-rooms for the use of the galleries of both concert-halls; also board-rooms and offices, and important staircases. At the rear of the small concert-hall (upper floor) is a lecture-room for 500 persons; also an extensive permanent picture-gallery off the corridor, and the adjoining gallery of the winter garden.

Special attention has been devoted by the architect to the easy access and egress to the several portions of the buildings, and ample water-closet and lavatory accommodation is provided throughout the buildings.

The winter garden is nearly 500 ft. in length, and contains a circular transept in the centre, leading into the pleasure-grounds by means of a colonnade and steps on to the terrace. Opposite each colonnade, breaking the line of steps, is a granite block to receive vases. A portion of the winter garden continues round the side of the main building towards the front of same, intended to be used as a permanent exhibition, the roof of which, to reduce the amount of light, is covered with zinc, laid in rolls, by the Vieille Montagne Company.

It is intended to have a large fountain and canal in the centre of the winter garden at the circular transept, which has been floored over at present, the space being required by exhibitors; but there are fountains in the pleasure-grounds, and a handsome and extensive cascade, seen from the entrance-hall in an effective manner.

Beside the Exhibition building is a large permanent annex, for machinery in motion, fitted up with two engines, one for pumping water throughout the building and to a large tank on the top of same, supplying fountains in the gardens. This engine also supplies hot and cold air as required throughout the various buildings, through large flues, 4 ft. 6 in. high, by 3 ft. wide, which are constructed underground, and run along the various corridors, branching into the concert-halls and all the important rooms, and through shafts into the galleries and rooms above. By this means the various halls can be charged with heated air, moistened to summer temperature, and discharging into large shafts constructed from the ceilings of the concert-halls, dining-rooms, &c., through the roofs externally, worked by means of a fan.

There is also an annex for carriages, and one for machinery not in motion; and a fourth for first and second-class refreshment-rooms and retiring-rooms, lavatories, &c.

The principal entrance to the buildings is from Earlsfort-terrace, through six pairs of gate entrances, for entrance, exit, and foot-passengers.

The grounds and drive in front are enclosed with a handsome chain-railing and rock-face wall; there is also an entrance through the pleasure-grounds by Harcourt-terrace.

We publish in our present number an interior view and details of the iron and glass portion of the building as seen from about the centre of the northern transept, and which is now fast approaching completion.

The inaugural opening of the Exhibition by his Royal Highness the Prince of Wales is fixed to take place on the 9th of May next.

The general dimensions of the building are shown by scales on the page illustrating details. The skeleton of the building is entirely of iron, and is in no way dependent on timber for its support, being so constructed that the side inclosures, gallery-flooring, roofing, &c., simply perform their respective duties as inclosures and platforms.

The building is on plan multiples of squares of 16 ft. 10 in., by which arrangement a certain regularity in the lengths of the castings is obtained, which is a great desideratum in all iron buildings. The Great Exhibition building dimension of 16 ft. 10 in. for the Dublin Exhibition was governed by the required dimensions of the masonry portion of the building.

The principal novelty in this structure is that the thrust of the arched roof is resisted without the assistance of diagonal bracing, which has almost invariably been introduced in buildings of this class, forming obstructions and giving the idea of after-thoughts. It will be seen by inspection of the section, that, by means of the buttresses, the thrust of the roof is conveyed to the second tier columns, which are strongly secured to the small arched roof girders, and connected at the bottom to the first tier columns. This arrangement causes a transverse strain on the columns, to resist which they are made thicker on the sides exposed to this strain. The first tier columns are again firmly connected to the transverse bracket-girders at the top, and to girders under the floor level, thus completing a rigid framework to resist the thrust of the arched roof; the sections of the columns and girders, and the strength of the wrought-iron connexions, having been all carefully calculated to resist the various strains.

The gallery flooring is trussed by wrought-iron rods, arranged diagonally in plan, by which arrangement the vertical pressure is at once brought on the columns and not transmitted by the girders, thus leaving them to their assigned duty of bracing the structure to resist the thrust of the roof. By this arrangement of the truss rods they also form a horizontal bracing to the galleries, which have recently undergone a severe practical test as to their strength and rigidity by the marching of troops over their entire extent. The columns, girders, buttresses, and girders throughout the building are of cast-iron. The arched ribs of the main roof are of wrought-iron, and the purlins of cast-iron.

The northern and southern transepts are enclosed and covered with glass fixed in wood frames and bars. The courts are partially covered with corrugated iron, and the roofs with zinc and glass.

The architect is Mr. A. G. Jones, of Dublin; the engineers are Messrs. Ordish & Le Feuvre, of Westminster; the general contractors, Messrs. Beardwood & Sons, of Dublin; and the contractors for the iron-work, Messrs. Rankin, of Liverpool.

The decoration of the buildings has been entrusted to Mr. Doyle; the prevailing colours are green and grey on the columns and ribs.\*

## PENS, INK, AND PAPER.

In the present time, when book-making, not only in a literary, but in a mercantile sense,—has so largely increased; when millions of letters are constantly pouring in and out of the Post-office; and when the increased spread of education is causing a call for copy and cyphering books; the constantly growing demand for paper is enormous; and now, too, as Mr. Gladstone predicted, paper is being used in the making of many things, such as carriages, which, even to us of the present day, seems remarkable. We will not just now speculate upon the means by which such huge masses of materials are to be provided in still larger and

\* In a previous volume will be found an exterior view of the design when it was first selected in competition.

larger quantities as each year rolls on, although this seems to be one of the world's wonders to those who have seen the great stacks of paper which are damped and prepared for each issue of the leading daily and weekly periodicals. Our object at present is to direct attention to the provision of enduring materials for the purposes of writing and printing matter which is of the greater importance when we consider that parchment has much gone out of use, even for very important documents.

The good state of preservation of some of the manuscripts in the British Museum, the Record Office, the hatches of ancient corporations, and the munition-rooms of religious houses and noble families, is remarkable. For instance, the chief portion of the Domesday Book, of Norman date, and other rolls and volumes now in existence in England, dating from 600 to 1,000 years ago, are for the most part so bright and fresh looking, that, but for the peculiarity of style, it might be thought that they had been executed not more than 100 years since. Those to which we refer are on parchment; but even as regards the writing and printing on this material, there is considerable difference, and many MSS. have become defaced and illegible. No doubt this is partly caused by want of care, and by exposure to damp, and other causes; but there is also much of this defect to be attributed to the nature of the materials.

During the past half-century, the process of paper-making has undergone a complete change; and the goose-quill pens have been superseded by those of iron. But for this, it is not easy to form an opinion as to what some would have done; for it seems doubtful if all the geese at home and abroad would have been sufficient to have supplied the writers of all classes in this reign of Queen Victoria. The materials of the writing-ink are also different; and acids have been introduced, which often do not act well on the paper, and which have also the effect of altering and eating away the tint of the colouring substance; and although these are a means of corroding those of metal; and even the dissolving of the metal is at times a means of altering the colour and of destroying some of the qualities of writing-inks.

We do not know how the penmen in the old times managed to hold in solution the ivory-black, or other materials, of which the ink was chiefly composed; but no doubt this was a difficulty then, as it is now; for in libraries, offices, and other places, where the air is dry and heated, the surface of the ink becomes of the consistency of jelly, and is unfit for use.

The easy working and the durability of writing-inks are matters of the greatest consequence, for on this depends the integrity of law papers, on which, in turn, property of immense value depends. There are also the accounts of great mercantile and other firms; and the letters and other relics of men and women famous in history, or in connexion with literature, science, and art. In the British Museum, a careful observer will find much that is instructive respecting the permanence of both writing-paper and ink; and it would be exceedingly useful if competent authorities were to classify the facts in connexion with this matter which there meet the eye, and offer suggestions for the advantage of the present and future generations.

In the MS. department of the British Museum there are letters of the English kings and queens which go back to a date more than three hundred or four hundred years ago. There are many other letters and documents of different classes, the copy of works which have become standard in our literature, and other matters which enable us to fix with certainty the date at which peculiar kinds of writing were executed, and to judge of the quality of the writing materials by the present state of their preservation. By means of our chemical knowledge and the aid of the microscope we may discover, almost to a certainty, the materials of which the paper and ink have been made; and by comparing various examples we may judge of what may be usefully imitated and of that which it would be well to avoid. In the public offices much information might be obtained on this subject. Take, for instance, that of the Registrar-General in Somerset House, where, we believe, the same ink and other writing materials have been in use since the opening of the establishment. If we were to compare the making of the ink here with that used—say twenty years back—in the British Museum, the Treasury, and elsewhere, we might learn much that is useful.

When we take in hand certain of the cheap but, so far as depends on the literature, good periodicals, and feel the flimsy nature of the paper, and note how it almost crumbles in the touch, and see the tints of pale green, bluish grey, and sickly yellow, and mark the thin and imperfect layer of ink which is placed upon it, we feel certain that the duration of those papers, when filed and preserved, is limited; and it would be a sad thing if this system of rotten paper and very indifferent ink should be introduced into our permanent literature.

#### THE DEPARTMENT OF ART AND THE PROVINCIAL ART SCHOOLS.

OBJECTIONS on the part of the Provincial Art Schools to the recent Minute of the Department continue to reach us, with resolutions passed and published. From the Yorkshire Central Committee of Art Schools we have received the statement of the Irish schools, of four important English schools, unconnected with each other, and of the six united Yorkshire schools; together with a letter, of which we give the principal portion—

"The opposition which has been brought into play by the foolish scheme of Government assistance proposed in the Minute, has come from the committees and supporters of art schools, and not from the masters. As yet there has been no action taken by the masters, who are, nevertheless, the greatest individual losers by the new regulations. From this it will be seen that the objections taken to the Minute are not those of individuals for an unfair confiscation of their own money, contributed by them in the form of taxes. And the one objection which is most generally felt and openly expressed by every committee of a school which has considered the question, is the Quixotic character of the scheme propounded, the utter and hopeless impracticability of the system of grant, and the flagrant want of experience and absence of knowledge betrayed by the framers of the Minute—of the subject of art-education in its application generally to the provincial towns. From this feature of the Minute, it is felt that Parliament ought not to sanction the application of so foolish a scheme. The Select Committee of Parliament condemned, and recommended the discontinuance of, the very features in the system of grant which the Minute adheres to, makes still more complicated, and develops into the fundamental principle of future grants,—I refer to the system of payment on results, complex though comparatively fair before; abstract and mysterious, and utterly unfair now. The Select Committee recommended, as the result of a most careful digest of all the evidence which the Art Department and the Provincial Schools could offer, a simple and just system of capitation grant on the instruction of artisans. The Minute rejects this recommendation of Parliamentary wisdom and provincial experience with contumely, discussing it in one short paragraph of what Mr. Beresford Hope calls 'irrelevant special pleading.'

It is but right, then, that the country should know how completely its rights and experience are being set at defiance, and even Parliamentary recommendations slighted and opposed by a few red tapists among its own paid servants; and this is not the opinion of those whose immediate interests are sacrificed, but of hard-headed business men who have taken for years active parts in developing the art-education of the country.

The masters, whose solemn contracts with the country are repudiated by its paid officials, can only throw themselves on the fair dealing of Englishmen who respect their own contracts, and who would not have their country's fair name made a by-word for repudiating her engagements. I hold four documents given me by the country, through its ministers, three signed by peers of the realm, Salisbury, Stanley of Alderley, and Granville, each contracting to give me 10l. per year so long as I fulfil my contract with the country. I am fulfilling it now, but I am not paid the stipulated sum, and these three peer-signed contracts the Government declares to be not worth the paper they are written upon. Hundreds of other men are in the same position as myself, and waiting, as I am, to see if Parliament approves of the morality of its Government.

The art-masters are waiting to see what Parliament will do, when the repudiators are

ministers of the Crown, peers of the realm, and the sufferers are fellow countrymen, Englishmen, whose lives have been spent in preparing for the service of their country, whose services have been approved of by Parliament's own appointed committee, and whose hard-earned wages in their country's service it is now proposed to confiscate. That is the art-masters' share of the suffering,—the morality which underlies the Minute. But the broad view of the case is even still more important. The art education of the kingdom, built up by its costly grants and its long experience, is being made the subject of a freakish experiment, in direct opposition to the wishes of Parliament, in opposition to national feeling, and contrary to the true interests of the country.

In such a case, the country can only appeal to its legislators and to a free press, to prevent an evil which will be national in its effects on the education of the country; and this the committees who manage the institutions whose extinction is threatened, have done, and are now doing.

Mr. Potter, the member for Carlisle, a man of great and long experience of schools of art, and a member of the late select committee on art schools, will test the feeling of the House of Commons when the vote for science and art is moved in the House; and it is to give the public a fair opportunity of learning the feeling of the country on the question that I am now instructed to write to you concerning it, and to request you, on behalf of the public interests, to make this appeal as public as the interests at stake.

WALTER SMITH,  
Hon. Sec. to the Yorkshire Committee of Art Schools."

It is very desirable, indeed, that the real effect of the new Minute should be thoroughly inquired into, and that the extent to which the Department has or has not acted in accordance with the report of the Parliamentary Committee should be well understood before the vote of funds is discussed in the House of Commons; but we cannot help feeling that such strong language as is being used in some places is unnecessary and unwise. The Department has fairly ceased and unwise. The Department has fairly ceased public its proposition some time before it can be acted on, and so that Parliament may say, can be acted on, and so that Parliament may say, "What you propose is or is not in accordance with the instructions given you." It may be right or may be wrong; but we have no reason to think it is not acting for what it believes to be the best. Out of doors, indeed, there are many who do not consider it altogether necessary that Government should pay part of the cost of teaching the middle classes. We have no intention of defending the Minute,—it seems to us a very hard Minute,—very unjust to the certificated art-masters. All we say is, discuss it calmly as a question of principles, not persons. A conference between representatives of the provincial art schools and the Committee of Council would probably lead to a better understanding and a more satisfactory Minute.

#### THE CONDITION OF PERTH.

In your remarks on the "condition of Perth," you state in reference to the outlet of the sewers in High-street and South-street, that "the river rises at full tide far above the lower levels, and consequently dams up and carries back their noxious contents."

This is not the case. The months of the sewers, even at spring tides, are not covered, and the sewage in consequence has free passage.

It is only when there are large floods in the river, about once or twice a year, that such takes place; and on such occasions I have tested them, and find that, in obedience to the laws of hydraulics, the water within the sewers requires only to rise a few inches higher than the level of the water in the river at the time, to secure a sufficient flow for the sewage entering them; and all that is required is to make provision by means of deodorising ventilators (which I have designed for the purpose), placed at the summits of the lateral drains and mains to allow the gases, after being deodorised, to escape into the air at a high level.

I have more than once within the last eighteen years seen many of the streets of the fair city covered with water during a flood in the river. At what height would you fix a high-level outlet to meet such a contingency? I fear the only way is to submit to the temporary inconvenience, or make a radical change in the level of the streets,—a thing not likely to take place for a

great length of time to come, if ever. The sewers, however, on such occasions will allow the water in future to pass off more rapidly as the river subsides.

From the above remarks you will observe that neither sluices nor high-level outlets are required so far as the tide is concerned, as it is no inconvenience; and that, seeing the maximum level of the floods is so high, they would be useless to meet the case of floods in the river.

In my opinion sluices would only create the evil you point at.

The following is an extract from my report to the Police Commissioners in 1862, when the High-street sewer was formed, which sewer is constructed of a size sufficient and at such a level as to receive all the sewage from the north and north-west parts of the town.

"In designing this sewer I have kept steadily in view the possibility of ultimately forming a catch-sewer, parallel to the river, along the proposed line of Tay-street and the shore, to intercept the whole of the sewage of the town, and cast it into the Tay at a remote distance below the city, or collect it for useful and profitable purposes, should further discovery establish the means of doing so. The height of the sewer above the bed of the river at the foot of the street will admit of this being done."

The above was published in the public newspapers in 1862, and shows what is ultimately intended in the way of drainage outfall.

The great difficulties the authorities of Perth have to contend with are the want of legal powers and funds. There is, however, every probability of these being shortly removed by the adoption of Provost Lindsay's Act.

John Young.

#### IMPROVEMENT OF NEW PALACE-YARD.

You have done good service in your late issue by calling attention to the condition of the precincts of Westminster Abbey, which I trust will awaken notice in the proper quarter. My object is now to call your attention to a cognate subject; that is, the present condition of New Palace Yard.

You will have, perhaps, observed, that Mr. Cowper has announced his intention to ask for a sum to enable him to have the unfinished front of the Clock Tower faced with stone; and also that some change is in contemplation by bringing Victoria-street through St. Margaret's-square. The public ought at once to be made aware of the exact plan, and particularly of the disposition of the now extended area of New Palace Yard,—a place hallowed by many historical recollections.

One of the main defects of the Palace is the lowness of the site, and yet it stands on what may be considered as the natural bank of the river; but this lowness is much exaggerated by the bridge and its approaches; indeed, the first impression it gives to a stranger viewing it from Bridge-street is, that it has been placed in a hollow, natural or artificial. This arises from the ground being sloped from both streets to the entrance of Westminster Hall. Now would it not be a main consideration to give architectural expression to the fact that it is the streets that are artificial mounds, and the Palace site the normal level? How best to accomplish this I would now with deference attempt to show. Excavate the whole space within the square formed by the two streets to the uniform level of the floor of Westminster Hall, and save the men, great and small, who enter that portal from the creeping pace and tentative steps caused by the awkward slope at the entrance. The streets should have substantial retaining walls relieved by slightly projecting piers, and protected by a parapet-wall not higher than that of the bridge, and to be duly stepped down in accordance with the slope of the two streets.

There is a great eye-sore in that gaping shed on the end of the Courts of Law, which ought to be done away with; and yet some substitute must be provided. Now, for that substitute let the ground-story of the Palace only be continued or returned from the unfinished side of the tower along Bridge-street, nearly as far as opposite the Hall door, say 50 ft. or 100 ft. Finish it by a flat terrace roof, with open-work parapet, the inside face to have the bays all open arches, which would answer the same purpose as the present unsightly shed. At the end of this addition, and exactly opposite the entrance to Westminster Hall, provide a fine flight of steps, landing at the corner of the terrace on a pave-

ment, which ought to be continued round three sides of the square, and finished at the two ends by two similar flights of stairs leading up to Parliament-street, one flight at the corner of the Courts of Law, the other within about 40 ft. of the intersection of that street with Bridge-street. The slope *inward* for vehicles should be adjoining the stair near the Law Courts, and outward that next to Bridge-street, the cab-stand remaining as at present. This arrangement would leave two oblong spaces, one between Bridge-street and the pavement in the yard in which, and extending from Parliament-street to the proposed flight of stairs near the terrace, the other the same width, but only extending along Parliament-street between the two slopes, and in rear of the cab-stand, these two spaces might be laid down in turf, and would form fine sites for statuary at some future time. The retaining walls should be of granite, and the parapet should be continued in open-work down the stairs and along the inside of the oblong spaces already described. If visions of idle boys riding on it disturb the architect, let him add between the piers a sloped coping, with a low sharp grille on the top.

J. W.

#### ABSORBING WELLS.

It would occupy not only too much of your valuable space, but more time than I can devote to the question, to enter into a chemical explanation of the changes produced in all arenaceous deposits on the quality and constituents of the water introduced into them. By the action of the sands, however, the deleterious ingredients held in solution become decalcified, and in that condition perfectly harmless. Indeed, the introduction of sulphates and other chemical elements aids the mutual reaction of all sands containing mineral substances in solution, and tends to free the water from impurities. Carbonic acid, always present in the sands of the plastic clay formations, precipitates lime and magnesia, converting them into insoluble carbonates. The action of water sets free in the *débris* of rocks of which the siliceous sands are composed, the alkalies and alkaline carbonates, which react upon the metallic salts, and a precipitate of insoluble oxides is the result. The mass of subterranean water is maintained in a state of comparative purity by the condition of the strata, having a tendency to contract its solvent power, and to re-combine the ingredients held in solution and to convert them into insoluble substances. The introduction of filtered sewage water has a direct tendency contrary to that of rendering the subterranean water impure.

The lower tertiary sands contain a large proportion of organic remains, sufficient, it would be thought, to have rendered the water contained in the mass permanently and hopelessly impure; but "the presence of animal and vegetable matter in a state of decay, either dispersed in accumulating strata, or dissolved in water, tends to decalcify various minerals and salts. Under these circumstances, sulphuretted hydrogen and carbonic acid gases would be generated by the decomposition of the sulphates and the latent combustion of carbonaceous substances. The peroxide of iron would be converted, first, into the protoxide, and then into the carbonate. The presence of vegetable matter would effect the alkaline silicates by supplying carbonic acid to their bases, whereby the silica would be precipitated, and alkaline carbonates disengaged."

As to the ammonia which your correspondent so fears as a dangerous compound to be mixed with water, and as one that can only be dealt with by vegetation on the surface, its constituents, nitrogen and hydrogen, are most rapidly separated and disposed of by our great laboratory; but ammonia can only be formed under peculiar circumstances,\* as when animal and vegetable substances containing hydrogen, nitrogen, carbon, and oxygen, are allowed to decompose and become putrid,—a condition that is specially guarded against by the arrangements made for receiving the water before entering the absorbing wells.

Mr. Fenton assumes the character of a dictator not unbecoming a chief of ancient date, when he holds with surprise that after a report of a Committee of the House of Commons, and after the works carried out under his direction at Croydon, any one should waste the fr-

\* A great part of nitrogen combines with hydrogen, and takes the form of ammonia.

utilizing matters contained in sewage. Does he for a moment imagine that such works were not carried out before he instituted them at Croydon? As a boy of eighteen I was engaged on extensive works of this character; and such works are still being carried out by parties who never heard his name. Further, can he not imagine there are cases in which it would be unwise, impolitic, and impossible, without the expense of machinery, and constant unprofitable outlay, to carry out such works?

With reference to the water in the sands and that in the chalk, I have well-authenticated information that I wish to make public, but I will not trespass on your space further this week than to repeat what I have said before. In nearly all cases an argillaceous bed of varying thickness separates the chalk and the tertiary sands, and prevents all, or nearly all, communication between them, especially in the north-western and north-eastern divisions of the tertiary formations. Mr. Robert Stephenson, in his "report to the Directors of the London, Westminster, and Metropolitan Water Company," expressed his strong opinion that the plastic clay sands are supplied with water chiefly from the chalk, and in some situations he is perfectly correct in this view; but that supply comes from the outcrop, and not from the bottom of the basin.

Mr. Fenton considers I am mistaken in stating that the water from the sands we refer to is often impure. My experience bears out fully what I stated, and I am satisfied to see it shared in by Mr. Mylne, Mr. Prestwich, Professor Brande, and others; and I have given sufficient reasons why it improves by use.

Mr. Fenton knows the position "of the absorbing well at New Barnet, and can state that it is within a short distance of the artesian well that supplies that place with water," and no doubt he also knows that I am now carrying out works and reservoirs for commanding a much larger area to be supplied with water. Well, the absorbing well is 2,900 ft. from the chalk well for supplying the water, and this is not very near, particularly as the water is all pumped from the chalk, and the absorbing well terminates in the sands; and, as all the water passes towards the valley of the Thames, and does not flow northward from that point, to say nothing of the existing argillaceous stratum above the chalk, and that the water from the sands cannot enter our pumping-well.

JOHN BLENKARN.

#### THE RAILWAY AND BUILDING MOVEMENT, AND THE DEMOLITION OF DWELLINGS.

I CAN readily show how Lord Shaftesbury's difficulty of raising 600,000l. to provide dwellings for 20,000 people may be removed.

The savings-bank funds, on the 20th November, 1864, amounted to 39,826,421l. 15s. 7d., and the profit fund to 392,590l. 16s. 11d.

Here, then, is a fund created by the *working* classes which *ought* to be advanced for their benefit: the security, that is the buildings to be erected, would be ample, and the benefit in an increased rate of interest beyond the present investment would increase the fund: the money is lent on *Turkish* bonds; why not on freehold security?

I have been for several years importuning Members of Parliament to introduce a Bill into Parliament to establish a Board of Commissioners, to be entitled the "Commissioners for erecting Workmen's Dwellings." There is an *unproductive* portion of the fund *more* than equal to hear the expenses of the Commission.

WM. WOODFORD.

#### WATER-LIFTS FOR RAISING WEIGHTS.

A YOUNG engineer of Paris, M. Léon Edoux, has lately contrived an excellent machine for raising weights vertically. The system, first essayed and put into practical use during the erection of a large mansion in the Rue Lafayette, consists in making use of water as a counterpoise to the materials required to be lifted to different heights above the ground. The apparatus consists of a double framework or tower of timber, formed of six uprights, and braced together by cross ties at distances. These uprights serve to guide the ascent and descent of two wrought-iron boxes or platforms of equal weight, and capable of holding two cubic metres or two tons of water each. A chain, connecting the two boxes, passes over two fixed pulleys at the top of

the framework, so that when one ascends the other descends, and the bottom of each box is furnished with a valve which can either be opened by hand or some contrivance on its touching the ground. To understand the working of the apparatus, let us suppose one of the platforms on the ground and the other at the top of the tower or framework; the bottom one filled with the materials required to be lifted. Water is admitted by means of a supply laid on from the water-mains into the upper vessel until not only the weight but the resistance from the friction of the chain is counterbalanced: as soon as this is the case, the platform containing the water descends and the materials in the other are raised to the required height. A break, to regulate the motion, renders this apparatus complete. As regards safety and certainty of performance, this lifting-engine is incomparably superior to all others for house building, and far cheaper also. The cost of installing the lift is about equal to that for raising weights by manual labour, and considerably less than that worked by Lenoir's gas engine. This system is by no means a new one, and Baron Ségnier states that Sir I. K. Brunel showed him, twenty years ago, at the Chatham Dockyard works, the application on a large scale, of the equilibration by water to the raising of immense loads of wood to considerable heights during the construction of a bridge. At the great tunnel under the Alps, the counterbalancing by water is applied to the working of an inclined railway at the Modane (Savoie) end, where the entrance to the tunnel is 3478 feet above the high road. Besides a road of moderate incline, and, in consequence, of some length, an inclined plane has been constructed, with a gradient of 1 in 2.23, part of the width (21 ft. 4 in.) being occupied by 464 steps, cut in solid rock, for pedestrians, and part by a railway forming a self-acting incline. This is worked by a rope, to either end of which is attached a wagon capable of holding two tons of water in a suitable tank, besides the materials required to be drawn up, passing over a drum at the top. The materials or implements required to be drawn up being placed in the wagon below, as much water is allowed to escape from the tank as will cause the weight of the upper tank to predominate, when the motion immediately commences, the heavier descending and the lighter ascending, while the velocity is controlled by a powerful break.

#### WINWICK, HUNTINGDONSHIRE.

THIS church has been thoroughly restored, at the cost of the patron, the Duke of Buccleuch. It was formerly in a most dilapidated state, and had suffered even more than usual from neglect and "churchwardens." It possesses many points of interest. The arcades and chancel are of a simple and beautiful type of First Pointed work. The south door of the aisle, though pointed, has most rich mouldings and zigzags, of a Norman character. A fine transept was added in the Third Pointed style, and a private chapel, screened off from the church by very elaborately carved screens. The roofs were of the Third Perpendicular period, and very richly moulded and carved, but were in a very decayed state. It was found necessary to rebuild portions of the chancel aisles, to rebuild entirely the transept clerestory walls and porch, inserting the old masonry of buttresses. The roofs were restored where found necessary, but every portion of the old work has been most religiously preserved. The chancel roof, being modern, has been removed, and a new roof of oak substituted. The seats are open, and very similar to the old bench ends found in the church. The pulpit is of stone, the upper part being open, and formed of columns, supporting a richly moulded cornice. The eagle is of oak, and carved by Mr. Pepper, of Brighton. The tower and spire have been partially rebuilt, the bells rebung, and one of them was recast.

A new parsonage-house has also been erected near the church, the material used being white brick, and stone dressings to the windows, &c. It is remarkable that in the recent conflagration, which destroyed almost the whole village, the church and parsonage, though surrounded on all sides by the fire, escaped unharmed.

The cost of the restoration of the church was 1,600l.; the cost of the parsonage-house, 1,850l. The works have been carried out by Mr. Walter Parker, of Thrapstone, under the inspection of the architects, Messrs. Slater & Carpenter, of London; the clerk of the works being Mr. Peebles, of Northampton.

## CHURCH-BUILDING NEWS.

*Thornton: Pickering.*—We are asked to mention that the name of the architect engaged in the restoration of this church is Mr. E. Wyndham Tarr, not Scott as stated.

*Bunney (Suffolk).*—A meeting of the ratepayers of St. Mary's (convened by the churchwardens) was recently held, to consider the proposal of the architect for restoring the parish church, and the best means of obtaining the requisite funds for carrying out the whole or a portion thereof. Mr. T. Owles, one of the churchwardens, says the *Suffolk Chronicle*, explained that the meeting had been convened, at the suggestion of the bishop of the diocese, for the purpose of forming a committee of ratepayers to consult with the churchwardens as to what repairs might be deemed necessary, and the best means of carrying them out. Mr. Owles justified the churchwardens in having undertaken certain work in the church since the last meeting, by explaining, that what had been done was essential to the safety of the fabric; and he read an extract from a report read by Mr. Gravatt, C.E., to Mr. Hartcup, in which he stated, the building is at present unsafe, and that divine service should be discontinued until four of the columns or piers, which had been pointed out to the churchwardens and others, were entirely rebuilt. Mr. Owles afterwards read extracts from a correspondence between the churchwardens and Mr. Drew, architect. The repairs were stated to be, "to restore the columns, clerestory windows, to clean the old plaster from the inside and outer walls, and to renew the same; to take down the old altar-piece and to restore the wall behind it; to remove the east window, by bringing it 14 in. to 18 in. lower, and secure the wall, and perhaps flint the outside; to face the outer walls with flint between the aisle roofs and the nave roofs; to secure the parapet walls where required, and to fill in and make fast all defective portions of the outer walls, and to secure the tie of buttresses and walls by proper pinnings;" and which work they (the churchwardens) had calculated would cost from 500l. to 600l. Mr. Drew, in his reply, said he would be willing to undertake the superintendence of an outlay on works not to exceed 500l. or 600l., if the services of an efficient clerk of works were allowed him; but at the same time he declined to express an opinion as to whether the proposed outlay would accomplish the work contemplated. Mr. Owles moved the appointment of a committee. A lengthened, very discursive, and warm debate ensued, in which an old question, "Why was the church wilfully mutilated?" was foremost, and this was urged with the greater force, as one of the churchwardens who had acted upon the "restoration committee," admitted, that at that time the condition of the piers did not appear to justify any fear of their stability and permanence; whilst Mr. Gravatt, in his report, had stated, "if the piers had not been so roughly handled, the supposition that they would have stood for very many years was not unreasonably." Mr. Hartcup, Mr. Brand, and others, stated their unwillingness to act upon a committee to restore the mutilation committed by the incumbent. Ultimately it was resolved to form a committee to consider the whole matter, and to report to a vestry meeting.

*Langar (Notis).*—The parish Church of Langar has been re-opened for divine service after its restoration. After the sermon a sum of 155l. 16s. 4d. was collected in aid of the funds for the completion of the tower. The original Early English structure had been nearly destroyed by time, only the tower and arches of the nave having preserved their character. The remainder of the church was of a decayed character, having been rebuilt in 1670. The north side was restored about twenty years ago, from designs by Mr. Hino; and the chancel about 1851, from drawings by the same architect. The present restorations comprise the south side of the nave and the south aisle, the north and south transepts, and the tower, which have all been taken down to the foundation and re-built. The Early English character of the tower has been preserved as far as it has as yet been completed, which is only to the roof of the nave and chancel, and the transepts have been rebuilt in the same style. It is intended to complete the tower on the model of the former work, preserving whatever stones are capable of being used again. The expense of the recent work has been nearly 1,000l., including the transepts, which are the burial-places of the Earl Howe and Mr. J. Chaworth Musters, and the expense of which has

been borne by them respectively. One of the improvements is the replacing of the pews with open seats, and removing the reading-desk and pulpit to situations which front the whole congregation.

*St. Juliot (Cornwall).*—The church, according to the *Cornish Telegraph*, is about to be completely restored under the direction of Mr. Sedding, of Penzance. The building is now in a deplorable state, part of the south aisle being open to the sky, the chancel walls being inside with ivy, and the tower cracked so seriously as to be in constant danger of falling. Many of the old seats remain, and will, with the old screen, be retained. New roofs will be added throughout the church, with new tile floors, altar, chancel fittings, and nave seats: the north wall of nave will be rebuilt, and the rest of the church thoroughly repaired.

## DISSENTING CHURCH-BUILDING NEWS.

*Morice Town.*—The *Devonport Independent* states that the new chapel, Haddington-road, Morice Town, is now completed, and opened for public worship. It has been erected in connexion with the "Bible Christian" denomination. Mr. P. St. Anlyn was the architect. The principal entrance is in Haddington-road, and consists of a vestibule with portico, supported by two fluted pillars. The body of the chapel is screened off by a transparent partition of fluted glass. The modern style of platform is substituted for a pulpit, and can be rendered available for meetings of every description. The contractor was Mr. W. P. Turner, of Stoke. The graining was executed by Mr. Cole, of Plymouth. The chapel is constructed to seat 500 persons. Adjoining the chapel is a vestry and a school-room, the latter to hold 200 children.

*Bowling (Yorkshire).*—According to the *Braford Observer*, the new Independent chapel in Bowling has been opened for divine service. The style of the building as principally shown in the front elevation to Essex-street, is Romanesque or semi-Norman in character, and the interior is of unpretending appearance. When the whole space enclosed by the main walls of the building is devoted to sittings, the accommodation will be for about 800 adults, and the internal dimensions will be 70 ft. by 45 ft., and 34 ft. high. At present a temporary wall divides the space into two portions, that in the rear being devoted to school purposes. The accommodation now provided in the chapel is for 500 adults, viz. 300 on the ground floor and 200 in the galleries. The pulpit is of the platform kind, and the front is of open iron-work decorated in simple colours and gilding. In front of the pulpit is a communion platform, raised 21 in. above the floor of the chapel, and surrounded by a polished oak handrail and iron standards, decorated in a similar manner to the pulpit iron-work. The floor of the school-room is on a level with the gallery passages and communicates with them. The room is 26 ft. wide and of same length as the width of the chapel, viz. 46 ft. It is boarded on all sides to the height of 4 ft. 6 in. from the floor. The ceiling is a continuation of the chapel ceiling, so as to be available without alteration when the chapel is enlarged. The windows, &c. are arranged with a view to adaptation to the future new school-room, space for which has been reserved on the site in the rear of the chapel. Underneath the school-room are three class-rooms, a class-room for infants, a minister's vestry, and all necessary conveniences. These all have an independent communication with the school-room by means of a stone staircase, which has been planned so that it will be equally available for the future school building. The whole of the buildings are heated by Messrs. Loughottom & Co., of Leeds. A shaft for the purpose of ventilation is carried up in the rear of the chapel, into which flues from the architects, under whose superintendence the whole of the works have been carried out, were Messrs. Paul & Aylife, of Manchester and Bradford; the general contractors, Messrs. Booth Dillingworth & Son, of Bradford. The gas-piping has been laid by Mr. Schofield, of Bradford. The clerk of works was Mr. Bottomley. The entire cost of the building, including the boundary fences and professional charges, amounted to 3,000l., besides the cost of the land, which was over 300l.

*Dairycoates (Hull).*—The foundation stone of a new Wesleyan chapel has been laid in this newly formed village, by the Mayor of Hull. This outskirts of the town has been formed

chiefly by the workmen engaged on the works of the North-Eastern Company, and to the present time upwards of 100 houses have been erected on the Hessele-road near the railway crossing. The building will be in the Gothic style, expressive of its character and purpose, but simple in detail. It will be faced with red stock bricks, relieved by the introduction of some few stone dressings and white stock bricks. In the front gable will be a three-light window, and on the sides a series of two-light windows, divided by mullions. The entrance to the chapel will be by a porch on one of the sides. The roof will be of considerable pitch, covered with slates, having an ornamental ridge, crest, and finials at the gables. The internal dimensions of the chapel are 41 ft. 3 in., by 25 ft., with sittings for 150 persons, of which one-half are to be free. In the rear of the chapel will be a Sunday school-room, 23 ft. by 16 ft. Mr. W. Botterill is the architect, and Mr. W. Barritt and Mr. J. Wales the builders. The cost, including the ground, will be about 500l.

*Corbridge.*—A new Wesleyan chapel, at Corbridge, has been opened for divine worship. The style of the building is Gothic, and the sittings will accommodate 360 persons, room also being left for a gallery, should such be required. There is a school-room attached, and the entire cost is estimated at about 1,000l. Mr. Haswell, of Shields, was the architect; and Mr. Harrison, of Gateshead, the builder.

## STAINED GLASS.

*St. Andrew's and St. Mark's, Lakenham (Norwich).*—A stained glass window has been put up in St. Andrew's, and two in St. Mark's, Lakenham. The window in St. Andrew's is the gift of Mr. James Stone, and is at the east end of the church. It represents the Christian seasons, the subjects of which are arranged in the following order:—"The Nativity," "The Adoration of the Magi," "The Baptism of the Saviour," "The Crucifixion," "The Resurrection," and "The Ascension." The panels beneath the main subjects are filled by representations of the three stages of the sacrifice of Isaac, which were suggested by the old glass which has been removed from the window. In the upper tracery of the window the apostles occupy the centre lights in two tiers, and on either side are seen figures of Moses and Elias, representing the law and the prophets, and on the other "The Fore-runner" and the "First Martyr." In St. Mark's Church two new windows have been put up at the east end—the centre window being the gift of the Rev. H. R. Nevill, the late minister, and of the Rev. N. T. Garry, the present incumbent. The subject in the left-hand light represents "The Agony in the Garden," and that on the right-hand "The Appearance of the Saviour to St. Thomas." The subjects of the north window are "The Last Supper" and "The Appearance to the Seven Apostles at Lake Tiberias." The south window was filled by painted glass before the consecration of the new chancel, a few months since, and thus all the windows at the east end are now completed. The artist of the three windows described was Mr. Hughes, of London.

*Lymington Church (Hants).*—The glass painting of the "Crucifixion," the gift of Lord George Gordon Lennox, has been inserted in the chancel window of this church. The painting is, we believe, one of considerable antiquity and value. The rest of the window, the stonework of which has been restored, has been filled in through the liberality of the Duchess of Richmond, with diaper-pattern glass of an amber and grey tint, to harmonise with the painting.

*Gloucester Cathedral.*—The memorial window to Dean Rice, in the east cloister of the cathedral, is now uncovered. The artists are Messrs. Clayton & Bell. Each window of this cloister consists of two lower tiers of eight lights, and lights in the tracery. In the memorial window to Dean Rice, as in most of the other windows, the lower tier is filled with decorated panes; on these are armorial bearings and artistic enrichments. The second tier of lights is filled with scenes connected with the birth of the Saviour. On the first two lights are the wise men discovering the star in the east. In the next two they are approaching Herod with offerings, and demanding, "Where is He that is born King of the Jews?" With Herod is one of the chief priests. In the next lights are shown the wise men presenting their offerings of gold, frankincense, and myrrh, to the infant Saviour.

In the seventh light the Virgin Mother is showing the child to the strangers. A star beams down upon the group. Joseph appears in the eighth light. From the centre light of the tracery a large star shines upon all the pictures. The other tracery lights are filled with quarries of white decorated glass, with central ornaments and ornamental borders. The figures are drawn on a blue enriched ground, with decorated borders. Nearly all the windows in the east cloister are now filled with painted glass. There are yet four windows to be filled, but these are now taken. The mullions of the second window from the south end are being prepared for the reception of glass by Hardman, as a memorial to Dean Plumtree. In the north aisle of the cathedral the five windows remaining unfilled will have painted glass in them before the Festival. The large window over the east entrance to the cloisters is about to be filled by Wailes, of Newcastle, in memory of a relative of the Rev. Sir Lionel Dorell. Mr. T. Marling has selected another of the windows as a memorial to the late Mrs. Marling; Clayton & Bell will supply the glass. The lower window is to be filled in memory of the late Mrs. Price: the artists are Ward & Hughes. The dean and chapter have voted money to fill the remaining two. Mr. Niblett has a window of Munich glass ready to be placed in the cathedral. This will probably take the place of the glass in the Davy window in the south aisle, which will be removed to another part of the cathedral.

## FROM IRELAND.

*Improvements in Belfast.*—There are several projects now on foot which all tend towards the increase of public accommodation and the general improvement of this town. A new club, in Donegall-place, the Northern, is either completed or nearly so, and ready for opening. A new theatre has been projected, and a new hotel, on a very large scale, in the neighbourhood of the Linen Hall: advertisements have also appeared for a site for a new concert-hall. In Bridge-street extensive new buildings are being rapidly erected by Messrs. R. McKenzie & Co., and adjacent improvements are being carried out by others. The demand for respectable dwelling-houses in the town and suburbs quite exceeds the supply. The building of really good dwelling-houses, at what would be called high rents, is not yet what it requires to be, but the building of small houses in all parts of the town continues with great rapidity, and new roads are being opened up at Castleton, Fort William, and other localities for the development of lands suitable for villa sites. The "Plains," a large district of grazing field, in Malone, have been drained, levelled, and laid out for streets, and the erection of houses has commenced. A new Methodist College is about to be erected on the Old Lisburn road on a large scale, and at a cost of 27,000l. On all sides are to be seen signs of rapid increase and improvement in shops, mills, and other premises. The Oddfellows' Society are about to build a new hall. The new Methodist church, at Fountainville, is completed. A new drinking-fountain is now almost finished, and stands at the angle formed by Great Victoria-street and the Old Dublin-road, nearly opposite the end of Donegall-pass. It is built of stone, and will combine a drinking-fountain and an ornamental lamp. The building may be said to consist of three divisions,—pedestal, shaft or lantern, and roof. The total height is 21 ft. The architect was Mr. W. J. Barre, and the builder Mr. Graham.

## PROVINCIAL NEWS.

*Framlingham (Suffolk).*—The Middle-class Albert College, at Framlingham, was opened on the 10th instant, by the admission of about 150 pupils, the formal and ceremonial opening being deferred till July, when it is hoped that the Prince of Wales will be present at the uncovering of the statue. There are now 274 pupils nominated, and only 300 will be admitted in all. The dining-hall is a large apartment, the ceiling of which is adorned with the coats-of-arms of the governors. The dormitories are lofty and well ventilated, with lavatories adjacent thereto, but distinct from, the bed-rooms. There are also convenient bath-rooms. In the erection of the college there were two fortunate occurrences,—the first, that excellent brick-carth was found in the fifteen acres of college ground, from which

all the bricks required have been made; the second, that a vein of gravel of fair quality was also found there, after having been vainly sought in the locality. The saving in the cost of the buildings, roads, and paths, is estimated at 1,000l.

*Uttoxeter.*—It is in contemplation by a number of gentlemen to erect a corn exchange and covered butter-market for Uttoxeter. The site it is intended the exchange shall occupy is at the present time covered by premises adjoining the Old Talbot Inn, in the market-place, in front of which the corn-market of late years has been held.

*Worcester.*—The Arboretum and the china works, or at least a portion of them, are to be used for the site of the works to be erected as the manufactory of the Royal Porcelain Company, whose business is now carried on at Diglis. The Arboretum has been purchased by the company, and possession of the grounds will be taken at Midsummer, and as soon as possible afterwards the erection of the new works will commence. The preparation of the plans has been entrusted to Messrs. Scrivener & Sons, of the Potteries, architects, who have supplied designs for many of the largest establishments of the kind; but the new Worcester works are to be superior in magnitude, in adaptability of construction, and in design.

## THE BUILDING TRADES.

The operative joiners of Halifax have resumed work, having been out on strike one week. They have accepted the masters' offer of 54 hours a week labour. The men wanted a reduction from 57½ to 52½ hours.

The painters and plumbers of Burslem and Tunstall are on strike for advance of wages. The masters met to consider the demand of the men. On that occasion all the Pottery towns and Newcastle were represented; and, after the hour session had been discussed, it was unanimously resolved that it should be introduced, and payment given at the rate of 6d. an hour for skilled workmen, and superior and inferior workmen at proportionate rates. The masters also notified that, unless the men acceded to their proposal, a general lock-out would take place. The men declined the proposal, and they are consequently locked out till the masters can again meet to consider the resolution of the men.

At Wolverhampton the delegates of master builders and operative carpenters and joiners in this town, having appointed Mr. Rupert Kettle, judge of the Worcestershire County Courts, to be the umpire at their conferences to draw up trade rules and to settle future disputes, and that gentleman having consented to accept the office, the delegates recently held a conference, under the presidency of Mr. Kettle, for the drawing up of the trade rules. The meeting was conducted in a conciliatory spirit on both sides, and the whole of the rules were mutually agreed to without the casting vote of the umpire being required in even a single instance. Mr. Kettle has offered his services as between the masters and the men engaged in other departments of the trade.

The masons of Bodmin call the attention of their employers to the present rate of wages as being below the average of other towns, and request a rise to 1l. per week. The present rate of wages, they say, will not average more than 12s. per week, taking the winter into account.

## RAILWAY MATTERS.

The works of the Metropolitan District Railway, which will complete the Inner Circle, are commenced in several places, among others at Cannon-street, City, where it passes under and communicates with the new station of the South-Eastern Railway; also at Earl-street, Blackfriars, where it communicates in the same way with the London, Chatham, and Dover line; thus enabling the public to pass immediately on arrival to and from both systems.

A new step has recently been introduced by the South-Western Railway Company, in order to provide against accident, namely, by painting the rear guard's van red. It is thus much more plainly seen. What a commentary on our practice of dressing our soldiers in red!

The proposed high-level bridge which is to carry the South Wales and Great Western Direct Railway across the River Severn, near to Chep-stow, is, according to the design of Messrs.

Fowler & Fulton, the engineers, to be two miles and a quarter in length, and is to have sufficient headway to permit masts of ships of 122 ft. in length to pass under when the surface of the river is at the main tide level, so as in no way to impede the navigation. The principal opening, which is to cross the low-water channel, is to be 600 ft. span, being the total width of the Thames at Southwark Bridge, or 150 ft. wider than the opening of the Menai Bridge. Messrs. Fowler & Fulton estimate the probable cost of this bridge at 980,000l., for which sum Messrs. Cochrane, Grove, & Co., bridge contractors, have undertaken to complete the work.

A house was lately set on fire by the engine of a train from Belfast, at Gorristown, Louth, near Drogheda. The wind being high, the fire destroyed all before it quickly, and burned both a dwelling-house and a car-house to the ground.

The traffic receipts of railways in the United Kingdom amounted, for the week ending the 1st of April, on 11,841 miles, to 607,094l., and for the corresponding week of last year, on 11,490 miles, to 599,787l.; showing an increase of 351 miles, and an increase of 7,307l.

## ACCIDENTS.

At Ossett, Wakefield, in a heavy storm, two men who were engaged at work on the top of a chimney, 34 yards high, became alarmed, and, losing their presence of mind, simultaneously jumped into the cage by which they ascended and descended. Unfortunately no one had hold of the rope at the bottom of the chimney to counterbalance their weight, and the cage descended to the ground with frightful velocity. One of the men had both his legs fractured, and was otherwise dangerously hurt. His companion escaped with a sprained ankle and a few bruises.—At Rockdale, during an election meeting of two or three thousand persons, a panic occurred: a gas-pipe broke, and the lights were turned out in an instant. Intense consternation and excitement were caused by this. Women and men were screaming, windows smashed to get out, and there was great rushing to the doors. The chairman implored the audience to remain quiet. Some only accepted the advice. Many of the persons present were severely bruised. After a time all were got out safely.—At Yarmouth the massive new crane recently erected on the town quay at the expense of Vice-Admiral Love, and manufactured at the iron works of Messrs. Lloyds, Foster, & Co., Wednesbury, at a cost of 200l., suddenly fell while hoisting out heavy blocks of Portland stone from a galliot. When lifting the first stone, the centre part of the main shaft, which is fixed in the ground at some considerable depth, broke short asunder by the weight of one block, estimated at 1½ ton only, which was about 2 ft. clear when the crane fell from this comparatively light burden. The crane was found to be very much damaged. The oak timber arm is broken in midships; the screw bolts in many parts are broken off; and the crane in itself is altogether crippled. It was guaranteed to hoist a weight of five tons when purchased.

## RECENT PATENTS CONNECTED WITH BUILDING.\*

TREATING CLAY, ARTIFICIAL STONE, METAL, OR OTHER PLASTIC OR MALLEABLE MATERIAL, TO RENDER IT MORE SUITABLE FOR CONSTRUCTIVE PURPOSES.—R. H. Smithett & J. Davidson. Dated 29th April, 1864.—The patentee claims rolling, casting, moulding, or pressing such material or materials between or in such rollers, moulds, or dies, as will produce bricks, tiles, blocks, or plates, having on one side projections of a pyramidal, conical, hemispherical, octagonal, or other analogous form, and on the other side corresponding holes or depressions of a similar form; the said projections and depressions being so arranged that they shall interlock when the bricks, tiles, blocks, or plates, are used for constructive purposes.

VENETIAN BEAMS.—D. Clarke. Dated 30th April, 1864.—The first object of this invention is to construct the laths and framework of Venetian blinds of iron or other metal, instead of wood, as heretofore. The patentee proposes that the laths shall be of corrugated iron. He proposes to give motion from the centre by fitting the frame with two or more uprights, upon which revolves

\* Selected from the *Engineer's* lists.

a spindle (by preference tubular), and upon which spindle the laths are hung and are free to revolve in either direction as may be required. Upon those parts of the spindle upon which the cords or chains of the laths are to work, he proposes to place vulcanised india-rubber sockets, so that the cords or chains may have a firmer hold or grip than they would otherwise have upon the metal, or instead of the india-rubber sockets he prefers, in some cases, to employ milled brass pulleys in which the chains and cords are free to work.

**FASTENING OR CONNECTING BRICKS TOGETHER FOR BUILDING PURPOSES.**—*R. H. Smithett.* Dated 29th April, 1864.—This invention consists in fastening or connecting bricks together for building purposes by casting, moulding, or otherwise forming two holes in such bricks, and connecting the same by pegs or dowels, as described.

**APPARATUS FOR VENTILATING, FOR PROTECTING FROM HEAT, AND FOR HEATING AND COOKING.**—*T. Steven & C. Batty.* Dated 14th April, 1864. This invention relates to, and consists in certain methods of producing or inducing atmospheric or aëiform currents with the aid of heat, and otherwise, for protecting from heat, and for heating; and the invention also consists in apparatus therefor, and for applying heat in cooling.

**MECHANICAL ARRANGEMENTS TO BE APPLIED TO DOORS AND CASEMENT WINDOWS TO PREVENT SLAMMING OR CLIPPING.**—*W. Owenden, sen. & W. Owenden, jun.* Dated 16th April, 1864.—This invention consists in a barrel, composed of brass, iron, or other suitable metal, varying in size according to the size of the door to which it is to be applied. This barrel the patentees fill with oil. In the inside of this afore-mentioned barrel there are two or more relieving passages, in order to permit the oil or air to flow more readily. Within the before-mentioned barrel there is a piston made of brass, or other suitable metal, and fitted with a piston-rod of steel, iron, or other suitable metal, passing through one end of the barrel, which is closed by a screw cap fitted with a leather washer to render it close, and fitted with a screwed gland, through which the piston-rod is cased to work tightly to prevent leakage. The gland may be covered with an ornamental cover or cap, if desired, which will hold and retain any drops of oil or air and lard that may escape. The end of the piston-rod is fitted with a fixing plate, whereby the apparatus can be attached to the jamb of the door, or the top panel thereof, or in any other position that may be required, by means of screws, nails, or other equivalent fastening. This said fixing plate is also furnished with a regulating screw, actuated by a nut, and secured by a clamping-nut, whereby the length of the piston-rod may be adjusted to the length of the before-mentioned barrel.

**CONSTRUCTION OF SUBMARINE WORKS.**—*B. B. Stoner.* Dated 16th August, 1864.—The patentee proposes to construct sea walls, piers, quays, breakwaters, and similar works of large blocks of masonry, brickwork, concrete, or other materials, which are first built in a convenient site, and then removed and deposited in their proper places in the construction or work in hand. As these blocks are intended to exceed greatly in their dimensions those which have hitherto been employed, it is requisite that specially powerful appliances be used in their transportation and manipulation. For this purpose it is proposed to use peculiar floating shears, consisting of a water-tight barge, having tanks or compartments, for holding the water to be emptied or filled, as occasion may require, in any well-known way. On the barge are fitted two pairs of shear legs and back stays, the one pair projecting over one end of the barge and the other pair at the opposite end. A crab, winch, hydraulic cylinder, or other similar contrivance, is placed on the barge, and from this a chain passes up to the top of each pair of shear legs. The block of masonry, or other load to be transported, is suspended by this chain from one pair of shears, a counterweight being suspended from the chain at the other pair of shears. In using these floating shears the barge is brought alongside the wharf or place where the blocks have been built, and the proper end of the chain is attached to a block. The rising tide, or power applied to the crab winch, will raise the block; and in order to prevent it from capsizing the barge, a tank or compartment at the other end is charged with water, while water is discharged from a tank or compartment at the end next the block. In this state the barge and block are conveyed to their destination, and the block lowered to its place. Water is then allowed to

escape from the tank or compartment remote from the block or load, and to enter that next to it, in order to restore the balance. The counterweight on the chain will assist in working back the crab, and so draw up the end of the chain again and prevent slack.

### Miscellaneous.

**COBDEN MEMORIAL.**—A statue of the late Mr. Cobden is to be erected in Manchester. A considerable sum has been already subscribed for the purpose.

**THE MARKET COMPETITION, SMITHFIELD.**—One of the competitors asks anxiously what the Corporation of London have done in this matter after four months' consideration. Perhaps the City Architect will kindly enable us to reply.

**PARIS INTERNATIONAL EXHIBITION BUILDING.**—We hear good things of the design that is determined on for the Exhibition Building of 1867, and which is to be erected in the Champ de Mars. May the doings of Peace ever thus supplant those of War. The centre of the building is occupied with a garden, round which radiate the courts.

**ROYAL ITALIAN OPERA.**—Since Madame Viardot Garcia there has been no *Fides*, in the "Prophète," anything like so good as Mlle. Philippine de Edelsberg, from Munich. Acting as well as singing is needed for the part, and in both respects the new lady is very satisfactory. Mario, spite of an occasional betrayal, is still supreme as *Jean de Leyden*; and the opera throughout is given in a style which few of us are likely to see surpassed.

**DEPARTMENT OF NATURAL SCENERY.**—The *New York Times* says the Legislature has passed a Bill declaring it a misdemeanour, punishable by fine or imprisonment, or both, to deface scenery, fences, monuments, or buildings, with advertisements of patent nostrums, such as for years have marred the natural beauties on the routes of travel by railroad and river throughout the State, and grossly offended the good taste of tourists and wayfarers.

**SHELLS IN FLOORS.**—One of our readers, who is always ready with an illustration or parallel, with reference to the observation at p. 258, ante, "the floor at Saville House filled in with cockle shells for pugging," says:—In the *Transactions of the Royal Institute of British Architects*, February 20, 1854, p. 65, "French Floors," it is noted:—"Mr. Inman (chairman) mentioned that a layer of cockle-shells, about 2 in. in thickness, was introduced into the floors at Hampton Court Palace, for the purpose of deadening sound." (Sir C. Wren's work?)

**SUGGESTIONS.**—Sir: Might it not be advantageous to suggest the removal of the diminutive dome from the roof of the river front of Somerset House; and also to suggest that by a small outlay the quadrangle might be put in order, and possibly the fountain made to act. Is the Armoury of the Tower not worthy of your notice? The rooms over the White Chapel have been very tastefully arranged, and there is now free access to the chapel.—W. H.

\* \* \* The Armoury has often had our attention. St. PATRICK'S CATHEDRAL, DUBLIN.—The south window of St. Patrick's (restored) Cathedral, Dublin, consists of three lights, filled with designs representing the Fall, the Redemption, and the Promises. There are also in the west window three lights, and in these are represented the Early Life, the Mission, the Preaching, and the Episcopacy of St. Patrick. Both windows are by Mr. Wailes, of Newcastle-on-Tyne.

**SEMIOS ACCIDENT IN THE SEVEN SISTERS ROAD.**—The tunnelling for the new sewer under the Seven Sisters-road, Holloway, had been safely completed, as well as a portion in Black Stork-lane; and on Saturday the men were engaged, under the contractor for the work, Mr. W. H. Rowe, of Clouster-place, in completing the brickwork and tunnelling at Strand-green-lane, at the junction with the Seven Sisters-road; and two of them, who were at the bottom, were putting things straight, ready to commence work on Monday morning, when a large portion of the heading gave way, and, falling upon them, entirely buried and killed one of them. The other was fortunate enough to escape, but received injuries from the earth falling upon him. The cause of the falling in of the heading is as yet unexplained.

**THE DOE PARK RESERVOIR.**—The magistrates have granted a certificate of the satisfactory completion of this reservoir.

**SEWERAGE OF WORKINGTON.**—The contractor for sewerage the town of Workington has broken ground. The work will be vigorously pushed forward, so as to be completed in ten months.

**BELLS.**—A complete peal of six new bells has been hung in the belfry of Gainford old church, which has recently been undergoing restoration. The bells were cast by Messrs. Taylor & Co., of Loughborough.

**BUILDING PROGRESS AT NORTH SHIELDS.**—It is stated that the Lawson Estate, which contains some of the best building sites in the west end of North Shields, has been purchased by Mr. G. O. Trevelyan, the amount of purchase-money being above 60,000l.

**CHURCHES FROM A MOULD.**—Sir: A new Congregational Church has been opened at Crediton, in Devonshire, having been erected from a model plan, for which the English Congregational Chapel Building Society awarded a premium a few years ago. This is the fifth place of worship that has been built from this design.

CAST WORK.

**MODEL OF SEBASTOPOL.**—A large plan, in relief, of Sebastopol, is now being arranged in the gallery of the Hôtel des Invalides, in Paris, where those of the fortified towns of France are placed. The plan in question is executed in plaster, in twenty parts, and, when put together, will measure more than 10 ft. in length, and more than 7 ft. in width. It is on the scale of one in 2,000.

**THE POLYTECHNIC INSTITUTION.**—The illustrations of Captain Burton's pilgrimage to Mecca and to Medinah (where Mahomet is buried), with the accompanying descriptive comments by Professor Pepper, in his pleasant manner, are very interesting. A new illusion, a cabinet seemingly empty, out of which comes a live man not before seen, and that affords a hiding-place to others who enter, is one of the additional amusements provided for Easter. The latter is very cleverly managed, and creates speculation.

**GALLERY OF ILLUSTRATION.**—"A Peculiar Family," written by Mr. W. Brough, is a peculiarly good thing of its kind, and just suits the peculiarities of this successful and always entertaining establishment, Mr. and Mrs. German Reed and Mr. John Parry. They are now in full run, and likely, we should think, to continue so. The *Opera di Camera* entertainment, on the morning of Tuesday and of Thursday, and the evening of Saturday, still consists of Macfarren's "Soldier's Legacy," and Mr. Reed's "Too Many Cooks;" the withdrawal, however, of these is threatened.

**"THE AURORA OF ITALY."**—Under this title Signor Raffaello Ceccoli, one-time Professor in the Academy of Athens, has painted a picture to indicate the rising hopes of the Italians. A female figure quite young floats upwards: the gauzy drapery that does not conceal her, tinted prismatically, suggests the national colours. At the foot of the canvass the sun rises over St. Peter's in one corner, and the top of the Column of St. Mark in Venice is seen at the other. The type of the figure is English, fresh and bright: "but for England," says the painter, "Garibaldi would have never done it." The darkness of the sky above suggests the heavy gloom from which Italy is now emerging full of hope. Some other canvasses in Sig. Ceccoli's studio correctly convey the costumes of Greece, and give bright ideas of its sun-shiny climate.

**EMBELLISHMENT OF TOWNS.**—M. Warcin, formerly *maire* of the town of Hazebrouck, who died a short time since, has left his property to be applied to the improvement of the place, of which he was long the chief magistrate, on conditions which (presuming he had no relations), deserve to be noted for the spirit which dictated them. In his will he expresses his belief that premiums offered to those who erect buildings with worthy frontages on the main streets, and the grand *Place* of the town, may aid the work, and directs that during the next ten years at least that system be tried. A few thousand francs a year spent in premiums, he thought, would cause four or five times the amount to be expended in embellishments than would have been without such a spur, and the working classes each year benefited by so much additional work to be executed.

**PHOTOGRAPHS.**—M. Naudin, who is active in selecting subjects with public interest, has published *en groupe, carte de visite* size, the plucky Oxford boat crew, that gave another victory the other day to their university. The heads of the whole nine come out remarkably well.

**PROFITABLE INDUSTRY IN WINCHESTER GAOL.** The last report of the visiting justices of Hampshire states that the receipts in cash for industrial labour during the first quarter of the present year amount to 406*l.*, against 47*l.* in the corresponding quarter of last year, the receipts for the last three quarters having together amounted to 717*l.*, against 84*l.* for the three corresponding quarters of the previous year.

**THE MARKLAND MEMORIAL.**—As it is proposed to place in the Abbey Church of Bath a Memorial Window to the late Mr. J. H. Markland, D.C.L., F.R.S., it has been suggested that it would be a graceful act on the part of those architects and others who are especially interested in Church Architecture to raise among themselves a special contribution towards honouring one who was among the most zealous pioneers in a revival of a true feeling for the subject. The subscriptions are not to exceed one guinea, and will be received in London by Mr. G. G. Scott, 20, Spring-gardens, S.W., and Mr. Joseph Clarke, 13, Stratford-place, W.

**DISCOVERY IN WINDERBEME PARISH CHURCH.**—A curious discovery has recently been made in this church. The plaster having come away over one of the arches, a band of red and black was revealed. On the removal of more of the thick layers of whitewash an inscription in Old English characters was found. Further search was instituted, and similar inscriptions have been discovered on all the walls between the arches in the nave. It is conjectured that these inscriptions were placed in the church at the time of the Reformation. We give one or two specimens:—"Is the breade and wine turned into ye boddie and bloode of Christe? No; for if ye turne or take away the signe that may be sene, it is no sacrament."—"In going to ye table of the Love what ought a man to consider or doe principallie? To examine him selfe."

**BRIGHTON.**—At a recent meeting of the town council the surveyor presented, through the works committee, his certificate of the completion, by Messrs. Aird & Son, of their contract for the construction of the central outfall sewer. The cost of the Outfall has been—amount, as per contract, 6,818*l.*; extra work in overflow-chambers, gasing, ventilating, drains, &c., 96*l.* 3*s.*; extra work in reconstruction and enlargement of the northern sewer, from the Outfall past the Albion Hotel (part of it having fallen in September, 1863), 595*l.* 13*s.* 8*d.*; making a total of 7,509*l.* 15*s.* 8*d.*—The works committee, at same meeting, reported the receipt of tenders from sixteen different firms, for providing and fixing an iron fence on the Marine Parade Esplanade, from the western entrance to the Chain Pier to the wall opposite the west side of Lewes-crescent. The tenders ranged from 1,470*l.* down to 785*l.*: the last tender, which was from Messrs. Reed, of Brighton, was accepted, as were also their surcies.—The newly-erected Hobden's Royal Baths and Swimming Bath, in the King's-road, have been formally opened. The architect was Mr. James Woodman.

**MANCHESTER ARCHITECTURAL ASSOCIATION.**—An ordinary meeting of this Association was held on Tuesday evening, April 4th, the president, Mr. Lawrence Booth, in the chair. Mr. James Redford, architect, of St. Peter's-square, was, on ballot, elected a member of the Association. A paper was read by Mr. H. Fisher on "Strikes in the Building Trades." An interesting discussion ensued, and the feeling of the meeting seemed to be, that the profession as a body could do little or nothing in the matter, but that a more advanced state of education was necessary in the working classes, and a greater regard for skilled labour on the part of the employers, before a satisfactory understanding could be come to on this vexed question, and before a sacred regard for each other's rights could be established between employer and employed. After the discussion, Mr. Ratray exhibited and explained, by means of a model, his "patent waterproof inside casement," which is now being used in the neighborhood of Manchester. The hon. secretary intimated that at the following meeting a paper would be read by Mr. R. W. Aitkin, entitled "Application of Building Materials to Wall Decorations."

**SUBURBAN MUSEUMS.**—The Committee of Council on Education, with the view of promoting the establishment, in the north, east, and south of London, of museums of science and art, intend to invite a meeting, early in May, of gentlemen who have interested themselves in this proposal, to consider the best means of establishing two or three such museums. We shall hope to find the meeting result in immediate action. Influential inhabitants of the quarters named, willing to interest themselves in such a movement, should make their willingness known to the secretary of the Department.

**CITY CHURCHES.**—St. Dionis, Fenchurch-street, is in course of restoration. The *Musical Standard* says,—"The fine organ screen is to be cleaned, but nothing is to be done to the instrument itself, which remains in pretty much its original condition, except that some of the stops are in disuse. If judiciously modernised, it might be made a very fine organ (judiciously, however). Another church, St. Catherine Cree, Leadenhall-street, one of the most ancient and interesting in the City, and a perfect victim to 'comp', has been externally improved, the stonework scraped and cleaned. Nothing is being done for the interior, nor is the organ to be altered in any way. Seeing the rage for 'meddlo and muddle' restorations, from which old organs suffer often to the total loss of their former quality of tone, we cannot say we particularly regret it."

**CATHEDRAL RESTORATIONS.**—Nothing can be more certain, says the *Worcester Herald*, than that the citizens generally would view with extreme regret the replacement of any portion of the cathedral organ in its late site, where it formed so notable an obstruction; also that, next to the great south transept, the projection of the organ against the arches on the north side of the choir, so as not to interfere with the view east and west, would be the second best scheme that has yet been propounded. The matter is shortly to be decided. The contract for the repair of the southern side of the nave of the cathedral has been undertaken by Messrs. Wood & Son, of this city, the price being about 1,800*l.*, and the work will be at once proceeded with. The dean and chapter of Hereford Cathedral have just sanctioned a scheme for restoring the pail of bells (said to be a good one) as soon as Mr. Scott gives his approval. The organ at Hereford, which is placed on the south side of the choir, is said to be a success, although not thought so at first.

**A CHURCH AND SCHOOLS SUPPLANTED BY A RAILWAY STATION.**—By the Bill of the Metropolitan Railway Company, which has passed the committee of the House of Commons, the company are authorised to take possession of and pull down the church and parish schools of St. Peter, Saffron-hill, situated on the west side of Farringdon-road, opposite the railway station, for the purpose of occupying the site for their railway and other works sanctioned by the Act. They are to pay to the Ecclesiastical Commissioners the sum of 17,000*l.* for the purchase of the church and schools, including the church fittings, except the east window. They are also to provide an iron church or other building for a temporary substitute for the church, and also a temporary building for the parish schools, until a new church and school buildings shall have been completed. Within two years of the time of taking possession of the church and schools the company are to provide a suitable portion of land equal in superficial area to that of the present site of the church and schools for the erection thereon of a new church and schools. If churches and schools can be so dealt with, could not something be done, in like manner, to insure the replacement of working-class dwellings when destroyed?

**SANITARY IMPROVEMENTS IN LEEDS.**—A correspondent, W. S., on this subject says, *inter alia*:—"We have lately established a sanitary association in Leeds, and propose to build lodgings and tenements in flats, at rents from 1*s.* to 3*s.* per week, so as to offer an asylum for the lives in cellar dwellings, when they are closed, which we hope will be soon. The Society for the Improvement of the Dwellings of the Working Classes in Leeds is just completing a block of eighteen houses, and laying out eighteen more. It is astonishing how the remarks in "Another Blow for Life" apply almost *verbatim* to the same features in the provincial towns. The writer might have been describing the condition of Leeds in many parts of the book."

**CHURCH OF BRADFORD ON AVON.**—At the last meeting of the British Archaeological Association, a paper by Mr. Pettigrew was read, "On Roman Materials found in the Church of Bradford-on-Avon." From various particulars the sculptured sepulchral figure found therein was determined to be that of Agnes, relict of Reginald de Auli, a great benefactor to Bradford in the thirteenth century. The paper gave rise to considerable discussion, in which Mr. Gordon Hills pointed out the similarity of the interlaced work in the church to what he had met with in Ireland, and of which he produced drawings.

**AN ORNAMENTAL EX-CEMETERY.**—The formal ceremony of opening the ornamental grounds in Stepney Churchyard has taken place in the presence of a large number of persons, accompanied by the ringing of the large peal of ten bells in the ancient tower of the parish church, and occasional firing. The south-west portion of the cemetery contains only a few gravestones, wide apart, and they did not interfere with the construction of an ornamental garden and promenade, by Mr. Preston, who laid out the walks and shrubberies in the Victoria Park.

**THE FORTHCOMING INTERNATIONAL EXHIBITION AT OPORTO.**—The Chambers of Commerce have received from the Committee of Council on Education a document containing the programme and regulations of the forthcoming Portuguese International Exhibition, to be opened at Oporto on the 21st of August. The programme states that the articles exhibited will be classified under one of the four following divisions:—Raw materials and their immediate transformations; machinery, manufactures; and fine arts; and these divisions will be further divided into forty-five classes. Articles must be delivered at the exhibition building at the owners' cost and risk; and the reception of goods and articles will commence on the 15th of May and continue till the 31st of July.

**HARTLEPOOL ROLLING-MILL.**—At the extensive new works erected for the Hartlepool Rolling-mill Company on the Hart Warren, by Messrs. Head, Ashby, & Company, of South Stockton, the rolling of the first plate has just taken place. Up to the present time, only a portion of the works have been got into operation. Sixteen puddling furnaces have been at work, a monster steam-hammer, and the apparatus requisite for the rolling and shearing or cutting of puddled bars. For cutting the plates there are two powerful shears. One of these for cutting finished plates, is capable, at a single stroke, of making a clean cut 6 ft. in length through cold iron plates, with about as little apparent effort as a lady would take to snip a piece of embroidery.

**ANOTHER NEW PROCESS OF ENGRAVING.**—A layer of finely pulverized chalk is compressed and smoothed by hydraulic power on a metal plate. The artist draws on this with an ink which makes the lines hard. A soft brush or a piece of velvet rubbed over the plate leaves the inky portion in relief. The whole plate is then saturated with a chemical solution, which turns the chalk into stone, somewhat analogous to Ransoms's principle seemingly. From this impressions may be taken, or stereotypes or electrotypes obtained. The cost of these "graphotypes" is said to be something like one-tenth the cost of wood-blocks, to which, the *Morning Herald* says, they are fully equal; but whether this process be likely to come to anything practical, or whether it is to follow so many others into oblivion, we cannot yet say: surely something useful will come of all these inventions at last.

**IMPROVED TRAVELLING CRANE.**—Mr. T. B. Burnett, of Mount Vernon, New York, has invented an improved travelling crane, very simple in construction, and of great value, from the facility with which goods can be removed by it from one place to another, without dropping or depositing the load. The gearing by which the weights are raised is similar to that on ordinary cranes, and the hoisting chain is led up over a boom, which is jointed at the bottom, so that it can be raised or lowered. The rigging is composed of heavy iron bars, and there is a counter-balance box behind the crane. When the crane has been loaded, and is ready to be transferred from the point where it is at work, the labourers apply themselves to handles which act on gearing below the platform on the front axle. By means of a small pinion meshing into this gear, they are enabled to remove any weight that can be raised by the crane to any point on the track.

NEWCASTLE.—It is proposed to erect a building here for a fat cattle and poultry show. A suitable building might be erected, it is said, for 5,000l. If the Corporation would erect the building, the interest upon the sum would be paid them by those interested.—A rate of not exceeding 3d. in the pound has been agreed to by the town council towards the cost of erecting a lunatic asylum for the town.

EASTER SEPULCHRE, ARNOLD CHURCH, NEAR NOTTINGHAM.—There is an interesting fourteenth century Easter Sepulchre in Arnold Church, at present in a bad condition. At the west side of the sepulchre is the founder's tomb, and above it is a window; the glass in the window being broken, the ivy has grown through, and now hangs down in the form of a festoon and renders the appearance most picturesque. The church is dedicated to St. Mary, and is just about to be restored under the joint superintendence of Mr. Henry Curry, of London, and Mr. S. Dutton Walker, of Nottingham.

SANDRINGHAM.—The improvements at the Prince of Wales's estate in Norfolk have progressed considerably of late. To afford assistance at any future fires, the prince has purchased a unique fire-engine, "The Sandringham," and a fire brigade for the neighbourhood is to be organised. The royal gardens approach completion. They cover an area of about 15 acres. Eight acres of the garden are inclosed by brick walls varying in height from 14 ft. to 18 ft. On the south side of the north wall are four vine-ries, each 50 ft. long. The new stables have been completed, but a further extension may be necessary. The existing stables will accommodate about forty horses. Over the stables are dormitories for the grooms and stablemen. The wants of the labourers are studiously considered, and hence the erection of more new cottages of a superior character. When these are completed, there will be ten new labourers' cottages, besides five or six keepers' houses. His royal highness has given directions for the fine old ruins of Appleton Church to be partially restored, and carefully preserved.

THE NEW BRIDGE AT EARTH.—There has been a general holiday at Earth, to inaugurate the re-opening of the suspension bridge, which has been rebuilt by Messrs. Garforth, of Ashton-under-Lyne, from the designs of Mr. W. H. Barlow, C.E. The old bridge, from its great span and slight construction, oscillated under heavy loads, and produced a moving wave in the floor that made it unpleasant to drive over; and after being frequently broken, it became positively unsafe, and a joint committee of Isle of Ely and Huntingdonshire justices was appointed to take the necessary steps for strengthening or rebuilding the bridge as they might be advised. Some three years ago Mr. R. B. Rowe, C.E., surveyor-general of Isle of Ely bridges, reported the bridge to be unsafe, and this was confirmed by Mr. Barlow, under whose advice the bridge was taken down, and the chains were connected with strong arched girders, strengthened by diagonal and suspension rods. From the chains and girders the floor is suspended, and made to rest upon new wrought-iron beams. To test the new bridge, Mr. Fairry's great fifteen-ton traction engine was propelled by its own steam power several times along it, both slowly and at high speed. The bridge, it is reported, scarcely sank a quarter of an inch, and sprang up to its former level as the ponderous machine reached the shore.

TELEGRAPHIC PROGRESS.—The *Great Eastern* will sail from Valencia (Ireland) about the 1st of July. There were 1,662 nautical miles of the Atlantic cable completed on the 21st of March, and the whole 2,300 miles will be made and on board the *Great Eastern* in May. The Admiralty have agreed to order two powerful steamers of the Royal Navy to accompany the *Great Eastern* from Ireland to Newfoundland, and also to afford assistance at Newfoundland. It is confidently expected that Europe and America will again be in telegraphic communication before the 20th of July.—Messages have been sent direct from New York to San Francisco, a distance of nearly 4,000 miles.—At the third half-yearly meeting of the Universal Private Telegraph Company, a dividend of 6 per cent. per annum for the half-year was declared, 1,000l. being also put aside towards a reserve fund, leaving a balance of about 900l. to be carried to the current half-year. The success and prospects of the company were said to afford ground for congratulation.

NEW LIGHTHOUSE AT BUDDONNESS.—The Seamen's Fraternity, says a Dundee paper, have resolved to accept the offer of Mr. William Anderson, Dundee, to erect two new lighthouses at the Buddonness, which are to replace those at present on that site. The highest tower will be of the height of 963 ft., while the seaward tower will be about 60 ft. or 70 ft. in height. The foundation is to consist of five courses of immense stone blocks; and the mason and brick work of the walls will be nearly 5 ft. thick all round. The lighting apparatus will be of the most approved kind; and it is expected that they will reflect the lights fifteen miles seaward.

LIABILITY FOR FOULING A STREAM.—A district Board of Works, acting under the provisions of the Metropolitan Local Management Act, in the execution of sewerage works in their own district, fouled a stream passing through their district, and thereby polluted the water of such stream beyond their district, and created a nuisance upon lands lying without their district. The question was, whether an action at law could be maintained in respect of the injury; or whether the remedy was for compensation under the Act. The Court of Exchequer Chamber (reversing the decision of the Queen's Bench) held, in the case of *Cator v. The Lewisham Board of Works*, that an action would lie.

NEW FUEL.—A new form of fuel, composed of peat and coke, has been patented by Mr. William Smith, of Dublin. The compound is intended to be used in the smelting of iron, and it is thought that its employment will result in the production of iron equal in value to that now manufactured in Sweden. The preparation is as follows: The coke (or charcoal) is reduced to powder and mixed with wet peat. The mixture is then passed through moulds, and the blocks thus formed are submitted to pressure and dried. The inventor states that near charcoal thus prepared will stand the blast and hrdren of a blast furnace, and may be used with as much advantage as perfectly pure charcoal.

LECTURE ON PAINTED GREEK VASES.—The Rev. Professor Churchhill Bahington recently delivered a lecture to the Cambridge School of Art, at the Town-hall, on the subject of Greek painted vases. Mr. Babington opened his lecture by remarking on the antiquity and importance of the potter's art, referring to the sculpturars of Beni-Hassan, in Middle Egypt (about 2000 B.C.), where the process of making earthenware was represented. He then quoted Homer, to prove the very early existence of pottery among the Greeks, and Alcaeus (B.C. 600) and Pindar (B.C. 460), as the earliest authors who mention painted vases. The lecturer proceeded to give an account of the rude vases of the heroic age, and exhibited a specimen, which might be 800 or 900 years B.C., and then enumerated the four styles commonly called Pæcæian, Eginetan, Etruscan, and Apulian, but which he preferred to designate the Brown figure, Black figure, Red figure, and Polychrome figure styles, specimens of each of which were exhibited. He enlarged most on the splendid vases of the second and third periods, especially condemning the epithet Etruscan as applied to the latter, and contending that they were of Athenian manufacture. The compositions on these vases, he thought, were taken from the great painters, as Polygnotus and Apelles; and he instanced the compositions of Raffælle, Marc Antonio, and Parmegiano, which occur on the Italian porcelain of the middle of the sixteenth century. In conclusion, he drew attention to the extraordinary beauty of the forms of Greek vases.

TENDERS

For additional buildings, at the Steam Brewery, Commercial-road, Guildford, for Messrs. Tanton. Mr. Henry Peak, architect.—

Nye	£1,068 19 0
Lee	1,797 0 0
Pollard (accepted)	1,650 0 0

For building manufactory, City-road, for Messrs. Elder & Sons. Mr. H. J. Hammond, architect.—

Smith	£1,379 0 0
Bishop	1,735 0 0
Hill & Son	1,724 0 0
Saunders	1,659 0 0
Brown & Robinson	1,673 0 0
Eaton & Chapman	1,493 0 0

For rebuilding the Old Barge, Frimley, for Messrs. Tanton (the contractor to take to old materials). Mr. Henry Peak, architect.—

Martin (accepted)	£100 0 0
-------------------	----------

For building manufactory, at Lampeter-street, Hoxton, for Mr. R. Johnson. Mr. C. A. Long, architect.—

Hardiman & Sanson	£2,400 0 0
Lemon	2,050 0 0
Turner	1,961 0 0
Perry	1,821 0 0
Eaton & Chapman	1,577 0 0

For alterations and additions to Sandhurst Church, Berks. Mr. H. Woodman, architect.—

Jenkins	£1,158 0 0
Lawrence	1,130 0 0
Sawyer	1,055 0 0
Revell & Sons	1,079 0 0
Pither	910 0 0

For the completion of a villa, at New Malden, Surrey. Mr. George Welch, architect.—

# The Builder.

VOL. XXIII.—No. 1160.

*The Sewage: How shall we Dispose of it?*

THE question of the disposal of the sewage of London is now brought into the position of having to be decided by Parliament in the present session, or of being held longer in suspense. There is sufficient reason to believe that the works as at present, by which a continuous flow in the sewers is substituted for an intermittent one, and for the consequent deposit and stagnation, will be attended with advantage, and that this may be increased by the completion of the Thames Embankment, even not estimating the sewer which it will contain; but the greater the attention given to the subject, the more does opinion tend towards the conclusion that sewage will return with the

tide. Of late years, from different causes, the chief of which is the abstraction of the river-water by the water-companies, the sea-water has been ascending higher than before: it has been found at Wandsworth; and even sea-weed has been noticed at London Bridge: hence it may be inferred that sewage would be returned also, diluted, and possibly, or to some extent, otherwise,—recollecting that it is lighter than sea-water. The belief that the sewage will return as far as Chelsea, is known to prevail even with some of those who conduced to the adoption of the system which Mr. Bazalgette has been engaged in carrying into effect. The grand question, which is that in all sewerage,—outfall, has been only put aside: what to do with sewage, as we lately said, might logically have been esteemed first of the points for solution; and the course of flow to outfall, or outfalls, might have been regarded as coming next under consideration. So great however had been the neglect, and so pressing became the need for "something to be done," that the strictly logical course had to be departed from in the case of London, as it has been in that of towns where some of the circumstances were less difficult.

The Metropolitan Board of Works having been from the first aware that more had to be accomplished than in passing the sewage into the river, and having procured through advertisement certain tenders or propositions, have lately been supporting the scheme which is embodied in the Metropolitan Sewage and Essex Reclamation Bill, promoted by Messrs. Hope & Napier, since that appeared to them the only definite tender they had received. We have very recently given some particulars of the project; but points involved in the adoption so far, of it, are too important to be left unnoticed. More than the one grand question which we are here alluding to, of the sewerage of London, has yet to be solved practically; there is that of the purification of the river from the sewage of fifty-six towns which are in the Thames basin above the chief in-take of the metropolitan water-supply, and from that of the populous districts (parts of London, almost), which lie between

Hampton and Hammersmith, including Kingston, Richmond, and Kew; and there cannot but be something to be enunciated in the way of general principle to be held applicable to the towns in the centre of England which are located on the banks of very small streams, or to enable us to clearly mark wherein may be the distinction between them and the metropolis.

If the right scheme for London involve the formation of an independent sewer-channel to the sea, should the conclusion point to adoption of a similar system for Birmingham? If on the other hand, for a small town, the principle of outfall by sewage-irrigation be the correct one, is London, from its vastness, to be considered exceptional? The two ways of regarding the case of this metropolis have had their supporters; and neither side has succeeded in placing the subject in a satisfactory position. The view which is embodied in the promised concession to the promoters of the Bill now before Parliament, is taken on the ground that there would not be a demand for the sewage at all times and seasons, or without involving that extensive storage which would be practically impossible, and that consequently there must be no letting go of the main stay, an outfall as at present, to waste, or on to ground to be reclaimed, similar to the Craiginity meadows, which have been formed from sand, by irrigation with the sewage of Edinburgh. With this view is conjoined that to the effect that cost of distributing pipes, hydrants, and hose and jet, with the labour, requisite to apply the sewage to all descriptions of ground, would not be reimbursed, and that the only economic mode of distribution must be that by simple gravitation, from open "carriers" or gutters. Some pumping, up to the main head, would be involved in any case, excepting such as that of a town on an elevation above a sufficient extent of declivity; but in the line of sewer projected by Mr. Hemans, one of the engineers for Messrs. Hope & Napier, there are lifts, which are essential to getting the requisite fall, like the similar provisions in the lines of the Low-level Sewerage within the metropolis. The other view attaches greater importance to the probable demand for sewage, seeing that in comparatively small dressings it is applicable to all kinds of soils and crops, in all situations, without nuisance, and that the only condition of success would be that a sufficient area should be under command; as to which it is deemed there should be no question, if really the soil is impoverished by withdrawing certain constituents, and not returning them as manure,—a practice said to have been going on in this country in a manner leading to the ultimate extinction of the productive power, instead of to a fertility such as would render unnecessary any supplies from foreign countries.

It must be observed that facts and opinions are unfavourable to the prospect of a sufficient demand by landowners and farmers, in the case of London. At Aluwick, the late Duke of Northumberland went to the expense of works; and the farmers were to pay the cost of pumping; but, after two or three years, the farmers discontinued paying; and the sewage is now wasted. The land is the proper place of deposit for sewage,—but in the view of the disinfection of the sewage, rather than in that of the economic production of all kinds of crops: without going to the question of dilution, it may be noted that the recent letters of Baron Liebig to the Lord Mayor, on which chiefly have been based the proceedings of the city of London, themselves admit that the proportion of one requisite of manure, phosphoric acid, in sewage, is small, comparatively speaking, and say that the deficiency ought to be made up, as by addition of bones or superphosphate,—for that, after some time, sewage alone will not produce good effects. That which will absorb the greatest amount of sewage, and the soil that will produce the best

crop of a particular kind, are by no means necessarily the same. Baron Liebig explains the fertility of the irrigated sands near Edinburgh, by supposing that they contain a proportion of clay or loam, saying that the view that sewage contains "the nutritive elements," and that the sand will be "the medium through which plants receive them" is "perfectly erroneous;" and that an acre of mere sand, with the largest dressing of sewage, "would not produce a single hundredweight of hay."\* It seems to us, however, that though this would be the condition of things on the first application of sewage, supposing the areas marked out by the Essex Reclamation Scheme were pure sand, it would be always correcting itself, merely by the silt that would be brought down with sewage. It appears plain from the Edinburgh experience, that a very small amount of loam or soil present with the sand, permits of very great fertility of a particular kind of produce, whilst that the sand will retain continuously its power of absorbing in the largest volume the sewage,—the disinfection of the latter being produced by the flow over the land, and through the roots of the grass. An arrangement for the outfall of the London sewage, in conjunction with the reclamation of the foreshore of Foulness Island, and adjacent areas, north of the mouth of the Thames, and called the Foulness and Maplin Sands, and the Denzey Flats, therefore appears to be fairly entitled to consideration; but we hope it will not be decided upon, or in any manner which may be considered as the settlement of principles, without attention to all that has appeared in evidence.

The printed matter pertinent to the general subject of the Distribution of the Sewage of Towns, and to the metropolitan question, has during the last fortnight received the important addition of the Third Report of the Royal Commission.† The Committee on the Bill before Parliament had previously concluded their proceedings; and the report and evidence are before us.‡ We will look at the Report of the Commission, first.

The Report proper, or that to which are appended the names of the five surviving commissioners, the Earl of Essex, Mr. Rawlinson, Professor Way, and Messrs. Lawes and Simon, does not extend to more than a page and a half of the volume, but embodies conclusions of great importance, based as they are fairly upon experiments of which the results are afterwards given, in great detail, in the form of a document which is entitled "Second Report of Experiments on the Application of Town Sewage to Grass Land, conducted at Rugby, by order of the Royal Sewage Commission," and partly upon notes of experience and observation which appear in appendices of the volume.

The Commission was originally appointed on the 5th of January, 1857. The second report bore date in August, 1861, and contained the results of experiments undertaken at Rugby in that year, by Mr. Lawes and Professor Way. These members of the Commission continued their experiments in the three years 1862-4; and the results appear in the report signed by them, of which we have quoted the title, and in forty-four tables of closely-printed figures. The experiments were not confined to the application

Presented to both Houses of Parliament by command of her Majesty." London: printed by G. E. Eyre & W. Spottiswoode. 8vo. pp. 210 & 82. Map and 2 plans.

‡ "Special Report from the Select Committee on the Metropolitan Sewage and Essex Reclamation Bill; together with the Proceedings of the Committee, and the Minutes of Evidence. Ordered, by the House of Commons, to be printed, 30th March, 1865."

of sewage in different quantities to land; but they extended to the consumption, by cattle, of the produce so obtained, and to the production of meat and milk; and they were accompanied by a careful record of the quantities and market-values of the products, and by numerous analyses of the sewage before and after irrigation, as also of the grass and of the milk. In the previous report, the conclusion had been arrived at, that to obtain the largest amount and value of produce at the least proportionate cost for distribution, dilute town-sewage should be applied to the growth of succulent crops, and that it was best adapted for grass. It was decided, therefore, to confine attention, at any rate in the first instance, to grass alone. The object being to provide a basis for the application of sewage most advantageously to both urban and rural interests, it was sought to determine,—

“1. The amount and the composition of the produce, in relation—to the amount of water supplied to the land by irrigation, to the amount of manurial constituents so applied, and to the amount of population contributing the manurial constituents to the water.  
2. The most profitable method of utilizing the produce; that is, whether it should be used in the green state or as hay; whether for the production of milk or of meat; and whether it should be consumed alone or in conjunction with other food.”

We need not give particulars of the experiments here.

In a concluding section of their report, embodying general considerations on the agricultural utilization of town sewage, Messrs. Lawes and Way say:—

“There cannot be a doubt that to obtain a maximum amount and gross value of produce from a given amount of sewage, it should be applied in small quantities per acre, and in dry weather.”

But this maximum value, they observe, would be obtainable only for short periods of the year.

“Adopting the favourable supposition that as high an average as 200 tons of sewage per acre could be utilized on arable land, and that as low an average as 5,000 tons per acre were found sufficient for Italian rye and meadow grass, the important practical questions arise—would the increased productiveness, and increased gross money return per ton, in the former case, justify the extra cost of distribution over a ten-fold area, and to a great extent by pipes and hose and jet instead of by open runs?—or, having regard, not to the greatest amount of produce and of gross money return, but to the greatest profit per ton of sewage, would it not be far more remunerative to limit the area, and cost of distribution, at a certain sacrifice of the productiveness of the sewage?”

They add, that probably the difference of area required under the two systems would be greater than is here assumed by them.

The great dilution, the large daily supply at all seasons, and the greater amount during wet weather, when the land least requires more water, make the metropolitan sewage, they say, inappropriate to arable land. But apart from this difficulty, the cost of distribution in small quantities over large areas, makes it “vain to hope that any large proportion of the manurial constituents derived from the consumption of human food in our towns, can be distributed over the area from which they came.” Instances are given of arrangements first devised for the application of the sewage to all kinds of crops, with hose and jet, over large areas, having had to be changed for the application to the Italian rye-grass exclusively, and over contracted areas. At Watford, although the abandonment of one acre of rye-grass would set free sewage enough for nearly forty acres of wheat, if only applied at the moderate rate yielding the large profit, the experience of the Earl of Essex has led him to prefer the application to the one acre and the rye-grass, rather than to the nearly forty acres and the wheat. The failure at Alwick, above alluded to, has been attributed to extreme dilution of the sewage; but the fact of this is not admitted by Mr. Rawlinson. The hallif of the district, in reporting the failure, expressed a strong opinion against the applicability of sewage to arable land.

As to the system of large dressings, it is not contended that in every case the best method is followed in details. At Edinburgh, where the largest amounts of sewage per acre are applied, and the largest amounts of produce are obtained, it is admitted there is great waste of manurial constituents, and very imperfect purification of the sewage. From the information which is given of the application of sewage in different localities, it may be gathered that the purification of the water, from sewage, is not complete as it flows out from drained land; but at Croydon, where the water is passed over the ground twice or oftener, the fish find it so far altered that they are disposed to ascend the drainage-outfall. Some interesting particulars

of the Croydon irrigation, communicated by Mr. Fenton, appeared in our volume for 1863.

In the course of a summary of results of the whole inquiry, Messrs. Lawes and Way, having observed that as there is a daily supply of sewage the year round, it should be applied in winter when it is comparatively of little value, as well as in summer when it is of more, say that by the application in winter, to grass land, green food is obtained very early, but that the amount is small for that of sewage employed; that by irrigation during the season of abundant supply, the period is prolonged; and that of two soils, one naturally less fertile than the other, the inferiority may be compensated for by irrigation; and note many other important facts.

In their general conclusions, they set it down as probable that about 5,000 tons of sewage per acre, judiciously applied to grass-land properly prepared to receive it, would generally secure the most profitable utilization; and, supposing this amount of irrigation per annum, that the purification of the water would be sufficient to admit of the drainage being turned into rivers without detriment to fish, whilst streams receiving such drainage instead of that direct from the town, would be vastly improved from their previous condition as a water-supply,—though whether the purification would be sufficient, would require farther experience and investigation, and might receive different answers according to the cases. Assuming that the average dilution of the metropolitan sewage, including rainfall and subsoil-water, will amount to 100 tons per head per annum, they say that 5,000 tons would represent the excremental and other matters of fifty individuals; and a population of 3,000,000 would require about 60,000 acres, constantly under irrigation. There has been an estimate making the number of acres ten times 60,000.

Upon the experiments of Messrs. Lawes and Way, the five Commissioners in their report, say that it appears to them, the experiments have solved many of the difficulties attached hitherto to the question of the agricultural application of sewage, and leave no reasonable doubt of the practicability and advantage of so employing the sewage of towns. As the results of their labours of eight years, they submit to the Treasury the following conclusions:—

- “1. The right way to dispose of town sewage is to apply it continuously to land, and it is only by such application that the pollution of rivers can be avoided.”
- “2. The financial results of a continuous application of sewage to land differ under different local circumstances: first, because in some places irrigation can be effected by gravity, while in other places more or less pumping must be employed; secondly, because heavy soils (which in given localities may alone be available for the purpose) are less fit than light soils for continuous irrigation by sewage.”
- “3. Where local circumstances are favourable, and undue expenditure is avoided, towns may derive profit, more or less considerable, from applying the sewage to agriculture. Under opposite circumstances, there may not be a balance of profit; but even in such cases, a rate in aid, required to cover any loss, needs not be of large amount.”

Finally, on the basis of these conclusions, they say that, in their judgment, the following two principles are established for legislative application:—

- “First, that wherever rivers are polluted by a discharge of town-sewage into them, the towns may reasonably be required to desist from causing that public nuisance.”
- “Second, that where town-populations are injured or endangered in health by a retention of cesspool matter among them, the towns may reasonably be required to provide a system of sewers for its removal.”

And they add that, should the law be found insufficient to enable towns to take land for sewage-application, it would in their opinion be expedient that the Legislature should give the requisite powers.

The Appendices, in the Blue Book, include Notes on the Edinburgh Sewage Meadows, and the Croydon Sewage Meadows, and an elaborate paper, to which are added numerous tables, by Dr. Stevenson Macadam. “On the Contamination of the Water of Leith by the Sewage of Edinburgh and Leith.” This last describes the sewerage of Edinburgh, treats of the liquid discharges and the sedimentary matters of the Water of Leith, of the gases evolved or dissolved, of the atmosphere in the neighbourhood of the Water, of the vegetable and animal life, and of the condition of the water as contrasted with the state of the Thames. The paper is full of valuable matter, much of it being suggestive of method and detail for other inquiries. Dr. Macadam mentions that the mixture of sea-water with the sewage in the harbour of Leith, “causes, besides ordinary putrefaction, the production of sulphuretted hydrogen in quantity,” this being specially

observable in mud dredged up,—just as the disengagement of the gas has been remarked previously, as in hot climates, where the organic matter meets with sea-water, and during certain years in the case of the Thames.

Preceding this paper is one on “Sewage of Towns” by Mr. Rawlinson. In mentioning the Italian irrigation, the author alludes to the fact that the entire volume of the London sewage is only a small fraction compared to the bulk of water used in Piedmont and Lombardy. He says:—

“Land is the proper place for liquid sewage; and in every instance where liquid sewage in its discharge from sewers, is liable to become a nuisance, the local authorities ought to be compelled to filter their sewage through land, even if at a pecuniary loss in the process. Towns can afford to pay the necessary costs of works capable of preventing both nuisance and disease.”

He remarks that the question of sewage-utilization has been thrown back by errors in works,—that too much has been expected and too much attempted. But,—

“To utilize fluid sewage, land is required, and a regular agricultural establishment must be set up.”

Town councils and local Boards have not as yet considered it their duty to obtain land, excepting in the case of Croydon; and there, an “injunction” was necessary. The Croydon case, he says, settles the question, inasmuch as it shows that irrigation by gravity over loamy ground, and producing grasses, will purify sewage without causing nuisance, and also produce a moderate income; but had the Croydon sewage required to be lifted, the balance might have been against the local Board. Works for irrigation by gravity, could be carried into effect, on both sides of the Thames, to a limited extent; and if found to pay, the experiment could from time to time be extended.

“To lease the sewage of London to a company, proposing to raise and expend capital by many millions sterling, will be ruin to confiding shareholders, and a cruel punishment to many innocent persons.”

Afterwards he says:—

“If the rivers of England are to be purified, it must be by intercepting canals to receive all fluid refuse and convey it to land for purposes of irrigation. The river Thames requires intercepting canals through its entire length. Such works need not be planted beyond the reasonable means of the populations resident on its banks, and who now contribute to the pollution of its waters. This form of improvement may also be carried out on every polluted river in the Kingdom with advantage. Any income derived from irrigation will be in reduction of first cost, establishment, and working charges.”

The only mention which Mr. Rawlinson makes of the scheme which is fostered by the Metropolitan Board of Works, is in four lines of a note, and upon a Map of the Thames Drainage Basin; but we might gather from words which have been quoted, that he is not in favour of that scheme; though he is plainly opposed, as much, to all costly appliances for irrigation.

The project of Messrs. Hoop & Napier was supported before the Committee, by evidence of much importance, including that of Messrs. Lawes and Way, and Dr. Voelcker, and of Captain Douglas Galton, who was one of the Referees by whom was put forth the scheme that included an outfall in Sea Reach, and was similar in principle to the arrangement to which the Board seem to be now tending. The only witness heard on the other side, was Mr. Thos. Ellis, who has proposed that the sewage should be pumped to reservoirs of sufficient dimensions, and that the sewage should thence distribute itself over large areas commencing in the immediate vicinity of London. We have left ourselves little space for noticing the features of the scheme embodied in the Bill, as they came out in the evidence of Messrs. Hoop, Bateman, Thwaites, and Hoop. We should mention, however, that the extension-line and branches are intended to take only the sewage in its least diluted state: or, at all events, the water in excess of the ordinary flow, or the larger rainfall, will be left to find its way into the river at Barking Creek, or by the storm-water outfalls. Also, as one of the features much relied on, we should mention that man-holes or apertures at each furlong of the total length of the sewer are intended, from which the land adjacent may be irrigated. The marsh-land, not drained, and which is mostly at too low level for drainage, we may remark, cannot form part of this. The committee reported, generally, that the scheme of Messrs. Hoop & Napier provided for the complete removal from the Thames of the whole of the ordinary sewage of the northern part of the metropolis, for the irrigation by sewage in whatever quantities might be found useful, of a considerable area well adapted for the purpose,—and

of such level that the distribution could be chiefly by gravitation, and for the application of what-over sewage might not be disposed of in the course, to the reclamation of a barren spot in a manner recommended by experience, and that the combination of the modes was of great consequence: the committee, in fine, were of opinion that the scheme was a useful and profitable mode of applying the sewage, and that they had no reason to suppose any more useful one could be devised. The Bill now awaits the decision of the House.

THE ART-UNION OF LONDON.

GENERAL MEETING.

The annual general meeting of the members of the Art-Union of London was held in the Theatre Royal, Adelphi, on Tuesday morning last. Charles Hill, Esq., F.R.S., presided in the absence of Lord Montagu, who was prevented by indisposition from attending. The theatre was full, including on the stage Professor Westmacott, F.R.S., Mr. S. C. Hall, F.S.A., Professor Bell, F.R.S., Mr. J. W. Butterworth, F.S.A., Mr. Charles Mayhew, Mr. R. R. Isaac, of Liverpool, Mr. Dealfosso, Mr. R. Z. Troughton, Mr. Edward Hawkins, F.S.A., Mr. Henry Hayward, Mr. Henry Baker, Mr. E. Anobrus, F.S.A., Mr. W. Frost, B.A., Mr. W. Broadwater, Mr. R. Hudson, F.R.S., Mr. Dobson, A.R.A., Mr. Fabry, &c.

Mr. Godwin, one of the Honorary Secretaries, read the following

REPORT.

The twenty-ninth year has elapsed since the foundation of the Art-Union of London and, in accordance with custom, your Council proceed to make to you their annual report showing the year's operations, and of the steps taken with a view to the successful progress of the Association in the time to come, a look forward as well as backward. Few who assisted at our first meeting, in the gallery in Regent-street, now the Gallery of Illustration, were sanguine enough to expect a course of such continuing success as that through which the institution has run; or ventured to prognosticate that it would bring in more than the classes at that date spending little on art, and would have distributed in aid of art and artists, the sum of 324,000*l.*; producing 200 British artists, 29 medals, and woodcuttings; 16 bronzes, 12 statues and statuettes, with figures and vases in iron, and a series of medals commemorative of British artists, the engraving of which, under the patronage of the Association, the distribution throughout the United Kingdom and the Colonies, of some thousands of pictures of modern artists, and some hundreds of thousands of impressions of engravings referred to. Such, however, has been the case, notwithstanding the difficulties with which the subscriptions for the first year were made to amount to 480*l.*

For the present year the sum of 11,743*l.* has been subscribed. Many circumstances, wholly beyond the control of the Council, regulate the annual income, which must be anticipated. The sum for the year "Claude Duval," by Mr. Limb Stocks, A.R.A., after W. F. Firth, Esq., R.A., has been delivered, for the most part, in payment of the subscription. It has elicited very satisfactory expressions of opinion from the periodical press, and appears to have been received with very good favour.

For the ensuing year your Council have had in preparation for some time past engravings by Mr. Louis Gruner after the series of illustrations of the so-called Norman Conquest, by Daniel Maclise, Esq., R.A., which were exhibited at the Royal Academy in 1857. These remarkable drawings are forty-two in number. Commencing with the departure of Harold on a visit to William of Normandy, the various incidents of the story are depicted, ending with the death of Harold, and the field on the night after the battle. The power and largeness with which these illustrations are drawn, the invention, the variety of expression, and the exactness displayed throughout the series will be observed by all. It is not too much to say that, bound as a whole, they will form the finest work of the kind produced in this country, and will probably lead to a large subscription. Looked at simply from a commercial point of view, the cost of the volume, were it obtained in the ordinary market, would be at least double the subscription of each member, who moreover, will doubtless have the chance of obtaining a prize.

In connection with the same artist, the Council announce with much gratification that they have obtained the copy-right of the great picture which adorns the walls of the Victoria Gallery, in the Palace of Westminster, by Wellington and Blucher after the Battle of Waterloo, and are making arrangements to have it engraved in the best possible manner, under the supervision of Mr. Maclise himself, for presentation to the subscribers of the ensuing year. To the production of this picture, a picture of which the devotees of Art may be justly proud, Mr. Maclise has devoted the best of his years, and has, in a picture of the size of the painting (it is 45 R. long, and 12 R. in height), the number of figures it contains, and the enormous amount of elaborate detail it includes, to engrave it with a large and costly apparatus, and to engrave it five years. Your Council, however, anticipate that you will agree with them in thinking that the time and money will be well bestowed, and that the undertaking has an interest which may be fairly termed national.

The condition of some of the paintings in fresco in the building named, is unfortunately such as to show that, notwithstanding the inquiries made in the first instance, possible means should be taken to prevent the decay which will ensure the duration of pictures so executed. The water-glass process employed in the production of the "Wellington and Blucher," at present bids fair to be satisfactory. No efforts, however, should be spared likely to lead to certainty on the subject. The time it may be hoped is not far distant when every

public building will be considered incomplete if they do not show artist-work on their walls,—if architecture, painting, and sculpture have not co-operated. Such of our painters as are disposed to devote themselves to the production of large works of the kind required might usefully bear in mind the course pursued by the great artists of the fifteenth and sixteenth centuries, who associated with themselves a number of pupils or "disciples," by whose aid, instructed as they were in their master's methods, and working under his eye and direction, a larger amount of work was effected, done than could have been effected by the chief's unaided hand. Thus it was that the immortal Raphael covered the walls of the Vatican with frescoes; and only in this way could Rubens have produced for the admiration and delight of the world the striking number of pictures that he has left behind him. Such an arrangement as this in England, not carried too far, so as to lead to manerism, would further afford to young artists the opportunity for methodical study now not readily found. From the studio of Raphael came Giulio Romano and Francesco Penna; from that of Rubens, Vandeyck and Depeuback.

A step in this direction, though with another material, has been taken by the authorities of the South Kensington Museum, who are offering premiums for a picture illustrative of workmanship in any decorative art or manufacture to be enlarged by students for execution in mosaic, &c. &c., under the superintendance of the artist.

Various commissions for large mural decorations have been given to different parts of the country, some of which may be mentioned, as having special interest with us, though not executed by a British artist, the series of pictures of Northumbrian incidents in the new state apartments at Alnwick, executed for our late Vice-President his Grace the Duke of Northumberland. By the death of this nobleman the Art-Union has lost an early and unreserved supporter. As Lord Prudhoe his Grace was one of the first appointed members, gave the sanction to the organization of the Association, and presided at some of the general meetings. Art, science, and literature flourished in Alnwick, Duke of Northumberland, a magnificent and discriminating friend.

The vacant places have been filled in the Council by the lamented death of George Dowd, Esq., and H. A. J. Mayo, Esq. To fill their places, Mr. H. Hood, Esq., the assistant Judge; Edgar Bowring, Esq., C.B.; and Sir Charles Nicholson, have been elected.

The Council consider it right to record briefly that, though instructed by a general meeting of the Association to take steps to acknowledge the services of the honorary secretaries, they preferred leaving such an act to the members and friends of the Association themselves. A subscription was accordingly made, and without trenching in any way on the funds of the Association, two works of art have been produced, and will be presented to-day to those gentlemen by the subscribers.

Your Council desire to repeat their thanks to the local honorary secretaries and agents throughout the world. The list, as they have often had occasion to say, is a remarkable one, embracing Australia, Barbary, the Cape of Good Hope, China, Denmark, the East and West Indies, Egypt, Italy, Natal, New Zealand, Russia, Nova Scotia, Spain, Sweden, Turkey, the United States, and Venezuela. To many of these distant places letters were sent last year: and it is interesting to notice the community of feeling displayed in consequence through the newspapers of the world.

In continuation of the series of medals commemorative of artists, the Council have decided on the production of one in honour of the late David Roberts, R.A. The career of this regretted artist and man is entirely calculated to encourage struggling talents. With little, if any, instruction or assistance, he emerged from a humble position, and ultimately took his place amongst the most eminent landscape painters of the time. While his first picture, rejected at the Scottish Academy, was afterwards sold by him for 30*l.*, and never paid for, for the last he painted he might have received from several quarters just what sum his class could afford to give. The medals already issued are now fifteen in number, and comprise five painters, four sculptors, five architects, and one medalist. The works to be distributed on the present occasion will be four medals from a model designed and executed in *repoussé* work by Mr. Baykentin. It includes medallions of Cupid and Psyche, with some elegant ornamentation. The medals are produced by means of the electrotype process, each example being afterwards chased and worked on by the artist.

The accounts have been audited by two members of the general body of subscribers, Mr. Burt and Mr. Ferris, and three members of the Finance Committee. The following is an abstract. The details will, as usual, be given in the printed report:—

Table with financial details: Paid for advertising, printing report and almanacs for subscribers, salaries, commission, exhibition expenses, reserve under charter, &c. Total amount allotted in prizes: £11,743 4 3

The amount set apart for the purchase of works of art from the public galleries by the prizeholders themselves is divided in this manner:—

Table showing the division of the amount for art purchases among 20 works, with a list of artists and their respective shares.

- List of artists and their works: 100 "Psyche" in Vases, Prince of Wales, from the original by Morton Edwards, 75 Statuettes in Porcelain, "Go to Sleep," from the original by Joseph Durhan, 200 Chromo-Lithographs, "Young England," 200 Chromo-Lithographs, "Wild Roses," 150 Volumes of Etchings, by R. Brandard.

Making, with the Paris busts due to those who have subscribed for ten years consecutively without gaining a prize, 1,001 prizes, in addition to the engraving received by every member.

On the plan followed last year, the smaller prizes will be allotted by numbers drawn from the wheel, in the same manner as the picture prizes; but as the drawing of these prizes would occupy more time than the proper business of the theatre would allow, the drawing will take place at the office to-morrow morning, at ten o'clock, when any members desirous of being present are invited to attend.

The reserved fund now amounts to 12,134*l.* The various pictures and other works of art selected by the prizeholders last year were exhibited as usual, by the kind permission of the Society of British Artists, in the Suffolk-street Galleries, and for a certain time were open to the public free and without the slightest limitation.

This course, which has now been pursued by the Art-Union for more than a quarter of a century,—affording pleasure to all classes, without any instances of misconduct or inconvenience, although on some occasions availed of by many thousands of persons,—has aided materially to remove an impression, at one time general, that such freedom of ingress could not be permitted with safety, which long and injuriously operated in shutting out the working classes of this country from our cathedrals, museums, and picture-galleries.

Your Council would urge on prizeholders, as they have before done, the importance of making a judicious selection from the public galleries, as well for their own sake as that the funds of the Association may go to advantage to higher objects it has in view. Using discrimination, and detecting rising talent where it can be found,—

"Be thou the first to try merit to befriend,  
His praise is lost who tries till he offend."

In consequence of the time that necessarily elapses between the opening of the earliest of the Exhibitions of the season and the distribution of prizes, the range of selection has been found narrowly limited there by previous purchases. To obviate this to a certain extent, the Council, at the present occasion secured, at the opening of these exhibitions, a few pictures to provide for those who commission the Council to select for them, and from which other prizeholders may select, if so desired. Bearing on the same point—considerable difficulty was experienced by prizeholders seeking works of art at the Royal Academy, in consequence of the want of any indication as to the pictures that were not for sale. A letter in consequence addressed to the Council of the Academy, suggesting that these works should be marked with a star in the corner, and an obliging intimation has been received from the secretary, J. F. Knight, Esq., R.A., that this will be done.

Amongst other works in metal contemplated by the Council, arrangements are being made for the production of a *plafond*, or splayed, suitable to stand on a sideboard. From the first establishment of the Association, the desirability of joining art to manufacture has been constantly urged; and a number of inexpensive works prepared with that end in view, and fitted to adorn ordinary houses, have been circulated among the members.

"Scatter the germs of the Beautiful  
In the holy shrines of home;  
Let the pure and the fair and the graceful here,  
In the lowly dwellings lustre confer;  
Leave not a trace of deformity  
In the temple of the heart;  
But guard about its hearth the germs  
Of Nature and of Art."

It was asserted, in a paper read at the Society of Arts some time ago, that "The Art-Union in our country has done much to develop the false taste which leads the public to prefer the enjoyment of its own individual fancy to the true interests of art, by encouraging this habit of 'hanging a picture up in your room' instead of contenting themselves with the reproduction of some noble work by the cheaper methods of 'engraving and modelling'; and yet the reader admitted, without any sentences, that "every institution that contributes in any way to diffuse the taste for the pleasures of the imagination amongst the public at large must do good." The address opinion here expressed,—which was backed by the assertions of M. Halévy, of the French Académie des Beaux Arts, to the effect that art must be retained for the enjoyment of the more refined classes of society, and that it avoids the noise and the glare involved in rendering popular,—represents the view held by a constantly decreasing body of objectors. It might be supposed from such assertions that before the establishment of the Art-Union every small tradesman's room was adorned with noble engravings of the "Last Supper" and the mighty visions of Michelangelo, and that such works were now put aside for pictures of small merit obtained through the Art-Union; and that painters of the highest class whose works were then sought for and purchased at great prices by the rich few, were now neglected. Such suppositions would not have a shadow of foundation. What has been done in England towards a large style of educational and elevating art, open to the observation of the multitude, has been done since the establishment of the Art-Union: with a more instructed public our Government, always lax in their aid to art, have felt themselves encouraged to vote larger sums for that purpose than they ever did before, and at no time in our history were there so many buyers for really good works of art, when produced, as there are now. Objectors on the score referred to urge that art must be "removed from the influence of the common people." We would object this by giving the "common people" the opportunity of improving themselves in this direction, by subjecting them to the influence of art, and by placing within the reach of all the delights and advantages it is prepared to afford. One unquestionable result of the operations of the Art-Union has been to extend an appreciation of art, to make the value of an art-education felt, and to open the eyes of many to beauties and enjoyments before denied them. Eyes alone do not enable the gazer to see; and it is written in Sanskrit, "Though the blind man hold a lantern, yet his footsteps stray aside."

Complete education in art requires long study and intimate acquaintance with the best models; but much may be done towards the improvement of taste without such devotion. Accustom the eye to good forms and harmonious colourings, so as to raise the standard of excellence in the mind. Cultivate the imagination and the judgment, and get knowledge so as to possess the means of contrast. The influences of art have been brought to bear on the mind in Great Britain during a much longer period of time than in this country; and, even in a commercial point of view, have produced enormous results, having developed a taste which has given great value to their manufactures. Of course it is not to be denied that artists should address themselves to the multitude. At a time when art had achieved an excellence never since approached, Plato wrote, "Do please the many, or to dispense the wise;" but the more extensively and completely

Association. About four explosions occur annually amongst the 6,500 locomotives of the United Kingdom; three have already taken place this year. In an average of 600 passenger vessels inspected under the Steam Shipping Acts, only three explosions had occurred since 1846. In Great Britain; viz., one at Lowestoft, in the *Tonning*; another at Southampton, in the *Parana*; and a third at Dublin.

#### ARCHÆOLOGICAL ASSOCIATION AT ROME.

AMONG the novelties of Rome, an event that bears promise of interesting, perhaps very important results, is the formation of an Archæological Society among the British residents in Rome, designed to include, also, visitors of other nationalities, and with the special object of studying, as well as illustrating, Christian and Medieval antiquities,—that range which (as the Society's prospectus sets forth) has hitherto been comparatively neglected, though offering such inexhaustible supply of interesting matter, amidst the superabundant labours dedicated to the Pagan monuments of this classic centre. The intention, in this undertaking, is to follow a mode of action similar to that of the English Archæological Societies and Fine Art Clubs of London, to hold afternoon meetings, at which papers may be read and objects of artistic or antiquarian character exhibited; also evening meetings at the houses of such members as may desire to offer hospitality, for exhibiting and conversing about similar objects suitable for presentation; and, moreover, open-air assemblies, or rather excursions, to visit sacred monuments or interesting sites under the guidance of gentlemen who may explain and point out facts or details of telling character, promoting the knowledge of Christian antiquity by the illustration of its most remarkable records *in situ*. Any discoveries that may be made by members in the antiquarian or artistic sphere, it is proposed to have photographed for communication to the London Society of Antiquaries, and for eventual publication as sanctioned by that body. It is determined that, besides permanent members, associates for the season may be admitted; and that ladies may be invited to join the meetings, as well as privileged to become members of the Society. Among the gentlemen whose names are given in the prospectus, pledged for co-operation and support, are Lord Talbot de Malahide, Mr. Odo Russell, Mr. Severn (British Consul at Rome), the Baron de Reumont, Mr. J. H. Parker, F.S.A., and Mr. Fortnum, F.S.A. The first meeting for preliminaries was held at the British Consulate on the 5th of April, when, after a brief address for proposing that appointment, Lord Talbot was declared president; the chair was taken by that nobleman, and an appropriate speech was made by him respecting the general objects in view and their intellectual importance. Next was despatched the business of choosing vice-presidents, the individuals nominated for and accepting which office were Monsignor Talbot, Mr. Odo Russell, Mr. Severn, and Mr. Parker.

A committee was then formed, including several of the gentlemen present, among them being Mr. Wreford, well known in Rome as correspondent of the *Times*; and Mr. Shakspeare Wood, a sculptor long established and successful in his art, was appointed hon. secretary, *pro tem*. It was decided by vote that papers read by members at the meetings should be communicated to the Society of Antiquaries, in order through that channel to be eventually made public. Another proposition put to vote and at once carried was the very judicious one of excluding, on principle, in the discussions and papers hitherto to occupy the Society every species of political and religious controversy. Some days afterwards was held the first open-air meeting, or excursion, the place of rendezvous being the Cælian Hill, the objects proposed for investigation some of the ancient churches,—those of St. Gregory, St. Stephen, SS. John and Paul, and that dedicated to four martyrs (the *Santi Quattro Martiri*),—on the same classic height.

The lecturer, who addressed a large circle of auditors, ladies and gentlemen, both in the open air and within these sacred edifices, was Mr. Parker, whose several discourses on this occasion it would be impossible to do justice to within narrow limits, and we must content ourselves with here stating that the ability displayed by this spokesman excited general admiration,

proving him to be thoroughly master of his theme and deeply read in the lore of Christian antiquity. With this success, and under these favourable impressions, did the British Archæologic Society in Rome auspiciously commence its proceedings.

We learn that the modern sculptures forwarded from this city for the Dublin Exhibition represent the value of 25,000*l.* sterling; and the well-known photographic artist, Mr. Macpherson, is the agent engaged for the business of transmission.

#### THE WATER-COLOUR EXHIBITIONS.

ON last Saturday both the Societies of Water-colour Painters gave their private view, and the members of neither had reason to complain of any disadvantage arising from the synchronism, if the circumstance of their respective galleries being crowded throughout the afternoon afford any evidence to the contrary. The double attendance of visitors to each on these occasions, and the opportunity of closely to all but those who advisedly went early. We are disposed to say that if the customary degree of excellence prevail throughout the collections, and the general height of their average obtains, there is nothing to induce the belief that in this case they go beyond it.

Apparently it is very much more easy to satisfy and delight by the same means, and repeatedly, than it is to describe them as often, or account for their lasting effects; or to guess when satiety may happen to lessen them, when any such consideration is so obviously ignored, and hitherto, just as obviously, with the best warrant for such persistency,—continued success and attractiveness.

Of course, there is proof enough now, as formerly, of that astonishing proficiency long ago attained by the most eminent members of the fraternities, from whom no one would be absurd enough to ask for the adduction of more: they live in the clamour of past exploit, and, deafened by the sound of it, keep now "the noiseless tenour of their way." Like men who have spoken well, long, and loudly, they could hardly hear themselves speak if they had anything more to say; and there can be no doubt of the intelligence and growth of power amongst those from whom a less undeviating course might be expected, but who show as little inclination to leave the one track selected at their outset as the elders, who at all events have been guided by experiment and experience to a preference. These exhibitions, as year after year presents them, vary so little in their character, always a high one and always sufficiently interesting in what they offer to illustrate the exquisite qualities of water-colour as a medium, as well as to show the perfect apprehension to be acquired of all its resources, that one depends entirely upon exceptional instances of production for the means of distinguishing one from another; and this time there are no works that make claim for superior excellence above antecedent, from the same hands, and not too many that can be classed with the very best pictures of their authors.

Perhaps the wide extension and general amount of ability displayed outside as well as within the walls of these institutions, lead to higher expectations from the more recognised sources than may be quite reasonable; and the little that is to be seen of the bad makes comparisons difficult. The multiplicity of these performances must presently, we should think, excite a healthful spirit of emulation, to stimulate those endowed with richer capabilities to a more independent use of them, and beneficially to prove that their sphere of action is a less restricted one than hitherto it has appeared to be, from the constant similarity of succeeding examples, owing to a confined practice of selecting incident, so remarkable at present.

The Exhibition of the Old Society consists of 320 works, whereof those of Mr. F. Burton, Mr. Duncan, Mr. Birket Foster, Mr. Holland, Mr. Jenkins, Mr. Naftel, Mr. S. P. Jackson, Mr. Topham, Mr. Smallfield, and Mr. Newton, offer the strongest claims for attention.

At the Institute of Painters in Water-Colours, there are 352 pictures, of which the most noticeable are by Mr. Louis Haghe, Mr. E. Corbould, Mr. Fahy, Mr. Boys, Mr. Shalders, Mr. E. Warren, Mr. E. Wainert, Mr. Carl Werner, Mr. Vacher, and Mrs. Elizabeth Murray.

#### CREEDS AND TEMPLES: THEIR RELATION TO ONE ANOTHER, IN PAST AND PRESENT TIMES.\*

THE early basilican churches of the fourth century were never complete without the addition of a circular building, called generally a baptistery, and probably used for the performance of all ceremonial rites, as funeral services, &c., the basilica being the place of general assembly for the ordinary public worship. This form was, as we have noticed, borrowed from the circular Roman temples dedicated to Etruscan deities; and the change may be traced from the little temple of Vesta at Tivoli, which has an external colonnade, through the tomb of Sta. Costanza, where there is both an external and internal colonnade, to the baptisteries at Nocera and elsewhere, where the external colonnade has disappeared and the style has become an internal one. The position of this baptistery was at first rather uncertain, but after the fifth century it was pretty generally placed at the west end of the basilica, as symbolical of the entry into the church by baptism. But as a principal object of these buildings was the admission of new converts into the church with all possible solemnity, it followed that from the seventh century, when infant baptism was introduced, and the reception of barbarian converts into the church became less frequent, the baptisteries fell rather into disuse, and were replaced by the font near the west door of the basilica. The circular form, however, long continued to be connected with the idea of a ceremonial church. Such was the one, before mentioned, built by Charlemagne to be the scene of the coronation of living emperors as well as the sepulchre of departed ones. This also, I think, was one motive for the universal preference of the circular form by the Templars, with whom the ceremony of investiture was so important. In the early Gothic period, the circular form on a large scale appears in conjunction with the rectangular form, both in France and Germany, but with the remarkable distinction that in the former country the circular part is always the choir or chancel, in the latter it is always the nave. The reason for this difference seems to be that the French always retained the idea of the connexion of the circular form with the more sacred and ceremonial parts of the ritual, and therefore, when they used that form, always appropriated it to the clergy; while the Germans, admiring the form architecturally, and being less under ritualistic influence, used it for their congregational churches, the straight-lined chancel being added, as the clergy increased in numbers and influence, as a place for their worship apart from the people. In the complete Gothic period, when the Roman see had acquired such general authority, the Germans forsook the circular for the orthodox basilica form; while the circular chancel in France merged into the polygonal apse characteristic of French cathedrals.†

The peculiarities of the Byzantine plan of church were due to architectural and not to ritualistic influence, the ritual being in early times very similar to that of the Western Church. Some of the points of difference which existed or arose between the two Churches, may, however, be noticed as influencing the buildings erected for the Eastern worship. One of these was the placing of the women in galleries, instead of dividing them from the men by a barrier on the ground-floor. The galleries and the two-storied porch for this purpose form a marked feature in the design of St. Sophia, at Constantinople. A more important point was the dislike in the East to sculptured decoration, which rose, in the eighth century, to violent iconoclasm, and gave additional impulse to a highly developed style of pictorial decoration, first in the form of mosaic, and later in that of painted pictures, for the exhibition of which a screen was always erected, called the *iconostasis*, completely across the front of the chancel, leaving only a doorway for the priests to enter, an arrangement which, whatever the interest of the pictures, must be very destructive of architectural effect. The Russians, when converted to the Greek faith, carried this pictorial decoration to the extreme, their churches becoming, from floor to roof, complete picture exhibitions, even the columns being painted round, after the manner of the Egyptians, with representations

\* See p. 275, ante.

† For the above explanation, I am mainly indebted to Mr. Huggins, the author of "the Course and Current of Architecture."

of the lives and miracles of the saints; and the porches adorned with figures of the great heathen poets and philosophers, each illustrated by some sentence from their writings which might represent them as the pioneers of Christianity. This is, I think, a very legitimate kind of symbolism; and if fresco-paintings were introduced into our churches, the idea would be worth remembering.

It does not appear that the Greek church ever adopted the dogma of transubstantiation with the same significance which was attached to it by the Roman; hence the chancel is but little developed. The persistency with which the style has been practised, and the same plan retained nearly to the present day, is a striking exemplification of the intense conservatism of the Greek Church, which regarded the innovations of the Roman pontiffs very much as the latter, in their turn, regarded those of Luther and Wickliffe.

The rise of Mahometanism, the greatest religious crisis between the Christian era and the Reformation, can hardly be said to have given rise to any form of temple peculiar to itself. The first founders of the religion were a Semitic people, and the religion itself the outbreak of the Theistic feeling so peculiar to that people, which had lain dormant since the extinction of the Jewish religion, and which was very unfavourable to anything like a pompous or ceremonial worship. With regard to the externals of worship, indeed, the Moslem was to the Eastern Church very much what the Puritan was to the Western,—both equally indifferent to liturgical forms, both regarding the spirit of the worship rather than the place in which it was performed. To the true Mussulman there was, in fact, but one sacred temple, that of Mecca, which was a comparatively insignificant building; and though, when the religion spread and gained power in other countries, it was found advisable to raise buildings commensurate in size and beauty with its importance, the plan of the original temples of the proselytized people was almost always adopted, and even the style of architecture, though this became speedily modified by the rich and brilliant fancy of the Saracens. Still, I do not think that the peculiar class of ornament and style of architecture called Saracenic can be rightly considered as the outgrowth of the spirit of the religion, but rather as arising from that taste for rich but sensuous beauty peculiar to the Arabic mind, and of which the Mahometan Paradise, with all its voluptuous delights, was only another development,—a concession, in fact, to the popular feeling; though, when the religion was adopted by a new people, these ideas may have re-acted upon the style of the architecture. To call the Saracenic the parent of the Pointed Gothic, through the medium of the Crusades, is surely quite overstating the case. It may have given additional richness and variety to the latter; but, even if it contributed the Pointed arch, this was only anticipating what the necessities of Gothic vaulting must have evolved very shortly after.

In tracing the variations in plan, among the Latin churches, no reference has been made to the phases of architectural style through which those churches passed; these being, in fact, almost wholly independent of religious influences, and none of them becoming elaborated into a distinct and complete style till we arrive at the true Gothic period in the thirteenth century. Here we meet with the third great temple style of the world, as complete in its way as the Egyptian and Greek; and, like those styles, arising under the influence of Polytheism; for every impartial student of ecclesiastical history must perceive that the faith of the thirteenth century, with its hosts of martyrs and saints, the objects of direct adoration, was in fact as completely Polytheistic as that of the Egyptians. The complete Gothic may be most fitly characterized as pre-eminently the monastic style. Monasticism had, indeed, existed for a long time before; but in the eleventh century it acquired great additional wealth and influence under the fostering care of the Roman Pontiffs, who took it under their special protection. The powerful and richly-endowed conventual establishments which arose at this time, soon gave expression to their religious feelings in those great piles of building of which the monks were themselves often the architects; and which, in the spirit of aspiration which everywhere pervades them, in the entire subordination of the horizontal to the vertical principle, are the most complete outward expressions of that morbid excess of religious zeal, that entire forgetfulness of the practical, which

he it remembered, existed at that time nowhere out of the cloister; as the comparison of the monastic with the secular poetry of the period, of Bernard of Clugny,\* with Chaucer, will abundantly prove. There is much, too, in the style to remind us of the Egyptian; the same vistas of aisles and columns, the same profuse use of symbolism, the same love of coloured decoration not of the most refined or artistic kind, is common to both styles; nor are the surrounding circumstances dissimilar. Both nations† were, at the culmination of their respective styles, in much the same state of civilization; in both the dominant sect was a numerous and powerful priesthood, held in superstitious reverence by an ignorant laity, whose chief religious instruction was derived from the paintings on the walls and windows of the temples. There is, however, one important distinction; the Mediaeval superstition had at least a background of truth: the saints who were worshipped were invested with characters above, and not below, ordinary humanity: instead of the fantastic deities of the Nile,

"Isis, Osiris, and the dog Anubis,"

or the ferocious Siva and obscene Vishnu of the Hindus, we have St. Peter and St. Catherine: it was a worship tending to expand the feelings rather than to contract them; and we find the buildings expressing this distinction; for while the Egyptian and Indian perpetually narrow as they are penetrated, till the shrine is found to be the meanest part of them, the Gothic temple, on the contrary, represented in such a plan as that of Rheims, with a comparatively small entrance, widens and expands as the shrine is approached, leading the eye continually upward and onward, and justifying Coleridge's remark, that the spirit of Gothic architecture was "infinity made imaginable."

With the fall of monasticism, however, and the rise of a purer faith under the influence of the Reformation, we again witness the decline of temple architecture, which has never since reassumed its old power, or produced a style peculiarly its own; for that of St. Paul's, and other great churches of the Renaissance period, besides that it was in great measure a copied and not an original style, arose from feelings and motives quite unconnected with religion; and it is not necessary to go into any proof of the neglect of internal beauty and decoration in churches since the Reformation. In the present day we have changed all this, and we pride ourselves on having resuscitated church architecture, and look with a smile of pity on the works of our grandfathers. But have we after all so much right to laugh at them? Are we in such a very satisfactory state ourselves?

It is remarked by Dean Stanley, in his lectures on Ecclesiastical history, that no word has been more debated in its significance than this same word "ecclesiastical." "It has come to signify," he says, "not the religious and moral interests of the social community, but often the very opposite of these,—its mere accidental, outward, ceremonial machinery. We call a contest about the abolition of vestments ecclesiastical, not a contest about the abolition of the slave trade." And surely we may see this feeling but too well imaged in the state of church architecture in the present day. For what is meant by the term "ecclesiastical architecture" by the majority of those who make most use of it? Not the provision of buildings suitable to the worship of the present day, and expressing in their style the more enlightened and reasonable faith which has succeeded to that of the Middle Ages; but rather of buildings suitable only to a form of worship in which ceremonies and symbols were all-important; and the spirit of which exists no longer but in the ideas of a few enthusiasts in whom love of ecclesiastical precedent has over-riden every other feeling. We have large and deep chancels for the accommodation of a priestly hierarchy which no longer exists, fitted with stone *sedilia* on which no one would think of sitting, and in the most recent instances

\* The great work of this really fine poet, "De contemptu mundi," some parts of which have been lately translated, might be almost described as "a French cathedral verified." The extravagant spirit of aspiration, the redundancy of ornament, the want of artistic self-restraint, are the same in the book as in the building. Chaucer has none of this; and it is remarkable that whenever he alludes to "the church," it is entirely as a spectator *ad extra*.

† The Celts, the chief originators of the Gothic style, are probably connected more or less with the Turanian race. Ferguson, indeed, speaks of them as "undoubtedly Aryans;" but may it not be more correct to call them "highly developed Turanians?" Philology, I believe, bears out this view to some extent.

railed across the front to protect the clergy from the intrusion of congregations who really, on the whole, are very orderly and well-behaved; receptacles for holy water which has long ago lost its efficacy; fonts placed, "for symbolical reasons," near the vest door, so that if a baptism is held in the course of the ordinary service the congregation may choose between remaining with their backs to the minister or sitting on the backs of the seats. We are so used to these things that we almost forget their absurdity, but it is amusing enough to see the same thing in another country. It appears that there is a sect in the Russian church who are possessed by the same mania. I quote again from Dean Stanley: "These churches have not a single feature that is not either old, or an exact copy of what was old. The long meagre figures of the saints, the elaborately minute representations of sacred history, are highly characteristic of the more than restoration of the melodious strains of modern Russian music, but with the nasal, almost piratical screech, which prevailed before the time of Niccon, and which is by them believed to be the sole, orthodox, harmonious, and angelical chant." But for the name of the Russian patriarch Niccon, this might be a description of one of our own paradises of Ecclesiastical Archaism. Some of our "ecclesiastical" architects might surely advertise for a draughtsman in the language of Kalfstaff,—"*O for a fine thief, of the age of two-and-twenty, or thereabouts!*" For even the accidental faults of the style must be copied. Because the Mediaeval architects occasionally committed the gross artistic blunder of bringing down a heavy buttress upon the roof of a porch, therefore this shall be perpetuated in a modern church, without the slightest reason or excuse whatsoever; because they decorated their internal walls with artificial jointing in coarse red lines, we are exhorted to follow so noble an example; because they could not draw the human figure, and left ample proof of their inability, our stained-glass windows shall exhibit portraits of saints, looking, as a modern writer has said, "like starved rabbits with their necks wrung;" and our chancel walls shall be painted or inlaid with grotesque figures, profanely put forth as representations of the Deity, and which at least do not transgress the second commandment, as they are certainly not the likeness of anything in heaven or earth, or the waters under the earth. Quitting, however, this painful subject, let us consider what are the real objects to be attained in a modern church service, and what the real requirements of the plan.

The public worship of the present day may be defined thus,—it is the meeting together of a number of people professing the same faith, for the expression of unanimous prayer and praise, according to a prescribed form, the mass of the worshippers being led in their prayers by ministers ordained for the purpose, and in their musical service of praise by a certain number of people more or less trained (generally less). There are, then, three divisions of worshippers to be provided for,—the clergy, the choir, and the people; and first, with regard to the people, I must protest against an idea that has lately been put forth, that their part of the church is to be treated as an *auditorium*, and planned, in fact, on the same principle as a theatre. This can only result from a very superficial view of the subject; for, surely there is a great difference between the meeting of a number of people to witness a dramatic performance, in which they take no part whatever, and their enjoyment of which depends upon their proper opportunity for hearing and seeing, and the meeting of the same people for an expression of their own feelings, in which they ought all to join, and the forms of which they all have, or may have, in print before their eyes. That it is practically necessary that the clergyman's voice should be heard I admit; but that the church should be planned as if this were the one object, and as if the people were not to hear a speech or see a spectacle, I entirely deny. The principal point to be observed is, I think, that all the congregation should have the reading-desk, the pulpit, and the communion-table within their view; and on this account I think that three-sided churches are, on the whole, to be avoided (unless the side-aisles be used only for passage) as the view can only be rendered clear to all the people by the use of thin iron supports for the clerestory walls, a device fatal to architectural effect. Long transepts, also, are of course quite inadmissible. I

should consider a separate baptistery a very desirable addition, as the practice of holding baptisms during the course of the ordinary service is being disused, and it is very comfortable for a dozen or so of people to meet in a large and often cold church. With regard to our second division, the choir, it is only necessary that they should be placed where they will be tolerably conspicuous and be well heard; and that they should be divided on opposite sides of the church for antiphonal singing, an effect too beautiful ever to be given up. They are generally at present placed in the chancel, in front of the Communion-rails, thus entailing the double advantage of placing the singers where their voices are much more confined than they would be in the nave, and of removing the clergyman, during the Communion service, as far as possible out of the hearing of the congregation: an amusing instance of the blunders people make by following precedent; for the choir sat within the chancel, in the early times, not because that was the best place for them as singers, but because they were always members of the clergy, and therefore to be separated from the people. The more the choir are made to feel as a part of the congregation, the better, I suspect, for their devotional feelings. The clerical requirements are, firstly, the chancel, which in the present day need only be large enough for the celebration of the Protestant Communion service, and for which the simple apse of the early churches furnishes the best possible model; the reading-desk, which should be placed in a convenient position on one side of the apse; and the pulpit, which must be placed where the clergyman may be best heard, the sermon being the only part of the service where the people depend entirely upon hearing him; with this limitation, that it should never be planted conspicuously in the centre of the church, as if it were the point to which everything else was subordinate. A vestry, also, is of course required for the clergyman, which I think should be a tolerably large room, capable of containing a bookcase, if necessary, and of affording comfort and convenience; not a mere ege, scarcely large enough to turn round in.

The introduction of a larger and finer class of organs into our churches than have hitherto been found there, claims some consideration, though this has been strangely neglected; and while drawings are furnished by the architect for every bench and hinge, the largest and most important piece of furniture in the church is left to the tender mercies of the organ-builder's joiner. The usual position of the organ, in a chamber built out from the chancel, is almost the worst in which it could be placed. It should be where it has free space to sound, not where the sound is driven down and smothered the moment it is emitted. In addition to this evil, the placing of the instrument between two or more outside walls, and with a roof close over it, exposes it to every change of temperature, which not only alters the tuning, but makes sad havoc with the delicate internal mechanism, and not a few instruments are now being ruined by being placed in this position: where it is necessary to place an organ so, there should at least be a dry area in the wall, and a eiled roof over.

The question of style is too important, and at present too difficult a one, to be tackled on the end of a paper; but I may venture a few remarks on general principles. Although I do not at all advocate the direct revival of the Gothic style, or think it fitted to express the feeling of the present day among the mass of the people, I nevertheless think it very important to preserve the feeling for breadth of effect and deep shadow in the mouldings and ornamentation so conspicuous in that style, and so admirably suited to our northern climate, of which it appears to me to have been the natural outgrowth; and while making all due concession to the design of a church, to nineteenth century ideas of comfort and civilization, I would avoid everything like littleness and tawdriness of effect. A church is not a drawing-room, nor is it to be fitted up, as a writer suggested lately, with curtains and draperies and arm-chairs, and everything with which the most ordinary associations are connected. It is a legitimate field for the display of architectural art in its highest form,—architecture of that lasting and durable character that is best described by the word "monumental." I should very much wish to see the domed form of roof more used. It is a difficult form to manage externally, on account of all its lines, on a near view, receding so fast from the

eye; but internally there is, I think, no effect comparable to it, and a church is essentially a building for internal effect. Galleries, I think, should be avoided, if possible. However well managed, they detract very much from the general effect, and principally, I believe, for this reason, that the impression produced on the spectator by a fine and lofty church is much enhanced, even without his knowing it, by the evident fact that it is so much more lofty than is really necessary; that the piers and arches, the dome, or the high-pitched roof, are carried up to that height purely for artistic effect. Place a gallery there, and you immediately weaken this idea by suggesting that, after all, the extra height is necessary to give room for the upper tier of worshippers, and the whole thing is more or less utilitarianized.

In looking back at the history of church architecture, there is one consideration, at least, which is encouraging—there is something left for us to do. As I have endeavoured to show, there has not yet been any style complete and artistic in itself, and expressive of the highest and purest form of Christian worship. It is left to us to originate such a style, and I see no reason why we should not, if we go the right way about it. As the descendants of the builders of Lichfield, Canterbury, Wells, and Salisbury; as the possessors, since then, of a literature second only to that of the Greeks, we surely are not by nature an in-artistic nation. But I suspect the secret is that we have no fixed principles, and take no trouble to fix any. Occasionally writers like Garbett, Ferguson, and Huggins, startle us by suggesting that all is not quite right, in spite of the architectural activity going on around us; but no lasting impression is produced, and things seem to go on much on the same principle of accidental selection, or no selection at all. It may be answered that the Mediæval builders did not trouble themselves about principles. I believe they did not; but they not the less worked on a principle—that of elaborating the details best suited to the eliminate upon the plan best suited to their requirements, and of always doing the very best they could according to their light. If they were not conscious of these principles, it was simply that they were never tempted to overstep them. But it is utterly impossible, in these days of travel, to place ourselves in the same position; and it is only, I believe, by attending to principles, and by fixing these principles on a certain basis, that we can guard ourselves against the indiscriminate copying of everything that strikes our fancy for the moment. Perhaps the study of the history of previous styles, with their surrounding circumstances, is not the worst way of attaining this; and, I believe that one very great step towards regulating and restraining our tastes would be an increased attention to the study and drawing of the figure, as an accessory to architecture, in that highest style of art of which the Greeks have left us almost unapproachable examples: and as their temples had friezes and sculpture representing passages in their mythology, I see no reason why ours should not also be adorned with bas-reliefs, in like manner, representing subjects from Biblical and ecclesiastical history (taking the word ecclesiastical in its widest sense). The healthy influence, at any rate, of such a study, would perhaps deliver us from the incubus of symbolism; would render it impossible for our eyes to be pained with the sharp, angular, bristling forms, the quirks, the crinkle-erankle, the utter absence of repose or beauty of line which characterize much of what is called "modern Gothic," but is based upon principles (if any) widely different from those of the real Goths; and would surely do more to resuscitate church architecture than the delineation of starved-looking angels with wings red on one side and green on the other, or than the most careful arrangement of flat brickwork in the most elaborate coloured patterns. H. H. STATHAM, Jun.

**COST OF SOCIETY OF ARTS' PRIZE COTTAGES.**

The following is the result of a trial to get cottages built on the plan described in your number of the 31st of December, as having obtained the Society of Arts' prize, and as estimated to cost 209l. a pair.

The cottages to be built were six in number; the locality was Bishop's Stortford; and the very best means were taken to ensure that the plan

and specification should be in strict accordance with the ideas of the designer.

Six tenders were obtained: three from London builders and three from the country. They were,—

Perry, Stratford, London	... 41,183 or 2397 13 4	the pair
Bell & Sons, Cambridge	1,272 or 524 0 0	"
Glasscock, Bishop's Stortford	1,380 or 469 0 0	"
Freeman & Sons, Ely	1,388 or 462 13 4	"
Pattick & Sons, London	1,592 or 461 0 0	"
Hill & Keddel, London	1,681 or 537 0 0	"

So that the lowest tender was nearly twice as much as the estimated cost of the prize cottage; the low estimated cost being, I presume, one of the principal grounds of awarding the prize to it. Any one can build a good labourer's cottage; the difficulty is to build one for little money. I have had occasion to build hundreds, but could never build one that a decent family should live in under 140l. or 150l. a single cottage.

ROBERT SINGLETON,  
Engineer-in-Chief, Great Eastern Railway.

**EXPLORATION OF THE HOLY LAND.**

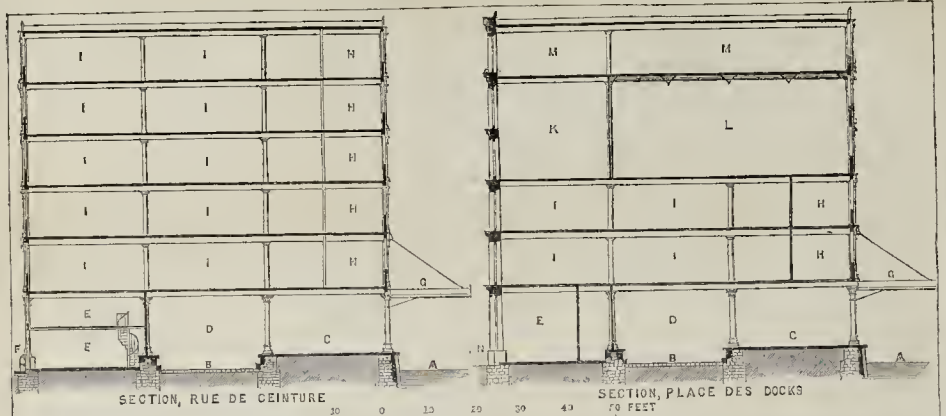

A COMMITTEE has been formed to organise a society for exploring the Holy Land for Biblical illustration, and a circular has been issued setting forth the objects it has in view and grounds for forming it. If they cannot do all that is desired,—“Much would be gained by obtaining an accurate map of the country; by settling disputed points of topography; by identifying the ancient towns of Holy Writ with the modern villages which are their successors; by bringing to light the remains of so many races and generations which must lie concealed under the accumulation of rubbish and ruins among those villages stand; by ascertaining the course of the ancient roads; by the discovery of coins, inscriptions, and other relics; in short, by doing at leisure and systematically that which has hitherto been entirely neglected, or done only in a fragmentary manner by the occasional unassisted efforts of hurried and inexperienced travellers. Who can doubt that if the same intelligence, zeal, knowledge, and outlay were applied to the exploration of Palestine, that have recently been brought to bear on Halicarnassus, Carthage, Cyrene, places without a single sacred association and with little bearing on the Bible, the result would be an enormous accession to our knowledge of the successive inhabitants of Syria—Canaanite, Israelite, Roman—and in consequence a flood of light over both Old and New Testaments?”

What is above ground will be accurately known when the present survey is completed; but below the surface hardly anything has yet been discovered. The Tombs of the Kings on Mount Zion—the course of the Tyropæon Valley—the real extent of the Temple enclosure—the site of the Tower of Antonia—the Palace of Herod—the Pool of Bethesda—the position of the towers of Hippicus and Psephinus—the spring and conduit of Hezekiah—are all awaiting excavation; and it is not too much to anticipate that every foot in depth of the “sixty feet of rubbish” on which the city stands, will yield most interesting and important matter for the archaeologist and the numismatist.

It will perhaps be said that many of the points above enumerated have been already examined—that Robinson, Stanley, Rosen, and others have done much in the department of topography—that Hooker, and more recently Tristram, have reported on the botany—that Roth and Tristram have brought home shells, birds, and eggs—that the researches of M. Lartet on the geology of the Dead Sea, and those of De Vogué and De Sauley on archaeology, are on the eve of publication. This is true; but without intending to detract from the usefulness or the credit of the labours of these eminent men, it is sufficient to observe that their researches have been partial and isolated, and their results in too many cases discrepant with each other. What is now proposed is an expedition composed of thoroughly competent persons in each branch of research, with perfect command of funds and time, and with all possible appliances and facilities, who should produce a report on Palestine which might be accepted by all parties as a trustworthy and thoroughly satisfactory document.

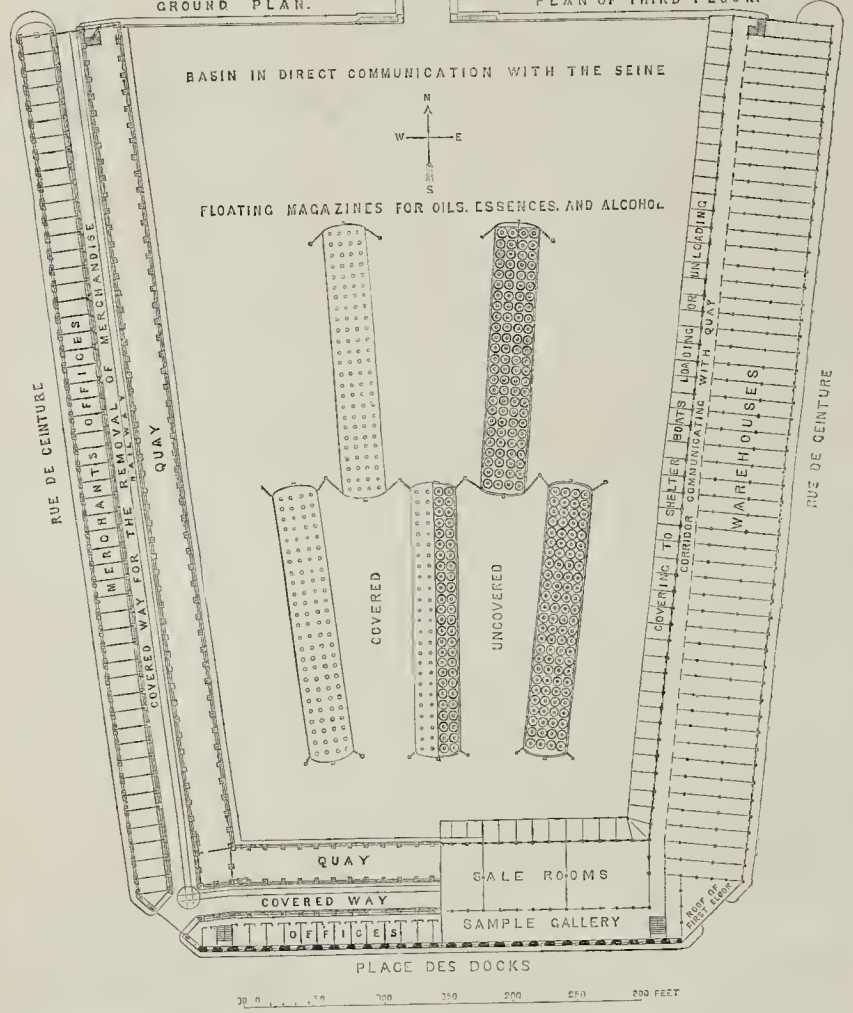

Mr. George Grove, who has devoted much of his spare time to Biblical topography and antiquities, is acting as honorary secretary. There could not be a better.

THE SAINT OUEN DOCKS, PARIS.—M. PREFONTAINE, ARCHITECT AND ENGINEER.

## THE PRESIDENCY OF THE INSTITUTE OF ARCHITECTS.

Mr. DIGBY WYATT writes to us as follows:—  
“A letter addressed to me by Mr. Tite having been recently very widely circulated, I am induced to forward to you a few lines I have this day sent to that gentleman in acknowledgment of his communication.”

It is not our custom to publish letters addressed to individuals, but, under the circumstances, we will not refuse in the present case. To make the matter clearer, however, and in justice to Mr. Tite, we must first print that gentleman's letter:—

“My dear Mr. Wyatt, — Your circular has excited my extreme surprise, because I thought you had embarked in the same cause with myself, and were contending for the same principle which received its emphatic solution when I was elected president of the Institute by so decided a majority in 1861, and when I found you one of my warmest supporters. I did not understand at that time that the question was whether Mr. B. Hope or Mr. Tite should be president, but whether the chief officer and public representative of the Institute should be an architect by profession or an amateur.

Mr. Donaldson understood it thus, and so did I; it was a principle for which I had been contending for years; and this is the real question at issue now. As to the feeling between Medievallists and Classicists—this is a point, in my opinion, which ought not to be imported into the present debate. I certainly understood Mr. Scott consented to be put in nomination as president, and accordingly he is the man whom we have been accustomed to look forward to for the present occasion. It is idle to pretend that there is any attempt to put down certain tastes or views; for it is the most eminent supporter of these very principles who is urged to preside over us by all who think with me.

Before I proceed to say a few words on the general question, I desire for my own sake to disclaim personal considerations. I have the honour of sufficient acquaintance with Mr. Boreford Hope to know that he is a very amiable man, well educated, and having considerable acquaintance with Gothic architecture. My objection to him is simply that he is not an architect, and therefore unsuited for the presidential duties. Look for a moment at what they are. He is to preside in the Council, where technical questions relating to our practice, our charges, and our disputes are constantly arising. Some years ago I obtained parliamentary recognition of us as a body, so that the important duty of examinations of district surveyors is confided to us: this at times might lead to technical difficulty. I have now before me an amended Building Act, which no doubt I shall be requested to introduce in Parliament before the session expires; and this again must bring the Institute before the public in its purely practical capacity. The Council is often chosen to arbitrate on disputes between architects and employers. You have established a tariff of charges. You have introduced a voluntary examination on all points of scientific and practical detail, of the greatest possible value to the profession. All these considerations combine in pointing to the advisableness of professional presidency. Again, at the meetings, questions of construction in iron, strength and stress of materials and their prices, questions of light and air, and so on, must be constantly before you, and must be increasingly so. I need not here compare the advantages of such a president as Mr. Donaldson or Mr. Scott on such questions, and the uselessness of an amateur.

One important fact occurs to me, that by the charter, an honorary Fellow has no vote, and consequently no casting vote.

I feel satisfied that if all this were candidly explained to Mr. Hope, he would himself withdraw from duties which it is useless to pretend he could satisfactorily undertake.

The case of Earl de Grey is not in point. I never knew him to attend except at an opening meeting or when some public occasion rendered it necessary. He was most useful at a time when our social position as architects was, with one or two important exceptions, nothing; and our numbers but few. However, my dear Mr. Wyatt, I would put the question on this issue: can you give me any instance anywhere in Europe where a scientific and working institution, like the Institute of Architects, exists without a professional president?

I fear that the architects of England do not

stand so high in the estimation of their professional brethren on the Continent as they ought to do. Are we to give colour to their opinion by informing all the world that we have not one amongst us worthy, in our own judgment, of the highest position we can confer, and notwithstanding our gold medals and the generous patronage and support of the Royal Family of England?

I love peace as well as any man, and would make any sacrifice to obtain it; but I cannot surrender views such as these to any considerations of expediency, and therefore I hope you will pardon my thus addressing you, and that you will use your influence to produce a sound and lasting peace by inducing Mr. Hope to withdraw, and by promoting the election of Mr. Scott, as president of the Institute of British Architects.

WILLIAM TITE.  
P.S.—Should Mr. Scott decline, why not nominate Mr. Salvin?”

“My dear Mr. Tite, — I beg to acknowledge the receipt of your letter, which reached me on the afternoon of the 20th inst., and to which I have given very careful consideration. Although I do not see any immediate benefit likely to result from a protracted correspondence, out of personal respect to you, I am unwilling to leave your letter altogether without reply. I beg, therefore, to observe that when I had the pleasure of supporting your nomination as president in 1861, I had the satisfaction of contributing to upset the arbitrary doctrine, traditional up to that date, that no professional man was fitted to represent the Institute as its president,—one which unbroken through would have become tyrannical and injurious. I further helped the election of a brother architect, as I believed, and as the result proved, exceptionally well qualified for the office.

I think it would be little less tyrannical and injurious to insist now that no unprofessional man could be fitted to represent the Institute. Your letter and Mr. Scott's show that there are two sides to the question, and the best way in which the Institute can shape its course between them will be, I think, by leaving itself free to select hereafter the most eligible candidate who may present himself, or be brought forward by the Council, irrespective of whether that candidate may be professional or unprofessional.

I most heartily endorse your view that the feeling between Medievallists and Classicists ought not to be imported into the present debate; and out of my strong conviction on this head arose my endeavour to induce the nominee of the Council to divest himself of party, and allow himself to be proposed in his simple position of an accomplished gentleman, possessed at least of the qualifications you state that you know him to possess.

Finally, you urge me to use my influence to induce Mr. Hope to withdraw, and to promote the election of Mr. Scott, — or, failing Mr. Scott, that of Mr. Salvin. Indeed, my dear Mr. Tite, you greatly overrate my influence; but, whatever it may be, you must pardon my not exercising it in the direction you suggest. I understood Mr. Scott to say two years ago that, with his current business engagements, it was impossible for him to attend to them properly, and to the presidential duties as well. As since then he has rather added to, than diminished, his professional responsibilities, I cannot but suppose him to be out of the field.

I doubt whether Mr. Salvin, who has recently settled in the country, relinquishing, as I understand, professional responsibilities, would be induced to come forward and allow his name to be substituted now, or, indeed, at any time, for that of any other gentleman nominated by the Council. With respect to the issue upon which you would put the question, viz., whether there is any country in Europe where a scientific and working institution like the Institute of Architects exists without a professional president? I would remark that the terms of the issue are too vague; since, for experience to be valuable as a final test, the conditions under which experiments are tried must be either identical or at least perfectly well known. This could scarcely be the case if precedents should be sought for from practice in different countries, and under different social and political systems. As you are, no doubt, aware, all scientific association abroad is under direct Governmental control, being either kept entirely under a minister specially charged to be, as it were, *ex officio*, president of all such societies, or put down. Europe, therefore, gen-

erally affords but little experience likely to be useful in this matter to England. Turning, however, to this country, we have several of the societies which best answer your definition with other than professional heads. The Society of Arts, for instance, which is eminently scientific and working; is presided over, if I remember rightly, by H.R.H. the Prince of Wales; who is also, I think, president of the Horticultural Society. If he should render to either of those bodies a tithe of the practical services his father did before him, neither will have reason to regret its existence without a professional president. I do not know that any society could be pitched upon as more strictly analogous to our own Institute than that of our brethren, the Naval Architects, whose useful president for the time being is Sir John Pakington. All the Antiquarian Societies have, I think, aristocratic presidents; and possibly there may be others similarly presided over which do not occur to me. Whether there may or may not be such is, I think, a matter of no great moment to us. What we have now to do is to effect a reasonable and peaceable adjustment between conflicting parties in such a manner as to leave any minority without legitimate cause of complaint; and to effect such an adjustment, both sides must yield something; for, as Mr. Mills so admirably says, ‘adjustments must generally be of the nature of compromises, not resting on fixed principles, but each side giving up something for the sake of peace.’

## THE ST. OVEN DOCKS, PARIS.

THE St. Owen Railway and Docks Company has been constituted, with a capital of 400,000*l.*, to unite in Paris the group of French railways with those of the navigable canals. This is being accomplished by means of a branch from the circular railway, which joins all the lines radiating in Paris, and the river Seine, at a spot between the villages of Clichy and St. Owen, a short distance outside the fortifications. The line branches off at Batignolles, starting from a vast goods shed; crosses the military road on the level, the ramparts by a tunnel, and the ditch of the fortifications by a wrought-iron bridge, and arrives at the docks, where a network of sidings and junction lines, of a total length of 1½ mile, communicates between the different portions of the docks and warehouses, so that railway waggons, boats, and carts can directly and safely exchange or tranship their merchandise.

The docks consist of a magnificent basin 656 ft. long, and of an average breadth of 410 ft., united to a canal 1,968 ft. long by 164 ft. wide, communicating with the Seine by means of a lock 196 ft. 10 in. long by 39 ft. 4 in. wide. The area of the basin and canal is 13½ acres; and around the former, which is completed, are being established vast warehouses, platforms, roadways, offices, cranes, &c. The foundations for the buildings are laid upon the tertiary strata called *Marne de St. Owen*, calculated to be about 40 metres (131 ft.) in thickness, and proved to be able to support a weight of 7 kilogrammes per square centimetre (99½ lb. per square inch) without sinking. All the materials for the masonry have been calculated to support pressures ½ of what would produce crushing; and for the iron work the utmost strain to which it can be subjected is only ¼ of rupturing force.

The walls of the basin are 23 ft. high, the base being 75 ft. 9 in. above sea level; and the water level is 95 ft. 2 in. above sea level, or within 6 ft. 7 in. of the top of the wall. The thickness at the base of the walls is 8 ft. 2½ in., and 3 ft. 11 in. at top; they are of squared rubble from Vergèze, and hammer-dressed millstone grit from Gif for the facework; and at every 13 ft. chain-and-courses are introduced, from top to bottom, of ashlar, from the Enville and Erouville (Lorraine) quarries. Three other walls, at distances of 26 ft. 3 in., surround the basin; these are of an average thickness of 4 ft. 7 in., and are also built in hammer-dressed and millstone grit, with copings of Enville ashlar and granite blocks to receive the iron columns, 13 ft. apart. On the east and west outer portions these blocks are of rose-coloured grès from the Vosges (the permian or magnesian limestone series of sandstones).

The southern exterior façade of the warehouses is to be in the style of Louis XIII., of brick, with ashlar bonding courses, at every 13 ft. 1 in., from the Soissons quarries. These bonds are 2 ft. ¾ in. thick at the base of the wall, and 15½ in. at the top. The remainder of

the walls are 15 $\frac{1}{2}$  in. throughout. The bricks are of a deep red colour, from the well-known kilns of Burgundy. The foundations are of concrete, composed of fifty parts of mortar to eighty of broken stone; the mortar consisting of one part sand and 0.35 part hydraulic lime, from the Yonne basin. All the interior façade, and the east and west exterior fronts of the warehouses, are entirely composed of cast iron and brickwork, the iron framework forming a series of six columns superposed, united together by cast-iron arches, and by window-frames of iron also, the columns being 13 ft. 1 in. apart. The partitions are of hollow bricks, with eight holes, measuring 8 $\frac{1}{2}$  in. by 4 $\frac{1}{2}$  in. by 2 $\frac{1}{2}$  in., and laid on the flat; they are of a light red colour, very compact, and well burnt. The columns internally are cylindrical; externally they are of a semi-circular section towards the outside of the building, and square towards the inside, with projecting ribs at the angles to receive the brick partitions. For the ground-floor the diameter of the columns is 9 $\frac{1}{2}$  in., and the thickness of metal 1 in.; for the upper floors they are 5 $\frac{1}{2}$  in. diameter, and  $\frac{1}{2}$  in. thick. The window-frames are generally  $\frac{3}{4}$  in. thick. The flooring is to be supported by wrought-iron girders of I shape, 19 $\frac{1}{2}$  in. deep and 9 $\frac{1}{2}$  in. wide at top and bottom, composed of  $\frac{3}{4}$ -in. iron, riveted together by angle irons, 3 $\frac{1}{2}$  in. by 3 $\frac{1}{2}$  in., with  $\frac{3}{4}$ -in. diameter rivets, 4 in. apart. The floor is to be formed of hollow brick arches, grouted with Portland cement, mortar, and covered with asphalt  $\frac{1}{2}$  in. thick. These arches, 13 ft. 1 in. span, are 4 $\frac{1}{2}$  in. thick; they are strengthened by wrought-iron ribs, 1 $\frac{1}{2}$  in. diameter, placed 6 ft. 6 $\frac{1}{2}$  in. apart. It has been proved by direct experiment that these arches are capable of sustaining without any alteration a weight of 3,000 kilograms to the square metre (614.1 lb. to the square foot). The third story of the south building is reserved for public sales; there are to be five great sale-rooms, 65 ft. 7 in. by 52 ft. 6 in. and 22 ft. 1 $\frac{1}{2}$  in. high. Behind these there is to be an immense gallery for samples, 328 ft. 1 in. long by 26 ft. 3 in. wide. On the ground floor there are to be 100 cabinets or offices for merchants, divided by a small floor into upper and lower rooms, access being obtained by a spiral staircase to the upper offices. There are, therefore, 100 of these cast-iron staircases. Five hundred ware-rooms or stores are to be provided 65 ft. 7 in. by 13 ft. 1 in. and 9 ft. 10 in. high, closed by corrugated iron doors moving on rollers. The hollow brick partitions will be made hereafter, according to the requirements of the different occupiers.

For the service of these warehouses twenty quay-cranes and as many hoists are to be furnished and worked by compressed air, according to the system of M. Neustadt, well known for his gas-chain cranes. The roofing of the warehouses is to consist of arches similar to those under the floors, covered with a layer of cement and a coating of Syssal asphalt. The quay, extending over 656 yards long and 29 ft. 6 in. wide, is paved with puzozolana composition, to the thickness of 2 in. Boats unloading or loading will be sheltered by an awning or "marquise," 656 yards long by 18 ft. projection, supported by wrought-iron framing resting on hollow beams, which are to repose on the capitals of the cast-iron columns of the ground-floor. This will be further strengthened by oblique tie-rods fixed to the iron-work of the second story. The whole of the rainwater from the roof and marquises will find its way into the dock through the means of the hollow cast-iron columns above described, every arrangement being made to preclude the possibility of infiltration of water into the warehouses.

There are in all 3,700 columns in the buildings, and about 57,000 lineal feet of girders of uniform section. The quantity of concrete laid in the foundations is 26,160 cubic yards at 9s. 9 $\frac{1}{2}$ d. per cubic yard. The squared rubble and limestone grit masonry amount to 23,500 cubic yards at a cost of 11s. per cubic yard; there are 39,000 cubic yards of asilar, at 73s. 5d. per cubic yard; 3,000 tons of cast-iron from the Marquis (Pas du Calais) foundries at 81; 3,200 tons of wrought-iron contracted for by Roussel, of Paris, at 14 $\frac{1}{2}$  per ton, put in place. The number of hollow bricks in the works will amount to 3,000,000 at 21 per thousand, delivered on the quay. The total expense is 240,060l. for 89,702 superficial yards of warehouse flooring, or at the rate of 53s. 6d. per square yard.

Five floating magazines for inflammable oils, spirits, and essences, are to be provided for the

grand basin; two are already afloat in it, one being filled with petroleum oil, and three are in construction. They consist each of a series of 100 wrought-iron circular tanks, riveted together and surrounded by a framework of timber. These cylinders are 8 ft. 2 in. diameter and 17 ft. 3 in. high, and are formed of  $\frac{3}{16}$  wrought-iron plate in the sides, and  $\frac{1}{4}$  at top and bottom ends. The liquids are introduced by holes 2 ft. diameter, at the top of the vessels, each cylinder containing 5,500 gallons, and each floating warehouse 550,000 gallons. Thus the five will contain 2,750,000 gallons altogether. Moored in the middle of the basin, these barges are free from all risk from fire, and can be swung round to any part of the quays, where machinery has been erected for ganging petroleum oil. In case that, from any cause, they become on fire, they can be easily drifted out of the basin into the Seine.

On the 13th November last the water was let into the basin, and one of the floating magazines launched, with great ceremony, in the presence of the Princes Poniatowski and Napoleon; and the warehouses have been in progress ever since, except during the severe frost. The organization of the Company is due to M. Préfontaine, administrating director; the surveys and studies of the works were under the direction of M. Fontaine, civil engineer, formerly élève of the Ecole Impériale des Arts et Métiers at Chalon-sur-Marne. The dock works were contracted for by M. Courtois, under the orders of the ordinary engineer, M. Henriot.

SHADOW AND OUTLINE.

As Shadow and Outline for Beauty contended,  
Our art's master critic pass'd thoughtfully by,  
And to him both appeal'd when their argument ended,  
Who smiled his assent with an eloquent eye.

Inspired by his presence, said Shadow, "Where'er  
The sun-ray is brightest I stronger appear;  
And Nature, delighting in broad masses ever,  
Taught man first by shadow to measure the year.

On the crest of the mountain bow solemn reposes  
The mantle of shade o'er the ravine of snow;  
And the prism of mercy more lovely discloses  
Its archway of light o'er the strata below."

"Tis to me," replied Outline, "these beauties are owing:  
The cloud and the mountain—the glories of day—  
More strongly and grandly by difference glowing,  
Would lose half their splendour were contrast away."

The stream and the forest their loveliness borrow  
From definite angles or subtly carved line;  
And the Garden of Eden were desert to-morrow,  
If you rend from its graces the charms that are mine."

"No longer content ye, twin forms of expression,"  
The umpire deciding with gentleness spake;  
"Your powers must unite you in peaceful concession,  
And sever from henceforth discussion awake."

In nature, in art, ye awake admiration:  
With nature let art by your concord compare;  
On the features of Myra let each take her station,  
And please and subdue us in harmony there."  
W. R. COOPER.

Working Men's College.

AN ARCHITECT'S DIRGE.<sup>1</sup>

Let softly on him, Earth, for he bath laid  
A fair and blessed burthen on thy breast;  
And now, while he, he asks a place of rest  
Within its holy shade.

Smile calm above him, Sky, for he did trace  
The blessed cross against thine azure arc;  
And ever faithful bear that holy mark  
Above his sleeping-place.

Shine brightly on him, Sun, in thankfulness  
For that he prison'd thee in storied pines,  
And made thy rays all glorious with hair stains,  
Bright as an angel's dress.

Sing to him, Summer Dreezes, restfully,  
And bring him all the changes and the swells  
And billows of his own fair steeps-bells,  
To be his lullaby.

\* These lines were suggested by an adaptation of the well-known epitaph "Lie heavy on him, Earth," &c., in your paper of Saturday last. They are not intended to apply to any person in particular.—E.

LECTURES IN CONNEXION WITH THE ARCHITECTURAL EXHIBITION.

The Committee of the Architectural Exhibition have made the following arrangements for the season:—

Tuesday, May 18.—"Incidents of Old English Architecture, Civil and Ecclesiastic, especially in small Towns and Rural Districts," by Mr. A. J. B. Beresford Hope.

Tuesday, May 23.—"The Arrangements of a Gentleman's House," by Professor Kerr.

Tuesday, May 30.—*Conversations.*

Tuesday, June 6.—"An Architect's Thoughts," by Mr. E. B. Lamb.

Tuesday, June 13.—On "Art-Foliage," by Dr. C. Dresser.

Tuesday, June 20.—*Conversations.*

All subscribers, exhibitors, and season-ticket holders will be admitted by their tickets to the *conversations*, and will be entitled each to introduce a lady.

THE LATE WYGGESTON'S HOSPITAL COMPETITION, LEICESTER.

The trustees, at their meeting on the 21st, awarded the second premium of 50l. to be equally divided between Mr. William Millican and Messrs. Goddard, architects, of Leicester; Mr. Sorby, of London, having gained the first premium which merges in his commission, he being appointed the architect for carrying out the works. Four Leicester builders were invited to compete for the contract, viz., Mr. William Neale, Messrs. Herbert, Mr. Thomas Bland, and Mr. J. B. Collins: the first-named being the successful competitor by 25l. only, is about to commence the works. The quantities were taken out by Messrs. Northcroft & Scott, of London. The estimated cost of the buildings complete is about 13,000l.

SCIENCE AND ART.

A LARGE and influential meeting has been held at Salisbury for the purpose of establishing a school of science and art for that city. The mayor occupied the chair.

After some preliminary remarks from the bishop of the diocese, the dean, and the members for the city, Mr. Buckmaster spoke to a resolution which he undertook to give him an opportunity of developing the whole scheme of the Science and Art Department with reference to instructions in science and art. After giving a sketch of the rise and progress of the Department, and the great success which had attended the Science Minute in the formation of evening classes, he said:—

"The true connexion between science and art has never been sufficiently recognised. Leonardo da Vinci is only known as a great painter, but he was equally great as a scientific man. He was one of the early practical reformers of science, and wrote thirteen volumes on pneumatics and hydraulics, which gave the earliest indication of that system of inductive philosophy with which the name of Bacon is associated. His great contemporary and rival, Michelangelo, was also thoroughly acquainted with all the then known sciences, especially those of geometry and mechanics. Phidias not only sculptured the statue of Minerva and the frieze which adorns the Parthenon, but he also superintended its building, and gave lessons on the sciences involved in its construction. Egypt, Assyria, Judea, Greece, and Rome have left us an unwritten history in their architecture; but the dawn and spread of Christianity was marked by the rise of a new era in art, which embodied the great ideas of sacrifice and hope, the noble expression of a great spiritual revelation, to which heathenism had succumbed, leaving to posterity the records of transcendent intellect in the Gothic churches of Europe and the masterpieces of art preserved in the Kensington Museum.

If we go back only a few years, we can call to mind one who never saw science without art, or art without science, who considered both as the great power by which the progress of humanity and civilisation was to be advanced in this his adopted country. In his public speeches the Prince Consort alluded constantly to this idea. He seized every opportunity of indicating the necessity of science and art as the two great manifestations of intellectual cultivation and social refinement.

The accurate representation of any natural object on a plane surface requires the combination of two elements—the one scientific, the other artistic. The scientific consists in the proper disposal of lines geometrically determined, the artistic in that soft gradation of tone which every opportunity of imitating in nature. This connexion between science and the art of painting did not begin till about the fifteenth century, and it was not till 1731 that the mathematics of perspective were demonstrated. From the time perspective was reduced to certain scientific principles and accepted by art, they were adopted as a necessary part of art-education, and no student in any of our art-schools would now produce a work which would a few centuries ago have been regarded with favour."

A committee was organised to receive subscriptions and make the necessary arrangements for a School of Science and Art for Salisbury and its neighbourhood.

## SANITARY MATTERS.

London.—At a meeting of the Representative Vestry of St. Marylebone, the subject of the apprehended Russian epidemic reaching this country, and the necessary sanitary precautions, has been brought under discussion in connexion with an important and exciting report from Dr. Whitmore (Medical Officer of Health), as to the state in which, on inspection, he had found the vaults of certain churches and chapels directed to be closed by order in council. Dr. Whitmore reported that the work was begun on the 28th of December last, at Trinity Church, beneath which sixty coffins had been deposited. Great difficulty was experienced in closing up the vaults, especially what is called "the Russian vault," enclosed by a pair of handsome lofty iron gates, which it was found necessary to brick up with the coffins. In these vaults many of the lead coffins had burst, and very noxious and overpowering gases were continually evolving; but the disinfecting composition used effectually absorbed them, and every trace of effluvia and unpleasantness had now been removed. The vaults beneath the parish church contained 366 coffins, some in tolerable preservation, others rapidly decaying. The necessary shifting for enclosures caused the most intolerable effluvia to arise, producing nausea and sickness in the workmen, rendering the frequent use of stimulants necessary. The work of hermetically closing had, however, been accomplished, and to further cleanse and purify these vaults, in addition to layers of mould and charcoal, he had directed them to be covered with a thick coating of lime-wash. Beneath Blandford Chapel the scene which presented itself was indescribably shocking, and some idea may be formed of the dangerous condition of the place from the fact that on first entering the cellar leading to the vaults, the flame of a candle was extinguished. This place, for so many years a loathsome and poisonous charnel-house, has now been rendered perfectly clean and innocuous. In the vaults under St. John's Chapel, 110 coffins were embedded. These were also in various stages of decay, and from many of them offensive effluvia arose, and the atmosphere of the place had become polluted; but by means adopted it had been got rid of, and thorough ventilation had been introduced, and the vaults had also been lime-washed. A communication was read from Dr. Holland, the medical inspector appointed by the privy council, landing the excellent manner in which the order in council had been carried out, and for which he considered thanks due to Dr. Whitmore. The report was ordered to be entered on the minutes, and a vote of public thanks to Dr. Whitmore, was carried unanimously. Dr. Whitmore thanked the Board, and in answer to a number of questions as to the prevalence of typhus fever, and as to steps necessary to repel the apprehended Russian epidemic should it make its appearance, urged rigid measures of street cleansing, and especially the prohibition of leaving about decayed animal matter. He alluded particularly to Gray's-buildings, inhabited by the Irish, which were in a frightful condition, and to which he was devoting attention. A special sanitary committee, consisting of two members of each ward, was appointed to co-operate with the medical officer of health on the subject.

Liverpool.—The local health committee are actively at work. At last meeting the inspector of nuisances reported that there were ninety-six houses where infectious diseases had occurred, and which required whitewashing and cleansing. There were also 111 houses in an unhealthy state which required whitewashing. The chairman said he was very sorry to see so many houses recorded as having had fever cases in them. There were sixty-five of them, and that was an increase; but it did not necessarily follow that fever was increasing in the same ratio. Mr. Robinson said, he had noticed in the *Times* that the medical officer for the City of London had stated that the closing as well as the cleansing of houses was the only effectual plan for getting rid of fever. Some houses had provided more than thirty fever cases, which it was found impossible to render healthy until the houses were closed and thoroughly cleansed. Orders were then given to issue notices for cleansing the houses referred to. As to the sanitary condition of the town, the chairman said the committee would be happy to see that there were not only a decrease in the number of deaths generally, but also in those recorded under the head of fever. There was only an increase of nineteen deaths on

the corrected average of the last ten years. An improved system of scavenging, at an increased cost, from 18,098*l.* to 21,004*l.*, was agreed to.

Manchester and Salford.—The first quarterly report of the local Sanitary Association, for the year 1865, has been issued. The following is an abstract:—Of 18,936 cases of sickness death occurred in 782, or 1 in 24. In the first quarter of 1864 the rate of mortality was considerably higher, no fewer than 884 deaths being recorded. The most unsatisfactory feature is the fever return. The total number of new cases of continued fever, using that word in its generic sense, and including under it the several forms of fever now generally recognised as more or less distinct, was 610; although in the preceding quarter the cases were still more numerous, the death-rate was considerably lower. On separating the typhus and typhoid seizures from those of simple febricula, we obtain the following results:—Of 355 cases of simple fever, only 10, or 1 in 38, proved fatal. Among the typhus patients, on the other hand, the mortality was far higher, no fewer than 55 of the 295 sufferers having fallen victims to the disease. These figures prove that fever of a highly malignant character prevailed to a very considerable extent. It does not appear to be the opinion of many who have been brought into close contact with the operatives that want of the necessities of life has undermined the health of the industrial classes. Another unfavourable feature in the present report is the continued prevalence of small-pox. In the third quarter of 1864 the seizures from this disorder did not exceed 100; in the next three months they rose to 242; in the late quarter they still continued high, amounting to 234, in which 13, or 1 in 18, appear to have ended fatally. It is so far satisfactory to find that the infantile death-rate was decidedly lower than usual. Of the 3,495 deaths, 1,377, or about 38 per cent, were in children under five years of age.

North Shields.—The chairman of the Tynemouth Board of Health, with several of the committee, have made an inspection of the lanes, alleys, and premises, from the Low Lights to Milburn-place, and orders will be forthwith given to all owners of property to remove every description of nuisance; to cleanse and pave the courts and yards; and, in default, the corporation will do the work, and recover the expense from the parties liable to pay.

Miscellaneous.—Fever and small-pox are still prevalent in Whitehaven, though not so virulent as they were. Small-pox has extended to Cleator Moor, Frizington, and Keeble-terrace.—For many months fever of a malignant character has prevailed in Leather Bottle-lane, Gloucester. Many of the sufferers were tramps, and all of them paupers. The surgeon of the local Poor Law Board, Mr. A. P. Carter, has been bravely fighting with fever cases in the common lodging houses, where he has been engaged almost night and day, according to the local *Chronicle*, often doing the work of nurse as well as surgeon. At a time when medical men are in so much peril, such cases ought not to be overlooked.—In the House of Commons, Dr. Brady disclosed a fearful state of things at Emneth, in the county of Norfolk, as regards infant mortality, which was declared to amount to 80 per cent. of those born. The local coroner and the parish surgeon did not hesitate to attribute criminal blame to the mothers, and they urged that it must be put down by the strong arm of the law. Starvation was said to be the cruel mode adopted for making away with the poor little creatures. Lochead cases are as nothing to this. The coroner promised to do what he could in the matter, and it is full time. He is a limb of the law himself, and ought to exert its power. It has since been said, however, that the coroner has exaggerated the evil. This itself may be a misstatement. The parish surgeon and the coroner ought to know.

## WATER LIFTS v. HYDRAULIC LIFTS.

Water may be economically used as power in many ways, namely—by gravity and also by pressure;—by simple gravity or actual weight in an open vessel; by pressure, as in Sir W. Armstrong's machinery, cranes, &c. One thousand gallons of water weigh about 4½ tons. In many towns where there is a water supply under pressure, this volume and weight of water can be sold to a profit at sixpence, and can be delivered into tanks or cisterns, according to the head of pressure, 50 ft., 100 ft., 150 ft., and

200 ft. and upwards. At Oldham, water is delivered and used at the railway warehouses in such manner that every gallon consumed at the station below, for locomotive or for other purpose, works its way down by lifting equivalent weights of goods into the several floors of the warehouses. At the Duke of Bridgewater's canal and colliery tunnels, water has been used more than a century for lifting coals at certain "balance pits;" the liberated water supplying underground canals. Lifts for warehouses, hotels, and even for private houses, are in use, on Sir W. Armstrong's principle, and such lifts may be made in a small compact telescopic form, to do much of the carrying-upstairs-work of a private house. These lifts may be as general as they are now rare. There is nothing new in the water-lifts of Paris.

## STEEP ROOFS AND FLAT ROOFS.

ALTHOUGH Mr. Kerr makes mention of tall roofs, he does merely that and no more, since he expresses no opinion whatever as to their recommendation, which I, for one, being utterly at a loss to conjecture, should like to have clearly explained. Can it be greater economy as regards material and construction, or the indication of the provision made for greater accommodation and comfort within, by these piling up aloft, far above ordinary "upstairs," a congeries of pigeon-holes and lumber-rooms, or is it simply the eumorphic and æsthetic effect alone that causes such extravagant, and, I should call it, equally absurd and ugly form of roof to find favour at the present day with some folks among us? Such question—least careful consideration.

It is all very well, but surely not all-sufficient, to say that "procrity and prolixity of roof," as the poet terms it, of course ministers to variety of sky-line,—a merit which some have of late so largely, that is, so violently insisted upon, that although it may, when full-grown, look to some eyes not very unlike an *extinguisher*, it seems to show in theirs very much like a *save-all*, for they appear to speak of it as being the very all-in-all of architectural design. To say nothing of the comparatively enormous cost of steep roofs, they are far from contributing always to the general nobleness of the structure on which they are superimposed. For, although not so intended, they are apt to dwarf all below them. No man can make himself look towering and Goliath-like in stature by wearing a tall steple-crowned hat: rather the contrary. So, too, there is something of the incongruous, if not of the ludicrous, also in the extravagant excess of roof which is occasionally affected. At any rate, it is at variance with what Ferguson calls "common-sense building."

Quite recently, however, a suggestion has been thrown out recommending the opposite extreme of roof construction, viz., that of perfectly flat terrace roofs, which shall be perfectly weather- and water-tight, and capable of being converted into gardens tossed up almost sky-high, though not, I fear, out of the reach of London fogs and smoke. Until I learn more about the hinted-at revolution in roof-building, I do not pretend to express an opinion either *pro* or *con*.

ART-LOVER.

## FREE METHODIST CHAPEL, POPLAR.

Sir,—In your last impression there was a list of tenders for the erection of this chapel, the lowest amounting to £,120*l.*, and greatly beyond the expectations of the computing architects was £,400*l.* Can any of your correspondents throw any light upon this?

A SUBSCRIBER.

## THE BUILDING TRADES.

THE master painters in the potteries have decided to bring men into the district, if possible, to the number of nearly 200. It was stated at a masters' meeting that several more men had accepted the masters' terms, and were working at Hanley and Tunstall.

At Keybam, about 200 excavators employed on the Government contract work have struck for an advance of wages from 3*s.* to 3*s.* 4*d.* a day. Certain rules have also been adopted by the men, to some of which the employers object. The smiths employed in sharpening the tools are out with the excavators, and the masons, consequently, have also been obliged to cease work. The masons have given notice of their

intention to ask for 5s. per day for country, and 4s. 6d. per day for town jobs, after the 1st of May. A report of the affair has been forwarded to the Admiralty.

At a recent meeting of the Yorkshire Association of Master Builders, the two following resolutions were adopted for acceptance by the operative masons of Leeds, giving them their choice:—

"1. That on and after the 1st day of May, 1865, the masons leave work at one p.m. on Saturdays, and in other respects the time to continue as at present; and that the wages be 5s. per day for the first five days of the week, and 3s. 6d. per day for Saturday, or 28s. 6d. per week. 2. That on and after the 1st day of May, 1865, the masons be paid 5s. per day, commencing work every morning at six o'clock, leaving off work at half-past five o'clock the first five days in the week, and four o'clock on Saturdays."

The master builders also agreed to the questions pending with the operative carpenters and joiners being put to arbitration.

Some two months ago the operative painters of Sheffield forwarded a notice and requisition to their employers, asking for an advance of wages and other changes in payment for overtime. The notice has expired; and, as no reply has been received, it was feared that a strike would ensue. Several of the principal employers had interviews, however, with their men, and made such concessions to their demands that it is now hoped, upon pretty good grounds, that a strike will be avoided.

A largely attended meeting of operative stone-masons in Huddersfield has been held, in reference to a request they have recently made to their masters. They want to cease work at one on Saturdays instead of four; to receive wages at the rate of 27s. a week from the middle of February to the middle of November, and at the rate of 24s. for the rest of the year; to have only one apprentice to five men; and to have other alterations made, including non-payment at public-houses. A letter was read from Mr. J. Sutcliffe, as representing the masters, declining to grant these terms, and the men then decided to strike on the 1st of May, unless in the mean time their request be granted.

A meeting of the operative carpenters and joiners at Rotherham has been held, to consider the propriety of moving for an advance of wages. A resolution was passed deciding to ask for an advance of 2s. per week. Notice of the motion, to expire on the 20th May, was to be forwarded to the employers.

The great bulk of the joiners and house-carpenters of Newcastle and Gateshead are now on strike for a half-holiday on Saturday. Twelve of the masters have acceded to the demand of the men, but forty-six of the other employers refused to do so, and the men, according to previous notice, have consequently struck work.

The strike of the painters in Carlisle is now at an end. The result is that the men's working hours will be shortened by two hours a week; but they will receive the same wages. With regard to the other branches of the building trade, affairs are unchanged among the joiners. The strike of the masons is at an end. The masters met a deputation of the men, when the hour system was withdrawn on the one side, and the notice for a reduction of the hours of labour, by half an hour a day, was withdrawn on the other. The only questions in dispute left were some rules in the proposed code as to non-interference and piece-work. The deputation of men went away to consult their club, and at another conference between masters and men all differences were removed. A code of rules was agreed to very similar to those adopted by the bricklayers, and so the strike, which has lasted seven weeks, has been brought to an end. Of the hundred men who went out seven weeks ago, only about fifty are now left in the town.

#### CHURCH-BUILDING NEWS.

**Ipswich.**—The chief stone of the restoration of St. Mary Tower Church has been laid. The stone was laid in the south-east angle of the churchyard. The tower will be 87 ft. high, and the spire 83 ft. high, the total height being 170 ft. The square at the basement will be 24½ ft. Vaulting groin stone will form the ceiling of the entrance, and each of the gurgoyles above will be figures of the four Evangelists. The bottom stage of the tower will be built entirely of Corsham Down stone, and the remainder of stone and hammered flint. The capitals will be ornamented with figures of a Scriptural character. The total cost is estimated

at 4,000l. The whole of this sum, as well as the entire cost of the work of restoration already completed, and which, we believe, is something like 10,000l., will be contributed by Mr. Bacon. The architect is Mr. R. M. Phipson, of Ipswich and Norwich; and the builders are Messrs. J. Stanley & Son, stonemasons, St. Stephen's, Norwich. It is intended to increase the peal of bells from ten to twelve. After the ceremonial and the workmen employed in the building, and others, partook of luncheon, provided by Mr. Bacon, at the Oak Rooms. About 150 sat down to the repast.

**North Kilworth (Leicestershire).**—The parish church of North Kilworth has been re-opened, after having undergone a restoration, under the superintendence and according to the plans of Mr. Joseph Clarke, of London, architect. The contractor was Mr. Law, of Luttrethworth. The old west gallery has been removed, and the west arch thrown open. The high pews have been taken away, and replaced with open seats. A new roof of polished oak has been put to the nave. A south aisle has been added, the church having previously consisted of nave and north aisle only. The porch has been rebuilt. A new stone and marble font, the gift of Miss Belgrave, the rector's sister, has been placed a short distance from the door. A new lectern, of carved oak, has been provided, the pulpit being composed of a portion of an ancient pulpit, the panels of which, with the tracery and colour still remaining, were found doing duty as an old clock-case. The clerestory windows in the north aisle, which were blocked up, have been thrown open and glazed, and the whole of the interior has been thoroughly cleansed and renewed.

**Bolton.**—A vestry meeting has been held at St. Paul's, for the purpose of submitting the architect's revised plans for the enlargement and restoration of St. Paul's Church. The Vicar said the revised plans had been considered and approved by the committee, and they suggested that a vestry meeting should be called without delay. After some discussion the plans were inspected, and Mr. R. Palgrave, being present, gave information respecting the proposed tower and spire and other matters of detail. It was then unanimously resolved, "That this vestry approves of the resolution of the Restoration Committee to reproduce the existing tower and spire of St. Paul's Church upon the present site." About 300 sittings, besides sittings for children, will be provided. It was also resolved "That the architect's amended plans as sent in for the sanction of the vestry, subject to slight alterations of detail, be carried out;" and "That this vestry empowers the Committee to commence the work as soon as the amount of subscriptions shall, in the judgment of the Committee, warrant them in proceeding."

**Aylesbury.**—A meeting of the subscribers to the voluntary church service fund was recently called by the churchwardens of the parish church of St. Mary, to receive the report of the architect, Mr. Scott, on the state of repair of the exterior, and his opinion as to what was necessary to be done to thoroughly repair and restore it, with the probable cost. After considerable discussion, the following resolution was carried unanimously:—"As it appears to this meeting that the sum of 2,000l. is required to place the whole of the exterior of the parish church in a condition of complete architectural repair, and that of this amount a large proportion is needed for the actual necessary repairs of the fabric, it is desirable to propose to the parishioners in vestry that the sum of 1,000l. be raised on security of the church rates, and that an immediate effort be made to raise the remainder by voluntary contributions."

**Middleton Cheney.**—The parish church has been re-opened, after restoration, from the designs of Mr. G. G. Scott, under whose superintendence the contracting builders, Messrs. Davis, of Banbury, have executed the work. The total cost of the repairs has been about 3,000l., of which sum 150l. were contributed by the authorities of Brasenose College, 600l. by the rector of the parish, and 600l. by a voluntary church-rate, the remainder being made up by contributions from various friends. The roof has been painted by Mr. Cottam, of Banbury; while a memorial window at the east end (the subject being All Saints), erected by Messrs. Morris, Marshall, & Faulkner, of London, in memory of the late Mr. William Croome, completes the ornamental portion of the work.

**Timperley.**—Christ Church, Timperley, has been re-opened upon the completion of the alterations, comprising the additions of transepts,

chancel, vestry, organ-chamber, &c., affording an increase in the accommodation of 300 persons. The new portion to a great extent harmonizes with the old building, except the seats, which are low and open benches in lieu of pews. The organ-chamber adjoins the chancel. The stalls for the choir are in the chancel, which is laid with enriched encaustic tiles. The lighting is by means of coronae, from Skidmore, of Coventry. The windows of the transepts are filled with stained glass by Edmondson & Son, of Manchester. An inclosure-wall of stone has been built to the churchyard. All the works have been carried out under the care of Mr. John Lowe, architect, by Mr. James Lucas, builder, both of Manchester, and involve an outlay of about 1,750l.

#### DISSENTING CHURCH-BUILDING NEWS.

**Weymouth (Dorset).**—Invitations for plans for a new Bethel building were recently issued, a premium of 10l. being offered for the best design. That by Mr. Norman (with Mr. R. Reynolds) has been accepted by the committee. The building, which will be capable of accommodating 250 people, will be in the Italian style of architecture. The chapel, 55 ft. by 27 ft., will face the harbour, and there will be a reading-room at the rear. Bath stone will be used in the building, with brick in the dressings.

**Lythcott Minster (Dorset).**—The foundation stone of a new Wesleyan chapel has been laid at Lythcott Minster. The proposed building will be a Gothic structure 45 ft. long by 32 ft. wide, and it is calculated to hold about 250 persons. It will be of red brick dressed with white stone, and will be lighted by four double windows on each side. The entrance will be by two porches, one at each of the front angles of the building. The architect is Mr. J. B. Cosby, of Stamford; and the builder, Mr. E. Sharland, of Corfe Hills. The site has been given by Miss Rowand.

**Ipswich.**—The new Congregational chapel and school, to be erected at the junction of Crown-street and High-street, will be faced with white bricks and stone dressings, with bands of coloured bricks introduced in string-courses and arches. The south front, towards Crown-street, will consist of a gable end, 50 ft. high, filled with a three-light traceried window of stone, with a deep arch of coloured bricks over it. Below this is an open-arched porch of stone, as the principal entrance leading to the lower story, with entrance to galleries on either side. The south front, towards High-street, consists of five bays, divided by projecting buttresses, each bay filled with a double-light traceried window, the whole height to the roof, and finished at each end with a hipped roof over the staircases, the gable end of the school forming a wing at the north boundary. The roofs are to be covered with slate, with ridges of tile cresting. The interior will have a gallery all round, the pulpit being opposite the entrance, and the organ gallery behind it, with vestry below. The roof will be in three spans, carried on iron columns, the centre span finished with arched ribs of timber, with tie-beams over the side spans, and five arches on each side, longitudinally. The principal timbers will be wrought, stained, and varnished, and the ceilings plastered, and open the whole height to the ridge. The internal dimensions will be 70 ft., extreme length, and 40 ft. wide. The number of sittings will be about 800, including 160 children in the gallery over the entrances. The dimensions of the school will be 60 ft. long, and 22 ft. wide, and it will be lighted with gable windows at each end, 18 ft. high from the floor, and three side windows, the roof being open to the collar-beam. There will be also two class-rooms, each 20 ft. by 10 ft., opening to the school. The contract has been let to Mr. E. Gibbons for 2,040l. The designs were prepared by Mr. F. Barnes, of Ipswich, architect.

**Knutsford.**—The foundation-stone of a new Congregational church and schools has been laid here. The church is designed to accommodate 350 persons, all on the ground-floor. The general arrangement is that of nave and south aisle, with chancel, and north transept for the organ. There are two vestries, one on the north and the other on the south of the chancel. The aisle is separated from the nave by an arcade of stone in four bays. The position of the fifth bay in the north-west angle is occupied by the tower and spire, the height of which will be 100 ft. The principal entrances are through the tower, from which aisles proceed, one 5 ft. 6 in. wide up the centre of the nave, and the other 3 ft. 6 in. wide

along the south wall. There is a second entrance in the north transept. The seats throughout are open benches. The church will be heated by hot water. The style adopted is Early Gothic of the French type. A large four-light window is in the west gable, and a triplet in the east end, surmounted by a wheel window. The clerestory windows are mixed trefoil, quatrefoil, and cinquefoil, in circles. Plate tracery is used throughout. The inside dimensions are,—from the west wall of the nave to the east wall of the chancel, 84 ft.; and the width of nave, 26 ft., and south aisle 12 ft. 6 in. The roof is open, with curved ribs, celled between the spars, and finished with a stencil pattern. The schools consist of infant schools, 24 ft. by 14 ft.; large room, 48 ft. by 24 ft.; and two class-rooms, 15 ft. by 13 ft. each. These are situated at the back of the church, and at a lower level, the whole forming one structure. The walls are of dressed brickwork, relieved by bands of blue Staffordshire brick, and arches of the same. The dressings are of white Alderley stone; the roof covering of tiles. The architect is Mr. J. C. Gilbert, of Nottingham; and the contractor, Mr. J. Paul, of Knaresford.

#### STAINED GLASS.

*Peterborough Cathedral.*—A stained glass window has been erected in this cathedral, the work of Messrs. O'Connor, London. It is a late fifteenth century window, and one of those forming the second range of the three series included in the north windows of the north transept. It is of two lights, with tracery. The subject is "The Last Judgment." In the eastern light is represented at the top Our Lord seated, one hand raised in the act of reprobation, the other bearing the orb. On the same range with this figure, and pointing to the Judge as standing, or, rather, poised in the air, is shown the archangel Michael, who has his sword drawn: he directs groups below, representing the angels of wrath and peace. They fulfil his commands to the elevation of the just and the condemnation of the wicked.

*Gazeley Church.*—A painted window, by Messrs. Lavers & Barrard, has just been fixed at the east end of the south aisle of this church, corresponding to another in the north aisle, presented by the Rev. Thomas Burroughes. The subjects are the "Baptism," "Temptation," and "Agony of Our Lord;" and in the central light below is a representation of Our Lord bearing the Cross, the two side lights containing texts applicable to the subjects.

*Easton Church (Wills).*—The east window, of Gothic architecture, in the Perpendicular style, has been filled with stained glass, executed by Messrs. Lavers & Barrard, in memory of a son of the pastor. The centre compartment represents the Birth of Christ, and the Crucifixion, with the Ascension in the quatrefoil. The side lights have figure subjects; "The Good Samaritan," and "Christ walking on the Water;" the smaller subjects of "Christ healing the Sick," the "Apostles at the beautiful Gate of the Temple;" with Faith, Hope, and Charity in the tracery. A monument in connexion with the same memorial has been designed and executed by Mr. W. T. Hale, of London, and consists of a black marble slab of pyramidal form, upon which is placed a Latin cross in white marble.

*Cardiff Cathedral.*—The memorial window to Dean Rice, in the east cloister of this cathedral, is now uncovered. The artists are Messrs. Clayton & Bell. The general subject is the childhood of the Saviour, the wise men discovering the star in the east, and their appeal to Herod; the presentation of offerings to the babe in the manger; the virgin mother and the reputed father. A star beams upon one group of figures, and a large star shines from the centre light upon all the pictures. Before the festival all the windows in the cloisters will be filled with painted glass.

*Whitley Church.*—Five stained-glass windows have been put up in this church. They are the gift of Mrs. Naper, of Cullercoats, and are dedicated to the memory of various members of her family. The principal figure in four of the windows is that of our Saviour, the chief figure in the fifth window being that of St. Peter. The windows were designed and have been executed by Mr. Barnett, of Newcastle.

*Stilton Church (Teister).*—A design for a memorial window to the late Archbishop Whitley in the parish church of Stilton, has been furnished by Messrs. Cox & Son, of London. It

is intended as an illustration of the text in Revelation, "Blessed are the dead who die in the Lord." The medallions which surround the central figure represent various acts of charity and kindness described in the Bible, and illustrative of the character of the late Archbishop of Dublin.

*Mullingar Church (Westmeath).*—A new stained-glass memorial window has been put up in this church. The artists were Messrs. O'Connor. The window consists of seven lights in three tiers, and the glass is graduated in colouring from the outside to the centre light. It has been erected at an expense of about 120*l.*, by the parishioners and others, in memory of the late vicar, the Rev. John Hopkins.

*Gloucester Cathedral.*—We are requested to say, the window recently erected here to Dean Rice, was executed by Messrs. Hardman & Co., and not by the artists named last week.

#### NEW THEATRES.

*South Shields.*—The proposal for a new theatre at South Shields has now assumed a tangible form, and a design has been chosen. A short time since the directors advertised, offering a premium of 25*l.* for the best design, which invitation was responded to by eight architects, viz.—Mr. T. M. Clemence, borough surveyor, South Shields; Mr. Thomas Oliver, Mr. Snaith, and Mr. Lambton, of Newcastle; Mr. Moore, of Sunderland; Mr. C. J. Phipps, of London; and two others under assumed mottoes. The directors, after considering all the designs, were of opinion that the plans and general arrangements, both before and behind the scenes, and the decorations of Mr. Phipps, were the best, while the elevation and frontage of the theatre and the shops in Mr. Clemence's design were preferred; and, after an interview with each of these gentlemen, it was unanimously decided to appoint Mr. Phipps and Mr. Clemence joint architects to carry out the work. The necessary plans are to be at once prepared, and the building commenced, so that it can be opened before the close of the present year. Mr. Phipps is at present engaged in the erection of a large theatre at Nottingham. The South Shields Theatre will accommodate 250 in the boxes, 500 in the pit, and 800 in the gallery.

*Hull.*—Last week, the foundation-stone of a new theatre was laid at Hull, on the site of the late Theatre Royal, which was destroyed by fire on the 13th of October, 1859. The stone was laid by Lord Londesborough. After the ceremony, his lordship addressed the company assembled, expressing the pleasure he felt in laying the foundation-stone of a building which would be a fitting addition to the many fine buildings in Hull. He had heard people sneer at the truisms enunciated in plays, and at the enthusiastic applause which good sentiments received, even from the galleries; but he thought that such influences could not be without good effect, and that the legitimate drama must have a tendency to elevate and purify the tastes of the people. The new theatre will be in the Italian style of architecture; the block of buildings to be 146 ft. by 72 ft. It will be approached by five distinct entrances, thus affording ample means of ingress and egress. The design is by Mr. R. J. Smith, of Hull.

#### RAILWAY MATTERS.

It is understood that, according to a report just adopted by the General Managers of the Railway Clearing-house, the committee have inspected and considered 196 inventions submitted to them for communication between the passengers and guards of trains; but the result has been merely to confirm the views expressed in the report adopted twelve years ago, to the effect that none of the plans suggested could be justifiably recommended. They "think it desirable, if practicable, to give passengers by express or other trains, running for considerable distance without stopping, the means of attracting the attention of the guard, and enabling him to stop the train at the next station, or under the protection of the next fixed signals;" and that with that view some of the most promising of the offered inventions should be further tested; but, before putting this into operation, they would insist upon Parliament passing penal laws to keep the wilful or over-timid public in order. As we have often said, the formation of a watch-

man's beat, either through the carriages or alongside of them, would do away with all difficulty, and nothing short of that will do; because, even were there the best possible means of calling the attention of the guard, how is he to know what is wanted, or whether there really be any necessity for stopping the engine and so plunging into new dangers, unless he can traverse the train, and see and hear for himself, and become assured that the call was not made by some practical joker or some nervous or foolish person of either sex?—The traffic receipts of the United Kingdom amounted, for the week ending the 15th of April, on 11,841 miles, to 659,958*l.*, and for the corresponding week of last year, on 11,490 miles, to 603,882*l.*, showing an increase of 351 miles, and of 56,076*l.*—An American paper states that a contract has been made with influential Germans, to bring from Germany 2,000 men, who will each take a tract of the Kickapoo Railroad lands, in Kansas, and work out its value on the railroad.—*Railway Companies and their Contractors.*—Although the engineer may, in directing certain works, exceed his power and authority, the company, by permitting the works to be proceeded with, and afterwards taking the benefit of them, is precluded from raising the question as to the propriety of them, and the powers of their officer to order them to be done. This was the holding of the Lords Justices in the case of Hill v. The South Staffordshire Railway Company, upon a bill filed by parties who had contracted with the company to construct part of their railway, seven miles in length, between Walsall and Dudley.

#### Books Received.

*Art applied to Industry.* A Series of Lectures by WILLIAM BURGESS, F.R.I.B.A. Oxford and London: J. H. & Jas. Parker.

THESE lectures, originally delivered by Mr. Burgess, at the Society of Arts, under the terms of the Cantor bequest, have been already published in the *Gentleman's Magazine*, and were referred to in our pages on various occasions. It will suffice, therefore, to mention their appearance as a whole, in a compact little volume, together with two other papers read, one at the Architectural Association, the other at the Architectural Museum.

*Handbook of the Steam-Engine.* Illustrated. By JOHN BOURNE, C.E. London: Longman & Co. 1865.

THIS Handbook is designed to constitute a Key to the author's "Catechism of the Steam-Engine," and a more elementary but not less practical treatise than his quarto on the Steam-Engine, already favourably noticed in our columns. The present work, according to the author, contains all the rules required for the right construction and management of engines of every class, with the easy arithmetical solution of those rules. It is illustrated by numerous tables and examples, also by sixty-seven woodcuts, and is altogether recommendable.

#### VARIORUM.

"THE Alternating System" is a sort of prospectus containing "a brief account of Mr. Bardwell's 'Improved method of utilizing sewage and urine, and for facilitating their passage through the pipes, to prevent the pollution of rivers and streams,' in accordance with his last patent, obtained for that purpose." A financial company, it states, is in course of formation in order to carry out the patent, which relates to the making of a dry manure of sewage deposit by means of sulphate of lime, to the production of sulphate of ammonia and carbonate of lime, while the purified liquor only is sent through mains and pipes alternately with sewage from the outfall, so keeping the way clear and clean. The necessity or advantage of having dry manure for certain crops such as wheat is urged in favour of this method.—*The Quarterly Review*, for April (Murray, Albemarle-street), contains a leading paper on the Galleries of the Louvre; another on Education in France; one on our Guns and Ships; and various others on more or less interesting subjects.—A Report of Proceedings at the Twelfth Anniversary Dinner of the London Association of Foremen Engineers, held at the Bridge House Hotel, London Bridge, on the 18th February last, has

been printed by King & Co., Queen-street, E.C.—“The Mule Spinning Process, and the Machinery employed in it described. By Kurt Neste. Heywood, Manchester, 1865.” This is a practical treatise on a curious and interesting subject, illustrated by eleven engraved plates of the mule spinning machinery used for “middle fine numbers.”

### Miscellaneous.

TEXIER & PULLAN'S “BYZANTINE ARCHITECTURE.”—The Empress of Russia has been pleased to signify her approbation of this book by sending Mr. Texier a diamond ring.

ARCHITECTURAL ASSOCIATION.—The Voluntary Examination Class will meet on Monday evening, May 1st, at eight o'clock. Subject, “Geometrical Drawing,” by Mr. Lacy W. Ridge.

LIVERPOOL ARCHITECTURAL SOCIETY.—At the last meeting of this Society, Mr. Joseph Boulton, presiding, mentioned with regret the death of Mr. Justin, one of their most active young members. Mr. H. P. Home read a paper on “Some Essentials of Architectural Art.”

THE LATE MR. STEPHEN BIRD.—Many of our London readers will hear with regret that Mr. Stephen Bird died on the 24th inst., at his residence in Kensington. Mr. Bird, who was nearly 85 years old, was successfully engaged for many years as a builder, and was well-known for his integrity and good sense.

SOCIETY FOR PROMOTING THE BUILDING OF SUBURBAN VILLAGES.—A prospectus has been issued preparatory to forming a Society to promote the building of suburban villages for the mechanics of the metropolis. Under the head of Council, it has the names of the Hon. W. Cowper, Mr. H. Pownall, Mr. T. Twining, Mr. H. A. Hunt, and Lieut.-col. Murray.

LONDON MEAT AND POULTRY MARKET COMPETITION.—In pursuance of a reference made to them in the Court of Common Council, the Markets Improvement Committee have reconsidered the designs sent in for the construction of the Meat and Poultry Market in Smithfield, and have resolved to recommend that plan No. 1, motto, “A Key,” should receive the first prize of 300*l.*; and that plan No. 3, motto “Citizen Stationer,” should receive the second prize of 200*l.*

SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.—This Society held its fourth conversation of the season at the Gallery of the Society of British Artists, in Suffolk-street, Pall-mall. The company was very numerous, and the rooms were brilliantly lighted, and hung with the pictures forming the exhibition of the year. On this occasion the silver medals awarded last year were presented by Mr. Percy Doyle, C.B., who presided in the unavoidable absence, through indisposition, of the president, Viscount Stratford de Redcliffe. The musical arrangements formed an agreeable feature of the *réunion*.

THE DÜPPEL MONUMENT AT BERLIN.—The ceremony of laying the first stone of the monument intended to commemorate the capture of the Danish entrenchments at Düppel took place on the first anniversary of the exploit. For some days a large square had been set apart in the centre of the Königsplatz, outside the Brandenburg gate of Berlin, between the Raczyński Palace and Kroll's concert-room, decorated with numerous masts and poles, bearing German flags. In this space, forming the site of the new monument, the first stone was laid. The king and the members of the royal family viewed the ceremony.

STRANGE VICISSITUDES IN ZION CHAPEL.—The chapel, long known to the religious world as Zion Chapel, was originally used as the place of worship for Lady Huntingdon's connexion. It was in this chapel that Irving poured forth his fervid and confused utterances; and it was here that Pugin, as a youth, was tortured, as he himself feelingly describes, not so much by the ravings of Irving as by the sight of the hideous building he was so often doomed to pass his Sunday mornings in; and now, this very Zion Chapel, once the head-quarters of Dissent, is devoted to the purposes of Roman Catholic worship, and its grotesque architecture which so afflicted the elder Pugin is being completely refashioned by his son, Mr. E. Welby Pugin.

THE MUNICIPAL SYSTEM IN TURKEY.—Local self-government is being introduced into Turkey, which will henceforth have its vestries and town councils like other civilized nations, instead of having all its affairs administered from Constantinople.

SANITARY STATE OF CORK.—A commission appointed to inquire into the sanitary condition of Cork, gives a fearful account of the state of the city. Scarcely any of the humble class of dwellings contain requisite sanitary accommodation, and the sewers are either defectively constructed or altogether absent. Many of the poorer houses are let to seven or eight families, so that the unhealthy overcrowding of these dwellings, aided by the disgusting state of the streets, conduce in the highest degree to the spread of fever and sickness.

SOUTH STAFFORDSHIRE BRICKYARDS.—Mr. Baker, inspector of factories, gives, in his report, just issued, a sketch of workers in the fire-brick yards of South Staffordshire, having been induced to visit brickyards in various parts of the kingdom last year, under the impression that they were included in the Factories Act Extension Bill of last session. In South Staffordshire, where the males are attracted to the ironworks, he found children of very early years and young girls in the clay yards, brought up amid excessive labour and scenes most demoralising.

ACCIDENT AT THE DRIBBICH WATERWORKS.—In the summer of last year the reservoir of the Dribbich Waterworks was completed, but on its being filled a leakage was discovered, and the only way that suggested itself to the contractor to stop the leakage was to dig a deep trench and fill it with puddle. Workmen had been engaged on this work during the winter, and a trench of about 50 ft. deep, 3 yards wide, and about 50 yards in length, has been dug on the north side of the reservoir. The siding of the trench, which is quicksand, recently gave way and buried and killed three men who were at work.

PERILS OF THE STREETS OF LONDON.—The *Telegraph* informs us that, having carefully prepared a census of persons killed in the thoroughfares of London, it has ascertained that the probable amount annually is some 252 persons. On the British railways the average is twenty annually. Comparing the 200,000,000 to 300,000,000 of passengers conveyed by the rail some 70,000,000 of miles yearly with the casualties of the London streets, the result is that the chances of death to the London pedestrian are as 100 to 1 compared with the railway traveller. Safe crossings are sadly wanted.

ST. JOHN'S HOSPITAL FOR SKIN DISEASES.—On Saturday last, the Rev. Alex. J. D. D'Orsey lectured at Willis's Rooms for the benefit of this institution. The lecture was on the English language. Having traced the two great branches of English, the Anglo-Saxon and Norman-French, to their sources, and shown how they formed and rolled together, like two powerful streams, the lecturer proceeded to ask what we are doing to preserve the noble heritage of language which had come down to us as a sacred trust from our ancestors; and dwell with keen irony upon the wretched mistakes in grammar and the use of the accent, made daily by men who ought to know better.

THE HOLBORN VALLEY IMPROVEMENTS.—On the 25th, the first case in connexion with the operation of the Holborn Valley Improvement Act came under consideration at the Lord Mayor's Court, before the Recorder and a special jury, “Seewright v. The Corporation of London.” It was brought to ascertain the value of some freehold premises, No. 5, Farringdon-street, required for the Holborn Valley improvements. Mr. Bovill, Q.C., and Mr. Murphy were for the claimant; and Mr. Hawkins, Q.C., Mr. Chambers, Q.C., and the Hon. Mr. Thesiger for the Corporation of London. The claim made was £172*l.*, and evidence as to the real value of the property was given on both sides. After a long investigation, the learned Recorder submitted the case to the jury, who returned a verdict for 3,830*l.* A special jury was also sworn in another compensation case arising out of the “improvements” referred to, viz., “Hearder v. The City of London,” in respect to premises on Snow-hill. The jury went to view the property, and the hearing was appointed for Thursday week. Mr. Coleridge, Q.C., and Mr. Hawkins, Q.C., are engaged in the case. The works so long contemplated for the improvement of Holborn Valley are at length about to be commenced.

THE IRON TRADE STRIKE AND LOCK-OUT.—The termination of the strike in N. Staffordshire seems to be as remote as ever. The masters have reopened their works, but refuse to return to the old rate of wages. The puddlers, consequently, are now turning their attention to emigration, and the Brierley Hill executive of the union has placed at their disposal for that purpose 2,000*l.* Besides this sum, the ironworkers in South Staffordshire who are now at work have agreed to a levy of 5*s.* a week to enable the emigration of North Staffordshire puddlers to go on. Over 300 have applied to be sent out. All the ironworks in North Staffordshire are in operation, but the puddling furnaces are chiefly worked by underhands, under the supervision of the managers. The lock-out in Scotland has terminated, the reduction of wages to be about 4*s.* a week, instead of 8*s.*

THE IRON TRADE.—Ryland's Circular quote; prices as follows, at Wolverhampton and Birmingham:—Puddled steel, 12*l.* 10*s.* per tons cast steel block (raw), 1*l.* 6*s.* per cwt.; cast hammered, 1*l.* 14*s.* per cwt., f.o.b., Hull; marked bars, 8*l.* 10*s.*; sheets, singles, 10*l.*; doubles, 11*l.* 10*s.*; lattens, 13*l.*; angles 8*l.* 5*s.* to 9*l.*; gas strips, 8*l.* to 8*l.* 10*s.*; puddled bars, 5*l.* 10*s.* to 6*l.* 5*s.*; scrap bars, 6*l.* 10*s.* to 7*l.*, according to quality. North Staffordshire.—Bars, 7*l.* 10*s.*, best, 8*l.*, best best, 8*l.* 10*s.*; best angle iron, 8*l.* 10*s.*; best T iron, 9*l.*; bridge and tram rails, 7*l.* 15*s.*; best plates, 9*l.* 10*s.* Puddled bars, 5*l.* 10*s.* to 6*l.*, delivered at Manchester, Liverpool, or this district. Welsh bars, 6*l.* 15*s.*; Welsh rails, 6*l.* 15*s.* to 7*l.* 2*s.* 6*d.*; Welsh puddled bars, 5*l.* 10*s.*, delivered to stations in this district. These prices are quoted as “at Works.”

THE OIL REGION OF NORTHERN PENNSYLVANIA.—A correspondent of the *Morning Star* says:—Men are boring several hundred feet into the earth in this region, and striking on a vein of this oil. In many instances the paraffin flows out 30, 40, 50, 100, 700, 2,000 barrels a day. Men almost beggars have been lifted into fortunes, in a few weeks, of from 20,000*l.* to a quarter of a million of money. This is no exaggeration. The mighty drill worked by steam power is tapping the earth in every direction. The vein is struck: out come first gas, then water, then the oil, in some cases spouting 70 ft. high. It is calculated that these oil-wells are producing four millions sterling a year, and still they are increasing. For fifty miles round and more the country everywhere smells of paraffin. One jot of the oil came with such force and in such quantities that it formed a river, took fire, and set the country in a blaze.

BEAUMONT'S TUNNEL DRIVING MACHINE.—An interesting experiment is now being tried at the seat of Mr. W. B. Beaumont, Upper Wood Hall, Barnsley, near to the South Yorkshire line of railway. The machine patented by Capt. Beaumont, of the Engineers, for driving tunnels in stone by machinery is the invention under trial. The result is said to have been that two yards may be regularly driven in eight hours. A series of cutters or jumpers are arranged around the periphery of a strong iron wheel or bore-head, which latter is also armed in its centre with a single tool. The system is set in motion by steam or compressed air, acting through the medium of a piston and cylinder, with its necessary accessories of valves, &c.; giving a series of heavy blows, while at the same time the bore head rotates slowly on its axis, thus cutting a continuous chise or groove, which isolates a cheso-shaped mass or rock. The centre tool or jumper has meanwhile cut a central hole capable of containing a sufficient amount of powder to shatter the rock thus left free to receive the full force of the explosion. The diameter of the tunnel now being cut is 5 ft. 2 in.

GAS.—The directors of the Arundel Gas Company have reduced the price of gas from 6*s.* 6*d.* to 6*s.* per 1,000 ft.; the Framlingham Gaslight Company's directors from 6*s.* 8*d.* to 6*s.* 3*d.*; and the directors of the Wigan Gas Company, from 3*s.* 9*d.* to 3*s.* 9*d.* to small consumers, and from 3*s.* 9*d.* to 3*s.* 4*d.* to large consumers; in the country district, the present prices are 5*s.* 6*d.* and 5*s.*, and these will be lowered to 5*s.* and 4*s.* 6*d.*—The recent lighting by gas of the farm buildings lately constructed near Blennerhasset, the property of Mr. William Lawson, says the *Carlisle Journal*, may furnish an excellent example of the improvements that may be effected with a view to economy in agriculture. The new apparatus is that produced by Messrs. Haughton & Thompson, of Carlisle.

**COPPER.**—There has been very little business done in the copper market during the past week, according to *Ryland's Circular*. Smelters quote:—Tough, 98l. per ton; best selected, 96l. per ton; manufactured, 100l. per ton. But where sales have been made, a decline from these rates is submitted to. Compared with the previous week's sale, the advance has been in the standard 1l., and in the price per ton of ore, about 1s. 2d. Compared with the corresponding sale of last month, the decline has been in the standard 5l., and in the price per ton of ore, about 6s.

**THE CASUAL POOR OF THE METROPOLIS.**—It is satisfactory to notice that, in various ways, the managers of the metropolitan parishes are endeavouring, by means of statistics, and by the arrangement of maps, which well define the parochial and clerical divisions, to lay before the public at large, much useful and interesting information. For instance, here we have a return by Mr. Douglas, the master of the Marylebone workhouse, of the places of residence of 4,325 casual poor who have been admitted into that establishment for a night's lodging. The figures show from what varied directions the veriest poor find their way to the metropolis. A similar return for the same period as that during which the 4,000 and upwards of applications were made to Marylebone from the other casual wards would add much to the value of Mr. Douglas's report. The small number of foreigners who have been obliged to apply for parish relief in this temporary way seems remarkable. The natives of France were only 4; Germany, 28; and America 29,—in all, 61. The applicants belonging to England were 3,129; Ireland, 984; Scotland, 103; Wales, 46; The Channel Islands, 10.

**CANNE COAL.**—About a century ago, the Duke of Bridgewater was the proprietor of a large estate situated at Worsley. This estate contained valuable coal seams, easily to be got at, but nevertheless comparatively worthless, in consequence of the great expence and difficulty of transporting the coal to market. Under the duke's directions, Brindley constructed a profit-paying canal between Liverpool, Manchester, Worsley, and the Great Wigan district. This canal appears to have been finished about the year 1766, and store-houses were built at various points in its course, where the duke's coal was deposited, for the purpose of supplying the immediate neighbourhood. At this time, says *Newton's Journal of Arts*, the word "kennel," or "kannel," was generally employed in Lancashire and Cheshire to designate an artificial water-course; and even Brindley himself, in some of his letters, speaks of the new undertaking as "the duke's kennel." It is not therefore surprising that the duke's coal should have received the name of "kennel coal," being, so to say, kennel borne; and this name would be peculiarly applicable at Liverpool, where sea-borne coal from Whitehaven, in Cumberland, had long been in use, and was, moreover, an article differing in many of its qualities from the duke's coal.

**USE OF WASTE HEAT IN KILNS.**—A Northfleet correspondent, "W. May, jun.," who appears to be a practical man, though not an available writer, addresses us on this subject. He speaks of the gases arising from Portland cement, and says that while it is burning in the kilns a great heat is obtained by consuming the gases, and then passing the same under a drying floor. When alight, the gases are like a rolling sea of fire, and this will travel a great distance before it requires a chimney-shaft;—that is to say, if the flues are in a straight line, the heat from the gas will dry well for a distance of 120 ft. in length and 60 ft. in width. The kilns he speaks of hold, when burnt, 150 casks. There is a greater improvement, however, which, our correspondent suggests, could be made: first, to let the heat work another set of flues while the men are taking off the stuff; and as soon as they have it off they could shut off another bay; or they might shut off nineteen flues out of twenty, and let the heat work up the one, which would be much better for men working on these hot flues. Secondly, by having a coke oven beside the furnace the gas from this would pass through the coke fire, and the coke from the oven would supply the furnace and much more heat. This plan of furnace could consume but a small quantity of coke, and could be applied to any kind of works for drying, and for material of any description; and if properly constructed would, he thinks, be preferable to any other.

**BRADFORD.**—The foundation stone of a Working Men's Teetotal Hall has been laid on vacant ground near the top of Bower-street. The building is to be erected from the designs of Mr. John Siddards, and will comprise three lock-up shops, two dwelling-houses, and a lecture-hall and vestry. The lecture-hall will be constructed over the shops and dwellings, and its size will be 18 yards by 12 yards. The price of the site, including paving and drainage, is 192l. The contracts amount to 910l.

**QUEEN ELIZABETH'S SCHOOL, IPSWICH.**—The school chapel has been lately beautified by the erection of a painted-glass memorial window, at the east end, by Messrs. O'Connor. It exhibits in the main lights groups of the six acts of mercy, upon a back-ground of the vine. In the upper part of the central light the lamb is represented, and in that of the side lights adoring angels. The tracery is filled with figures of the Four Evangelists, together with emblematic representations of the cardinal virtues—Fortitude, Prudence, Justice, and Temperance. The window is erected by subscription of the masters, and former pupils, and other friends of the school, to the memory of two pupils.

**READING.**—The foundation stone of new almshouses has been laid here. The buildings will accommodate twenty-eight persons. The houses will be in two continuous rows on either side of a central roadway, about 35 ft. wide, running from Castle-street to the Holy Brook. The houses are to be in blocks of four, half being on the ground story, and half on the floor above, with a central hall to each block, in which will be the staircase to the upper houses. Each house will have a living-room about 15 ft. by 10 ft.; bedroom, 13 ft. by 9 ft.; pantry, lobby with sink, water-closet, a small yard, and a coal cellar. The walls are to be of red brick, with grey bands, and stone dressings to the windows and doors. The design has been prepared by Mr. W. H. Woodman, the architect appointed by the charity trustees, and the builder is Mr. Sawyer, of London, who has undertaken the execution of the work for 3,450l.

**NEWCASTLE-UPON-TYNE.**—The foundation stone of a Mechanics' Institute for Newcastle, has been laid by Sir George Grey. The new building, which has been designed by Mr. Thomas Oliver, architect, stands on a piece of ground in New Bridge-street, lying between the Weaver's Tower and the Church of the Divine Unity. The style is Italian. The interior will consist of six large sized class-rooms, a library, a lecture-room, a news-room, a "smoke" room, and an extensive corridor leading from the entrance to the grand staircase. The lecture-hall, which is situated on the ground-floor, is semicircular in form and will measure on an average 35 ft. by 58 ft. On the second floor is the news-room, 32 ft. by 24 ft. Situated at the back, and immediately above the lecture-hall, and the same size, will be the library. The estimated cost of the whole work is 3,000l.

**COITAGES OF THE AGRICULTURAL POOR.**—A report by Dr. H. J. Hunter, on the state of the dwellings of rural labourers in different parts of England, made to the medical department of the Privy Council, contains much valuable and interesting information on the subject. Dr. Hunter pursued his inquiry during the summer of 1864, and examined, in different counties in England, as many as 5,375 occupied houses. To the insufficient quantity and miserable quality of this accommodation, almost every page of Dr. Hunter's report bears testimony; and the evil, especially within the last twenty or thirty years, has been very rapidly increasing. Dr. Hunter describes great owners as escaping from poor-rates, through the intentional depopulation of lands over which they have control, the nearest town or open village already crowded receiving the evicted labourers. Among the exceptions to this kind of relation between the large landowner and the labouring population are mentioned the properties of the Dukes of Bedford, Rutland, and Newcastle, and of the Marquis of Exeter. While our poor-law, however, continues unaltered in its provisions concerning settlement and chargeability, such instances must tend to become still rarer and more exceptional; "for, practically, any future may be foretold from the known interests of those who can control it; and it would be too much to expect that landowners, as a class, should be the voluntary bearers of a taxation while the law leaves it optional with them to escape."

**LYTHAM, LIVERPOOL.**—The new pier at Lytham, the construction of which was commenced last year, has been formerly opened. It is 914 ft. long, and is similar to that at Blackpool.

**NEW R.C. SCHOOL, AT ELSECAR, NEAR BARNESLEY.**—On Easter Monday, the corner-stone of a new school, to be built here, was laid by Mr. William Locke, of Manchester, brother of the engineer, Joseph Locke, and father of the pastor of the place, the Rev. C. J. Locke. The building will be 75 ft. long and 25 ft. wide, built entirely of stone. Style, First Pointed. The roof has framed braced timbers; and the plan includes class-rooms, porch, &c. The architects are Messrs. M. E. Hadfield & Son, of Sheffield; and the contractor is Mr. Hartland, of Elsecar. The site, three acres in extent, is laid out for a church of size and style suitable to the rapidly-increasing requirements of the great Yorkshire coal and iron district in which it is situated, with presbytery and convent, the whole of which will doubtless ere long be completed.

**TENDERS**

For Working Men's Hall, Stratford, Essex:—

Cardoyer	51,834 10 6
Pikington	1,638 7 0
Chiffins	1,687 0 0
Emery & Co.	1,645 0 0

# The Builder.

VOL. XXIII.—No. 1161.

*Ely Cathedral: the Paintings on the Roof of the Nave.*

THE Cathedral of Ely, commenced in 1082, and carried on, century after century, up to the middle of the sixteenth century, has been the object of care for some years past, as most of our readers know, and is now in

such a state as to make a visit to it a pleasure of no common kind.

The most recently-completed work there is the painting of the roof of the nave, commenced by Mr. Le Strange, and carried out by Mr. Gambier Parry; and our present purpose is to give an account of this remarkable undertaking, with an engraved view of the ceiling.\* Before doing so, we must say a few words of the cathedral itself, and of other works done there; reminding our readers, by the way, of the beautiful series the building presents in respect of styles. Thus we have in the lower part of the transepts, if not elsewhere, eleventh-century Norman, and a grand nave and west front of twelfth-century Norman. The great porch, or "Galilee," at the west end (before 1215), and the extreme east end of the building (say 1240), are exquisite examples of Early English: the choir, and what is called the Lady Chapel, both belonging to the first half of the fourteenth century, are not anywhere surpassed as specimens of Decorated; while Alcock's Chapel and West's Chapel, at the eastern end of the choir aisles, are characteristic specimens of fifteenth and sixteenth century work, when Renaissance details were being mixed up with the Gothic forms. Add to this the unique and beautiful arrangement by Alan de Walsingham, of the "Octagon" (where the transept crosses), with its wooden lantern; the widely-known "Prior's Door,"—an elaborate piece of Norman carving; an early Norman monumental slab, displaying, under an arch surmounted by a mass of buildings, an angel protecting apparently, in the form of a small figure, the son of a bishop; and some of the best modern work of Mediaeval character that we can yet show; and some idea may be gained of the numerous attractions offered by Ely Cathedral.

The restoration of the central Octagon and lantern was undertaken, it will be remembered, as a memorial of Dean Peacock, who did much for the building. As the present Dean, Goodwin, says in a statement recently issued by him, it is not generally understood that the Ely lantern is a wooden structure, suspended with skill upon the walls of a stone Octagon, which encloses the central area of the Cathedral. This central stone Octagon was built, and the wooden lantern erected upon it, in the middle of the fourteenth century, on occasion of the fall of the original central Norman tower. Alan de Walsingham,

the then sacrist of the monastery, evidently a man of remarkable genius, seized upon the misfortune which had happened to the church in the fall of its central tower to give the building a new and original feature of its own. He cut away the four piers upon which the Norman tower had stood; and so, by taking one arch from the nave and one from the choir, one from the north and one from the south transept, he gained a central octagonal space; the octagon, however, not being regular, but having four long sides and four short ones. Upon this octagonal space he built a stone octagon, having four noble arches for the four long sides, spanning the nave, choir, and two transepts, and four small arches, with windows above them, for the four short sides. Upon this stone Octagon he suspended, by a system of beam-work, his wooden lantern-tower. The lantern is a regular octagon, the angles of which correspond to the middle points of the sides of the irregular stone octagon below; the beam-work being concealed from view by a system of boarded groining. The lantern-tower also served the purpose of a boll-tower: indeed, it is described in the sacrist rolls as *Novum Campanile*. The bell-chamber constitutes the upper portion of the tower, and originally contained four bells. The work which has been in hand for the last two years is the restoration of this wooden lantern-tower, or *Campanile*. The windows, which had been reduced by Essex to little more than half their original size, have been restored, and their heads filled with rich tracery, designed by Mr. Scott in accordance with the slight indications which could be discovered of Alan de Walsingham's work. Five of the eight windows are already glazed, and the other three are in progress.

Externally, the whole of the lantern is covered with lead, and displays some good work in that material, for which we must give praise to Mr. Hall, of London. The woodwork was executed by Mr. Freeman, of Ely. The wooden vaulting of the Octagon calls for attention; and externally the stone work of the Octagon requires completion, including a number of pinnacles which would surround the foot of the lantern and join one to another. At present the great difference in the size of the lantern and the Octagon, and the violent contrast of the forms, produce an ugly appearance. The work here simply waits for funds, and ought not to wait long.

Entering at the west porch of this, the longest cathedral in Europe, the view seen, especially if at early morning, is one not likely to be forgotten. Well-known words come into the mind to give utterance to the impression:—

"What awful perspective! While from our sight  
With gradual stealth the lateral windows hide  
Their portature; the stone-work glimmers, dyed  
In the soft chequerings of a sleepy light."

The chancel screen, of oak, beautifully designed by Mr. Scott, and executed by Mr. Rattee, of Cambridge, who has done much of the work here,—Mr. J. Philip carving the figures in the screen, as well as in the stalls and the reredos,—does not interfere with the view. The reredos, of alabaster, inlaid in parts with agates and crystals, full of sculpture, and touched here and there with gold and colours, is a most successful and lovely work, and does honour to all concerned. It is not at all discredited by Miss Blencowe's finely-worked altar-cloth, Marbles and tiles cover the chancel floor and steps; carved panels fill many of the spaces below the canopies of the stalls; and stained glass fills most of the windows. The carved panels are being proceeded with gradually, and put up when finished: thirty-four of them are there, and with the exception of one, are the work of M. Aheloo, of Louvain. They are wanting in expression, and in other respects are less satisfactory than we had expected to find them. They are mostly the gift of individuals: the subjects run thus on the south side:—1.

"Adam and Eve in Paradiso." 2. "Fall of Man." 3. "Expulsion from Paradiso." 4. "Adam and Eve at work." 5. "Cain killing Abel." 6. "Noah building the Ark." 7. "The Deluge." 8. "Sacrifice of Noah." 9. "Promise to Abraham." 10. "Isaac carrying the wood." 11. "The Sacrifice of Isaac." 12. "Isaac blessing Jacob." 13. "Jacob's Dream." 14. "The Burning Bush." And, 20. "David anointed by Samuel."

On the north side we get,—1. "Nativity." 2. "Presentation in the Temple." 3. "Adoration of Magi." 4. "Murder of Innocents." 5. "Flight into Egypt." 6. "Our Lord disputing with the Doctors." 7. "The Baptism." 8. "The Temptation." 9. "The Miracle at Cana in Galilee." 10. "The Transfiguration." 11. "Mary anointing the Lord's Feet." 12. "The Betrayal." 13. "Our Lord before Caiaphas." 14. "Our Lord blindfold." 19. "The Entombment." 20. "The Resurrection." 21. "Our Lord at Emmans." 22. "The Incredulity of St. Thomas." And, 23. "The Ascension."

The effect of the choir as a whole is truly glorious,—nothing short of it.

Hastening on, let us briefly mention what are the chief works of necessary restoration or improvement now needed, in the hope that by chance the remark may lead to assistance.

1. The stonework of the octagon, as before described. 2. The repaving of the nave, towards which the sum of 500l. has been left by the late bishop, and which would probably require 1,500l. more. 3. The restoration of the Galilee. This beautiful specimen of Early English requires a good deal of attention in the way of restoring Purbeck marble columns, and other matters, which it is not necessary to specify. And, 4. The warming of the cathedral. The problem of warming large buildings appears to be now better understood than formerly; and there seems to be no reason why the warming of Ely Cathedral should not be effected. Certainly, if warmed, its utility would be much increased. If the four not very gigantic works above specified were carried out, the restoration, and more than restoration, of Ely Cathedral might be said to be effected. Nevertheless, as the Dean writes, there would still remain one work necessary for the perfection of the building—the re-erection of the north-west transept. The absence of this member is an unspeakable eyesore to a spectator at the west or north side of the church: not only is its presence necessary to complete the grand western façade, and to give the tower its due effect, but its absence gives a general character of ruin to the whole of the building. The re-erection of this transept, however, is so great an undertaking, and must so obviously yield precedence to all other works of restoration and improvement, that he has never yet seriously contemplated it. The time, however, may come.

We must now return to our more particular object, a description of the paintings on the roof of the nave, and this will be best done by Mr. Gambier Parry himself, who thus writes to us:—

At your request I send the following description of the paintings on the ceiling of the nave of Ely Cathedral. I leave, of course, all expression of censure or approval to yourself. The westernmost half of that painting was the work of my friend, Mr. Henry Styleman le Strange, of Hunstanton, in the county of Norfolk. He interrupted his great undertaking at the close of the year 1861, to work upon cartoons for wall paintings, proposed to be executed at the east end of St. Alban's Church, Holborn. Before these cartoons were finished he died.

The Dean and Chapter of Ely being anxious to have their nave ceiling completed, applied to me to paint the easternmost half of it. It was at the end of 1862 that they did so. My friendship with Mr. Le Strange had dated from early days at Eton. Our tastes, pursuits, and opinions,

\* See p. 315.

had been much the same through life. I could have undertaken such a work as was then proposed to me, only out of regard to his memory, and our very old friendship. I have now completed it, as a memorial to him. It was finished at Christmas, 1864.

If I could have supposed that by undertaking it I should have stood at all in the way of professional artists, I should have declined it; but its conditions placed it out of the reach of at least most professional men. The style was unavoidably peculiar, understood or cared for by very few. The dimensions of the work were very great, and any payment for it impossible. Under any circumstances it must have been done for love and not for money. Mr. Le Strange had desired to harmonise his work with the architecture, and had therefore followed rigidly a peculiar form of Norman art of about the date 1180. In the papers he has left, he says that by the ceiling of the western tower (115 ft. from the pavement) was completed by him in twelve weeks, in 1855. In the following year he began the cartoons for the nave. His actual work of painting upon the nave ceiling was spread over three years. It was greatly retarded by the residence of his family on the Continent. His first scheme was a simple one. He proposed to divide the ceiling into bays corresponding with the arches beneath, and to cover them with paintings expressive of Our Blessed Lord's connexion with mankind. He began this series with Our Lord as the "Word," the Creator, and intended, after two, or at most three subjects, such as "The Fall," "The Sacrifice of Isaac," or the reconcentric figure of "Jesse" over all the rest, only in the last bay to have painted a "Majesty," marking the Manhood by the quotation written round it, "I am the root and the offspring of David, and the bright and morning star." But his scheme expanded as he went on. He disregarded his first idea of it, and at his death he left one-half of that ceiling covered with sacred subjects. The arrangement of subjects kindred to these in one of the painted windows of Chartres Cathedral, had suggested to him the general laying out of his work. The early paintings at Hildesheim had suggested to him the method of connecting the genealogy of our Lord (as detailed in St. Luke's Gospel), with the rest of the work; and MSS. of the twelfth century, especially a psalter in the British Museum (in "Nero, c. iv."), gave him the characteristics of the art contemporary with the architecture of the cathedral. The six westernmost bays are his work; the six easternmost are mine. The scheme is this—to illustrate one great subject in his spiritual and human aspects, which cannot be better described than in the words of the Dean of Ely, as "an epitome of the sacred history of man."

It was natural that an amateur, a country gentleman of large property, with other multifarious demands on his time and attention, both public and private, should have hesitated to cover so vast a surface as the covered ceiling of a nave, 200 ft. long, with elaborate sacred subjects. He had, however, developed his first more simple scheme, and had carried a series of subjects through the first six bays. He proposed, after them, to have made the rest an easy work, in the form of a Tree of Jesse, consisting of scrolling foliage, with a few busts of figures amongst it. On my taking up the work after him, I came fresh to it. I wished to do honour to my lost friend. I felt that I was justified in at once throwing over this comparatively poor scheme of a Jesse Tree, which he had himself put off from time to time, substituting the richer effect of sacred subjects for it: I therefore took up the thread of his own idea; and I have endeavoured to work it out by sacred subjects, increasing in richness and interest, as they progressed eastward; and I have completed them, as he had proposed, with a "Majesty," or the glorified manhood of our Lord.

I found a few small sketches by Mr. Le Strange for the "Jesse" and the "Majesty;" but coming as I did, fresh and unfatigued, to the work, I thought it best to make all designs my own. Those sketches of his were but first ideas, and of a character which I cannot believe he would have carried out: so I discarded them.

Such is the history of this work. The ceiling is about 86 ft. from the pavement. Each of the twelve bays has nearly 1,000 superficial feet of painting in it, from its curved shape. The figures are of various sizes, mostly 9 ft. and 10 ft. high. The designs and compositions, both of subjects and ornamentation, are original. I believe them

to be so in Mr. Le Strange's part; I know them to be so entirely in my own; with the exception of two or three forms borrowed from his drawings and introduced in my first design (Jesse), for the purpose of linking together our two works the more harmoniously.

For a description of the ceiling, I cannot do better than to transcribe a few paragraphs from a printed report circulated among subscribers to the restoration of the cathedral by the Dean of Ely. He writes thus:—

"The principal subjects occupying the central portion of the ceiling, beginning from the west, are as follows:—1. The Creation of Man. 2. The Fall of Man. 3. The Sacrifice of Noah. 4. The Sacrifice of Abraham. 5. The Vision of Jacob. 6. The Marriage of Boaz and Ruth. 7. The Jesse. 8. David and attendant Musicians, Angels, &c. 9. The Annunciation. 10. The Nativity. 11. The Adoration of the Shepherds and the Magi. 12. The Lord in Glory.

These central subjects are supported by figures, which are for the most part representations of patriarchs and prophets, carrying scrolls upon which are written words of their own, bearing more or less forcibly upon the coming of the Messiah. The arrangement of these supporting figures is as follows; the numbers correspond to those given above:—

#### NORTH.

1. JACOB.  
'The sceptre shall not depart until Shiloh come.'
2. BALAAM.  
'There shall come a star out of Jacob.'
3. NATHAN.  
'I will establish the throne of His kingdom.'
4. JOEL.  
'I will pour out My spirit upon all flesh.'
5. HOSEA.  
'O Grave, I will be thy destruction.'
6. ISAAH.  
'There shall come a rod out of the stem of Jesse.'
7. HAGGAI.  
'The desire of all nations shall come.'
8. EZEKIEL.  
'My servant David shall be a Prince.'
9. NABUM.  
'Him that bringeth glad tidings.'
- ZEPHANIAH.  
'The Lord their God shall visit them.'
10. TWO EVANGELISTS.

#### SOUTH.

1. ABRAHAM.  
'My son, God will provide Himself a Lamb.'
2. JOB.  
'I know that my Redeemer liveth.'
3. MOSES.  
'The Lord shall raise up a prophet like unto me.'
4. JONAH.  
'Thou hast brought up my life from corruption.'
5. AMOS.  
'I will raise up the tabernacle of David.'
6. MICAH.  
'Out of thee, Bethlehem, shall He come forth.'
7. DANIEL.  
'He shall confirm the covenant.'
8. JEREMIAH.  
'I will raise up unto David a righteous Branch.'
9. ZEPHANIAH.  
'I will bring forth My servant the Branch.'
- MALACHI.  
'The Son of Righteousness shall arise.'
10. TWO EVANGELISTS.

The eleventh subject has, properly speaking, no supporters; but the Magi and the Shepherds are so arranged as to carry on the artistic effect of a central group with conspicuous lateral figures.

The twelfth and last subject has also no supporters; the picture extending entirely across the ceiling. This subject demands more particular description and explanation. In the centre is the Lord Jesus in His glorified humanity, seated on a throne, round about which is a "rainbow like unto an emerald." Above His head is the choir of seraphim, painted in prismatic colours and reflected in the "sea of glass before the throne." On the right and left are the figures of the twelve apostles seated. Beyond them on the dexter side are two archangels, St. Gabriel, 'the angel of redemption,' holding the standard of the Cross, and St. Raphael, holding a sword with its point downwards, expressive of victory and peace. At their feet rise three figures, typical of the hellsed received into glory. On the sinister side are also two archangels, St. Uriel holding his sword downwards, and St. Michael spearing the Dragon, expressive of the condemnation of and victory over sin. The figure of our Lord is connected

with the tree of Jesse by its last branches, which break into scrolls and golden fruit at His feet. Around His figure is the text, "I am the root and the offspring of David, and the bright and morning star."

Mr. Le Strange began this work by inscribing at the west end the prayer, 'Sit splendor Domini Dei nostri super nos, et opus manuum nostrarum dirige super nos, et opus manuum nostrarum dirige.' Mr. Gambier Parry has finished the work by inscribing at the east end the *thanksgiving*, 'Non nobis, Domine, non nobis, sed nomini tuo da gloriam.'

The whole of the painted ceiling, as above described, is bordered by a series of heads, which form (as it were) a cornice to the roof and connect it with the walls. These heads represent the human ancestors of our Lord, according to the genealogy in St. Luke's Gospel: they commence at the eastern extremity and terminate at the western, thus linking together the Incarnation, as exhibited at the termination of the series of pictorial representations, with the Creation of Man at the commencement: in other words, 'the first man Adam, of the earth earthy,' is connected with 'the second Adam, the Lord from Heaven,' by the chain of human links which the genealogy supplies.

It will thus be seen, that, besides being an elaborate work of pictorial art, the ceiling of Ely Cathedral is a carefully-studied epitome of the sacred history of man, as recorded in Holy Scripture.

The plan we both adopted was, by studying old art, to enliven ourselves with the tone of its feeling, and then to work out our own ideas as far as possible in harmony with it; not pretending to mock old work, but to give such expression to our own work as an artist might do in sympathy with and in reverence for artists of old days. We wished to work harmoniously with art and architecture of the twelfth and thirteenth centuries, without for a moment designing to conceal that ours was the work of the nineteenth. He has done this faithfully. I have endeavoured to join my work to his as well as I was able; but the very nature of the subjects makes it inevitable that my half of them should have a richer appearance than his. Mr. Le Strange intended the work to grow more rich in colour as it progressed eastward. I have therefore only carried out that intention. I have maintained, so far as I thought it necessary, the characteristics of the twelfth and thirteenth century art, to give unity to the whole work; yielding to a less rigid style as I progressed eastward.

Such then it is, for better or for worse, done as well as two country gentlemen, with very much else to attend to, could manage to do it. I trust that we have in no way encroached on the sphere of the professional artist. We have worked fast, but very carefully. It cost him three years and me two of hard and constant application to make and to execute our designs. Our assistants have been two careful men, whom we have trained to our special purpose. The work has been done in a modification of oil painting, chiefly with copal and gold size. I have coated my part over with fine wax hardened with resins. The whole was executed (*in situ*) on deal boards, nailed upon the rafters of the roof. It was a very awkward work to execute, lying on one's back, in a painfully bad light, impeded by the scaffolding, and without possibility of one's getting a clear view of it at a fair distance, to judge of it in the various stages of its progress.

Thus far Mr. Parry himself. The view we give will serve to convey a general idea of the arrangement and the position of the various subjects; but we are bound to say, taken from one point of view, and necessarily showing the figures foreshortened, it does not do justice to the excellence and beauty of the work, any more than it can show the harmony and modesty of the colour. We must confess to a certain misgiving when about to enter the cathedral, produced by a recollection of some other modern Medieval colourings. But this was quickly dispelled. There is here nothing staring or hard, no ostentatious ugliness or voluntary bad drawing. We are forced to give the preference to Mr. Parry's part of the work; it displays more sentiment and more force; but he has contrived to make the change so gradually that there is no incongruity, but a gradual and apparently designed increase of richness towards the east end. When we remember how difficult was the task of painting on this huge scale, lying on his back, and without ever being able to get a fair sight of what he was about, the success

of the undertaking seems marvellous. For special admiration we would point to the head of the glorified Christ and to that of the Virgin next it. It was a noble work to do, and it has been nobly done: and while we give praise to the authors of it, we must at the same time say that they were fortunate to have the opportunity and the power to tie their names worthily to this grand and beautiful building. The good opinion left behind him by Mr. Parry we heard everywhere. Whether from the loquacious waiter at the comfortable "Lamb," old Partridge, with his stick, stumping about the Cathedral, or the select of the Chapter, the expression is the same. We may not, however, dilate longer, though there are many things here of which we would willingly speak. We may hope that what we have already said will serve to lead some of our readers to pay a fresh visit to Ely Cathedral, and to see for themselves, in addition to the structure, which we will suppose known, its beautiful records, delightful ceiling, and admirable restorations.

#### THE ROYAL ACADEMY EXHIBITION.

PERHAPS Sir Edwin Landseer meant to indicate by those good-natured-looking dogs he designates "The Connoisseurs" (152), his appreciation of criticism; either deploring satirically the culpable animosity that is so often and justly considered to be the chief failing of the critic in these times, or simply to suggest that they never grow when looking over his shoulder, at all events; or it may be a defiance, for he might confidently affirm that this, the ninety-seventh anniversary of the Royal Academy Exhibition, does not offer much opportunity for his friends to make much disturbance at, unless they bayed at Mr. Poole's moon that lights his lovers at "The Parting Moment" (263), with such an excuse as that of its being so beautifully real in appearance and illusive word provide, or for just such another reason attacked the heels of Mr. Millais' British hero in the "Romans leaving Britain" (294), for never were legs and feet more life-like in painting.

There is quite sufficient distinctive claim to make this year's collection memorable, *per se*, and to give it advantages for comparison if it were at all necessary to enter upon its relative superiority or inferiority to those of the past; and not only because it happens to be signalled—how considerably now will deny—by including Mr. Fritz's much talked of, anxiously expected, and successfully completed representation of "The Marriage of their Royal Highnesses the Prince of Wales and the Princess Alexandra of Denmark"—a very successfully, the stupendous difficulties of such an undertaking being fairly taken into consideration; or from the coincidence of there being more instances than usual wherein individual exertion announces itself in works of a more important nature and on extended scale compared with antecedent; but more especially from the almost unexceptionable character of excellence that prevails throughout. Such interest as a variety of subjects lends to an assemblage of pictures belongs to this, and whilst appealing to diverse sympathies, for the most part these are not too much confined to particular tastes; and there are fewer illustrations of those incidents that have become threadbare in service and are now but time-honoured amongst a large aggregate of examples that have narrative for a basis.

Mr. John Phillip, R.A., illustrates "The Early Career of Mirillo," 1634 (156), and has selected an episode from "Striving's Annals of Spanish Painters," to prove his right by analogy of being considered one of them. There is more to imply the popularity than a clever, self-reliant, lucky boy may hope to secure for himself, in this animated and picturesque scene from such a stirring drama as only romance in more prosaic times can compete with in imagining, or credulity accept, as the ordinary course of existence shared by those glorious and gifted luminaries, described by Vasari and others after him, who have written of the old masters; and something dissonant in connecting any idea of poverty or want with so bright an image of hopeful boyhood as the hero and the circumstances present. Reduced to earn his daily bread by painting coarse and hasty pictures for the Fena (weekly fair), held in a broad street, branching from the northern end of the Old Almada and in front of the old church of All

Saints, the unknown youth is seen surrounded by gipsios, muleteers, mendicant friars, and such frequenters of the market as even now resort to it; selling for a few reals those productions of his early pencil, for which royal collectors are now ready to contend; and which even then found appreciators, judging by the expressions of pleasure and surprise attending the examination of them; shared in even by the swarthy beauty who, it may be guessed, has served as a model for Fruit-seller, Flower Girl, or Virgin, according to the exigence of the occasion, and is now exhibiting that impatience common to her order to ascertain how she has been made to look; or if the artist has discovered all the aptitude she thinks her plump baby possesses for fulfilling all purposes required of it, whether bodily to represent an infant saint, or bodilessly a cherub. It is no exaggeration to say that this picture is magnificent in the proof it gives of consummate manipulative power, and having great pretensions to value in its close association of facts with probabilities than historical subjects generally can inherit, it may be considered Mr. Phillip's greatest achievement.

"Sweet are the uses of adversity" when a not too severe form of it to one who suffers it secures prosperity to another who makes more of it than the sufferer could dream of; but a decadence so absolute as Sir Edwin Landseer has typified, reversing the arrangement of its occurrence, is enough to make a horse sick in its contemplation, if ever the thorough-bred in "Prosperity" (102) cast his reflective eye on such an ugly possibility as "Adversity" (112). It is likely he did, and from slaying too often at speculative evils in by-paths was driven to acquire a knowledge less obscure in a cab radius of sixpence a mile experience. But who could have the heart to say it served him right that saw how carefully he had been tended in 102, with nothing to burden his back or his conscience but the love of a lady such a creature was born to be subject to, and could behold him in 112 reduced to the lowest rank of equine standing, subservient to the badge and vehicle of his punishment—gored by the harness he has never been broken to—without lamenting that misfortune, bad habits, or ungrateful discontent should be so many saddles that fit so many horses with similar disagreeable consequences.

Misfortune and annoyances, however, are so often followed in preponderating degree by such recompensing benefit as must leave it doubtful when to commiserate or congratulate with propriety; and although there can be no promise of amelioration held out to Sir Edwin's horse—beyond the enduring honour of bearing still a little farther the fame of his master, if it be possible for the quadruped to hold out under such weight and for such an incalculable distance—the remark is enforced by very convincing evidence in point from Mr. F. Goodall, R.A., in (8) "The Rising of the Nile." "The inhabitants of the plains of Gizeh leaving their inundated villages for the higher ground," have the consolation of knowing that the annual overflow of their great river is really essential to the fertility of the country; but its rising even to the height of a few feet above the periodical average is the occasion of desolation and ruin. It is quite pardonable if in the inconveniences of so hasty an ejection, half the advantages to be derived from the water-lord's unannounced visitation should be lost sight of, and cause the commotion and derangement Mr. Goodall has so admirably availed himself of, on a large canvass. In long procession these involuntary emigrants are hurrying to secure some safe standing-place, and what with the obstinacy of the camel whose opinion seems materially to differ from the old Egyptian's who is urging him up the bank, and the uncertainty of the frightened women and children, the prospect of ultimate safety is left quite conjectural, and of little regard, perhaps, to the old invalid carried by slaves and seditiously watched by his daughter, more careful for him than herself. This is by far the most interesting and important application by the artist of knowledge gained by his Eastern travel.

Mr. P. F. Poole, R.A., is also exceptionally well represented by his poetically-conceived, though rather painful situation of a Pompeian family during the eruption (of 79 A.D.) when the city was buried under showers of ashes from Vesuvius. A Roman father is surrounded by his dying children and their mother; the effects of suffocation are conveyed with extraordinary likelihood. One youth is pulling himself

up to the roof, through which dead birds are dropping to show how abortive all such attempts to gasp air have become. A curious picture, without doubt, but a power of fascination accrues to it, partly from that peculiar and instructive use of colour always remarkable in Mr. Poole's works, its originality, and the poetry which disguises its tendency to morbid taste. Quite as poetical, and with no such taint to condone for by its subsistence, "The last of the clan" (150) by Mr. T. Faed, A., is pathetic enough to appeal to the same sensibilities without disagreeably shocking them. An old clansman, too old to see the feasibility of beginning a new life in a new home, is watching the departure of his kinsmen in the emigrant steamer just loosed from the hawser, and carrying them from the land once their own. The dejection and resignation of the poor broken-down elder, bestriding lax and motionless a pony as feeble and as much past work as its master, is contrasted with the more demonstrative grief of his grand-daughter standing by his side.

What a worshipper of truth Mr. Hook, R.A., must be, and how fond Nature must be of him if there is any reliance to be placed on the adage "that we love those best who use us well," but then there is another that says "that we like those the least to whom we rest under the weightiest obligations;" and as the latter is the most generally learnt, and therefore the easiest to be understood, it is possible that the painter is not most fond of that which he paints best after all. However, Mr. Hook is not the man one would select to tell a story to; he has such a clear perception of truth in its broad open aspect; of facts clear as daylight, and as constant as the tides to the sea, which he knows by heart, and yet is never tired of observing; and besides, a story would be of no use to him—he tells his own with facts for a basis, and no extraneous ornament to adorn his oratory beyond the simplest prohibitions. Whether in Britain or Brittany, he never fails to give convincing proofs of his adherence to truth, and such pure pleasure as only such a source could enable him to offer, and so universally. His pictures this year are all exquisite alike.

Mr. Millais, R.A., is exemplary for the wide range he allows himself for selecting subjects for his pencil, and the judgment of this is perceptible in the freshness it gives to his works. One of the main causes of his great success may be supposed to exist in his general acceptance of everything as paintable, though some allowance must be made for an extraordinary capability for so utilizing matters that have little inherent value in themselves. The gift is more than usually apparent in all five of his present contributions, including "The Romans leaving Britain" (294), or, to be more precise, a Roman soldier taking leave of his love, his principal work. Nothing can be more simple in arrangement than this, or in the appliances made to be the means of relating a most touching story; but in addition to that rare faculty of imitation and adaptativeness patent to him, the artist has invested this with some of the higher qualities that used to be more closely associated with his name formerly—intensified expression amongst them—than now, when the majority of his productions are but wonderful specimens of painting, though as such it must be conceded that they are of unsurpassable worth: for witness, see the armour of "Joan of Arc" (208), the silk embroidered drapery of "Esther" (522), and the acme of such perfection to predominate over all else, though the charms of the idolized are unquestionable enough to attract any dicky-bird, and excite a lover's rhapsody, in (391).

"O swallow, flying from the golden woods,  
Fly to her and pine, and woo her, and make her mine,  
And tell her—tell her—that I follow thee."

Going from this personification of ineffable grace and sweetness to the wicked old gentleman of other and extreme affinities, sowing tears and tares (528) will, it may be supposed, very clearly illustrate what is meant by the inclusive comprehension of subject matter before alluded to.

Mr. F. Leighton, A., has succeeded but imperfectly in gaining sympathetic attention to his ideal of "Helen of Troy" (309) through the greater claims his smaller but more satisfactory "David" (5) presents for recognition; and even in this the prevailing excess of a particular phase of refinement or elegance, approaching in some cases mere prettiness, has the effect of depreciating the valuable character that to some extent be-

longs to all his works. (305) "The Widow's Prayer" and (316) "In St. Mark's" are very beautiful and very indicative of a foreign, classic art education. Something more herafter.

#### ARCHITECTURE IN THE ROYAL ACADEMY EXHIBITION.

An inculcation of the essential art, in the works of "artists," has been recognizable several times, of late years, in the mottoes prefixed to the exhibition-catalogues of the Royal Academy. It appears this year in lines from the "Essay on Criticism" of Pope, a poet whose canons, and those of his master, and Boileau's, Horace, are pertinent to each of the arts represented in the Academy, as they are to poetry, and as we are inclined to believe they are especially to a living art of architecture. It may be difficult to say which part of a picture is representation, and which invention: for, the complete observation and delineation of scenes and incidents hardly can be considered as possible, or memory of them capable of being possessed, without the possession of the power to originate; nor can there be the art, which involves the latter power, without the ability to represent. Still it is certain that that which is deficient in invention is not to be rightly called a work of art. Yet, the invention itself must be in accordance with rules, namely those which there are in the works of Nature, or which, deducible from the works, would have been applied to the new case. The result in architecture is at once a harmony with Nature, and a contrast. Our art, in common with Nature, has fitness of form to use and structure; whilst its lines, and its exact balance of parts, go to the production of contrast with the works of Nature, as those works contrast with one another. "Nature corrected," or the "Nature to advantage dress'd" of Pope, may be phraseology calculated to offend some persons; but the meaning intended to be conveyed, comes from a correct view of what constitutes art. Were this view that generally of painters, they might justly rank ours as the highest of the arts, because requiring invention, and yet an art at once admitting no transcription of the works of Nature, and at the same time one the most observant of Nature's laws,—

"These rules of old, discover'd, not devis'd,"

which in the next line we are told,—

"Are nature still, but nature methodiz'd:"

What should be the sort of recognition or furtherance of our art by the Academy, this is not the place for discussing; our remarks, in continuation or repetition of those of former years, are merely intended as reminder, that so long as the treatment of architecture, and we might say sculpture, is what it is, there is difficulty in seeing that the purpose and attributes of art are understood by the Academy as they should be in an academy of arts or art.

The drawings which are under the heading "Architecture," this year, in the galleries in Trafalgar-square, are arranged in the same manner, and take up the same space, as of recent years. That is to say, they fill about half the space in the room at the top of the stairs, and one-half of them are placed at much greater distance from the eye, than architectural drawings in particular ought to be at any time. There are 68 numbers in the catalogue,—some of the drawings, as usual, being merely representations of old buildings; but in one or two cases, a number will comprise two designs or drawings of works in progress or lately completed. It is difficult to say what number of drawings, with photographs of buildings, should be set down as exhibited in the Conduit-street Galleries: we make the numbers in the catalogue there, 389. As commonly, some of the most important works of the year are shown in neither collection. Several buildings are represented in both places, or by different drawings, which properly should have been seen together. Drawings from the recent competition of designs for Grocers' Hall, are similarly distributed between the two collections.

The drawing which has the first number (770) in the series, is exhibited by Mr. D. Brandon, and is a "View of St. John's Church, Kingstone, Staffordshire, erected for the Earl of Shrewsbury and Talbot." It is of plain Early English character, and has a broach spire, tiled, with overhanging eaves. Mr. R. M. Phipson exhibits a view (781) of the interior of Igboro

Church, Norfolk, which is being rebuilt from his designs, at the cost of Lord Ashburton; a view (782) of St. Giles's Church, Norwich, showing the intended new chancel; and one (783) of Burgate Church, Suffolk, which is to receive new roofs. Mr. J. D. Wyatt contributes (789), a view of the choir of Hereford Cathedral, displaying the new screen and organ, and the general effect as restored by Mr. Scott. The organ is at the side, filling one of the arches, and corbelled out above the stalls. Mr. E. L. Blackburne shows (825) "Ospringe Church, Kent; new Tower and other Restorations now erecting" from his designs. The tower is finished with a saddle-back roof. Mr. W. Burgess has a view (785) of the "Interior of Worcester College Chapel, Oxford," as re-decorated under his superintendance. What he has done is more completely shown by drawings which he has in the Conduit-street Exhibition. The members of the architecture are Italian in style. Chromatic features that are prominent in the view, are red stripes to the lower portions of the shafts, and the necking of the capitals, the same colour, which in the latter case is too prominent. Mr. G. Goldie's "Interior (786) of the Church of St. John of Jerusalem, Great Ormond-street," has a common defect of Italian church interiors which await the decorative painter, namely a bareness and poverty in the spaces of the wagon-headed vaulting, between the coffered ribs. The dome, on pendatives, the *baldachino*, and the gallery projecting above the doorway, contribute to the resemblance that the whole interior has to numerous churches classed as Italian, and a resemblance which must be deemed somewhat too great.\* A "North-East View (788) of St. Nicholas Church, Great Yarmouth, as proposed to be, and already partially, restored," is exhibited by the architect, Mr. J. P. Seddon. This church is one of the largest, not cathedral, in the kingdom. The drawing shows large eastern windows, of Geometric tracery, and a spire, to be added, which is lead-covered, the rolls being disposed chevron-wise. The drawings of other works in progress include (796) "St. Mary's Church, Idle Hill, Kent," by Mr. C. H. Cooke, and one (773) of a "Church now erecting at Boston, United States," by Mr. T. N. Laslett; and Mr. R. Palgrave exhibits (812) "Design for the Restoration and Enlargement of St. Paul's Church, Bedford," a large Perpendicular Gothic structure. All these buildings are Gothic, with the exceptions mentioned. Almost the only work of Gothic ecclesiastical architecture claiming more particular notice, is Mr. F. Marrable's "New Church of St. Peter, about to be erected for the Rev. Joseph MacCormick, M.A., in the Wickham-road, Deptford." It is shown by two views, namely one (802) of the exterior, and one (811) of the interior. The internal arrangement and effect seem likely to deserve commendation. Though there is no plan, we gather from the drawings that the aisles are narrow, and to be used chiefly as passages, after the principle discussed at length in a notice of the Conduit-street Exhibition of a former year. The resulting proportions of the nave and aisles, with the western tower, externally, are not quite satisfactory; nor is there much freshness in the details of the exterior, which has as a conspicuous feature in the west front, three porches grouped together and occupying the full width, the side-porches being apparently in communication with stairs to a western gallery. In the interior, where there are no side-galleries, there is novelty and effect in the treatment of the arches, clerestory, and ceiling. The aisles are low, and open from the nave by low pointed arches having corbelled impost. In the clerestory, which is lofty, each bay is formed as a deeply recessed pointed arch with square reveal,—a similar square reveal bounding the window-opening; whilst the ceiling, which is plain-groined, and banded in the eaves with occasional red courses, has the principal-ribs carried by shafts,—the crown of the groin in each bay having a circular opening, which is no doubt made to serve for ventilation. The chancel-end of the nave is terminated by a centre arch, and two side arches. Red brick, throughout, plays an important part in the effect; which as we have intimated, is, in the drawing, very good.

Mr. T. H. Watson's "Design for an Asylum, to which the Soano Medallion was awarded by the Royal Institute of British Architects, 1864" (807), has a cleverly grouped and detailed tower and spire, as well as other features, all drawn

with an able hand. The building would be somewhat costly for the number of pensioners intended to be accommodated.

It may be desirable that appearance of buildings should be in harmony with their uses,—although it should not be expected that the appropriation and use of a structure should be capable of instant recognition; moreover there is a diversity of style in the buildings of this day, which is not to an equal extent accompanied by art; and which, where the art exists, interferes very much with the appreciation of it by the public. But some kinds of buildings are getting too much of family-likeness; and amongst these are schools. Great importance given to the roof, by carrying the one slope down, where there are any adjuncts to the school-room, nearly to the ground; the line of eaves broken by long windows which are in part dormers; and Gothic details, are observable in most of these designs. Some or all of the features referred to characterize the "Schools now being erected in the village of Littlebury, Essex" (779), by Mr. E. Barr; and "The accepted Design for Christchurch Schools, Battersea, about to be erected" (820), by Mr. E. C. Robins.

The Gothic character is that of "The Richmond-Hill Hotel" (771), now being erected under the superintendance of Mr. J. Giles. In the principal front it has a recessed centre, and two verge-board gabled wings, from which project bay-windows; whilst at one side, is the inevitable square tower of modern design,—the whole building being brilliant with green-painted verandahs and balconies. The effect, however, of the building, seems likely to be very much superior to that of the hotel in Langham-place; which, really, by its height, its disposition on plan, its arch-headed windows, too frequently repeated, and suggestive of a deficiency of light from the form of head, and its bay-windows, is an intrusion in that part of London. The "Design for a Block of Offices on Land the property of the Worshipful Company of Grocers" (772), does not, to our thinking, represent what would be a desirable addition to the street-architecture of the City of London. Whatever art there may be in such compositions cannot be appreciated, out of character as it is with everything near to it. The drawing shows a building, of four principal stories, dormer-windows, and a basement, the second and third story windows being in each bay recessed and grouped together under a pointed arch springing from the piers; whilst a "drop-arch" of the same character of style spans the recess of the ground-story,—the horizontal courses and the arches being marked by particular material. Very different from this Gothic, is that of "Clandebye, the Seat of the Right Hon. Lord Dufferin" (787), as being enlarged and altered by Mr. B. Ferrey; who shows, by marginal sketches, that the work has been designed cleverly, the original structure being a plain "square house." The portion of the plan given to the staircase is carried up as a square tower, with an arcade, corbelled angle-turrets, and a plain pyramidal roof. An equally clever conversion from an old building, is that by Messrs. Banks & Barry, of "Bramling House, near Wingham, Kent" (784). Considerable additions are shown to have been required. The new character imparted is Jacobean; but the windows have no mullions; generally, the features are simple strings, and a block-cornice, a balustrade with dormers, lintels to the windows grooved as ornamentation, and the stones of the jambs bonded in. The entrance is emphasized by superimposed rusticated pilasters, and by decorative accessories of the gable enclosing a window. Mr. W. M. Toulon has adopted the Jacobean character in "Overstone Hall, Northamptonshire" (778), which has a square entrance-tower with the features "of the period" in angle turrets, not unsuggestive in character. "The Entrance, Park Hill, Wyersdale, Lancashire" (775), by Mr. R. H. Potter, reminds us somewhat of that of Lambeth Palace.

Mr. M. D. Wyatt exhibits (799) five drawings of "The 'Ham,' Glamorganshire," the residence of Mr. Ilyd Nicoll, as re-erected. The building is Gothic, with Elizabethan features in the interior. The Hall has an open-timbered roof; and the staircase leads up from the end, the landings having each an opening and out-look into the hall. Mr. Wyatt shows also a view (821) of "Addenbrooke's Hospital, Cambridge, as re-erected" from his designs. It is a long three-storied front, with a centre having loggias in two recesses, and in the three stories; and the third story of each wing has an arcade with shafts, which are carried partly by corbels and

\* A view will be found in another volume of the Builder.

partly by buttresses that there are to the two lower stories. Where the upper loggia is the cornice in the intercolumns is formed in the manner of lintels which are carried by corbels from the capitals of the shafts or columns. We cannot like Mr. Wyatt's "Design for the Proposed Shakspeare Monument at Stratford-on-Avon," made at the request of the Committee, of which he shows the "original study" (322). The balustrade, or cresting, of Elizabethan scroll-work, and some other features, are simply ugly; moreover, the notion that in a monument to Shakspeare we should adopt the Elizabethan style, thereby producing a work hearing the appearance of having been erected not by ourselves, but by his contemporaries, is child's-play rather than art, and is calculated to perpetuate error that we are so often committing. A monument to Shakspeare, erected in the nineteenth century, should, in mere justice to those erecting it, seen in every respect of the century; and why should it not?

Castle Carr, Halifax, now in course of completion for Mr. J. P. Edwards (813 & 833) by Messrs. A. Smith & T. Risley, may be described simply as imitation-castellated in character. No. 791 is "The Randolph Hotel, Oxford," a building which is being erected near the Martyr's Memorial, opposite the Taylor and Randolph Building. The latter is dwarfed by the contrast. The new design is conceived with those features of pointed-arched windows with red vousoirs, and hipped roofs, that are of the new Gothic which is so discordant with the older style at Oxford, as also with the Italian. A drawing (776) of the "Bath Forum House, Mineral Water Hotel, and Bathing Establishment; competition design to which the first premium was awarded, February, 1855" (though afterwards withdrawn), is exhibited by Mr. C. E. Davis. It is an Italian building of five stories, with a deeply recessed centre. Porticoes of superimposed columns project from three of the fronts of the quadrangle. In this last are statues "taking the air." Attached to the ends of the wings are porticoes, boldly projecting, of superimposed columns, to two of the stories, and carried by a piazza of the lower story. "The Great Eastern Hotel, now erected at Harwich, for the Great Eastern Railway Company" (777) by Mr. T. Allom, must be a satisfactory production, if cement be not the material of the decoration. It has four stories, including an attic, which however is weak. The general material appears to be white or yellow brick, rusticated with dog-tooth ornament, as in the Charing Cross Hotel, being apparently used in the case of the piers of the centre and ground-story. The ground-story has arch-headed windows, with archivolts springing from Corinthian columns,—each column having a block, coursing with the ordinary masonry, to break the shaft; and these windows appear to have a peculiar pedestal, with pinnated dado, in each recess. In the spandrels of this ground-story, on the piers, are circles with busts, or medallions. Above this story, the piers comprising the two next stories of windows, are terminated by capitals carrying the main cornice; which is cantilevered, and coffered in the spaces between the cantilevers. The windows in each bay, of the two stories, second and third, are grouped together, with an intermediate balcony, and have square *antæ* as decoration. The front has a pediment in the centre, enriched with ornament. There is a large flat, railed in, in the centre of the roof.

The "New buildings of the Piazza Statuto, Turin, now in course of erection for the International Financial Society (Limited) of London," which were originally designed by Signor Bollati, of Turin, are shown in a view (794), by Messrs. Banks & Barry, by whom the design has been altered and amended; and under whose superintendence the works are being carried into effect. This drawing was referred to by Mr. Tite, on the occasion of the Academy dinner. Mr. Tite, attributing the design to Messrs. Banks & Barry, called it a "heavenly" one, and considered "some of the works exhibited as showing a revival of excellent Italian architecture, and none more so than the 'Piazza Statuto,' at Turin." But, art will not be benefited by mere revivals, whether sixteenth and seventeenth century Italian, or Medieval Gothic; we want, not old art, but veritable art; for what is not fresh and new to some extent, is not art at all. The fifteenth, sixteenth, and seventeenth century work of Italy was art, not because it was a revival of the old art, but because, except at the commencement in some of the buildings of Brunelleschi or Alberti,

it had imported into it continually new matter. The Italian architects of the end of last century, and beginning of this, have seemed oppressed by the weight of the history and reputation of former deeds. Palladianism, which is a very different thing from the architecture of Palladio himself, has been dominant in Italy, as lately it was throughout Europe. It is the worn-out Palladianism that makes the character of the Piazza Statuto, rather than the Italian as it has been since revived. The buildings in progress at Turin have a piazza in the ground story, of arches and Roman Doric columns: above this is a Corinthian pilasterade spanning the height of two stories. Above the order is an attic with dwarf-pilasters; and there are dormers to the roof. There are pavilions; but they are not marked as features: the order goes round them; and the value of contrast is sacrificed.

We shall return to the room next week.

#### THE ARCHITECTURAL EXHIBITION.

The pressure on our columns prevents, this week, our saying much more of the collection in the Conduit-street Galleries, than that the Exhibition was opened on Tuesday evening with the usual *conversations*. The Exhibition is altogether an advance upon that of last year; though it leaves much to be desired, and still contrasts with the exhibitions that were there about the time of the first occupation of the present quarters. The Western Gallery has been given up to the Photographic Society, for their exhibition, which consists chiefly of portraits and landscape-subjects; and the works forming the Architectural Exhibition itself, or exclusive of the specimens of materials and manufactures, are all in the Great Gallery. The committee were under the impression that there would be difficulty in filling more than the Great Gallery, with architectural drawings, and that the photographic collection might draw visitors, and result in the attention of a greater number of persons to the architecture, as well as in benefit to the funds; which, during the last year or two, have not been in a satisfactory state. We regret such a state of things as that which has appeared to involve the necessity for interfering in some respects with the importance of the Architectural Exhibition itself.

Considering solely the interests of our art, we question whether these would not be best advanced, even were the attendance at first small, by keeping the available space for architectural drawings exclusively,—unless photographs of architectural subjects took the place of the present conspicuous portraits. Moreover, there are drawings now in the Great Gallery, which would have been placed with advantage on the walls of the West Gallery. They are disposed on seven screens, which are badly lighted, and are much in the way on the evenings of *conversations* and lectures. The *conversations*, when well managed, are by no means unimportant in enlisting the public interest in architecture; and this year, arrangements have been made for a greater number of them than usual. The rooms were crowded on Tuesday night, though the number of persons present was small comparatively; and when the Society for the Encouragement of the Fine Arts hold their *conversations*, it will be impossible for many persons to pass round the galleries, unless some change be made.

Since the last exhibition, the ceilings and walls of the galleries have been coloured; so that they appear at least clean; but that the floor, and its covering, had not sufficiently participated in the cleansing, was evident on Tuesday night. After some time had been spent in looking at the objects in the galleries, Mr. Beresford Hope was called to the chair, and addressed the company, stating some particulars of the progress and condition of the undertaking. Afterwards, Mr. Edmeston and Mr. Lamb spoke, the former being careful to point out that arrangements for the accommodation of societies, not architectural, were regarded by the Committee as provisional, and only maintained pending the growth of proper support to the Architectural Exhibition, more especially by the London architects,—the country architects, this year, having not held back. It will be seen by our notice of the Royal Academy Exhibition, that certain important buildings, and projects, are represented there, and that some are represented in both places. In Conduit-street, there are about 400 drawings and models in the Great Gallery. In the

North Gallery and the East Gallery, there are 38 collections of specimens of materials, or manufactured articles,—but, at a glance, not presenting much except what we have seen before. Competition-drawings hold a much less important place in this exhibition than on previous occasions. The chief competitions reproduced,—and they are represented very partially,—are the Grocers' Hall Competition, and the South Kensington Natural History Museums Competition.

Amongst the principal exhibitors are Messrs. S. S. Teulon, M. D. Wyatt, Owen Jones, A. W. Blomfield, J. Whichcord, W. White, T. C. Sorby, E. Holmes, J. E. Goodchild, E. Christian, E. B. Lamb, G. Goldie, R. N. Shaw, Slater & Carpenter, C. H. Cooke, E. T'Anson, F. P. Cockerell, T. H. Watson, H. Currey, E. M. Barry, F. C. Penrose, J. K. Colling, W. Burges, C. F. Hayward, G. E. Street, G. Truedit, R. P. Spiers, C. Gray, J. D. Wyatt, O. Hansard, W. C. Brangwyn, J. P. Seddon, R. Kerr, H. H. Burnell, and some whose names we do not immediately recollect. Before next week we shall have had time to give to the collection in detail, the attention which it so much deserves.

#### SIR JOSHUA REYNOLDS AND HIS TIMES.\*

MR. MURRAY, of Albemarle-street, has contributed a pleasant passage to Mr. Tom Taylor's volumes. It is in the shape of an advertisement, and runs (we will not be answerable for the English), in these enticing words:—

"Shortly will be published, with illustrations, fcap. 4to., a Catalogue Raisonné of the Works of Sir Joshua Reynolds, with notices of their present owners and localities. By Tom Taylor and Charles W. Franks. The numerous inquiries necessary for careful compilation of the Catalogue Raisonné of Sir Joshua's pictures, and the Compiler's desire to avail himself of any information as to pictures that the publication of the Life and Times may elicit, have rendered it necessary to postpone the publication of the catalogue. But the main portion of the materials is ready, and it may be expected in the course of the year."

A Catalogue Raisonné of the kind Mr. Murray announces will give to Reynolds what *Gentleman's Magazine* Nichols gave to the admirers of Hogarth, in his trustworthily "Catalogue of Hogarth's Prints," and will, doubtless, form a very useful supplement to every Life of Sir Joshua. A work of the kind has long been needed, for Mr. William Cotton's valuable "Catalogue of the Portraits painted by Sir Joshua Reynolds," published in 1857, requires many additions and more corrections.

Friday, the 2nd of May, and Saturday, the 3rd of May, 1856, are memorable days in the history of Reynolds's reputation, though Mr. Taylor has overlooked them. On the Saturday the Great Room at Christie & Manson's was crowded, and crammed to witness the sixth day's sale of the collections of the poet Rogers. One hundred and five pictures composed the one hundred and five lots of that day's sale, and eight Sir Joshuas, of extraordinary interest and excellence, were among them. We were present on the occasion. The first Reynolds put up was "The Mob Cap," the principal figure in the composition of "The Infant Academy." The hammer appraised it at 780 guineas. Six intervening lots allowed breathing time, and then a second Sir Joshua, "A Girl with a Bird," was knocked down at 230 guineas. Another interval, and the market-price of the Marchioness of Thomond's picture, "A Girl Sketching," was fixed by the hammer at 350 guineas. A longer interval, and then lot 601 was up for sale amid a volley of tributary cheers and clapping of hands. One of Sir Joshua's very first works,—a master-piece,—is under the hammer; yes, the far-famed "Strawberry Girl" is to be sold to the highest bidder. All is silence now save the well-known voice of the auctioneer. A thousand guineas are offered, then 1,200 guineas, then 1,500 guineas,—you might have heard a pin drop,—then 1,600, then 1,700 guineas,—then hearty cheers,—and then intense silence; but are offered that it will fetch 2,000 guineas: 1,800 guineas are offered for the charming "Strawberry Girl" of England's Sir Joshua. 1,900 guineas are now offered amid renewed cheers. Another pause, and the hammer of the auctioneer is in the air ready to descend. "Two thousand guineas!" is

\* See p. 270, ante.

then the cry, Christie's face beaming with delight as he announces the bidding. A longer pause on account of renewed cheers, as if Christie's great room, not Cheapside, were "mad." Another bidding is heard, and at the price of 2,100 guineas Sir Joshua's "Strawberry Girl" is sold to its happy purchaser The Most Noble Richard Seymour Conway Marquis of Hertford. The sale advances, and a landscape by Sir Joshua, after the manner of Titian, is sold for 105 guineas. "The Strawberry Girl" and Sir Joshua, and The Marquis of Hertford, and 2,100 guineas for the "Strawberry Girl," are on the lips of all who love art and pleased to spread the reputation of England's Sir Joshua.

Talk about Sir Joshua was carried into the next day, when three more well-known Sir Joshuas, and favourites with the poet whose property they were, are up for sale. Sir Joshua's second example in landscape-painting, a "View from a Window in his Villa at Richmond," is to be sold,—and sold it was, for 430 guineas. A second Sir Joshua is offered (lot 706), "Cupid and Psyche," one of the most important and beautiful of his fancy subjects,—the hammer falls, and 400 guineas is the price. Breathing time is again allowed, and the "Puck," of Sir Joshua (a master-piece in art), can be had for money. Here is an opportunity for a lover of art, with a long purse,—cheers are as loud as yesterday;—"Lord Hertford will have Sir Joshua's 'Puck' for certain," is on many lips. His lordship, however, is not a bidder, and the starting price of 800 guineas, advances by tens and twenties to 950 guineas, and finally closes at 980 guineas. Then the purchaser's name is announced,—"Earl Fitzwilliam" is heard and repeated,—cheers are renewed, and the question is asked and answered, what Mr. Rogers gave for it. The poet (we learn from a well-known dealer and historian of picture-prices) secured his favourite "Puck" for 215*l.* 5*s.* The wealthy earl to whom it passed for 980 guineas, sat to Reynolds as a boy, and remembered Reynolds, as we heard him say at his seat in Yorkshire, when we had the advantage and the pleasure of seeing him before it. The animated boy of the picture was plainly visible in the living and aged man.

Sir Joshua (like Sir Godfrey Kneller before him) was the most fortunate of painters in finding some ten or eleven engravers who could translate his colours into black and white and transfer his best qualities from canvass to paper. Nay, at times he had engravers who could improve upon him. Wilkie was equally fortunate in Burnet and Raimbach; Landseer has been alike fortunate in his Father, in Consins, in Gibbon, in Watt, and a few others. Hogarth and John Martin frequently engraved their own works; and translated, and, at times, improved upon their own originals.

To read Reynolds "aright" one must not only have seen his happiest works, but his least successful; and these seen, he must be carefully studied in the numerous engravings from his works that passed under his own eyes before publication.

The link are on copper, of a large size, and in mezzotint. Mr. Taylor, with his dramatic power of reproducing and setting pictures in words, might have given us a chapter,—and a welcome one it would have been,—on the Raimbachs, and Burnetts, and Charles Warrens of Sir Joshua. As Mr. Taylor is silent about them, a few words will not be out of place. In what we have to say we shall omit all reference to the "Collected" engravings after Sir Joshua made by S. W. Reynolds and his pupil Mr. Samuel Cousins; many are good, some are copies of copies; but the whole work is not only a noble monument to the memory of Sir Joshua, but a fudge-book for portrait painters,—past, present, and to come.

In Sir Joshua's life-time line-engraving was in little repute and little understood, save by one man, and that man a master—Sir Robert Strange. Sir Robert, whose soul was with Guido and Vandyck, cared little for Sir Joshua. They were not friends, though neighbours, and each alive to their distinct excellencies; yet the great engraver living in Castle-street, Leicester-fields, within a gun-shot of the great painter and fellow-pensioner in Leicester-fields, did not, through a thirty years' close application to his graver, attempt to transfer a Sir Joshua to copper. Sir Robert looked on his own art as one little inferior, if indeed inferior, to the art of the painter. Sir Joshua's "Holy Family" was a poor performance in the eyes of Sir Robert, and money conditions, however tempting, would

have failed to make Sir Robert Strange sit down to engrave it.

Though Sir Joshua failed to catch Sir Robert Strange as a translator of his works to paper, there are some line and stipple engravings from his paintings that are marvellous in their way. William Sharp, in his engraving of Reynolds's "John Hunter," is as great as Reynolds himself. Till Mr. Henry Farrer restored Sir Joshua's fast "flying colours," in this noble portrait, Sharp's inimitable engraving was the best "transmitter" of the fine head and face of the great surgeon. After Hunter's "Sharp," we must place Mr. G. T. Doo's "Lord Heathfield," done for the late and short-existing Society of Engravers of Pictures in the National Gallery.

Of engravers after Sir Joshua in the stipple style of engraving, Francis Haward, who engraved "Mrs. Siddons as the Tragic Muse," and the playful composition of "The Infant Academy," stands pre-eminent. The stipple style, in Haward's hands, conveys Sir Joshua's texture, a merit that the mezzotinters never caught.

Miss Caroline Watson's engraving of the Portrait of Sir Joshua, in spectacles, is in stipple, and marvellously fine it is,—the very picture itself in black and white. Contrast it with Mr. Francis Holl's repetition of it in the second volume of Messrs. Leslie & Taylor's "Life and Times," and mark (one cannot fail to see at a glance) the superior skill of Miss Caroline's touches on copper over Mr. Holl's dottings and touches on steel.

Francesco Bartolozzi, whose "Clyto," after Caracci, is the admiration and envy of engravers, caught Sir Joshua's manner in the Thrale picture of musical Dr. Burney, and in a few others, such as Pope's Murray (Lord Mansfield), *Shakespeare Malone*, Angelica Kauffman, and the "Masters Lamb."

Of the mezzotinters (or scrapers, as the liners or linesmen contemptuously call them, or rather, did call them), the earliest employed by Reynolds is one of the best. This was James McArdell, who, dying in 1765, lies hurried in Hampstead Churchyard. One of his finest engravings after Reynolds is his "Horace Walpole," of which there is a repetition in a varied style before Dallaway's edition of "Walpole's Anecdotes."

James and Thomas Watson were both admirable engravers, or scrapers, after Sir Joshua. The former engraved Sir Joshua's "Blinking Sam," or profile portrait of Sir Joshua; the latter has left a marvellous proof of his skill in Sir Joshua's life-like portrait of Garrick, with his thumbs together and a prologue before him. Watson's engraving is taken from the picture then (1779) in the possession of Sir Thomas Mills. Who has it now?

There are several fine engravings after Sir Joshua by John Raphael Smith, of whom Chantrey made a most admirable bust, with a cap on his head, and a marvellous look of thoughtful penetration. Smith's Lord Richard Cavendish, and Master Crewe, after Reynolds, are well known and greatly admired.

Valentine Green, with whom Sir Joshua had his Mrs. Siddons Tragic Muse parcel, or "rupture," to use Mr. Taylor's favourite word, engraved "The Waldegrave Girls," a very noble example of his art.

Dixon's engraving (1775) of Sir Joshua's "Duke of Leinster" (painted in 1774) is, in the opinion of William Smith, late of Lisle-street (a most competent judge), "a masterpiece of art, and has never been excelled."

Of equal excellence in our eyes is Edward Fisher's engraving (1762) from Sir Joshua's "Garrick between Tragedy and Comedy." Mr. Taylor omits to tell us that this noble example of Reynolds's skill was sold by auction in the year 1782, at Lord Halifax's sale. The price (it deserves to be known) has escaped us. Reynolds must have heard of its sale, and awaited the news of the price it brought with very mingled feelings of anxiety and pride.

Giuseppe Marchi,—Reynolds's first pupil (he became acquainted with him in Italy),—is the engraver of Sir Joshua's bead of Goldsmith.

What Reynolds's contemporaries thought of his likenesses and of the engravings from his works, we will give an unpublished instance in a MS. letter now before us, from a very competent authority,—"The mezzotint print" (Joe Warton writes to *Shakespeare Stevens*) "taken from the picture of Mr. Warton (his brother Tom)," now in my house, is certainly a likeness, though a likeness rather coarse and too big and

broad." The admirers of Tom Warton, the historian of English poetry, will be pleased to learn what "Joe of Winton" thought of Hodge's engraving from Sir Joshua's portrait of "Trinity College Tom."

John Hall (Raimbach's master) conveyed to copper Sir Joshua's efflorescent and dehaunched face of Richard Brinsley Sheridan.

John Keyse Sherwin's engraving from the Royal Academy three-quarter of Sir Joshua, by himself, is highly praised in the quarto volume of Testimonies to the Memory of Reynolds, published immediately after the great painter's death. Has not Mr. Taylor (vol. ii., p. 382) confounded Sherwin the engraver with Hamilton the painter? William Hamilton certainly did paint Mrs. Siddons in "The Grecian Daughter."

Another good contemporary engraver after Sir Joshua was Jones, the father of George Jones, the painter and Royal Academician, and one of Chantrey's friends and executors. Lord Crewe's portrait of Charles James Fox was engraved in 1784 by Jones. The Crewe portrait is (we believe) the original picture,—the Holland House and Holkham pictures repetitions only touched upon by Sir Joshua. Mr. Taylor (vol. ii., p. 430) thinks differently, but omits to mention that Jones's engraving was made from Lord Crewe's picture, and that Reynolds and Fox were both alive when Jones's engraving was made. And here observe, attentive reader of Mr. Taylor's volumes, that in page 586 of the same volume, Mr. Taylor informs you "That the last portrait from Reynolds's hand is that very fine one of Mr. Fox, at Holland House, in which not the slightest diminution of power is perceptible." We have our doubts, and believe in the Holkham picture, not the Holland House one.

We wish that Mr. Taylor could have found a place for the preamble or opening paragraph of Sir Joshua's "Will." It is very touching:—

"As it is probable that I may shortly be deprived of my sight, and be incapable of executing any formal will, I desire that the following Memorandum may be considered as my Last Will and Testament. I commend my Soul to God in humble hopes of His mercy, and my Body to the Earth."

The preserver of the lineaments of two generations of English talent and English beauty had not forgotten in old age the lessons he had learned in his youth from his father at Plympton.

We shall return to these volumes. What Mr. Taylor calls Reynolds's "rupture" with the Academy, well merits extracting, and calls for criticism. One word more by way of present conclusion. Sir Joshua's "Funeral Card" was the work of Bartolozzi's graver; we know of only one copy of it. A fac-simile of the card would have been an acceptable addition to Taylor's "Life and Times of Sir Joshua Reynolds."

#### THE CORONER'S ANNUAL REPORT FOR CENTRAL MIDDLESEX.

DR. LANKESTER'S second report to the Social Science Association, has been issued (1, Adam-street, Adelphi, London). It runs from 1st August, 1863, to 31st July, 1864. Accidental deaths had increased greatly; there were seventy cases. Increased traffic and the enormous development of building industry in the centre of London, are stated to have been the chief causes of the increase. The latter, the coroner says, he has no hesitation in ascribing chiefly to the rashness and carelessness of workmen, and to intoxication; the precautions made in many instances by masters being set at naught. As to the former, the reporter suggests that vehicles ought to be compelled to proceed at a walking pace in turning corners, and in passing great crossings. One half of the accidents occur to persons above sixty, a large proportion of them to persons above sixty; showing that activity is requisite to escape accident in the streets. The deaths from natural causes requiring inquests arose chiefly from diseases of the heart and lungs; there was an increase of 120 on such inquests. The increase of infanticide is fearful; the coroner estimates that there must be 12,000 women living in London alone who have secretly destroyed their offspring! Twelve thousand female infant-killers! One great cause of this, besides the public reprobatation, and the fear of losing caste, is the fact that the putative father of the child very seldom contributes to its support. Of seventy-five cases added, only two were exceptions in this respect. The increase of infanticide in London is so alarming that the coroner thinks it demands a special inquiry.

## ANCIENT CHRISTIAN TOWNS IN CENTRAL SYRIA.

THE ARCHITECTURAL MUSEUM.

A LECTURE was delivered on Tuesday night last, in the theatre of the South Kensington Museum, before the members of the Architectural Museum, by the Rev. George Williams, B.D., Fellow of King's College, Cambridge:—Subject, "Ancient Christian Towns in Central Syria," recently discovered by Count M. de Vogüé. The chair was occupied by Mr. Bressford Hope, President of the Society.

The lecturer, having been introduced to the meeting by the president, proceeded to say that he had only one matter to regret in presenting himself before the meeting, namely, that the Count de Vogüé himself was not there to tell them of his remarkable discoveries in Central Syria. The count was about to visit the country, but, unfortunately, not before the present session of the museum had been brought to a close. The plans and drawings before the meeting were kindly sent to him by the count, with a view to illustrate the lecture. The first thing to be explained was the situation of the recently discovered cities. Two groups of cities had, in fact, been discovered, but the lecture would be confined to one of them. The count spoke of both groups as being situated in Central Syria—one in South-Central, the other in North-Central Syria; and reference would on that occasion be made to the northern group. They lay in a mountain region, in a triangle of which Antioch, Aleppo, and Apameia were the apices, and on the right bank of the river Orontes. On the several parts of the district were known in the country by the names of Jebel Riba, Jebel Ala, Jebel Alaka, and Jebel Semad. A great part of the country was quite unknown, and has been, and is still, quite a blank in our geographies. Thanks to the successful explorations of the Count de Vogüé and his companion, Mr. Waddington, in the year 1862, it would not remain an unknown country. He would give them, in the count's own language, an idea of the extent of his discoveries in this particular place. Writing of the district, he said,—

"I do not believe that there exists in all Syria a collection which can bear comparison with that presented by the ruins of these countries. I am almost tempted to refuse the name of ruins to a series of towns almost intact, or, at least, of which all the elements remain, sometimes overthrown, never dispersed, the sight of which transports the traveller to the sites of a lost civilization, and reveals to him, so to speak, all its secrets. In passing through those deserted streets, these forsaken courts, these porticoes where the vine entwines itself round mutilated columns, the experience is sometimes analogous to those which are felt more strongly at Pompeii—for the climate of Syria has not preserved its treasures so well as the winds of a tempest, but more freshly here, for the civilization which we here contemplate is less high than that of the Augustan age. In fact, all these cities, which are more than a hundred and fifty in number, within a space of thirty or forty leagues, form a whole, from which it is impossible to detach any part; where, by a method and a system, belonging to the same style, to the same system—in short, to the same epoch, and that the epoch of primitive Christianity;—where, hitherto the most unknown in an artistic point of view; extending from the fourth to the seventh century of our era. We are here transported into the midst of a Christian society, and discover its manner of life,—not a life of luxury and splendour, as has been commonly imagined, a degraded, timid, suffering state of existence; but a life of freedom and opulence, addicted to the arts; in large houses built with huge blocks of dressed stone, perfectly arranged, furnished with their covered galleries and balconies, beautiful gardens planted with vines; with wine-presses, cellars, and stone casks; with large subterranean kitchens, and stables for horses, in courts surrounded with cloisters; elegant bath; magnificent churches supported by columns, flanked by towers, encompassed by splendid tombs. Crosses and monograms of Christ are sculptured in relief on most of the gates, and numerous inscriptions may be read on the monuments; in which however—from a sentiment of Christian humility, which forms a remarkable contrast with the vain-glorious display of the ancient nations—are to be found no proper names of individuals; only pious sentences, passages of Scripture, monograms, and dates. But the tenor of these inscriptions points to an epoch closely following the triumph of the Church. . . . By one of those phenomena of which the East offers frequent examples, all these Christian towns were abandoned on the same day, probably at the time of the Musulman invasion; and since that time they have remained untouched. But for the earthquake, which have thrown down many of the walls and columns, nothing would be wanting but the timber and wood-work of the houses."

That was a general description of what he would endeavour to refer to in more minute detail. Time would not permit him to go into a history of Syria during the fifth and sixth centuries, but during that period the state of Syria was highly unsatisfactory. It suffered from invasions of the Saracens, who captured and destroyed the three boundary cities. It is also matter of history that Justinian caused the cities to be rebuilt, and with such strength and beauty that they became more prosperous than before. One had little reason to doubt that the group of

cities was rebuilt about the year 544, and it was believed that they were abandoned about the year 638. They were not destroyed by the Arabs, who dwell not in houses but in tents, a fact which accounted for the comparatively perfect state in which they were discovered by Count de Vogüé. He desired to say a word as to the importance, in an architectural point of view, of those recovered cities; and here he would again allow the Count to speak, as it was well shown in his "History of the Temple of Jerusalem," the 5th part of which had just reached this country. He said,—

"In the west, from the fourth to the eighth century, the style of building is miserable: the Basilicas of Rome, constructed during that period, are an unsightly collection of materials, torn from ancient monuments, supported on bad walls of rubble-work. Architecture eked out an existence on an old fund of Roman traditions, which continually becomes more and more exhausted. In the east—at least in Syria—during the same period, the art did not undergo the same deterioration. Under the impulse of an emancipated Christianity, a wealthy society, habituated to material property, less manacled in its existence than the western provinces of the empire, built themselves towns and country houses, churches and tombs. The Greek artists employed remained faithful to the good traditions of the school, and to massive masonry without mortar—to the judicious and discriminating employment of materials—to the study of the special conditions of climate and design. In this way and under the empire of necessity, they created by degrees a new style, which has neither the delicacy nor the perfection of the ancient, but which has a logic and sometimes an originality of its own. The old processes were familiar to them; they still knew how to build in great blocks of from 15 ft. to 17 ft. in length; to quarry monolithic columns; to place them in porticoes; to arrange them along their churches. They knew how to carve stone windows in slabs of basalt; to cover stone houses with long tiles of stone; to carve capitals in a style, debased indeed, but still vigorous. Byzantine art has been generally unfairly judged up to this time, because the elements necessary for a serious appreciation of it were wanting. It was only known at all by some small monuments of a late date, erected during a period of real decay, &c., after the Mahomedan invasion, and the great disturbances consequent upon it. The period, truly fruitful, and important for the history of art, viz., that which extends from the fifth to the eighth century, was not represented, or, rather, the monuments of that epoch which are found in Syria were not known; and, although they are numerous and very well preserved, they had escaped the notice of travellers. Entire towns remain in the mountains which surround Antioch, with their public and private edifices, civil and religious, still standing, and accompanied with inscriptions which give their date. This whole collection has been recovered by us, and I venture to say that the publication of our drawings, no epoch will be better known in all its most minute details."

He had made inquiry of the count in reference to the material used on the buildings, and had ascertained that it was calcareous stone, and almost Jurassic limestone, only not so hard; that it was easily cut when new, and hardened when exposed to the air. He might mention that the stone for each building appeared to have been quarried on the spot, and that the quarries were afterwards utilized, being used for kitchens, or basement stories, or for cisterns, or other useful purposes, in connexion with the building. The drawings and plans before the meeting, gave a very accurate idea of the arrangement of the dwellings. Here was one (pointing) the pavement of which remained fully perfect. The houses were of two stories, and were surrounded by vineyards. There was a colonnade along the front of all of them, almost always round the south and west sides. The next plan he would refer to was a villa residence—a palace, as the count called it. There was first the porter's lodge; then the entrance by which visitors would approach; then a hall leading into an open court, with portico, from which court there was an entrance to a dining-room, apparently, or into another chamber at the side of it, or the visitor might go by another passage into the great hall, which was 50 ft. or 60 ft. long, by 30 ft. or 40 ft. wide,—the principal room, no doubt, of the house. There were two terraces, and underneath them the kitchen and offices of the building, and there was a raised court, with stables, and probably coach-houses. The count mentioned, as a remarkable feature, that near the house was the family mausoleum, and in its vicinity other tombs, perhaps those of the servants and dependents of the family. They were covered with texts and emblems, full of the glorious hope of the resurrection to eternal life. There was nothing indicating sadness or mourning. It was clear that the survivors regarded the tombs of their relatives and ancestors with no such gloomy views of death as he was afraid were very commonly entertained by Christians of the present day. The lecturer having pointed out the details of other houses by the aid of diagrams, proceeded to speak of the ecclesiastical ruins discovered by Count de Vogüé. One was seen, by reference to the plans produced, to be a large church with its portico and colonnades in front, and its narthex, a peculiar feature in Eastern churches; another

was a long church with single aisle, with apsidal termination in the middle; an altar, with, at either side, the prothesis and the diaconicon. At the north was a small chapel unconnected with it; and another lay to the north of that, only separated from it by the street. It had its narthex, and also a curious feature in many of the Eastern churches, namely, that the north and south ends of the narthex formed towers. He should mention that all the porticoes faced either south or west. Another of the churches had a double aisle and a narthex, the north and south terminations of which were taken off to form towers. Some of the churches had evidently been originally constructed running north and south, and had been subsequently altered so as to run east and west. The most important and interesting of the ecclesiastical remains he had now to allude to, namely, the Church of St. Simeon. If a line were drawn on the map between Aleppo and Antioch, the church would be a little to the north of it. The district took its name from Simon Stylites, who lived in the church or convent of which a drawing was before the meeting. There were also enlarged plans, by which they would be enabled to follow the general arrangements. It was built in the fourth or fifth century, and was thus described by the historian Evagrius, who lived about 100 years after it was built. The extract he was about to read was translated from the original Greek by Mr. Paley, of Cambridge, he (the lecturer) not wishing to do so as he had a theory on the subject of the church, and preferred that it should be done by one who had not, and who besides had published several works on architecture, Gothic mouldings, &c. Evagrius said,—

"Let me now give an account of another wonder which I have myself seen. I was anxious to examine the holy place where this saint resided, distant about 40 miles from Antioch, and situated near the very summit of the mountain. The natives call it 'The Monastery,' holy Symeon, I suppose, having been queathed to the place a title suited to his ascetic life. The slope of the mountain extends about three miles. The plan of the church is cruciform, being built with porticoes (i. e., nave, transept, &c.) on the four sides. Along each side of these porticoes are ranged pillars, beautifully wrought, of cut stone [or polished marble], which carry up the roof to a considerable height. The central part of the church is a court, open to the sky, and on the finish of which the most art has been bestowed. There stands the famous pillar, 60 ft. high, on which that incarnate angel on earth passed his celestial life. Towards the roof of the porticoes described are small barred [or closed] apertures, or windows, as some would call them [i. e., clerestory] looking both into the open space above mentioned, and also towards the porticoes. On the left side, then, of the pillar [standing], close at the window, I saw, together with the whole crowd of people assembled there, as the rustics were dancing round the pillar, [i. e., with the crowd in the portico who were looking through the window at the rustics dancing in the central court.] a very large star gliding across the whole space of the window, and flashing light; and this not once, nor twice, nor thrice, but many times. Often it would disappear, and then again suddenly show itself. This only occurs on commemoration days of the saint. There are some who assert (and we have no right to reject the miracle, both from the good faith of those who relate it, and from the other miracles which I have myself witnessed), that they have seen the actual face of the saint flitting hither and thither, with a long beard, and the head enveloped in a tiara, as had been his custom in life. For thus close do the men who are natives of the district approach without let or hindrance, and often go round the pillar with their beasts of burden. There is, however, a very strict guard (I know not why) to prevent women from entering the church: they stand outside by the threshold and view with amazement the miracle, for one of the doors is right opposite to the glittering star."

The same delusion as to the Holy Fire was long kept up at the Holy Sepulchre in Jerusalem, and the one was no doubt borrowed from the other. At the east side of the church were its apsidal terminations. The centre was a court open to the sky, as was also the centre—according to Eusebius—of the Church of the Holy Sepulchre. The western end of the church was supported on arches, owing to a steep valley, which rendered such an arrangement necessary for the protection of the building. Mr. Pocock

100 years ago gave an interesting account of this church. Mr. Josiah Conder, speaking of it, and introducing what Pocock had written, says,—"About six hours north-west of Aleppo, and to the north of the road, is the rimed convent of St. Simon Stylites, which, in the sixth and seventh centuries, was very famous," as well as on account of the devotion paid to its saint as for the spaciousness and magnificence of its buildings. Some say the saint lived here on the top of a pillar; others, that he lived on the top of the mountain for sixty-eight years.\* The whole convent is above a quarter of a mile in length. "The church especially," says Pocock, "is very magnificent. It is built in the form of a Greek cross. Under the middle of an octagon dome are the remains of the famous pillar on which they say St. Simon lived for so many years. What remains of it was hewn out of the rock, that is, the pedestal, which is 8 ft. square, and a very small part of the column. The part of the cross to the east of this was the choir, at the east end of which are three semicircles, where, without doubt, there were three altars"—(they were not altars, but an altar, the prothesis, and the diaconicon)—"and the entrance to them are adorned with reliefs. The whole church is of the Corinthian order, which is executed in the best proportion under the octagon dome;"—(writing 1,200 years after Evagrius, Pocock makes especial mention of this fact, which Evagrius also particularly notices)—"but the other parts," continued Pocock, "show something of the decline of architecture." It was a remarkable fact that Mr. Paley, in drawing a diagram of the form of the Church, made its court an octagon, and that without any mention of it by Evagrius, and without having seen the plans or heard anything upon the subject. He did so, he subsequently stated, when he came to consider how the various parts mentioned could best be brought together, and having in his mind at the time the tower and lantern of Ely Cathedral. The photographs of the apse would show its present state, and the meeting would see with what immense solidity the building must have been erected. He (the lecturer) trusted that now the way had been opened up by the Comte de Vogüé and Mr. Waddington, the country would be even more fully explored. They had, however, left little for their successors to do, as they possessed every qualification for the task which they undertook and which they had so successfully carried out. In the absence of the Comte de Vogüé he could only express the satisfaction he (the lecturer) felt that it had fallen to his lot to introduce to that large audience those important and most interesting discoveries.

Mr. Bevesford Hope, in proposing a vote of thanks to the lecturer (which was subsequently carried by acclamation), said that one would have thought, from the thorough acquaintance with the subject manifested by the lecturer, that it was he, and not the Comte de Vogüé, that had made the explorations. It was saying little to mention that those discoveries marked an epoch, not merely in the history of architecture pure and simple, but in the history of Christianity, and of civilization itself. They had been as it were brought face to face with the recovered cities, and saw how much of teeming life they contained, and how high a state of civilization had been attained there; and, what was of more interest, that that teeming life was not the life of Paganism, but of Christianity engrafted on the purest type of art. He had no doubt that the ground, once opened up, would be thoroughly investigated; and he hoped that when it was, the man to whom the credit of the discovery was due would not be forgotten in the later researches of those who came to reap the harvest which he with so much labour had sown.

#### THE APPROACHING DANTE FESTIVAL.

The Dante Festival, to celebrate the sixth centenary of the birth of the great Italian poet, is now occupying the attention of all classes in the capital of Italy. Strangers are flocking in from all parts: rumours are heard that crowned heads are expected to honour with their presence

the approaching *fiets*. The city itself is beginning to hustle with innumerable flag-staffs with gilded heads, destined to hold the national banners,—the town of the "Contadi," (or divisions of the town) &c. The statue, to be inaugurated on the 14th, the first day of the festival, is being now raised to the top of the pedestal prepared for it in the Piazza Sta. Croce. The piazza is covered around the statue, almost to the houses, with flooring, on which seats are raised, for those persons who form the procession on the 14th. The open space between the buildings of the Uffizi is being prepared for the people's ball, on the night of the 16th. Libraries and depositories of archives have been searched for rare editions of Dante's works, and all memorials relating to him, or any persons or subject of interest mentioned by him in his works, or connected with him. These are to be exhibited in the Bargello during one of the three days of the festival, and will be to many the chief attraction offered. Other towns of Italy, in which different periods of Dante's youthful life were passed, and Ravenna, where he died and was buried, will also commemorate the day, with all available and appropriate honours.

In Florence, the birthplace of the greatest poet of his time, and, according to some authorities, the abode of his ancestors so early as the eighth century, will be concentrated, during these three days of festivity, all that is interesting to the antiquary and the artist, connected with the period in which Dante Alighieri lived. The programme now issued announces that, besides the numerous analogous decorations of those parts of the city through which the procession will pass, on all those houses in which were born, lived, or laboured the most renowned citizens, shall their names be inscribed, and ornamented with trophies, laurels, and flowers.

On the morning of the 14th, will take place, as we have said, the inauguration of the statue of Dante, preceded by a procession of the representatives of the Italian municipality, literary and scientific academies, universities, colleges, societies, all with their respective banners, through the principal streets of the city; illuminations, music, choruses in honour of Dante in the evening.

Monday—in the morning, literary meetings in different localities; in the evening, a musical entertainment in honour of Dante in one of the theatres.

On Tuesday there are so many different attractions for every hour of the day, that the obitutions alone are likely to profit by them all.

The most interesting will be the assembly of confraternities of artisans, and benefit societies with their respective insignia.

"Quadri Viventi" tableaux vivants, the subjects chosen from the "Divina Commedia" of Dante, with recitations.

Opening of the Dante Exhibition in the Bargello.

Then there will be a popular *fiets* in the Cascine (the Hyde Park of Florence) in the afternoon.

Horse races. The people's hall in the evening. Picture galleries, theatres, horticultural gardens. All to be opened to the people during the three days. The King of Italy will of course be present at the uncovering of the statue and the greater part of the festival.

Although, as is most evident, all tends to make the approaching festival a *fietsa del popolo*, still there will be much to gratify the eye and instruct the mind of the lover of archaeology.

#### ON DEFENCES AGAINST EPIDEMIC VISITATIONS.

MR. EDWIN CHADWICK recently paid a visit to the neighbourhood of Salisbury, and, by invitation, examined the new drainage works in that city. There was a city meeting, to hear an address from him on these works, the result of the formation of which we have already noticed in the *Builder*. Mr. Chadwick also treated of the means of meeting epidemic visitations. The mayor was in the chair, and the meeting was attended by the members for the city, the clergy, and local medical authorities, together with the chief inhabitants of the city.

In course of his address, Mr. Chadwick said:—

"The extraordinary epidemic which is spreading in Russia is described as the plague, and the plague is now generally admitted to be an intense typhus. Medical officers who have served during plague visitations in the Levant have described to me typhus cases with buboes (which occasionally occur in this country during severe

epidemic visitations of typhus) as identical with those they have dealt with at Malta and in the East as 'the plague.'

In respect to the new works which the city has provided for itself, and set an example to all other cities of what they may do for themselves, having examined them, I now state, in the form of what system of what system of self-cleaning tubular drains and sewers, human fecal matter is no longer retained in cesspools, or in brick house drains, or in larger sewers of deposit, to stagnate and ferment, and give off foul emanations from beneath and amidst habitations, but is in a constant state of removal, and is removed before it can enter into advanced and noxious stages of decomposition. The excreta of the morning is received into the water with which every house is now provided. It is immediately removed in water. Before noon it is distributed in water. In its unfermented, and, as nature, in its unworked condition, it is for the most part,—for this portion of the work is not quite so complete as it might be,—exercising its fertilising power over the water meadows below the town. The sewage discharged from the old sewerage works of London and other cities into the sewers in putrid sewage generally a year old, flushed out in annual cleanings or by occasional storms. The fresh sewage constantly discharged from your new works may,—sometimes within little more than a week,—be converted into sweet-smelling grass,—may be fed upon and returned to the town as enriched manure. By a good arrangement of water-closet apparatus and self-cleaning house drains, and sewers in substitution of the ancient cesspools, you have set a mechanical example to the British metropolis, and to the most advanced cities of the world. The cesspools, which are only extended cesspools, costing twenty thousand pounds per annum for intermittent cleansing; you set an example to the French metropolis, which, in the summer time is rendered unpalatable to those who can get away from the emanations from the accumulations retained within its fosses or cesspits; to Manchester, the city of mud-puddles, where, in twenty-six thousand cesspools, the most unhealthily in England; your mechanical example has gone far to show to such cities that at less than the annual cost of cleansing those cesspools, and accumulating labour, and the expense to the man and the *eidgenour* may be dispensed with. But with the engineering example, you present to them the vastly higher example of the sanitary results obtainable by the mechanical power of household and civic drainage. Your ancient cities, in the former entire ignorance of sanitary science, scourged with such plagues as that which scourged the celebrated city of Petersburg, and the ordinary death-rate in the old and small-roomed houses was, so far as may be made out, about forty-four in a thousand—a rate such as yet prevails in the lower districts of New York, as well as in our older and richer cities. By larger and somewhat better houses the death-rate was reduced. On examining the statistics of the nine years before the completion of the new works, it appeared that the rate is rendered unpalatable to those from twenty-two up to thirty-five in a thousand, or an average of about twenty-seven in a thousand exclusive of the cholera year. The fluctuations during the nine years, since the completion of the new drainage works has been from twenty-five to fourteen in a thousand, or an annual average of twenty in a thousand; and to every case of death reduced, the rate is generally only about twenty cases of sickness reduced. In round numbers the average death-rate may be said to be reduced one-third, that is to say, it is now as if every third year were a jubilee year in which the death-rate was reduced one-third. We looked with attention has been great in the deaths from foul air diseases, as might be expected, but most marked in those which are intimately connected with moisture, as well as those of which the deaths result from phthisis, and hence drainage had been reduced to an average of one-half that which prevailed before drainage. Your existing death-rate, I should say, after present sanitary arrangements, is now as if you have reduced the exposure of the population to extraordinary epidemics by about one-third.

My more immediate object is to point out the simple available means by which exposure, both to extraordinary and ordinary epidemics, may be still further diminished. Whatever may be the causes of extraordinary epidemics, the greatest intensity of the attack upon human beings is almost always found in certain localising conditions. The first renewed visitation of cholera in different towns often appeared in the same streets, on the same sides, in the same houses, and sometimes in the same rooms, though the inhabitants had changed. In the course of my inquiries I met with one instance in the city of York, of a small court which, by tradition, was the spot where the great sweating sickness of 1551 appeared, then the great plague of 1664, then others, and the first visitation of cholera; the place was popularly called the "hogworm's nest." The hogworm is a species of snake which haunts dung-heaps. We looked with interest to see whether the place was true to its traditions in the second visitation of cholera, and we found it was so. We know the chief localising materials for epidemic visitations. There is, as it were, the charcoal, the nitre, and the sulphur which exist in ordinary times inertly, till there comes some atmospheric condition, the light which creates the explosion and makes the materials destructive. Some forms of extraordinary epidemics we can create. In two prisons there were extraordinary epidemics of a dysenteric form; in both, after a time, it was found that old sewers had been allowed into the walls from which the prisoners were supplied with water. In one prison there was an extraordinary epidemic of typhus. It was found that the antecedent cause was the clearing of the adjacent ancient mill, the wind having been slowly and steadily in the direction of that part of the prison where the epidemic first appeared. It was and is very extensively prevalent in the pestilence brought into towns by tramps. The first outbreaks of fever are in common lodging-houses. But where the provisions of the Lodging House Regulation Act are not observed, the more free from fever than are prevented, where some means of ventilation for the sleeping-rooms have been enforced, water introduced into them, cesspools abolished, and means of cleanliness promoted, the inmates are more free from fever than are the great bulk of the artisan class, the occupiers of weekly tenements, to whom no such protection will be conceded—by the landlord legislators of the House of Commons. If the sanitary measures which have been accomplished in this city—a constant water supply, the abolition of the poison-pit, the cesspool, or the midden-street, and complete new drainage works, and tubular drains—were accomplished in London, and all other cities, towns, and villages, the saving of life in England and Wales alone would be upwards of one hundred thousand per annum. But if the sanitary condition of the wage

\* May not both statements have been correct? May he not be conceived to have "passed his celestial life," of entrancement, by night, on the top of the pillar; and his ordinary or terrestrial life either on the mountain or elsewhere? Such an arrangement would have at least been less preposterous and impossible than the common idea as to St. Simon Stylites.—Ed. B.

THE CHURCH OF ST. BARTHOLOMEW, DUBLIN.—MR. T. H. WYATT, ARCHITECT.

Plan.

THE NAVE ROOF, ELY CATHEDRAL; LOOKING WEST.  
PAINTED BY THE LATE MR. LE STRANGE AND MR. T. GAMBIEP PARRY.

## THE ARCHITECTURAL ASSOCIATION.

The usual meeting of members was held at the House, in Conduit-street, on Friday, the 28th ult.

The chair was occupied by the president, Mr. J. H. Christian.

Mr. H. Lockwood, of 8, Euston-road, was elected a member of the Association.

Mr. J. Lemon stated that the programme of the voluntary examination class had been settled, and that there would be three meetings in May, two in June, one in July, three in October, two in November, and one in December, the series terminating on the 11th of that month, when the subject would be "Gothic Architecture," and the "detail," "plan, section, &c., of wall of house five stories high, with fire, &c." The other subjects included in the programme would embrace geometrical drawing; carpentry and joining; strength of materials; iron; heat, light, and ventilation; Classic architecture; valuations and compensations; masonry; estimating artificers' work; mechanics; and plumbing, painting, and glazing. Mr. Lemon added, that it would be desirable that members attending the class should bring a subject for detail with them. The first would be a timber truss for an open roof.

Mr. J. D. Mathews reported that about fifty members of the Association had, on the 8th ult., visited the new hotel at Charing Cross, in course of construction, under Mr. E. M. Barry; and that subsequently they had paid a visit to the church of St. Bartholomew, West Smithfield, now in course of restoration, under the direction of Mr. T. Hayter Lewis, who had kindly made arrangements for the admission of members of the Association to take drawings within the building.

A vote of thanks was passed to Mr. Barry and to Mr. Lewis, for the facilities they had extended to the Association.

Mr. Mathews stated that he had received a communication from Mr. Burns, the architect of the new mansion now in course of erection at Whitehall Gardens, for the Duke of Buccleuch, stating that the works were not yet in a convenient condition for inspection, but expressing his readiness at a future time to admit the members of the Association to view them.

A member inquired whether the report was correct, that the mansion in question had been purchased by Government with a view to its conversion into a public office.

The Chairman said he believed such to be the fact.

Mr. L. W. Ridge announced that on Saturday, the 6th instant, at 3 o'clock in the afternoon, it was proposed that the members should inspect the new model dwelling-houses for the poor erected by the trustees of Mr. Peabody's gift in Green Man's-lane, Essex-street, Islington, under the direction of Mr. Derbishire.

Mr. Mathews brought under notice a letter which had been received from the Royal Institute of British Architects on the subject of the memorial presented by the Association in reference to the voluntary examinations. The letter stated that the memorial had been laid before the council at their last two or three meetings, and that after careful consideration the honorary secretaries were instructed to state as follows:—

"The names of all passed candidates would be printed in the same manner as the prize-list year by year in the Transactions of the Institute. Thus one of the chief points of the memorial, which we hope, will be made satisfactory. The others, it seems, can hardly be now considered, as the regulations have been circulated so far and wide as applying to next year. But this is only one of many reasons which have led the Council to postpone the further consideration of the suggestions till after the next examination. It is hoped that the discourses now being delivered at the Institute on subjects peculiarly connected with examination papers, and the readiness the Council always shows to listen to every suggestion from those proposing to be examined as well as from the examiners and others engaged in conducting the examinations, will prove the increasing interest of the Council in the matter of the voluntary examination. In order to make them again successful it is only necessary for the students to offer themselves in sufficient numbers for the regulations to be properly carried out."

The Chairman said, that in his opinion this communication was a most unsatisfactory one. The first portion, it was true, conceded what had been asked in the memorial, but the remaining portions of that document had been entirely shelved.

Mr. Ridge observed that there was an idea prevalent among architectural students that there would be no use in going up for the examination this year as the whole matter would have to be reformed next year. This consideration, no doubt, operated in the minds of many

who would otherwise prepare for the examination.

Mr. L. C. Riddett considered the letter most unsatisfactory, as it was not in fact an answer to the memorial. There was not, for instance, any reference to students having the use of the library of the Institute on payment of one guinea.

A member inquired whether any answer had been forwarded to the letter just read, which he described as an extraordinary piece of composition coming from a learned body.

Mr. Mathews said, the letter (which bore the date April 26th) had only just been received, and that no answer had been sent to it.

The Chairman said, he was certainly in favour of not allowing the matter to rest where the Institute appeared disposed to leave it. At the same time, he would recommend gentlemen to prepare themselves and go up for the examination, but that the Association should not accept the answer of the Institute as final.

Mr. Blashill quite agreed in the view taken by the Chairman, and recommended, that as many members as possible should go up for examination. It ought not, he thought, to be forgotten, that they had many friends in the Institute who might be discouraged if the Association were to hold back.

After some discussion, in the course of which a very general opinion was expressed that the answer of the Institute ought not to be considered as final, more especially as a new council would shortly be elected, it was resolved that the letter should be referred to the committee of the Association.

Notice was given for the approaching "business meeting" of a motion to alter the hours of meeting from half-past seven to eight o'clock, experience having proved that business was not commenced at the former hour.

Mr. T. R. Smith then read a paper on "the conduct of business."

It was announced that the next subject for the Class of Design would be the "Interior of a Belfry;" and that on the 26th instant, Mr. C. L. Eastlake would read a paper on "Nuremberg."

## INSTITUTION OF CIVIL ENGINEERS.

At the meeting, April 11th, Mr. Hutton Gregory, V.P., in the chair, the paper read was on "The Festiniog Railway for Passengers, as a 2-ft. Gauge, with sharp Curves, and worked by Locomotive Engines," by Captain H. W. Tyler, R.E.

This line was designed to facilitate communication between the principal slate and other quarries in the county of Merioneth and the shipping places, and for the conveyance of coals and other heavy articles to the quarries and mines. As in 1832, when the Act for its construction was obtained, the population was very limited, the line was laid out in an economical manner, with a width between the rails of 2 ft. only. It commenced at Portmadoc, and after passing along the Traeth Mawr embankment, it ascended to the mountain terminus at Dinas, the level of which was 700 ft. above the station at Portmadoc, by an average gradient of 1 in 92, for 12½ miles, the total length of the line being 13 miles. The steepest gradient on the portion now used for passengers was 1 in 79-82, and on that traversed by locomotive engines 1 in 60. Some of the curves had radii of 2, 3, and 4 chains. The maximum super-elevation of the outer rail on 2-chain curves was 2½ in. for a speed of 8 miles an hour. The estimated cost of the line was 24,185l., but the parliamentary capital was raised to 50,185l.

The quarries being situated at different altitudes in the mountains, the slates were first brought down the quarry inclines to the railway, and the trucks were collected until fifty or sixty had accumulated to form a train, which was then allowed to run down by gravity. Until the year 1863, the empty trucks, or those loaded with coals, goods, furniture, materials, machinery and tools for the quarries and the neighbourhood, were drawn up by horses, who travelled down with the trains, as on mineral or colliery lines in the north of England. As the traffic increased, the line was gradually improved, by flattening the curves, by making heter gradients, and by improvements in the permanent way, and as the trade still continued to progress, the practicability of employing locomotives was constantly discussed. The apparent difficulties caused the idea to be more than once abandoned; but ultimately, in June, 1863, two

locomotive engines, designed by Mr. England, under the direction of Mr. C. E. Spooner, the engineer to the company, were placed upon the line, and having been found to be successful, two others were subsequently supplied. These four engines had run 57,000 miles up to February, 1865, without leaving the rails. During the last autumn, the company carried passengers without taking fares, but at the commencement of the present year the line was regularly opened for passenger traffic. In ascending from Portmadoc, the passenger-carriages were drawn by the engines with other vehicles, the passenger-carriages being placed between the empty slate trucks, which were always last in the trains, and the goods waggons which were next behind the tender. In descending, the loaded slate trucks, with empty goods trucks attached behind them, ran first in a train by themselves: the engine followed, tender first, and the passenger vehicles brought up the rear, with a break in front, but detached from the engine and tender, and at a little distance behind them. The speed was limited to about six miles an hour in passing round the sharpest curve, and to ten miles an hour on other parts of the line.

The author conceived that the employment of locomotive engines on this little railway, and its opening for passenger traffic, were not only highly interesting experiments, but were likely to be followed by important results. Although there were still doubtless, numerous districts where railways on a gauge of 4 ft. 8½ in., might be profitably made, yet there were also many others in which lines of cheaper construction were required.

It was, however, illegal at present to construct any passenger lines in Great Britain on a narrower gauge than 4 ft. 8½ in., or in Ireland than 5 ft. 3 in. Consequently, it would appear to be desirable to endeavour to obtain the repeal, or at least a modification of the provisions, of the Act 9 and 10 Vict., cap. 87, which regulated the width of the gauge of passenger lines, as there was now an increasing demand for railways of a minor class.

## OUR THEATRES.

The sole advantage which can be claimed for the theatres of the ancients over modern ones, is that they were not at all of a tinsel constitution,—not in the least liable to be attacked by a sudden mortal inflammation in the bowels, by which disorder more than one theatre has lately been carried off. Yet, with that single exception in their favour, those venerable archaic theatres must be confessed to have been most bunglingly contrived, or rather not contrived at all, to produce anything like scenic illusion and stage effect. For expressing my not very flattering opinion of primitive theatres thus unceremoniously, I ought, perhaps, to make apology; yet, as that might detain me too long, I pass on to the rather irksome question: after all our experience, and undoubtedly great, even vast, improvements in theatre building, have we at last reached that unfortunate full stop and *plus ultra* beyond which further advance is quite hopeless? Notwithstanding the perfection to which scenery and spectacle have been brought, the importance attached to, and the expenditure lavished upon them, the arrangement of our theatres is, and is likely to continue to be, such that the stage decorations can be seen—as far as seen at all—only to a very great disadvantage by a very large proportion of the visitors.

The evil is not irremediable: on the contrary, the cure for it is obvious enough; but perhaps it will be thought too much akin to the wisdom of teaching children how to catch birds by merely putting salt on their tails; for the remedy resolves itself into the simple artifice of putting all financial considerations, with their attendant obstacles, entirely aside.

It is palpable to common sense that every one should be seated, not only directly facing the stage, so as to have a clear view of it—which, by the by, was not the case in the arrangement of an ancient Greek theatre,—but likewise, as nearly as possible, on the same level as the stage itself. Yet how is this simple common-sense rule attended to? or what would be the consequences if it were? Why, at one fell swoop, away go all side-boxes and the acroatic tiers of these or any other boxes, whose those so unluckily placed and piled up to the very ceiling might be termed well-flowers, of which Royalty itself is made one, being thrust into almost the very worst situation for obtaining anything like

a proper view of the actual stage and its scenery. In looking, or even pretending to look, at a picture, no one places himself so as merely to glance at it; but in theatres as hitherto arranged, full more than half of those who are by a sort of legal fiction supposed to be spectators, can obtain no more than a mere glimpse of the stage, and that only by squinting or looking quite askance and askew; for were they to look straight forward, they would see only their opposite neighbours across the pit. Nearly sixty years ago, Thomas Hope, of ultra-Classic and architectural memory, animadverted very stringently on the grossly-preposterous arrangement of modern theatres, in which the boxes are sometimes continued nearly up to the curtain, for the small detriment of the general effect, for there should always be a neutral ground between the audience and the actors. The inconvenience is further increased when there are numerous tiers of these, in which visitors are piled up to the very ceiling,—consequently have to look down on the heads of the performers,—and of the stage can see very little more than the floor. Nor is that all; for, in case of an alarm of fire, the staircase becomes choked up by people rushing down frantically from every tier and landing.

With respect to scenery and its display, great depth of stage is the reverse of an advantage: it considerably increases the difficulty of closing in the stage by those scraps and fragments of scenes technically called "wings," which at the best are only awkward expedients and makeshifts, which, being unavoidable, must be excused and overlooked. By some,—surely rather commonplace and unimaginable sort of persons,—it has been pointed out as a very gross and palpable absurdity, that in scenes representing rooms those who enter seem to pass through the walls. Yet, taking it at its worst, that absurdity which appears to scandalize matter-of-fact people is a mere trumpery peccadillo in comparison with the outrages against probability in other respects which are so complacently tolerated and condoned. For what can be more contrary to verisimilitude than that people should let their visitors burst in upon them unannounced; and then, instead of so much as offering them a chair, leave both them and themselves to keep standing up and stalling about while they are talking? Is there not a very strong touch indeed of the ultra-absurd when one of the persons on the stage suddenly turns his or her back upon the others, and, advancing out of the stage framing nearly up to the foot-lights, becomes attacked by a perfect paroxysm of vocality? Is that at all in consonance with any other nature than what might be looked for within the walls of Bedlam? The prosaic dailies whose minikin criticism just enables them to detect a *sonnet* of the improbable, if not impossible, when the performers are made to make their entrances and exits through the walls of a room, might as well go just a step further, and try to convict Shakespeare of being unfaithful to nature; for never did any of our Richards or Henrys express themselves in anything like the splendid diction he has put into their mouths,—to say nothing of the more potent emphasis of poetical ideas which he has attributed to them. In the drama and upon the stage the aim at reality may be carried too far. Without conventionality and exaggeration we should get little better than the naturalness of tame insipidity; and the sparkling dialogue of a Congreve or a Sheridan ought to be condemned as decidedly extravagant, and grossly overstepping the modesty of nature; for never, except on the stage, did people keep up an uninterrupted flow of diligently elaborated wit; whereas they may, perhaps, without any violent effort of the imagination, be supposed to be there fully capable also of entering a room by passing through its walls, especially if made of such papery penetrable stuff as are the partitions of a London house. This last remark—an ungracious one, perhaps, it is—lands me again upon the difficult problem of either improving the constitution of side scenery—that is, the stage wings—or else getting rid of them altogether, which last expedient has been had recourse to by halting up the sides of a room-scene; also furnishing it, though in a queer sort of way, and covering the floor with carpeting, or what may pass for such; but, after all, with so little success that the very best managed attempt of the kind has as yet proved no better than a very painstaking hodge, though to the eyes of the galleries it might show as the fac-simile of a handsome drawing-room,—a tolerably large one

at any rate, there being no means—at least, yet adopted—of so contracting the stage opening as to reduce it in the dimensions of both height and width to those of an ordinary-sized room. Those who can gulp down the extravagance of a room in a cottage as big as a barn, can surely be in no danger of being choked by attempting to swallow the marvellous yet indisputable fact that, upon the stage, people can come on and go out through walls. Desisting from further remarks of this kind, I will now add no more than that, however great the artistic talent displayed in them, the productions of the scene-painter are only ephemeral, and known to his contemporaries alone. This, at least, might, in some measure, be corrected by the worthiest of them being rescued from oblivion by the graver, when, refined by soering down, and stripped of all stage drawbacks and incumbrances, they would, without retaining aught of the *stage*, preserve to us all the genuine essence of the *scenic*.

ART-LOVER.

#### ABSORBING WELLS.

I SHOULD have replied last week to the defence of the absorbing well at Barnet contained in Mr. Blenkarn's last letter, but wished first to communicate with one of the gentlemen whose name he gave in that letter as an authority for the statement that the water arising from the sands under the London clay was impure. Before I constructed the artesian well and water-works at Braintree, Mr. Pustwich so correctly indicated the depth of the different strata through which we should pass, and the depth at which the water would be obtained, that I have entire confidence in his ability; and if he had sanctioned Mr. Blenkarn's statement, although I know of more than twenty wells which derive a supply of good water from this source, I should have hesitated in repeating my conviction as to the purity of the water from the Thanet sands; but I find that there is no foundation for the assertion that any such opinion has been given by him.

The other positions taken up by your correspondent are so extraordinary that I cannot let them pass. He justifies the passing of sewer-water into the Thanet sands by the opinion that "by the action of the sands the deleterious ingredients held in solution become deoxidized, and in that condition perfectly harmless;" and that "the introduction of filtered sewage-water has a direct tendency contrary to that of rendering the subterranean water impure" or, in other words, that the sewer-water, loaded with organic matter and either ammonia or nitrogen, has a tendency to purify the main springs. If he really believes this, why does he think it so important that the artesian well at Barnet should be at a distance of 900 yards from his pure water inlet? If the *subterranean* waters are purified by the introduction of impure water, why not urge the Clipping-Barnet Local Board to form absorbing wells on the line of the ditch that passes within 40 ft. of his artesian well, so that the inhabitants using the water may have without fail the benefit of the sewer-water that runs along that water-course?

How is it, if the Thanet sands are so adapted to purify the sewer water that is let into them, that they do not have the same effect on the water that saturates them, and which he asserts to be impure?

With regard to the distance of the absorbing well from the artesian well, I do not consider 900 yards a great distance; and if, as he states, the dip of this stratum of sand is from north to south, the artesian well at the Colney Hatch Asylum will have the benefit of the purification arising from the influx of sewer water at New Barnet.

I am not aware that I have claimed to be the first who has used the sewer water for irrigation purposes. Before making the plan for the Croydon irrigation fields, I visited all the irrigation works at Edinburgh and other places then in operation; and I claim the credit of designing works within a few miles of the metropolis on a different plan from any before laid out, and which, if worked properly, will create no nuisance. I should like to know where Mr. Blenkarn carried out irrigation works more than twenty years since. If they were satisfactorily planned, I regret that he should have adopted a different mode of overcoming the sewer-water nuisance—a plan involving such serious consequences, and needing an array of chemical terms

to allay the alarm that must be caused to all owners of artesian wells by this scheme.

I suppose that Mr. B. claims to be the inventor of absorbing wells; but from the note at the foot of my former letter, it appears that in France the same attempt to poison the main springs has been made, but that the Government, acting under the advice of eminent scientific men, have put limits to the adoption of this method of getting rid of the sewer-water.

I cannot conclude this letter without saying that there are very few places where the irrigation system cannot be carried out both with profit and freedom from any annoyance; and Barnet is not, in my opinion, one of these exceptions.

JAMES FENTON.

#### THE JUNIOR CARLTON CLUB.

THE Committee of the Junior Carlton Club have completed the purchase of freehold property on the north side of Pall-Mall, having a frontage of 121 ft. in Pall-Mall, and a similar frontage in St. James's-square, by a depth of 65 ft., exclusive of areas, upon which it is intended to build a new Club-house, according to the plans which have been made by Mr. David Brandon. The building will be begun as soon as arrangements may be completed with the tenants who at present occupy the houses upon the site.

#### SANITARY MATTERS.

*Gateshead.*—A report from Dr. Robinson, the newly-appointed officer of health for Gateshead, reveals a frightful state of things with regard to the sanitary condition of this borough. In one of the busiest thoroughfares of the town, upwards of two hundred persons are located in dwellings unprovided with water-closets and undrained; and other districts are not much better off. It is considered surprising, high as the rate of mortality has been from typhus fever and other diseases engendered by filth and bad living, that the mortality has not been still higher. The Council are now determined to do what they can to improve matters, by reminding landlords that "property has its duties as well as its rights."

*North Shields.*—The chairman of the Tyne-municipal Board of Health, with several of the committee, have made an inspection of the lanes, alleys, and premises, and orders will be forthwith given to all owners of property to remove every description of nuisance; to flag, cleanse, and pave the courts and yards; and, in default, the Corporation will do the work, and recover the expense from those liable to pay. A deputation from the Board of Health inspected the cottages at Whitehill Point, occupied by pitmen, and they found that, out of about thirty cottages, typhoid fever had been existing for some months, more or less, in over twenty of the houses. The drains were in a very dangerous state, so much so, that the stench, during the summer of last year, in some of the houses, was intolerable. The Board has given notice to those responsible to, have the premises forthwith put into a more healthy condition.

*Spalding.*—A letter by the Vicar of Whapload on the Russian plague has called attention to the abominable pits of mud in his constantly fever-stricken parish. These abominations have cost thousands of pounds, and yet no effort is made to abolish the nuisance.

*Birkenhead.*—Pig-keeping here is a great nuisance. On a piece of ground in Market-street, a great number of pigs are kept in styes. The stench is very bad, and there has been a great number of cases of fever in the neighbourhood. The houses are in a filthy state and overcrowded. In twelve houses there are living 145 persons, and sleeping-rooms are built over privies. Some of the pig-keepers are being brought before the magistrates and fined.

*Kilkenny.*—Typhus fever of a very virulent type has been seriously on the increase of late in this city. The Blackquarry district, where the fever first broke out, is now quite clear of the disease; but it is particularly rife in Upper Patrick-street and Queen's-hill, and also counts many victims in the various lanes through the city. The mayor has been getting the lanes and suburbs lime-washed, and intends to apply to the Town Council for an additional sanitary inspector.

**COST OF SOCIETY OF ARTS PRIZE COTTAGES.**

WITH reference to Mr. Sinclair's letter in the *Builder* of the 29th ult., I feel called upon, as the author of the design referred to, to state that the plans and specification, upon which the estimates obtained by Mr. Sinclair were based, were, as indicated in his letter, prepared by me, and embodied not only the improvements and additions suggested by the judges in their report, but also such other improvements as had occurred to me since the preparation of the original design, in order to make them complete in every respect, without special regard to the estimated cost. It cannot therefore be expected that the estimated cost of the original design will bear a favourable comparison with the tenders obtained by Mr. Sinclair for the altered and improved plans and specification furnished to the company.

I may mention that, further than the preparation of the said plans and specification, I was not professionally employed, being quite unacquainted with the locality where the cottages were intended to be erected, and the nature of the site, and had not even heard the result of the tenders until observing Mr. Sinclair's letter.

Unquestionably the tenders obtained by Mr. Sinclair are high. Had a greater number of builders in the immediate neighbourhood, and in a much smaller way of business, been applied to, the result would, I have little doubt, have proved more satisfactory.

I have lately had occasion to obtain several estimates from local builders for similar cottages which I am now erecting upon an estate on the borders of Kent and Surrey (about nine miles across country from the nearest railway station), the result of which I beg to subjoin:—

R. Ward, Warrington.....	£312	0	0	a pair.
Kesterton & Head, Lingfield.....	257	10	0	"
R. Belchambers, Westerham.....	285	0	0	"
F. Shorter, Edebridge.....	259	13	0	"
G. Crane, Cudham (accepted)	216	0	0	"

These estimates, however, were framed upon a plan and specification embracing the improvements suggested by the society, besides plastering and colouring to walls (not included in my original estimate), but with certain modifications in regard to the offices; i.e., dispensing with the W.C. apparatus, lead pipes, cistern, force-pump, and well, and substituting a rain-water tank, 5 ft. diameter and 8 ft. deep, with pump, privies, and cesspool at end of garden, and including the cost of a pigery to each cottage, which, however, has been dispensed with in the tender accepted. Neither the timber for the roof nor the cartage of materials is included in the contract, the value of which, when added to the lowest estimate, will represent a sum close upon 250l., the actual cost of the cottages per pair to the proprietor, bearing a favourable contrast with the average cost of good cottages, with similar conveniences, stated in the report of the judges previously referred to.

It will be observed, that the locality where these cottages are being built is by no means easy of access; and it may be reasonably inferred, that under more favourable circumstances a considerable saving might be effected in the carriage of materials, an item of much importance in cottage building.

JOHN BIRCH.

**SOCIETY OF ARTS COTTAGE COMPETITIONS AND THE ARCHITECTURAL ASSOCIATION.**

SIR,—The letter from Mr. Sinclair which you published in your last, showing that the price of cottages which were to be built for 200l. a pair will cost nearly 400l., does not in the least surprise me. It is too late now to agitate the question of the revision of an unjust decision; but I think it would be wrong to allow the subject thus mooted to be dropped, without renewing in your columns the protest that the members of the Architectural Association made at the time against the double injustice of depriving them of any premium, and giving one to a design manifestly ineligible. For, sir, though the prize design was not within the margin, many of our designs (and good cottages, too) were within it. I know cottages upon my design could be built, where materials were to be had at the prices stipulated for—400l. a pair; for I had a tender from a highly respectable builder to do it. I fully admit that my cottage was not so picturesque nor the rooms so good as in the prize design; but that was solely because I did keep within the money, and

not because, had I chosen to disregard the conditions, I could not have designed as good a cottage as the premiated one. And what I know of my own design, I know also of the designs of several of my friends in the Association.

Would it not be, sir, satisfactory to the Society of Arts, finding (as they now must), that they have premiated an ineligible design, to be helped out of their difficulty by having access to a design which can be done for their money? If so, I believe I can answer for the competitors from the Association, that not for individual credit, but for the credit of their Society, on which they feel a very undeserved slur was cast, they, or as many of them as are now accessible, will place their designs at the disposal of the Society of Arts, for some competent judge, other than those who advised the course which the Society unfortunately adopted, named by the Society of Arts, and approved by the committee of the Association, to select the best for publication, on condition of their giving the money prize to our library, and the medal to the author of the design, and publishing it with his name and address, and the words "Member of the Architectural Association." I may be mistaken, but I think the Association men would all agree to this; and I think such a proceeding might be of real use to the cause of cottage improvement, and might also go far to efface feelings of dissatisfaction, which ought not to exist, but which I believe do exist between two societies, unequal, indeed, in influence and magnitude, but not on that account the less fitted for friendly relations.

A MEMBER OF THE ARCHITECTURAL ASSOCIATION.\*

**COMPETITIONS.**

**Brighton Workhouse Site.**—There were twenty competitive plans for laying out the present workhouse site for building purposes, so as to produce the greatest amount of revenue to the parish. The committee selected the design bearing the emblem of "The Rose, Shamrock, and Thistle." The probable amount which the ground would yield, if laid out according to this plan, was estimated at 38,114l. The author of the plan is Mr. J. Dalimore, of Richmond-place, Brighton, a gentleman who was for many years foreman to Messrs. Cheeseman, builders.

**Queen Adelaide's Dispensary, London.**—A design by Messrs. Lcc & Long has been selected.

**Ipswich Town-hall.**—The town council have unanimously resolved to adopt plans by Messrs. Bellamy & Harty, of Lincoln, for the proposed town-hall, with such modifications as the committee may deem advisable.

**THE BUILDING TRADES.**

IN Nottingham, the building trades have entered upon another strike, almost before commencing the summer's work. The bricklayers gave the master builders three months' notice last year for an advance of 6d. per day, to commence on the 1st of May. The wages, prior to the advance, were 24s. per week. The masters acquiesced to their request with the most friendly feeling. This year, on the 1st of May, the bricklayers have struck work without giving the slightest notice, for another advance of 6d. per day, making 6s. per week advance in twelve months. The master builders think this a very unjust strike; as, by the bricklayers' own laws, they give three months' notice of any alteration.

The strike of the joiners and carpenters of Blackburn, which originated in a demand for an increase of 2s. per week in their wages, has terminated, the master builders conceding the advance solicited.

The masons in Barnsley have now been idle for some weeks, and there appears to be no immediate prospect of a resumption of work. What the men have struck for is an advance of 2s. per week on the present scale of wages, and the extension of the breakfast time in winter from twenty minutes to half an hour. The masters having met the men, have offered to concede the 2s. advance, but refuse the ten minutes' extension of the winter breakfast time, unless 1s. of the advance be abated in consideration of such extension during the months for which it is required.

A movement is on foot amongst the operative painters of Newcastle to obtain the Saturday half-holiday, and to have a wage of 26s. a week.

\* We have received two other letters to a similar effect.

A strike has taken place among several of the trades in Paris, and has extended to the workshops of M. Adolphe Viollet, contractor for the building of the new Opera House as well as for those going on at the Prefecture of Police. M. Viollet has inaugurated a new system of paying his men according to a certain measurement of the stones cut by each workman, the result of which is a reduction of two francs per day on their pay. The men struck work, and have given M. Viollet notice that, unless he can satisfactorily explain the motives of this change within three days, they definitively give up his service.

**SOME NOTES FROM THE NATIONAL LEDGER.**

Most people would be lost in the ocean of figures needed for the right keeping of the nation's accounts, which are so large and complicated that we would almost doubt a Cocker as to their management; but year after year, however, Mr. Gladstone sums them up, seemingly to his own delight and also to the satisfaction of others. It is impossible for us to enter much into this account, but we will notice that in the year which expired on the 30th September, 1864, the imports were 274,000,000l.; exports, 487,000,000l.; showing an increase of 219,000,000l. (nearly one-half) since 1854. The railway companies receive 30,000,000l. a year from the public, and they have added to the national wealth to the extent of not less than 30,000,000l. a year in addition. The expenditure of the year is given at 66,130,000l., and the income, about seventy millions sterling, will leave a surplus of over four millions.

It is not easy to form a tangible estimate or idea of the enormous extent of these figures, or the varied and peculiar machinery by which the account of them is managed,—of the departments by means of which the revenue is collected and disbursed, with such exactness, that in all those immense national accounts, the greatest as well as the most minute, should not be a shilling in error. There is, however, a difference of opinion as to the exact degree of care with which these hooks of the nation are kept; and many think, that with less adhesion to old-fashioned methods, we might, in the management of the notes of our gigantic revenue, not only effect a great saving of money, but also much simplify the accounts and render their thorough correctness more sure. It must, however, be admitted that the labour is a Herculean one; for, putting the revenue at 70,000,000l. a year, in every hour of both the day and night nearly 8,000l. sterling are falling into the national treasury. But the greatness of the amounts which have to be dealt with by an English Chancellor of the Exchequer is perhaps more clearly seen by such items as show that the reduction of 6d. per lb. off the duty on tea will cause a loss to the revenue of 2,300,000l. (the consumption in 1865-6 has been estimated at 92,000,000 lb.); but the Chancellor, in consequence of the reduction in the price of this article, estimates the recovery of a quarter of a million from the above sum.

The reduction of the duty on malt to an extent which would reduce the price of beer to the consumer by only a farthing a quart, would cause a reduction of revenue in the first year of 2,480,000l., and in the second year of 3,360,000l. Respecting the consumption of beer, Mr. Gladstone says that in England, in 1722, there were 6,000,000 barrels of beer consumed. The population then was just 6,000,000; so that there was one barrel of beer for each head of the population. In 1832, the consumption of beer had declined, so that it was only about two-thirds of a barrel per head. In 1861 the old times were revived, and, with a population of 20,000,000, the consumption of beer was about 20,000,000 barrels. The Chancellor reckons that more than 40,000,000 are laid out in beer by the population of England, and relates an anecdote of the consumptive power in this way, which he would not have believed except upon the most undoubted authority. The subject of the story was a labouring man, whose ordinary vocations were on the river Thames. There was nothing peculiar in the heat or atmosphere in which he worked, but great muscular power and exertions were required. He met with an accident to his hand; and the treatment at one of the East London hospitals was not so satisfactory as the medical attendant expected, and he wished to open the hand once more; but before he determined to perform the operation he was

anxious to know whether the man was, in every sense of the word, a temperate man, and was assured by the people that he was, and always had been, strictly so. "What is your consumption of beer?" was asked. The man said, "Never more than eight quarts a day." And on the medical gentleman inquiring what was the consumption of an intemperate man, if a temperate man was limited to eight quarts, he was told that an intemperate man drank from twelve to sixteen quarts a day. But if the population of England be taken in general, and the number of barrels of beer that are brewed in England also, and those barrels be reduced to quarts, and a fair deduction be made for the population of Ireland and Scotland,—who, in proportion, drink very little beer,—and for women and young persons under fifteen years of age, who drink but a small proportion, it will be found that the quantity of beer consumed in England is not far short of 600 quarts a year for every adult male.

The duty upon malt was, in the last year's estimate, stated at 5,800,000*l.*, but has yielded a sum of 6,377,000*l.*, or an excess of 577,000*l.* beyond the sum expected. During the same time the duty on spirits was estimated at 9,650,000*l.*,—the actual produce was, however, 10,173,000*l.*, a sum over the estimate of 523,000*l.*

Notwithstanding the disadvantages which beset the foreign trade in paper, it is remarkable that in 1859 the amount of the raw material imported for making British paper amounted to 13,700 tons; in 1862 it had risen to 20,450 tons; in 1863 to 44,000 tons; and in 1865 to 67,000 tons.

In 1859 the total amount of trade with France, was 26,431,100*l.*; in 1864 it was 49,797,000*l.*, showing an increase of 23,366,000*l.*

We have remarked that nearly 8,000*l.* are, according to the present extent of our Government expenditure, paid into the exchequer every hour; and of course in each week the sum paid is 1,344,000*l.* and a few shillings. Great buildings like St. Paul's Cathedral could be erected for but a tithe of this sum alone. With this yearly income of seventy millions, seven thousand churches might be built, at a cost of 10,000*l.* each, or with the same sum 350,000 dwellings for the industrious and labouring classes might be reared, at a charge of 200*l.* for each home; and this, allowing an average population of five persons in each, would accommodate one million and three-quarters of people. The interest of the seventy millions at 5 per cent. per annum, would come to three millions and a half of money; and with this rightly used, what wonders might be done in art and other education. To think, however of these and the many other uses to which a year's revenue might be put, is but arial castle building, which, although for the most part vague and unprofitable, does not at times fail to awaken pleasant and useful thoughts; but the uppermost feeling is that of bewilderment at the huge income which the Chancellor of the Exchequer has to dispose of.

#### AN ICE-WELL IN PLYMOUTH.

An ice-well of large dimensions has been built in Plymouth lately, in Woolster-street, in connexion with the mayoralty stores, kept by Mr. J. Bigwood. This is the only ice-well of any size west of Bristol, and no cost has been spared to make it as efficient as possible. The floor of the building is cemented, and is constructed 1 ft. below the general level of the other parts of the building, and in addition to this it has been made to slant, in order to carry off the waste that arises from the melting of the ice into a pit, whence it is carried off into the sewers. The walls of the building are of peculiar construction, to suit the purposes for which it is built. The inside of the well consists of the wood-casing, made water-proof by the application of certain articles, inside of which is 1 ft. of sawdust, the whole being inclosed by a stone wall of the thickness of 8 in. to 2 ft. The four sides of the building have this lining of sawdust, the amount of which material used may be estimated when it is known that its cost was 15*l.* to 20*l.* The inside of the well is of the following dimensions;—30 ft. high, 40 ft. long, and 20 ft. broad, enclosing a space of 24,000 ft.<sup>3</sup>, in which can be stowed very nearly 1,000 tons of ice. Upwards of 800 tons have already been stowed away, the ice having been procured from Norway, and discharged from the Great Western Docks. The ventilation of the building has been well attended to. Over the well is a spacious open loft, from which open

several ventilators, which are opened or shut according to the dryness or humidity of the wind blowing. There are also ventilators in the side of the well, for the purpose of allowing of the escape of mist, &c., which arises from evaporation. There is a series of doors running the whole height of the well, which are opened as the consumption of the ice takes place. The whole of the doors are 6 in. thick, having a lining of sawdust. The appliances for the storing and for the removal of the ice are of a first-rate description, whilst the cleanliness of the ice is well looked after by the application of clean shavings to the ice, so as to prevent its coming in contact with the wood-casing. The amount of waste of the ice by evaporation, in consequence of the admirable construction of the well, does not amount to more than 15 or 20 per cent., which is a small percentage for it in the southern parts of England. The usual percentage of waste in small ice-houses in the neighbourhood generally approaches as high as 75. It is stated that the cost of the well is 2,000*l.*

#### FROM SCOTLAND.

*Edinburgh.*—Arrangements for the rebuilding of the Theatre Royal upon the old site at Broughton-street have been completed. The contracts have been accepted, and the contractors are bound over to have the building completed early in November next. Mr. Robert Hutchinson, builder, has received the contract for rebuilding the theatre, and has commenced operations.—A large new warehouse has been erected in West Register-street for Messrs. Cowan & Co., paper-makers, from designs by Messrs. George Beattie & Son, architects. The style is Venetian Gothic. The building has fronts to the east, south, and west, and is four stories in height above the street. It consists of six stories, however, but one is below the level of the street, and the uppermost shows towards the street only by gablet windows in the roof. One feature of the building is a profusion of carved work: no two capitals nor spandrels are alike. The contractors are: for mason's work, Mr. J. Alexander; carpenter and joiner's work, Mr. J. Gilfillan; cast-iron work, Messrs. J. Learmonth & Co.; plumber's work, Messrs. R. Thomson & Co.; slater's work, Mr. Wm. Anderson; plasterer's work, Mr. J. Annan; glazier's work, Mr. D. Conacher; brick work, Mr. H. Springall; and carved work, Mr. Wm. Pearce.

*Glasgow.*—Trinity Congregational Church, hall for the congregation under the pastoral oversight of the Rev. Wm. Pulsford, was opened for public worship on the 30th ult. The church has been erected from the designs of Mr. John Honeyman, jun., architect. The style of architecture is Early Decorated. The plan is cruciform, the transepts being merely short side aisles of two bays each, separated from the nave by arches resting on clustered shafts of polished Peterhead granite, having richly-carved capitals. An organ stands at the south end of the nave, and the pulpit at the north; and there are galleries in the transepts only. The windows at the north end of the church are filled with mosaic glass, by Mr. D. Cottler. The framing of the roof is partly exposed to view and partly concealed by a plaster ceiling, which is divided into panels by the couples and parings. The spandrels above and below the hammer-beams are filled with Gothic work, and the brass coronas which light the church are fixed on the ends of the hammer-beams. The extreme length of the church inside is 92 ft. 6 in., and the width at transepts is 80 ft. It is seated for about 900, but, by a slight change in the arrangement, its accommodation can be increased, if desired, by about 100 sittings. Underneath the church is a spacious hall; also a manager's room, vestry, headle's house, and other accommodation. The spire rises to the height of 150 ft. above the foot-path. The first floor forms the entrance porch, and is paved with Maw & Co.'s encaustic tiles. Above this is the ringing-chamber, where the machinery for ringing the peal of a set of six bells has been hung by Messrs. Naylor, Vicars, & Co. There is a good deal of stone carving on all sides of the building and in the interior, which has been executed by Mr. Wm. Mossman. The figures at the angles of the pulpit have been carved in wood by Mr. Grassby. The pulpit is of pitch pine, French polished, but it is not yet completed. The cost of the building will be about 7,000*l.* The mason-work was executed by Mr. James Grant, jun., and the wright-work

by Mr. James Connell. The contractors for other works were Mr. William Darrie, slater; Messrs. Ingleton & Phiips, plumbers; Mr. Alex. Campbell, plasterer; Messrs. W. & P. M'ellan, gas-fitters. The clerk of works was Mr. William Kent.

*Hawick.*—The successful contractors for building the new bridge over the Teviot are Messrs. Marshall & Ballantyne. It is to be of ashlar work, and will have three elliptical arches. The contractors are to have the arches thrown by the end of August, and the whole work completed in October. The present bridge, which is inconveniently steep and narrow, will be taken down immediately, and probably a foot-bridge will be thrown across the Teviot a little further up to suit foot passengers till the new bridge is completed. The contract amounts to 1,670*l.*

*Dumfries.*—In the suburbs, residences are rapidly springing up in every quarter. Mr. M'Kie, says the *Courier*, has resolved to sell or let for building purposes the whole of that extensive property belonging to him, known as the Queen-street Nursery-grounds, and extending from Shakspeare-street, on both sides of the New-road, to the Millburn. When the building sites are disposed of, it is Mr. M'Kie's intention to construct a new street from Shakspeare-street downwards to Mr. Crackstone's cottages. At a distance of 122 yards from Shakspeare-street, this road will be intersected by another new street, entering from the New-road.

*Linlithgow.*—The new Sheriff Court Buildings have been formally opened for public business. They were begun in January, 1863, and erected from designs furnished by Messrs. Brown & Wardrope, architects, Edinburgh. They stand on the south side of the High-street of Linlithgow, a few yards west from the market-place, a number of old tenements having to be displaced to make way for them, one of which, tradition asserts, occupied the site of the house from the window of which the Regent Murray, while passing through the burgh, in 1570. The main edifice is a somewhat plain structure, having, in outward appearance, a stronger resemblance to an old English manor-house than what it really is, a public building. On the ground-floor there is accommodation for the sheriff-clerk and procurator-fiscal, with apartments for the horse-keeper. In the second and highest flat there are two court-rooms, one a large and commodious room, for the transaction of the ordinary court business, and the other of smaller dimensions, for taking proofs, the declaration of prisoners, &c. There are also rooms for the sheriff, procurators, jury, and witnesses, and the general accommodation for the legal business of the county. At the south-east wing of the Court Buildings, and attached to it, is the county police-office, also a new erection.

#### PROVINCIAL NEWS.

*Reading.*—The old almshouse, scattered in different parts of the town, being in dilapidated state and generally inconvenient, the trustees have determined, with public assistance, to erect new ones on the south side of Castle-street. The plan is by Mr. Woodman, architect. There are twenty-eight residences in all. The foundation stone has been formally laid by the mayor and corporation.

*The Potteries.*—The principal front of the proposed new building for the North Staffordshire Infirmary, according to Mr. C. Lynam, the architect, will have a western aspect, and will look in the direction of the Clayton Hills. The difference of level in its surface amounts to as much as 30 ft. between the highest and lowest point. Speaking generally, however, the southern half of the building will stand on one level and the northern half on the other; the average difference being about 15 ft. The higher level has been taken for that of the principal ground-floor, and the lower level for a sub-ground floor; so that the northern half of the plan will have one story below that of the southern half, in which the dispensary, laboratory, drug-stores, "exceptional cases," horse-stores, one ward for "exceptional cases," bed-rooms for the nurses and servants, pantries, larders, servants' hall, &c., will be obtained. The principal buildings are arranged round a central garden court, about 140 ft. long and 70 ft. wide, its length being in the direction of east and west. This garden-court is surrounded by a glazed corridor or cloister, one story in height, and forming an open terrace above, which connects, and affords a communication between, all

parts of the buildings. To the west or front of this court is placed a central block of buildings, three stories in height, containing the principal entrance, board-room, and chapel, and apartments for the house-surgeon and pupils. Immediately in the rear of this block are placed the museum and library, with the operating theatre above, which will be lighted by a northern window and a roof light, and to which will be attached a patients' lift. To the east of the central court is another block of building, containing the matron's rooms, house, dining-room, kitchen, scullery, lichen store, &c. On the southern side of the central court the male division of sick wards is arranged. They consist of two large and one small intermediate pavilion, and one large and one small special case ward. These pavilions are two stories in height, and have their longer axis north and south, so as to present the largest extent of surface to the light and warmth of the sun's rays. The front or western pavilion is to be devoted to an accident-ward on the ground-floor, and a general surgical ward on the first-floor; the eastern pavilion to medical wards on both the ground and first-floor; the small pavilion to "exceptional cases" on the ground-floor, and on the first-floor to burnt cases. The two other small wards run east and west, and, with a patients' day-room, connect the two larger pavilions together. The distance between the larger pavilions is 130 ft., which will not only allow of a free and full circulation of air around the wards, but also secure a view from the rear pavilion of the open country in the western prospect. The northern side of the central court has corresponding pavilions to that of the south, occupied by the female division of sick wards and the out-patients' department. The latter is placed in the western pavilion, and is two stories in height, and consists of two large waiting-rooms, with water-closets for males and females attached; five consulting-rooms for the surgeons and physicians; a surgery, private examination room, dispensary, laboratory, and drug-store. The eastern pavilion contains one large surgical ward, and one large medical ward; also the dormitories of the nurses and servants. The small central pavilion on this side consists of a medical and a surgical ward. The western and eastern pavilions are connected, as on the males' side, by two small wards for special cases and a day-room. Each ward has a nurses'-room, scullery, and clothes-room attached to it; also a bath-room, lavatory, water-closet, sink, a shoot for foul linen, a service-lift, and fire-hose. To the accident-ward is added a reception-room, where serious cases of accident may be received, immediately attended to, and admitted into the ward without further trouble or delay. The large wards will be 88 ft. in length, 25 ft. in width, and 15 ft. high, giving 1,500 cubic feet for each bed. A larger quantity of cubic space is provided in the wards for special cases. The floor-boards of the wards will be of oak, and the walls finished in Parian cement. The windows will be sashes, placed in the opposite walls of the wards, and hung in two parts, both of them made to open; and glazed with strong plate glass. They will reach from within 2½ ft. of the floor to 1 ft. of the ceiling. The wards will be warmed by open fire-places, situated in the centre. Fresh air will be admitted into them by the opposite windows, and by external openings provided for the purpose, and the vitiated air will be drawn off by extracting shafts. In addition to the principal group of buildings, two detached blocks, one for males, the other for females, are proposed for the reception of fever and other contagious diseases. These are planned on the same principles as the main wards, but a larger quantity of cubic space per bed is given to them. The main buildings are designed for the accommodation of 160 beds, and the fever wards for 20 beds. The buildings, in external appearance, will have no pretension to architectural display. The roofs are to be covered with tiles: the walls are to be of red bricks, with a slight admixture of blue bricks in chequer-work patterns. In the minor features, such as archways, doorways, windows, &c., the arched form of head is employed, and rounded bricks are slightly introduced. The members of the sub-committee have devoted much time and pains to the furtherance of the plans, and the architects have visited the newly-built hospitals in this country and in Paris.

**Norwich.**—The building trade of Norwich is expected to be in an active state this season, according to the *Norfolk Chronicle*. The tender of Messrs. Curtis & Balls has been accepted for the mansion which Mr. R. J. H. Harvey is about

to erect on his estate near the city. The amount of the contract is understood to be 30,000*l.* The contract for new premises for the Norwich Branch of the Consolidated Bank (Limited), has been taken by Mr. Hall for 3,400*l.* When account is also taken of the new church at Thorpe, and the number of houses in course of erection at Heigham, in Prince of Wales's-road, and other districts, it will be seen that there is employment assured to Norwich builders for the ensuing summer. The new bank of Messrs. Harvey & Hudsons, on the Castle Meadow, will not be ready for occupation before October: this structure has cost about 13,000*l.*

#### BUILDERS' ACTIONS.

**Bliss v. Smith: in Chancery.**—This suit was instituted by the assignees of Mr. Davies, a builder, who entered into a contract with Mr. E. T. Smith, owner of Cremorne Gardens, to complete the ball-room to the satisfaction of two architects, Messrs. Allom and Laforest. The bill alleged that the architects, in collusion with and at the instigation of Mr. E. T. Smith, had declined to certify the amount due under the contract to the plaintiffs as such assignees, and had thereby prevented them from recovering in a court of law the amount to which they were entitled. The bill therefore asked that accounts might be taken between the parties in respect of all work done under the contract, and that Mr. Smith should pay the costs of suit.

His Honor said the plaintiffs had no ground for coming to a court of equity for relief. They had failed to prove that there was any collusion between Mr. Smith and the architects. In fact, the evidence proved that there was no such collusion, and that the defendants had acted fairly and *bona fide* throughout the whole matter. It showed also that the defects, such as they were, were the defects of Mr. Davies, who undertook the work without having sufficient capital to complete it, and, in consequence, resorted to various expedients, such as using improper materials and the like. The accounts between the parties were not of that complicated character which would prevent them from being taken in a court of law. Therefore the bill would be dismissed with costs against all the defendants, but without prejudice to the plaintiffs to bring such action at law against Mr. Smith as they might be advised.

#### CHURCH-BUILDING NEWS.

**Istham.**—The parish church has been reopened. The material of the original structure was almost entirely the hard chunch for which the district is famous, the only exception being the pillars of the nave, the string-courses and dressings of the exterior, and the pillars of the porch, which are of Barnack stone—a lasting material for building purposes. Flint ashlar, with stone dressings, have replaced the chunch rubble and dressings of the original tower, which was of clunch, and fell some time ago. In rebuilding the tower, the staircase has been enclosed in a semicircular flanking turret, carried no further than the ringers' floor. The proportions and details of the original structure have in other respects been preserved, the height being increased by a few feet. It is capped by a high pitched roof, with red tiles, surmounted by a water-cook—a mode of roofing massive towers such as those which abound in Suffolk and Norfolk. The peal of five bells has been replaced. The whole of the work appears to have been executed by Mr. Hubbard, of Downham. The body of the church needed no reconstruction, but the ruins and dilapidated condition into which it had fallen rendered necessary very extensive repairs and restoration. For these works upwards of 3,000*l.* have already been subscribed, and there still remains a debt of more than 300*l.* Mr. Street was the architect employed.

**Uppingham (Rutland).**—The chapel built for the use of the grammar-school has been opened for divine service. The style adopted is Early Decorated. The interior area is 100 ft. long by 30 ft. wide. The east window is of five lights, with tracery. The easternmost window in the south wall is of three lights, with tracery: this has been filled with painted glass, representing the Resurrection. The nave on this side is lighted by four windows of two lights each, with a quatrefoil in the head. There are corresponding windows in the north wall. The west wall is enriched with a wheel window, and below are three single trefoil-headed lights. The pulpit is of alabaster, intermixed with Derbyshire, Irish, and Italian marbles. The chancel is divided from the nave by a dwarf stone screen, the altar being approached by seven steps. The floor is laid with encaustic tiles, intermixed with black

and white marble. The roof is open, and of Memel timber. The chapel will be connected with the recently-built school by an open porch having a groined ceiling, over which will be the vestry. On the north side, partly in the wall, will be a round tower and spire about 90 ft. high, which will be ascended by a spiral staircase, and by which the vestry will be entered. The chapel has already cost nearly 6,000*l.*, and it is believed that at least 5,000*l.* more will be required to complete it according to the adopted designs. The architect was Mr. G. E. Street. Mr. J. Foxton was clerk of the works; and the contractors were Messrs. J. & T. Davis, of Banbury.

**Bedford.**—St. Cuthbert's Church has been reopened, after enlargement. The contract was taken by Mr. Conquest, of Kempston, builder, for 1,260*l.* He did not arrive to superintend the works, but they were carried out under his foreman, Mr. W. Harris. The enlargement consists of north and south aisles, the latter, on account of its close proximity to the street, having an apsidal termination to the west, in which the font is placed. Each aisle opens to the nave by two wide arches resting upon slight granite columns. The columns which abut on the north-west and south-west angles of the tower being detached from the solid piers supporting it, the obstruction to sight and sound usually occurring in the case of a central tower is considerably diminished. The heat is provided for by the Gill-stove of Mr. Goldsworthy Gurney, placed within grated vaults in the middle avenue of the nave. Mr. Penrose was the architect employed.

**Sittingbourne.**—About 1,252*l.* have been either paid or promised towards the fund for building a new church in this town, and steps for the commencement will shortly be taken by the architect, Mr. R. C. Hnasey. According to the plan, the building will be sufficiently large to accommodate 300 persons.

**Lewisham.**—The new church of St. Stephen, at Lewisham, has been consecrated by the Bishop of London. The church was designed by Mr. Scott, in the style of the thirteenth century, and built by Messrs. Bowley, of Westminster, at a cost of 12,000*l.*; the entire sum, together with the endowment of 2,000*l.*, having been provided by the Rev. S. R. Davies, of Lee, the patron and first incumbent. The site was the gift of Lord St. Germans, and the foundation stone was laid in May, 1863, by Viscount Holmesdale.

**Clent (Worcestershire).**—The parish church has been restored and re-opened for divine service. Excepting the chancel and tower, the whole of it has been reconstructed; that is, walls, arches, and piers, taken to pieces, and every old stone that was sound reset in its former place, and new work added where necessary. Entire new roofs, except that of the chancel, have been put on and are of open wood-work; a new north aisle, carried out 9 ft. further than the old one, has been added; and the south aisle has been widened by 6 ft. A new stone porch has been erected on the south side, where the old one stood, and that which formerly opened into the north-west angle of the building has been dispensed with. At the east end of the new north aisle is now a flight of steps leading up to a chamber on a level with the chancel, a portion of which chamber will be partitioned off for a vestry, and the remainder, it is hoped, will be occupied by an organ. The new arcade separating the north aisle from the nave has been made to harmonise, to a certain extent, with the Norman arcade on the south side. In restoring this Norman work the capitals were found to be coloured, evidently with the view of bringing out the carved work into higher relief. The tower is at the west end. The floor underneath was formerly 6 ft. above the level of the church floor: this is now carried up 3 ft. 6 in. above the apex of the tower arch, and the roof of the belfry reconstructed, louver-boards inserted in the tower, &c., so that the west window and the space under the tower have now been opened to the church. In the restoration of this Perpendicular window, the old tracery has been restored and new mullions inserted. Several ancient monuments taken from the old north aisle and other parts have been fixed up on the interior of the tower walls. As to the windows generally, Decorated ones have been supplied to the new aisles, and it is contemplated to erect a memorial window (site not fixed) to the late Miss Goodman, who gave 600*l.* towards the restoration. The glazing of the windows, which is of transparent glass, has been done by Messrs.

Chance, Brothers, of Birmingham; and the ventilators by Mr. Moore, of London. Mr. Beale, of Newcastle-on-Tyne, carved the bosses, corbels, and the termination of the hood-mouldings of the arches. There is new seating, of varnished deal, the seats being open, and the backs slightly sloping. The church now contains about 500 sittings, which is an increase of 100 over the old accommodation. The architects were Messrs. Kirk & Parry, of Sleaford and London; builder, Mr. Lovatt, of Wolverhampton; clerk of the works, Mr. H. Charlton. The expense of the restoration has been so far about 2,500l., though more than that sum will be required. The deficiency prior to the re-opening was about 200l.

**Fladbury.**—The chancel of Fladbury Church has been for some months under repair, and will be re-opened shortly, when the new schools will also be opened, and a large addition to the churchyard consecrated. The same architect, Mr. F. Preedy, of London, is employed both for the restoration of the chancel and the erection of the schools. A stained glass window, the gift of Mr. J. Cartwright, of Crayonhe House, has been placed at the east end of the chancel. The reredos will be of alabaster, by Mr. Bolton, of Worcester. The floor will be paved with Minton's tiles. The contract is taken by Mr. Espley, of Evesham, who has executed the stalls and roof. The builder contracting for the schools is Mr. Griffiths, of Eldersfield, near Tewkesbury.

**Feckenham (Worcestershire).**—The foundation-stone of the new church which is to be erected at Bradley, near Feckenham, on the site of the old dilapidated chapel which formerly stood there, has been laid by Lady Georgina Vernon. The design for the new church is by Mr. W. J. Hopkins, of Worcester, diocesan architect. It is of an Early Decorated character, and will consist of a nave 55 ft. in length by 24 ft. 8 in. in width, and about 30 ft. in height; chancel, 23 ft. in length by 18 ft. in width, and about 25 ft. in height. It will have a tower and spirelet 90 ft. in height, placed at the north-east corner of the nave. The lower portion of the tower will serve as a vestry. Over the vestry and approach, by means of a spiral staircase, will be the belfry. The porch entrance is to be on the north side of the nave. The church will be lighted by means of a large rose window at the west end of the nave, and by clerestories of a very simple character on the north and south sides. The windows to the chancel consist of single lancets, and a three-light Early Decorated window at the east end. The roof of the nave will be a plain open-timbered one; that to the chancel being of rather a more ornate character. The whole of the seats are to be open. The church will accommodate 200 persons. The contract for the whole, including tower and spire, is 1,200l. Mr. W. Nelson, of Dudley, is the builder.

#### DISSENTING CHURCH-BUILDING NEWS.

**Clapton.**—A new Wesleyan church has been opened at Clapton for divine worship. The style is Decorated, and the plan is a parallelogram, which measures 116 ft. 6 in. from end to end, and 57 ft. across. A tower and spire occupy the centre of the front, rising 165 ft. from the ground. The exterior of the walls is of Kentish rag stone, the interior of brick, finished with rough stucco and jointed. The public entrances are three in number, the centre one being the most important in size and appearance, occupying the base of the tower, having a stone groined ceiling, and ornamented with carving. The height of the chapel from the floor-line to the highest point of the ceiling is 45 ft. 6 in.; but on the outside the building rises from the ground to the ridge to the height of 62 ft. 6 in. Under each principal arch, reaching from column to column, spans the whole width of the chapel. The columns run up on each side of the building and support the galleries, continuing upwards to the underside of the hammer-beam, from which point a series of smaller arches spring longitudinally, the open spaces at the back being filled in with traceried woodwork. The roof is ceiled off above the arches with match-boarding and felt. The three windows of the apse and the centre window of the front are filled in with stained glass, which was supplied by Messrs. Ward & Hughes, of London. The front window is a present from Mr. James E. Vanner. The building has been erected from the designs and under the superintendence of Mr. John Tarring, of London; and the works have been carried out by Messrs. Dove, Brothers. No clerk of works has been employed. The warming appa-

ratus has been supplied and fixed by Mr. Boulting, of London; and the whole of the gas-fittings have been executed from the designs of the architect by Mr. Rothwell, also of London. The total expense, including stained-glass windows, warming, lighting, boundary inclosure, and architect's commission, has been about 5,500l.

**Finchley.**—A new Congregational chapel has been opened here for divine service. The style is Decorated Gothic, and the walls are of Kentish rag stone, with Bath stone dressings. There is a north-west tower, surmounted by a slated spire rising to the height of 100 ft. The chancel, which has a three-light window filled with the stained glass, is entered from the holy of the church by a moulded arch. Minister's and deacons' vestries are on either side the chancel. An organ is placed in a loft in the north-east angle of the church. The seats are open. The place is heated with hot-water, and lighted by starlight burners depending from the roof. There is a range of buildings for schools, and a house for the residence of the minister, to be called "the parsonage house," is to be erected. The architects are Messrs. Searle, Son, & Self, of London. The total cost of the erection of the chapel and schools was 5,500l., and the value of the land 500l.; making in all, 6,000l. The land for the chapel and schools was given by Mr. Puget, of Totteridge, who also defrayed half the cost of erecting the schools, and the sum of 2,500l. was given by one friend, who desired that his name should not be publicly known. The same giver has promised to pay half the expense of erecting the minister's house, which it is estimated will cost 1,200l.

**Annesley.**—The foundation stone of a Methodist chapel has been laid here. The chapel is situated on a very prominent site, at the junction of four roads. The design is Decorated Gothic. The material will be wall-stones and ashlar dressings of stone from the district. The plan comprises nave and aisles, organ chancel, with vestry below. The total length is 91 ft. and the width across nave and aisles 55 ft., the height to the nave ridge 55 ft. The tower and spire which stand at the corner of the road rise to the height of 135 ft. The organ chamber is elevated and forms a chancel, having a large pointed arch to the front. The roof is supported by five laminated principals resting on ornamented iron columns. The centre portion of the roof is divided into panels, and is intended to be decorated by stencil ornament. The interior woodwork of the roof, gallery fronts and seats, &c., is to be red deal, stained and varnished. The principal entrances face Horton-lane: the side entrances are for the galleries. A five-light window is placed over the principal entrance. The aisles are lighted by two-light tracery-headed windows formed in dormers. The pulpit is proposed to be of Caen stone. The heating is to be by hot water. The chapel is intended to accommodate 1,000 persons, and the whole of the works are let for a little over 3,000l. to local tradesmen. The architects are Messrs. Andrews, Son, & Pepper, of Bedford. The contractors are,—excavators and masons, Messrs. F. Barraclough & Co.; carpenter, Mr. Wm. Crabtree; plumber and glazier, Mr. J. Schofield; plasterer, Mr. M. Bolton; slaters, Messrs. Hill & Sutcliffe; painter, Mr. W. Hird.

**Puisley (Yorkshire).**—The chief stone of a new Congregational church has been laid by Mr. W. H. Conyers, of Leeds. The church, which will be built upon the site of the old chapel, is in the Early French Decorated style of architecture which flourished in the thirteenth century. It consists of a nave and aisle, and transepts. In the front elevation there are three entrances, those at the sides leading to the gallery, and the middle one giving admission into the area of the church. Above the centre doorway there is a St. Catherine's window, and to the right and left of it are two long lancet windows. One of the windows on each side is set in a gable breaking the roof-line on the exterior. At the angle formed by the junction of the Fulneck and Lew-ton Roads, and directly opposite to the Bradford road, a tower with a spire will rise to the height of 105 ft. In the interior the chancel will be 75 ft. long by 41 ft. wide. The ceiling will be arched, with curved principals moulded and plastered between them. The pews will be open, low, with leaning backs, and about 30 in. wide, accommodation being provided for about 300 adults. The windows will be glazed with cathedral glass with coloured margins. The warming will be by hot air. The church will be lighted by large gaseliers, with brackets under the galleries, which will run round the whole of

the interior. The architects are Messrs. Pritchett & Son, of Darlington. The contract has been let for a little over 2,200l., and the whole expenditure is expected to be about 2,500l.

**Whiston (Rotherham).**—The chief stone of a new Wesleyan chapel has been laid here. The style is the Early English Second Pointed, the walls being of random stone with dressed facings. Large three-light windows will be placed at the east and west ends; on the north side will be four single-light windows, and on the south side will be two windows, and a tower 65 ft. high, under which will be the entrance porch. Accommodation is provided for 250 persons. At the south end of the chapel will be a school-room to hold 100, which will be shut off by folding doors. The cost is estimated at 600l., more than half of which has already been subscribed. The contractor is Mr. Harper, of Masborough; and Mr. Hoddiss is acting as clerk of the works. The design was supplied by the Rev. J. P. Johnson, the superintendent of the district.

#### STAINED GLASS.

**Bosley Church.**—Three stained-glass windows have been placed in the chancel of this church, by the Rev. F. J. Richards (the vicar) and his family, in memory of their parents. There are two subjects in each window, and they include "The Annunciation," "The Meeting of Mary and Elizabeth," "The Virgin and the Child in the Stable," "The Presentation at the Temple," "The Saviour and the Woman in the Garden," and "Christ reproving Thomas for his unbelief."

**Sutton Coldfield Church.**—An unpretending window has lately been placed in the north chancel aisle of this church. The situation of the window facing north, strictly speaking, could not admit of highly-coloured glass, and has been filled, by Messrs. Hardman & Co., of Birmingham, with diaper and flowered quarries, every alternate four having a trefoil, but in the higher parts of the lights are medallions containing three shields of arms.

**Staveley New Church.**—Two painted windows have been placed in the new church at Staveley, near Ripon, lately built from the designs of Mr. John Lowe, of Manchester, architect. The style of the church is Early English, and the window in the nave has been filled with a picture of the "Raising of the Widow's Son," surrounded by suitable canopy-work and enrichments. This has been erected to the memory of different members of the family of Mr. John Freeman, who was the contractor for the building of the church. A window has been placed in the tower end of the church, of which the cost has been defrayed by public subscription. The subject is "The Ascension," and is arranged in two vesica-shaped panels, surrounded by deeply-coloured ornament. The upper panel contains the figure of Our Saviour, the lower being filled with the Apostles. These windows were executed by Messrs. R. B. Edmundson & Son.

**Trinity Church, Southport.**—A painted window has been placed in the nave of this church. It is formed of one large opening, of the Early Pointed style, and contains a picture of the Resurrection. The subject comprises a figure of our Saviour ascending, with an inscribed banner. The Roman soldiers are represented at the base of the picture, across which is written the text, "I am the resurrection and the life." The whole is enclosed within richly-coloured canopy-work and bordering. The artists were Messrs. R. B. Edmundson & Son.

#### Miscellanea.

THE PRESIDENCY OF THE INSTITUTE OF ARCHITECTS.—On Monday last, Mr. A. J. Borsford Hope was elected President of the Institute.

ALOE.—The timber trade of Canada, in 1858, included the export of 555,000 cubic ft. of alow wood. What is this timber used for, to require so large a quantity? Or is the word a misprint?—W. P.

METROPOLITAN DISTRICT MUSEUMS.—The Lord President of the Council has fixed Saturday next, at twelve o'clock, for holding the conference with those who are interested in establishing Metropolitan District Museums, already alluded to. The meeting will take place in the Lecturo Theatre of the South Kensington Museum.

THE TERM "THEOPHILITE."—A writer in Notes and Queries says:—"Has not an accident discovered the true derivation of this word? I have before me a copy of Ezequies Physico-Mathematicæ, de momentis gravium, de vecte, &c., dedicated to D. Carolum Theodolum, Marchionem S. Viti. Roma, 1685. He is described as belonging to a family renowned for their interest in mathematical studies. Is it not very probable that the instrument was named after him or one of his ancestors? I have less doubt in offering this suggestion, as all others hitherto given seem so manifestly impossible."

PROPOSED PUBLIC BUILDINGS FOR WOLVERHAMPTON.—The special committee to whom this subject was referred by the town council have reported on it, to the following effect:—Your committee are of opinion that a new sessions-house, with the necessary offices, suitable police-barracks, and prisoners' cells, may be erected on the site in North-street, at the rear of the town-hall, at a cost of about 8,000l. There appear to be two plans worthy of the consideration of the council, in case they resolve upon the proposed removal and erection. One plan is to erect, at the cost already stated, upon the 3,500 yards of land now vested in the municipal corporation, a sessions-house, police-court, police-barracks, and cells. The other plan is to pull down the whole of the North-street premises, and erect, de novo, a town-hall, sessions-house, and other public offices. Your committee are of opinion that the latter course is the preferable one. The erection of a new town-hall and offices would involve, in addition to the sum of 8,000l. above mentioned, a further outlay of about 4,000l.

METALLIC CEILING.—While all other departments in the internal decoration of houses have kept pace with improvements in other branches of industry, it is a somewhat remarkable fact, and one that has long engaged the attention of architects, that the ceiling of our rooms, with their unseemly blisters and network of cracks, are still, generally speaking, just what they were many years ago. Mr. Little has invented a system for the construction of ceilings, which consists in the application to the jointing of very thin-stamped incrust metal in ornamental embossed panels of such sizes and shapes as may be required. These stamped panels are fitted for every kind of decoration in colour, and, if inserted as plain surfaces, may be used as the ground for every description of cartoon painting, combining with lightness and durability artistic and ornamental effect, at a comparatively small cost. Besides its applicability to the ceilings of rooms, and all public buildings, churches, &c., the system may be made use of with the same effect in staircases, halls, and porticoes, and even on the walls of rooms.—Byland's Circular.

TENDERS

For upper school, vestry, and raising tower-roof of Congregational chapel, Milton-next-Sittingbourne. Mr. W. F. Ponton, architect:—
Bennett ..... £433 0 0
Beaumont (accepted) ..... 377 5 0
For sundry alterations at the Crown and Woolpack Tavern, St. John-street-road, Clerkenwell, for Mrs. F. Hemmord. Mr. D. Gylby, surveyor:—
Warne ..... £295 0 0
Hodges ..... 487 0 0
Penlington ..... 434 0 0
Hall ..... 398 0 0
Selleck ..... 286 0 0
All the above exclusive of painting and decorating.
For sundry alterations at the Balmoral Castle, Calodan-road, for Mr. W. Earl. Mr. D. Gylby, surveyor:—
Extra Fittings Total
Selleck ..... £38 ..... £269 0 0
Martin ..... 18 ..... 244 0 0
Davies ..... 20 ..... 220 0 0
Whiting ..... 20 ..... 170 0 0
Williams ..... 169 0 0
All the above inclusive of painting and decorating.
For alterations and additions to warehouse, No. 8, Castle-street, City, E.C., for Knight, Wells, & Braham. Mr. Huberd Ford, architect:—
Palmer & Son (accepted) ..... £300 0 0
For addition to warehouse, 6, Russia Milk-street, City. Mr. William Smith, architect:—
When (accepted) ..... £139 0 0
For new shop front and internal alterations at 7 and 8, Railway-place, Holloway. Mr. William Smith, architect:—
Harvey (accepted) ..... £209 0 0
For infant school in connexion with Hancourt Chapel, Canonbury, Stoke Newington. Mr. William Smith, architect:—
When (accepted) ..... £340 0 0

For alterations to premises No. 30, Patrick-street, Cork, for Messrs. Hawkins, Robertson, & Co. Mr. William Fogarty, architect. Quantities by Mr. E. P. Gibbon. Amounts exclusive of plate-glass, revolving shutters, gables, and chimney-pieces:—
Barrett ..... £1,900 0 0
Evans ..... 1,865 0 0
McMullen ..... 1,690 0 0
Ryan & Son ..... 1,484 0 0
Walker ..... 1,493 0 0
O'Callaghan (accepted with some modifications) ..... 1,393 0 0
Accepted for alterations to the Queen Insurance Office, Westmoreland-street, Dublin. Mr. Fogarty architect:—
Conolly ..... £566 0 0
Accepted for alterations to the West of England Insurance Office, Dame-street, Dublin, exclusive of painting and paperhanging. Mr. Fogarty, architect:—
Conolly ..... £673 0 0
For new house and shop at Battersea, for Mr. Thornthorn. Mr. Charles Bowes, architect. Quantities not supplied:—
Baker ..... £439 5 0
Lahay, Brothers ..... 415 0 0
Lacey ..... 1,741 0 0
Godbolt ..... 402 0 0
For restoring and reseating the parish church at Embsay, near Wisbech. Mr. William Smith, Adolph, architect:—
Tooley ..... £1,653 0 0
Bennett ..... 1,742 0 0
Girling ..... 1,741 0 0
Browne ..... 1,696 0 0
For alterations and additions to the mansion of Mr. W. U. Heygate, M.P., on Charwood Forest. Mr. W. Millican, architect. Quantities not supplied:—
Wykes ..... £4,601 0 0
Osborne, Brothers (accepted) ..... 4,591 0 0
For re-forming the road and footways in School-house-lane, and laying in drains, &c., for the Guildford local Board. Mr. H. Peak, surveyor to the Board:—
Tunstet ..... £250 0 0

# The Builder.

VOL. XXIII.—No. 1162.

## Travels and Discoveries in the Levant.\*

AS soon as the Natural History Collections shall have been removed from the British Museum to their destined galleries at South Kensington, and the fine suite of well-lighted rooms they now occupy shall be filled with the antiquities at present stored in out-of-the-way places; as soon as the sculptures from

Halicarnassos and Cyrene shall be properly housed, either in the east wing of the building or in other appropriate places—and there is space for the proper arrangement of every fine piece of sculpture in the light most suited for it,—then our National Museum of Antiquities will be the finest in the world, and we shall have no occasion to envy other nations the extended space of their museums, nor the facilities thereby afforded for such an artistic arrangement of sculpture as may be observed in the cool halls of the Glyptothek, the Tribune of Florence, or the Octagon of the Vatican. We have now no cause to envy them for the number nor the quality of the works of art they possess; and, thanks to the liberal co-operation of Government with the Trustees of the British Museum, we have lately gained, and shall probably gain, year by year, many more valuable additions to the collection from the old long-buried world of art in the Levant, by means of information afforded by, and through the exertions of, consuls and other agents of the Foreign Office in that part of the world. We have good reason to thank Lord Clarendon for the appointment of so experienced an archaeologist as Mr. Newton to a vice-consulship at Mitylene; for it is to this circumstance that we owe the Budroum marbles, and indirectly those of Cyrene.

Other appointments have also been subsequently made which have added to the number of archaeologists in the East; and in this manner our National Museum will be greatly increased without detriment to the public service. Indeed, we consider a slight acquaintance with archaeology a most desirable acquirement for a Levant consul, especially when he is stationed in the interior of the country; for, now that the Ionian Protectorate has been abolished, the lonely official, without society, except that of stray travellers, and disgusted day by day with the thick atmosphere of deceit which hangs over all the East, may possibly fall a prey to *envie* unless he can take a direct and absolute interest in the things around him. But if he be ever so little of an antiquary, every carved stone which he sees in his rambles (and he cannot go many miles without finding some such record of past times) will afford subject for speculation; and every coin or gem he obtains from the peasants will be a source of great interest, and will tend to reconcile him to his otherwise monotonous existence, and probably to make him prefer it

to life in modern cities, where monuments of the past rarely abound. Great must have been Mr. Newton's interest in antiquity, and profound his knowledge of archaeology, to induce him to devote seven years of the prime of life to a residence on the shores of the Levant; and proportionately valuable must be the record of his experiences there, contained in the two volumes now before us—the *complete rendu* of his researches and discoveries during that extended period which culminated in his discovery of the Mausoleum. Though less strictly archaeological, and, from its lighter character, more addressed to the general reader than his former work, this has more solid qualities than most modern books of travel, and will therefore outlast them as a book of reference, and will be classed as a standard work on the East, and be placed on the library shelves of the scholar by the side of the volumes of Leake and Dodwell.

The narrative consists of extracts from letters written between the years 1852-59, with more recent interpolations. The epistolary form is preferred by our author because "the record of a traveller's first impressions in their original freshness will, in most cases, interest the public more than any subsequent composition which may be distilled in the laboratory of his memory out of confused and faded images."

Mr. Newton's first year in the East was spent chiefly in the beautiful island of Mitylene,—where he was vice-consul,—in making himself acquainted with the duties of his post, and in excursions to Salonica, Constantinople, and the Troad. With regard to the site of Troy, he is not favourable to the theory that the hill at Bonnarbart was the real Pergamos. "If this hill has ever been an acropolis, we might expect to find those fragments of very early pottery, which, as was first remarked by Mr. Burgon, are so abundant on the Homeric sites of Mycenæ and Tiryns. Of such pottery I saw not a vestige in the soil, nor could I discover anywhere on the surface of the rocks those level beds cut to receive the foundations of the walls which may be generally traced out on the sites of the Early Greek citadels, and the marks of which are as imperishable as the rock on which they are cut." Without entering into this much-vexed question, we may remark, that Mr. Newton's opinion is in opposition to the theories of most travellers who have visited the spot, viz., Choiseul, Gouffier, Lechevalier, Morrit, Hawkins, Gell, Hamilton, and Leake, who seem not to have noticed the remarkable circumstance that every ancient site in the East is distinguished by broken pottery, which will not remain buried, but always comes to the surface, to protest against the site of the buried town beneath being entirely forgotten. Mr. Newton's notes on Salonica are very slight; he does not even mention the splendid Byzantine structures which adorn it. We presume that a natural disinclination to rob the ancient city of one of its ancient glories induced him to abstain from seeking the removal of the "Incantadas." We regret to say that Mr. Muller, the agent of the French emperor, being less scrupulous in this respect, has lately succeeded in obtaining them for the Louvre.

In 1853, Mr. Newton went to Rhodes to act for the consul there during his absence. Rhodes afforded a wide field for his researches, as it contained the two most ancient cities of Lindos and Kamircos, besides the very interesting works of the knights; which happily our author does not neglect, as he devotes a whole chapter to them. This is the more valuable, from the fact that the Church of St. John the Baptist, there described, was, together with many of the surrounding buildings, subsequently destroyed by a terrific explosion of gunpowder stored in the vaults beneath it, through the negligence of the Turks, who despised lightning-conductors and trusted to *kismet*. Since this occurrence, however, the magazines in the castles of Kos and

Budroum have been furnished with lightning-conductors. The history of Mediaeval architecture in the Levant has still to be written. M. de Vogué has thoroughly illustrated the churches of Palestine, but there are many remains of Middle Age buildings, at Latakia and other places on the coast of Syria, at Larnaca and Famagusta, in Cyprus; Rhodes, Lindos, Kos, and in many of the Greek islands, well worth illustrating, as developments of Gothic architecture in an Eastern climate.

The next two years were spent by Mr. Newton in exploring the islands of Rhodes and Mitylene, in excavations in the island of Calymnos (which resulted in the discovery of several valuable bronzes); in a visit to Constantinople, and in a journey to England. Upon his return to the East in 1855, he visited Budroum for the first time, and while there, saw sufficient evidence of Greek work underground to induce him to apply to Government for the expedition which had for its result the discovery of the Mausoleum.

The second volume contains a detailed account of the progress of the discoveries at Budroum, and from its pages may be gathered some idea of the difficulties the explorer had to contend with. These arose chiefly from the unwillingness of those persons whose houses and gardens stood upon the site of the Mausoleum to part with their possessions on anything like reasonable terms. The houses and gardens had to be bought one by one, and at exorbitant prices. At page 90, there is an amusing account of the determined hostility of an old woman, the *harem* of a Turkish prizefighter, and how she revenged herself upon the "big corporal" who superintended the "diggings." However, with perseverance, these difficulties were surmounted; the side of the monument laid bare to the very rock; and all the subterranean passages in its neighbourhood thoroughly explored. In proof of the care with which the task of exploration was conducted, and of the vigilance of the native workmen, we may mention that many very minute articles were found amongst the accumulated dust of ages, such as an ivory elephant, measuring about a quarter of an inch each way, small ear-rings, and an onyx ball, about half an inch in diameter. The progress of the excavations is described in a more continuous form, and in a more popular style than in the previous work. The evidences for the restoration of the Mausoleum are not recapitulated. We shall not now enter upon the question, as the subject has been before discussed in these pages. We are glad to find correct and beautiful representations of the principal sculptures that adorn the Mausoleum in a series of photographs from admirable drawings by Mrs. Newton's pencil. In many respects, this mode of illustration is to be preferred to photographs from the object itself, for by it many details of beauty can be illustrated that would not be illustrated by photographs taken from a single point of view. The etchings of Budroum, too, convey an excellent idea of that most beautiful spot.

The excavations at Budroum occupied from December 1856 to May 1859, at which period the expedition removed to the opposite peninsula of Cnidus, where a detached party had been at work for three months, and where that remarkable monument the Lion Tomb, and the grand sculptured lion which surmounted it, had been discovered. Here Mr. Newton remained digging, with varied success, until June, 1859, when the labours of the expedition,—the most successful of modern times,—were brought to a close.

We heartily recommend these interesting volumes to the public, as they contain a faithful account of the working of an exploring expedition which will be especially interesting at the present moment, when the exploration of Palestine, which we have lately advocated in these

\* Travels and Discoveries in the Levant. By G. T. Newton, M.A., Keeper of the Greek and Roman Antiquities, British Museum. 2 vols., 8vo. Day & Son (Limited), 6, Gate-street, London, W.C. 1865.

pages, is about to assume a tangible form. They afford a precedent of the manner of conducting an expedition of an archaeological character; explain the manner in which excavations are carried on under the difficulties which arise in uncivilized countries; and show how necessary a previous training for, and experience in, similar undertakings, combined with a knowledge of the language and of the habits of the natives, are to success in expeditions conducted, like that to Budroun, upon an extensive scale.

#### STREET ARCHITECTURE OF THE OLD TOWN OF EDINBURGH.

In our last paper\* we omitted to notice an occasional and very picturesque feature of the older stone tenements. On the ground floor there is sometimes found an arcade formed of a series of arches resting on pillars, whose massiveness is adopted to sustain the superincumbent weight of the upper stories. Until 1814, when it was totally destroyed by fire, there existed in the High-street a substantial building called "Bishop's Land," from its having been the town residence of the celebrated prelate, Archbishop Spotswood, the ground floor of which was formed of a deeply-arched cloister or piazza, supported by massive stone piers. The date of the erection of this mansion was 1578. A brass balcony projected from the first floor. The ground floor of the south facade of the Earls of Selkirk's mansion in South Gray or the Mint Close, appears to have been originally an open arcade or cloister. Sir Walter Scott passed much of his early youth, it may be mentioned, in this old mansion, which was occupied by his maternal grandfather, Dr. Rutberford, in the end of last century. From the first floor on the west side a picturesque turret staircase juts out into the close. There is an old building on the north side of the Kirkgate of Leith, which has a piazza formed by semicircular arches resting on massive round pillars, with moulded capitals, which extends along nearly the entire front, but which has been filled up and converted into shops. A building with the date 1579, in the Sheep's Head Wynd, Leith, has a piazza of a similar description. The quadrangle of Holyrood Palace, rebuilt in 1671, is surrounded by a piazza formed by semicircular arches resting on massive square piers. There are also piazzas on two sides of the quadrangle of Heriot's Hospital.

In the reign of James V. a castellated style of mansion, which was borrowed from the French, was introduced. It was chiefly characterised by circular turrets, with conical or ogee roofs, which rested on corbels, and were placed at the angles of the building so as to command the intervening curtains. These turrets, commonly called *pepper-box* turrets, generally present a stern bulging abruptness. In the lane which leads into St. Anne's Park at the back of Holyrood Palace, and which bears the Gaelic title of *Croft-an-righ*, or the King's Field, there stands an old mansion belonging to this style of architecture. It was purchased, in the time of Charles I., by William Graham, Earl of Arbroath, by the Earl of Linlithgow, at the pressing instigation of his wife. The earl has left an account of the manner in which he was inveigled into the purchase. It occurs as the third of a list of grievances he had to complain of, and is extremely amusing.

"This *would wife* wife of mine," he says, "made proposition to me that she conceived it not honourable for me to pay rent for one house, as I did then for a little house I dwelled in, besyde the church-yard, pertaining to one Ridderford, who lade it in heritage; which foolish desire of *that wicked woman* I refused, and toulde her that I knew not bow long I should stay at Edinburch, and would not give my money to buy one house thair. Bot she replied, that it would serve for one house for my lands of Kinpoint; which foolish answer of *that wicked woman*'s sband her vanitie, and the great desyre she had to stay still at Edinburch; for the like was never heard, that the house standeth seven mylls from the lands, Kinpoint being seven mylls from Edinburch. Alway, ther being some things between the Earl of Linlithgow and me, he did offer to dispoone to me his hous, which he had at the back of the Abbey of Hallihood, which sumtyme belonged to the Lord Elphinstoun. The E. of Linlithgow and I, for the pryce of the hous, yards, and

grass yards, at the pryce of eight thousand fyve hundredth merks, did agrie, and he dispoone them to me. And it was no ill pennieworth: for it was worth the money, had my *goode wyfe* contened herself so; bot shee thocht the hous too little for my familie, though it was large enough. It is to be remarked also, that so shoone as I removed from the little hous I dwelt in besyde the church-yard, and came to remaine in the bous I bocht from the E. of Linlithgow, at the back of the Abbey, that fals knave Traquair did instant come to reside in the little bous wherain I dwelt befor, pretending that it wes to be neire the counsell of state, which did sit in the Abbey; bot it wes for no other end, that the villaine might wrik his ends against me. And, presentlie after this, I wente up to London; and I wes no shoone gone, bot my wyfe sett to werke all sorte of tradesmen, such as quarriers, maissions, skaitters, vrigts, smiths, glasers, painters, and plaisters; and I may say treulie, that the money which she bestowed upon hir re-edifying of that hous and gardens wes twyse so much as I gave for the buyng of them from the Earle of Linlithgow. So that in good faith, that bous, and the gardens and orchards, and other things which my *wyse wyfe* bestowed upon it, stode me in above 25,000 merks Scott money, bot I will only set down heir 20,000. Bot after all this, when I wes to remove from Edinburch, I dispoone to my son James, heretablie, that hous, gardens, and orchards, and grass yards; and within two years after, or thereby, that hous took fyre accidentally (as I conceave), and wes totallye burned, as it standeth now: and so became of everye thing that the *winkypie woman*, my *wyfe*, lade *hir hand to*." He pathetically adds: "Bot this is nothing to that which will follow heirafter." His son afterwards dispoone it (it had been rebuilt) to Charles I., and in that transaction his mother's evil star seems still to have been in the ascendant, for he never received payment of the price.

The square tower and spire of the Canongate Tolbooth, which was built in the year 1591, on the site of an older building, are flanked by two pepper-box turrets in front, from between which projects a gallery leading to a clock-tower, which is surmounted by an ogee roof, and rests on cast-iron supports springing from the wall-face, which have been substituted for the original oaken supports. The tower, which is more German than French in character, is exceedingly picturesque, and is much and deservedly admired. The very curious dwarf, antique, polygonal building near the Water-gate, which is known as Queen Mary's Bath, but which was one of the gate-houses of the abbey, has one of these circular cone-roofed turrets boldly corbelled out from the eastern angle. Pinkie House, a very elegant mansion in the vicinity of Edinburgh, built in the beginning of the seventeenth century, is adorned with turrets of this description; but their proportions are much more slender and graceful than is usual, and they are surmounted by waving tabernacular roofs. Altogether they much resemble the turrets of the French Renaissance. One end of this fine Scotch baronial mansion, of a considerably earlier date, is flanked by two very handsome square hanging turrets, which have high-peaked roofs, and are connected by an embasured bartizan, behind which rises a gable with crows-steps, ornamented with *bottle and fillet* mouldings. The very beautiful corner turrets upon the towers of Heriot's Hospital have, in addition to their other ornaments, cannon-shaped gurgoyles of various and elegant designs. In a view of the hospital, which was engraved in Holland in 1650, and which is believed to afford an accurate representation of the original design, the large towers are seen covered with ogee roofs, and it would appear that two of them had been so covered, and afterwards altered. The staircase turret at the north end of the ancient royal palace in the castle is covered with a lead ogee roof, as were also originally the turrets of the east and north wings, which were erected in the year 1616. It is evident from the notes of Sir William Forbes & Co.'s bank, that the Old Parliament House was ornamented with a variety of square corner turrets, resting on corbels, and surmounted by ogee lead roofs. Some of them still remain in the back part of the building. In the appendix to Mr. Daniel Wilson's admirable book, "The Memorials of Edinburgh," there is a view given of the picturesque castellated mansion of Wricht's house, unfortunately taken down in 1800, from which we see that the central range, which was built in the reign of James VI., was

adorned with corner turrets with conical roofs. Near its site still stands, ornamented in the same manner, the venerable castle of Merchiston, memorable as the birth-place of John Napier, the illustrious inventor of logarithms. It is to be regretted that some modern additions, in the worst possible taste, have been made to this fine old castle. A circular tower, carried on very curious corbels, and ornamented with a handsome string-course, occupied one of the angles of a house in the Old Bank Close, which was taken down in 1835. In Mr. Wilson's "Memorials of Edinburgh," there is preserved a view of the French Ambassador's chapel, in the Cowgate, in which a long, graceful, circular turret is seen occupying the angle between the projecting staircase tower and the front of the building.

In James V.'s tower, Holyrood, the conical turrets, which still remain, and which rise from within the battlemented and corbelled-out parapet, previously to 1554 terminated in open crowns. In 1764 the Nether Bow Port, the most important as well as the most picturesque of the six gates of the ancient capital, was demolished by order of the magistrates, in order to improve the city! We are fortunately enabled, by the existence of some old drawings, to give a description of the "Temple Bar of Edinburch," as it was rebuilt in 1606. In the "Diurnal of Occurrences," the journalist says at p. 241, "The Lords and Captains of the Castle causit big one new Port at the Nether bowl, within the auld port of the same, of ailar wark, in the maist strenthie manner; and taik, to big the samyn wail, all the ailar stans that Alexander Clerk had gadderit of the Kirk of Restalrig, to big his hous wib." This venerable collegiatio church had been thrown down a few years before, by order of the General Assembly of the Kirk of Scotland, as "a monument of idolatry." The Nether Bow Port, so constructed, presented to the spectator standing in the Canongate two massive circular towers, flanking and commanding an intervening curtain, which was pierced by a broad low-browed archway. The latter was furnished with strong iron-clad doors, and a grille above; while the cordeliers' rope formed the principal moulding of the arch. The towers were connected by a bold string-course, which marked the division of the first from the second floor, and had battlemented parapets carried on machicolated corbels, which were also continued along the face of the curtain. Within the parapet over each tower rose a conical turret, similar to those on James V.'s tower in Holyrood Palace. This feature, common enough in Scottish baronial architecture, is worthy of notice, there being no example of it, so far as the writer is aware, in England. Above the curtain, and in the centre, rose a square tower, divided by a string-course into two stages, and surmounted by a spire. This square tower was battlemented and machicolated, and had cannon-shaped gutter-spouts. A clock partially concealed a window filled with louvre boarding. The spire, which was octagonal, with four pyramidal pinnacles at its base, was divided by cornice into three stages, on the middle one of which were four gablet windows facing the cardinal points. A vane and weathercock surmounted the whole. In the angles formed by the round towers described and the main portion of the building, which stretched transversely across the street, with its gables facing north and south, were two circular turrets, one stage higher, and surmounted by conical roofs. Several stone panels, one of which contained the city arms, further adorned the walls.

Beyond their extreme height and the picturesque manner in which they are associated with the gables, the chimney-stalks seldom present any peculiar feature, and are singularly devoid of ornament. Sometimes, indeed, in the old timber-fronted lands, they seem thrust through the roof in what, to a stranger, is quite an unexpected and unlikely position, an effect arising from the upper stories projecting so much beyond the ground-plan. They are generally surmounted by a flat coping-stone, and not infrequently taper in breadth as they ascend, the sides being divided into two or more stages, after the manner in buttresses.

When the chimneys are on the first or second floor, they are frequently carried so far through the thickness of the wall as to render it necessary to corbel out the chimney at the back. A good example of this arrangement is to be seen in Lord Dirleton's mansion, in the Canongate. I have said that the chimney-stalks are generally devoid of ornament; but Heriot's Hospital is a striking exception to the rule. There the roof is

\* See p. 258, ante.

adorned with beautiful groups of clustered chimneys,—cylindrical, hexagonal, and octagonal,—enriched with spiral flutings and zigzag ornaments.

Towards the close of Charles II.'s reign, the principal features of the Italian style began to be adopted. The corbie-steps gradually disappeared, and the gables assumed the form of pediments, surmounted by urns and similar ornaments. The land on the south side of the Castle-hill, adjoining the Assembly Hall, is a good example of this style, which wants the picturesque of the one it superseded, or at least succeeded. The façade to the street is in the form of a pediment finished with coping-stones, and surmounted by urns. On the keystone of the centre window on the second-floor, are wrought the initials of Robert Mowbray, of Castlewan, who built it in 1740. In Riddle's-court, Lawnmarket, there is a very handsome house, ornamented by string-courses, and surmounted by a triangular pediment, with finely moulded coping-stones and gloch-shaped ornaments, at the three angles. The house of Catherine, Countess of Galloway, in the Horse Wynd, is in the same style, having a handsome pediment in front, surmounted by urns.\*

I shall just mention one other example, the Golfers' Land, in the Canongate. Beneath a slah in the basement story, which contains an elegant Latin epigram from the pen of Dr. Pitcairn, are the words:—"I hate no person;" an anagram upon the name of the builder, John Paterson, who is said to have received a large sum of money from James VII., as a recompense for the assistance he lent the king, then Duke of York, in winning a match at golf against two English noblemen. Paterson's arms are sculptured in a large handsome tablet, placed on the front of the building.

The archways and square-headed entrances to the wynds and courts, which date from this period, are often highly ornamented, having pendent keystones, capitalised pilasters, and Doric entablatures. An archway nearly opposite St. Magdalen's Chapel, in the Cowgate, which gives entrance to the court of the house occupied by the celebrated Sir Thomas Hope, King's Advocate of Charles I., that over the entrance to the Hammermen's Close and a square-headed gateway in the Potterow, bearing the date 1668, are worthy of notice. A gateway adorned with a Doric entablature, on which is the date 1690, forms the principal entrance to Milne's-court, a fine open paved square, the principal building in which, forming the north side of the court, has a handsome entrance, with good mouldings. The court was built by Robert Milne, seventh Royal Master Mason, who was the builder of the most modern portions of Holyrood Palace. Alison-square, though of more recent date, is built in the same style. The broad low-ironed archway, which gives admission to it from Nicholson's-square, is ornamented by a pendent keystone. At the sides, square piers, with capitals and bases, support an ornamental Doric entablature. Pendent keystones also adorn the principal doorways on the walls and south sides of the square. The large square-headed windows are entirely devoid of ornament, and the general appearance of the square, once a fashionable and aristocratic locality, is undoubtedly monotonous and depressive. In one of its houses Burns had his first interview with Mrs. Macleod, the Clarinda to whom, under the name of Syriander, he addressed those amorous letters, which are as styled and inane as his love-songs are simple and beautiful. We shall add only one more example of the new style of architecture, interesting not so much as such, as from its being associated with the most eminent Scotchmen of the last century. To the east of Milne's-court is James's-court, erected in 1727. This is a large quadrangle paved with flag-stones, and walled off from the Lawnmarket by the intervening houses. It is entered by a low narrow alley. The buildings are lofty and substantial, but possess no other merit. Lord Alva, Lord Bankton, Lord Fountainhill, Hume the historian, Dr. Blair, and Dr. Johnson's biographer, Boswell, were among the distinguished residents in James's-court. Here, in 1771, Boswell entertained the patriot Corsican chief Paoli, as also the great lexicographer, when he passed through Edinburgh on his way to the Western Isles. There is one feature connected with the buildings on the north side of the court, which is thus described

by Mr. Burton in his life of Hume (vol. ii. p. 136):—"Entering one of the doors opposite the main entrance, the stranger is sometimes led by a friend, wishing to afford him an agreeable surprise, down flight after flight of a stone staircase; and when he imagines he is descending so far into the bowels of the earth, he emerges on the edge of a cheerful, crowded thoroughfare, connecting together the old and the new town, the latter of which lies spread before him, a contrast to the gloom from which he has emerged. When he looks up to the building containing the upright street through which he has descended, he sees that vast pile of tall houses standing at the head of the town, which creates astonishment in every visitor of Edinburgh. This vast fabric is built on the declivity of a hill, and thus one entering on the level of the Lawnmarket is at the height of several stories from the ground on the side next the new town. I have ascertained," he adds, "that, by ascending the western of the two stairs facing the entry of James's-court to the height of three stories, we arrive at the door of David Hume's house, which, of the two doors on that landing-place, is the one towards the left."

The most of the streets of the Old Town are *causewayed*, that is, laid with small blocks of whin or other stone, firmly jammed together by means of a wooden pavier or hammer, while, for the convenience of foot-passengers, the margins are laid with pavement, or *plainstones*, as they were formerly termed. It has been said, and often repeated, that the High-street was first *causewayed*, in 1532, by two brothers, John and Bartonne Foliot, Frenchmen; but this is evidently a mistake, as the desperate street fight between the rival factions of the Barls of Arran and Angus, which took place above the Nether Bow on the 30th April, 1520, has ever since been known by the name of *Cleane the Causey*, from the scene of contest. In 1535 we find the King granting to the Abbot of Holyrood a duty of 1d. upon every loaded cart, and a 4d. upon every empty one, to repair and maintain the *causeway* of the Canongate.

Side pavements seem to have been introduced about a century later. That they were not common before the beginning of the seventeenth century is evident from the petition of one Alexander Noble, in 1616, who prayed the Town Council for leave to "raise the calsay forment his tenement of land lyand at the fute of the Bow, forment the grey wickat, and to lay the same with plane stanes." In the Grassmarket a tenement bearing the date 1634 forms the front building at the entrance to Plainstone's Close,—a name evidently given to it as distinctive. Previously to the commencement of the South Bridge, in 1785, a row of six stones, forming the shape of a coffin, indicated the grave of Marlin, a Frenchman who first furnished the High-street with side pavements in the sixteenth century. By the end of the seventeenth century they had become quite general, and frequent allusion is made to them in the local legends of the time. Thus Robert Sempill, in his "Banishment of Poverty," a poem referring to the year 1680, says:—

"I grieved to gang on the Plain-stanes,  
To see it comrades would me ken;  
We twa gaid passing there our lains,  
The hungry hours' twixt twelve and one."

We come now to consider the internal architecture and ornamentation of those old houses whose external features I have endeavoured to portray.

The principal staircase is, as already mentioned, almost always of the kind called *turnpike*, the spiral stairs winding in corkscrew fashion, round a central newel. There is a landing-place at each successive story or flat, giving entrance to a passage guarded by a door, and from the passage open the doors of the different houses on the flat. In houses built during the reign of James IV., the staircases were lighted by unglazed loop-holes in the wooden front, which were sometimes square, sometimes round, and which were called *shots* or *shot-windows*. Frequent mention is made of these in old ballads and contemporaneous chronicles. Cawin Douglas, Provost of the Collegiate Church of St. Giles in James IV.'s reign, thus describes the wintry prospect he beheld from his own window, from which he turned to his fireside, and the translating of Virgil:—

"The dew-droppis conglit on stibhill and rynd,  
And sharp balistans mortfandett of kynd,  
Hoppand on the thak and on the causy by;  
The schot I cloist, and drew inward in by,

Chyrrand for cold, the season was so snell,  
Schupe with layt flambe to felym the freezing fell,  
And as I bowyt me to the fyre me by,  
Bath up and down the howe I did aspy;  
And second Virgill on ane latron stand,  
To write onone I byat a pen in hand."

We read, too, in Calderwood, how, when the Earl of Morton was held by the Maiden, for the murder of Barmley, "Phairmirst stood in a sbott over against the scaffold, with his large rufles, delving in this spectacle."\* There are good examples of these shot windows in the antique tenement, known as the Cunzie Nook, in the Candlemaker's-row, one of the most interesting and picturesque of the old Edinburgh houses. In houses of later date the staircase windows are of good size, and generally strongly stanchelled with iron. Sometimes the grille is made of wooden in place of iron bars; and sometimes, as we have seen, the lower half of the window was occupied by two wooden shutters, which might be closed in bad, and opened in good weather, while the upper part was glazed. The glass was not usually fixed in the stonework, but was fitted into casements, which were moveable, and could be taken out and packed up when the family were from home. On a building to the west of Heriot's Bridge, in the Grassmarket, there may be seen a window with an oak transom and shutters, and the glass above set in an ornamental pattern of lead. Prior to the fourteenth century, when glass was introduced, thin horn or tale was made use of to fill the casements.

These winding stairs are by no means narrow or confined, but, on the contrary, are wide, commodious, and of gradual and easy ascent. Indeed, nothing is more likely to strike a stranger than the convenience of the Edinburgh turnpike stairs, which are comparatively rare in English houses.† Within the houses, too (for the turnpike stairs can be scarcely said to be within), the staircases are broad and commodious, and flanked frequently by curiously-carved banisters of oak. In that wing of the Cunzie House which was built in 1674, two broad flights of steps, with an oak banister on the left side and oak panelling enriched with carving on the walls on the right, lead from the principal floor to that above it. There still remains in Sir John Hope's house, although much dilapidated, an old oak staircase; and in the ancient tenement in Anchor's Close, which tradition asserts to have been once occupied by Queen Mary, there are some very fine oak balustrades. In describing the palace of Mary of Guise, Mr. Wilson says,— "There was access to the different apartments, as is usual in the oldest houses in Edinburgh, by various stairs and intricate passages; for no feature is so calculated to excite the surprise of a stranger, on his first visit to such substantial mansions, as the numerous and ample flights of stone stairs, often placed in immediate juxtaposition, yet leading to different parts of the building."‡

The doors opening from the turnpike stairs to the different flags are very strong and substantial, and are thickly studded with large iron nails. Bells were not known till a very late period, and their predecessors, the iron knockers, were themselves preceded by the risp or tirling-pin already described. The inner doors of the better class of houses were often made of oak, finely panelled and carved. At the demolition of the Guise Palace, in 1845, there was removed from its first floor to the Museum of the Society of Antiquaries, where it now is, a beautifully-carved oak door. It is divided into four oblong panels, the upper two of which contain shields with heraldic bearings, supported by winged cherubs. The two lower panels contain portraits of James V. and his queen, Mary of Guise, carved in high relief, in closed in circular borders, above and beneath which are ornamental scrolls of different designs. The door is furnished with a lock, which, however, has no ornamental pretensions. In the same building two richly-carved stone recesses were furnished with oak doors, on which were carved dolphins and other devices; and there was also found the finely-carved oak door of a cupboard.

The ground-floor was generally vaulted, and over it was placed the hall or principal apartment. The ceiling of the hall was sometimes arched, as in the house already mentioned as having the inscription "Lans Deco" on its front; at other times it was waggon-shaped, as was the case in two of the principal apartments in the

\* In the statue of the Ridotto of Holyrood House, the Countess is described as

"— a lady well known for her sirs,  
Who ne'er goes to revel but after her prayers!"

\* Calderwood, vol. iii., p. 675.

† There is a good turnpike staircase at Langley Castle, in Northumberland.

‡ "Memorials of Edinburgh," v. i. p. 146.

Guiso Palace, which I shall have occasion to revert to by-and-by, and in General Dalryell's house, which was taken down about twenty years ago.

The earlier fireplaces were of immense dimensions. It is problematical whether, with one exception, any exist in Edinburgh which are of earlier date than the sixteenth century. In the fourteenth and fifteenth centuries the fireplace always had a hood over it of greater or less projection, and was generally corbelled out in a bold and picturesque manner; but Edinburgh possesses no fireplace of this description. In the kitchen of General Dalryell's house there was a fireplace of huge dimensions, formed of a plain semicircular arch. In a house which stood to the east of Sempill's Close, but was removed about thirty years ago, and was probably one of the oldest in Edinburgh, there was in the principal apartment, which occupied the whole of the ground-floor, an immense fire-place raised above the level of the floor and guarded by a stone ledge or fender.\* In a very fine old stone mansion, in Sandiland's Close, supposed, on probable grounds, to have been the residence of Bishop Kennedy, in the reign of James III., there is a very fine old fireplace, one end of which only, however, can be seen, in consequence of some old partitions and panelling which conceal the rest. In that part of the architrave which is visible, being one of the corners, there is boldly sculptured a group of figures, which seems to be intended to represent the offering of the magi. The Virgin holds out the infant Jesus in her arms, while one of the Magi on his knees tenders his offering to the babe.† Unfortunately this interesting piece of sculpture is much disfigured by whitewash. In the quadrangular palace called Lockhart's-court, which was removed in 1785, to make room for the new building of the South Bridge, and which was the temporary residence in 1591 of James VI., and his queen, Anne of Denmark, there was a chimney-piece in the drawing-room of the most magnificent workmanship, and which reached to the ceiling. On it were carved the words, "Va d'un vol à Christ" (Go with one flight to Christ).—an anagram upon Nicholas Edwartus, the Latinized name of the proprietor Nicol Edward, provost of the city.‡

There yet exist in Edinburgh, in houses of the sixteenth and seventeenth centuries, some large and very beautiful Gothic fire-places, decorated with rich mouldings, and with the mantels supported by clustered pillars with regular capitals and haases. There is one such in a very dilapidated house situated on the west side of the Old Fleshmarket Close. In Edward Hope's house in Todd's Close, removed about twenty years ago, there was another very beautiful Gothic fire-place, adorned with roses filling the interstices of the clustered pillars. There were several beautiful fire-places in the same style and of the same large dimensions in the Guise Palace. There is a fine fire-place still existing in an old stone land at the head of Lady Stair's Close; another in a house on the west side of Sellar's Close; and another, lined with Dutch tiles, in a house in Boswell's-court.§

#### THE MAJESTY OF ARCHITECTURE.

ALL study confirms the proposition that there are but few subjects in the range of history, art, and science, that are undebated to architecture either for illustration or confirmation. Thinking, in the exigencies of our daily tasks, of the requirements of modern life to be provided for in modern buildings, we are apt to undervalue the versatility, overlook the antiquity, and deny the majesty of the grandest of the arts. We have been especially impressed recently with the services architecture has rendered to ethnologists. No one now treats of the origin of the races of man without bringing forward in evidence the remains of Egyptian buildings. Dr. Nott, in his "Types of Mankind," Dr. Colenso, Mr. R. S. Poole, all produce the testimony of Egyptian remains in support of their views. Dr. Nott writes,—"Ethnology was no new science even before the time of Moses. It is clear and positive that at that early day (fourteen or fifteen centuries B.C.), the Egyptians not only

recognised and faithfully represented on their monuments many distinct races, but possessed their own ethnographic systems, and already had classified humanity, as known to them, accordingly. They divided mankind into four species, viz., red, black, white, and yellow. . . . When Egypt first presents itself to our view, she stands forth, not in childhood, but with the maturity of manhood's age, arrayed in the time-worn habiliments of civilization. Her tomba, her temples, her pyramids, her manners, customs, and arts, all hetoken a full-grown nation." We are not going to follow Dr. Nott in the inferences he draws from this early civilization, our object being simply to show how ethnologists have turned to the architecture of the Egyptians as to a storehouse of proof of the antiquity of man. In the same strain we have Leguin's writing (*Briefs aus Egypten*).—"We are still busy with structures, sculptures, and inscriptions, which are to be classed, by means of the now more accurately determined groups of kings, in an epoch of highly flourishing civilization, as far back as the fourth millennium before Christ." Delitzsch awaits the proof of a manifold division of the human race from an investigation of Egyptian monuments. Kenrick notes that, 1,000 years before the Deluge, the same hieroglyphics were used on monuments as at the end of the monarchy of the Pharaohs, marking an organised monarchy and religion in that remote era. Additional researches have been made in the same field for the same purpose by Bunsen, Birch, Hinsholdt, Hincks, and Osborn. The size of the human race, too, in old times, is determined by the same test. The traditions of former gigantic stature are exploded by the passages, chambers, and sarcophagi of the pyramids. Again, students of theology, deciphering with microscopic care every passage in holy writ, find in architectural remains some of their most stupendous references. Thus, Dr. Colenso, connecting the mention of the tower of Babel with the famous unfinished temple of Belus (Birs Nimrod), quotes Kalisch for a description of that terraced pyramidal edifice. "The tower consisted of seven distinct stages, or square platforms, built of lime-burnt bricks, each about 20 ft. high, gradually diminishing in diameter. The upper part of the brickwork has a vitrified appearance; for it is supposed that the Babylonians, in order to render their edifices more durable, submitted them to the heat of the furnace; and large fragments of such vitrified and calcined materials are also intermixed with the rubbish at the base." Professor Rawlinson thus interprets the history of it, as related on the cylinders by Nebuchadnezzar, who endeavoured to complete the work. "The building named the Planisphere, which was the wonder of Babylon, I have made and finished. With bricks, enriched with lapis lazuli, I have exalted its head. Behold now the building, named 'the stages of the seven spheres,' which was the wonder of Borsippa, had been built by a former king. He had completed forty-two cubits of height; but he did not finish the head. From the lapse of time it had become ruined. They had not taken care of the exit of the waters; so the rain and wet had penetrated into the brickwork. The casing of burnt brick lay scattered in heaps. Then Merodach, my great lord, inclined my heart to repair the building. I did not change its site, nor did I destroy its foundation platform. But, in a fortunate month, and upon an auspicious day, I undertook the building of the raw brick terraces, and the burnt-brick casing of the temple. I strengthened its foundation, and I placed a titular record on the part which I had rebuilt. I set my hand to build it up, and to exalt its summit. As it had been in ancient times, so I built up its structure. As it had been in former days, thus I exalted its head." Oppert, however, substitutes for the sentence "From the lapse of time it had become ruined," "Since a remote time people had abandoned it, without order expressing their words," thus making the cylinder bear evidence of the identity of the building with that mentioned in the mosaic writings. We must see the incomparable value of ancient architectural testimony as opposed to that of early writings. In the latter case meagre outlines are filled up by different readers, according to their own measure of learning; but in the former there is reality before us. The superb remains uncovered by Mr. Layard in Assyria impress us more with the magnitude of that monarchy than any literary work could do.

Nowhere is the majesty of architecture more apparent than in our own land. What grandeur is shed upon the memory of the ancient Briton

by Stonehenge and Abury! In these examples of early effort we may recognise how potent architecture embodies those who pay her tribute. But for these stupendous monuments of organized labour we should view with scepticism the Triads of Dywval Moelmd, imputing a high degree of cultivation to the Cambrians 2,000 years ago. But with these temples before us we read them with light upon the page. Dywval Moelmd speaks always of a verdict of 300 men to decide disputed questions. All contests about land were decided by appeal to this large number of men. "The counter party shall stand by the person who purchased the land, upon taking possession, and bringing forward unquestionable evidence of heirship, shall repay a just counter price to the previous purchaser, and shall lay down the money upon the back-fire stone, horse-block, boundary-stone, or upon the nearest white stone that is found in the place, or into the hand of the judge of the Court of the Cmmot, or upon the area in the presence of the Court. Where this is done the country enacts that he is to have his land, and the defendant the counter-price." Can we not picture these assemblages of 300 jurymen with almost photographic precision as we linger among their "stones of convention?" There is another triad we could scarcely comprehend, but for some such assurance of power and skill as the disposition of these mighty stones gives:—"There are three things that preserve a record respecting land and family, and stand as decisive evidence,—a back fire-stone, a lime-kiln, and a horse-block,—because the arms of a family are cut upon them." May some of the enigmatical figures now found in different parts of the country incised on rocks be interpreted as these "arms, or distinguishing marks?" "There are three other stones," says another triad, "which, if any man remove, he shall be indicted as a thief,—the boundary-stone, the white stone of convention, and the guide-stone; and he that destroys them shall forfeit his life." Mention is made of a custom of writing the warning of the country upon the king's posts or stones. But these have all been lost sight of, as completely as we have lost all trace of the ship of Nwydd Nav Neirion, which brought in it a male and female of all living things when the lake of floods burst forth; or of the large horned oxen of Hu the Mighty that drew the corndillo from the lake to the land; or of the stone of Gwyddon Ganhehon, upon which all the arts and sciences in the world were engraven; whilst Stonehenge and other specimens of their concentric monolithic architecture stand as a testimony of labour as organised as that which conveyed the winged bulls to their sites in the palace at Konyunjik, and as sufficient as that employed by the ancient Egyptians in moving their colossal figures from the quarries. So expressive, too, as well as majestic, is architecture, that we may truly say, Show us a building or a pile and we will tell you who built it. Who could have reared Stonehenge but a race rejoicing in strength and might, scornful of ornament, regardless of colour, unimpressed by beauty of form, apparently conscious only of the dignity of simplicity? And, as if to confirm this estimate of the taste of the ancient Britons, we find their representatives, the Welsh, at the present day engaged in two undertakings, neither of which has colour, form, or ornament, in its composition. The principal manufacture of the modern ancient Britons, if we may call them so, is the colourless woollen textile known and esteemed as Welsh flannel: the principal export is slate despatched from the Cambrian shores in the same condition as that in which it is procured from the quarries. The unextinguished cast of mind that put the huge blocks of Stonehenge into place and left them in their natural simplicity is here apparent; we see no artistic feeling stirring to find vent in a manipulation of the slate; no craving for colour satisfying itself in rich dyes of the staple manufacture. The huge blocks of slate tell again of confidence in strength, and might, and admiration of masses, undisturbed by creations of the imagination calling to be expressed in material forms; and the vast lengths of colourless flannel, of continuous labour handed down from generation to generation in a certain groove, unassailed by temptation to riot or revel in the gorgeousness of colour. Contrast this with the tendencies of the Oriental mind, every phase of which, in its exhibition of colour, is as a plane upon a crystal prism, and which, in like manner, exhibits the same tastes as ancient buildings indicate that the remotest occupiers of the soil possessed. Exhumed pe-  
ci-

\* A very similar fire-place of the thirteenth century still exists at St. Mary's Abbey, York.

† A similar piece of sculpture, representing the offering of the Wise Men, occupies the tympanum of one of the doors of the church of Notre Dame de Treves.

§ To be continued.

mens of Assyrian architecture, with their brilliant blue and red, deep yellow, and black and white decorations, assure us that under the glaring sun of the desert the earliest races rejoiced in colour as their modern representatives do to this day. They display, too, further characteristics of their builders which are also present in the people now occupying their neighbourhood. We have, in the multiplicity of figures and incidents, depicted in their basso-reliefs traces of the root of the restless, passionate, impressionable temperaments that now inhabit the desert. The eye-hunger for colour of the ancient Assyrian could not have been more insatiate than that which induces the owners of the white asses of Bagdad to dye them with kenna and dip their tails and ears bright red, or dictates the use of variegated turbans and striped abas to the Bedouins, or of robes of the scarlet silk of Damascus, or of scarlet and white fretted with threads of gold worn by the ladies of Bagdad.

Philological archeology affords us many clues which, if we follow, will lead us back across Europe and through faint-tinted and faint-outlined centuries into our old Asiatic home. Professor Simpson notes that the vast populations springing from the Arya stock "all use words which, though phonetically changed, are radically identical for many matters, as the nearest relationships of family life, for the naming of domestic animals and other common objects. Some of these archaic words indicate by their hoary antiquity the original pastoral employment and character of those that formed the parental stock in our old original Asiatic home; the special term, for example (the 'pau' of the old Sanskrit), which signified 'private' property among the Aryans, and which we now use under the English modifications 'peculiar' and 'pecuniary,' primarily meaning 'flocks,' or possession of flocks; the Sanskrit word for protector, and ultimately for the king himself, 'gopa,' being the old word for cowherd, and consequently for chief herdsman; while the endearing name of daughter (the 'duhitar' of the Sanskrit) as applied in the leading Indo-European languages to the female children of our households, is derived from a verb which shows the original signification of the appellation to have been the *milk* of cows." But architecture, in its calm enduring majesty, does still more than this. The sculptured decorations of the ruined palaces and temples on the banks of the Tigris and Euphrates show us that their builders were acquainted with most of the arts now and in Medieval times, common to Europe. The various contrivances used in the Middle Ages in warfare were all known to the people who reared and subsequently abandoned these piles. The movable tower running on wheels, the battering-rams, the catapult, scaling-ladders, huge shields capable of covering several men at work at the various processes of mining and picking a breach, were depicted by the Assyrians and Egyptians thousands of years ago. The prophet Ezekiel, announcing the approaching destruction of Tyre, says of Nebuchadnezzar, "He shall slay with the sword thy daughters in the field: and he shall make a fort against thee and lift up the buckler against thee. And he shall set engines of war against thy walls, and with his axes he shall break down thy towers." And the storied sculptures and bricks of the overthrown structures of Nebuchadnezzar—mere disregarded mounds in the desert for centuries—when examined "in a fortunate month and upon an auspicious day," confirm the fulfilment of the prophecy. In a word, Assyrian architecture tells us the language, the arts, and the materials at command of the nation in the days of its magnificence. Egyptian architecture, after centuries of reticence, yields similar information to modern explorers. We are still more familiar with the fidelity with which Roman buildings reflect the successive acquisitions of the mistress of the world. Seeing, then, that architecture thus tells the history of peoples, and thus teaches the measure of man's learning in so many of the arts and sciences, is it not meet that we should approach its practice with due reverence and understanding?

#### ARCHITECTURE IN THE ROYAL ACADEMY EXHIBITION.

CONTINUING our survey of the architectural drawings in the rooms of the Academy,\* we next meet with a design for the Scottish National Albert Memorial (801), exhibited by Mr. W. A. Carter. It represents a lofty and ponderous, but richly decorated, Gothic structure, having a peculiar character of termination, consisting of flying buttresses somewhat after the manner of those carrying the spire in the churches of Newcastle-upon-Tyne, and St. Dunstan's in the East, but here bearing aloft a coronet. Through the interspaces of them appears what might have been the actual termination to the structure, having a domical form, and finished by a finial. The whole of the upper portion of the memorial is carried by canopied arches, which spring from the slightest of coupled columns. We do not know how the structure could stand; but there is merit in some of the details of it, and in the drawing; and the chief feature might have a good effect. A design for the same Memorial, by Messrs. Slater & Carpenter (810), consists of different octagonal stages in the superstructure, and pinnacles upon a square base formed of four arches under pediments or gables of the Italian Gothic character, which is that of the whole design. The piers are enriched with nook-shafts. The idea, in the monument, is the same as in all works of the class,—a shrine over a statue. The Italian Gothic "proclivities" of some of our architects do not result satisfactorily. They indicate that there has been a certain sort of study,—that which should produce art; but the result generally is not what we can call work of art. Mr. R. P. Spiers's "Design for a Museum of Natural History and Science" (815) is that for which the travelling studentship of the Royal Academy was awarded in December, 1864. It displays much invention in detail, combined with good taste. The piers between the windows finish in coupled pilasters, the junction being concealed by tablets and busts. Suggestions have been derived from recent buildings of Paris, but not to a greater extent than would be permissible in like cases. The design has one attribute which we have taken opportunities to remark must belong to a work of good art-architecture at the epoch of its production: it is difficult of description in the language of words. Mr. Spiers has also exhibited some of his sketches of examples of architecture in Italy, as the "House of Cornelius Rufus, Pompeii" (819), "Arch of Titus, Rome" (835), and "Chapel of St. Bernardino, Perugia" (836). Of works connected with the metropolis, there are several illustrated in drawings which we have reserved for notice. Mr. Bazalgette's Southern Outfall Station of the Main-Drainage works is shown in two views (808, 809), but of course not in the most interesting part of it, which is below ground. The most important work decoratively, is the "National Provincial Bank of England," which is now in course of completion, by Mr. John Gibson. It is represented by two views, one (814) of the exterior, and the other (805) of the interior. It is described as in Threadneedle-street. The chief part of the site, and the main front, however, are in Bishopsgate-street, next the South Sea House. Both exterior and interior should be looked at with acquaintance with the fact that everything has been designed under influence of difficulties of site, and of the rights of adjoining owners, such as are rarely experienced even in the City of London. The curvature of the street-line, together with value of ground, led to the curve just at that part of the frontage where the entrance is, which the architect, by extending and converting into a larger sweep, has made a feature in harmony with that portion of the front which is parallel with Bishopsgate-street. The necessity for not interfering with "ancient lights," combined with the effort to give as much height to the banking-room as possible, led to the cove which is so marked a feature in the ceiling. The principal features of the exterior are an order and six bas-reliefs. There are four bays, or intercolumns, on the Bishopsgate-street side, where the windows are, and two on the curve. The columns at the ends, and on the curve, are coupled. The capitals are of mixed Corinthian and Composite character, but, like the details throughout, are of an original treatment. There is only one range of windows, the intercolumns in the upper part being occupied by the bas-reliefs, which will represent the Arts, Commerce, Science, Manufactures,

Agriculture, and Navigation. Statues on the cornice of the building will, we believe, represent England, Wales, London, Birmingham, Newcastle-under-Lyne, Dover, and Manchester. Without going much further into description, which we shall have opportunities of resuming, we may mention that the interior of the banking-room is lighted in the main portion of its length, through the ceiling, by three domical lanterns, in each of which the ribs terminate at the top in a large circle or "eye," from which hangs a pendant, in glass and metal-work, ending in the "sun-burner" light, and serving the ventilation. The ends of the room are divided from the centre by arches, springing from columns, or rather directly from an interposed cornice and blocks. The columns are on pedestals, the columns detached from the walls being grouped, four together on a pedestal, whilst the columns next the walls will be coupled, and the shafts throughout will be of red marble. Not far off in the City, or at the corner of Leadenhall and Bishopsgate streets, are the London and Lancashire Insurance offices, now building, of which Mr. T. Allom exhibits a drawing (774). The general character is Italian. There will be four stories, and a range of dormers, arch-headed windows in the ground-story, and a canted or rounded angle, where is the doorway, which, as well as the features above it, will be of good character.

Mr. R. W. Edis exhibits a drawing of the new warehouses in Wood-street, Cbeapside (780), which have been lately erected for Mr. W. Haynes. There are four stories of wide openings as required for light, and very narrow piers. Each of the three lower stories is arranged as an arcade, whilst the top story has the piers carrying the horizontal line of the cornice. The arches spring from enriched capitals; and in the top story, each opening is divided into two lights by an iron column. The style may be called Classical or Renaissance, with a Gothic modification. Some of the details are not good; but the design has character. Coloured marbles are introduced in panels; but they will be of little value for the effect in a couple of years. We advise all architects who would use coloured marbles on the exteriors of their buildings, to see what is the present appearance of those on the drinking-fountain erected by Miss Burdett Coutts in the Victoria Park, which was illustrated in our pages not very long ago. They are now no better than common slate. The white marble even has stood better than the coloured; though of what is the condition of that material very soon, in any part of London, we need say nothing. The statue of the Queen in the Royal Exchange, has been some time in a state which seems disgraceful to the citizens. Mr. E. Ellis exhibits under the title "City Improvements" (824) a view of the Queen Insurance Buildings, Gracchurch-street, lately mentioned by us; one of Offices in Billiter-street, with the usual wide openings; and one of Messrs. Hambro & Son's Offices in Old Broad-street; which last is Gothic, in part.

Messrs. Banks & Barry's "Westminster Chambers, Victoria-street" (793), have been illustrated in our pages. Their character of art, despite the ugly balls repeated in two of the lines of balcony, is vastly superior to that of the Piazza Statuto, supposing for a moment the latter to be their work. The five stories group well; for the second and third story-windows are joined; and the string-and-balconet-line above, and that below, are well marked. The "Mansion for Sir S. Morton Peto, Bart., M.P., Kensington Palace Gardens," a view (823) of the garden-front of which is shown by the architect, Mr. J. Murray, has good Italian details. There are two octagonal two-storied projecting windows, and one similar feature, but square.

The select competition of designs for Grocers' Hall is represented by drawings by Messrs. E. M. Barry (800 and 816) and W. A. Boulnois (818). Mr. Barry's design externally, shown in No. 816, has a rusticated basement, with caryatids and arch-headed entrance-ways in the centre; and, above, there is an order of Corinthian columns, taking in the height of two stories, the centre of the front having the columns coupled in the depth. The centre and wings are carried up with attics. We admire this sort of design in a work of the date of Somerset House; but in order that work which is of the present day should be capable of being pointed to as art-work, there should be something added to it. The added element used by

ARCHITECTURAL ASSOCIATION.—The meetings of the Figure-drawing Class will cease after Thursday, the 25th inst., to be resumed in October, unless the education scheme proposed by the Royal Institute of British Architects be then in working order.

\* See p. 303, ante.

very little; indeed, seeing that novelty, or rather what is the pretence of it, just now commits greater errors than skilful adaptation, or even copyism, we would prefer that the addition should be little, and that the bulk of the effort of the designer should be given to the skilful welding of all the elements which go to the formation of high art-architecture. There is no very new feature, more than in the exterior, in the interior of the Livery Hall (800) of Mr. Barry's design; but the members of the architecture are such as, arranged with skill, never fail to produce effect. They include salient columns, carrying arches which groin into a cove, and enclose lunettes. Of such an interior, perhaps the best example in London is in Clothworkers' Hall, of which Mr. Samuel Angell was the architect. A portrait of Mr. Angell, by Boxall, painted for the Clothworkers' Company, we may mention as being in the exhibition (No. 150). There is also a portrait of Mr. Thomas Page; it is by J. W. Walton (540). There is one feature in Mr. Barry's interior, that is not so common. Chandeliers are dispensed with; and the hall is lighted by three "sun-burners," placed in domical-formed spaces in the ceiling. Chandeliers, hanging from the ceiling, however effective in themselves they may be, are obstructive of intended general effect; and it is almost impossible, ventilating the lights, not to have something that is very unsightly. But "sun-burners" have yet to be made tasteful, as well as with variety in their forms. Eventually, as we believe, there will be a great modification in the architecture of interiors, through the extension and artistic treatment of methods of "exclusive" and ceiling lighting; and there will certainly be great sanitary benefit. What Mr. Gibson has designed will go some distance in showing the way. The design by Mr. Boullenois for the interior of the Livery Hall (818) has a ceiling having a central space and coves at the sides, the total length being divided by ribs, and each bay of the centre having a domical light carried by pendentives and lunettes-arches; whilst the lower half of the cove has three lunette-arches in each bay, and the upper half is enriched by scroll-work on a blue ground. The walls are pilastered in the upper part, and have piers and wainscoting below. A loggia or gallery at the end, looking into the hall, is the best feature of the design.

Some time last year, the Marquis of Westminster procured from several architects, designs for houses which might be erected on ground between Grosvenor-crescent and Ilkln-street. Mr. Street's design, Gothic, in red brick and stone, is represented in the Academy exhibition by a view (795). Bay-windows, with the Venetian tracery; gabled hoods to the doorways, on very bold corbelling; window-lintels carried by corbelling from square reveals; and a window, circular on plan, with a balcony, corbelled out very boldly from an angle, are its chief features. Mr. E. M. Barry's design (806) is put forth as suggestive of the employment of terra-cotta. This material, red, would be used for the window-dressings, principal cornice, pilasters, and friezes. Certain columns, of a colour resembling stone, we imagine are intended to be of the light-coloured terra-cotta. The main walling would be brick, rusticated with the dog-tooth ornamentation, as in the Charing Cross Hotel. Windows holdily projecting to the extent of the ground usually occupied by the area, are features of the ground-story. The balustraded spaces to flats at the top of these windows, are joined across the front, and to the porch, by a balcony. There are balconies to three of the stories; and the pedestals in each case carry flower-pots. The plants and flowers in these, go to make much of the effect of the drawings.

We have omitted to mention the "Factory in course of erection at New Cross, Deptford, for Thomas Letts & Sons" (832), which was designed by Mr. J. P. Jones. It is a four-storied red-brick and stone structure, divided by broad and banded piers into five bays, each filled with window-openings of many lights. The general character is Italian. The piers are crowned by large vases, above the cornice; and there is a great arch, or one taking in the height of the second story, to the entrance. A drawing of the interior of the Sainte Chapelle is exhibited by Mr. W. Bayliss (831).

CHICHESTER CATHEDRAL.—The first stone of the spire of this cathedral has been laid by the Duke of Richmond.

#### THE ROYAL ACADEMY EXHIBITION.\*

THERE is a scarcity of such productions as are illustrative of Biblical history, and nothing either of cognate attempt or accomplishment to compete with Mr. E. Armitage's masterly presentation of "Esther's Banquet" (422). Haman, kneeling at Esther's feet, is beseeching her to intercede for his life at the time that he is about to be seized and conveyed for the death the king has condemned him to. All the painter's generally accorded excellences, extraordinary skill in composition and drawing, with rare apprehension of apposite expression, are exhibited in great force; and in addition there is more appreciation of the worth of rich colour, with extra use of ornamental detail, than is common to most of his works.

If Mr. J. B. Herbert, R.A., is not very conspicuously represented this year by his single, and, for him, rather unimpressive picture of "The Sower of Good Seed" (46),—for the parable is not so significantly rendered as to be at once defined,—it is to be identified with more important productions by the simplicity of its design and the appropriation of present Eastern facts with their earlier associations, in preference to a more imaginative treatment of such subjects. As a record of customs and costume which obtain, in all their primitiveness, to this day, and therefore afford the most reliable authority for the propriety of such employment, there is great interest attached to it.

Mr. J. F. Lewis, R.A., is less curiously elaborate than is usual with him, though it would be difficult to find any other than he who could exceed the exquisite brilliancy and finish of the various flowers collected "In the Bey's Garden" (254) that a favourite Circassian slave is choosing from and gathering; or the delicacy with which the characteristic type of her race is preserved in this graceful figure. But in (121) "A Turkish School," a greater breadth of manipulation has imparted to it an appearance of solidity and force that, with more minute observation of detail, he sometimes but partially succeeds in conveying. There is admirable variety of natural attitudes amongst the group of scholars, and every head is a distinct and lifelike study, with some real sunshine to lighten them.

Writers may differ in estimating her claims to it, but few characters have retained so permanent a position as Queen Mary Stuart, or stand out in more prominent relief, even in those pages of chronicle most replete with dramatic incident, and most remarkable for the confidence of actors and actions that are among the least likely to be forgotten. Further to commemorate one of the circumstances that help to lend the charm of romance to her biography, Mr. E. M. Ward, R.A., has selected the death of Rizzio, and, without depicting the actual deed, has most vividly implied the particulars of it. The moment of an apparition from the grave enters like an apparition from the grave to disturb the supper-party, consisting of the queen, the hapless musician, and the Countess of Argyll, attended by Arthur Erskine the equester, Lord Robert Stuart, and the queen's French physician, on "The Night of Rizzio's Murder" (258). He has been preceded by Darnley, who, as a signal for a still less agreeable intrusion, embraces his wife. Mary, suspecting the two to be in concert, answers his kiss with the one word, "Judas," and confronting the ghastly Ruthven, demands his mission;—"Let your man come forth; he has been here over long." Rizzio, shrinking from the grasp of the outstretched hand, abjectly appeals for protection, but all save the colloquists appear to be paralysed, and there is evidently no chance of escape for him, the wretched victim of a fond woman's favour. This picture may be ranked with the best of Mr. Ward's illustrations of English history: for its admirable technical qualities it is a very valuable work. To succeed in acquiring fresh interest for an oft-told tale is the narrator's greatest triumph, and the attraction his version proves to be possessed of, whilst saying much for the enduring nature of the text, is a stronger attestation still of his power who propounds it.

Mr. Moore, R.A., has painted very beautifully, with a strong opposition of gas-light and moon-light to help him in effects, a striking instance of the terrible results that so certainly await the votaries of "play," if the misnamed disease be allowed to obtain its thorough influence; but fortunately the episode taken for illustration

(138) must only be accepted as probable,—less probable of occurrence than powerful to point a moral, though this force is weakened by its attending suggestiveness of improbabilities. A foreign visitor to a German spa—a girl without protection—or a naughty truant from it?—has retired from the gaming-tables, after having staked and lost all her immediately available means of living but those a handsome tempter is offering to provide for her, and she is hesitating to accept, involving as they do a further conjugation of the verb "to lose." Mr. Elmore leaves the quiet shades of convent gardens for no less a change than Baden would offer, and forsaking the edifying society he has seen so singularly happy in gaining access to—that of the pensive nuns,

"Devout and pure,  
Sober, steadfast, and demure,"—

for contrast, perhaps, introduces a sister of another community, of whom it may be asserted, doubtful as her after-fate threatens to be, with so ominous an intimation of it as her conscience is making questionable, that, at all events, "she won't be a nun." For a young lady who shares in that reckless spirit of gambling that knows no limit, and is capable of becoming regardless of consequences in the indulgence of a mercenary disposition, there can be little hope of escaping that vortex "on the brink" of which the artist has so clearly presented her. That she is more likely to take the plunge into the black tide of bitter experiences, than a pledge to forewear as a falsehood its allurements, is too clearly shown to make the picture a pleasant one to contemplate.

It is some time since Mr. F. R. Pickersgrill, R.A., has been seen to such advantage, with regard to manipulative proficiency, as in (76) "A Royalist Family, 1651," though the "unfriended" are too clean and nicely clad to betoken all the hardships of their momentous position, which is more that of cleverly prescribed arrangements for picturesque representation, than indicating those hastily conceived by the proscribed for hiding. The female figure is extremely refined, and the painting throughout very pure and bright. Mr. J. C. Horsley, R.A., essays to show the earliest period at which the fair sex evince the dominant spirit of coquetry; but obviously his pretty little specimen of six or seven summers old is a long-practised torturer, and she has kissed—or been kissed by—many a live doll, "Under the Mistletoe" (146), as that envious and worried Romeo, at least by one year her senior, knows to his cost, and he hates the wooden one who is now monopolising all these attentions and favours that the bewitching object of his consuming passion does not always withhold from him.

Another miniature edition of the volumes such early speech of instincts mean in proving the innate propensities of little men and women, is furnished by Mr. G. B. O'Neill (199), "The anxious Mother," a dot of a matron,—

"Who has so many children  
She doesn't know what to do,"

and has carefully tucked up her family of dolls, whose wide-awake eyes have no speculation in them, or they certainly would never go to sleep for wondering at the most comically serious expression of enjoined silence that ever tender parent with a "hush," and a premonishing finger on her lips, could possibly wear, as she sits by their bedside. It is pleasant as well as instructive to learn some of Nature's lessons in small print, and never too soon to recognise the lovable phases of it—for children do but grow—that promise so faithfully for the future; and where any, even the remotest indication exists, of a pinaford pet maturing into such womanhood ("save the mark!") as Mr. Simeon Solomon reveals, O you to whom babies' shoes and bread and butter are no myths, and of whom it can be said, "Hahet" (431), do as Saturn did, with no such justification—eat it, as soon as conveniently possible (N.B., the baby, not the bread and butter).

But Mr. Solomon's fish-blooded monstrous beauties are horrid mistakes, and all alike;—their apathy quite incompatible with the excitement such savage spectacles entirely owed their popularity to; and he has worked to little end beyond that of immortalizing about the ugliest mode of dressing hair modern European ladies ever adopted. He is a clever artist for all that. In some respects, analogous to this, is the "Bravo Toro" (304), of Mr. J. B. Burgess, but with such compensating excuse as the oppor-

tinuity it has given him for some capably-expressed knowledge of Spain and Spaniards, with their very varied emotions and characters, besides the palliation of having a large proportion of the spectators, men, and no great display of callous indifference on the part of the women. This is a great advance compared with antecedent, and amongst the most remarkable contributions from these exhibitors not directly connected with the Academy.

Mr. G. F. Watt's study of "Esau" (11), of rather gigantic stature, is distinguished by qualities not too frequently to be noticed,—simplicity of treatment and independence of conventional aids amongst them; but in the (251) "Portrait of V. Bowman, Esq., F.R.S.," because it is so far above common-place in a department where common-place is most prevalent, Mr. Watt's relative position is more thoroughly announced.

Not but what there are others who leave the beaten paths, and succeed, like Mr. H. T. Wells, in shaking off at least some of the restrictions that would appear to be patent obligations which who practise portraiture, did not such instances as (173) "Preparing a Tableau Vivant" occur in contrary evidence. But to return to subject-pictures, there was hardly material enough in Mr. J. Pettie's conception of (192) "A Drum-head Court-Martial" to make it worth an assumption of the importance assigned to it; and though very cleverly done, the execution is too sketchy to warrant it being considered a picture: another failing in it is that the heads are too small, and this with more direct reference to the triumvirate of judges. On the contrary, in Mr. F. D. Hardy's very telling tale of domestic trouble, "The Leaky Roof" (265), which appeals to so wide a circle of sympathisers, a very ordinary event is related with such eloquence of pencil as to raise prose to poetry by investing it with rare artistic performance.

Surely, Callot himself would have envied Mr. H. S. Marks his long list of acquaintances amongst those happy miserable of the cadging crew (331) who, to the timely barking of dogs, are coming to town. It requires something like an initiation properly to value the distinctive attributes of this interesting fraternity, but from the old inned one on two sticks to the youngest, but not the least clever, of the gang, there is consecutive evidence enough that—

"Of all the occupations  
A beggar's is the best;  
For, whoever he's weary,  
He can lay him down to rest."

With no ugly dreams, founded on naked facts, of rent and taxes to pay, and no troublesome doubts as to how one is to return oneself under schedule D.

The individuality of all the heads is one of the recommendations of this work; and the firm, solid painting throughout of well-considered accessories, another,—whether dogs, draperies, or quaintly-carved old buildings. There is humour, without vulgarity, in all Mr. Marks's pictures, as his impersonation of "Francis Pebble,—Woman's Tailor" (591), may assist in proving.

(327) "The Lay of King Canute," in a boat, with the lap of a lady for a cushion, is, at the best, but an inanimate theme for a painter to give vitality to; and Mr. H. O'Neill, A., has been less happy than is often the case with him, both in choice of matter and method of dealing with it. The king is requesting the rowers to near the land, in order that he may hear the song that the monks of Ely are singing so merrily. There is a want of that realistic appearance which, in the absence of higher merits, would constitute all the worth of a meaningless representation.

#### METROPOLITAN DISTRICT MUSEUMS; AND A HINT.

THE conference on the 6th inst., invited by Lord Granville to consider how far, in establishing suburban museums, the original iron building at South Kensington could be made available, was numerously attended, and included many influential men from the various quarters of the metropolis. Lord Granville, who was supported by Mr. H. Cole, C.B., said, in opening the business, he should not like to perpetuate ugly buildings in different parts of the metropolis; but he had little doubt that, if advantage were taken of the offer of the Treasury to give the materials for the formation of museums in

the several districts desiring them, and that the necessary ground were obtained, great efforts would be made to complete their establishment. He had equally little doubt that the buildings once erected, the collections would soon become large and interesting. If they would permit him he would throw out the crude suggestion that different portions of the present iron building might be lent at a moderate rent-charge, or that they might be sold at the mere cost of materials, the money to be supplied by the different localities. He had very little doubt but that, when once established, the people of the several districts would soon make efforts to procure handsome buildings of their own. Claims were then made in rapid succession by the Rev. Newman Hall, Mr. Mandley, Mr. Antonio Brady, Mr. Harvey Lewis, M.P., Dr. Hewlett, Capt. Rogers, and others, for various quarters of the town. Mr. Tite, M.P., did good service in showing how the building might be divided. Mr. Beresford Hope urged that five museums were required, and should be provided. Mr. Lucroft, a cabinet-maker, pointed out very sensibly the wants of his class in this respect. Lord Ebury, Mr. Briscoe, M.P., and others, spoke; and ultimately it was arranged that six months should be given for the consideration of the question in the districts, and that within that time special applications in writing should be made, showing what the neighbourhood in each case was willing to do. The building, which cost originally about 12,000*l.*, could be made to form three structures, each about 120 ft. long, and 90 ft. wide. A new roof would probably be required, and the expense of re-erecting with a fresh arrangement would not be trifling.

We have to express a hope that in considering applications that may be made, preference will be given to those that are accompanied by evidence that there is good probability of the building being properly filled, and that the collection of objects to be exhibited will be under competent direction. Reference was made by one of the speakers to the Working Classes' Industrial Exhibitions that have been opened, leading to the notion that the exhibition of a collection similar to these was contemplated. We would carefully avoid saying one word damaging to the idea of these exhibitions. Honour to those who have promoted them, though they are overdoing it, and, if they go on subdividing as they have done, they will bring them to an end very shortly. Nevertheless, the collection to be formed in the museums contemplated must be of an entirely different character, and calculated to increase knowledge and improve the public taste; with a view to which it is clear that they must be under a different sort of guidance from that which serves well enough for the Industrial Exhibitions.

We should betray a trust if we did not say that, however interesting as evidence of advance under difficulties and the satisfactory employment of spare time, the "works of art" sent to these Exhibitions have been, as works of art, they were for the most part atrocious and frightful, damaging to the eye and mind of those who were led to contemplate them.

We are glad to learn that the South of London will not let the question of a museum for that part of the metropolis sleep, and that before the publication of our present number a public meeting will have been held to ascertain the amount of pecuniary support that could be obtained, whether for the erection of a new building or for the adaptation of that portion of the Kensington Museum which may be obtainable from the Committee of Privy Council.

#### THE ARCHITECTURAL EXHIBITION.

RENEWED attention to the drawings in the Conduit-street Exhibition has served to confirm our impression of its excellence by comparison with the exhibitions of recent years. There is indeed in it, evidence of the divergent practice which we have heretofore held had the tendency to exalt observance of style at the expense of art, or of so much of the manifestation of art as may be considered common to all styles, and to perpetrate controversy rather than to induce appreciation by the public, of what is the valuable part of architecture. There is also observable in the works of some of our best draughtsmen, an appreciation of what is rather quaint and Mediaeval, than beautiful and in association with the period of actual production of the designs. The mistaken taste for strong contrasts of colour,

and for colour in the architecture of the exteriors of buildings, as contributing to effect which predominates over that from form, is also manifested, as also is the seeking for variety which should be that of individual treatment in the field of art, in the merely varied selection of styles reproduced. Nevertheless, as we have said, we are disposed to regard the present Exhibition, not only as an improved representation of what may be the state of art in architecture, but as the evidence that the state is more one of progression than that of which we had evidence last year. It is clear that we, architects of the nineteenth century, heirs "of all the ages," are but children in the use of the abundant materials which we have been so industriously digging up; we have yet to learn that true architecture is the pursuit of a living "thing of beauty," and not the production of any "galvanised corpse" of any period. The style through which our art in architecture may be expressed, should not, perhaps, be such as to be recognisable now, or at least such as that of any distinctive previous period; but it should be such as will be recognised as of our age, by our successors. There are those who think that the works of this time will be recognisable as ours, though not standing forth so markedly to ourselves. In the improvement which we detect there is reason for such view. Much, however, remains to be done ere a tone sufficiently congratulatory can be assumed. The divergency which presents us with variety of imitation, and sometimes even with too much of mere novelty, rather than with art, is still characteristic of those in practice who should be identified as artists; whilst the quantity of art was never at any time more out of proportion than it is now, with money spent, with the quantity of carved ornaments and other decoration, and with the extent of the introduction of the members of architecture and styles.

Leaving these indents from the form and pressure of the actual architectural time, for the appreciation of them which our readers may deem fitting, we proceed to mention the designs in the Conduit-street Exhibition, which, for one order of merit or another, have most registered themselves on our attention. Our notice must be less detailed than usual, not with our wish, but from circumstances to which we may hereafter make allusion.

There is no architecture that is more deserving the attention of the student than that which is practised in the present time in France,—given all the faults that have been ascribed to it,—and those in many respects, as our readers know we consider, justly. The design bearing the first number in the catalogue, which is one that we noticed in the South Kensington Natural History Museums Competition, by Mr. W. Harvey, is one that might have claims to notice, did we not find in it too conspicuously reproduction of the features of certain well-known works. In this case the buildings are the new portion of the Louvre, the Palais de l'Industrie, and the Bibliothèque de Ste. Geneviève. The last-mentioned of these works seems to have struck out a train of ideas to an extent not usually to be credited of productions of our time. There are traces of the influence in some of Mr. Spiers's designs; but they are so largely accompanied by other ingredients, such as always have an origin in examples, models, and precedents,—whilst neither is reproduction the characteristic, nor is the formative process evident in its stages,—that the designs are as good in point of the art-element of architecture, as any that are now produced. They include drawings (225, 226) of the "Design for a Museum of Natural History, to which the travelling-studentship of the Royal Academy was awarded, December, 1864," and a "Design for an Academy of Music" (224). Mr. Spiers has done an abundant amount of work to make manifest that he can design and draw; let him now show, by favour of the public, that he can build well; for, it is the latter qualification conjoined with the other, be it ever repeated, that constitutes the artist-architect. Our mention of the South Kensington Competition should not conclude without saying that some of Mr. F. P. Cockerell's drawings (87, 88) which bore the motto "Sublime Moliar Atrium," one of those belonging to Mr. Kerr's design which gained the second premium (326), and a design by Mr. Thomas Porter (143), all of which we described at the time, are in the galleries; but in neither case is the design adequately explained without the other drawings of the set.

From the Grocers' Hall competition, we find

designs by Messrs. Blomfield (16 to 22), Penrose and Goodchild (169 to 171), and H. Currey (189), in addition to those mentioned as at the Royal Academy. The first is Gothic. The most striking drawing is a view (19) of the Livery Hall. This apartment has a lantern-light in the centre of a ceiling that has sloping sides, the collar being round in cross-section, or having turned mouldings. The construction of the roof does not readily suggest itself. The character of the design accords with that of some of Mr. Blomfield's works which we have illustrated; only it is translated in stone, and with much use made of "plate-tracery," which is become the feature of modern Gothic designs to much too great an extent. "Plate-tracery," which really should not be called tracery at all, is manifestly an imperfect thing. The view, and other drawings, even the sections, have figures in Medieval costume, and titles lettered in the ornamental Medieval fashion. Surely, the love of accessories of this character in drawings, as well as illegible inscriptions in buildings, would tend to show that the art is not that, of our time, which should find expression in our architecture. The design by Messrs. Penrose and Goodchild, of an Italian character, has, in the Princes-street front, the entrance formed as a semicircular recess. The best portion of the design is the internal court, of which a bird's-eye view (171) is shown. Mr. Currey's design for the Princes-street front is at once effective and original. It may be called Italian with a combination of Gothic in some important, and indeed what may be leading, features. These consist of a range of gables. It must be obvious to any one who will read signs of the times, that the gable will be one of the chief contributions from the Gothic, to the architecture of the future. The progress towards the tasteful use of the gable, where it would be well suited to play a part, as in our street-architecture of narrow frontages, and varying heights, is slow; but Mr. Currey's design may mark a step; though the front in this case does not immediately seem one that required the gabled treatment. The triangular form of ground led to ingenious planning in several of the designs sent in.

As we proceed with our inspection, we find some drawings from other competitors than those named last week. The most striking of these drawings in many respects are those from the Bradford Exchange Competition. The quality however that is most marked in the designs, is Mediaevalistic quaintness, rather than beauty in true art-architecture. Sculpture, somewhat extensively used, is contrasted with the most unsmooth forms; and what would be only tolerated as accidents, were the designs real Mediaeval, are here introduced with a purpose of what might seem "malice prepense." The most noticeable design of this class, as shown, is that by Mr. R. N. Shaw, in drawings Nos. 67 to 70. The design of Mr. Burgess, for the same building, as to the exterior (207), is marked by a similar inharmonious combination of architecture and sculpture to that found in the other design. One of the drawings (208) shows a portion of the interior, a glass-roofed area. The pinnacles on the angles of the building, externally, as shown, planted behind a parapet, rather than terminating lines rising from the ground, are badly placed, besides that they are inelegant in themselves. Mr. Kerr was quite justified in remarking that there "has been growing up an incredible worship of the Ugly." Delicately skill, which should be the servant of art, seems, conjoined with the influence of the habit of observation of old models,—observation which should supply the food,—to be constituting for itself the mastery. Were this to be the universal end of the acquirement, we might almost ask whether it were worth the getting. Possibly there is one class of mind which is peculiarly fitted for work in the "restoration" or conservation of ancient monuments, and another similarly for architecture in its highest sense of art, and that the one capacity is to some extent in antagonism with the other.

One of the most interesting drawings in the room (66) represents the Church of the Austin Friars, in Old Broad Street, as restored by Mr. T. Anson and Mr. Lightly. The aisles are left free, the seats being in the nave; and the area which they occupy is enclosed by close screens, or boarded partitioning, plain in character, but according with the architecture of the church. The preservation of this building from the entire destruction by which it was menaced after the

chronicled of recent efforts for the preservation of such records and examples. What are important works of a very different class, are represented in Mr. Owen Jones's drawings (29 & 30) of his decorations of the Chinese and Indian Courts of the South Kensington Museum. Excellent however as the drawings are, they fail in conveying the beauty of the decorations themselves. All representations by even tints, of surfaces of colour that are over one or two superficial feet, belong to the class of working-drawings, and do not give the variation of surface-effect which is caused by accidental shades; moreover, the decorations at South Kensington require to be seen in their positions. But whether judged of there, or in the drawings, they reflect the greatest credit upon their designer.

A "Warehouse lately erected at Leicester" for Messrs. Hodges & Son (5) by Messrs. Shenton & Baker, is a commendable work of the class of which too little account is taken in estimates of the architectural movement in England. This building, which is in red-brick and stone, is of three stories. Corinthian pilasters occupy the height of the two upper stories, and are massed at the angle, where the entrance is, and in a corresponding position. By the arrangement of breaks in the frieze, pleasing variation is given from the ordinary Corinthian entablature; so that the latter forms of an order, and the cornice suited to the entire building, are well combined. The buildings in the City of London which also express the advance, are only part of them of the warehouse class. Amongst them, shown in a drawing (86), are the "New Warehouses, Wood-street, Cheapside," by Mr. R. W. Edis, spoken of as represented in the Exhibition of the Academy, where the drawing differs from that which is here, in some of the details. Mr. Edis also contributes a drawing (125) of "New Warehouses, White Hart Court, Bishopsgate-street, now in course of erection." Mr. Tanson's works in the City, have been chiefly buildings for offices, such as the work represented in No. 85, "Street Architecture, 27, Mincing Lane," which is marked by rather more of Gothic in the detail, than there is generally in his works. This character is observable in the rain-water pipes, and in the coin-blocks, the angles of which are slightly notched where one stone rests upon another.

Mr. M. D. Wyatt exhibits (6), "Original Sketches," nineteen in number, "for the architectural portion of the Terrace Gardens" Castle Ashby. They give chiefly forms of vases and balustrading. Mr. Wyatt's principal contribution (Nos. 115 to 120) is that of six working drawings, including one to half-inch scale, elevations of different fronts, and of the stables, of a mansion to be erected for Mr. J. G. T. Sinclair, of "the Mount," Norwood. The general character is Italian; and the large drawing shows a considerable amount of surface-enrichment,—how to be executed is not described, but possibly in stucco by one of the methods coming quietly into use. One of these has been used by Mr. R. N. Shaw, in a plaster-ceiling to a new dining-room in Wellesley House, Kent, which is represented in a view (387). In this case, the plaster was lined and stamped whilst wet, and almost entirely by two country-bricklayers, to whom the work was entirely new. Detailed drawings in pencil, to half-inch scale, were sent to them; and with very little direction, they set out the various figures the full size, and marked the patterns, the architect says, "with remarkable precision." The drawing is exhibited only to show that a considerable amount of ornament may be obtained, using the commonest materials and the local labour. Mr. Lamb's designs, as usual, are characterized by art as one of the elements in their architecture. The "Design for the Town-hall, Ipswich" (51), is a very satisfactory evidence of independent thinking. This is remarkable as much in its general massing as in its detail. "Allenheads, Northumberland, designed in 1846" (52), is excellent in grouping, and in the harmony and continuity of major and minor elements of the design,—the latter including the garden-walls,—and remarkable for the effect produced with a simplicity that is not poverty. Mr. Lamb's contributions also include "Holt Hall, Norfolk, showing the alterations and additions recently completed" for Mr. John Rogers (44), "West Elevation of St. Martin's District Church, now erecting at Kentish Town" (53), "Manor House, Aldwick, near York, recently erected" (55), "House intended to be erected near York, for Captain Barnes" (289), and "First Sketches for

the Parsonage House, Whitton, near Hounslow, about to be erected" (290).

A view (38) of the Organ and East End of St. George's Hall, Liverpool, is exhibited by Mr. J. E. Goodchild; but it is not the best of his drawings; and it omits some of the important features of the interior, the pendent gaseliers, or *corona lucis*, amongst the number. Messrs. Thos. Smith & Son exhibit a view (94) of the exterior of "Christchurch, Naples," a building which is Gothic, and English in most of its features, but has an arrangement of western porch that is designed with a reference to the circumstances of the climate. A view of this church has appeared in our pages. Noteworthy designs in some points, are these for the new Auction Mart, namely, one (81), by Mr. F. Chancellor, one (138) by Messrs. Wadmore & Baker, and one (196) by Mr. T. C. Clarke. Mr. E. M. Barry contributes a drawing (145) of a work in progress, the "City Terminus Hotel, Cannon street." The view shows the front that will be on the station side, and which has a general resemblance to the similar front of the City Cross Hotel. The "Sablonière Hotel, to be erected in Leicester-square, for the Foreign Hotel Company, Limited" (188), is shown in a drawing by Mr. J. Whichard, who is also the author of designs for "New Buildings to be erected in King's-road, Brighton" (127, 128); but in none of these works has he quite met the difficulty of external effect, which is apt to be entailed by the provision of stories that are many in number. It may be desirable that the appearance of the actual number of floors should not be lost; but we cannot think a satisfactory effect can be given, unless the total height is divided into a much smaller number of main divisions than that of the stories, that is unless the latter are grouped in parts together. There is some very good design in Mr. Colling's Liverpool Exchange Competition Drawings (180, 195, 197, 198). Mr. C. F. Hayward has an effective Gothic design for the re-building of the Bell Hotel, Gloucester (204), besides some other works.

Mr. Truettitt is as usual a contributor of clever representations of picturesque and well-grouped buildings which he is erecting, or has lately erected (211 to 215). They include Little Barford Rectory, St. Neot's; a cottage at Worthing, two houses at Sydenham Hill, and a house in Tufnell Park, Holloway. Mr. Truettitt is one who can be indebted to the Gothic, without producing what is Mediaevalistic, and whose power of pencil does not get "the whip-hand" of him. Mr. C. Gray's "Queen's Gate Terrace" building, is shown in photographs (239, 240), and has been partially illustrated in our pages. It is one of the best of its author's works; which are very unequal, and present some ineffectual forms, as in cantilevers, and some defects of proportion; but which nevertheless, or several of them, contain much that deserves praise. Yet the talk of the neighbourhood is against this house, and decidedly prefers the houses class by which are of the speculative-bricklayers' sort of Italian, repulsive in their soot-begrimedness as they might be to us. It is impossible to induce the speculative builder to change his style, whilst there is demand for it; we may however bring about infusion of a better character of art in his buildings; and the talk of Queensgate-terrace might give a hint of how to get the infusion made. Mr. J. P. Seddon exhibits a considerable number of works, amongst which are elevations of St. Nicholas Church, Great Yarmouth (315 to 318); and many good designs for encasement tiles for Messrs. Maw (320, 324, & 325), and for various articles of furniture (323). We should not conclude our notice, which does not pretend to be at all complete, without naming Mr. H. H. Barnell's "Japanese Villa, with Offices," (328) to be erected for Mr. James Veitch, at Coombe Wood. Contemplators of the changing presentations of our art have got to the state of not being surprised at the advent of any foreign style, and copyism of it; but ought the importation, which is that of the style, rather than of any lesson in art, to go on,—since, under present circumstances, often, the more material we have, the less good use we make of it?

Whether we can return to the Exhibition must depend on circumstances.

After having devoted, during many years, some of our best exertions in furtherance of the interests of the Architectural Exhibition, we find ourselves under the necessity of offering to the committee a particular remark in the way of suggestion, namely that they should make such

arrangements at the galleries, as may prevent the possibility of insinuation to a representative of the press.

## CONTINENTAL NEWS.

**St. Petersburg.**—The Imperial academian, Mr. Mikechine, was requested last year to submit a design for a monument to Catherine II., of Russia; he did so, but certain alterations were suggested and insisted on, which led to the artist remodeling the whole design. This has now been done, and the monument is at present being executed. After the manner of Rauch's Frederick the Great, at Berlin, the figures are arranged in such a manner as to give the idea of generals and others supporting and guarding Royalty. The empress stands on the upper pedestal, whilst a little below her are ranged Derjavine and Madame Daschkow on the left, Betzki and Bezborodko on the right, and Rumiantsow, Potemkin, and Suwarow in front. The figures, medallions, &c., will be in bronze, the pedestal in Labrador stone from Kiew, and gray Serdopol stone, and the plinth and steps in red granite. The whole monument will reach a height of 48 ft., and will take three years to finish. The estimated cost is 35,000*l.* It was Catherine II. whom Byron called "the greatest of all empresses and"—we forget the rest of the quotation.

**Mr. Bernadaki,** a wealthy Greek, has given 100,000 francs towards the erection of an Archæological Museum in this city, in the hopes of inducing others to follow his example. Of the plans submitted for this purpose that by Professor Lange, of Munich, was chosen, and will, it is believed, be carried out at once. The Royal Commission appointed to conduct excavations and other archæological researches, stopped working, and also the collection of funds for the purpose, when the revolution broke out, and King Otho was driven away. Lately, however, the Commission has been armed with fresh powers, and now continues its work with new energy. —The new Roman Catholic Church in the University-street is being rapidly completed, and will, when finished, be one of the chief ornaments of this city. The great Sina Academy, the works of which were stopped for upwards of a year from want of funds, is also progressing.

**Dresden.**—An enormous musical festival is about to be held here this month, and 600 men are daily at work in erecting the hall in which the concerts are to take place. The building covers an area of about 100,000 square feet, and will be about 92 ft. high in the centre. There will be comfortable sitting-rooms for an audience numbering 28,000, besides an immense orchestra, and ten refreshment-rooms, of which eight are specially for beer, whilst the other two will supply wine, coffee, cakes, &c. In order to avoid the difficulties which would constantly arise from the variety of money brought by people from all parts of Germany, a special temporary coinage will be adopted which will have currency not only at the hall but throughout the city, and which can again be exchanged for real money at certain offices opened for the purpose. It is expected that the advantage will be very great, and that the expenses will be covered by the number of coins left unexchanged, because taken away to thousands of homes as mementoes of the festival. —A statue of Melancthon, to be erected by the side of that of Luther, on the market-place at Wittenberg, will be inaugurated on the 25th of next month, in the presence of the King and Crown Prince. The 25th of June, 1524, was the day of the publication of the Augsburg confession.

**Brunswick.**—As was to be expected, the rebuilding of the palace, which was for the most part destroyed by fire, one bitterly cold night last January (a court ball going on at the time), is at once being proceeded with, and all rubbish and charred débris are being carted away. Before being taken away, however, everything is carefully examined, and all ashes are screened; by this means several diamonds and pieces of gold have been recovered. —The fine old Kaiserhans, in the neighbouring town of Goslar, seems in danger of "going" from sheer old age. It was built by Henry III., in the year 1050, as the residence of the Sâlic emperors, and has of late years been used as a granary. A few days ago the greater portion of the south-western front suddenly

gave way and fell, fortunately inwards. Means were immediately taken to prevent the whole building from collapsing, and it is to be hoped that this interesting specimen of secular Mediæval architecture may yet be preserved.

**Cologne.**—Whilst engaged in deepening a dry well near the church of St. Martin, the sinkers came upon two daggers at about 4 ft. below the bottom of the well, which was 50 ft. deep. One of these daggers was found deeply inserted in a human skull; the blade, about a foot long, is of iron as is also the cross hit. The handle is of hard wood carved and inlaid with coloured stones. —The King of Prussia has notified to the committee of the restoration of the Dom at Aix-la-Chapelle, that he will give the munificent sum of 52,000*l.* towards the restoration, provided the remainder of the sum (50,000*l.*) can be collected by the Karlsruverein and its branches. The Karlsruverein, like the Cologne Domverein, is an association for the worthy and efficient restoration of the church founded by Charlemagne.

## THE PRACTICE OF VACCINATION IN FRANCE.

From time to time, when the effects of small-pox have been more severe and fatal than usual, we have directed attention to an objection which a very large number of persons, not only of the poorer classes, but also those in a superior position, have to the system of vaccination as generally practised in this country. —that if vaccination as practised be a means of preventing a large part of the mortality which would otherwise result, contamination and impurity of blood are caused by the transfer of the lymph of children whose constitutions are scrofulous and in other ways diseased. Difficulty has thus arisen in applying with vigour the law which exists respecting the enforcement of vaccination, especially since eminent authorities also differ respecting the safety of the applications of the vaccine matter throughout a long succession of persons; and the anxiety of medical men to vaccinate from healthy children, shows a latent opinion that otherwise it may be injurious. On this most important subject M. Depaule, the director of the small-pox hospital of Paris, has reported to his Government the serious evil that exists in inoculating children with vaccine matter taken from diseased or scrofulous constitutions. That gentleman enumerates instances in which healthy children have been thus injured for life.

In France no conscript is allowed to enter the army, and no boy received at either a public school or a college, unless he can produce a certificate of vaccination. M. Depaule justly observes, that as Government enforces this precautionary measure, it is bound at least to see to its being enforced in the most safe manner. He therefore urges the primitive system of vaccinating from the cow, which was Jenner's original idea,—being again resorted to. The only European city where this is practised is Naples, and there M. Negri has established a park of heifers, which he infects in rotation with cow-pox, in order to have a fresh supply of pure matter. Last year he vaccinated 12,000 persons, and sent to the Medical Congress, held at Lyons, his friend Dr. Palesiano, to explain to the French physicians the advantage of the Neapolitan system. The result has been that Dr. La Noix started for Naples, and after studying the subject, purchased an infected heifer, with which he returned to Paris, telegraphing, however, to the Lyons College of Physicians that he and his heifer would arrive by a certain train at Lyons, *en route* for Paris. Dr. Favre, of Lyons, with several adults and children, met him at the station; and while the train waited the usual three-quarters of an hour, all these persons were vaccinated from the infected heifer; and notwithstanding the extreme cold of the weather, the exposure to the outward air at the platform of the railway terminus, and the hurried manner in which the operations were necessarily performed, all succeeded perfectly. M. La Noix has now established a park at Bel Air, where he has inaugurated the Neapolitan system. The Parisian correspondent of the *Star* mentions that, strange to say, the vaccine matter which M. La Noix has in use at Bel Air may be traced to a royal gift of Queen Victoria, in 1855, to M. Negri, of matter taken from a cow on one of the Royal farms discovered to have natural cow-pox.

All the pupils of the Prince Imperial College

at Vannes have been re-vaccinated at Bel Air, but it is reported that the most curious instance of its efficacy is the case of a child, which the doctors of Nogent-sur-Marne had vainly attempted five times successively to vaccinate. As he could not produce his certificate of vaccination, he was refused admittance into all the schools in the department. The boy was vaccinated by the Neapolitan method, and the result is that he is learning to read.

The lesson in vaccination which has with so much advantage been taught in Naples and Paris, should not be without use in our own country, and in its metropolises and large towns especially. The medical officers of health should spare no exertion in placing the question of vaccination completely beyond dispute, and should adopt such measures for carrying a proper method completely into use, that none may have an excuse for neglecting the application of an important means of preventing a deadly and loathsome disease.

## ADMIRAL FITZROY.

This gentleman may be classed in that numerous band of martyrs who, in these days especially, have sacrificed themselves for the advantage of others. Admiral Fitzroy had bestowed long and intense study on the discovery of means for the protection of those who are generally provided with learning, but who are exposed, even more than miners, or those who form the ranks of our army and navy, to sudden destruction.

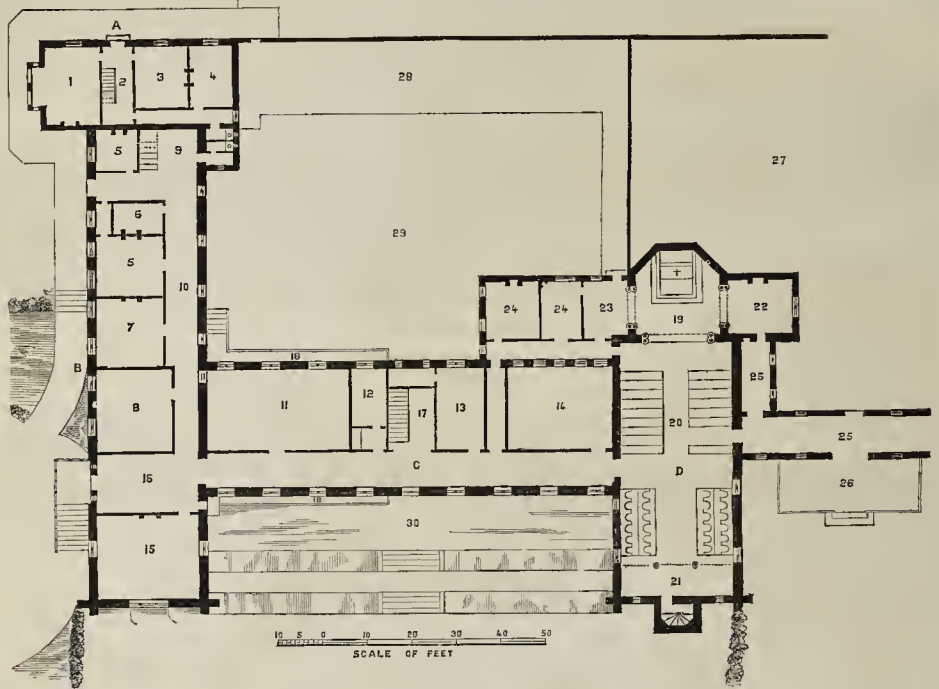

To the sailors of our coasting vessels, to the fishermen who, in their comparatively frail boats, put to sea in all seasons of the year, on all parts of the British coast, the labours of Admiral Fitzroy have been of the most vital importance. To many a woman and her children—the father—the bread winner—has been spared; and, as time rolls on, in each year, if proper management be used, we may expect a large salvation of life in consequence of better understanding the principle of storms, which Admiral Fitzroy succeeded in discovering to a certain extent. Although much had been done by the deceased gentleman in giving warning of coming storms, still the principle has not yet been reduced to a certainty, and partial failures probably caused Admiral Fitzroy intense worry of mind; and this was increased by the circumstance that the admiral felt himself on the verge of discovering one of nature's laws, which, rightly established, would be the means of preserving the lives of brave sailors and fishermen, and valuable cargoes, to an extent of which we can form but little conception. Many a man has been placed in similar circumstances to those under which the Admiral stood, who, feeling on the verge of a great discovery, applied himself more and more to conquer what was deficient; and so the most intense mental work went on, nature was over-taxed, and in the end the intellect gave way, and the kindly-hearted gentleman, who had laboured and striven with so much perseverance for the good of others, brought his own life to a lamentable close. It is to be hoped that his labours may not prove in vain. It has happened before now that when a man who, having ability himself, and support from the strength and intelligence of the country, had closed his labours, cold water was thrown on the department which he had endeavoured with success to establish. Let us trust that, in the case of Admiral Fitzroy, the Government will not act in this way. We require, in fairness, that some public monument should be erected to his memory; and it would be far better than works of stone and other memorials to give the useful support to Admiral Fitzroy's department, and enable those who are capable of doing so to continue the inquiry respecting the cause of storms—to afford the opportunity of collecting and arranging the materials which are gathered in many parts of the world,—until, in the end, the coming of storms and their peculiarities may be foretold with certainty.

## MONTREAL.

Amongst the new works in progress here, of which particulars have reached us, is Erskine Church, now in course of erection, at the corner of St. Catherine and Peel streets. It is for the congregation of the Rev. Dr. Taylor, one of the oldest and most respected ministers of the

\* "Achilles' self was not more grim and pory Than thousands of this new and polished nation, Whose name want nothing but—prosecution."

THE ABBEY DUN ESK.—Plan of Ground Floor.

Scottish Presbyterian Church. The design was accepted in competition in August last, and the foundations having been put in, the works have just been resumed, and are now being proceeded with rapidly. The walls throughout are of the Montreal limestone, in small regular courses, with rough faces, with cut stone quoins, window and door panels and arches, tower, &c. The interior has a gallery on three sides, open-timbered roof, groined recess, &c. The pews are radiating from the pulpit, and, together with the galleries, will contain 1,250 persons. The roof is covered with purple, green, and red slates, in ornamental bands. The total height of the tower and spire is 190 ft. The amount of the contract for the whole of the work is 8,300*l.*, exclusive of ground. The architect is Mr. C. P. Thomas.

Some large warehouses are in progress, with cut stone fronts, at a cost of 16,000*l.* To show what is doing in Canada, now so often discussed, we shall take an opportunity to publish a view of these buildings.

#### THE BENEDICTINE CONVENT AT TEIGNMOUTH.

THE new Benedictine Abbey at Teignmouth, of which we give a view and plan, crowns the locality known as Dun Esk. It is built of limestone, crossed at intervals with bands of red sandstone. The sills and pillars of the windows are composed of freestone. On entering the door at the west-end of the terrace, the visitor finds himself in a long corridor, upwards of 90 feet in length, which runs the entire length of the building, and communicates at the further end with the church. Numerous apartments branch off this long passage,—a spacious chapter-room, the lady abbess's room, and the nuns' dining-room, in one corner of which is an apparatus

for lifting the viands intended for the repast from the kitchen.

At the southern extremity of the church is a gallery or tribune for the organ, and at the northern end is situated the sanctuary. This is separated from the main body of the church by an arch supported by pillars formed of polished Devonshire marble. Two chapels branch east and west from the sanctuary: one is for the laity, and the other belongs exclusively to Miss English (the lady-founder), who has a passage communicating therewith from her dwelling-house close by. The roof of the church is panelled, and the various arches are relieved by the introduction of red sandstone. Carved capitals adorn the sanctuary, side chapels, and organ gallery. The altar is sculptured in stone, with marble columns, and the floor is laid with tiles.

Ascending the stairs, we find, another long corridor, similar to that on the first floor, runs throughout: the apartments which open on either side are for the inmates of the house; and, at the extreme end of the passage, and in communication with the church, are the sick wards and lavatories. Another flight of stairs leads to the nuns' dormitories. At the further extremity, forming a wing of the main building westwards, is the children's dormitory, with a large oriel window looking south. Another apartment on the same floor is a lavatory for the children, fitted up with marble basins. On the lower floor of this wing are school-rooms, refectory for children, communicating with the kitchen by a lift, parlour, &c. At the rear of the school wing, and entirely separated from the other portion, is the residence of the clergyman belonging to the establishment. This comprises sitting, dining, and bed rooms, &c. The woodwork throughout is of red pine and pitch pine. All the walls are coloured in distemper without papering. The tower forms the principal feature outside. It stands at the

southern extremity of the church, and attains an altitude of 65 ft., surmounted by a bell turret. It bears on its front an image of St. Scholastica, the patron saint of the order, presented by the architect.

Mr. Simpson, of London, was the contractor: Mr. Copping was the clerk of works: Mr. Earp, of Lambeth, executed the carving; and the iron crosses and finials came from the workshops of Messrs. Beard & Co. Mr. George Goldie was the architect.

THE ABBEY DUN ESK, TEIGNMOUTH.—MR. GEO. GOLDER, ARCHITECT.

## POCKET-HANDKERCHIEF ART.

WHEN we look around (and in our pockets) at various articles which are made in enormous quantities for the use of particular classes, it seems wonderful, in the first instance, how manufacturers are found who undertake, at a large pecuniary risk, the production of such things; and also, where the purchasers are to be met with who render these speculations remunerative.

Amongst many other matters which are curious in their way as examples of the condition and progress of taste, is art as it has been shown for at least fifty years in pocket-handkerchiefs. These are in many ways singular, and deserve a little passing attention. A long time since, we can remember pocket-handkerchiefs for children on which there were boys and girls at play, cottages, lambs, shepherdesses, and a variety of other devices. And there was no lack of picture pocket-handkerchiefs for those of older years: for sportsmen and others there were printed on these articles representations of fighting-cocks, dog-fights, hunting scenes, stage-coaches, and horses; and even recently, there have been shown in this way ships and steamers of various kinds, and conspicuous amongst them the *Great Eastern*, in divers positions; groups of sailors with the Union Jack and other devices; soldiers of the cavalry and the line; parties of pitmen, navigators, cotton spinners, and those who form representative figures of large classes.

In our time we have noticed many peculiar hobbies of collectors, some having bestowed an extraordinary degree of pains and industry in collecting play-bills, election signs, caricatures, &c. We once knew a collector who had, at considerable expense, purchased little pieces of the ropes by which notorious criminals had been put to death, and the instruments with which murders had been committed. This, however, is, we hope, a rare kind of collecting; but it would not be so singular or objectionable if some persons may have been minded to collect picture handkerchiefs. They would present a curious illustration of passing events. We should find portraits of George III. and the Princess Charlotte, William IV. and Queen Adelaide; Earl Grey, Lord Brougham, and their associates in the passing of the Reform Bill; then of Lord Palmerston, Sir Robert Peel, Bright, the lamented Cobden, Garibaldi, and so on. There would also be representations of Tom Spring, Tom Sayers, and many others who have achieved fame in the fistie line. Thurell and other murderers have in this way been handed down to detestation; and such events as Ross's voyage to the North Pole, the burning of the Tower of London and the Royal Exchange, the shooting of the elephant in the Strand, which have shared a large amount of public attention; also views of noted buildings and large towns, have all been thus depicted more or less graphically.

Some of these illustrations are printed on humble cotton of various tints, others on silk of an expensive kind; and, no doubt, before the days of illustrated publications, the picture work of this kind was not without its use, however tasteless or objectionable the application of pictorial art in this direction may for the most part have been.

## THE NEW BRIDGE AT HAY.

WHILE the Hereford, Hay, and Brecon Railway was in course of construction, it was found necessary either to erect a new bridge, or to carry the line round the town. The former alternative was decided on; and Mr. Savin, the contractor of the line, offered to erect a new bridge at a higher level than the old one, on the grant of a lease of the tolls for ninety-nine years. The undertaking has now been carried out. The new structure is of iron, and is a lattice girder bridge, the girders 71 ft. long, 7 ft. high, and weighing each 8 tons. It stands at an elevation (counting from the parapet) of 50 ft. above the bed of the river,—16 ft. above the level of the old bridge. It consists in all of six bays, four of which cross the river in spans of 76 ft. each, while the two remaining ones carry the roadway over the railroad on the Breconshire side, and over a corresponding interval on the Radnorshire side. The total length of the bridge is 388 ft. The supports of the central bays are wrought-iron columns fixed in caissons, which are sunk into the bed of the river. The side bays are supported by stone piers of masonry. The floor of the bridge is of

wrought channel iron. It is trussed below so as to give it the necessary rigidity. A coping, surmounted by eight pairs of lamps, gives a finish to the whole. The bridge was designed by Mr. Hughes, of the office of Mr. Piercy, engineer, and executed by Messrs. Handyside, of Derby, under the superintendance of Mr. J. Smith, as resident engineer. Mr. H. Wakefield, of London, examined and reported on the bridge. It is said to have stood the test satisfactorily, the deflection amounting only to 5-16ths of an inch. Mr. Wakefield made some suggestions with regard to details.

## THE BRITISH MUSEUM, NATIONAL GALLERY, AND KENSINGTON MUSEUM.

ON the motion for going into Committee of Supply in the House of Commons,

Mr. Gregory called attention to the condition of the National Gallery, the British Museum, and the Kensington Museum. He declared that these valuable collections were in a state of chaos, and laid the blame of this on the Government. If the Government had come forward with all their strength with a well-arranged proposal for the extension of the National Gallery they would have carried it. He contended that the cartoons from Hampton Court ought to be in the National Gallery, and that some of the pictures in the South Kensington Museum and the National Portrait Gallery ought to be there also. He did not wish to see the Royal Academy removed from the National Gallery, but he urged that steps should be taken to secure space for the enlargement of the gallery. He urged the Government to take steps for providing more accommodation for the Museum.

Mr. Cowper said the delay in dealing with the National Gallery and the British Museum had arisen from a difference of opinion as to what should be done. So far as the National Gallery was concerned, however, it had been determined to extend the building, and they must do the best they could with it.

Mr. Tite said he had no doubt if a comprehensive plan for dealing with the National Gallery were introduced it would be freely supported.

The Chancellor of the Exchequer said that in these matters the Government had deferred to the wishes of the House. Eight acres of land would be required for buildings for the natural history department of the British Museum. The land in the neighbourhood of the Museum would cost 50,000*l.* an acre; but a good site had been obtained at 7,000*l.* an acre. The Government were proceeding in the matter in connexion with the trustees, but they could not lay a vote on the table until a plan was arranged. When the proposal was made the House would judge on it.

Some other members also spoke, and the subject then dropped.

In reply to a question by Lord J. Manners in the House on another occasion, Mr. Cowper said it was his intention to submit to Parliament an estimate for enlarging the National Gallery in the rear on the north side; and that the estimates will be laid on the table of the House in time for full consideration before the vote comes on.

## COMPETITIONS.

*Cheltenham College Boarding Houses.*—The building committee received twenty-three sets of plans in competition for the above works, and have accepted the designs submitted by Messrs. Medland, Maberly, & Medland, of Gloucester, under the motto "*Finem respice.*" Four houses are to be commenced immediately.

*New Public Dispensary, Leeds.*—A design submitted by Mr. William Hill, architect, Leeds, was selected in a competition confined to local architects. A premium of 10*l.* was awarded to Messrs. Perkin & Son for a design contributed by them. The design selected is in the Italian style of architecture. The building will be of brick, ornamented with stone dressings. The principal entrance, which will be under a portico, with coupled columns, is in the centre of the elevation to Belgrave-square. The base of the building will be battered and moulded; the windows enriched with carved and moulded impostes, archivolts, and sills; the main cornice ornamented with moulded modillions, and surmounted with balustrade, relieved at the breaks with

pedimented blocks supporting moulded bases. The accommodation will embrace on the ground floor, physicians' and surgeons' consulting-rooms, with retiring-rooms attached, office for house surgeon, two offices for assistants, dispensary, laboratory, and large waiting-room to accommodate 200 persons. The board-room, private rooms for house surgeon, and kitchens, will be on the first floor; store-rooms will be on the basement, and attics on the second floor. A private entrance is provided for the house surgeon, and a separate entrance and outlet for the patients. The building is estimated to cost 3,500*l.*

## LIVERPOOL ARCHITECTURAL SOCIETY.

The annual meeting of this Society was held on Wednesday evening, the 3rd instant, at the Royal Institution, Mr. Joseph Boulton presiding. The report, which was read by the hon. secretary (Mr. Chas. Z. Hermann), stated that the Society continued in an improving condition. A private entrance is provided for the house surgeon, and a separate entrance and outlet for the patients. The building is estimated to cost 3,500*l.* Twenty-three new members of all classes had joined the Society during the past session, whilst they had lost only six in the same period; thus giving a net increase of seventeen members. Owing to the state of the finances, the publication of the proceedings for the past year had been suspended. It seemed probable that by the end of the financial year the Society would be clear of all liabilities. The want of interest shown by the students in the competition was a source of much regret, and the council reported that they should be reluctantly obliged to discontinue offering prizes should they not receive greater encouragement from those for whose benefit they were designed. The committee recommended the following gentlemen for the officers and council of the Society for the next session:—President, Mr. Joseph Boulton; vice-presidents, Messrs. W. H. Pictou & F. Horner; librarian and curator, Mr. Wallace; treasurer, Mr. J. B. Bradley; council, Messrs. Weightman, Audsley, Grayson, Whyte, and James Hay; honorary secretary, Mr. Charles Z. Hermann.

## THE COLOSSUS OF RHODES.

DR. C. F. LIDERS, professor at the Johanneum at Hamburg, has just published a critical-historical treatise on the Colossus of Rhodes, about which the most crude ideas and fabulous exaggerations exist in the public mind. According to the researches of Dr. Lidiers, this monument, one of the seven wonders of the world, is reduced to nothing more than a colossal statue, standing on terra firma, like the Bavaria at Munich, but near the harbour, and dedicated to Phoebus Apollo. He insists upon it that its standing upon a log-heap across the mouth of the harbour, and being used as a light-house, is a pure invention, and an emanation of fancy from later writers. Who is not reminded of Robert's picture, its bold conception, and wonderful colouring?

## COMPENSATION CASES.

*Holborn Valley.*—At the Lord Mayor's Court, last week, in a compensation case "*Hearder v. The Corporation of London,*" a special jury awarded 2,439*l.* 15*s.* for the premises and loss of trade as a bootmaker, in Skinner-street, Snow-hill. The case occupied several hours.

*London, Chatham, and Dover Railway.*—On the 6th, in the same court, *in re Balemound and London, Chatham, and Dover Railway,* the company had taken the whole of the property, nearly all freehold, in New Bridge-street, Blackfriars, between Union-street and Earl-street, and the claim made out by several witnesses in their behalf exceeded 26,000*l.* After being viewed by the jury, and hearing evidence of valuation on the other side, a sum of 17,500*l.* was agreed upon between the parties.

## DOMESTIC INSECTS.

IN this great and marvellous universe, of which the best of us form such minute atoms, an all-wise Creator has sent amongst us visitations which in our short-sightedness we are too liable to look upon with impatience; and, instead of judging them to be as they are, blessings in disguise, to consider them as harsh dispensations of that beneficence from which we have daily good; but careful comparison and investigation

show that in the storm, pestilence, and fire,—even in the stark wandering of famine and the ravages and dire doings of war,—there comes a universal advantage, for which we cannot feel sufficient thankfulness.

Wolves, lions, and other wild beasts have been a means of advancing civilization; and the carrion and other birds of the air, the fishes, and the insects have all their appointed work; the house-flies, the beetles, and other loathsome creatures—the house rats and mice—are not without their use; and if we fail to see their sanitary advantage in some cases, the fact that their presence leads to the enforcing of cleanliness and care amongst those who would otherwise be negligent in this respect, is at any rate too apparent to be disputed.

We have before briefly referred to rats, flies, and some other household pests; but there is one of such a loathsome nature, that hut for the present extent of the annoyance which it causes in so many houses, both in town and country, and the likelihood that if vigorous measures be not resorted to, the evil will be increased in the metropolis and the suburban parts by the alterations which are now going on, we should have preferred some other subject. In nearly all the old houses of the metropolis, the bug, that plague of the housewife and the detestation of all, has firmly established its unwelcome presence; and even new houses are not without these visitors, in consequence of the working into them of old materials which are inhabited by the vermin.

To thoroughly clean and keep a house and the furniture within it clear of these vermin, is a matter of anxious care to all good housewives; and there can be no doubt that the efforts made for this purpose, although the labour is considerable, are of advantage to the health of families in more ways than one. Without, however, further considering the matter in this way, there is undoubtedly an incessant warfare being waged between house-wives and these domestic enemies; and in this, as in connexion with other battles, it is useful to resort to those stratagems which will be likely to produce the most decisive results. But, as we have said, the unpleasant nature of these creatures has prevented that amount of inquiry respecting their habits, being made, that would render their destruction more easy. Even the date when these insects were first introduced into England seems to be a matter of doubt. It has been said that hogs were unknown in England before the rebuilding of that part of London which was destroyed by the Great Fire of 1666; and it is supposed that they were brought in the timber which was imported on that occasion. This, however, appears not to have been the case, for Muffet, in his "Theatre of Insects," published in 1634, says,—“In the year 1503, when Penniss [Dr. Penny] writ this he was called in great haste to a little village called Mortlack [Mordlake], near the Thames, to visit two noblemen, who were much frightened by perceiving the prints of wall-lice, and were in doubt of I know not what contagion; but when the matter was known and the wall-lice were caught, he laughed them out of all fear.”

A writer says, that the favourite ailment of these insects is blood; but in unfavourable situations where this is not to be found, they feed on the sap of various kinds of wood, such as deal, heech, and osier; but from oak, walnut, cedar, or mahogany, they are unable to extract any nutriment. Several pairs which were kept in these last-mentioned kinds of wood soon died; while those kept with the other kinds continued to live throughout the year. The female generally lays about fifty eggs at a time, which are white. When first laid they are covered with a viscous matter; and this, by firmly hardening, sticks them firmly to the substance on which they are deposited. These eggs are usually hatched in about three weeks; and the same writer says, the usual times of laying are March, May, July, and September, and that from every female bug there is an average of about 200 young ones produced every season.

If these particulars are to be relied on, we have a hint of the best periods for dealing effectually with these troublesome creatures; for, if the means for their destruction be taken at the right times the effect will be much more satisfactory than at others.

As regards the best methods of destruction, a skilful hunter suggests that we should reduce one ounce of corrosive sublimate (perchloride of mercury) and one ounce of white arsenic to a fine powder, two ounces of oil of turpentine, and

two ounces of yellow wax, to which add eight ounces of olive oil. Put all these into a pipkin, placed in a pan of boiling water, and when the wax is melted, stir the whole till cold in a mortar. This seems to be a powerful decoction, and, says our authority, “applied to the crevices and holes in which the unconscious innocents secrete themselves, will effectually do their business.”

A more simple recipe is, that at the breeding seasons above mentioned, the beds, &c., which are infested should be stripped of all the furniture, which must be thoroughly washed; if linen, it must be boiled; and, if stiff, it must be hot-pressed. The bedstead must be taken to pieces, dusted, and washed with spirits of wine in all the joints and crevices. This done, all the cavities should be filled with the best soft soap, mixed with verdigris and Scotch snuff. It is said that upon this composition the young will immediately feed after leaving the egg (if any escape the cleansing), and will be destroyed, as well as such of the old ones as happen to have been left.

At present we have many (so called) certain destroyers of hogs and other house troubles advertised, and some of these powders have a destructive effect; but the most effective means of keeping bed-rooms free from invasion, is to use metal bedsteads instead of those made of wood; to do away with bed-hangings; and to place at windows only such curtains as can be easily and frequently washed. Wall-paper is a sure nursery for hogs, and for this and other reasons should be exchanged for coloured washes or paint. But when once hogs have got a firm establishment in a house, it is only by incessant care and watchfulness that they can be kept under: the ill-fitting parts of skirting boards, mantel-pieces, and door jambs, should be attended to, and such open spaces as are visible filled with destructive paste or powder, and putty then freely used.

The cracks in ceilings, the openings between the planks of floors, staircases, and other faulty parts of badly-finished houses, should all be filled up, and by this means many of these creatures would be effectually shut up and killed, and others would fail to find a harbour. Great good has often been done by caulking the openings in the hoards: this gives some trouble at the time, but the ultimate advantage will be considerable.

The worry, vexation, the sleepless nights, and other sources of inconvenience which are experienced in many houses, in consequence of the inroads of these insects, render the subject, unpleasant as it is to think, speak, or write about,—one which should have more serious consideration than it has yet had. The matter, as we have said, is beset with difficulty, for even as to new houses we cannot be sure that they are free; and if they should be so, the first tenant is liable to introduce troublesome company. And in tenement dwellings, the cleanest and most careful persons often strive in vain to prevent the consequences of the want of attention by others.

#### ABSORBING WELLS.

It is probable I may publish a pamphlet on the subject of absorbing wells and borings, and on their influence on the underlying strata, and water contained in it. In continuation of my communication, I am desirous of stating that absorbing wells are common enough both in this country and on the Continent; but the system of filtering and purifying the water, as far as practicable, by the method I adopt, and the saving of the filtering materials as manure, are matters new in their present form as concurrent arrangements. As a few examples of the mass of information that I have collected relative to the distinct character of the water, chemically considered, and the geological separation of the water above and that in the chalk, I append the following:—

At the outcrop of the tertiary sands near Ewell, in Surrey, they yield no water without deep sinking, but the water in the chalk adjoining is close to the surface.

At two borings at Merton, not far from the railway-station at Wimbledon, the sands, when reached, supplied an overflow of decidedly chalybeate water, perhaps three gallons per minute, from each boring; but on sinking to the chalk, the other water being stopped over, the pure chalk water rose 4 ft. 6 in. above the surface of the ground, and flowed over the stand-pipe at fifty gallons per minute from each boring. The

distance from one boring to the other is less than 400 ft., yet they do not seem to affect one another in the least.

In a boring at Garrett-lane, the sands were reached, in which was a large quantity of free water; this was tubed out, and the boring was continued into the chalk without success: the consequence was, that holes had to be bored through the piping to let the water in from the sands.

At East Ham, a boring was made, and the sands reached with a good supply of water; but it was decided to sink down to the chalk, and more than 50 ft. of the chalk had to be pierced before water was found.

In our well at Barnet, for the water supply, the sand water, when reached, was inferior in quality and small in quantity; it was effectually stopped from the well, and the chalk bored into, which yields an abundant supply of excellent water.

In fact, I have always found, not only that the character of the water in the chalk and in the sands differs greatly in its chemical qualities, but I have also found an argillaceous stratum at the bottom of the sands of the plastic clay formation, which effectually prevents any percolation (in almost all cases) of the water from that deposit into the chalk. I have given but a few, but I have many other examples in my possession.

Without proper filtering apparatus and proper filtering materials, I should hesitate to construct absorbing wells of large capacity, even into the sands of the plastic clay formation. I take care also to make proper arrangements for the filtering materials to be changed at proper times, because (and this is universally the case with all filtering matters), when once the materials are thoroughly saturated, they no longer act as filters in a proper sense.

I will now refer to a few absorbing wells without proper arrangements for filtering. One was constructed several years ago in the city of London, not five minutes' walk from where I am now writing, in the cellar of a butcher's slaughtering place, for absorbing the blood refuse and soiled water from his premises: this continued to act for years, but at last became stopped, by reason of solid matters, through carelessness, having been allowed to pass into the boring. It was cleaned out, and again set to work. No sewerage then existed.

An absorbing well existed, or does exist, at the City of London Cemetery, capable of swallowing seventy gallons per minute. This became choked with sand and solid matters, and had to be cleaned out: an operation described to me as not to be envied.

The cemetery at Nunhead is, I believe, drained to this day by what the French call a “bois-tout,” and many other cemeteries possess similar contrivances.

An absorbing well was attempted at the Woking Necropolis, and a considerable sum was expended upon it; but it proved a failure. The Bagshot sands are not favourable to schemes of this kind. I have now nothing to add further than that I have selected but a few out of the many examples of wells into and through the tertiary sands. The outcrop of the plastic clay series is less known to geologists and engineers generally than any other formation I can mention. A correct map, embracing all the upper and lower tertiaries, would be a boon to the public.

With reference to the construction of absorbing wells in the French empire, I was not aware of any prohibition, but simply what would be a very desirable regulation in this country. The following is a translation of what I allude to:—“A Police Regulation of the 20th of July, 1838. No wells of ordinary construction, nor absorbing wells, shall be bored, nor any digging work in connexion therewith shall be undertaken; no cesspool or private sewer shall be established, without previous notice given in writing to the prefecture of police in Paris, and at the town-hall in suburban districts; and this notice shall point out the spot, where the proposed works are to be carried out.” The 14th clause states:—“No cesspool, no absorbing well, shall be made without special authorization, which will be granted if thought proper, according to the notice required by clause 1.

The depth of the absorbing wells shall be fixed in the permission which will be granted if thought fit. All the arrangements in connexion with cesspools shall be also applicable to cesspools [filtering beds] to be made near to or at the openings of absorbing wells.”

JOHN BLENKARN.

PROVINCIAL NEWS.

**Eastbourne.**—The new pier and hotel have been commenced. The foundations for the hotel are got out. Mr. T. E. Knightley, of London, is the architect engaged; and the contractor is Mr. Foster, of London. The plans for this building were before the Society of Arts last year, and were for some time hung up in the rooms of that society. The coffee-room will have a pitch of 17 ft., and its sitting accommodation will be 73 ft. by 27 ft. There will be also fresh and salt water baths, and the bed-rooms will be laid out in the Continental style. Altogether the building will contain about 140 apartments, besides conservatories, &c.

**Maidenhead.**—At a meeting of the town council it has been finally decided to build a new town-hall and hotel. The money, a little over 3,000*l.*, is to be borrowed on the security of the rates, to be repaid in thirty years. A yearly rate of 1*d.* in the pound will be sufficient for the purpose, it is thought.

**Petersfield.**—The site selected for the proposed new corn exchange is opposite the Swan Inn, and known as Moulds-corner, leading from the square to the railway station. It has been unanimously resolved at a local meeting,—"That, in the opinion of this meeting, it is desirable to build a corn exchange in Petersfield; that a company, to be called, 'The Petersfield Corn Exchange Company (Limited),' be formed to carry out the objects proposed; and that a subscription-list be at once circulated, and the gentlemen and farmers in the neighbourhood invited to subscribe." It is understood that 500*l.* were subscribed in the hall.

**Gateshead.**—The foundation-stone of the St. James's Lecture-hall, Park-lane, Gateshead, has been laid by the Ven. Archdeacon of Durham. The building is at the expense of Mr. Bruce, who has offered to erect it to meet the growing demand for a building to allow meetings to be held in connexion with the Church Mission. The building is of Gothic architecture, 45 ft. by 26 ft., and is of stone, with oaken timber roof. It has four windows on the east side, and two at the front of the building. There will be, in addition to the large room, another room at the back of the building, 26 ft. by 16 ft., for tea meetings. There will be accommodation for 400 persons. Mr. John Harrison, of Gateshead, is the builder; and Mr. Thompson, of Newcastle, the architect.

**Carlisle.**—Great improvement has taken place within the last few years in the street architecture of Carlisle. In English-street, Devonshire-street, Botchergate, and elsewhere, new business premises have been erected to supersede insignificant buildings, and the work of improvement is still progressing. Mr. Head having sold the Old Bank to the Cumberland Union Banking Company (Limited), says the *Carlisle Journal*, the building is to be pulled down and a new bank erected, from plans that are now being prepared by Mr. D. Birkett. It will be the largest establishment of the kind in the county. In connexion with this rebuilding of the corner of Botchergate, probably the erection of the new County Hotel Hall will be proceeded with. This new hall will be but a small room, calculated to accommodate only some 600 or 700 people. The great desideratum in Carlisle is a hall capable of holding from 1,500 to 2,000 people. The theatre question, it is said, is not quite dead: the proprietors of an eligible site have been asked to put a price upon it, with a view to the erection of a theatre. A wooden booth on the Sands is the only refuge of the drama at present in Carlisle.

THE BUILDING TRADES.

At Kildrminster, the bricklayers and bricklayers' labourers are on strike. They regard the suspension of work, however, more as a lock-out than a strike. A meeting was held not very long ago with the view of devising means for the settlement of trade disputes by arbitration, and on that occasion delegates were appointed, mutually on the part of masters and men, to draw up rules and arrange other details. Since then the delegates have met, and come to an agreement as to the rate of wages, working time, &c. One point, however, was mooted, upon which it appears both parties did not so well agree. This was the question of "non-interference" with society and non-society men. The delegates, on the part of the masters, proposed the following

rule on this point:—"Every master or employer shall be at liberty to employ any man or men he may think proper, and that no interference shall be made with society or non-society men. The society men pledge themselves not to interfere with non-society, and the masters pledge themselves to allow no interference with society men." The men opposed this rule, and on the 21st ult. the masters' delegates cancelled it. The masters have now brought it forward again, and require the men to adopt it. The men refuse to do so, and they state that is the reason they are not at work, the masters wanting them to sign it, "or," say the men, "they will not let us go to work." An increase of wages has recently been agreed upon, and the question at issue is said to have no connexion with that of wages.

In consequence of the strike among the artisans and labourers at Plymouth, and of the interference of the union men with others willing to work, the Government has, it is said, determined to suspend, for the present, all progress in the construction of the fortifications in that vicinity.

The master builders of Stockport have advanced 2*s.* per week on the rate of wages to the carpenters and joiners in their employ.

The dispute between the master plasterers of Leeds and the workmen has been arranged. The masters have agreed to grant the terms demanded, viz. 2*s.* instead of 2*s.* 6*d.*, and 56 hours' work instead of 59 hours per week. At the same time, the code of rules drawn up by the masters was adopted by the workmen, with some slight alterations. A meeting was to be held for the purpose of coming to an agreement, if possible, with the labourers.

The strike of the joiners of Newcastle, we regret to say, still continues without any immediate prospect of a termination. The only works of an extensive character at which the men continue their services are those of Messrs. C. & W. Burnip, at the Barras Bridge; but these gentlemen, equally with the rest of the more extensive employers, resist the demand for a half holiday.

MASONIC MUSINGS.

THE ARCHITECTURE OF THE GAEL.

WEIRD old sentences of monarch time,  
Mute and motionless, yet mighty and erect,  
Closer than thy concrete bond in lime,  
The secret lies of thy unknown architect;  
Egyptian, Syrian, Roman, Greek, and Goth,  
Their spires and shafts, and pyramids will fail;  
Wizard Round Towers, that shall perish not,  
The grand old architecture of the Gael.

The world long since had solved thy mystery, if  
In Copie, Senecit, or Arabic tongue;  
Nor Hebrew, Greek, nor graven hieroglyph,  
Nor complex Ogham would have held it long;  
Keeps, heilts, beacons, or what else thou wert,  
Decay and war as what may assail,  
Wizard Round Towers, time-proof on the earth,  
The grand old architecture of the Gael.

Oh! couldst thou speak, we surely then would hear,  
Did Druids hold converse, in your cone-copp'd head,  
To fix the stars and cycles for each year,  
Or offer holocausts to gods instead,  
Pagan or Christian, wherefore unexplained,  
Why standing lorn thou in Innisfail;  
Wizard Round Towers, proudly you have reigned,  
The grand old architecture of the Gael.

Old bards have sung and senachies relate,  
Thy founder was the mighty Goban Seer;  
Who flourished back, beyond the Christian date,  
A wondrous architect without a peer.  
With many a castle and old fort, his name  
Is linked by ood and Ossianic tale;  
Wizard Round Towers of his majestic fame,  
The grand old architecture of the Gael.

Live on, old sentinels of monarch time,  
Your heirs are dead, your treasure-drove is gone;  
Some grand old prophet, with a soul sublime,  
May tell thy secrets to the world anon.  
Live on, old wardens, challenging assault,  
Inspire with hope, give courage to the frail;  
Wizard Round Towers, piercing heaven's vault,  
The grand old architecture of the Gael.

C. C. II.

THE COURTS OF JUSTICE BUILDING, AND SITE BILLS.

On the motion in the House of Lords that the Building Bill do pass, Lord St. Leonards moved to leave out clause 16, allowing the Lord Chancellor to purchase or redeem Chancery compensations with the moneys forming funds belonging to the suitors of the Court of Chancery in addition to the one million of stock previously authorised to be taken from the same funds.

The Lord Chancellor, the Earl of Derby, Lord St. Leonards, and Lord Chelmsford spoke on the subject, and the clause was finally struck out by a majority of 47 to 46, amidst loud cheering; and the Bill, as amended, was then passed.

The Sites Bill having been read a third time, Lord Redesdale moved to omit the words "bridge over or" from clause 14, which provided for a communication across the Strand between the Temple and the proposed courts. It was simply impossible to devise any such bridge so as not to disfigure, and very difficult to contrive one so as not to obstruct, that crowded thoroughfare. His lordship was content, however, to make his protest, and did not trouble their lordships to divide.

The words were, therefore, retained.

Lord Redesdale then moved a new clause to follow clause 18, to the effect that no notice should be given of an intention to take any property under the Bill and no contract should be entered into until plans and estimates had been prepared, and until they had received the sanction of Parliament.

The Lord Chancellor said he hoped this clause would not receive any countenance from their lordships. It would require the spirit of prophecy to say exactly what would be the sum actually expended; but the utmost care had been taken to obtain the most trustworthy estimates. If the cost should exceed the sum which had been named, he must remind their lordships that the tax which it was proposed to levy might be doubled without inflicting the least hardship upon the suitor. The noble lord proposed that no notice should be given to take the lands until plans should be prepared by Government. He (the Lord Chancellor) did not want the plans to be prepared by Government, but by the profession with the aid of the Government, who should then hand over the building to the architect. It was impossible that the commission to be appointed could alter the space till the buildings now thereon had been cleared away. He never knew an amendment which contained within itself more impossibilities than did this. The noble lord proposed that they should stay their hands till they saw what land they required, but they could not possibly tell till they had cleared the site, and determined not only on the plan, but the manner in which it was to be carried into effect. The measure had already received a severe blow, but this amendment would defeat it altogether if carried.

The Earl of Derby thought the course proposed by Lord Redesdale was the one which would be taken by the private individual of ordinary prudence, and one which ought to be taken by the Government.

The Duke of Argyll remarked that the last words of the amendment would prevent anything being done till another Act of Parliament had passed.

Lord Redesdale said it would be impossible to begin the building till next year or the year after. There was plenty of time.

The Lord Chancellor said if the amendment were agreed to there would be no less than four distinct Acts of Parliament required to carry out the Bill, and therefore the amendment was nothing less than a covert way of defeating the Bill altogether.

The House then divided on the question that the clause be added to the Bill.

Contents ..... 47  
Non-contents ..... 44-3  
The Bill as amended was then passed.

QUERIES CONCERNING STAINED GLASS.

The following queries, suggested by the late exhibition of Mr. Winston's drawings, were sent to us "not for publication." As, however, they are calculated to induce thought, and may possibly lead to some useful expression of views, we overlook the prohibition:

1. What is the object of stained glass: is it an effect of colour?
2. What is good colour in stained glass: loud and glaring or quiet and cool?
3. Is it advisable to place figures coloured on broad spaces of white glass, as in Perpendicular glass? Does not this get a quiet, cool effect?
4. Ought canopies to be much coloured, or in simple white and black, to get quiet effect; and how drawn, with reference to next paragraph?
5. Ought geometrical diagrams to be drawn with absolute mechanical accuracy, or to be freely drawn?
6. How ought draperies to be drawn; thinly, or richly & la Dürer?
7. What is the difference between a thinly designed or richly designed canopy?

FROM SCOTLAND.

**Auchtermuchty.**—The foundation-stone of a new town-hall has been laid here with Masonic ceremonial.

**Montrose.**—A rather odd occurrence has taken place at Sunnyside Asylum, thought to be caused by strong gales of wind. The smoke chimney-stalk immediately at the back of the Asylum, and built on the top of the engine-house, was discovered to have shifted about 6 or 6 inches to the west from its original position. The change in the position of the stalk was discovered by the small amount of draught in the chimney.

**Inverness.**—The new public hall, occupying the centre of the north side of Union-street, is now on the point of completion. The interior is about 80 ft. by 40 ft., with lofty ceiling.

**Duthil.**—A memorial stone has been erected on the bank of the Spey, to commemorate a traditional "dividing of the waters" which afforded a pathway to a funeral procession from the Bracs of Abernethy to the churchyard of Duthil. The occurrence took place in the begin-

ning of the thirteenth century! It may be a question whether it was the river or the funeral procession that became "dry," but if the latter, no doubt the "mountain dew" had found a pathway down their thirsty throats long before they reached the Spey.

**Cathcart.**—The new Free Church, Cathcart, has been opened. The situation is about equidistant from the town of Cathcart, Langside, and the rapidly extending suburbs of Crosshill and Prospect Hill. The church, which is a very simple little Gothic building, is cruciform in plan; the east end of the nave being semicircular. The entrance is on the south side by a porch, which has an open timber roof, and a floor laid with Maw's encaustic tiles. There are no galleries, but the pews rise considerably towards the end, and are in the transept at each side. The pews are all 33 in. wide, and 20 in. are allowed for each sitting. At the west end there are session-house, vestry, and other apartments, and the west gable is surmounted by a slender timber belfry. The church is seated for 500 persons, and the cost (including varnishing, hot-water apparatus, gasfitting, &c.) will be a little over £500. The accounts, as far as received, including that for mason-work, are said to be all under the original estimates. The whole has been carried out according to the designs of Mr. J. Honeyman, jun., architect. The contractor for mason and wright work was Mr. A. Fraser; and the clerk of the works was Mr. J. M. Robertson.

#### FROM IRELAND.

**Drogheda.**—The first sod of the new water-works has been laid by the Lord Lieutenant of Ireland, who then opened the new town-hall. The first sod of the waterworks was turned at Killencer, a few miles outside the town. As stated by Lord Wodehouse, the new works will supply 800,000 gallons of water a day. Half the cost has been subscribed by Mr. Benjamin Whitworth, of Whitworth & Brother, of Manchester, who must be a sort of Brother Chesable, in his way. The contract for the execution of the works has been taken by Mr. Ashcroft, of Preston. The site of the new town-hall was given by Mr. St. George Smith, and the building by Mr. B. Whitworth. A manufactory has also been commenced by Mr. Whitworth, and is destined to employ a very large number of hands.

The *Dublin Exhibition* has been opened very satisfactorily.

#### PARIS.

Two new schools were opened, some months ago, by the Society for the Professional Instruction of Females, at the Rue du Val Sainte Catherine and the Rue Rochechouart; and so far as they have gone they have been a complete success, especially in the wood-engraving branch, which is eminently adapted for female students, as they can work at their homes without interfering with their domestic duties. The school in the Rue Rochechouart was opened last October, and at the end of six months counted thirty scholars. M. Isaac Pereire has liberally come forward in aid of the above Society, and M. Alexis Godillot, the celebrated manufacturer, has decided upon paying half the expenses of any of the children of his numerous workmen sent to these classes. The payment is 10 francs a month (not quite 5l. a year), and the general course of instruction comprises morality, French language, arithmetic, history, geography, applied sciences, writing, drawing, &c. There are four special courses,—commercial, industrial drawing, wood-engraving, and the making up of clothes and linen. These schools are the germs of future establishments, the want of which is daily manifested with increased energy among the labouring classes.

The neighbourhood of Saint-Antoine and the ancient valley of Fecamp in the Fambourg Saint-Antoine is undergoing a complete transformation by the opening of new thoroughfares, and a circular place is being formed in the Rue Rambouillet, from which several new streets will radiate. On this spot, in 1465, was signed the treaty of peace putting an end to the *ligne du Dieu public*, and in which Louis XI. skilfully evaded the onerous conditions imposed upon him. This ground was for a long time afterwards known by the name of Le Champ des Trahissons; and in 1562 were found the remains of a cross, with the date

MCCLXV. marked thereon, recording the above event, and invoking, by an inscription, a malediction upon the authors of the treaty.

The works for the further development of the arterial drainage are continued actively during this season. At the Butte Montmartre the sewerage is being carried as far as the top of the hill by the Rue du Vieux Chemin, where it lies at a depth of 21 ft. 4 in. below the surface. The drainage of the northern slopes of Montmartre will be collected by the main sewer of the exterior boulevards, which falls into the great collector of Anières, beyond the Boulevard Malesherbes. Meanwhile, operations of another nature are being carried on to improve the aspect of Montmartre by filling with cartworks and new thoroughfares the ancient quarries which have, since the commencement of the seventeenth century, furnished so much stone and plaster to the capital. Hence the name of Ville Blanche given to the Marais quarter, which was built with stone from these quarries. New sewers have been laid down in the Rue de Balaguy and the ancient Chemin des Beufs, and the Chemin des Epinettes is about to undergo the same alteration. There remain yet in the outskirts of the capital in this quarter a few open drains or sewers, but they are soon to give place to the extended system of sewerage now in progress.

#### IMPROVEMENTS AT SYDNEY, NEW SOUTH WALES.

Two blocks of buildings are about to be erected in the most central part of Pitt-street. Adjacent to the Union Bank of Australia four spacious warehouses have been commenced, after the designs of Mr. T. Rowe. On the opposite side of the street, adjoining Mort's-buildings, the foundations are being excavated for the erection of three lofty houses with shops for Mr. H. Bell. The masonry will be carried out by Mr. M. Credic, and the interior fittings by Mr. Dyer; the architect being Mr. Muuro. At Darlinghurst Gaol, the four watch towers for the use of the warders are nearly completed, the masonry having been prepared by the prisoners. Competitive designs for the enlargement of the Congregational church in Pitt-street having been invited from some of the Sydney architects, that of Mr. G. A. Mansfield has been selected. The estimated cost of the enlargement is 6,000l. A contract was recently taken by Messrs. Lovelock for a stone tunnel for the sewerage of Woolloomooloo Bay. Plans are being prepared by the city engineer for covering the new market ground at the Haymarket. Under the colonial architect's department contracts have been taken for an additional wing to the Tarban Creek Lunatic Asylum, for a lock-up at Ashford, and for additions to the court-houses at East Maitland, at Bathurst, and at Braidwood, and to the police-station at Urara. At Wollongong, the masonry of the new basin is nearly finished, and the outside wharfs will be completed in about a month. The harbour works at Kiama have been temporarily stopped in consequence of a dispute between the contractor and the Government.

#### ALOE WOOD.

This is the common name for the wood of a large Eastern tree, a native of the mountainous districts of Cochin China and the East Indian islands. It belongs to the family of pod-bearers, and amongst its other members may be mentioned the indigo plant of commerce, liquorice, earth-nut, manna, tamarind, cassia, and the gum-bearing acacias, not forgetting the peas and beans of our gardens. Aloe-wood, or *Aloexylon agallochum*, is also known under the name of lign. aloes and calambac wood; its popular name of aloe-wood is evidently derived from the scientific name of the genus, and is in no way connected with the true aloes, which are succulent plants. It is said to attain a height of 60 ft., and to contain more resin than any other known wood; it is extremely inflammable and highly aromatic; of little weight and very porous; the interstices being filled with a sweet-scented resin. It is held in high estimation in the East on account of its perfume and medicinal properties, and is occasionally used in the higher class of manufactures. In ancient times it was burned by various Eastern peoples in their religious observances; many poetical legends are extant, regarding this tree and its origin, that are of extreme interest.

W. G. S.

#### LABOUR SAVED, BOTH TO MAN AND HORSE.

SIR,—While we admire the buildings and monuments, in your publication, do we not often forget the unnecessary labour, both of man and horse, in their erection? You will ask, how can this be diminished? I answer, first, by laying down a granite tramway (not raised) for the transit of the heavy materials, Mr. Jessop having proved that one horse on the Darlington rail drew twelve tons three miles an hour, and that one gig-horse drew forty-two people eight miles an hour. Next, a carriage which would convey the men to and from their work, propelled by themselves. I have tried it with success, even on a common road. Lay a platform on the axle (perhaps that of a pair of wheels, with a smaller guide-wheel in front, and a broad step behind: let two arms open like a pair of compasses from the axle near each wheel, and from the two arms let two legs press the ground together, or alternately, the arms being pulled down by ropes from a cross-bar. To impede it down-hill, there are many ways: perhaps 5 or 6 inches of gravel or sand may suffice.

NEMO.

#### WATER FOR LONDON.

SIR,—Is it impossible to effect an amalgamation of the water companies in the metropolis so that they may jointly obtain Parliamentary powers to procure the requisite increased supply of water from the Severn? The town of Cheltenham is proposing to make use of the same source.

J. W. H.

#### "METALLIC CEILINGS."

SUCH a material as that quoted from *Ryland's Circular* in the current number of the *Builder* would make our living-rooms unwholesome, and to be public buildings, churches, &c., the worst possible description of ceiling, it being of great importance, in a changeable and humid climate like our own, to provide a certain and a large amount of absorbing or breathing surface in rooms. Witness the bad effects where the walls are painted and woodwork varnished; moisture may be seen trickling down them, and for this reason oil-painted ceilings are objectionable. Plastering, if properly done, and the coats laid at proper intervals, will never crack objectionably: the whitening fills up all the fine pores, and gives texture, which it seems the object of modern improvements to ignore. For decoration the new material offers no advantage over plaster, the treatment of which may be very much improved. Mr. Norman Shaw opportunely shows (No. 357, Architectural Exhibition) a very suggestive revival carried out by him, of an old method of plaster decoration, something similar to which, in a primitive way, may now be seen on vineyard walls in Tuscany.

THOMAS H. WATSON.

#### SHOE-TIES AND BOOT-LACES DANGEROUS TO THE WORKING CLASSES.

It is a pity that the revolution of fashion has put away the usage of buckles as fastenings for boots or shoes amongst our working population, because neither a boot-lace nor a shoelace is so much to be depended on.

In a social point of view the boot-lace is a ruinous loss to the house-wife who has a large family, and her hand is never out of her pocket to supply it. People in a higher position can scarcely form any idea of the yearly expenditure of poor families alone for these frail unserviceable cords, or strips of leather. Nor is this the only point in which they are to be condemned; for (quietly be it spoken) they have been the fruits of many a "corner's inquest." In the shop-yards they are guilty, as elsewhere, of tripping little rivot-boys, as well as men, into eternity.

But this is not the only argument against their usage. You must count uncomfortable journeys, and the slovenly swings of the loose lace painting your polished boot with mire every stride, until, probably, some friend calls your attention to it. You must have sprained ankles, stockings holed, and awkward gait, to be the result. Ask the workman how many inconveniences he has had from them,—how many heart-palpitating races he has had through their use to catch the workshop gates open at six o'clock in the morn-

ing,—how many quarter days he has lost. Ask the workmen how many oaths they have sworn while their patience has been strained and tampered with by laces creaking at every twitch, and having them to do and undo; and then, after all, to be accommodated. The boot-lace, or shoe-tie, is one of the greatest of pests they have to deal with; and, therefore, one cannot but think that the sooner the old-fashioned buckle (somewhat modernised) is adopted the better. The tradesman of the future, then, who rescues the *British workman* from the slavery of such dangerous shoe-fastenings as have been commented on, is worthy of all the patronage that will ensure his permanent respectability.

ALEXANDER HAY.

#### DE TURRIBUS.

Sir,—It is now six years since I wrote upon this subject, under the head of "Notes on Towers;" and, as so many bell-towers have lately been and are being erected, intended to contain peals of bells, or large bells, it may be as well to say a few more words upon the subject, particularly as we often see structures of this kind erected only with a view to architectural effect.

Before I say anything with regard to the building of new towers, I must make an observation or two upon furnishing with bells those already built.

If a church-tower be of a certain internal capacity, and the walls ever so thin, and the foundation ever so bad, perhaps Mr. Green, the churchwarden, at the instigation of Mr. Nottoblane, the brass-founder, without consulting an architect, will get on the right side of Sir Good-natured Fool to supply funds and hang in the flimsy structure before mentioned a set of bells which will have the ultimate effect of involving both tower and church in ruin. Nothing of this kind should be attempted without the advice of an architect versed in these matters. I once heard of a person who had hung three bells in a chapel tower offering to hang six in the tower of the parish church, the walls of which were 14 in. thick, the quality of brickwork rendered invisible with compe, and the foundations probably like those of a common house.

Though it is my opinion that one good-sized bell of 4 or 5 tons has a much better effect, especially in a large city, than a peal; though this may be my private opinion as a matter of taste; and though bells of this size are not generally raised, and are consequently safer; there are many at the present day who cannot endure the thought of being summoned to church by the sound of less than at least five bells; and it is therefore as well to consider how a tower for this purpose can be constructed.

I noticed that (vol. xvi. p. 260) the towers in Suffolk were built without diminution of diameter towards the top; and this being the case I am not surprised that so many of them are totally in ruins, simply from bell-ringing and bad construction. Here are a fraction of their number: Whitton, East Bergholt, Trimley, Fleampton, Westleigh (rebuilt since), Bradfield Combust, Thurston (rebuilt immediately), Sutton.

For the foundations, if the soil be faulty or of plastic clay, or abounding in springs, by all means give up your bells in favour of some other luxury, such as stained glass, pictures, or sculpture; but if, on the other hand, the ground is solid and regular, it will do no harm to dig down to a depth equal to half the width of the tower if concrete is required; but if no concrete is wanted, considerably less. Then upon the concrete or natural bottom lay 6-in. York landings in two or three courses, according to size of proposed superstructure.

To get the outline of the tower in elevation: describe a circle about the outer line of its plan, and make this circle the base of a cone four or five times the height of the tower. Through one side of the line of plan project a plane, cutting the cone parabolically. The parabolic curves thus found will serve as the outlines of the tower in elevation. A tower thus constructed will be much stronger than a straight-sided one, and will not have the same top-heavy appearance.

A tower of parabolic outline exists in London in connexion with that hideous structure White-chapel Church; a church, by the way, standing on a site which ought to be occupied (and might be) by a most magnificent structure. For it is the best site, notwithstanding the inferior class of houses surrounding it, in any part of London, to show off a good building.

There is another at Hendon; and the old and lower part of St. Clement Danes tower is thus constructed; also the new tower at Kirstead, in Norfolk. Mr. Christian's tower, in Nutford-place, is also diminished slightly towards the upper part.

There should be an offset to support the ringing floor and the bell floor, so that no timber be run into the wall to act as battering-rams. Neither should a bell be hung on cross-beams resting on the walls, but always in a trussed cage. To get the thickness of the upper walls let diameter of

tower at bell-floor =  $a$ , then  $\sqrt{\frac{a^2}{2}}$  = internal diameter, and  $a - \sqrt{\frac{a^2}{2}}$  = thickness of two opposite walls.

There should be as many ringing bells as can hang upon one level. If there is too much space their sound is lost before it comes forth, as at St. Alban's, Trinity, Paddington, and Bury St. Edmunds. If they are hung in two tiers in one story it impairs the sound.

Sir Christopher Wren's towers, and those built immediately after his time, are well worthy of study: though Italian in detail, they resemble in their plans some of the Mediaeval Gothic specimens on the Continent.

W. SCARCELL.

#### CHURCH-BUILDING NEWS.

**Cirencester.**—The augmentation of funds since the recent meeting in February last, although far short of the required 12,000*l.*, approximates to an amount which has enabled the committee to give instructions to Mr. G. G. Scott for proceeding with the church works as soon as the tenders shall be received from proposed contractors. The sum promised and paid, including interest, together with the first portion of the grant from the Warford Ecclesiastical Charity, amounts to 9,650*l.* The committee have recommended that the contracts shall be undertaken in such a form, as that tradesmen in Cirencester may have an opportunity of tendering for portions in detail, according to their business, as glass, lead, iron-work, &c. The churchwardens will, in course of time, dispose of materials and internal fittings, which consist of oak-panelling, gas standards, and other available articles.

**Frome.**—Another portion of the work of restoring the parish church has just been completed, namely, the south porch, which has been entirely rebuilt. Over the arch, which is carved, is sculptured the emblematic lamb and banner; and over the inner arch is a triptych filled with sculpture representing St. John and St. Peter "going up together to the Temple at the hour of prayer." The sculpture is the work of Mr. Ezard, of Bath.

**Liverpool.**—The foundation stone of a church, to be called the Church of St. Mark the Evangelist, the fifth district church in the parish of Behington, has been laid near the river at New Ferry. The building, of which Mr. Edward Haycock, jun., of Shrewsbury, is the architect, will be Gothic in style, and consist of a nave, north and south aisles, chancel, chancel-aisle, vestry, porch, and bell-turret. It is to be built of Transire stone, with Stretton dressings; and will contain open-seat accommodation for 450 adults and 100 children. The contractor is Mr. R. Lloyd, of Shrewsbury, who hopes to complete the building by the end of the present year; and the cost will be about 2,500*l.*

**Bury (Lancashire).**—The Bishop of Manchester has consecrated a church dedicated to the Holy Trinity, which has been erected in this town. The site is in Spring-street, and is the gift of the Earl of Derby, who has also subscribed 1,000*l.* towards the endowment fund. About 5,000*l.* have already been expended on the building, and the entire sum has been obtained by voluntary subscriptions. The church has been erected from plans by Mr. Paley, of Lancaster, architect. The style is Early Gothic, and comprises a north aisle and nave with chancel, to which is yet to be added an ante-chapel, another aisle, and also a tower and spire. The arches are constructed of red and blue bricks, and the windows are filled with geometrical tracery. The church will accommodate upwards of 600 persons, all free. The building is not yet completed.

**Hamer (Manchester).**—The corner stone of the proposed new church of All Saints, Hamer, has been laid. It is to be built on a site adjoining

the grounds of Mr. Entwisle, of Foxholes, by whom the ground is presented. The rapid fall of the ground on the south and west will add to the effectiveness of the building. The plan of the church consists of a rectangular chancel, having north and south aisles, the former of which, under a lean-to roof, will contain the organ; and the latter, gabled towards the east, is arranged for vestries for the clergy and choristers. A lofty arch, springing from corbelled marble columns, marks the division between chancel and nave: the latter is of six bays, with north and south aisles, the pillars supporting the arcades of which have carved and flowered capitals of white stone, and cylindrical shafts of red sandstone. At the south-west corner of the south aisle is the steeple, the basement of which forms a porch, and is the chief entrance to the church. From the south aisle projects a double transept, equal to two nave bays in length, and with a porch and double doorway for the use of the school children, whose seats are here. The chancel rises two steps from the nave, the sacrumum two steps more, and the Lord's table stands upon a foot pace. The stylo is Early Decorated. The spire will rise to a total height of 133 ft. from the ground. The belfry is adapted to receive a full octave of bells, with about a 14-cwt. tenor. On the south face of the tower, in its lowest stage, is a shallow open porch, with moulded, enriched, and shafted archway, through which the lower porch is entered. There is a large west window of four lights, and an eastern window of five lights. The aisle windows are of two and three lights, and the clerestorial lights are circular and cusped. From the south chancel wall rises the chimney, not disguised. The church will be of stone, and altogether there will be eight or nine kinds employed. The roofs will be slated, with coloured boards, and the ridges finished with ornamental cresting. There will be seats for about 650 persons in open benches. The contracts have been taken by Mr. W. Leach, for the masonry; J. Dawson, for the joiner's work; W. H. Best & Brother, for the plastering and painting; G. Kirkley, for the slating; and J. Kershaw, for the remaining trades. The architect is Mr. J. M. Taylor, of Manchester.

**York.**—A new church has been erected in the grounds adjoining the Lunatic Asylum in Bootham, for the use of the patients in that establishment. It has been erected at the sole charge of the asylum authorities, the cost amounting to about 1,500*l.* The architect for the church was Mr. Rawlins Gould, and it has been built for the accommodation of 200. The building, which is in the Geometrical style, is 72 ft. long, 22 ft. broad, and 19 ft. high to the wall-plate, above which is a perforated frieze. There is an open timber roof, covered with green and blue slates, which are surmounted by ornamental iron cresting. A spire, about 66 ft. high, rises from the south-west corner of the building, the dressings of which are of Ancaster stone, and the walling is composed of stone from Bradford. There is a transept on the south side, and a vestry on the north side. The entrance to the church is by the west end. The fittings are of oak, and the seats are surmounted by carved poppy-heads supplied by Mr. Shepherd, carver. The stone carving was done by Mr. Hessay. In winter the church will be heated by an apparatus supplied by Mr. Longbottom, of Leeds. The following were the contractors for the work:—Messrs. Bowman & Co., the builders; Mr. Franklin supplied the iron-work; Mr. W. Ellis was the slater; Mr. W. Hartley the plumber; Mr. F. Rawling the plasterer; and Mr. R. Pearson the painter. The two acres of ground on which the church stands are being laid out as a pleasure-ground for the patients.

**Wellburn.**—St. John's Church, Wellburn, which was built several years ago by the late Earl of Carlisle, in memory of his mother, has been consecrated by the Archbishop of York. The church was built from a design by Messrs. Mallinson & Healey, of Bradford, and is in the decorated style of the fourteenth century. The church is dedicated to St. John, and stands in a very conspicuous position on a knoll to the south of the village, and in full view of the mansion of the Howards.

#### SCHOOL-BUILDING NEWS.

**Norwich.**—A new parish school in St. Peter's Mountergate has been opened. Last year, a piece of ground adjoining the church, on the north side, was purchased of the Town Council

for 300l., as the site for the school, the building of which was commenced by the contractor, Mr. Fyson, in the following September. The structure, of red brick, and designed by Mr. R. Kitton, is oblong in form, and Elizabethan in style. It will accommodate 200 children, and is lighted by windows at the east and west ends, and on the south side. The window facings are of red brick. The total cost of the work, including site, fittings, &c., is 1,000l.

*Deptford (Newcastle-upon-Tyne).*—New parochial schools have been opened at Deptford. Messrs. Austin & Johnson, of Newcastle, were the architects for the building, which is situated in Neville-street, not far from the church. The schools, which are on one flat, under the same roof, are capable of accommodating about 400 children. The entire cost of the building is 1,833l. 5s. 6d.; value of land, 453l. 2s. 7d.; making a total of 2,336l. 8s. 1d. Mr. J. H. Aylmer gave a site for the schools, which was subsequently sold to the North-Eastern Railway Company at a profit of about 510l.

*Higher Crumpsal.*—A new school and lecture-room have been recently erected in St. Mary's-road, and opened. The room is intended to serve as a Sunday-school in connexion with St. Mary's Church, and also as a lecture-room for the working classes, and for tea parties and public meetings. It is a plain Gothic structure, placed in the centre of an open space of ground. Its cost has been 470l., and it will accommodate about 250 children.

### Books Received.

*A Manual of Gothic Mouldings, with Directions for Copying them and for Determining their Dates.* By F. A. Paley, M.A. Third edition. With additions by W. M. Fawcett, M.A. London: Van Voorst. 1865.

MR. FAWCETT has added a number of woodcuts, by way of additional illustration, to Mr. Paley's well-known and useful little volume, and given such further explanations as seemed desirable to render parts clear. The necessity for using what is called "correct mouldings," mouldings exactly like those employed at the different periods of Gothic architecture, seems urged in the book; and if the object be to produce an exact imitation of a building of the twelfth, thirteenth, or other century, this advice may still be dwelt on. This, however, was not the course pursued by the men who created these buildings, as the author shows by a quotation from the "Analysis." In completing or altering buildings at a later date, even if the style were occasionally imitated, the mouldings were always worked in conformity with the system prevalent at the time, and thus the actual date of the erection is marked.

It is, nevertheless, desirable that the peculiarities of the mouldings of the different styles should be thoroughly understood; and, towards that end the book before us will be found a great assistance.

*The Early English Organ Builders and their Works.* By E. F. Rimbault, LL.D. London: Whittingham.

AN "unwritten chapter on the history of the organ" by the Musical Examiner of the Royal College of Preceptors cannot but be interesting to all who love music. This volume comprises a lecture delivered before the College of Organists in November last; and it treats of the history of the noblest of instruments from the fifteenth century to the period of the Great Rebellion,—a new field of inquiry, and of more than archaeological interest.

*A Dictionary of Science, Literature, and Art.* Edited by W. T. Brande, D.C.L., and the Rev. Geo. W. Cox, M.A. London: Longman, Green, & Co. Parts I. & II.

BRANDE'S Dictionary, excellent when first published, has fallen behind the age, which has been going fast for four-and-twenty years. Since that event, the owners have wisely determined on a new edition, revised and added to throughout, and Parts I. and II. already published show that this will be well done. A long list of contributors to the new edition is given, but it is scarcely fair, perhaps, to omit the names of the original writers. For example, "Architecture" stands in the present edition against the name of the Rev. G. W. Cox; but the article under that special title is, in truth, Gwill's article, though

revised. The exact state of the case, however, will doubtless be explained in the work.

The Dictionary will be completed in twelve monthly parts, forming three volumes. A more legible type than that used in the first edition is adopted, and the titles are made very prominent.

### VARIORUM.

"A DESCRIPTIVE Catalogue of the Geological, Mining, and Metallurgical Models in the Museum of Practical Geology." By Hilary Bauerman, F.G.S. London: printed by Eyre & Spottiswoode. 1865. The skill with which this instructive catalogue has been prepared is endorsed by Sir Roderick Murchison, director of the Museum. It contains descriptions of numerous models, as of boring machinery, cranes, pumping-engines, &c., as well as of geological strata, and other useful matter.—"London Society" for May contains a very good portrait of William Paterson, of Dumfries, the founder of the Bank of England, from a pen-and-ink drawing in the British Museum, together with a memoir, forming a portion of the series of chapters on the Merchant Princes of England.—"The Churchman's Family Magazine," May number, has a paper on "Christian Art in Scripture," besides the Churchman's usual mental provender.—The March and April parts of "Casell's Illustrated Family Paper" contain a great deal of useful and entertaining matter, with engravings, which are often surprisingly good for a penny periodical. Casell's paper, we are inclined to think is not only superior in itself to most of the other penny papers, but has been the means of improving them, at least in respect to engravings, which had degenerated into scratchings of a horrid description, such as even now, not seldom disgrace and must damage even a penny periodical.—Notwithstanding the invariable difficulties attending first numbers, the first of the *Shilling Magazine*, produced under the editorship of Mr. Samuel Lucas, is a fairly good one, including contributions by Mr. Stirling, of Keir, Mr. W. J. Thoms, Mr. R. Bell, Mr. Edwin Arnold, and others. Mr. Tom Taylor, in an article on "The Pictures of 1865" (too wide a title), speaks of Mr. Ford Madox Brown and Mr. Holman Hunt, and weighs with candour the characteristics of these artists, condemning in them a deficient sense of beauty, some harshness, and proneness to excess of labour in details, while applauding the conscientiousness of their work, their earnestness, and rejection of dead conventionalities.—

"The school of painting," says the writer, "to which Mr. Holman Hunt and Mr. Ford Madox Brown belong has done much to bring these great life-giving influences to bear upon English art. They have asserted the need and nobility of zealous labour from nature, the dignity of fact, the necessity of the painter's looking at things for himself, and his right to bring Art to the standard of truth. They have revived landscape-painting, and given a new interest to the representation of incident. But, like all young proselytisers, they have rushed from one extreme to another; have pushed truths so far that they become, in their turn, errors; have strained their eyes so in gazing at one kind of light, that they have become blind when turned to other objects. Even the sun of truth may blind us if we do not use the proper media for its contemplation, 'smoked' glass, if need be."

—In the current number of *Fraser*, on the other hand, is found a paper on Mr. Madox Brown's exhibition, by Mr. W. M. Rossetti, wholly laudatory and without qualification.—Mr. W. F. Watson has printed a "Catalogue of original drawings, engravings, &c., selected from his private collection," for the inspection of the members of the Architectural Institute of Scotland, at his private residence on a recent occasion. The general subject is indicated as being "Edinburgh: its Houses and its noted inhabitants." The selections, says Mr. Watson, "are from the portfolios of a general series of contemporary and other portraits; original manuscripts, letters, and documents; prints, drawings, and printed papers, mounted on sheets of Bristol board of three sizes, demy, folio, and imperial, grouped or otherwise, thereby attempting to display a man's likeness, birthplace, and tomb; his writing, drawing, or etching; his calling card, book-plate, or coat of arms; the advertisement of his works; the proposal for publishing, or title-page of his book; the intimation of his death, or invitation to his funeral; or, it may be, ticket for his trial or speech at his execution." Mr. Watson's collection must now be an exceedingly valuable and curious one, being the result, if we mistake not, of the continued accumulations of at least more than a quarter of a century, made by one who possesses both the knowledge and the opportunity requisite for making such a collection.

### RECENT PATENTS CONNECTED WITH BUILDING.\*

APPARATUS USED TO REGULATE THE SUPPLY OF WATER TO WATER-CLOSETS, WASH-HAND BASINS, AND URINALS.—F. G. Underhay & C. Heyworth, jun. Dated 19th August, 1864.—For the purposes of this invention a vessel, by preference a cylindrical vessel, is used, which is closed at the bottom, within which vessel another vessel of smaller dimensions and closed at the top, works readily up and down. Around and near the lower part of the inner vessel is a cupped leather, or other suitable flexible material, the lower edge of which cupped material descends into oil or lubricating fluid at the bottom of the outer vessel each time the inner vessel is caused to descend, by which the interior of the outer vessel is lubricated each time the inner vessel is raised. At the upper part of the inner vessel an air-cock or valve is applied, the passage through which is capable of being regulated according to the time during which it may be desired the inner vessel should take in descending. The outer vessel is fixed in any convenient position, and the inner vessel is connected to the lever or other instrument of a water-closet, which acts on the water-supply cock or valve in such a manner that, when the lever or instrument is acted on, it moves the inner vessel above mentioned, which it can readily do by reason of the cupped leather or other cupped flexible material giving way and acting as a valve, while, in its return, the pressure of the air keeps its outer edge against the interior surface of the outer vessel. By this arrangement there is no induction air-valve other than the cupped flexible material around the inner vessel required. This arrangement of apparatus, when applied to a wash-hand basin or urinal, is similarly to be connected with the lever or instrument acting on the cock or valve by which water is supplied, and the weight or spring acting to close the same will be retarded by the regulating apparatus.

MACHINERY FOR DRIVING DRIFTS OR GALLERIES THROUGH STONE OR ROCK.—F. E. B. Beaumont. Dated 30th July, 1864.—For the purposes of this invention the patentee employs a series of chisels or jumpers worked so as to produce a continuous chase or groove, not a number of holes. The chisels or jumpers act to cut the stone or rock by striking it with blows, which are rapidly and continually repeated, and they are made to cut a continuous chase or groove by causing them each to take short steps forward in the intervals between the blows. He prefers to employ a strong disc with the chisels or jumpers fixed around its periphery at equal distances apart: this disc is mounted on a strong axis, which is carried in bearings on a base plate or carriage in such manner as to be able to slide longitudinally, and also to rotate. The longitudinal sliding motion is conveniently given to the axis by a cylinder and piston worked by compressed air, or by water, and in this manner the disc (with its chisels or jumpers) is made to move to and from the face of the stone or rock in which the chase or groove is to be cut, and the chisels or jumpers strike the stone or rock at each stroke. It is convenient to make the cylinder itself the axis of the disc, and to work it in conjunction with a stationary piston fixed to the frame. The slow rotary motion is given to the disc and cutters in any convenient manner; it may be by having a groove on the axis, into which there enters a stud capable of being slowly traversed around the centre of motion.

MANUFACTURE OF GLAZES OR ENAMELS FOR POTTERY WARE.—J. H. Johnson. A communication. Dated 2nd August, 1864.—This invention relates to the manufacture of certain glazes or enamels suitable for pottery ware of all kinds, which glazes or enamels are perfectly innocuous, both to the user and to the manufacturer, by reason of the entire absence in their composition of all deleterious or poisonous metallic oxides so objectionable in the glazes or enamels ordinarily employed, while at the same time their cost is not augmented. In carrying out this invention for the manufacture of glazes or enamels which are to be applied to the articles of pottery ware by the ordinary process of dipping, two successive operations or processes are employed. The first process consists in the preparation of a frit, and the second in effecting the intimate admixture of this frit in proper proportions with clay of a peculiar composition.

\* Selected from the *Engineer's Lists*.

## Miscellaneous.

**BRISTOL ARCHITECTURAL SOCIETY.**—"The Architecture of Towns" formed the subject of a lecture read by Mr. J. Hine, of Plymouth, at the meeting of the Bristol Society of Architects, on the 3rd instant, and this meeting brought the Society's present session to a close.

**ROYAL ITALIAN OPERA.**—"L'Étoile du Nord" has been given with considerable success; Madame Van den Heuvel (better known as Caroline Duprez) singing the part of *Catterina*, if not powerfully, very pleasantly. Signor Atrii is the *Pietro*, and acts the part better than he sings. The "getting-up" of the opera is beyond all criticism.

**BUILDING OPERATIONS IN LEWES.**—The pasture field to the left as you walk down Rotten-row, is about to be absorbed by the builders, who have already laid the foundations for several residences, which will apparently present "villa" characteristics. The growth of the Sussex town of Lewes has been very palpable during the past ten years, a better class of houses having been erected according as the demand for modern dwellings has increased with the prosperity of the town.

**UTILIZATION OF SEWAGE.**—The experiments carried on at Moor's Farm have been most successful. The grass of the acre first irrigated by Mr. Nicholls is in a luxuriant condition, being in most parts 18 in. high, with a thick bottom growth. That portion of the acreage recently irrigated shows a corresponding increase, while half an acre left untouched is almost barren. The cattle show a decided preference for the grass on the irrigated land.—*Cheltenham Times*.

**OPENING OF BOGNOR PIER.**—The ceremony of opening the pier which has recently been completed at the improving watering-place of Bognor has just taken place. Since its connexion with the London, Brighton, and South Coast Railway it has greatly increased in importance. Mr. J. W. Wilson, of London, engineer, devised the form which the pier should take, and the work was placed in the hands of Mr. Dowson. The first pile was fixed in the month of April, 1864. The pier is constructed on the screw principle, and is mainly of iron. It is 1,000 ft. long; the head is 40 ft. across; and the width of the deck is 18 ft., and its height above high-water mark about 12 ft.

**BRICK-KILNS IN LIVERPOOL.**—At the local health committee's usual weekly meeting, among the notices reported as served was one on Messrs. George Thomson & Co., in reference to a brick-kiln in Bootle-lane, just beside the Industrial Schools, on the ground that it was injurious to public health. Notice was given that proceedings would be taken if the kiln were used. Dr. French said he had in no instance taken action where the kilns were not prejudicial to health. The one in question was within 4 yards of a public thoroughfare, and even horses passing might be frightened by the smoke. Mr. Jeffery said, the inhabitants around were under the impression that they had no control over these kilns, and it was under that impression that they had suffered them to remain there. Alderman Dover said he had been told, that in some parts of London the burning of bricks was prohibited altogether. The engineer stated that this was only where it was injurious to health.

**NEW EXPERIMENTS WITH MAGNESIUM.**—In experimenting with this new metal Mr. J. N. Hearder, of Plymouth, is said to have discovered some explosive compounds of tremendous power and striking peculiarities. He ignited a small portion (about 20 grains) of one of these compounds during a lecture which he gave at the Plymouth Mechanics' Institute, the instantaneous and dazzling effect of which upon the audience was like that of a flash of lightning. On causing two bars of magnesium to form the terminals of a powerful voltaic battery, a most intense combustion ensued: one of the bars speedily became red hot, entered into ebullition, and then burnt so furiously that it became necessary to plunge it into water to prevent its falling on the platform. In this process portions of the burning metal detached themselves, and floated blazing on the surface of the water, decomposing it after the manner of potassium, and liberating hydrogen, which also burned.

**THE LIVERPOOL BOROUGH ENGINEER'S SALARY.**—An increase of Mr. Newland's salary to 1,300*l.* per annum has been agreed to.

**MONUMENT TO RAFFAELLE.**—The eldest son of Victor Emmanuel has accepted the honorary presidency of a committee formed for the purpose of erecting a monument to this great artist in the city of his birth, Urbino.

**ENGLISH COMMISSION FOR THE UNIVERSAL EXHIBITION IN FRANCE.**—Her Majesty has nominated a commission to act for England in connexion with the French Universal Exhibition. The Prince of Wales is President. Lord Granville, several peers and gentlemen, with the presidents of artistic and commercial bodies, are appointed. Mr. Henry Cole will act as secretary.

**WALL DECORATIONS, SOUTH KENSINGTON.**—It will be remembered that the Department of Art have invited designs in competition for a picture illustrative of workmanship in any decorative art, to be afterwards enlarged, and executed in mosaic. Three artists were each to receive a special fee for their design, the competition beyond that being open to all. The three artists who have undertaken to submit designs under these terms, are Mr. F. Leighton, Mr. Byre Crowe, and Mr. Marks. Mr. E. M. Ward, Mr. Holman Hunt, and some other leading artists have undertaken to paint each a figure of an artist for execution in mosaic for the panels in the courts.

**JUNIOR ATHENÆUM CLUB.**—It is understood that the committee of this club will continue to elect original members, with an entrance fee of twenty guineas, to the 5th of July next, when the list of original members will be closed. We are glad to hear of its steady progress. We are told of a movement to form a new artistic club. Such a scheme could not be better carried out than by junction, if it could be arranged, with the club we are speaking of, the Junior Athenæum having already a body of carefully-selected members attached to art and literature.

**CRYSTAL PALACE.**—The advantages offered to purchasers of the new guinea season ticket are such as will probably induce a large sale. What with Ten Opera Concerts, comprising the entire artistes of the Royal Italian Opera, and her Majesty's Theatre; the Great Flower Show of the Season in May, the Rose Show, the German Gynastic Fête, the Dramatic College Fête, the Archery Fêtes, with a Grand Pyrotechnic display, and many other great gatherings, including the Winter Saturday Concerts, of which last year there were twenty-six, and some advantage as to the Handel Festival, there will certainly be plenty for the money.

**THE INAUGURATION OF THE BREST RAILWAY.**—On the 25th ult. the Brest Railway, opened for the last two years as far as Guinecamp, added another length of communication to the lines of Brittany. One of the most important works of this line is the Gonet Viaduct, 249 yards long and 187 ft. high, built of semicircular arches, 49 ft. 2½ in. span. The cost did not exceed 120,000*l.*, which was defrayed by the State, who undertook the earth works and masonry of the line from Rennes to Brest, leaving the company of L'Ouest to lay the permanent way and build the stations. A banquet followed the ceremony of opening the line. Thus Brittany has been brought within the pale of railway civilization. The immense works of the Port Napoleon, at Brest, are carried on actively, and for which the town has engaged itself to pay to the State the sum of four million francs (160,000*l.*).

**THE NEW SURREY THEATRE.**—The foundation stones of the New Surrey Theatre was laid on Saturday last in the presence of a large concourse of persons, including Mr. W. Early (the clerk of the works), Mr. Bilborough (the foreman to Mr. Wilson, the builder, of Whitefriars), and others. Mr. Albert Harris laid the first brick of the side wall next the Equestrian Tavern, and other gentlemen also laid bricks in commemoration of the event. The new theatre will differ materially from the old one, inasmuch as it will occupy a far greater space of ground. What was considered waste land at the back of the stage will be thrown into the building, and the boxes, pit, and gallery will be constructed in a new form. The entrances and the means of exit will, it is said, be well considered. It is expected that the theatre will be finished in about five months.

**THE PHOTOGRAPHIC SOCIETY.**—The president and Council of the Photographic Society held their annual *soirée* on Monday evening last, May 8th, in the Architectural Galleries, Conduit-street. The rooms were crowded, and the evening passed off remarkably well.

**THE RESTORATIONS AT MANCHESTER CATHEDRAL.**—The hoarding recently placed on the south side of the cathedral, enclosing the three windows on the west of the chapter-house, and defining the extent of the Byron chapel, denotes that this portion of the cathedral is about to be restored. Miss Atherton has undertaken the work at her sole cost. The Trafford chapel now alone awaits the hand of the restorer. Meanwhile the works at the tower are progressing, the style and dimensions of the east window, and the entrance porch, being observable.

**PROPOSED ENLARGEMENT OF THE GENERAL HOSPITAL, BIRMINGHAM.**—The board of governors have unanimously confirmed a resolution by the weekly board on this subject, and referred the matters in question back to that board to be carried into effect as speedily as possible. The resolution of the weekly board, which was also unanimous, is to the following effect:—"That it be recommended to the quarterly board to sanction the removal of the present fever wards, the conversion of the present out-patient department into wards, and the erection of a portion of the proposed east wing, consisting of a new out-patient department, two wards, and nurses' rooms, in Loveday-street, the whole at an estimated cost of about 5,800*l.* They further recommend that, if during the progress of the work the public generously supply the necessary funds, the whole of the proposed east wing, consisting of four wards, be erected instead of the two wards as suggested above, at an estimated further cost of 2,600*l.*"

**CRIMINAL RETURNS: METROPOLITAN POLICE.**—These instructive returns, for 1864, have been printed and issued. The table of comparative statements shows an improvement in police practice since 1831, the first year here recorded. Thus, out of 72,824 persons taken into custody in 1831 no less than 48,026 were discharged by the magistrates, while in 1864 the number taken into custody was 65,827, and of these only 29,610 were discharged by the magistrates: while the number convicted and sentenced moreover, was 3,042 in 1864; only 1,932 were convicted and sentenced in 1831. The number acquitted in 1831 was 616, while in 1864 it was 557. In 1831 the number of cases summarily disposed of was 21,843; in 1864, 32,387. It thus appears that while fewer persons are now taken into custody by the police, more in number than formerly are convicted and sentenced, which goes to show that more discretion is exercised in depriving persons of their liberty, and more activity and skill displayed in bringing real criminals to justice; and that with less of reckless show in doing their work more really useful work is done.

**ON FOOD AND WORK.**—At the Royal Institution, after the Easter recess, Professor Lyon Playfair delivered a lecture "On the Food of Man in relation to his useful Work." In his treatment of the subject he considered almost entirely nitrogenous food, or that kind which produces flesh, on which he remarked the power to do work depends; and consisting of the lean part of flesh, of corn, beans, and peas; such food as fat and potatoes only tending to keep up the animal heat. The amount of work which a man could do in a day had been estimated to be equal to a force that, if properly applied, would raise the weight of his own body one mile—the standard weight of a man being assumed to be 150 lb. To enable him to do that amount of work he should eat 4½ ounces of nitrogenous food, in addition to food that produced only heat. A horse could do eight times as much work as a man, but it eats rather more than eight times the quantity of nitrogenous food in beans and corn. The lecturer alluded to the dynamical theory of heat, according to which heat and mechanical power may be converted into each other; but he did not explain why that theory does not apply to heat-producing food, such as fat and potatoes, which ought, he supposed, to have its dynamical effect. He mentioned, indeed, that the heat-producing food might probably contribute something towards the work done, but he considered it to be an insignificant portion, if any, and that the useful work of man is produced almost entirely by nitrogenous food.

**THE PROPOSED MEMORIAL IN BIRMINGHAM TO JAMES WATT.**—The local Watt Memorial Committee have resolved that the memorial to be erected shall take the form of a statue. The subscriptions already received amount to about 750*l*. Arrangements have been made for a canvass of the engineers, and also of the working classes, in support of the movement.

**SHEFFIELD WATERWORKS AND THE INUNDATION.**—The directors of the Sheffield Water Company have issued a circular, in which they state that the total amount claimed against the company for damage done by the flood was 455,164*l*.; and the amount of claims to be paid by the company, as determined under the Inundation Commission, was 276,821*l*., being little more than three-fifths of the amount claimed. The directors estimate that not more than 130,000*l*. will be required to meet those claims and the yet unpaid costs.

**THE DWELLINGS OF THE POOR IN IRELAND.**—A meeting has been held in Dublin, for the purpose of establishing a society, on the principle of limited liability, to improve the dwellings of the poor. At a meeting of the committee, held at the Mansion House, with a large and influential attendance, it was resolved, on the motion of the Lord Mayor, that a sub-committee be appointed to confer with the leading manufacturing firms in the city, and others employing many workpeople, for the purpose of ascertaining how far they would co-operate with the company about being formed. The sub-committee consists of the following gentlemen:—Alderman Hudson; Mr. Valentine O'B. O'Connor, D.D.; Mr. Maclean, T.C.; Mr. Georgehegan, C.E.; Mr. Norwood, T.C.; Mr. Byrne; and Mr. Nugent Robinson, hon. sec.

**STRIKES AND LOCK-OUTS.**—In the House of Lords, Lord St. Leonards has laid upon the table a Bill to establish councils of arbitration to settle disputes between workmen and employers. His lordship justified the proposed Bill by reference to the recent strikes in the iron manufacture in North Staffordshire. He thought that the mode of settling disputes between labourers and capitalists by strikes and lock-outs was a disgrace to what was called the civilization of the age. Three different committees of Parliament had reported in favour of courts of conciliation and arbitration; but past legislation establishing arbitration was imperatively, because the workmen did not like the modes of arbitration established by that legislation. The proposed Bill he did not intend to proceed with further than the first or second reading, because he thought it right to have it circulated. It provided for the establishment of courts of conciliation, by authority of the Crown, and to consist of not less than two or more than ten masters and men. It would also establish, on the model of the French law, a Bureau de Conciliation. The object would be to prevent strikes.

**ACCIDENTS.**—A serious accident, which resulted fatally to three men, has happened at a mill situate at Gaythorn between the Rochdale Canal and the viaduct of the South Junction and Altrincham Railway. Owing to the mill being considered unsafe by the city authorities, the premises required to be strengthened, and with that view six men were employed in erecting brick pillars in the basement for support of iron girders, over which arches were to be built. The part of the building where they had been employed, namely, towards the centre of the lower end of the mill, gave way, and fell in from the roof downwards. The crash carried away the whole of that portion of the building which connects the two main portions of the mill, and the whole materials of eight stories fell upon the unfortunate men, and buried them, killing three of them as already said.—For some time past a large engine-shed has been in course of construction at the Pontypool-road station of the Newport and Hereford (Great Western) Railway. The building was about 200 ft. in length, and constructed in three sections. The centre and left sections gave way, and fell, carrying with them every portion of the works, and burying many of the workmen in the ruins, two of whom were crushed to death, four seriously injured, and several others but slightly hurt. There were upwards of fifty labourers about the building, and the escape of some of them was marvellous. It is said to be believed that the accident arose through the iron pillars or supports not being placed exactly vertical, and the roofing in consequence slipped.

**THE LOCAL GOVERNMENT ACT.**—One of the largest and most important town meetings ever held in Froome has just resolved on adopting the Local Government Act of 1858. The vestry-room of the parish church was found totally inadequate for the purpose of accommodating the ratepayers, and an adjournment was made to the Court-hall. The resolution was ultimately carried by a majority of two to one. The number of commissioners was fixed at 15.—By a majority exceeding two-thirds of its members, the Town Council of Canterbury have decided to adopt the Local Government Act.

**A FLOWERY TESTIMONIAL.**—The friends of the East Grinstead Dispensary, for which Dr. Rogers has worked earnestly from the commencement, as well in establishing it as in carrying on its operations, subscribed something like sixty guineas, and presented it to him, to mark their sense of his arduous and voluntary labours on behalf of that charity. In acknowledging the receipt of the testimonial, Dr. Rogers said he had decided it should take the form of a conservatory, which to him was a constant source of pleasure and occupation for leisure hours. Thus he will never walk amongst his plants without recollecting how good opinion, at first backward, has grown; and seldom cut a flower without being reminded of the fragrance of good deeds.

**PLANS OF TOWNS: CHESTER.**—At a recent meeting of the town council of Chester it was resolved "that the offer of Messrs. Pain & Son to furnish the council with a block plan of the city, upon the scale of 40 ft. to an inch; two plans upon a scale of 3 chains to an inch; and three plans upon a scale of 6 chains to an inch, for the sum of 157*l*. 10*s*., be accepted." "I will plan," said the mover of the resolution, "I will show the projections in the streets and in the rows, all the gas and water mains—in fact, everything desirable they should possess. It will give the boundary-stones in the borough. Of several towns that have maps of the description, that for Derby cost 1,500*l*.; the one for Coventry, 890*l*.; Cambridge (which was done by contract), 650*l*.; Reading, in Berkshire, 900*l*.; Carlisle, 75*l*.; Wigan, 400*l*."

**WEEK-NIGHT OPENING OF THE NATIONAL COLLECTIONS, &c.**—The popularity of the movement for the week-night opening of the national collections, and the establishment of local museums, appears from the experience of the South London Committee on Museums. Petitions to Parliament have been sent, not only from inhabitants of the district, but from workmen of particular trades, such as builders, fire-engine constructors, engineers, floorcloth manufacturers, and others. Those forwarded, however, are not a tithe, it is said, of the number known to be in course of signature in the factories, workshops, and yards. Unanimous resolutions have been passed by twelve public meetings, attended by 4,174 persons, and petitions have been officially signed by the chairmen. Votes have been taken in eighteen societies, having 3,842 members, and the officers have, with the unanimous approval of the members, signed petitions on their behalf. Cordial and unreserved support has been given to the movement by persons whose lives have been passed in the voluntary service of the country. Foremost among these may be named Miss Florence Nightingale.

**THE FIRST IRON SHIP.**—An ironmaster, named John Wilkinson, writes to the *Kendal Mercury*, stating that he has found among the letters of his grandfather, James Stockdale, of Cork, one addressed to him on 14th July, 1787, by John Wilkinson, of Castlehead and Brosely, "the great ironmaster" of the time, in which he says,—"Yesterday week my iron boat was launched. It answers all my expectations, and has convinced the unbelievers—who were 999 in 1,000. It will be a nine days' wonder, and then be like Columbus's egg." The correspondent of the paper named, therefore thinks that John Wilkinson, and not Mr. Ramsden, was the inventor of iron ship-building. John Wilkinson was an eccentric man. In his garden grounds at Castlehead, for many years, he kept a large iron coffin to be ready for himself. It stood amongst the laurel trees near the house, along with many other smaller ones, which he took a delight in showing and offering to his friends gratis, to their utter horror and dismay. This coffin led to his being three times disinterred and four times buried.

**TYPHUS AND OVERCROWDING.**—A severe form of typhus fever has lately been very prevalent in several of the country districts in Malta. Its virulence has now abated; and, from a report made by order of the governor, it appears that it was due to overcrowding in ill-ventilated apartments.

**TENDERS**

For four houses and shops at Forest Gate, Essex, for Mr. Jarvis. Quantities supplied by Mr. F. Warburton Stent—  
Rivett ..... £1,143 0 0  
Fisher ..... 1,075 0 0  
Mortar ..... 1,683 0 0  
Hill & Keddell (accepted) ..... 1,036 0 0

For alterations to the Town-hall, Huntingdon. Mr. Robert Hutchinson, architect—  
Smith ..... £230 0 0  
Rowe ..... 303 0 0  
Richardson ..... 273 0 0  
Thackeray ..... 265 0 0

For additions to the Race Stand, Huntingdon. Mr. R. Hutchinson, architect—  
Bulmer & Rowe ..... £310 0 0  
Smith ..... 305 13 0  
Cannery ..... 300 0 0  
Maile ..... 295 0 0  
Thackeray ..... 269 0 0

For alterations and additions to the Bourne Valley Wharf, Nine Elms, for Messrs. Standing & Marton. Messrs. Wimble & Taylor, architects—  
Stone & Pearson ..... £1,032 0 0  
Bancroft ..... 675 0 0  
Smith ..... 726 0 0

For the erection of two warehouses, Love-lane, Liverpool. Messrs. J. A. Pictou & Son, architects. Quantities supplied:—  
Burroughs ..... £7,256 0 0  
Ray ..... 7,220 0 0  
McLinn ..... 7,190 0 0  
Hughes ..... 7,100 0 0  
Haigh & Co. .... 7,098 0 0  
Wimson ..... 7,042 0 0  
Jones & Son ..... 6,973 0 0  
Holme & Nichol ..... 6,750 0 0  
Tomkinson (accepted) ..... 6,673 0 0

For Messrs. Letts, Son, & Co.'s factory. Quantities supplied by Mr. Campbell. Mr. J. P. Jones, architect:—  
Rider ..... £6,630 0 0 ..... £892 0 0  
Gammon ..... 6,250 0 0 ..... 873 0 0  
King & Sons ..... 6,180 0 0 ..... 830 0 0  
" Anley ..... 6,540 0 0 ..... 892 0 0  
" Myers ..... 5,825 0 0 ..... 850 0 0  
Piper & Wheeler ..... 5,770 0 0 ..... 895 0 0  
Dove, Brothers ..... 5,702 0 0 ..... 719 0 0  
Scrivenor & White ..... 5,514 19 3 ..... 977 18 3  
" Matthews ..... 5,469 0 0 ..... 877 0 0  
Sharpington & Cole ..... 5,120 7 10 ..... 832 10 7  
Stredder .....  
For Iron Work only.  
Shaw ..... £398 15 0  
Norton ..... 917 0 0  
Cartwright ..... 785 0 0  
Hood ..... 785 0 0  
Smith & Wood ..... 708 16 11

For erecting the New Cripplegate Boys' Schools, Bridge-water-square, City. Messrs. John Young & Sons, architects. Quantities supplied by C. J. Shoppes:—  
Piper & Wheeler ..... £2,987 0 0  
Oxford ..... 2,880 0 0  
Henshaw ..... 2,873 0 0  
Larks ..... 2,849 0 0  
Prince ..... 2,849 0 0  
Turner ..... 2,815 0 0  
Brass ..... 2,750 0 0

For restoration of St. Giles's Church, Norwich. Mr. R. M. Phipson, architect—  
Burrell ..... £3,650 0 0  
Pocking ..... 3,506 0 0  
Rust ..... 3,321 0 0  
Brown & Bailey ..... 3,062 0 0  
Lacey ..... 2,979 0 0  
Balls ..... 2,959 0 0

Accepted for the erection of a Methodist New Congregation Chapel, at Forest-hill, Kent. Mr. William Hill, architect—  
Mr. J. W. Sawyer ..... £2,350 0 0

Accepted for the erection of a Methodist New Congregation Chapel at Wakefield. Mr. William Hill, architect:—  
Brickeylayer and Mason's Work.  
E. Latham & Son ..... £230 0 0

Joiner's Work ..... 608 0 0

For a house and stabling, Mostyn-road, Brixton, for Mr. Abbott. Mr. S. C. M'Murid, architect:—  
Brown ..... £291 0 0  
" ..... 730 0 0  
George ..... 697 0 0

# The Builder.

VOL. XXIII.—No. 1163.

*The Dublin Exhibition Building.*

HE Dublin International Exhibition, which was opened with a suitable ceremonial by the Prince of Wales on the 9th of this month, reflects great credit upon those who have undertaken it. Not

the least noteworthy, and we are glad to be able to add, by no means the least successful of the features of this Exhibition, is the building in which it is held, erected from the designs of Mr. Alfred G. Jones, a Dublin architect; and we propose to give some account of this building, gathered from a careful inspection made at the time of the opening. A plan and interior view with some description were given at p. 279 of the present volume, and in our volume for 1863 will be found a view and some statement of what at the outset of the undertaking it was proposed to do.

The Dublin building stands at some disadvantage as compared with all previous buildings employed for International Exhibitions, in consequence of its not having been exclusively built for an Exhibition. It has been designed to combine a permanent group of public rooms and a large conservatory, or winter garden, with a comparatively small Exhibition building; and some inconvenience, though not much, has been experienced from some of the peculiarities of such parts of the structure as were not intended for the purpose to which the whole is just now put. The public-rooms part of the building is of brick and stone, with a cement face, and the remaining portions are of iron and glass; but the architect, instead of masking his iron construction externally by his brick building, as was partly done in 1862, has adopted the bolder and wiser course of placing the two side by side.

It was no doubt a difficult task to harmonize the two adjoining buildings into one whole, and we cannot say that the wide difference between masonry and what we may call crystal-building has been entirely overcome; but there can be no question that it has been successfully grappled with to a very remarkable extent, and that the resulting effect is picturesque, and in the main satisfactory. Beyond and in addition to these two classes of buildings a third description of erection, in the form of timber annexes of an extremely inexpensive character, occupies part of the site. These, which are not shown on our engraved plan, are unsatisfactorily prominent in most aspects of the group of buildings, but in themselves they are cheap and not ugly.

The reader can form a general idea of the arrangement of the plan of the structure, by comparing the iron and glass building to a capital L, of which the long arm is the Winter Garden building, and the short arm the permanent Exhibition building, while the masonry building would be represented by a square block filling up the internal angle of the L. The entrances from the high road are all through the masonry block, and an open porch of iron and glass, running completely across its front, affords shelter to those arriving at the several entrances, and also serves an artistic purpose

by helping to connect the two classes of construction together. Passing direct through one of the wide corridors provided for circulation, we will suppose that we reach the iron structure without pausing on our way to notice the public rooms and picture-galleries.

The whole of the iron structure is planned with bays of 16 feet 10 inches from centre to centre. The winter garden has a width equal to five of these bays, or 84 feet 2 inches, divided into a nave of three bays, or 50 feet 6 inches, and aisles, of a single bay each, at the sides. The aisles are of two stories in height, reaching to the springing of the nave ribs; the floor of their galleries is about 18 feet from the ground, and they are roofed over with a continuous span roof. The columns are of cast-iron, and are square, with the angles rounded. They have spreading bases, and other features of an ornamental character, designed with much originality; and the points of connexion between them and the girders carrying the galleries, and all similar points of junction, are suitably and skilfully emphasized.

The nave roof is carried on semicircular lattice ribs built up of wrought-iron, and growing wider as they approach the columns from which they spring. A very ingenious kind of flying buttress, above the roof of the aisle, distributes the thrust of the nave roof between the outer and inner line of columns, and as these are connected together by strong plates below the ground-floor level, and are braced diagonally with horizontal braces at the level of the gallery floor, it has been found possible so to stiffen the whole aisle, as to form a series of buttresses or piers to the nave roof, without recourse to diagonal braces fixed vertically.

The bracing of the gallery floors especially deserves notice, as it is cleverly contrived to discharge two duties at once; it stiffens and supports the floor, at the same time that it retains the columns in their position. The covering of the main roof in the winter garden part of the iron building is entirely of glass—and lengths of straight glass extend from purlin to purlin, approximating to the curve of the extrados of the rib sufficiently to satisfy the eye both inside and outside the building, without the use of curved glass.

In the centre of the winter garden occurs a polygonal, apse-like projection, on the side next the pleasure grounds (for the building stands on a large piece of ground laid out ornamentally) and this central feature forms both internally, and externally a satisfactory break.

The angle-ribs of this apse, and the hips at either end of the nave-roof, have presented difficulties which appear to have been carefully considered, and on the whole are very satisfactorily got over; and round the octagon an external gallery or balcony has been thrown with very good effect.

The winter garden portion of the building we have been now describing has a total length of 477 feet. At right angles to it is the permanent exhibition portion of the iron structure, forming the shorter arm of the L, and to which a greater width has been given. This portion of the building is seven bays (or 112 feet) wide in place of five, and its galleries are two bays wide. It differs also from the winter garden in having its nave partly covered with an opaque roof (of Italian zinc), and in having no central projection. The two parts of the structure are ultimately intended to be separated by some sort of glass screen. At present, however, no such separation has been made, and the best view of the building is obtained from the gallery near the angle, from which point both arms can be seen at once.

This iron structure has the merit of being well proportioned, as well as good in detail. Its module is smaller than we have been accustomed to, and the same moderation in dimensions has

been observed throughout. A bay of 16 feet 10 inches is not, however, by any means so well adapted to the requirements of an Exhibition building as the 24 feet bays of 1851, and the 25 feet bays of 1862; and some inconvenience has evidently been felt in the arrangement of goods. The height, up to the galleries, though considerably less than in the buildings we have just quoted, or than at Sydenham, is perhaps ample for galleries of one bay in width, considering how much narrower the bays are than in previous instances; but it is not sufficient to be satisfactory in the part of the building where the galleries are two bays in width, and throughout the building there is a want of height in the aisle roofs, producing an impression of contractedness which is to be regretted.

Another defect is the entire absence of courts for exhibiting goods. All the large cases placed on the ground floor are either put under the galleries, where they are not well seen, or put in the nave, where they will interfere with circulation in the principal promenade, and where they certainly damage the general effect of the interior. In this respect, the arrangement of the goods is hardly as happy as it might have been made, even in the building as it is, and is certainly inferior to what would have been natural and practicable had they not been placed in a structure the larger portion of which is intended ultimately for the reception of plants. No attempt whatever has been made to cluster the articles round the columns as was so happily done in 1851, and at present the nave seems encumbered rather than adorned by its contents. There is, too, a superabundance of light in the Winter Garden, and those who were oppressed throughout a long bright day by the heat of the building on the day previous to the opening were heartily glad that during the ceremonial itself the sky was overcast rather than fair. The opaque roof over part of the nave in the Exhibition-building proper is a great improvement upon the entirely glazed nave of the main limb; but here there are places under the wide galleries where there is a deficiency of light, rendering some of the most convenient exhibiting space less valuable than it otherwise would be, and suggesting the thought that well-holes, or even open courts, might be formed with great advantage by removing the flooring of some of the exterior bays of the gallery. In fact, this portion of the Dublin Exhibition building seems to demonstrate that galleries, two bays wide, although they may themselves furnish good exhibiting space, are damaging to the value of the space under them.

The ironwork of all this portion has been obtusely decorated in colour, but with a rather timid hand, and the features of the building are not brought out as they might have been by bolder treatment: this is especially the case with the roof, the curves of which are far less prominent than we should wish to see them owing to this circumstance. It is to be regretted that Mr. Owen Jones was not consulted upon this head, and upon the general arrangement of the contents of the building.

Externally, the curved forms of the iron flying buttresses bring down the line of the nave roof to the aisles in a line very satisfactory to the eye. The segmental heads of the openings, shown in our recent illustrations, are extremely simple, but answer their purpose; and certain ornamental finials freely used on the exterior deserve a passing word of praise, as clever examples of inexpensive ornament.

It is now necessary that we should glance at one or two of the features of the stone building. This block is two stories in height, and on plan is divided by an entrance-hall running through it from front to back and opening into the winter garden opposite the central projection. Nothing can look better than this arrangement does on paper, but its actual result in the building has

failed of success, and in a manner which is instructive as showing that symmetrical planning does not necessarily produce all the results one might hope from it. The entrance to the winter garden from this hall has been partially blocked up for purposes of exhibition, and hardly catches the eye at all; while just beyond it, and on the same side, the end of a very much larger feature, the music-hall, abutting on the winter garden has been for the present left entirely open, and catches the eye at once almost as prominently as the apse on the other side, producing the uncomfortable effect of two features intended to be opposite to one another which have been misplaced and do not match. It is probable that when the Exhibition is over this will be remedied. At present, however, it is an unfortunate defect.

Of the entrance-hall itself, however, it is possible to speak in terms of high praise. This hall extends through the height of both the floors of the buildings, and is lighted from the top only. At the level of the upper floor of the adjoining structure, it has a broad gallery supported by columns and the wall-space above this gallery is intended for and employed in exhibiting pictures, while the lower portion is used as a sculpture hall. The ceiling, which was to have been ornamental, is left in an unfinished state to save expense; but the general proportions are good, and the lighting, both of the pictures and of the most conspicuous statuary, is admirable. The walls of the lower part of the hall have been decorated in dark colours, Pompeian red being the prevalent tone, and this, deepening the gloom of the shadow thrown by the galleries, serves to throw up the sculpture, which stands well forward from the walls, in a remarkable manner. In fact, it is not too much to say that in no previous International Exhibition has the sculpture been at all so well displayed; and this is the more fortunate since the collection in Dublin is one of unusual merit. The lighting of this gallery by night in a manner similar to that followed at the South Kensington Museum, is as successful as are the arrangements for admitting the daylight.

A picture gallery, built as such, in this part of the building, may also be named as a satisfactory specimen of lighting. The pictures exhibited in the upper part of what is to be the small concert-hall are by no means so well seen.

This block of buildings contains a large concert-hall, of the merits of which it is hardly possible to speak, as it is seen at present incomplete, and with its chief architectural features encumbered and concealed by a series of large cartoons, for the display of which no other place seems to have been found.

This hall seems to have been designed with a general reference to the interior of the Free Trade Hall, Manchester, and seems to promise well as a music-room, so far as its capabilities can be said to have been fairly tested by the performance of a band and chorus out of all proportion to the dimensions of the room, and accommodated, for the most part, in a temporary orchestra. This hall is lighted at night by sun-burners.

The block of buildings containing these halls also includes sundry committee-rooms, refreshment-rooms, and other apartments not calling for special notice. It appears to occupy about an acre of ground, and the permanent iron structure not quite so much as an acre and a half more. This space, however, would have been quite insufficient for the display of the goods sent, and about another acre is covered by annexes. Of these buildings, one portion is rather strongly built with iron columns and girders, and will, we understand, remain permanent.

The other annexes, which will be removed as soon as they have served their purpose, are remarkable as specimens of cheap temporary structures. Their roofs are segmental in section, and covered with felt, resting on boarding, the boarding being carried by wooden lattice-trusses or girders of very considerable span, but made of material little stronger than common laths, and with ribs and ribs of the lightest possible scantling. So slight, indeed, are these trusses, that some difficulty was at times experienced in getting them into place without their breaking under their own weight; and yet, when fixed and steadied by having the roof-boarding nailed to them, they prove sufficient for their purpose. In annexes of this character are placed the whole of the display of carriages, and many of the special refreshment-rooms, the permanent annex being occupied by the

display of machinery, a section of the Exhibition in which a great deal still remains to be done.

The contents of the building it is not proposed here to examine in detail. As has already been noticed, the collection of modern sculpture is a good one; this has been chiefly contributed from Italy. The paintings, modern and ancient, are also of great merit, and include a series of water-colours, a small gallery of old masters, and several valuable specimens of Continental contemporary artists, as well as British pictures. Among the Continental contributions to this gallery some modern Spanish pictures have attracted notice. The other departments of the Exhibition we cannot even mention: they will be found more or less complete representatives of the industry and the arts of various parts of the world. Of one department, however, it is impossible to omit a notice as conspicuous for its completeness, the excellence of its specimens, and its forwardness at the time of opening; we refer to the Indian collection, arranged by the skill of Dr. Forbes Watson, in the northern gallery. This department will well repay a careful study, as will also the beautiful contributions of Sévres and Gobelins work, exhibited by the Emperor of the French.

The opening of the Exhibition was a complete success; and, as a display, was as charming to witness as it would be impossible to describe. The building proved well adapted for the purpose of such a ceremony, and nothing that Dublin—in fact, that Ireland—could do was wanting to add brilliancy to the scene. A considerable number of persons interested in arts and manufactures had come over from England to be present, among them several gentlemen officially connected with the proposed Indian International Exhibition, to be held at Bombay, and the architect of its buildings. Several London faces that one naturally looked for were absent; but this is a time of year when it is difficult for those much occupied in London to leave town. Altogether, however, the Dublin people are to be congratulated upon the successful inauguration of their scheme, and upon the satisfactory nature of the building with which the skill and labours of their contractors, engineers, and architect have furnished them.

#### THE CULTURE-HISTORY OF MANKIND.\*

THESE are, and have been in all historic time, curious coincidences in the matter of manners, customs, and legends, in different parts of the world, among the various races of men, that lead to one of three inferences;—Common descent from one origin; or means of early intercourse of which no tradition exists; or that the human mind is so constituted that under whatever circumstances it may be placed, it is likely to generate a similar class of ideas. As an instance of our meaning we may cite the use of bows and arrows in the most remote ages in Europe, Asia, North and South America, and Polynesia. In which of these three ways can this coincidence be accounted for? Did the residents of both worlds spring from one family? as Professor Harley inquires, the members of which, before its various branches began to spread abroad over the face of the earth, were familiar with the use of the bow and arrow; or were all races distinct from vast ages, but managed from time to time to meet and teach each other the use of these weapons; or were they the independent invention of all these races? When we come to look around for further instances of similar wide-spread customs, we find their name is legion, and that the consideration of them opens out trains of facts bearing with much weight upon the origin and diffusion of mankind. Mr. Edward Burnet Tylor has been at the pains of collecting a large quantity of this peculiar information, and of arranging it under several headings in a volume entitled, "Researches into the Early History of Mankind," which we recommend to our readers, impressively, as of more than ordinary interest. He first treats of the various ways in which man has uttered his thoughts,—by gestures, words, pictures, and writing; next of the condition of mind inducing a belief in magic and worship of idols; then of the growth and decline of culture; and, lastly, of curious customs, with a classification of myths and an indication of their geo-

graphical distribution. He aims not so much at drawing conclusions, the time for which he believes has not arrived, as at grouping the mass of evidence in such a manner, and at bringing into view certain lines of argument, as may lead to the possibility of doing this with greater certainty than we may now calculate upon,—a task hitherto unattempted and sufficiently difficult. To show the amount of caution to be exercised in the acceptance or rejection of evidence, and the startling way in which new information sometimes turns up and upsets that previously relied upon, Mr. Tylor mentions that after having followed other observers in setting down as peculiar to the South Sea islands, in or near the Samoan group, an ingenious little drilling instrument, he found it kept in stock in the London tool-shops. Again, in looking over the general prevalence of the conviction of the soul's existence after death as a proof that all mankind inherited such a belief from a common stock, because it is possible that certain natural phenomena, such as dreams or phantasms, may have suggested to the mind of man, in different regions and at different times, the idea of the future state. But when we find, as in the class of stories known as beast-fables, that similar myths are found current in widely distant regions, for the invention of which no natural phenomena can account, we may fairly view them as important clues by which we may hope to unravel the early history of man. After having, however, run through all that can be said for and against the various ethnological theories, from a consideration of the evidence of which we are now in possession, we must be struck with the uniformity of the human mind. The skull of the Australian is supposed to present the greatest difference from that of the most civilized races; and yet he is scarcely in the practice of an art or custom, or in the enjoyment of a belief, that cannot be found in some other race separated from him by thousands of miles of ocean-waters. The Australians have a mode of raising scars on their bodies as practised by African tribes; they circumcise as Jews and Arabs have done since the days of Abraham; they bar marriage in the female line like the Troopius; they maintain a constant change in their language by dropping out of it all words resembling those by which the dead were recognised in their lifetime,—a practice found in Africa and South America; they endeavour to bewitch their enemies with locks of hair, and perform quack-like cures upon the sick by pretending to suck stones through their skin. The most distinctive item they possess is the boomerang, and their other weapons, utensils, canoes, fire-drill, &c., being all found elsewhere. Out of a list of twenty items of art or knowledge taken at random from any uncivilized race, it is difficult to pick out one to which something closely analogous may not be found among some other race.

An illustrated chapter in Mr. Tylor's work is that in which our readers are likely to be most interested, on picture-writing. The dumb make use of a kind of picture-writing when they wish they are referring; and savages largely avail themselves of gesture-language to assist in conveying their meaning. Captain Burton mentions a tribe who make such an extensive use of gesture that they can hardly understand one another in the dark; and, to converse with a stranger, they are obliged to repair to the campfire; and there is a large array of further evidence in favour of the existence of tribes whose vocabulary is so scanty as to necessitate the use of signs. From making outlines of objects in the air with the hands, it is but a step to make them upon convenient surfaces with an implement. We find the North American Indians clever at outline drawings, which they make on pine-trees, barked on purposes in patches. These consist principally of the figures of animals, dots, strokes, canoes, hatchets, pipes, &c., and serve them as records of hunting-parties, battles, treaties of peace, &c. They incise, too, upon grave-stones, figures and strokes which serve to indicate the tribe to which the dead warrior belonged, the number of battles he had fought, the honours awarded him by his fellow-braves. But as these curious drawings are as difficult to describe intelligibly without *fac-similes*, as they are to be read by those outside the circle to whom they are addressed, or as some of our own technical forms of expression are to be rendered in terms more familiar uses, we will pass on to our author's interesting arguments connected with image-worship, contenting

ourselves with directing attention to the fact that he looks upon rock-sculptures as an ancient form of picture-writing. The natives in the neighbourhood of rock-pictures generally say they were done by the people long ago. They are to be seen in Mexico in places well-nigh inaccessible at the present day; but a reply made to Humboldt, in answer to his inquiry as to whom some figures of animals and symbolic signs sculptured high up on the face of the crags along a river were to be attributed, explains this circumstance, and, at the same time, confirms the supposition of their great antiquity. "At the time of the great waters our fathers went up to that height in their canoes."\* We should scarcely suspect ourselves of retaining any traces of the rudest picture-writing. But the Roman numerals have this pictorial origin; and our almanacs, in signs for the sun and moon, "☉ before clock 4 min.," and "☽ rises at 8 h. 35 m.," perpetuate the practice. The T square is an instance equally familiar.

A most important difference between the mind of an educated man and a savage is the ability to separate subjective and objective impressions. An uncivilized American or Polynesian gradually acquires the strength and stature of a man, while his mind remains at a stage we can only compare to that of a child. Toys furnish to the latter exactly that material form to deal with without which his play is at a standstill. Take away the rough bits of wood or empty reels with which he is making believe, and the child is at a loss immediately. As years pass on, we acquire mental strength enough to do without material objects to strengthen our ideas; although we are under the identical influence when we derive definiteness in our conception of a transaction by seeing it described in a picture. But the savage never gets beyond an unflinching confusion between the image of an object and its reality. When a North American squaw loses her child, she carries its cradle about with her, and talks to it as though her baby were still in it. In Africa the bereaved mother and the expectant mother alike carry about with them a counterfeit baby; and, among the Ostyaks of Eastern Siberia, a widow consoles herself for some time by caressing a rude wooden image of her husband. The idol fills the same void for the savage that the doll does for the child. He sees in it a material form from which his powerful imagination is enabled to make its sluggish flights towards the realization of a higher being; and he dresses it in precious stuffs, or assigns it a place of honour, or propitiates it with offerings according to his conception of what is likely to be acceptable to the vague personalities it represents. Mr. Tylor takes up the original view that the idol thus once served a definite and important purpose in the education of the human race. When we treasure a lock of hair we know that all real connexion with its owner has ceased, although from its intimate association with our reminiscences of that person we permit ourselves to regard it as still belonging to him. The uncivilized man is unable to see this distinction. For him the lock of hair and its owner have still an objective relation, and magic arts practised upon the former will, he believes, affect the latter. The sorcerer has only to get possessed of clippings of the hair of his enemy, or perings of his nails, and leavings of his food, to bring about his death. Mr. Turner, in his work on Polynesia, relates that there was a colony of disease-makers on the island of Tanna, that lived by their art. When any one fell ill they knew that one of these sorcerers was practising upon some of his leavings in the way of food; and night after night a melancholy too-tinging might be heard from the signal shell-trumpets beseeching the wizards to desist from torturing their victims, and to wait for the presents that would be sent in the morning. And when a disease-maker fell ill, he was so persuaded of the adequacy of his own sorcery, that he believed some other wizard was practising upon him, and had his shell-trumpets blown for mercy. The fear of being bewitched through the instrumentality of a lock of hair is one of the widest-spread opinions; it is found all over Polynesia, in Africa, in India, in North and South America, in Australia, and even in Italy, as recently related by Mr. Story, in his

"Roma di Roma." When Dr. Martius, the Bavarian traveller, saw an old woman, a captive, got up from the corner of the hut in which he and his Indian host and family had disposed themselves for the night, and, quietly blowing up the fire, commence a course of magic arts upon bits of the hair of her enemy's children so as to insure their destruction, he remarked upon the complicity of the delusions and darkness that must have been working in the human mind to complete the degradation of a pure worship of nature into an invocation of dark unknown powers for another's hurt. Mr. Tylor thinks this deduction the reverse of fact; and that the practices of sorcery among the lower races, as a whole, have not the appearance of mutilated and misunderstood fragments of a higher system of belief and knowledge, but should be dated from the childhood of the human race; and if we take into consideration the fact of the important part the rattle plays with the magician and medicine-man we shall probably agree with him. A rattle is carried before a Siamese prince when the dignity of manhood is conferred upon him, to show that up to that point he is still a child; and the savage clings to the use of the same instrument as if to show by its means his place in creation. Sometimes it is a bunch of hoofs tied together, or a blown bladder with peas in it, and more frequently a calabash with stones or bones or shells in it; but in whatever form, the rattle is the great instrument of cure and the symbol of the profession of medicine. The connexion of the drum with sorcery in Lapland, in Siberia, among some North American and some South American tribes, is consistent with the theory that rattles, drums, and sorcery belong to the infancy of mankind; and the similarity that prevails in many of the magical practices would seem to indicate one geographical source.

To pass from the presumed connexion between an object and its image to that believed to exist between an object and its name, we come to another curious string of facts extending over a large geographical area. In some uncivilized tribes a man will not utter his own name; in others, husbands and wives will not utter one another's name, or a son or daughter-in-law will not mention the name of the father or mother-in-law, and vice versa; and in others the name of the chief, or of supernatural beings, or animals to which supernatural powers are ascribed, must be scrupulously left untold. Among the Algonquins, the real name of a child seldom transpires, and is indeed only known to the old woman who confers it in secret, the one in use being a nickname, such as "Little Fox," or "Red-head," and that inscribed on his grave-stone being the *totem*, or clan-name of the tribe. A Hindoo wife speaks of her husband as our domestic servants speak of their employer, "the master," taking scrupulous care not to degrade him by uttering his name. Among the Omahas of North America, the father- and mother-in-law neither speak to their son-in-law nor mention his name, an arrangement that looks upon the face of it to be highly conducive to domestic peace and concord. The Arawaks have a custom that many a long-suffering benedict would rejoice to find spread over a district that included his own. They never look upon the faces of their mothers-in-law. If these ladies live in the same house with them, a partition is set up to keep them out of sight; and if they travel by any chance in the same boat, they enter first, so as to keep their backs towards their sons-in-law. The Caribs, too, deny themselves the pleasure of ever conversing with the relations of their wives, except on very extraordinary occasions; and other tribes in South America exercise similar exclusiveness, even going so far as never to enter the houses of the parents and brothers of their brides, and to go a bowshot out of their way rather than pass near them. In North America there are the same curious restraints put upon family intercourse. We, perhaps, might look in the right direction for the origin of them, if we turned our eyes to those dim times when a man captured his wife from another tribe, and so was not desirous of confronting those whom he had robbed of a daughter. Among some of the Arab tribes they keep up a trace of this wife-stealing age in another way, having mock-fights and captures in the wedding ceremonies.

If we would explain many of our own customs we must refer to their origin among rude and early peoples. The ear-rings still worn by European ladies are traces of the very general and ancient custom that prescribed the use of similar ornaments on the nose and through the

lips. Cross the Asiatic frontier and you will find the nose-ring still in use among ladies of rank. Mr. Tylor refers the practice to a state of society identical with that which approves of the thrusting of rings, bones, and feathers through the cartilage of the nose, the letting in of ivory studs in the corners of the mouth, the larding of the human cheek with the teeth of animals, stuck point outwards &c.; and points to it as an instance in which progress has not been positive in adding, but negative in taking away. When we tie a knot in the corner of a handkerchief to assist us in remembering anything, we unconsciously use the most primitive form of keeping count of all things. The Chinese have a legend to the effect that, before the invention of writing, they used little cords on which they made knots to assist their memories. The rosary and wampum-string are other forms of the same invention. In an elaborated form, known as *quipus*, these rope records served the Peruvians for army registers, census records, taxation lists, accounts of the property of deceased persons, &c. Von Tschudi says this mode of reckoning is still in use among the herdsmen of the Puna (the high mountain plateau of Peru), who, by its means, keep count of their herds, flocks, produce, &c. One cord, known by its colour, or by the twisting of its knot, or by its place on the root-cord on which the others are fastened, relates to the number of bulls, the next registers the cows, divided into two kinds—milk and dry; the calves are counted on the next branch, then the sheep are numbered another; additional cords give the number of foxes killed, or of cattle that have died, the quantity of salt used, the quantity of milk, cheese, and wood yielded. The drawback to knot-reckoning is that oral information must be added, or it is impossible to make out their subject-matter.

Another early custom that we retained long after it was superseded by new inventions, was the giving of wooden tallies for exchequer-receipts. We yet use the tally in the counter-foil in a banker's cheque-book. It was this same retentive feeling that induced men to build in stone precisely the same designs they had before been accustomed to rear of wood; and that is present to-day as in old time in the resistance to any kind of change, in many minds. Why does a gentleman take off his glove when he shakes hands? Because his forefathers, some hundreds of years ago, took off their steel gauntlets to perform the same greeting, and the habit has not yet died out. There are, however, customs in savage life which we retain no trace of, and can scarcely account for, and yet they are spread over a large area. Why, in Africa, as in Siam, are divine honours paid to white elephants? How can we account for the general belief in the sucking cure? In Africa, in North and South America, and in Australia, sick persons consult sorcerers and doctors who pretend to suck out of them small foreign substances, such as grain of Indian corn, bits of knives, bits of wood and stone, bones, balls of hair, and sometimes lizards, and produce these objects to their patients' gaze. In the *cowade*, or "hatching," we have a custom that, although unaccountable, has some grounds for recommendation. In several nations when a child is born the mother goes about her work as if nothing had happened, and the father takes to his bed with the baby, and remains comfortably ensconced there, the object of great attention for days and days. The savage concludes there is a link between him and his offspring which entails on it suffering for any error of diet or accident on his part. Dobrizhoffer relates of a fierce equestrian tribe of the Abipones,—"No sooner do you hear that the wife has borne a child, than you will see the Abipone husband lying in bed, huddled up with mats and skins lest some ruder breath of air should touch him; fasting, kept in private, and for a number of days abstaining religiously from certain viands, you would swear it was he who had had the child. . . . For they believe that the father's carelessness influences the new-born offspring, from a natural bond and sympathy of both. Hence, if the child comes to a premature end, its death is attributed by the woman to the father's intemperance, this or that cause being assigned. He did not abstain from meat; he had loaded his stomach with water-hog; he had neglected to shave off his long eyebrows; he had devoured under-ground honey, stamping on the bees with his feet; he had ridden till he was tired and sweated. With raving like this the crowd of women accuse the father with impunity of causing the child's

\* This is of interest with reference to our suggestion as to the cause of the rock sculptures of Northumbria, being all on high ground. If the low land was under water at the time, they could not be there produced, and hence their extreme antiquity may be inferred from their high level, unless we consider their connexion with fortified heights to be sufficiently explanatory of this fact.

death, and are accustomed to pour curses on the moffending husband."

There are other customs which do not recognise physical severance in individuals, or, as Mr. Tylor puts it, in which man does not separate the subjective mental connexion from the objective physical connexion; the connexion which is inside his mind from the connexion which is outside it. When a Greenlander dies, those who mourn his loss, knowing the long travel on which his soul has set out, abstain from all moist work and from certain food, so that it may be undisturbed and unburnt. The imaginary tie even extends to birds and animals, who are supposed, in some places, to be affected by the diet of their owners.

The mass of information concerning traditions and myths of observation test the truthfulness of the moral of the old story of the three black crows, in the frequency with which "it may have been" is converted, in telling, into "it was." Given any suggestive object, and a story more or less extravagant is coined to suit it and handed down as a fact. Thus the small round stones, about the size of lentils, found among the masons' rubbish, in front of some of the pyramids, were set down, in the time of Strabo, to be theavings of the workmen's food turned to stone; and large bones, whether fossil or recent, are deemed, in most parts of the world, to be portions of the skeletons of giants. From the fact of the Siberians finding teeth and bones of mammoths imbedded in the faces of cliffs and river-banks, at some distance below the surface, accidentally exposed by landslips or other causes, they have come to the conclusion that they were huge hurrowing animals that lived underground; nay, more, they sometimes feel the earth undulating as the monstrous creature is picking its way to its subterranean residence. The Chinese, following the theory started by these semi-barbarous savans, have given it a place in their natural history, and describe it, under such names as digging rat, hurrowing ox, and mother of mice, to be of the form of a rat and size of an elephant, excellent eating, and as yielding an ivory of better quality than that of the last-mentioned animal. We all know that the Persians, Hindoos, Chinese, Greeks, &c., employed and preserved traditions, parallel to the Mosiac accounts, of the fall of man, expulsion from Paradise, the Deluge, &c.; but it is rather surprising to find that some of the rudest tribes are in possession of legends embodying the events related in our most popular national stories. "Jack and the Beanstalk," "Tom Thumb," "Little Red Riding Hood," have their analogues, as well as the story of "Jonah and the Fish," of "Noah and his Ark," of "Cain and Abel," but we must leave this branch of Mr. Tylor's contribution to ethnological lore, to give a sample of the materials he has collected on fire-making, cooking, and vessels.
