The lowest condition of mankind of which we can form conception is that of a people living without fire, and in ignorance of the art of making it. Early travellers have frequently declared they have met with such people, whose food consisted of raw fish, fruit, vegetables; but when their accounts come to be critically examined, or when further intercourse has taken place with these people, it turns out that although they ate their fish raw, they could kindle a fire if they desired to do so. The stunted imaginations of uncivilized people seem to rejoice in creations of tribes destitute of something that is common to man, such as speech, ideas of superior beings, dreams, names, and even months, heads, and noses; or else possessed of additional features, such as four eyes, eyes under the armpits, ears large enough to cover the body, long tails, just as in a more advanced stage their artists delighted in the marvellous. But these curious tribes are never seen; they are simply heard of. Mr. Tylor finds more evidence of the possibility of the existence of people possessed of fire, but unable to make it for themselves. A native of Van Diemen's Land informed Mr. Backhouse that his ancestors had no means of making fire before their acquaintance with Europeans. They got it first from the sky, and preserved it by carrying firebrands about with them, and if these went out they looked for the smoke of the fires of some other party, or for the smouldering remains of some of their own fires, and so procured fresh. Curiously, some of the highest races of mankind have clung to the rudest processes of making a fire, when it is unlikely that they could have adopted a newer mode if they had chosen to do so. Russian peasants and Portuguese Brazilians, within the

last century, have used the "fire drill" for this purpose. This is a wooden stick with a point at one end, which is made to revolve quickly in a hole in a flat piece of wood, by rolling it back, wards and forwards in the hands. This plan, improved by the addition of cords so arranged that they cause the stick to revolve by twirling round it on being pulled, has a large geographical area, while a still simpler process, that of rubbing a pointed stick up and down a groove in a flat piece of wood, has a very limited one. Possessed of fire, the next difficulty to be overcome by the human race was the want of vessels and apparatus by which to cook their food. Roasting and broiling were probably the first forms of cooking, as the processes simply require exposure to the open fire. The oven, perhaps, we may look upon as the first contrivance. Some islanders use hollow trees for this purpose: in Africa an empty ant-hill is made use of, which, made red hot, bakes such dainty dishes as joints of rhinoceros. In the Canary Islands the meat is huried in a hole in the ground, and a fire lighted over it; but the most common oven is the pit into which hot stones are put with the food. Boiling was a later process, owing to the advance required to invent a vessel that would at once hold water and stand fire; and the first step made in this direction is probably that retained by many uncivilized tribes to this day, which Mr. Tylor calls *stone-boiling*. Catlin describes this process as carried into effect by the Assinaboins, whose name, "Stone-boilers," has been conferred upon them in virtue of this art. They dig a hole in the ground, and line it with a raw hide. This sort of pot thus formed they fill with water, and place the meat in it; and then, from a fire close by, they throw in red-hot stones, till the water has boiled long enough to cook the meat. The Sioux, Micmacs, Souriquois, Blackfeet, and Crees, are known to have used the same tedious process, and other tribes to have varied it by throwing the red-hot stones into vessels instead of pits. Captain Cook saw the stone-boiling mode of cooking at Nootka Sound; La Pérouse, at Port François; Sir Edward Belcher, at the Ice Cape. Thomson mentions that the New Zealanders made their shellfish open by dipping them into water, in wooden vessels, brought to the boiling point by red-hot stones dropped into it. That it is likely that stone-boiling was practised in Europe seems evident from two facts collected by our patient author, who appears to have examined every traveller's tale that has ever been told. Limans states that the Finns prepared their liquor called *lura* much in the same way that other beer was made, except that it was not boiled,—red-hot stones being thrown into it instead; and quantities of calcined stones are found in our own country, on the sites of ancient dwellings, which may have been used for boiling as well as baking. The vessels used for the higher kind of boiling are of various materials. Panniches of animals slung over a fire seem one of the rudest contrivances; but these paunch-kettles, as Mr. Tylor calls them, have been observed in use in Asia, among the Esquimaux, and in the Helrides. Vessels of pot-stone, lapis ollaris, hark, split hamboos, the spathe of palms, of coccoanut-shells, of whale's fins combined with stone, have been resorted to as links in the chain that resulted in pottery and metal pans. Goguet, in the last century, assumed that the potter's art must have developed itself out of a savage practice of dashing combustible vessels with clay, to prevent them burning; and all evidence collected since his time tends to confirm his view, indicating the gradual steps from covering gourd or wicker-work moulds with clay, to the inverse process of lining these rough moulds with clay, and the ultimate production of independent clay vessels. Dr. Klenk observes,—“In the Friendly Islands we find vessels which are still in an early stage: they are made of clay slightly burnt, and enclosed in plaited work; so also the oldest German vessels seem to have been; for we observe, on those which remain, an ornamentation in which plaiting is imitated by incised lines. What was no longer wanted as a necessity was kept up as an ornament.”

We have thus slightly indicated the nature of the contents of this thought-stirring volume, although there are still classes of facts we have left untouched. We have, however, shown the attraction of the subject, and indicated its bearing upon such old-world races as the Swiss and Scottish lake-dwellers, the Reinder tribes of central France, and those who in British graves have left us specimens of their rude arts. Mr.

Tylor does not indicate his preference for any theory as to the origin of the various types of mankind; he shows all the facts and leaves his readers to apply them. And we are bound to say, that those who entertain the conviction that the various races of man have come of one medium type, which has been divided, by the influences of climate and circumstances, into several, will find as much to confirm their views as those who point to Egyptian, Assyrian, and Mexican monuments, the Jews, the Gipsies, and the Negroes, as evidence of fixity of type, will see. But both theorists will realize that the condition of mankind, socially, is one of progress, and that in the uncivilized tribes of to-day we may perceive much of the rough schooling and gradual culture of the human family from its infancy.

#### SIR JOSHUA REYNOLDS AND HIS TIMES.\*

In our last notice (p. 309) of Mr. Taylor's volumes we expressed a wish "that the authors could have found a place for the preamble or opening paragraph of Sir Joshua's will." A correspondent (who gives his name) directs our attention to vol. ii., p. 621, of the volumes, where the preamble, he says, is printed,—and so it is, but imperfectly. Hear what it says:—

"On the 5th of November 1751 he [Sir Joshua] made his will, writing it himself, with this affecting preamble:—  
"As it is probable that I may shortly be deprived of sight and may not have an opportunity of making a formal will, I desire that the following memorandum may be considered as my last will and testament."

Now, in reply to our correspondent, we beg to observe that the words in Sir Joshua's will are instead of "may not have an opportunity of making a formal will," these, still more expressive of his condition, "he incapable of executing any formal will." But the omission of *all* is Sir Joshua's commendation of his soul, though not in words uncommon:—

"I commend my Soul to God, in humble hopes of His mercy, and my body to the Earth."

Sonthey, in his Life of Cowper, expresses a sort of holy horror that Churchill, the satirist (who had been in holy orders) died, leaving a Will without any expression of commending or bequeathing.

Another correspondent sarcastically tells us, "when you don't find anything in 'Leslie and Taylor' where it ought to be (as you would in other books) conclude that it isn't there." The writer refers to Walpole's eulogium on Reynolds, vol. ii., pp. 308-9, of Mr. Taylor: we will ask our correspondent, in reply, if he can find in Mr. Taylor's volumes any allusion to this Walpole remark to the purpose. Walpole is talking to Pinkerton:—

"Sir Joshua gets avaricious in his old age. My picture of the young ladies Waldegrave doubtless is very fine and graceful; but it cost me 800 guineas."—*Walpole's Letters*, p. 108.

And in the next edition of the "Life and Times of Sir Joshua" it will be well not to ascribe Walpole's "quickeness of art" in his quotation from the Walpole eulogium to the year 1780 (as he does, vol. ii., p. 308), but to Walpole's "Advertisement to the Fourth Volume of the Anecdotes of Painting, edit. 4th, 1786." The "hundred trihute," as Mr. Taylor calls it, of Walpole, must be post-dated from 1780 to 1786.†

A tradition of the London studios may be related here. Pallet, the painter, a well-known character of Smollett's "Peregrine Pickle," was meant for Reynolds. Peregrine was published in 1751, and has many personalities in it. The Reverend Alexander Dyce has proved beyond all question that the English physician whom Pickle encounters with Pallet the painter in the Palais Royal at Paris was the poet and physician Akenaide. The poet and physician has a most entertaining conversation there with the painter Pallet. The talk is high about Homer and Michelangelo, Pyndar and Poussin. The poet is most amusingly ignorant, self-important, and self-sufficient. Chapter xlv. of Pickle is thus headed:—"Peregrine resolves to return to England, is diverted with the odd characters of two of his countrymen, with whom he contracts an acquaintance in the apartments of the Palais Royal [in Paris]." And then Smollett proceeds:—

"As Peregrine proposed to make the tour of Flanders and Holland, in his return to England, he resolved to

\* See pp. 270, 309, ante.

† See "Walpole's Works," 4to, vol. iii., p. 398.

‡ Which, curiously enough, Reynolds afterwards did.

stay in Paris a week or two after his affairs were settled, in hopes of finding some agreeable companion disposed for the same journey; and, in order to refresh his memory, made a second circuit round all the places in that capital, where any curious production of art is to be seen. In the course of this second examination, he chanced to enter the Palais Royal just as two gentlemen alighted from a fiacre at the gate.\*

The conversation begins at once, and expressions of "magnifique" and "sans prix" are translated by the painter into expressions of "manufacture" and "Ponssin." The almost superabundant humour of the whole scene is in Smollett's richest vein:—

"When they came to consider the 'Murder of the Innocents,' by Le Brun, the Swiss [the guide] observed that it was an *beau morceau*, and Mr. Pallet replied,— 'Yes, yes; one may see with half an eye that it can be the production of no other; for Donoro's style, both in colouring and drapery, is altogether peculiar; and his design is tame, and his expression sane and unamused. Doctor, you have seen me 'Judgment of Solomon'?"

"In this manner did Pallet proceed with an eternal rotation of tongue, floundering from one mistake to another, until it was the turn of Poussin's 'Seven Sacraments' to be examined. Here, again, the Swiss, out of the abundance of his zeal, expressed his admiration, by saying these pictures were *Lapadales*, when the painter, turning to him with an air of exultation, 'Pardonnez-moi, friend; there you happen to be mistaken. These are none of *Lapadales*,' but done by Nicholas Poussen. I have seen prints of them in England, so that none of your tricks upon travellers."

Let us add what handbooks do not tell us, that the Palais Royal "Poussens" of this diverting conversation came to England with the Orleans Collection, and are still a part of the Bridgewater Gallery in London.

A little bit of "Sir Joshua" that has been missed by all who have written about him contains a piece of advice that may still be of use. Reynolds painted the portrait of Robert Dodsley, the celebrated bookseller. It was painted in 1760 for his friend Shenstone the poet. When the picture was sent to the Leasowes, Dodsley wrote to Shenstone thus:—"If the picture should be turned yellowish, by being packed up, Mr. Reynolds advises that it be set in the sun for two hours, which will quite recover it." Let us add that the "whereabouts" of Reynolds's Dodsley has eluded our researches. There is an engraving of it by Ravenet.

Sir Joshua was fond of attending sales of pictures, drawings, and prints by the old masters. One of the pictures he acquired at a sale at Christie's in Pall Mall was the well-known Sebastian Bourdon, "The Return of the Ark"—now in the National Gallery, part of Sir George Beaumont's generous gift. Sir Joshua bequeathed it to Sir George; but what Reynolds gave for the picture has not been told. The picture was brought to England by Sir Robert Strange, and sold, 5th May, 1775, at Christie's to Sir Joshua—the price twenty-three pounds two shillings. The description in the catalogue is as follows:—

"48. *Sebastian Bourdon.*—'The Return of the Ark,' in which is introduced a variety of figures, characterised with simplicity and expression."

Reynolds has praised this picture in one of his discourses, and Mr. Wornum, we would suggest, should relate the history of the picture in the next edition of his National Gallery Catalogue. Mr. Taylor mentions the bequest of the Bourdon to Sir George, but when, where, or for what sum Sir Joshua acquired it, is not told.

How, in the name of the prophet Figs, Mr. Taylor when mentioning (vol. i, p. 187) Sir Joshua's portrait of Lord Erroll, could have omitted to insert Johnson's rapturous encomium on the painter made before Reynolds's Lord Erroll, we are at a loss to understand. Johnson and Boswell were on their tour to the Hebrides, and at Slanes Castle were reminded of their friend in Leicester-fields by the sight of Lord Erroll's portrait from his pencil. "Sir Joshua Reynolds, sir!" exclaimed Johnson, looking intently at Boswell, "is the most invulnerable man I know; the man with whom, if you should quarrel, you would find the most difficulty how to abuse." This noble compliment to Reynolds adds a money value to the Erroll portrait.

And how, in the name of the same Vicar of Wakefield prophet, did Mr. Taylor omit inserting Reynolds's dedication to Goldsmith of the print called "Resignation"? "This attempt to express a character in the 'Deserted Village' is dedicated to Dr. Goldsmith, by his sincere friend and admirer Joshua Reynolds." We do not find, either, a note of the price paid to him by Sir William Chambers, the architect, for the "Theory of Painting," let into the ceiling of the Council-chamber of the Royal Academy in Somerset House, and since removed to Trafalgar-square.

Some of the most valuable contributions to

Mr. Taylor's volumes—we use a long term for a few words—are in the shape of notes made at the time by Horace Walpole in his Royal Academy catalogues, to which Mr. Leslie had access through the late Mr. Sheepshanks, to whom they belonged. As these are scattered rough-cast throughout Mr. Taylor's volumes, we were at first inclined to bring them together, but space prevents us. "A word on the spot," says the poet Gray, "is worth a cartload of recollections."

Our readers will be pleased, we have little doubt, with some extracts from Mr. Taylor's volumes. Here is an "Appendix" passage on "Reynolds's Early Reading":—

"As to Reynolds's knowledge of Latin and early reading, I have some little evidence in his school 'Ovid,' well thumbed in parts, and in the commonplace-book mentioned at p. x. It is inscribed in a stiff but neat hand, 'Joshua Reynolds, ejus liber ex dono Patris mei.' Evidently his first 'cast,' for a giftive for father was *patris*, and he rests content with *patris*. But the extracts show a varied and very intelligently directed course of reading; and it is worth noting that the great majority of them indicate a decided turn for the calm, sense, and tranquillity, in life and manners. The extracts are (on life and morals) from Theophrastus, Plutarch, Seneca, Marcus Antoninus; (on criticism and for poetry) Pope (a great favourite, especially in his letters), Shakespeare, Milton, Dryden, the 'Spectator' and 'Tatler,' Cat's 'Book of Emblems,' and even Alfa Behn; (in art) Leonardo da Vinci, Da Fresco, and Richardson; and (in religious matters) Nelson and the Bible, Ecclesiasticus chiefly."

Another Appendix bit gives us something new about Sir Joshua's father, the Rev. Samuel Reynolds:—

"Since this volume was printed off I have come upon some very characteristic letters of Samuel Reynolds, showing both his intelligence and gentleness, from which I extract.

Speaking of his eldest sons, March 3, 1742.—  
"I have disposed of my eldest sons entirely to my satisfaction, because it is to their. In relation to my elder son, among my other studies and amusements, I have ordered masters so that I believe there is no admiral's son better put in hand for the sea than he is. He has by my means the whole foundation for the theory of navigation, so that there is nothing that he need take upon trust; and that he may have demonstration for if he pleases, it having been my way to fill up the intervals of his coming home by going on just where we left off last; and thus I have gone through with him the first six books of Euclid (and half the eleventh (which was all that was necessary); plane trigonometry, the last of which was very riding, and which I was forced to write out of several authors to make clear work. I was entering into astronomy when he was last called off."

S. REYNOLDS.

In another letter, January 11, 1736, he says:—  
"I cannot forbear adding that the mathematical education I have given my eldest son has been hitherto attended with success vastly beyond my expectations, from the kindness and character he has received from those officers under whom he has served, and likewise from the facility he has found, even in these times, in obtaining such a post as is proper for him to pretend to."

S. REYNOLDS.

"Writing in allusion to the death of a son, he says:—  
"That Providence orders all things for the best, I do verily believe, and I presume upon it in the conduct of my life. But still I should be glad to make it out free from all clouds of objections more clearly than I can. But still that argument does not come to the point in our grief for persons deceased; in other afflictions it does. When Job loses his sons, would it have been a proper consolation to say, 'You shall have as many in their room?' That argument would do for his sheep and oxen well enough, but not for his children. But in submitting to the will of God I allow that there is a pleasure which I never yet attempted to describe, any more than I believe will be to those persons who are dear to us, for I am in doubt whether all these things are not better left undeciphered. It may seem an extravagant thought of the Archbishop of Cambray, speaking of the death of the Prince of Burgundy, but I admire it. "If there needed no more than the moving of a stone to bring him to life again, I would not do it, since the Divine pleasure is otherwise." I doubt whether fully can say anything more noble. Thoughts that impress themselves so strongly on the mind I have no wish to criticise upon."

Ten pages of hitherto unpublished extracts from Reynolds's "Notes on Pictures at Rome and Bologna," enrich an Appendix. The notes are preserved in the Soane Museum:—

"Reynolds's notes," says Mr. Taylor, "on the works of the Bolognese School are only second in interest to his notes on the Venetian pictures. It is instructive to see how completely he ignores the earlier schools of Bologna, and how even the beautiful frescoes of Francia are passed unnoticed. He probably never saw them. On the other hand, we may well wonder not at the praise given to the Carraci, or even Guido and Guercino, but at the respect with which men like Tiarini are here treated, and the notice taken of some of the lower ranks of painters now held in even less repute than Tiarini. The perusal of these notes should impress on us the useful lesson of toleration and distrust of our own judgments and those of our generation, by the evidence they afford in so many places of the degree to which, according to the present estimate of painters and schools, even Reynolds was blinded and misled by the conventional taste of his time."

We shall part company from Mr. Taylor by extracting the final paragraph of his preface:—

"In sending to the printer the last sheet of 'The Life and Times of Sir Joshua Reynolds,' I lay down a task which would have been delightful had I not felt so painfully my own inadequacy to complete Leslie's unfinished work, and had I not been hampered by the sense that much which I was attempting could only be well done by a painter. I may have erred in my conception of the way in which the work ought to be done, but I can conscientiously say I have not spared on it either time or trouble. I love and honour by my subject and the man to whose unfinished labours I succeeded too much not to do my best for the sake of one as much as the other."

THE MANUFACTURE OF ENCAUSTIC TILES AND CERAMIC ORNAMENTATION BY MACHINERY.\*

It was in the year 1830 that the late Mr. Samuel Wright, then of Shelton, North Staffordshire, revived the manufacture of encaustic tiles, by specifying, under his patent of that date, his mode of making them. He employed a mould within an iron frame, with a removable top and bottom, the inner surfaces of the mould being of plaster of Paris, which does not adhere to plastic clay. Once set, plaster of Paris is very hard, and hence Mr. Wright found no difficulty in forming in it the most intricately wrought designs, in alto-relievo, for impressing the upper or outer surface of the tile. It is now time to describe the manufacture of encaustic tiles, as patented by Mr. Wright, from whom Messrs. Minton & Co. obtained a licence, extended by a prolongation of the patent by the Privy Council, to 1851. There are, no doubt, some gentlemen here who accompanied the Archaeological Association to Shrewsbury, in 1850, and who then partook of the elegant hospitality of Mr. Maw, at Benthall Hall, near Broseley, and who there listened to a very succinct and interesting account, from that gentleman, of the whole process of encaustic tile-making. While referring to that account, the author gives the following, almost identical with it, but derived from his own observations in the potteries.

The stronger and purer clays and marls, from the coal measures, as also other clays brought from the south of England, burn, without the mixture of colouring matter, into red, buff, and fawn-coloured tiles; and, with the addition of different proportions of oxides of iron and manganese, they burn into the black, chocolate, and grey tiles. The higher qualities of tiles, such as the white and those of richer colour, are made from a kind of porcelain clay, or Parian, the white being left uncoloured, while the blues and greens are coloured with oxides of chrome and cobalt. Where the clay is too strong or adhesive, from a deficiency of silica, a greater or less proportion of sand is added for the coarser tiles; but for the finer qualities, the proper proportions of silica and alumina should exist in natural combination in the clay itself. The clay is all the better if "weathered" by exposure, in thin layers, to sunshine or to frost, the effect of both of which is to break it up into fine particles, and to secure increased waxiness, if the term is permissible, in working. The clays are then, and in mixture with whatever colouring matters are employed, reduced to a state which is not only potter, but many others besides, know as "slip;" that is, they are mixed with water until the mixture becomes sloppy, and in this state they are strained through a sieve of fine lawn; the finer the better; and the fineness often amounts to fifteen thousand meshes or perforations in the square inch. This process of subdivision, resembling filtration, although only the coarser matters are retained by the lawn, gives great fineness and evenness to the texture of the clay, while it adds also to the brilliancy of the colour. Thus strained, the viscous clay is then dried to a plastic state, upon what are called the slip kilns. It is as well to say at once that, even for plain tiles, or those of but a single colour, two qualities of clay are taken, one for the body of the tile, the other and finer sort for the upper, or perhaps, both the upper and the lower surfaces. As in much modern furniture, so in tiles, where the visible grain and colour are but superficial, the coating of the finer material is called veneering. The workman first fills the bottom of his plaster-mould with a thin layer of the finer or veneering clay, and then beats upon it the coarser or body clay, of which nearly seven-eighths of the whole thickness of the tile is formed. Upon the body clay he places a further coating of veneering, and upon this he closes the mould. The bottom of the plaster-mould has raised upon it, in alto-relievo, the design for the impressed pattern, and on reversing and separating the parts of the mould, and removing the tile, it is left standing with its impressed design on its upper face. In its still plastic state, the impression upon the tile is filled with a semi-liquid preparation of clay, or "slip," of a quality which hurms to the contrasting colour or colours of the pattern. This "slip" not merely fills, but overflows the impression, and leaves the tile covered with a rough coating, in which state it is taken to the drying kilns, and in perhaps forty-eight hours

\* From a paper by Mr. Zerah Colburn, read at the Society of Arts, on Wednesday, May 17th.

(often much more) it is brought to the consistency of bees-wax. In this state of the tiles a workman, provided with a flat steel blade or scraper, proceeds to scrape down or shave off the superfluous coating of overflowing "slip" on the surface, and he continues this operation until he has removed it exactly down to the original surface of the tile, so as to bring out the pattern sharply and distinctly. The tile is then ready for the burning kiln. The burning occupies, in all, about a week, half the time being occupied in gradually raising the heat, and the other half in as gradually letting it down. This stage of the manufacture requires much care, as is indeed the case with all the finer kinds of terracotta and pottery. The goods gradually shrink in burning, and the progress of the burning is indeed judged of from the appearance of proof-tiles, introduced with the charge, and successively withdrawn, as the fire is got up and let down. The shrinkage is not always uniform, and tiles intended to be of the same size, inasmuch as they were formed in the same mould, often differ so much in their dimensions after burning that they cannot be laid in the same pavement. They are, therefore, carefully gauged, and assorted into lots each of one size.

Tiles so made are comparatively indestructible. A sharp file will hardly cut them, and considerable exposure to the weather affects them but little. Ancient tiles are still found, sharp and apparently unchanged in colour, where stone of strong texture has crumbled almost into dust. Care is requisite, in order that the body clay of the tile and that introduced into the pattern have equal shrinkage, as otherwise the pattern will not be firmly attached to the body. Encaustic tiles made from well-selected clays, and properly burnt, will not, when broken up by a hammer, show any separation of the veneering from the body, or of the pattern from the veneering. In other words, a fracture across any joint between different clays will bring off portions of both in each and every fragment broken off.

But, apart from pugging the clay and first drying and afterwards burning the tile, the process of hand-moulding is not a rapid one. A good workman will mould from 20 to 220 tiles, each 6 in. square, and in two colours only, as an ordinary day's work. Plain tiles, or those in one colour, are moulded at the rate of only 750 quarrs, each 6 in. square, per day, although very rapid workmen may turn out as many as 1,000. In the Potteries it is estimated that the cost of labour only in moulding and trimming encaustic tiles is from 1s. 9d. to 6s. per dozen tiles, or from 5s. 3d. to 18s. per square yard, according to the intricacy of the patterns and the number of colours filled into them. This may be much cheaper than mosaics, but the cost is still sufficient to preclude the use of encaustic tiles in a vast number of cases where, but for their cost, they would be most usefully and suitably employed. Where, on the one hand, the architect can command the means requisite for the best class of ornamental paving, he will naturally select the smaller and richly variegated *terresse*, arranging them in mosaics of his own or of some approved design; but where he is limited to encaustic tiles, the very considerable difference between the cost of the plainer and the more elaborate designs will often induce him to employ the former, to the sacrifice of effect; and where the choice lies only between tiles and oil-cloth, the latter, although not nearly so durable, will commonly produce by far the best effect for the money.

It must have long ago occurred to many persons interested in constructive and decorative art, that to introduce encaustic tiles extensively it would be requisite that they were made by machinery. It is a singular thing that the art of working in clay—possibly the earliest of all the arts practised by man—should have been almost the last to derive advantage from mechanical ingenuity. Not but that there have been many attempts to employ machinery in brick-making; but even here it is but a few years, very few, indeed, since machine-made bricks were scarcely known. It is ten years only since the first step was taken towards the manufacture of encaustic tiles by machinery; the son of the late Mr. Samuel Wright, the inventor of the band process already described, having, as a joint inventor, obtained his first patent in 1855. The encaustic tile machine, the joint invention of Mr. Samuel Barlow Wright and Mr. Henry Thomas Green, has been successively improved, until it now appears to have been perfected, and it is in successful use in the Potteries, although

not to an extent commensurate with the importance of the new manufacture. The machine is very simple, and its general construction and mode of action may be easily understood from a verbal description and without illustrative drawings. At one end of the machine are three common pug-mills, placed side by side in a row, in the direction of the length of the machine. The middle and larger mill is for pugging the coarser body clay, the other mills at the same time tempering the finer clay for the top and bottom veneering of the tile. The three pug-mills discharge their clay in three continuous streams, between a pair of polished rollers, which compress and, so to speak, weld the three streams into one. This is received upon, and carried forward by, an endless travelling table, or band, which extends horizontally for the whole length of the machine. As delivered upon this table, the compound stream of clay is of the intended thickness of the tile before burning, and of a little more than its intended width. It first passes under an impression roller, perhaps 2 ft. in diameter, and around the circumference of which are fixed the plaster dies, corresponding to the intended encaustic pattern on the face of the tile. In the old or hand process the die is flat and the face of the tile is formed by pressing the clay equally over its whole surface. In the machine the convexity of the die does not admit of a simultaneous impression of the entire pattern over the whole surface of the tile, the place of deepest impression, at any moment in the progress of the clay, being in a line across the width of the tile. But notwithstanding this fact, and that the alto-relievo surface of the die (being one-eighth of an inch, or so, further than the bottom from the centre of the impression-roller) moves forward about the one-hundredth part faster than the surface which presses upon the face of the tile, the impressions are nevertheless sharp, no matter how intricate the pattern may be. The impression-roller, as well as all the other working parts, must be driven so as to correspond exactly with the progress of the travelling table, or, in other words, with the progress of the advancing stream of clay. It will be understood that the impression-roller does not revolve by friction merely, as the clay is drawn under it, but that it is driven by gearing, at a definite speed, or, as mechanics would say, it has a positive motion. As soon as the continuous slab of clay has received the intended impression, it is cut into lengths corresponding to the intended size of the tile. This is effected by a guillotine wire cutter, which rises and falls at definite intervals, cutting the clay in its descent. Although the action of this cutter is only in a vertical direction it is so arranged that during the brief interval while it is passing through the clay it shall move forward with it, returning again to its original position after the cut is completed.

Simple as all the parts, so far described, may appear to be, everything depends upon absolute synchronism in their action. A greater amount of ingenuity, or, perhaps, it will be more truthful to say, of ingenious perseverance, has been devoted to this point than those unacquainted with the constant, but seldom recorded, skirmishes on the outposts of invention, would perhaps believe. Six years ago, my friend, Professor Hughes, or rather, his representative, Mr. Henry Hyde, described in this room his beautiful type-printing telegraphic instrument, to which, perhaps, we owe the introduction of the shilling telegram, which promises to become as general throughout Great Britain as the penny postage of Sir Rowland Hill. As in Messrs. Wright & Green's tile-making machine, so in Professor Hughes's telegraphic instruments, everything depends upon synchronous action; and this has been at last secured beyond all doubt, in both inventions. In the tile-making machine, the rate of progressive motion is about 12 ft. per minute, corresponding to the moulding of twenty-four 6-in. tiles per minute, or to 14,400 in ten hours, as compared with 200 or so moulded by hand in the same time. It is absolutely necessary that the pug-mills deliver at the prescribed rate, that the polished compressing rollers move at that rate; and that the travelling table, the impression-roller, and the guillotine-cutter exactly conform to it. The rate may be 10, 12, or 20 ft. per minute; but, whatever it is, all the parts of the machine must, as they do, work in perfect concord with each other.

After the advancing slab of clay has been cut into tiles, it passes under a reservoir or trough, of which indeed the procession of tiles forms the

bottom, and within which the clay for the contrasting colour of the pattern is mixed with water to the consistency of "slip." The slip is filled into the impressions upon the tiles, and overflows the whole surface of the tile to the depth of perhaps an eighth of an inch. The tiles are taken from the travelling table as they emerge from the end of the slip trough, and are conveyed thence to the drying-kilns, where they remain until they are of the firmness of wax. They are then taken to a machine, consisting of a vertical spindle, in rapid revolution, and having one or more cutting blades fixed to its lower extremity, and revolving in a horizontal plane, as in one form of planing-machine for planing wood. The tiles being placed, one by one, upon a horizontal bed-plate, which can be elevated or depressed through a small range beneath the revolving cutters, are rapidly surfaced, the overflown slip being removed, and the pattern brought sharply out. This operation is almost instantaneous, and it leaves the tile with its two surfaces absolutely parallel with each other, and insures perfect equality of thickness in any number of tiles surfaced. Thence the tiles are squared to gauge upon the flat revolving side of a large grindstone, and, this operation being over, they are ready for burning.

The machine, with two or three attendants, does the work of from sixty to a hundred hand moulders. It works the clay more uniformly into goods than can be done by hand, and the slip pattern is deposited with more uniform density and with less risk of imprisoned air, so that the pattern burns better, and is still less likely than in hand-made goods to crack out from the body of the tile. Nothing, it is believed, can exceed the sameness and truth of the machine-made tiles here upon the table; the patterns being as integral with the veneering, and the veneering with the body, as if the various clays had been actually incorporated together into one homogeneous mass. On the other hand, although the machine can make tiles with most intricate and delicate designs, even to the filiform tracery or tendrill-like stalks of the most curious arabesques, it can only make bicoloured tiles, as the details of the pattern can only be filled from one and the same trough of slip clay.

Another, and possibly a still more important purpose of the machine is that of making both intaglio and relief ornaments on slabs of plastic clay, to be burnt into terra cotta decoration for walls. In this way cheap and most durable friezes and dados, enriched arches, and other work, whether anaglyphic or sunk, and, indeed, ornate slabs for covering the entire façades of buildings, may—if we disregard the extra cost of the finer clay required—be made almost as cheaply as bricks themselves. No matter how enriched may be the design, these slabs may be produced by one machine at the rate of 5,000 square feet per day, equal to the covering of a façade, allowing one-half its surface for windows, of 200 ft. long and 50 ft. high. Such ornamentation, produced by hand moulding, has been more or less employed for a long time, but it is costly in the first place, and it is commonly made of a close-grained clay, which does not withstand the weather as it ought. By the aid of machinery, with its increased power of compression and consolidation, a more open and durable quality of clay—that is, one having more silica—may be employed; and, at the same time, still larger slabs may be produced. The known cost of production is so low that it may be at once declared that such slabs may be sold at a cost below that of rough stone, at the quarry or without labour, the plainer slabs being sold at 6d. per superficial foot, and the enriched patterns, which are made with almost the same facility, at from 9d. to 1s. 6d. Ordinary bricks are now made by machinery, with projecting dovetails, and these bricks may be built into walls, so as to project from two inches to two and a half. The terra-cotta slabs are formed with corresponding grooves. When the brick-work is raised to the height of one course of blocks, these are affixed, and the joints run with cement grout; and the façade of slabs is secured in successive courses in the same manner until the whole is complete. In this way a building of a richly ornamented character could be erected in less time, and at a little cost, as the present insignificantly structures in brick.

It may be that enough has been already said of the commercial advantages of the new manufacture. Far more might, however, be added. In the presence of so practical an assembly as this, it

may be as well to enable those who are disposed to check every statement of the cost of production, to do so with the light already derived from experience in working the new machine in the potteries. For a production of 12,000 6-in. tiles per day, or 2,000 square yards of tiles per week, about 72 tons of body clay and 43 tons of slip or veneering clay, would be required weekly. In certain localities, furnishing the required quantities, the coarser clay can be raised and moved for 3s. 6d. per ton, and the finer for 7s. 6d. per ton, including royalties, making 30l. 12s. weekly for clay. The coloured slips might cost 10l. more. The wages of men and boys at the cost of labour in facing and edging tiles as 25l. The cost of setting, burning, and drawing the tiles may be set down as 18l. more per week. The coal for drying and burning, and for the engine, may be taken as 20l.; the cost for warehousing, sorting, and packing as 10l. per week; wages of engine-driver and fireman as 3l.; and wear and tear, oil, and grease, as 5l. The cost of management, clerks, and designs would be, say 21l. per week; rent and taxes, 1l. 6s.; commission on sales (450l. weekly at 10l. per cent.), 45l.; stationery and advertisements, for the first year, 22l.; loss and contingencies, supposing them to be 20l. per cent. upon the whole sales, 50l.; and interest on capital expended, say 30l. This makes in all, 337l. 12s., or say 16,800l. per annum. The sales, on the other hand, at 2,000 square yards weekly, for 50 weeks in the year, at the low price of 4s. 6d. per square yard, which is less than the cost of labour alone in making hand-made tiles of equal quality, would amount to 22,500l., leaving 5,620l. profit, or about 22½ per cent. profit upon a fixed investment of 25,000l., in itself ample for the working of a single machine. The profits upon an additional investment to the same extent, in the department of terra-cotta or ceramic decoration, making 30,000 square feet weekly, to be sold at 6d. per foot, would, upon the ordinary experience of potters, be quite as great. These details, the result of careful inquiry and of accumulated experience, are given rather to show the advantages in cheapness and in the character of work obtainable in the new manufacture. The architect—as are nearly all who are engaged in the arts of construction—is more or less bound in his designs by commercial considerations; and to give him a known material at a cost commercially within the limits of general application, where previously it could only be sparingly employed, is virtually to give him a new material.

#### THE HOMERIC MARBLE.

MR. GAORE has presented to University College, London, a large and costly work, by Baron H. de Triqueti, entitled by the sculptor, the "Marmor Homericum." It has been called a *sgraffito*, and so it is, in so far as *sgraffito* means "scratched." But it is not the sort of work that is ordinarily described by the term. This is the mode of executing a *sgraffito*: the ground is prepared with dark stucco, on which a white coat is applied. This white coat being scratched away with an iron instrument, the black ground is seen through, and forms the shadows. In M. de Triqueti's work, on the other hand, the forms are engraved on marble, and filled in with coloured cements, which, the sculptor asserts, have "the same hardness, adherence, and durability as the marble itself." This, however, we must take leave to say, is open to doubt; and should the colours fly, in the way we know them to do from the monumental stones of our cemeteries, the picture would of course proportionally disappear.

The "Marmor Homericum" consists of a large central composition, with smaller compositions in a border all round it, and marble bas-reliefs at the four external angles. The central group represents Homer singing to the Grecian people of Delos. "His song depicts the agony of Andromache." Around him are grouped the Delian maidens attached to the Temple of Apollo, with listeners of various character. In the border, on the left side, top and bottom, we have a symbolic figure of the Liad suspending, in token of triumph, the shield of Minerva at the feet of Victory; the quarrel of Agamemnon and Achilles; and Achilles, in his tent, mourning with his followers the death of Patroclus; Priam, embracing his knees, supplicates him to surrender the body of Hector. On the right side are a symbolic figure of the Odyssey.—Calypso,

in obedience to the commands of Jupiter, conveyed by Mercury, consents to the departure of Ulysses; and Ulysses slaying the suitors. The first arrow has pierced the throat of Antinous, who overthrews in his fall one of the festive tables.

The white marble retains its natural colour for the flesh, and is modelled by slight hatchings in red, indicating the principal forms; while in the back-ground, draperies, and accessories, the engraved lines are filled with cement of various colours.

The question of durability, as regards the coloured cement, is of importance to us, inasmuch as M. de Triqueti is commissioned to execute a number of pictures in this manner for the Memorial Chapel at Windsor. The "Marmor Homericum" is in many respects a fine work: the forms are for the most part good, and the intended expressions are well conveyed. It is not to be denied, however, that its general effect is somewhat cold and hard.

#### DWELLINGS FOR THE LABOURING CLASSES.

The committee appointed by the council of the Society of Arts to consider this subject have made a report, from which we take some passages:—

At the first meeting of the committee it was unanimously resolved that it was not necessary to collect facts to establish the unfitness of the greater part of the dwellings of the labouring classes as habitations for respectable and well-conducted families, or to prove that the excessive overcrowding which now exists in such dwellings promotes crime and immorality, harbours disease, and materially lessens the effective power of the working classes, by injuring their health and shortening the duration of their lives.

Nor was it considered necessary to inquire into the effect produced by these badly-constructed, ill-ventilated dwellings on the poor, or into the amount of discontent which the admitted want of proper dwellings creates in the minds of the working-classes. The committee also recognised the distinction which must be drawn between associations for providing improved dwellings by investments for the labouring classes, the capital for which is subscribed with the double object of obtaining a fair interest on the money advanced, and of elevating the social and moral condition of the working classes, and the regular investment in such buildings by builders who must obtain the ordinary commercial profit on capital used in business. In the first case, a dividend of 5 per cent., with an ample fund to provide for all contingencies, might be considered sufficient, whilst in the other case a very much larger return would be required. Considering these facts as fully established, the committee proceeded to inquire into:—

1. The causes which appear to retard the erection of proper house accommodation, and the improvement of existing houses, for the working classes in town and country.
2. The operation of imperial and local taxation on such dwellings; and the expediency of relieving them from all or a portion of such taxation.
3. The effect of the law of settlement and removal of the poor upon such buildings in country districts.
4. The probable effect of extending the area of local taxation in town or country.
5. The operation of the laws relating to the transfer of real property in small plots, and the conveyance of chambers and suites of rooms.
6. The operation of the destruction of houses by railways and other local improvements.
7. The desirability of facilitating the conveyance of labourers to and from their work by railway.
8. Whether the provisions contained in the existing Acts of Parliament for granting loans for the improvement of estates, might not be extended to the building of cottages, and if so under what special conditions.
9. Whether the provisions of the Common Lodging-house Act, and other statutes relating to the public health, might not be advantageously extended.
10. Whether there are any other means by which the Legislature can promote the object in view.

It was at first proposed to divide the subjects between three sub-committees, according to their relation to town dwellings, country dwellings,

and proposed legislation; but it was found in practice better to amalgamate the sub-committees, as the subjects referred to each sub-committee were so similar. The following gentlemen attended the meetings: Mr. W. Hawes (chairman), the Hon. and Rev. S. Beat, Mr. D. R. Blaine, Mr. C. B. P. Bosanquet, Mr. C. S. Barker, Mr. Edwin Chadwick, C.B., Mr. G. R. Burnell, Mr. H. Cole, C.B., the Right Hon. W. Cowper, M.P., Mr. J. B. Denton, Mr. J. Dillon, Mr. H. B. Farnall, Mr. P. Le Neve Foster (secretary to the Society of Arts), Professor Fawcett, Mr. C. Gathiff, Mr. G. Godwin, F.R.S., Dr. Greenhill, Mr. T. Hare, Mr. H. Harwood, Mr. E. T. Holland, Mr. C. Wren Hoskyns, Mr. H. Maynard, Mr. H. Pownall, Mr. S. Redgrave, Mr. B. Shaw, Dr. E. Smith, F.R.S., Mr. S. Tenlon, Mr. T. Twining, Mr. G. H. Walker, Mr. Alderman Waterlow, Mr. G. F. Wilson, F.R.S., Mr. T. Winkworth, Mr. J. Young; and Mr. M. Ware, who acted as secretary to the committee.

Various resolutions were passed with respect to the questions considered by the committee, the recommendations of which are embodied in this report.

*Improved Dwellings for Labourers not Remunerative.*—It was shown that labourers living in the metropolis and other large towns pay a larger proportion of their income for rent than any other class in the country, and even then are unable to obtain suitable accommodation. The immediate cause of this state of things, in places where the law of parish settlement does not cause an additional difficulty, is the fact that providing such dwellings for labourers has not been found commercially remunerative. The efforts of societies and benevolent individuals are every year becoming more extensive, and from the beginning have been appreciated by the industrious classes. They have already accomplished a great amount of good, and have set an example which, it is hoped, will be more extensively followed; but it will be long before the existing evils can be more than slightly mitigated by such means. At present the dwellings provided in this manner in the metropolis only accommodate about 7,000 persons, and the commercial results are not such as to encourage builders and capitalists to undertake the building or renovation of dwellings for labourers as an ordinary matter of business. It appears, from the statistics collected by the Society of Arts, that it rarely happens that such undertakings produce a higher dividend than five per cent. on the original outlay, and that in most cases the returns are smaller. This rate of interest may be expected to satisfy a large number of capitalists, who are willing to accept a moderate return upon capital when connected with such important philanthropic objects; but it can hardly be expected that dwellings will be provided in anything like sufficient numbers until they can be made to produce such a return as will compensate a builder for investing his capital in this kind of property, attended as it is with so much more risk and trouble than houses of a superior class.

The difficulty of remedying this state of things is aggravated by the fact that the wretched houses which too many of the labouring classes now inhabit are, in their present condition, highly remunerative to the landlords. Consequently such houses fetch a high price when brought into the market. They may be made to yield a good profit in the hands of those who care nothing for the moral and physical well-being of their tenants; but the expense of putting them into proper sanitary condition, and adapting them to the wants of respectable working men, reduces the returns so much as to render the undertaking, in a commercial sense, unprofitable.

\* \* \* \* \*

*Enforcing the Sanitary Laws.*—Whatever progress may be made in building or adapting houses by individuals or societies, the great mass of the labouring population for many years to come must necessarily live in very crowded neighborhoods, in houses now existing, and not originally adapted to contain several families under one roof.

It is, therefore, of the first importance that the owners of existing houses, inhabited by the poor, should be obliged to provide those sanitary appliances which are required for the preservation of the health of their tenants, and to check, when it occurs, the progress of infectious disease. Long experience has shown that nothing but constant inspection and compulsory measures will meet the carelessness and cupidity of the owners of this kind of property.

The present sanitary laws are comprehensive, and on the whole efficient, although there are some particulars in which the committee think they require amendment, especially with relation to the inspection of houses let to lodgers, but not now subject to the provisions of the Common Lodging-house Act. The provisions of the sanitary Acts are not, however, sufficiently known, nor do those who are qualified by intelligence and position to attend to the sanitary condition of their own neighbourhood interest themselves as much as could be desired in seeing that the powers of the law are put in execution.

The committee recommend that a concise analysis of the sanitary laws should be prepared, and that the defects of the existing law should be pointed out and circulated. In this way the attention of men of education and intelligence would be called to the subject, and they might be induced to take part in sanitary work in the neighbourhood in which they reside or carry on business.

In the country districts the sanitary condition of the people is regulated by the Nuisance Removal Acts, 18 & 19 Vict., c. 121, and 23 & 24 Vict., c. 77, and the Local Government Act, 21 & 25 Vict., c. 98; the power being vested in the Local Board of Health, or, if there be none, in the corporation of towns, boards of guardians, or parish vestries, according to the circumstances of each locality.

In the City of London the power is vested in the Commissioners of Sewers, under the Acts regulating the administration of the City.

In the other metropolitan districts the vestry or district boards are the local authorities for the removal of nuisances, under the Metropolitan Management Acts, 18 & 19 Vict., c. 120, and various Amendment Acts.

By the 21 & 22 Vict., c. 97, the powers of the General Board of Health were transferred to the Privy Council, which has a general superintendence of sanitary matters. This branch of their duties is practically exercised by the medical officers of the Privy Council. The committee think that there should be a separate department, to which appeals might be made from the local authorities, and whose duty it would be to consider the recommendations dictated by the experience of the district medical officer.

They also recommend that the appointment of proper inspectors of nuisances should be compulsory in all places, so that it should be the duty of such inspectors to report forthwith to the local authorities all nuisances which exist without waiting for the complaint of other persons.

The committee further recommend that the medical officers of health should be irremovable without the consent of the Privy Council, and that the amount of their salaries should be subject to the approval of the same authority. The duties of these officers, if properly performed, are able to bring them into collision with the interests of persons having influence in the vestry, and it appears of great importance that their independence of action should be secured.

It appears also to the committee, that both the Nuisance Removal Acts, and the Metropolitan Management Acts, are deficient in not giving to the local authorities sufficient powers to oblige the builders of houses to make proper provision for drainage and ventilation.

The 29th section of the Nuisance Removal Act (18 & 19 Vict., c. 121), also requires amendment. It gives power to the local authorities to take proceedings against the owner of a house inhabited by more than one family, if it shall be found to be overcrowded; but it leaves in doubt the case where particular rooms in a house are overcrowded, as well as the case of a single family in a small house of one or two rooms. It is, however, to be remarked that the medical officers find it impossible to interfere as they wish with the overcrowding of houses, because of the difficulty, it should rather be said the impossibility, of the poor finding accommodation elsewhere. In this, as in other details of sanitary inspection, over-strictness may become oppression, and aggravate instead of alleviating the hardships of the poor. Until more and better dwellings are provided, and until the labouring classes have learnt more fully themselves to appreciate the blessings of air and cleanliness, no sanitary regulations can be satisfactorily carried out.

The committee, in conclusion, recommend to the Council—

1. That corporations, limited owners, &c., should have increased power to sell land for the

erection of dwellings for labourers, under conditions as to proper drainage, ventilation, and sanitary regulations.

2. That the Public Loan Commissioners should be authorised to lend money, at a rate not exceeding 3½ per cent. per annum, for building dwellings for the labouring classes, under suitable guarantees and with due regard to sanitary arrangements.

3. That in all future railway Acts, and Acts for local improvements, when houses inhabited by the working classes are destroyed under compulsory powers, such companies should be compelled to provide, within a convenient distance, other dwellings in lieu of those destroyed.

4. That the following amendments should be made in our sanitary laws:—

a. That the appointment of inspectors of nuisances throughout the country should be compulsory.

b. That increased power be given to the proper local authorities, to oblige builders of houses to provide adequate drainage and ventilation.

c. That the medical officers of health should be irremovable without the consent of the Privy Council, and that the amount of their salaries should be subject to the approval of the same authority.

d. That houses in which lodgers are taken, especially where particular rooms in a house are overcrowded, should be brought under more efficient inspection.

5. That, with the view of extending an accurate knowledge of the powers contained in the various Acts relating to the removal of nuisances, the council is recommended to prepare and publish a concise analysis of the existing law, calling the attention of the educated classes to this important subject, and pointing out how they may, merely by a little attention and exertion, confer most important benefits upon a large mass of working people, and upon the country generally.

6. That the council be requested to take such measures as it may think advisable to bring the first four of these recommendations as soon as possible under the notice of her Majesty's Government.

#### BRIGHTON.

It is intended to form a limited liability company for the purchase and rebuilding of the present theatre, or the erection of a new one, and about 6,000*l.* worth of shares are already promised to be taken up. Two sites on the Pavilion estate are probably open to negotiation, and there are now two others equally eligible. Mr. George Cobb, the owner of the existing theatre, is willing to arrange as to the purchase of the present theatre.

A new "Catholic Apostolic" church has been built and consecrated, in the angle formed by Carlton-street with the Grand Parade. The congregation are commonly known as "Irvingites," although they themselves repudiate this and every other sectarian title, calling themselves simply members, together with all baptised Christians, of the one Catholic and Apostolic Church; or, in other words, they are desirous of adding all other sects to theirs. Their distinctive position is said to result from their belief that the Lord of the Church has already restored apostles and prophets to prepare it for His own immediate coming, although it is said that His second coming will be sudden and unexpected, and although, at His first coming, He first came and then appointed His apostles, without any such preparation in His absence.

The new building is entered from Carlton-street by a Gothic arch, from which a narrow pathway leads to the north door. It is plainly built, in the Gothic style, the material being variously-coloured bricks, with occasional stone facings. The window over the altar is coloured, and other windows are, it is said, intended to be also coloured. The seats are all free and open, made of light wood, and facing the altar, which stands at the west end. The chancel is spacious, and furnished with the necessary chairs, kneeling-deaks, &c.: at its south side, but external to its precincts, stands the pulpit, opposite to which is a barmonium.

The first stone of the new workhouse has been laid, on the site purchased thirteen years ago, for the parish of Brighton, at the top of Elm-grove, where considerable progress has already been made in getting out the ground, and putting in the foundations of the building. Mr. G.

Maynard, of Brighton, is the architect; and Mr. J. Reynolds the builder.

The governors of the Sussex County Hospital have decided on a plan for the enlargement and improvement of their hospital, at a cost of 4,206*l.* The plans have been provided by Mr. Scott, a local architect.

#### THE HOLBORN AND WHITECHAPEL IMPROVEMENT ACT.

This important measure has received the Royal assent. With reference to Middle-row, Holborn, it provides for the speedy removal of that portion of the public thoroughfare of High Holborn which has been for many years an impediment of a serious character to the traffic east and west of the metropolis, known as Middle-row, Holborn, in the parish of St. Andrew, Holborn-above-Bars, immediately westward of the City boundary in that direction. The words of the Act are (sec. 7), "To widen and improve the public thoroughfare of High Holborn, near its junction with the city of London, at Holborn-bars, by removing the dwelling-houses, messuages, and premises forming the north side of the passage or place commonly called Middle-row, and lying between that passage and the north side of Holborn aforesaid."

*High-street, Whitechapel.*—The Act also provides for the opening up of a spacious and convenient communication between High-street, Whitechapel, at its junction with Leman-street, and Commercial-road East, at its junction with Church-lane, the said extension "to commence at or from High-street, Whitechapel, at or near its point of intersection by Leman-street and Commercial-street, and terminating at or near the west end of the street or road called Commercial-road East, at its junction with Church-lane."

The Act is to be carried out by the Metropolitan Board of Works.

#### ARCHÆOLOGIC ITEMS FROM ROME.

The longer one considers the procedure of those responsible for the interests of antiquity in Rome, the more is one astonished at those inconsistencies and the strange contrasts from time to time presented, between inertness and zeal, carelessness and neglect. For some time have been progressing works for a new road towards the central railway-station, which now obtrudes a frightful and paltry front on the planted esplanade where the *Thermae* of Diocletian rise in ruins, to so great a degree obscured by the *Carthusian* monastery in their midst.

Various remains of those imperial baths, in form of low brickwork vaults, extending in a direct line westward from the entrance to the monastic church, have been gradually laid open, and we may suppose these to be bathing-chambers for private use, of whose masonry only remain inner walls and hemicycles thus preserved. Near to the church front have been found other objects—the remnant of a semicircular structure in laterial brick, two wells of some depth, two marble baths, the imperfect shaft of an enormous granite column, and various other fragments in marble. One detail worth noticing is the *opus reticulatum* in these smaller structures, a series of semicycles, like the inner extremities of many ancient Roman interiors, being in this style of tufa masonry, said to have fallen into disuse soon after the time of Antoninus Caracalla, but in this instance shown to have been continued by Roman builders till the beginning of the fourth century. The absence of statuary from these *thermae* is accounted for by what several writers of past ages—Albertini, Flaminio Vacca, Ficorini—tell us respecting the successive discoveries and removal of buried sculptures from this site, between the earlier years of the sixteenth and the end of the seventeenth century; on one occasion eighteen busts of philosophers, immured together in a recess like an oven, as described by Vacca. The same line of new road is now being carried on through a hitherto solitary and picturesque region—the narrow valley, occupied by gardens, between the Quirinal and Viminal Hills. Opposite the isolated old church of S. Vitale, on the slopes of the Viminal, has been laid open, a long substruction, partly of the same reticulated tufa, partly of brickwork, opening in several niches, or small chambers, along the front, with vaults retaining coloured stucco on their surfaces; in one of these was a mosaic, not without beauty, representing a female in the act of leaving the bath, whilst a servant-maid presents to her

a mirror, which valuable art-relic, through the clumsy proceeding of those who endeavoured to detach it from the wall, was totally destroyed. On the story supported by this substructure are traceable the plans of several rooms, with some portions of wall, on the stuccoed surface of which are painted ornaments of graceful character; elsewhere, on the areas of two chambers, remains some tessellated pavement; and, under the acclivity of the hill, open several galleries, or cloisters, whose walls are covered with inland work known as *opus signinum*. As yet we are left quiet in the dark respecting the future fate of these lately disinterred ruins; but antecedents must lead us to conclude that they will share the destiny of various other antiquities in Rome, swept away for utilitarian purposes. Thus were doomed to disappear the structures found, in 1862, near the railway station, consisting of a encolpated hall, and several bathing-chambers, enriched by mosaic pavements and fresco-pictures representing females in the act of dressing or undressing before and after the enjoyment of the bath. Another interesting discovery, among results of the works for levelling on this spot, was that of the Agger, and a remnant in massive stone courses of the walls called after Servius Tullius; and, though the originals of those frescoes have been destroyed, we may console ourselves by the knowledge that, in copies at least, they will be banded down to posterity, as engraved in the annals of the Archaeologic Institute.

Two sites, where the Papal Government is now carrying on excavations, are Ostia, and an estate on the western slopes of the Palatine Hill. At that ancient part of Rome has lately been opened a sepulchre, whose owners were the Caclian family, profusely adorned with stucco reliefs and paintings; among the subjects of the latter, figures of a priest and a genius; Saturn in the act of seizing one of his children while a stone is presented to him by Rhea; also the "Rape of Proserpine." In a sepulchre near this had been previously discovered several other mythologic paintings,—“Orpheus and Eurydice,” “Pinto and Proserpine,” and one of the numerous mosaics, in temples or thermæ, found at Ostia, within recent years, is now being laid down in a hall (not yet public, but eventually to be so), in the Vatican.

The excavations ordered by the Emperor of France, on the Palatine, are being prosecuted with regular activity; and the public are admitted every Thursday to see discoveries important in respect to light thrown on topography and general plans in the very complex structures on that Imperial Mount.

The Pope has approved a project for enlarging the Lateran basilica, by the addition of arcades and pilasters, between the transepts and the tribune, which would involve the necessity of taking down (to be reconstructed) the most interesting, the only venerable and hitherto unspoilt antique portion of this church; its apse, namely, with the fine mosaics of the thirteenth century, and the (for Rome) unique example of the semicircular pillared aisle, with grained vaulting, behind the same ancient sanctuary, part of the buildings raised in the tenth century. That such procedure should be projected by artists, and approved by highest authority here, is a deplorable fact quite beyond comment.

The English Archaeologic Association has held four meetings since its birth in the last month,—two for the examining and explaining of ancient churches *in situ*; one at the Christian Museum, in the Lateran Palace, for the study of the monuments in that collection; and one at the English Consulate, for a lecture on “Ancient Roman Mosaics in Great Britain,” delivered with much ability and knowledge of the subject by Dr. Wollaston, who illustrated his exposition by various coloured drawings and engravings as he proceeded. As this society is now definitively organized, its vice-presidents (Lord Talbot de Malahide being president) are the Hon. Henry Walpole, the Rev. Dr. Smith (a Benedictine priest and professor of Hebrew), Mr. Severn (H.B.M. Consul), Mr. G. N. Parker, and Mr. C. D. Fortnum; and a committee of six members,—Messrs. J. Lecky, Christie Miller, Charles Perkins, C. J. Hemans, Francis Samwell, Charles Wilshire,—meet, as occasion requires, at the house of the secretary, Mr. Skakpene Wood. After the last lecture, which gave general satisfaction and elicited a vote of thanks to Dr. Wollaston, the committee met to bring to a close the proceedings of the season, in the intent of resuming operations, with ampler means and larger projects it may be hoped, in the ensuing autumn. On an average about fifty ladies and

gentlemen have been the number of auditors hitherto at the several *réunions*, to which admission is by ticket or invitation, the party who reads on, or otherwise explains the archaeological subject of the day being entitled to invite six strangers: occasional hearers admissible by tickets at one scudo.

## HOW METROPOLITAN NEIGHBOURHOODS GROW.

THE CALEDONIAN-ROAD, ISLINGTON.

It happens to be Saturday night: brilliant gaslights are blazing. In all directions the shops of the grocers, butchers, bakers, green-grocers, coal dealers, pawnbrokers, stationers, newsmen, and others are thronged with customers; the resplendent public-houses and beer-shops, which stand on the line of this thoroughfare, number about twenty: the goods of leather-dressers' and grindery shops, tailors, hair-dressers, and almost everything which is needful for the support or covering of the body, are here now to be found in profusion. Even the coffinmaker has not failed to establish his trade. Ballad-singers, beggars of various kinds, a long line of costermongers, their goods lighted with smoky lamps; fish, fruits, and flowers, are mixed in profusion; and in the press and confusion of this part of the thoroughfare it is scarcely possible for the people who are marketing to pass along the foot-path.

Remembering the scene which was presented here about twenty-five years since, the change is remarkable. Then at King's-cross stood that statue which has given name to one of the most bustling and important central points of the metropolis of the present date. The Fever and Small-pox Hospital stood in its own grounds, on a site which forms part of the front of the Great Northern Railway terminus. Agar Town, and the changes which are in progress there, have already been referred to by us; but for the present purpose it will be sufficient to mention that at the date in question there were two lines of road leading from King's-cross or Battle Bridge northward, viz.—Maiden-lane, now the York-road; and Chalk-road. With the exception of the large tract on which the premises of the Great Northern Railway Company stand, the York-road, until it reaches the new Cattle Market and Camden Town, has been but little changed. The old taverns have been enlarged, and some new ones built in anticipation of increased traffic arising thus in consequence of the removal of the Cattle Market: on the west side of this road there was a view over the fields to Agar Town, and Belle Island formed the northern point of building on the east side.

Along the Euston-road, as it is now named, to the “New” St. Pancras Church, the transformation of the garden-ground into shops is being carried on extensively. Statuary, architectural ornaments, and other matters are displayed. Amongst them is a monster reflecting-telescope, and there may be also noticed the covered sheds of carriage-makers, and others: where flowers and shrubs formerly grew, the sheds of the photographers now are reared; and in this and in other parts of the same road, the covered seats which, shaded by trees, stood in the frontage of the public-houses, in which, on Sundays and holidays especially, the Londoners liked to partake of refreshment and enjoy their rest, have been removed to make way for gaily-decorated and handsomely-fitted bars, in which “Old Tom,” the “Dew” from Glenlivet, and other civil commodities are shown to the best advantage.

About twenty-five years since Mr. Rhodes's fields of mangold-wurzel, and other parts of his great milk-farm, kept a considerable space open from the neighbourhood of Mornington-crescent towards the old church of St. Pancras. Part of Cadden-street, College-street, King's-road, Pratt-street, Clarendon-street and square, &c., were built, but in the neighborhood there were several nursery gardens; on portions of these the model houses for families, and Oakley-square, have been erected; then, looking westward from Maiden-lane, the huge dust-heap, the dwarfed and unwholesome cottages, the picturesque weather-beaten tower of the old church, the thick white masses of the gravestones of St. Pancras and St. Giles-in-the-Fields, the unsightly range of the workhouse, and afterwards the temporary church and school, formed a sort of margin between Camden-town, Somers-town, and Islington.

Near Battle Bridge, on the “Chalk-road,” now

the Caledonian-road, a few houses had been erected: amongst these are Caledonia-crescent, and some of those houses which are still remaining near this point; but standing here and looking northward was seen an open road. In parts the hedges and palings had been broken down, and what had once been green meadows had either been trodden by numerous foot-steps, or broken by chalk and other quarries. In one part on this ground there was a group of ill-constructed hovels, in front of which were swings, ginger-beer and fruit stalls, pop-guns, pitch-and-toss, and other doubtful kinds of amusement, which were allowed to go on with the greatest activity on the Sundays. Then (a quarter of a century since) we have no recollection of buildings, except sheds, along the line of this road from near Battle Bridge to the Royal Caledonian Asylum; an excellent institution, from which this now well-known thoroughfare has been named. In several directions the tile and brick makers might be seen at work, and the line of the Caledonian-road became more distinctly marked; the foot-path was indicated by a marking of curbstones; and no end of rubbish was shot on what was afterwards destined to be the carriage-way, over which, in succeeding years, countless numbers of vehicles and droves of animals of various kinds were to move from year's end to year's end again,—from morning to night and night to morning, with a slight lull of an hour or two in the night,—when even the metropolis is in a state of quiet and repose. Notwithstanding, the road for a long time continued to be of a troublesome nature,—and especially when the weather was wet: when the thaws in winter time occurred, it was not good for either man or beast. Improvements came slowly, and builders and others saw the value of this road as a means of communication between the Borough, the City, and the vast population which is in the course of being planted in the north-west portions of Islington, in Highbury, and in the districts of Camden Town, Holloway, &c. There seems, however, to have been a sort of rivalry between the York-road and the Caledonian-road; and certainly the former is very direct in its course towards the neighbourhoods mentioned; and also to Hampstead, the Regent's Park, and elsewhere; whereas at the north extremity of the Caledonian-road there is a troublesome elbow, which was made formerly of more consideration, by reason of the turnpike-act which blocked up the freedom of the way in all northerly directions. The results of experience, however, show in favour of the Caledonian-road; for, with the exception of the railway works in the York-road, the place has made but little progress; whereas, in the other instance, the onward course has been remarkable.

Near Thornhill Bridge, not far from All Saints' district church, is one who carries on the business of a chemist and druggist, and who also manages one of the two district post-offices which are now in the thoroughfare, and to whom we are inclined to give the position of the oldest inhabitant; for when he opened his shop there was no other finished and occupied. Then, however, the land, on which there was soon to be gathered a large population, had for the most part been partitioned out in a wholesale way: the lawyers were kept busy enough in preparation; and then more lawyers, on a smaller scale, arranged for the sub-division and terms of ground-rents. All this was, however, done with due regard to the ideas and instructions of the chief proprietor, into the possession of whose family it is probably destined to fall in after-years. Then came the negotiations of builders; and, always having reference to the original intention, the neighbourhood began to be planned out, and pieces of less traffic were joined to this leading thoroughfare. But the main road was itself a source of trouble, and long after this had been reduced into some kind of order, the tributaries were a cause of annoyance; and even now we doubt if the drainage is in such good order as it should be. However, as time passed on, the Caledonian-road presented a handsome and complete appearance, for both the roadway and footpath were wide, and in parts, where the slopes had not been brought out, the garden space, of somewhere about 30 ft. on each side, added to the good effect; and, although the Caledonian-road seems to have been planned as nearly as possible along the line of the original way, it is for a considerable distance perfectly straight,—a circumstance which helps to the general effect.

The gas-lighting, the water-supply, the pave-

ment, the houses and shops, &c., being in tolerable order, the tenants were not long in taking possession; but the time of their stay, except in very few instances, was of very short duration. And it is to be remarked here, as we have noticed it in other localities, the publicans and those who are connected with medicine were the first to commence business; for in the metropolis, except under peculiar circumstances, business comes slowly to the newly-established medical practitioner, and it is often found to his advantage to begin in a recently built and improving neighbourhood. In the Caledonian-road, without taking into account the streets which lead into it, there are now either nine or ten medical practitioners and chemists. Public-houses are also a matter of much speculation: persons who have capital and a fair character purchase or take a lease of one of those large buildings which are reared in what seems to be a desert region, for the purpose of a public-house: for this a beer licence is easily got, and a trustworthy person is put in to manage, and in due

sively brought into use; and the observant wayfarer will note the increased number of assistants who are behind the counters, and the substantial Oxford-street kind of appearance which the road begins to assume. The great Model Prison, as it is called, is a feature of the Caledonian-road; and towards the north, where a junction is formed with the Holloway-road, there is a view of the City prison. These are in no way connected with the prosperity of the neighbourhood, but in this way the new Cattle Market has done useful work; and although the viaduct of the North London Railway has not added to the picturesque beauty of this street, it has brought into it a very large amount of traffic. In the mornings thousands, with carpet-bags in hand, come and go this way citywards; many go to the King's-cross railway station, which has also been a means of causing numbers to come this way. Often at night-time we used to come westward from Islington; and, when we think of the solitude which then reigned, and of the quiet nooks

elsewhere in Ireland. In 1862 a minute description of them was given in a series of articles in *Harper's New York Magazine*. One of the numerous illustrations accompanying them

represented a skeleton which was found "standing with its face to the east," and enclosed between slabs of stone. The student of Celtic antiquities will not require to be reminded that, before his death at Tara, King Lennox (Leary) directed that he should be buried "standing, with his face to the east." The place where he was buried is so precisely indicated in the "Annals of the Four Masters," that there would be no difficulty in digging up his skeleton. E. CULLEN, M.D.

Building in advance.

course of time the proprietor applies for a spirit licence, and this, if the position is well chosen, is worth five or six hundred pounds, and often a very much larger sum. In some cases the speculator is satisfied with this amount of profit, and he disposes of it to some one who intends either to try to make a living out of the business, or to improve it, so that, as the locality improves, the sale of the goodwill, &c., would produce a larger sum in the market; and in this way, in the course of a few years, premises of this kind change hands with profit several times. In connexion with business of this kind, the sums advanced by the great London brewers, so that they may ensure the opportunity of supplying houses with ale, porter, &c., are enormous.

At the first opening of the shops in this thoroughfare, they seemed in most instances to be a sort of forlorn hope. Some houses and shops were let to women whose husbands were engaged in some pursuit which turned in a small but certain amount of income, with a view to add to the sum provided for the family support. Many opened newspaper and tobacconist shops: they also let off apartments; and, in consequence of not getting the rent regularly, and not rightly understanding the trade in which they had embarked, such persons have often found themselves in a very short time in debt to the extent of 100l. or 200l. and more. Widows, and persons who have failed in business, have in those new shops embarked all they possessed in the toy or sweetmeat business, and have generally lost it. Some, with ill intention, have taken houses at a quarterly rent, and having let apartments weekly, have received the lodgers' money, and when the time came for settling with the landlord have gone away without doing so. Many grocers' shops, which have been opened with flourishes of music, have soon become closed; and the experienced eye might formerly have noticed a large quantity of "dummies," in the shape of hams, sugar-loaves, tea-chests, and other things sold in the chandlers' trade. As the adjoining streets began to become properly inhabited, businesses began to have more substantial results; and there could be no doubt that the butchers', and some of the other shops, had become firmly established, and year after year the number of removals has become smaller. And as the demand for shops became greater, the gardens were taken possession of, and devoted to trading purposes; and now the old shops are being newly decorated, plate-glass and brass-work are more exten-

sively brought into use; and the observant wayfarer will note the increased number of assistants who are behind the counters, and the substantial Oxford-street kind of appearance which the road begins to assume. The great Model Prison, as it is called, is a feature of the Caledonian-road; and towards the north, where a junction is formed with the Holloway-road, there is a view of the City prison. These are in no way connected with the prosperity of the neighbourhood, but in this way the new Cattle Market has done useful work; and although the viaduct of the North London Railway has not added to the picturesque beauty of this street, it has brought into it a very large amount of traffic. In the mornings thousands, with carpet-bags in hand, come and go this way citywards; many go to the King's-cross railway station, which has also been a means of causing numbers to come this way. Often at night-time we used to come westward from Islington; and, when we think of the solitude which then reigned, and of the quiet nooks

#### THE CHURCH OF THE AUGUSTINE FRIARS, OLD BROAD STREET, LONDON.

WHEN two some time ago destroyed the roof and fittings of the church formerly belonging to the house of the "Austin" Friars (founded in the year 1243) the removal of the ancient structure, it will be remembered, was threatened. Fortunately, however, better councils prevailed, and London still retains one of the landmarks of its ancient history. Henry VIII., at the dissolution, gave away the house and grounds, but reserved the church, which his son, Edward VI., gave to the Dutch or German nation (1550) "to have their service in, for avoiding of all sects of Ana-Baptists, and such like." From that time to this it has continued in that use. In our second volume will be found views showing the aspect of the church at the time of their publication.\*

The present fabric is the nave only of the original building, which was granted by Edward the Sixth to the strangers in London. This contained also, north and south transepts, choir, chapels of St. John and St. Thomas, chapter-house, cloisters, &c., and there was a remarkable spire, or *flèche*, at the intersection of the cross, all of which were destroyed by the Marquis of Winchester, to whom they had been granted at the Reformation.

The extreme length between the walls is 163 ft., divided into nine bays; the extreme width is 83 ft., the nave being 32 ft. in the clear, and the aisles 21 ft. each. The internal walls are of chalk, and have been carefully restored; the external facing is of Kentish rag, the restoration of which has also been commenced. The window-tracery, where too much decayed to be retained, has been restored with new Portland stone, and all the windows have been glazed with plain glass, by Messrs. Powell. The roofs of the nave and north aisle, which were destroyed by the fire, have been replaced by under-bowed roofs of fir, and the plaster ceiling of the south aisle was removed, and the old roof made to correspond. The tie-beams which secure the walls together form an important feature of the design. The old south porch has been removed. The new interior fittings are all of oak, as are also the two vestries at the ends of the north and south aisles. The general works have been carried out by Messrs. Browne & Robinson; the oak fittings, by Mr. Spawll, of Norwich; the encaustic tile paving, by Godwin, of Hereford. Messrs. Hill & Sons are handling the organ, Messrs. Edward Panson & William Lightly are the architects, the latter gentleman having, we believe, furnished the designs.

#### THE PETROGLYPHS.

SIR,—Having read with great interest the articles which have appeared in the *Builder* relative to the petroglyphs, or circles incised on rocks in Northumberland and Scotland, it occurred to me that they might have had some symbolical meaning in reference to serpent-worship, and that the cup-like hollow in the centre might have been intended to represent the head of the serpent. This conjecture will appear somewhat plausible when it is considered that similar markings have been found on rocks in Central America, and that occasionally also, in the same country, representations of a serpent have been discovered. On this point the following extract from a letter from the Hon. E. G. Squier, American consul at Nicaragua, October 10, 1849. A short distance back from Santiago is the crater of an extinct volcano filled with water. It is surrounded by bare cliffs, some 3,000 or 4,000 feet high, in all places perpendicular, and having but one narrow descent to the water. Upon these cliffs, at the height of 50 ft. or even 75 ft., are paintings of the aborigines, precisely in the style and of the character of those found in the Mexican and Guatemalan MSS. They more closely resemble those of the MS. of the Royal Library of Dresden than any other, which MS. I am convinced was of Guatemalan origin. Some of the figures are identical, and amongst them stands out the *symbolical feathered serpent*, of which I enclose you a sketch. This is a valuable fact in my serpent philosophy. The lake bears the name of Nehapa.

A more decided instance of resemblance between the Celtic remains and those of extinct American races is presented by the monoliths which have been found in immense numbers from Ohio to Mexico, and which are precisely similar in construction to those at Dowth, and

THE INTERIOR OF THE AUSTIN FRIARS' CHURCH, OLD BROAD STREET, LONDON.  
RESTORED UNDER THE DIRECTION OF MESSRS. EDWARD PANSON AND WILLIAM LIGHTLY, ARCHITECTS.

## OUR SOOT-BEGRIMED STATUES AND BUILDINGS.

We have complained many a time, and others have done the same, of the state of the street statues in various parts of the metropolis. Bright and clean as newly-coined money do the memorials of our eminent men appear when they first leave the studios of the artists, and are inaugurated with much pomp and ceremony. Soon, however, their appearance changes, and the countenances of certain of our sovereigns, statesmen, and soldiers assume an Ethiopian tint, which much damages the effect of these works of art. Notwithstanding all complaints, it seems that but little has been done. Within the City the street statues are small in number, and within the metropolitan circuit these art works are but few and far between. To wash them, and make them pleasant-looking would be but a small labour, and would be attended with very little cost. An experienced fire-man, with the judicious use of either the hose, or one of the hand fire-engines which were so much recommended by the late Mr. Braidwood, could soon put a new face upon them. The process of cleaning might be managed at the cost of a few pounds a year. In some instances there is a doubt as to whose duty it is to keep the street monuments clean. This is a question which should at once be settled. The example which might thus be set would, perhaps, be usefully followed in other ways; for instance, in connexion with the City buildings, some of which, now span new, and looking resplendent and bright, will soon, like the statues and so many buildings of older date, be black and unsightly unless something be done to prevent it.

## COMPETITIONS.

*Covering in Area, Abbey Ruins, Reading.*—The committee appointed to obtain designs for the above have selected that submitted by Messrs. Wm. & J. T. B.own. The competition was confined to local architects. The dimensions of the building will be 160 ft. by 90 ft.

## COMPENSATION CASE.

*Combe and Delfield v. The Metropolitan Railway Company.*—This was a compensation case in the Sheriff's Court, Red Lion-square, before Mr. Humphreys, coroner, and a special jury, and occupied several hours. It was for the George the Fourth public-house, Farringdon-road, and adjoining property. The claim was 7,750l. the property was said to be worth between 4,000l. and 7,000l.

The jury assessed the value at 4,750l. In answer to the court, the jury said they did not include the tenant's right in the sum. They intended that he should still have the claim on the railway.

## NEW WING FOR ST. MARY'S HOSPITAL, PADDINGTON.

AND with its new wing, may the hospital take higher flight! On Tuesday next, at half-past three o'clock, H.R.H. the Prince of Wales is to lay the first stone of the addition, of which Mr. Petherden Young is the architect, rendered necessary by the growth of the district. Since 51, when the hospital got into work, about 700 cases annually have been received within wards, while upwards of 150,000 have been treated in the out-patient department. The head of the metropolis generally has, however, little effect upon this particular district; and at barely supplied the want of 1851, is found wholly inadequate to meet the requirements of 1865. Additional accommodation to provide for the unusual influx of accidents or urgent cases is consequently imperatively called for, and it has therefore been decided to erect a further portion of the building contemplated in the original plan. Great preparations have been made for the ceremony. Seats have been built up and covered over, and an energetic committee of influential ladies have been working hard to give the ceremony a success. Now, then, you are disposed to help, walk up with your friends! The Prince will himself receive them.

## SIR GOLDSWORTHY GURNEY AND THE STEAM-JET.

SIR GOLDSWORTHY GURNEY, on whom the honour of knighthood was conferred in September, 1863, for his services, was but two months afterwards seized with a violent attack of paralysis, materially induced by constant mental application to those services which nearly put an end to his life. He has ever since been completely withdrawn from the scientific world, his right side being still so affected that he cannot rise from his seat, or walk across the room without assistance. He has great difficulty in talking so as to make himself understood, and signs his name only with his left hand. He had previously held the appointment of director of the lighting and ventilating of the Houses of Parliament for ten years. Leave of absence from his duties was granted up to the 20th of July, 1864, when there being no chance of his recovery, he was compelled to retire. During his absence, his system of lighting and ventilating was conducted by Mr. A. Gordon, and it speaks well for the soundness of the system that a comparative stranger to it should have been able at once to conduct it satisfactorily.

Sir G. Gurney first introduced his mode of lighting into the temporary House of Commons in 1839, and his plan continued in use till the new Houses of Parliament were opened; his light was then placed in them, under other management, and without reference to him, and was not arranged so as to give satisfaction. His services were therefore again required, and he made the same arrangement for the new Houses of Parliament that he had made for the temporary House of Commons. His Bude light gas-burners are placed over the ceilings, which are of glass, and so contrived that no heat from the light is allowed to enter the Houses.

The Houses of Parliament are warmed by apparatus invented by him especially for this purpose, viz., by small batteries, which are placed under the floors; they work well, and regulate the temperature of the Houses, which during the sittings is by this means almost self-adjusting, and but few attendants are required to watch it.

When Sir G. Gurney was requested to arrange the lighting of the new Houses of Parliament, he found great complaints with the ventilation; and having suggested the application of his steam-jet, he was engaged to arrange the ventilation of the House of Commons, and succeeded so completely, that in 1854 he was, at the recommendation of committees of both Houses, appointed to take the whole charge of the lighting and ventilating of both Houses.

The steam-jet is used not only for the ventilation of the Houses of Parliament, but also for the sewers underneath those buildings. It was also used for the ventilation of the Friar-street sewer, at a time when its noxious vapours were poisoning the whole neighbourhood, and a report of this operation was printed by order of the House of Commons in 1850.

He had indeed suggested the steam-jet for the ventilation of coal mines, before a committee of the House of Lords on accidents in coal mines, so long back as 1835; and the principle was introduced at Seaton Delaval, where it continues to be used with complete success. He also extinguished the Ashley coal-pit fire, by using it to draw choke-damp through that mine, in 1850.

The steam-jet is used in the blast furnaces in Wales; and for chemical works in the north of England. Where great heat or great draught of air is required, it is a steam engine in itself; and for these purposes no other steam-engine need be used in connexion with a boiler. The steam-jet is applied to many great and useful works in this and in other countries.

This steam-jet, indeed, may be described as Sir G. Gurney's greatest invention; he conceived the idea, during a course of lectures on the "Elements of Chemical Science," which he gave at the Surrey Institution in 1822, and the jet itself was used by him in the year 1825 for creating a draught through the boiler fire of a steam carriage, which he had constructed to run on common roads, and with such success that a journey from London to Bath, on the 28th of July, 1829, with this carriage was accomplished at a rate of from fourteen to twenty miles an hour. Some of these carriages were finished in 1830; and Sir C. Dance ran them between Cheltenham and Gloucester four times a day for four months—from the 21st of February to the 22nd of June, 1831—at the average rate of twelve miles

an hour on the common road, the rate at times being twenty or more; but alarm being felt by the public, and opposition arising from the coach proprietors, Parliament was induced to suppress these carriages, by imposing heavy and prohibitory turnpike tolls upon them.

Three months after Sir G. Gurney's successful journey to Bath, his invention of the high-pressure steam-jet was applied by Stephenson to railway carriages, and the slow rate of travelling previously obtained by them, viz., eight miles an hour, was by their means suddenly raised to the speed of forty miles an hour.

Sir G. Gurney's steam-jet was about the same time applied to all steam-vessels, and their speed was also proportionally increased by this powerful agent.

In 1822 Sir G. Gurney had invented a blow-pipe for mixing the inflammable gases with safety, for which he was presented, by the Duke of Sussex, with the Gold Medal of the Society of Arts; he burnt the gases on lime, and thus discovered the lime-light, which he treated of in his lectures, published at that time by Whittaker. And, when his common road steam-carriage project was crushed, he again turned his attention to light, and was engaged by the Trinity House to perfect the lime-light for lighthouses; which, however, could not be done owing to its liability to sudden and unexpected extinction, from the cracking of the lime under the intense heat of the flame. His experiments were made at Bude (his residence), which resulted in the discovery of what was afterwards called the Bude Light.

The last light invented by him was the oil gas light: it has been in constant use in H.M.S. *Resistance*, where it was placed by him more than two years since.

To this light-apparatus he added a plan for flashing in time (as by the electric telegraph); and suggested to the Admiralty, War Office, and Trinity House, a mode for ship and land signalling with it (by day as well as by night); in other words, for a flashing-light telegraph.

At a *séance* of the Royal Society, held at Burlington House, on the 2nd of May, 1863, the Prince of Wales flashed this light. Sir G. Gurney was again turning his attention to light-houses; and was writing a pamphlet showing a means whereby a seaman may identify light-houses and find his ship's distance therefrom; when his hand was seized, and his career of usefulness suddenly brought to a close.

## THE BUILDING TRADES.

*Dorking.*—The bricklayers' labourers in the employ of the different builders in this town have struck for an advance of wages, an increase of 6d. a day being stipulated for—a request, however, their employers have not yet acceded to.

*Plymouth.*—The Government authorities have arranged for the employment of soldiers where their services can be made available, and of convicts as excavators, and have expressed their intention of relieving the contractors from any penalties arising from the non-execution of any work according to the terms of the contract. It is estimated that some 4,000 to 5,000 workmen in the various branches of the building trade will be thrown out of employ should the dispute remain unsettled.

*Swansea.*—The painters of Swansea, who have been out on strike, have resumed work, the masters having unanimously agreed to grant the advance of 6d. per day.

*Wolverhampton.*—The bricklayers and labourers are now on strike for an advance of fourpence a day. The painters have also given notice for an advance of sixpence a day. The works of the new Independent Church, now in course of erection at the top of Queen-street, have for the third time been brought to a standstill by strikes.

*Darwen.*—The master plasterers have complied with the request of the men in their employ for an advance of 3s. per week on their former wages. All the men have resumed work.

*Stockton.*—The joiners of Stockton-on-Tees have struck. They demand a half-holiday on Saturday, and an advance of 2s. per week on their present wages.

*Rotherham.*—The bricklayers and their labourers at Rotherham are for the most part out on strike, in consequence of the employers having refused to accede to their demands. A month ago the men gave notice of moving for an advance of wages. The bricklayers asked for an advance from 4s. 6d. to 5s. per day, and the

labourers from 18s. to 20s. per week. A stipulation was also made that the employers should engage no men but such as were connected with the unions. Some of the employers have decided to give the advance asked for, and some will not; but they are unanimous in refusing to have anything to do with the question whether or not a man is a member of the union. Under these circumstances most of the men have left their work, and are now out on strike. The measures taken by the operative painters to obtain an advance of wages have proved successful. A resolution was passed, and forwarded to the employers, asking for an advance of 2s. per week upon the present rate of wages. The employers promised to grant the advance asked for. The standard wages of the painters in this town will now be 21s. per week.

**Newcastle-upon-Tyne.**—The operative painters of Newcastle, a short time ago, gave notice to their masters for an advance of wages. A deputation from the men has waited upon the masters, and the result was that the masters offered to give the men an advance of 1s. a week, and 6d. an hour overtime. The men accepted the offer, and, to the satisfaction of all parties, a strike was avoided.

**Penrith.**—The joiners and carpenters of Penrith, having been working at the rate of sixty hours per week, and having observed the successful issue of the late strike in Carlisle, a large portion of them solicited a reduction of two hours per week. The employers resolved that a six months' notice should be required. The men have offered to "split the difference." The painters, plumbers, and plasterers have made application for an advance of 2s. per week. It is thought the employers will accede to the application.

#### THE ARCHITECTURAL ASSOCIATION.

The usual meeting of members was held on Friday evening (the 12th inst.), at the House in Conduit-street.

The chair was occupied by Mr. R. W. Edis. Mr. T. W. M. Mansell, of 9, Alma-terrace, Kensington, was elected a member of the Association.

The Hon. Secretary reported that a visit had been paid by some of the members to the model lodging-houses now being built by the trustees of the Peabody Fund, in Islington, under the direction of Mr. Derbishire. A vote of thanks to Mr. Derbishire for his courtesy in the matter was agreed to.

Mr. H. Dunphy withdrew his motion to alter the hour of meeting to eight o'clock, explaining that he found it unnecessary to press it, as practically the hour for assembling was nearer to eight o'clock than half-past seven, as it had been predicted it would be when the change was made.

Mr. J. D. Mathews read the report of the delegates from the Association who had attended the meeting of the Architectural Alliance on the 6th of July last.

Mr. L. W. Ridge read the draft of a circular suggested by the Architectural Alliance to be forwarded to the managers of competitions.

The Chairman said that as two of the delegates who had attended the meeting of the Alliance were present (Mr. T. Blashill and Mr. T. M. Rickman), it might perhaps be desirable to ascertain whether they had any observations to make.

Mr. Rickman said that the delegates did not desire to express any decided opinions upon the circular, as they conceived it to be their duty simply to report, and leave the matter to be dealt with by the Association. He might, however, observe that the circular was intended for the guidance of such persons as might be unfortunate enough to be in the position of inviting competitions.

Mr. Ridge expressed his opinion that the circular might, perhaps, do some good, but that he objected to many of the details as being minute and unnecessary. He objected, for instance, to its being laid down that the walls should be coloured with Indian ink, sepia, or neutral tint, &c.; that no colour should be used in perspective drawings; and so forth. He suggested that all the paragraphs relating to these details should be struck out.

Mr. Mathews also stated his objections, and suggested that the circular should be sent as early as possible, in order to be of use. He was decidedly of opinion that the question of cost

was essential, and that the scale of drawings should also be fixed.

The Chairman was of opinion that many of the paragraphs in the circular were susceptible of modification, and hinted that it would be desirable in the preparation of such a document to avoid the use of any terms which might be considered in the slightest degree dictatorial. He was sure that those who might invite competition, and that their only object in moving in the matter was a desire that those who might devote their time and trouble in preparing designs should be fairly treated. He agreed with the last speaker in thinking that the question of cost was a *sine qua non*; and he also thought that the scale of drawings should likewise be fixed. With regard to drawings he thought the point ought to be left open, as it would be impossible to give the necessary effect to certain drawings without the introduction of colour. In the paragraph suggesting as an invariable condition that the author of the selected design should be employed to carry it out at the usual rate of remuneration, "should be a person of sufficient experience to warrant the promoters in entrusting the work to him," he would suggest that all the words after "remuneration" to the end of the sentence should be struck out. He quite agreed, however, with the circular that, in certain cases when works of any magnitude were to be carried out, it would be desirable, in order to secure a more experienced tribunal than a committee, that the matter should be referred to one or two architects of "admitted experience, honour, and discretion."

Mr. Rickman said that, as the great object of competitors was justice, it was but right that they should keep to their instructions; and to enable them to do so, the instructions ought to be as clear and explicit as possible. This was what the Alliance recommended. In his opinion an architect wishing to compete ought to send to the Alliance for a copy of their circular, in order to adhere as much as possible to its suggestions.

After some further conversation, The Chairman read the suggested amendments, which were eventually agreed to, and a vote of thanks was passed to Messrs. Blashill, Rickman, and Bunker, the delegates of last year. Messrs. T. R. Smith, Rickman, Christian, and Eddis were elected as delegates for the current year.

The Chairman brought under notice the recent cottage competition of the Society of Arts, and observed that, in his opinion, the Association had been badly treated by the council. He called upon Mr. Blashill to make a statement relative to the matter.

Mr. Blashill said that the instructions issued by the council were very clear, and that the task of competing was a very severe one. Nine designs had been forwarded by members of the Association, and ninety-nine were sent from the United Kingdom. Looking at those proportions, he could not agree with the judges that the Association had not been well represented. He thought the report was a very unfair one, and that the Association ought to protest against it.

A protest in accordance with the views of the meeting was agreed to.

#### THE BRAYE MONUMENT, STANFORD-ON-AVON.

The Countess of Beauchamp, one of the four owners of the Stanford estates and one of the four co-heirs of the barony of Braye, has recently erected, in the church of Stanford-upon-Avon, in Northamptonshire, the mausoleum of the Cave family, a monument to the memory of her mother, the late Baroness Braye, the joint production of Mrs. Thornycroft and of Signor Giovanni Fontana, kindly superintended by Mr. Gibson, the sculptor.

It consists of a life-size portrait recumbent statue, in Carrara marble, the feet resting upon a greyhound couchant, by Mrs. Thornycroft. The figure reposes upon an altar tomb, of statuary marble, on which the inscription and the heraldic quarterings of the deceased are carved. The background of the monument is formed by a bas-relief, the work of Fontana. It represents a figure kneeling by a cross near a bed of snow-drops, finely carved, above which float a group of three angel children, designed by Gibson, supposed to be in the act of receiving the spirit of the departed.

The bas-relief is inclosed in a moulded Gothic

arch, of Sicilian marble, 10 ft. 8 in. high, supported by two buttresses, 12 ft. 8 in. in height, in the style of the architecture of the church. The text, "I know that my Redeemer liveth," is carved in raised white marble letters above the arch, surmounted by a battlemented cornice.

The architectural portion of the work was executed by Mr. Underwood, of Camden Town. The white marble platform, on which the altar tomb is placed, is inlaid in Mosaic, by Mr. Poole, of Westminster, in the style of the *tre-cento* period of Italy: the pieces of marble employed are cut from 700 fragments of antique marbles, collected by the lady to whose memory the monument is erected, at Tuscum and other ancient ruins in Italy. The design for the mosaic was suggested by a mosaic in Westminster Abbey. This platform is approached by a plain white marble step, upon which are placed, in relief, some religious emblems to illustrate an illuminated marble scroll, with the 5th, 6th, and 7th verses from the 12th chapter of Ecclesiastes. The cost of the monument exceeded 2,000l.

#### PROVINCIAL NEWS.

**Horsham.**—It has been determined to establish a corn exchange and market here, by means of a joint-stock company.

**The Potteries.**—We are requested to state that the architects of the North Staffordshire Infirmary are Messrs. Lynam & Nichols.

**Towyn (North Wales).**—New brick-fields have recently been opened in this neighbourhood, and excellent clay found for the purpose. Machinery, stoves, and sheds have been erected at Bronpys Brick and Tile Works, which have changed hands lately; and at Caedlle Yard, a large water-wheel is in course of construction, besides all the other requisites for carrying on an extensive trade. Brick-fields near a neighbourhood like Towyn, where so much building is going on, and where there is every likelihood of a large town being built near the beach, will be very convenient.

**Blackburn.**—The new Exchange has been opened. Its site presented difficulties. Besides the irregularity of the plan, the levels must have caused trouble, there being over 6 ft. of fall in the length of that which may be called the principal front: for one-half of this front faces the town-hall, whilst the other half forms the north side of King William-street. The latter portion may be described as retiring from the line of the former at about 45 degrees, the apex of the obtuse angle being curved by a large radius. The front in Town-hall street forms an acute angle of about 70 degrees with that facing the town-hall, and presents the same difficulties in the levels of the ground as in the main front. The Exchange-room, with its minor entrance-hall, approaches to the basement, &c. occupies the whole site in King William-street. The room is 53 ft. in clear width, from wall to wall, and 149 ft. in its extreme length, giving an area of about 800 square yards. Centred with the room at one end is the principal entrance vestibule, an octagon of 25 ft. in internal diameter, having two entrances from the street, one parallel with King William-street, and the other parallel with the town-hall front. From this vestibule is also the principal entrance to the exchange-room, the news-room, and the approach to the other portions of the building, to be retained for the business of the Exchange Company. This vestibule external finishes as a tower of separation to the two portions of the principal front. The Exchange proper has been treated as a distinct feature in the composition, excepting that all the main horizontal moldings above the plinth are to be repeated, and will be on the same level also, as the other fronts. The first contract has been confined to the Exchange, and the principal entrance vestibule or tower, up to the level of the parapet, with the offices and ware-rooms the basement. The style of architecture adopted was suggested by the irregularities of the site which precluding the use of any architecture Classic severity, Gothic was chosen by the architect, who studied under Sir Charles Barry. The building is wholly of stone, excepting the piers and groined arching of the basement, &c. the cross walls of the offices, which are of brick and cement. The tower vestibule is faced, both inside and out, with Longridge stone, as well the front of the exchange externally, and the external dressings of the back and flank, which Darwin stone parpouts are used for the wall face. The internal dressings of the exchange

are of Burnley stone. Mr. Brakspear, of Manchester, has furnished the designs for the whole of the works, and under his direction they have been carried out. Mr. J. Simpson has acted throughout as the clerk of works. Mr. Farrell, of Manchester, has been the general contractor, under whom many townscpeople have acted as sub-contractors. Messrs. Gabbutt & Son, of Liverpool, were the contractors for the masonry and brickwork; Messrs. Edmondson & Son, of Manchester, for the glazing throughout; Mr. J. H. Dovey, of Manchester, for all the metal-work and gas-fittings; Mr. J. Casartell, of Manchester, did the asphaltting of the roof; Mr. Banks, of Manchester, executed all the wood-carving; and Mr. Gregg, of Darwen, all the stone-carving; Messrs. Minton & Co. were the contractors for the tiling; and Messrs. Haden & Son, of Trowbridge, for the heating.

**Cockermouth.**—A company is likely to be formed in Cockermouth for the purpose of building a public room for entertainments, lectures, &c., with shops on the ground-floor. Building appears to be in an active state in Cockermouth. Station-street is springing up, as also is the Mountain View suburb. It is not unlikely, it is said, that a hotel will be built close to the new railway station.

#### WESTMINSTER PALACE.

On the vote of 49,466l. for defraying works and expenses of the new Houses on Parliament, being taken in the House of Commons on Friday last, Mr. Cowper, in reply to questions asked, said that upon the recommendation of the Select Committee, it might be remembered, the sum to be paid to Mr. Herbert for the painting of "Moses delivering the Law," was raised to 5,000l. The committee also recommended that the existing agreements, being found inapplicable to present circumstances, had better be cancelled, and this had been done. The Government had also asked Mr. Herbert what sum he would receive for the other painting, the "Judgment of Daniel." Mr. Herbert had mentioned that that was a very proper sum; accordingly, an agreement had been entered into with Mr. Herbert for that amount. The design for this picture had been approved by the Fine Arts Commission, and was greatly admired. Mr. Faclise had nearly finished his picture, and he would be entitled very shortly to receive payment for it, the sum having been raised to 1,000l. In the same way the paintings of Mr. Hope and Mr. Ward were to be raised by 1,000l. each, and every painting would in future be made the subject of a separate agreement.

The sum proposed for the completion of the clock tower and New Palace-yard was intended to be spent in this way. The clock tower was to be completed, so that the side which was now imperfect might have the same form and the same front as the sides which were finished. It was proposed to take the opportunity of making a subway, by which hon. members might reach the other side of Bridge-street by a much safer route. This subway would open into the station of the Metropolitan District Railway, which was proposed to be made on the other side of Bridge-street, so that persons coming to and from Westminster would be able to pass into and out of the station without crossing the road.

With regard to the open space it was not considered desirable to carry out the suggestion of Mr. C. Barry, of constructing New Palace-yard into a quadrangle. There was now such an opportunity for producing space in combination with the Parliament-square, that it was thought desirable that attention should be directed to other means of producing a large open area than to diminish it by new buildings. Hence the space would remain. An iron railing would be substituted for the wooden temporary fence which is now erected, and the slope would be turfed and planted with trees.

There was to be a station of the Metropolitan Railway opposite the clock tower. The remaining houses in Bridge-street would be given up to the company for that purpose only on the understanding that they would erect their buildings in a style that would harmonise with the new buildings,—namely, in the Tudor style.

**ARCHITECTURAL MUSEUM.**—On Tuesday last a paper read was on "The Precinct of a Gothic Master," by the Rev. Mackenzie E. C. Walcott. This was the last lecture for the season.

#### FACTORY CHIMNEYS.

MR. PETER CARMICHAEL has recorded a series of experiments for ascertaining the best size for factory chimneys, in a paper read at a recent meeting of the Institution of Engineers in Scotland. He observes that the importance of an effective chimney need only be named. On it depends in a great measure the success of the firing, so as to raise steam quickly and keep it up steadily, and also the perfect combustion of the fuel with the least amount of smoke. With a draught in the chimney less than 5-10ths on the pressure-gauge, the firing of the furnaces will, in most cases, be a constant toil to the fireman. He cannot avoid making a large quantity of black smoke, and in cases of an extra demand for steam, it is impossible to meet it, for no stirring or coaxing of a fire will make it burn brightly, or produce the red glow which is the perfect condition for raising steam, without a full command of draught. His experience is, that most factory chimneys are too large for the work they have to do; not too high (they can hardly be that), but too wide, especially at the top. In their practice, invariably as more boilers and furnaces have been added to a chimney the draught has been improved, and it is obvious that if the opening in the chimney be too large compared with the whole of the openings in the dampers passing into it the draught will be reduced. Hence it is very noticeable in many chimneys, which are large in proportion to the number of furnaces they serve, or the coals consumed, or where a new chimney is put up to serve for prospective additional furnaces, the smoke issuing from such has a very lazy ascent, and they are generally blackeued a long way down from the top by the smoke; for when a breeze is blowing, the smoke, instead of ascending, falls down the leeward side of the chimney, and elings to it like a ragged black flag. From observations, frequently repeated and tried under various circumstances, it has been found that the temperature is nearly uniform at 600° behind the dampers. He builds his chimneys in the form of an obelisk. The taper top is found to answer the purpose well, the smoke ascending from it very freely, especially when there is a breeze of wind. At such times the ordinary top is acted on like a key when blown into to make it whistle, the blasts of wind affecting very perceptibly the draught of the furnaces. In the taper top this is not much felt, as the wind can only blow into one or two of the four compartments at a time, and this still allows the other two to vent freely. The greatest want of draught is occasionally on Monday mornings, after a cold wet Sunday. In such cases the flues and chimney are cooled down, and the draught greatly reduced, so that the firemen have much difficulty in getting the fire to burn brightly, and keep up the supply of steam.

#### ARCHITECTS' ACTIONS.

**KNIGHTLEY v. WAITE.**—This was an action in the Lord Mayor's Court, before the Recorder and a common jury, to recover 12l. 12s., for architectural drawings for stables.

Mr. McIntyre, in opening the plaintiff's case, stated that in October last he received a communication from the defendant, a gentleman of Norbiton, requesting him to make drawings for some stables. This was done, and the drawings duly delivered. After some delay, the defendant made an objection to the expense that would attend the erection of stables upon the drawings furnished; but the drawings had not been returned, and it was clear plaintiff should be paid for them.

Evidence having been called in support of this case, Mr. Talford Salter urged that the defendant should not be called upon to pay the demand. He had taken a cottage for three years, and the landlord had allowed him 200l. to build certain stables. The plaintiff's drawings and estimates would come to 500l., and he was requested not to exceed 200l. The defendant had had very convenient stables erected at a cost of 200l.

His lordship, in summing up, pointed out to the jury that they would have to say whether the plaintiff had obeyed the instructions of the defendant as to the expense of erecting these stables.

The jury found for the defendant.

#### TOTTENHAM COURT ROAD TO THE STRAND.

SIR,—As your paper is the only reliable organ of information regarding public improvements and the construction of new streets, I have ventured to call your attention to the strange apathy exhibited by the promoters of the North-Western and Charing-cross Railway Bill with the contemporaneous formation of new streets from Tottenham-court-road to the Strand. It

is now some nine months since the Bill became law, and they have made no sign. It was carried through Parliament with a high hand, at a vast expense, with the unanimous approval of an able and painstaking committee; the engineers, of the highest standing, including Mr. Hawkshaw; the London and North-Western Railway giving their support to the undertaking. Accidents are of constant occurrence, especially at the junction of Chandos-street and St. Martin's-lane, in addition to others in the neighbourhood of St. Giles's. Probably the insertion of the above, or a few remarks from you, may rouse the dormant energies of the originators to a sense of their obligation to the public, as the thoroughfares in this district are daily becoming more crowded and dangerous.

A DENIZEN OF CHARING-CROSS.

#### ST. BARTHOLOMEW'S, DUBLIN.

SIR,—In the account of St. Bartholomew's Church, Dublin, in the number of the *Builder* for May 6, it is stated that "the Archbishop of Dublin contributes the handsome donation of 500l. in aid of a fund for augmenting the endowment." This sentence is from the original circular respecting the church, but it requires considerable modification. In the first place, we must read, "the late Archbishop of Dublin," for it was Dr. Whately who gave this contribution. And, in the second place, instead of its being devoted to augmenting the endowment, "it was thrown into the building fund," which, even so, exhibits a deficit of nearly 2,000l. This sum I am now making earnest efforts to raise, and I trust that many who are friendly to the principle of free and open churches will be moved to aid me.

ARTHUR DAWSON, Incumbent.

#### CHURCH-BUILDING NEWS.

**Diss.**—A school-chapel has been opened at Diss Heywood. The edifice is of red brick, and in the Early Decorated style. The school is held in the western part. The cost amounted to 725l. The backs of the benches, by the adjustment of a screw, are elevated so as to form desks, and by being further elevated into a horizontal position they become tables. There is a residence for the schoolmaster attached.

**Knapwell (Cambridgeshire).**—The parish church of Knapwell has been consecrated. The old tower still remains, but the rest of the church has been completely rebuilt. As the village is small (consisting only of a population of 150), and the funds were not abundant, it was not considered advisable to attempt to build on the original design; and therefore a nave and chancel, with vestry on the north side, form the present plan. The chancel is furnished with an apse at the east end, and separated from the nave by a small screen. There is no chancel arch, but the formation of the roof is different, so that the division is marked. All the seats are made of oak, and the old altar has been re-worked into the new one. The church is 17 ft. 6 in. wide, and 61 ft. long, and accommodates 119, including the school children. The contract has been executed by Messrs. Bell & Son, of Cambridge, and the whole work has been designed by Mr. W. M. Fawcett, of Cambridge, architect.

**Idle Hill (Kent).**—The foundation stone of the new church, in this village, has been laid. It is in the Early Decorated style, and consists of nave, chancel, north and south transepts or chanceries, and a tower and spire. The height of the tower and spire together, is 90 ft. The church is to be built to seat 200 persons. The architect is Mr. C. H. Cook, of London, and the contractor is Mr. John Kirk, of Woolwich. The cost will be about 2,500l.

**Cranley.**—It has been resolved that the alterations and additions in the church shall be made, as originally contemplated, under the superintendence of Mr. Woodyer, the architect; and that Mr. Thurlow be required to enter into a bond, to commence and complete the work in a stated time, and in such manner as may be approved of by Mr. Woodyer, on the part of the parish, and according to the plans submitted to the vestry.

**Romsey.**—The subscriptions for the new roof of the north transept of the Abbey church are progressing. Upwards of 500l. it is said, have been promised, and there is good probability

that the sum required for this alteration and improvement of the church will be soon realized.

**Tettenhall Wood (Staffordshire).**—The foundation-stone of a new church at Tettenhall Wood has been laid. The edifice is to bear the name of Christ Church, and is to have a separate district assigned to it. The designs of the church have been prepared by Messrs. Bateman & Corser, of Birmingham, architects, whose plans were selected in a limited competition of local architects. The style of architecture adopted is Decorated Gothic, of simple character. The length of the building will be 100 ft., the width 60 ft., and the height 75 ft. The tower and spire will be 150 ft. high. The church will consist of nave, north and south aisles, with north and south porches, chancel and chancel aisle, tower and spire, with vestry in tower, and organ-loft over. The whole of the roofs will be open-timbered. The nave will be separated from the aisles by four arches, and the aisles covered by four span roofs at right angles with the nave. In each aisle will be four three-light tracery-headed windows, and a five-light window at the west end of the nave; and in the chancel (which is apsidal) will be three-light windows, with external gables over each window. The church will provide accommodation for 700, and the school children will be located in the chancel aisle. The whole of the exterior of the church will be built of Colwall stone, as also the internal arches and piers. Mr. John Cockerill, of Wolverhampton, is the contractor for the building, which is to cost about 2,700*l.* exclusive of the tower and spire.

**Llanely.**—We understand the contract for erecting St. Peter's Church, Llanely, has been taken by the firm of Messrs. Jones & Co., of Gloucester, the contractors who are erecting Neath Church.

### Books Received.

*The New Path: a Monthly Art Journal.* April, 1865. New York: James Miller, Broadway.

*The New Path* for April contains a paper on Miss Hosmer's statue of Zenobia, and one titled "Our Furniture: what it is, and what it should be." The writer of the first, instead of taking a new path, follows an old one, and a wrong one, in asserting that the American works sent to the 1862 Exhibition were treated with the same "studious disregard which everything American instinctively received in England at that time." Mr. Page's portraits, says the writer, were left to shiver by themselves in the gloomy American department; Mr. Story's fine statues were placed so that they could not be seen; and Miss Hosmer's "Zenobia" had an "ignominious position" at the "back door" of Gibson's Temple. Such evil misrepresentations are to be regretted; and, when made, as in this case, by one professing to write with high aims, and with truth for a watch-word, to be wondered at. The position of Mr. Page's pictures was determined by the small committee of Americans who at the last moment arranged their department: one of Mr. Story's striking statues was placed so that it was the first thing that met the eye on entering the Roman Court, and the other so that it was the last object seen on quitting it; while Miss Hosmer's "Zenobia," set up by special arrangement in connexion with her master's works, had one of the most prominent sites possessed by statue in the whole exhibition. Not the least curious part of the matter is that, after these unfounded complaints, the writer proceeds to show, by nine columns of print, that the "Zenobia" is a thoroughly worthless statue, unworthy of any place at all!

We have pointed to these observations because we revolt against any attempt that is made to foster unkind feelings between two kindred nations, speaking the same tongue and animated to a great extent by the same motives; and would reprobate it strongly from whichever side of the Atlantic it might proceed.

*Lacon in Council.* By J. F. Boyes, author of "Illustrations of Æschylus." London. 1865.

Books of aphorisms are generally peculiarly interesting as well as instructive; they may not quite resemble "the liad in a nutshell" but they may be regarded as the concentrated essence of the thoughts of an observing and reflective mind. We know few books more attractive, or the spirit of which more thoroughly penetrates, and communicates its flavour to,

our own mind, than Arthur Warwick's "Spare Minutes," or Owen Feltham's "Resolves." Save Colton's "Lacon," few modern works of the kind have appeared which have attracted a moderate degree of attention for even the clever "Guesses at Truth" made their way slowly into favour. French literature has always been much richer in works of this kind than our own. It may be that the French mind is more readily taken with anything that partakes of epigrammatic smartness, or antithetical point. It may be, also, that John Bull's John Bullism indisposes him from accepting readily the thoughts of another man, when offered to him in a shape that seems to indicate that they are in any degree better than his own; hence he looks at them askance, and with some sort of jealousy, as if they jarred against his *amour propre*.

From the works thus alluded to Mr. Boyes's differs, inasmuch as each subject is introduced by a quotation from some other writer. These quotations are made the subject of comment, either in confirmation or elucidation, and sometimes in refutation: they show a range of reading only surpassed in extent and variety by that of Southey, as manifested in his "Common-place Book." To attempt to convey an accurate notion of the contents of this work from a single or a few specimens would be nearly as ridiculous as the conduct of the well-known foolish fellow who carried a brick about with him to give an idea of the house he had to sell. One such, however, we must give:—

"When writing earthworms meet th' unwelcome day,"  
Blossfield: "Spring."

"As true of the human heart as of the field, when the sun and the ploughshare of truth and conviction are at work upon it."

To the book itself we refer our readers, not doubting but that by its perusal they will obtain a rich supply of intellectual matter, which they may read, mark, and inwardly digest.

### VARIORUM.

"Murray & Co.'s Book of Information for Railway Travellers and Railway Officials." By R. Bond. Murray & Co., Paternoster-row. This is both a useful and an amusing volume; but it must be kept in mind that it gives the public advice and instruction from the superintendent's point of view, the author being the superintendent at the Newport station of the Great-Western Railway. The information is illustrated with anecdotes, &c., which render it all the more readable and instructive.—"The Acts concerning Inventions and Designs exhibited at the Dublin International Exhibition, 1865, and Industrial Exhibitions generally." By F. W. Campin, barrister-at-law. London: Stevens, Lincoln's-inn. This comment on the Act 25th Vic., cap. 3 and cap. 6, will be useful for the purposes in view. It contains notes and citations of modern and important cases, as to exhibition, publication, and user; also a statement of some principal points in the law and practice of patents; with an appendix, containing the provisions of the Art-copyright Act, 1862, and the Merchandise Marks Act, 1862.—"An Appeal to all Christians and the Jewish Nation to liberate Jerusalem." By C. F. Zimpel, F.M.D., Chief Engineer of different railways in America and Europe. London: Stevenson, Paternoster-row, 1865. On the title-page of this pamphlet are the words, "100,000 copies in different languages," which mean, we suppose, that 100,000 copies have been so printed, or are to be. The author ingeniously proves that Jerusalem and the surrounding country belong at present to the Devil, at least if that gentleman is to be believed; for he himself said, upon a well-known occasion, "It is delivered unto me and to whomsoever I will give it." Mr. Zimpel does not want either to purchase or to ask it from the present proprietor, but he wants his fellow Christians, and the Jews, to help him to take it from him and to hand it over to the proper owner. If this can be done, by running railways through it and otherwise improving it, as Mr. Zimpel no doubt contemplates, good and well: the proper owner is one who requires no other sort of human agency to help him towards the repossession, if he desires it. Perhaps he did not unmercifully deliver it over to the Devil after all, although the Devil said so. We ought, at all events, to have better authority than this before we cast a greedy and worldly eye upon a fine country in possession of even "a sick man" whose Christian and semi-Christian subjects we have already defended from the attack of a Christian emperor

who coveted this neighbour's land, as others seem to be inclined to do. Our possession, we fear, would not make it more holy or less desecrated than it is: witness even now the unseemly Christian squabbles over the holy sepulchre itself.

### Miscellaneous.

**ARCHITECTURAL PUBLICATION SOCIETY.**—The annual general meeting of this Society will be held on Friday afternoon, the 26th instant, at No. 9, Conduit-street, Mr. Beresford Hope taking the chair at three o'clock.

**THE DANTE FESTIVAL, FLORENCE.**—The Festival passed off most successfully. The statue is described to us as horribly ugly and out of drawing. An expected account of the Festival, from our correspondent there, had not arrived at the time of going to press.

**THE SURREY THEATRE.**—We are requested by Mr. C. N. Foster, the builder, to state that the formal doings as to the laying of the first brick in the foundation of the new theatre, of which an account was recently forwarded to us, was an affair of the neighbourhood; and that due notice will be given of the formal laying of the chief stone.

**PERUVIAN RAILWAYS.**—The National Bank is authorised to issue 66,800 shares of the Peruvian Railway Company, Limited, of 25*l.* each, representing a first issue of capital aggregating 1,670,000*l.* The Peruvian Government have granted a concession in the shape of a guarantee of seven per cent. per annum on the whole capital, viz. 3,340,000*l.*; and a redemption fund is also to be formed from the capital raised, by means of which shares will be periodically drawn after the expiration of twenty years, and paid off at a stipulated premium of 100 per cent. The International Contract Company, Limited, have entered into a contract for the construction of the works.

**INSTITUTION OF CIVIL ENGINEERS.**—The anniversary dinner of the Institution of Engineers was held on the 12th instant, in Willis's Rooms, St. James's. The chair was occupied by Mr. John R. M'Lean, C.E., the president, who was supported by Mr. Fowler, Mr. Gregory, Mr. Scott Russell, Mr. Chhitt, Mr. Harrison, Mr. Hemans, Mr. Vignoles, &c. The company numbered between 200 and 300, and included the Duke of Somerset, Earl Granville, the Earl of Devon, the Earl of Donoghmore, Lord Stanley, M.P., Sir Charles Wood, bart., M.P., Sir John Pakington, bart., M.P., General Sabine, Sir Roderic Murchison, the Lord Mayor, Sir Rowland Hill, Admiral Robinson, and many other men of note.

**THE BALL-ROOM AT CREMORNE.**—Sir: With reference to the report of the action, "Bliss & Smith," in the *Builder* of the 6th inst., I beg to say that I in no way acted in conjunction with Mr. Allom, in the construction of the hall-room at Cremorne Gardens, my duties being solely in connexion with the building of the new suite of offices attached to the Cremorne Hotel. Both works were certainly proceeded with at the same time, and included in the same contract between Mr. Smith and Mr. Davis, but our duties were quite separate and distinct. Since am not anxious to rob Mr. Allom of any portion of the credit duo to him from the design of the ball-room, you will oblige me by inserting this in your next.—JAMES J. LAFOREST.

**METROPOLITAN MARKET BILL.**—On the motion for the second reading of this Bill, Mr. Co. objected to the Bill, on the ground that it would authorise the conversion of two large buildings in the Cattle Market into model lodging-houses, and would appropriate space which would be required for the extension of the market. He moved that it be read a second time that day six months. Mr. Crauford said the buildings referred to had been originally erected for hotels, but they had been found unsuitable for that purpose. It was therefore proposed to turn them into model lodging-houses and he thought, considering the great clearance which was being effected in the City by railways, that this was an object with which the House would sympathise. Alderman Siddons thought the ground of objection to the Bill unreasonable. After some remarks from Mr. Ayrton the amendment was withdrawn, and the Bill read a second time.

**WELDING STEEL AND CAST OR MALLEABLE IRON.**—Mr. William Carson Corsan, of Sheffield, provisionally specified the use of a composition, consisting of borax, fifty parts; Calais sand, thirty parts; emery, ten parts; and manganese, ten parts, in the welding of steel and cast or malleable iron; but he does not restrict himself to these precise proportions.

**USE OF WASTE HEAT IN KILNS.**—Our North Devon correspondent, "W. May, jun.," again presses us on this subject. He says,—"I propose my plan of furnace to another good purpose,—for drying Portland cement before sent, where cement-makers dry with ovens instead of the waste of the kilns. This plan of waste burns the gases from the kilns; and, by conveying it to outlets of ovens, why should this be an answer for consuming the smoke from the chimneys and using the heat from the same, instead of its going into the air as waste, and a great deal of fuel also? If cement-makers were to do this into consideration, a great saving of fuel might be effected by this simple plan." Mr. May also speaks of a method to prevent the heat in forcing out the walls of the floors, which wets well. This improvement, he says, can be applied at a small outlay, or it might be effected on the principle of "no cure, no pay," which would soon pay for itself.

**WELLSFORD SEWAGE WORKS.**—The experiments are at present entirely confined to the trial of the tank which has its outfall at the Arle tank, which comprises that of the town on the right side of the Chelt. The outfall of the Arle tank is into the Chelt, which runs close by, and attention of the surveyor, Mr. Humphris, has been for some time directed to this tank as being a situation favourable for experiments in irrigation, and because the diversion of the sewage into the Chelt had become absolutely a necessity. The course of the sewage has already, it is reported, had a most marked effect on the character and quality of the herbage within the limits of its fructifying influence. A meadow which it bears a crop of grass which is not to be somewhat astonishing. By rapid irrigation offensive odour seems to be avoided. The power which the land possesses over sewage is shown in one or two spots very strikingly. The liquid running in the carrier along the top of a ridge has percolated through the soil into the furrow, and there collecting, is as bright and colourless as though it had escaped a limpid brook.

**MASTERS AND OPERATIVES.**—Lord St. Leonard's case has been printed. It proposes that a number of masters and workmen in any trade or profession, having been for the previous six months resident householders, or part occupiers in the district (the masters having carried on their trade for the six months, and the workmen having carried on their trade for the seven previous years), may at a meeting agree to form a council of conciliation and arbitration; and, after due notice in a local newspaper, a licence may be granted by the Crown for the formation of such council. The council is to consist of masters and workmen, not less than two nor more than ten each, and a chairman unconnected with trade, to be elected by the council. The council is to be elected annually by masters and workmen qualified as above described, the masters appointing their portion of the council and the workmen theirs; and a register of electors is to be formed and kept by the clerk of the council. The council are to have power to hear and determine all disputes and differences between masters and workmen, as set forth in the Act of the 14th of George IV, cap. 96, which may be submitted to them by both parties, the award to be final and conclusive; and the council may adjudicate in any other disputes submitted to them by the mutual consent of masters and workmen. But nothing in this Bill is to authorize the council to establish a rate of wages, or price of labour or remuneration at which the workman shall be employed; or to be paid; and no member of the council is to be paid; and no member of the council is to be adjudicated in any case which he, or any relative of his, is plaintiff or defendant. Disputes are to be first referred to a committee of the council, the committee of conciliation, consisting of one master and one workman, who are to endeavour to reconcile the parties; if they are unsuccessful in this, the dispute is to go before the council, a quorum to consist of not less than one master and one workman with the chairman. Counsel or attorneys are to be allowed to attend any hearing.

**METROPOLITAN MEMORIAL OF RICHARD COBDEN.** It has been resolved to erect a statue of Cobden on a site at the entrance to Camden-town, granted by the vestry of St. Pancras for the purpose.

**PROPERTY IN THE CITY.**—The premises No. 29, Cornhill, lately vacated by Messrs. Currie & Co., were, on Wednesday, sold by auction by Messrs. E. Fox & Bonfield, and realised the sum of 40,000l. The tenure was freehold, and the superficial area 2,200 feet.

**DEMOLITION IN CLERKENWELL.**—The fittings have been removed from upwards of fifty houses, situated in Baker-street, Lloyd-square, Wharton-street, Bagnidge Wells-road, and in the Farringdon-road, Clerkenwell, which have been purchased by the Metropolitan (Underground) Railway Company, who require the sites for widening the line, which is rendered necessary in consequence of the junction of the London, Chatham, and Dover Railway, and the Finsbury extension of the line. The houses above alluded to are to be pulled down immediately after the commencement of the works. The City dwellings for the industrious classes have not been erected too soon.

**BRITISH ARCHAEOLOGICAL ASSOCIATION.**—At the annual general meeting, May 10th, Dr. James Copland, F.R.S., vice-president, in the chair, the report of the auditors, the balance-sheet of the treasurer's accounts, and the list of associates elected, withdrawn, deceased, and proposed to be removed from the list of associates for non-payment of their subscriptions, were read and adopted. The state of the Association was pronounced to be very satisfactory,—an increase of fifty-five members in the year, fifteen withdrawals, thirteen deaths, and six to be removed,—a balance of 26l. 6s. 4d. in favour of the society, and every account discharged. Thanks for services were voted to the president, officers, auditors, &c., and a ballot was taken for the executive for the session 1865-66.

**THE METROPOLITAN GAS COMPANIES.**—The receipts by each company in 1861, 1862, and 1863, from the sale of gas, according to a table in the *Mining Journal*, were as follows:—

Company.	1861.	1862.	1863.
Chartered	4297,661	222,919	4231,220
City of London	81,277	82,378	94,917
Commercial	94,325	108,554	113,129
Equitable	66,063	69,361	69,627
Great Central	61,883	72,483	73,740
Imperial	358,839	397,917	419,061
Independent	59,381	69,659	69,667
London	127,683	135,776	142,895
Phoenix	127,431	136,512	142,973
Ratcliff	27,477	29,093	29,969
South Metropolitan	57,407	61,168	65,327
Water Consumers'	46,419	49,292	51,989
Western	62,134	69,150	77,465
Total	1,374,732	1,493,670	1,673,261

**RESERVING "MINERALS" ON SOLD LAND.**—In a case *Bell v. Wilson*, before Vice-Chancellor Kindersley, the question was the construction of a reservation or exception contained in a deed of conveyance of lands in Northumberland, at a place called Long Benton, dated in 1801. The bill was filed by the owner of the land to restrain the defendant from digging freestone, the plaintiff representing the purchaser, and the defendant the vendor. The reservation, as far as was material, was in these words:—"All mines and seams of coal, and other mines, metals, or minerals." Freestone was commonly found in the district, at distances varying from 6 ft. to 20 ft. below the surface. After hearing the parties, the Vice-Chancellor said that there was great difficulty in determining what the word "royalty" meant, but the strong probability was that in this particular locality it was understood to apply to "mines and minerals." As to the exception, the word "mineral," in its largest sense, applied to every production constituting the earth's crust, even including the mould on which the vestre grew, but it was hardly possible to conceive that a vendor having sold land to a purchaser could reserve the right to that which formed, in fact, the whole subject matter; and it must, therefore, have some more limited meaning. The etymology of the word mineral was, that which was dug from a mine; but there was a clear distinction between a mine and a quarry. The words used did not include freestone; "mines" being the governing word, and inasmuch as it never could have been the intention that having sold the soil the vendor should have a right to come and break up the ground at any time and to any extent, the plaintiff was entitled to a decree for an injunction, for damages, and an account, with costs.

**NEW DOCKS AT PRESTON.**—New docks, which will cost between 30,000l. and 40,000l., are about to be made at Preston. The river Ribble will have to be diverted for a mile, opposite Preston, in order to afford the necessary accommodation.

**THE COYDRAINERS' COMPANY'S SURVEYORSHIP.** Arrangements are making to supply this vacancy. Mr. Harry Oliver, of the firm of Wigg & Oliver, appears to be the favourite candidate. The company could scarcely get a better man for their purpose.

**OXFORD SCHOOL OF ART.**—It is understood that the sub-committee of this institution have appointed Mr. R. Macdonald, of the South Kensington, and formerly of the Dundee School of Art, as instructor to the school about to be opened here.

**A CAUTION TO PLUMBERS.**—The ball-tap, connected with a kitchen-range at Reading being out of repair, a plumber was sent for to remedy the defect. The ball was placed on the fire, when a loud explosion followed, water having found its way inside the ball. One person sustained a severe cut by the fall of a fragment of the broken range, and others escaped with slight bruises. Fortunately the windows were open at the time of the explosion.

**NEW FRENCH CHURCH IN LONDON.**—Under the title of "Notre Dame de France à Londres," a French Roman Catholic church (it is said) is to be founded in Leicester-square, the quarter in which the greatest number of Frenchmen of all classes reside, and there will be annexed to it free schools and an establishment of Sisters of Charity. Subscriptions are said to have been received on so liberal a scale, as to enable the promoters of the project to secure the site on which Burford's Panorama stood for many years. Previously to the erection of the church, the Sisters of Charity will occupy the building.

**PHOTOGRAPHY ON WOOD.**—A new process of photographing on wood has been patented by Messrs. W. & H. Smith & Co., Bow-lane, Chesham. For decorative purposes, it is said, it will be found advantageous, as pictures can be transferred to panels, ceilings, or any surface that may require ornamentation. Graining can by this new process of photography be multiplied and transferred to a surface with accuracy. For household ornamentation, and for decoration of public edifices, this method of applying photography is said to be economic in its application and artistic in its effects, while it is as durable as the material upon which it is fixed.

**THE DEODORISING WORK AT STROUD.**—The system introduced by Dr. Bird for deodorising the sewage of Stroud has been in operation for several months. Some gentlemen, on behalf of the Bristol Board of Health, have just made a formal survey of the works, with a view to the recommendation of the system for adoption at Bristol. Dr. Bird took his visitors to the waterfalls, and, having filled a jug with the water, showed its comparative purity. One or two of the deputation tasted the liquid, and agreed in stating that there was no offensive taste. They were shown samples of the different qualities of the manure. A farmer's man, who had come for a supply, said that where the manure had been tried the grass was very healthy and strong. The deputation expressed their satisfaction at the completeness of the deodorisation and the purifying process.

**EPIDEMIC AT ALDERSHOT.**—We are sorry to hear that there is an unusual mortality amongst children at Aldershot. On falling sick they are immediately ordered into hospital, and all access to them denied to the parents. The highest state of excitement prevails in the camp amongst the married people, and the harsh measures of the medical authorities have provoked some half-frenzied parents into acts of insubordination in their attempts to see their children. A Board of Inquiry on the subject has been held, in which the chief medical officers of the camp took part, when it was determined to remove those families where the sickness has been, out of the camp under canvas. There are great complaints of the crowded state of the quarters in camp, and of the scarcity of water, there not being sufficient to flush the drains. The system of drainage at Aldershot was never of the best, and with a deficiency of water it is now in a very bad condition.

**RAGLAN CASTLE.**—We are glad to find that, in consequence of the assessment committee having reconsidered and rescinded their late decision in reference to Raglan Castle, on which we recently commented, the Duke of Beaufort has given directions that the castle and grounds be at once re-opened.

**ST. BARTHOLOMEW'S CHURCH, ISLINGTON.**—The ceremony of consecrating this church, situated in Shepperton-street, New North-road, Islington, took place on Friday, the 12th instant, in the presence of a crowded congregation. It was expected that the Lord Bishop of London would have consecrated the church, but owing to his being unexpectedly summoned to the House of Lords the Bishop of Ripon performed the duties.

**BREATHING IN SMOKE AND POISONOUS VAPOURS.** An ingenious Frenchman has invented a respiratory apparatus, by means of which a man, it is said, may breathe and walk about in the midst of the most deleterious atmosphere. The invention consists of a tin knapsack, which is strapped to the back, and filled with compressed air. Communicating with the mouth is a series of tubes, which supply fresh air to the lungs, and carry off the exhalations; while the nostrils are closed with a spring, and the eyes protected from the action of injurious vapours or dense smoke, by tightly-fitting glasses. Experiments are being made with this apparatus at the Polytechnic.

**COMPRESSED-AIR HIGH-SPEED HAMMER.**—Mr. W. D. Grimshaw, of Birmingham, has read a paper at the Institution of Mechanical Engineers, descriptive of a high-speed compressed-air hammer, for planishing, stamping, &c. The air is compressed by a force-pump, worked by a crank-pin on the driving-pulley, and is delivered into the interior of the hammer-hammer, which forms the reservoir. The working cylinder and piston, with hammer, are arranged as in an ordinary steam-hammer, but driven by the compressed air, which is admitted above and below the piston alternately by a slide valve, the pressure of the air being regulated by a throttle-valve worked by a foot-treadle. The force, rapidity, and quality of the blow given by the hammer can be changed with great promptness and accuracy; and the hammer is found very advantageous in many situations, such as where there would be a loss of power by condensation in bringing steam from a great distance, or where the damp from leakage of steam or the dropping of condensed water on the anvil would be objectionable, as in planishing bright work.

**HYDRAULIC POWER AT THE MIDLAND RAILWAY CO.'S STATION.**—At the goods station of the Midland Company, Agar Town, the trucks are brought up to the landing-stage by hydraulic machinery, loaded or unloaded when required by hydraulic cranes, and they are shifted from one set of rails to another by means of traverses worked by hydraulic power. Press a lever, and in an instant the loaded truck glides noiselessly away; another lever is pressed, and forthwith a bunge halm of goods, or a heavy forging, is seen dangling in the air, and is swung round, and deposited in the truck or wagon, as tenderly as a mother would place her sleeping child in its cradle. The *Railway News* says,—The machinery by which all this power is made so readily available consists of the water-engines of Sir William Armstrong, situated some hundred yards distant from the place. Our readers are familiar with the principle upon which this power is obtained and applied. The effect of a pressure of water from natural sources is got by what are termed "accumulators," which, in this instance, consist of a large reservoir formed of iron plates, and filled with seventy tons of gravel and sand, and its pressure is about equal to that of a head of water 1,500 ft. This force is raised by the hydraulic power, and is ever ready and available for acting on a column of water, and the pressure may be regulated as required over every part of the system. A small steam-engine is employed for pumping the water into the cylinder of the hydraulic press. This hydraulic pressure is obtained at a very small cost. Some engines of this description which are employed at the Newport Docks, in Monmouthshire, delivered, last year, 219,000 tons of coal, at a cost of about one farthing per ton for pressure, and about one halfpenny for wages, stores, and repairs; the cost of loading by hand having previously been from 5d. to 7d. per ton.

**CHURCH-BUILDING IN THE SANDWICH ISLANDS.** There are about 100 meeting-houses in the Sandwich Islands, erected by the islanders, at a cost of 150,000 dollars. The one at Honolulu is built of coral rock.

**ORIGIN OF THE WORD "NAVY."**—The ordinary idea as to this is, that the word is a contraction of "navigator," as first applied to the workmen of our "inland navigation," or canals; but a writer in *Chambers's Journal* rejects this theory, and suggests that the word "navy" is "identical with *Nabbi* or *Naabbi*, a word of Danish origin, but in common use among the Celtic population of the counties of Sutherland, Ross, and Inverness, to denote neighbour. During the construction of the Crinan Canal, which connects Loch Fyne with the Atlantic, and was commenced in 1793, numbers of Highland workmen were assembled from the counties just mentioned, and by them the word *Nabbi* or *Naabbi* was constantly employed in addressing each other, just as an Englishman in similar circumstances would use "mate" or "comrade." This is a well-ascertained fact; and it is also equally certain that most of the engineers and contractors connected with the works came from, and returned to, the south of Scotland and England."

**TENDERS**

For erecting two small houses near Wimbledon station, for the British Land Company, from plans and specifications by their architect, Mr. Henkan:—  
 Hatcher ..... 2645 0 0  
 Robinson ..... 630 0 0  
 Smith ..... 597 0 0

For erecting a warehouse, No. 4, Chiswell-street, Finsbury, for Messrs. Blyth & Sons, Mr. F. G. Widdows, architect:—  
 Child & Son ..... £3,460 0 0  
 Piper & Wheeler ..... 5,257 0 0  
 Axford & Co. .... 4,900 0 0  
 Hack & Son ..... 4,747 0 0  
 Browne & Robinson ..... 4,747 0 0  
 Henshaw ..... 3,650 0 0  
 Anley ..... 3,650 0 0  
 Ennor (accepted) ..... 3,622 0 0

For pair of villa residences, London Road, Enfield, Mr. T. J. Hill, architect. Quantities not supplied:—  
 Patman ..... £2,760 0 0  
 Barker ..... 1,783 0 0  
 Cushing ..... 1,730 0 0  
 Ashton ..... 1,476 0 0

For new kennels and stables for the Craven Hunt, at Little Waleot, Berks. Messrs. Money & Son, architects, Newbury:—  
 Brown ..... £1,340 0 0  
 Martin & Hookings ..... 1,315 0 0  
 J. & E. Harrison ..... 1,248 0 0  
 Woodridge (accepted) ..... 1,110 0 0

For the erection of warehouse, &c., Gun-alley, Bermondsey, for Mr. Faulstich, Mr. R. Gale, architect:—  
 Wells ..... £2,730 0 0  
 Wood & Mann ..... 2,570 0 0  
 Prince ..... 2,345 0 0  
 King & Sons ..... 2,203 0 0

For works at the Brunswick Tavern public house, Old Kent-road, for Mr. J. Dickson, Mr. Frederick Holworth, architect:—  
 Deal and Oak Mahogany Fittings. Fittings.  
 Selleck ..... £587 178 ..... 206  
 Tracey & Son 876 ..... 174 ..... 234  
 Lawrence .. 808 ..... 140 ..... 159

For shop, Eastgate-street, Gloucester. Mr. H. James, architect:—  
 Sheppard & Meredith (accepted) £303 0 0

For a pair of houses at Morley-road, Lewisham. Mr. Banks, jun., architect:—  
 Hammond (without fencing) ..... £336 0 0  
 Mortimer (with fencing) ..... 830 0 0  
 Gent, Brothers (without fencing) 790 0 0

For the St. Helen's Brewery new tavern, Wavertree-road, Liverpool. Mr. Geo. B. Isborn, architect:—  
 Fyrot ..... £1,730 0 0  
 Pollock ..... 1,500 0 0

For a house at Redhill, Surrey, for Mr. Perrin. Mr. J. F. Matthews, architect. Quantities supplied:—  
 Cook ..... £240 0 0  
 Holdsworth ..... 835 0 0  
 Thomson ..... 623 0 0  
 Sheppard (accepted) ..... 623 0 0

For three houses at Peckham Rye, Mr. H. Jarvis, architect:—  
 Colls & Son ..... £3,173 0 0  
 Tarrant ..... 3,084 0 0  
 Marsland & Sons ..... 3,015 0 0  
 Sharlington & Co. .... 2,997 0 0  
 Piper & Wheeler ..... 2,925 0 0  
 Henshaw ..... 2,834 0 0  
 Kynock ..... 2,925 0 0

For new farm buildings on the estate of the Rt. Hon. Earl Amberst, at Seven Oaks, Kent. Mr. J. F. Matthews, architect:—  
 Henderson ..... £1,204 0 0  
 Wood ..... 1,200 0 0

For house for Admiral Sir Baldwin Walker, Bart. T. Jeckyll, architect:—  
 Gibbons ..... £1,600 0 0  
 Carroll ..... 1,500 0 0  
 Balls ..... 1,788 0 0  
 Godbold ..... 3,400 0 0  
 Smith ..... 3,200 0 0

For stabling, &c., Stones End, Borough. Mr. Jarvis, architect. Quantities not supplied:—  
 Kent ..... £397 0 0  
 Henshaw ..... 597 0 0  
 Marsland & Sons ..... 592 0 0  
 Thompson ..... 580 0 0

For warehouse, Wilson-street, Finsbury. Mr. G. W. architect:—  
 Couder ..... £2,232 0 0  
 Hack & Son ..... 2,192 0 0  
 Chessum ..... 2,083 0 0  
 Brown & Robinson ..... 2,075 0 0  
 Henshaw ..... 2,005 0 0

For two houses, Kingsland-road. Mr. Gliddon, architect:—  
 Room ..... £1,158 0 0  
 Patman ..... 1,158 0 0  
 Foxworth ..... 1,078 0 0  
 Flint ..... 1,085 10 0  
 Maera ..... 1,030 0 0  
 Salmon ..... 1,020 0 0  
 Henshaw ..... 1,020 0 0

For two houses, City-road. Mr. Hammond, architect:—  
 Sanders ..... £2,158 0 0  
 Eaton & Chapman ..... 2,128 0 0  
 Henshaw ..... 1,809 0 0  
 Chessum ..... 1,850 0 0  
 Turner ..... 1,782 0 0  
 Bishop ..... 1,733 0 0

For brewer's house, Westgate Brewery, Bury St. Edmunds, for Mr. Edward Greene, Messrs. Bacon & B. architects:—  
 Jackman (accepted) ..... £701 19 0

For alterations and additions to 25, Gerrard-street, Mr. E. Wood, Mr. F. F. Holworth, architect:—  
 Lawrence ..... £397 0 0  
 Manley & Rogers ..... 845 0 0  
 Selleck ..... 794 0 0  
 Tracey & Son (accepted) ..... 787 0 0

For erecting portions of the Dominican church priory at Haverstock-hill, London, Mr. Gilbert N. Bior architect. Quantities supplied by Mr. J. Carow:—  
 Lucas ..... £2,201 0 0  
 Trollope ..... 21,233 0 0  
 Patman & Fotheringham ..... 21,063 0 0  
 Wood ..... 20,383 0 0  
 P. Aaron ..... 19,043 0 0  
 Bird ..... 18,607 0 0

For warehouse, Golden-lane, for Mr. F. G. Debenham, Messrs. Wimple & Taylor, architects:—  
 Brass ..... £2,380 0 0  
 Adamson & Sons ..... 2,373 0 0  
 Ramsey ..... 2,254 0 0  
 Colls ..... 2,245 0 0  
 Kilby ..... 2,078 0 0  
 Hill & Sons ..... 2,028 0 0  
 Wills ..... 1,970 0 0  
 Hack & Sons ..... 1,977 0 0  
 Hariman & Sandon ..... 1,970 0 0

For new buildings, High-street and Carls-lane, Leister, for Mr. W. Burley, Mr. T. J. Goodacre, architect:—  
 Neale ..... £2,277 0 0  
 Herbert & Son ..... 2,272 0 0  
 Porter ..... 2,257 0 0  
 Osborne, Brothers ..... 2,219 0 0  
 Durbury ..... 2,200 0 0  
 Hutchinson & Son (accepted) ..... 2,130 0 0

For additions to a house, King-street, Borough. S. Dyball, architect:—  
 Terry ..... £798 0 0  
 Hill & Sons ..... 650 0 0  
 Perry ..... 620 0 0  
 Drewitt (accepted) ..... 500 0 0

For villa at Upper Norwood, for Rev. E. Birch, S. Dyball, architect:—  
 Francis ..... £2,502 0 0  
 Sharpington & Cole ..... 2,187 0 0  
 G. & R. Buck ..... 2,187 0 0  
 Sawyer ..... 2,047 0 0  
 Seymour ..... 1,908 0 0  
 Perry (accepted) ..... 1,847 0 0

For excavator, bricklayer's, slater's, plumber, mason's, and smith's work for a residence on Calverly estate, Sunbridge Wells. Mr. James Blundell, architect:—  
 Pink ..... £562 0 0  
 Strange & Sons (accepted) ..... 522 5 0

For Plasterer's Work  
 Mason ..... £170 15 0  
 Wenban ..... 172 0 0

For enlarging and altering Hawley-road Church, Kentish Town, for the Rev. E. White, Mr. E. C. Klot architect. Quantities supplied by Mr. H. Snell, amounts less deductions for old materials:  
 Hale ..... £3,742 0 0  
 Newmann & Mann ..... 3,244 0 0  
 Sharpington & Cole ..... 3,178 0 0  
 Manly & Rogers ..... 3,163 0 0  
 Mann ..... 3,145 0 0  
 Scrivener & White ..... 3,062 0 0

For Fulham and Hammersmith sewers, Fulham district, King-street, Hammersmith, and High-road, Fulham:—  
 Moxon ..... £3,020 0 0  
 Thrist ..... 3,040 0 0  
 Emsly & Rogers ..... 3,163 0 0  
 Wigmore & Whittick ..... 3,199 0 0  
 Reddin ..... 3,100 0 0  
 Williams & Co. .... 2,800 0 0  
 Stansfield ..... 2,703 0 0

# The Builder.

VOL. XXIII.—No. 1164.

## The Prevention of Strikes.

**D**URING some considerable time we have been content chiefly to note in our pages the incidents of dispute in the building-trades throughout the country, and

to mention different measures proposed or taken with the view to improved relations between capital and labour, without otherwise attempting to contribute much, or by our individual efforts, to the permanent solution of the still difficult questions which the relations involve. But the incidents referred to are becoming so serious from their frequency, and the measures are so far important in their aims, that we cannot longer refrain from the endeavour to promote at

tainment of a position more healthful and political-economical than that which exists. A list, roughly made out, of some of the strikes and outbreaks continuing or commenced this month, in the building trades, gives twenty-six different towns or districts, and a greater number of trades, as suffering through contention such as is perpetually recurrent, as to what is "a fair day's-wages for a fair day's-work," or what are the respective shares of that "common-fund" which neither the employer nor the employed can draw from in excess of what may be his share, unless with injury to the mutual interests. Evidence that particular strikes, or outbreaks, have resulted in circumstances worse than those precedent to the dispute, have had no mere effect in preventing recurrence of disputes, than evidence of the fact of mutual injury has had in preventing nations from recurring to a state of war. The direct tendency of every war is to produce another war, at some period, between the same combatants; as has been plainly shown of late, by the ablest French advocate of peace, M. Emile de Girardin. No feeling of self-interest will held passion in check: the only hope of a fresh start, unclogged by animosities, and of lasting peace, lies in mutuality of interest and interchangeability of respect. Let it be once comprehended that war is a thing which is always undertaken with a view to peace, tends to war, and there may be less disposition in nations to go to war, and greater readiness to submit to arbitration, or the control of the comity of nations; which has prevented some wars,—though it may have failed to prevent all.

A dispute between masters and workmen has been likened to a state of war: the means that may be taken towards prevention of one and the other form of strife, are similar; and, similarly in the cases, they will not universally be sufficient till mutuality of interests has been well established. Arbitration cannot altogether prevent strife arising out of the relations of capital and labour: it could prevent that state of war only where the decision was made with perfect knowledge of the circumstances,—knowledge that could seldom be found, excepting with the parties them-

selves,—that is where the decision would have the justice which, rather than any force of law, would make it respected; or it could similarly operate to prevent, only where there might be the disposition on both sides to concessions. It is worth while to have arbitration available: but it will not be all-sufficient; neither will it be of equal service to other means, not of settling disputes, but for avoiding them, that are coming to hand, and which there is promise will be ere long largely developed.

Before proceeding to describe what these proposed means are, we should advert to certain facts that were lately noticed by Mr. Thomas Hughes, in a letter to the *Spectator*, as showing the fresh importance of our subject. Mr. Hughes finds that the principal unions of the men, supposed to have received considerable damage during the last fifteen years, have actually increased greatly in strength; and he believes that the increase has been the result of the entleeks, or acts of the masters. He first mentions the Amalgamated Society of Engineers. At the time of the great outbreak, when all the workshops in Manchester and London were closed by the masters, in order to meet the strike against the establishment, the Society had, he says, 11,829 members. At the end of the five months' struggle, the Society had lost upwards of 2,000 members, and almost the whole of the reserve fund, whilst subscriptions were greatly in arrears. It was thought, even by friends, that the Society could not recover. But, within eighteen months, the numbers stood as high as before the outbreak. In three years they became 12,553; and from that time to this, they have increased by about 2,000 a year. The report for 1863 gives the numbers as 26,058. At the time of the outbreak, the Society had 121 branches, all in the United Kingdom, and all but 13 in England. In the very year, 8 branches were added; and in the following year 12 branches more. In 1863, there were 262 branches, whereof 5 were in the Australias, 1 in New Zealand, 4 in Canada, 1 in Malta, and 5 in the United States. In the same year, notwithstanding an expenditure of 52,000l. to members out of work, or in other allowances, and 10,000l. for other objects, the reserve fund stood at 67,410l.; and in 1864, the progress continued. As another example, there is the case of the Amalgamated Society of Carpenters and Joiners. The following tabular statement is given:—

Dates.	1860.		1861.		1862.		1863.		1864.		Net Increase of Branches, Members, and Funds.	
	Branches.	Members.	Branches.	Members.	Branches.	Members.	Branches.	Members.	Branches.	Members.	Branches.	Members.

Mr. Hughes believes from such statistics as these, that a great strike or outbreak, no matter which side is in the right, or whether the men gain their point or are beaten, only stimulates the growth of the Society. He anticipates that by unions amongst the trades, the masters will be beaten in the long run. The latter, he thinks, cannot remove their capital away from the coal and iron, whilst the men can remove their labour, taking advantage of their branches. It is evident that emigration is now playing an important part, antagonistic to the apparent interests of the masters; and Mr. Hughes looks "with great dread on the turn our civil war without firearms is taking." He says,—“Unless some change comes, there will soon be a constant and ever-increasing drain of the picked men from this country, and we shall be left with the drunkards and the idlers.”

In 1859, during the outbreak after the strike

against Messrs. Trollope, we discussed, in a leading article, the question, what means there were open to the workman to better his condition, without recourse to a strike. The present state of the question of capital and labour, and the direction taken alike by the friends of workmen, and by masters, serve to shew us that we viewed the question correctly. We referred to three agencies for adjustment of the difficulties between masters and workmen. They were emigration, arbitration or councils of conciliation, and "co-operation." To the last we attached the chief importance. When we wrote, the Society of the Rochdale Pioneers had been scarcely noticed at all by the press; the book of Mr. Holyoake, "Self-help by the People; History of Co-operation in Rochdale," to which we were indebted, was little known; and important papers and articles by Professor Fawcett, and others, had not appeared. The course of the subject will bring us again to co-operation, but to a new form of it which is especially important as tending to diminish strikes.

If we still name emigration as one of the resources for the workman, we do so only that our enumeration may be complete, of those out of which choice can be made, and in order to point to the fact that this resource is being taken advantage of to a considerable extent. We may however remark that the common reasoning teaching emigration after a strike, that the fact of the emigration shows there had been a superabundance of labour, and that a strike for higher wages was not calculated to succeed, has been sometimes too prominently advanced; for, it is quite possible that men may emigrate, preferring that course to a return to work with the same masters, and that on termination of the contest a corresponding deficiency of labour may be felt. Emigration, when there is a superabundance of labour, and likely to continue for some time, or when the workman wedded to a single handicraft, has been superseded by a machine, and yet has the energy and strength of arm that are chiefly in demand in a new country, may afford the means of restoring a balance,—moreover, there are men who require the spur of difficulties, or to have "burnt their ships," to have their energies called into action; but it is not altogether desirable for the old country to lose its available hands; and this has been the view taken of late, by true philanthropists, in the cotton-manufacturing districts, where emigration has gone on to the greatest extent, and of course advantageously in many respects. The real object before emigration is largely resorted to, as under the direction of trades-unions, is for the employers and employed to discover means by which the latter may understand whether there is really the surplus of labour after the employer has taken his fair share from the common fund; or whether, in the other case, the need has arisen for the employer to be checked from adding to his profits, because doing so out of what should increase the wages of the workman. Now it is impossible that each party can be satisfied unless the partnership, which there is in theory,—in theory however that has the ultimate basis of fact,—be made an actual partnership in feeling or in fact. The partnership that we have called a feeling, is that which endeavour is made to reach through the agency of arbitration and councils of conciliation: the partnership as fact, exists in those concerns which are based on true "co-operative" principles, or in which the workmen are admitted to share in what are ordinarily called profits; and it is sought to be promoted in the "Bill to amend the Law of Partnership," now in the House of Commons, a measure the importance of which to the future condition of the working classes it is impossible to estimate too highly. That either co-operation of workmen, or that combination of co-operation with

the old relation of master and servant which may be preferable for some time to come, will prevail to the exclusion of establishments on the old relation, is not to be expected immediately; and the exclusion may not ever be to be desired. The remark was we believe made by the Earl of Lichfield, during the period of his recent exertions in Staffordshire, that had there been one establishment in the district, conducted on the principles of partnership between master and workmen, its rate of wages would have been taken as guide, and no strike of the iron-workers would have ensued.

To simulate in other establishments, that community of interests which, as we shall show, is to be calculated upon in those conducted on the united limited liability and co-operative principle, or which even is already found to exist, arbitration in some form may conduce. But, too much has been lately expected of it. Courts of conciliation on a modification of the French system, which might reduce the number of strikes, by settling many of the questions arising, and by preventing others through creation of a good understanding between masters and men, could be easily instituted; but they would not prevent strikes entirely. In Paris, just lately, there have been a great number of strikes. The frequency of them has been explained by the over-eagerness of workmen to exercise the right, newly accorded them, of coalition. It is satisfactory to see that in Staffordshire, the men are alive to the evils of strikes; but it is less satisfactory that they should have calculated upon arbitration as an all-sufficient substitute. It has been remarked in an able article in the *Pall Mall Gazette*,—"Phrases about the 'principles of right and justice' are always suspicious and generally fallacious. Right and justice are excellent things. Right and justice are nothing to do with the rate of wages; they belong to a different order of ideas altogether. They are law phrases, implying the existence of fixed rules, which confer powers and impose commands on those whom they affect. If a man contracts to work for another for a week for a pound's wages, then right and justice have a meaning." The right and justice in contracts are unchanged, whatever the disproportion between the amounts to be paid and the article to be supplied. The rate of wages, the writer shows, is determined exclusively by self-interest, the interest of the master being to give as little, and the interest of the men to get as much as possible. The rule may be departed from through kindness; but if a master keep his works open at a loss, it is an act of charity. Now, who can decide what it is the man's interest to take, but the man himself? or who what the master should give, but the master? The slightest thought will suggest many considerations that the master or man will bring into the question, that would occur to no one else, and that could not be decided except by the party himself. If the parties were to be compelled to act upon the opinion of a third person, as to their own affairs, there would be an end of personal liberty on the one side, and of the rights of property on the other. An arbitrator's award, he says, must be either legally enforceable and binding on both parties, or it must be mere advice. In the latter case, the benefit must depend upon what may happen to be the particular qualifications of the adviser, amongst which are the possessing more knowledge, and the taking more pains, than the person whose interest is concerned. Considering the arbitrator as a judge, two difficulties immediately present themselves. First, there are no rules by which the judgment can be guided. There is no such thing as a *fair* rate of wages, or a *just* rate. How is it possible to lay down rules as to the amount which it is the interest of the one party to give, and of the other to take? Then, how is the award to be enforced? "Practically it is impossible to make men work well when they are not satisfied with their wages, or to force masters to pay wages at a higher rate than their interest permits. The man whistles and loiters till he has watered down his labour to what he considers a proper level. The master contracts his operations or shifts the employment of his capital." The plain truth is that the question is one of individual interest, which the master and man must settle for themselves. Thus far the writer in the *Gazette*, whose views would have deserved to be given even more in detail, with their illustrations. We direct attention to the observation that it is impossible to

make men work who are not satisfied with their wages; because, shortly, we shall speak more precisely of endeavours to which we have already alluded, that would convert the unwilling machine into the active and interested co-partner.

Notwithstanding the limited scope of arbitration,—limited even though Courts of Conciliation were legally constituted,—and that there may be reason in Mr. Hughes's assertion that "in any case it will only be an armed truce," we incline to the opinion that it would be of service; and, judging from the Bill of Lord St. Leonards, the attempt is to be made to introduce it with improvements upon the French system. We have already mentioned the Bill; but a new statement of its main features, in our pages, will assist the object for which it has been printed, namely, to allow masters and operatives to see what sort of court would probably be established in the event of Courts of Conciliation being agreed upon. The Bill is "intituled an Act to establish Equitable Councils of Conciliation to adjust Differences between Masters and Operatives." In the preamble it refers to preceding Acts, of which the existence even may be unknown to many of our readers; albeit we have sometimes had to speak of them. These Acts are the Act of the 5th year of the reign of George IV., intituled "An Act to consolidate and amend the Laws relative to Arbitration of Disputes between Masters and Workmen," and the Acts of her present Majesty's reign, 1851, cap. 67; 8th & 9th, cap. 77, and cap. 125. It is there stated that it is expedient, without repealing the said Acts, to enable masters and workmen, when licensed by her Majesty, to form equitable Councils of Conciliation, and that the powers in the said Acts should be extended for enforcing awards under the new Act. The first clause enacts that if any number of masters or workmen in any particular trade, or trades, householders or part occupiers of any house or premises within a city or district (the masters having resided or traded for six months, and the workmen having resided for the same time, and worked for seven years, in the place) shall jointly petition for a licence to exercise the powers under the previous Acts, and setting forth the names of the petitioners, and certain particulars of the management proposed, it shall be lawful for her Majesty, or the Secretary for the Home Department, to grant such licence, provided notice of the petition has been published. By the second clause, the Council is to consist of not less than two masters and two workmen, and not more than ten masters and ten men, and a chairman; and no member of the Council to adjudicate in a case in which he may be interested. The third clause requires the petitioners to proceed to the appointment of a council from amongst themselves within thirty days; and the fourth clause gives the power to appoint the chairman, and to adjudicate in cases submitted to them by mutual consent,—this involving the power of enforcing awards by distress, sale, or imprisonment; but nothing in the Act is to authorize the Council to establish a rate of wages. The fifth clause makes the quorum to consist of three, one a master, one a workman, and the other the chairman; and also provides for a Committee of Conciliation, consisting of one master and one workman, who, as in the French system, are to consider cases in the first instance. The next clauses provide that the chairman shall be unconnected with trade; that no counsel or solicitors shall attend any hearing; that the Council and chairman shall be appointed for one year; and that vacancies shall be filled up within fourteen days. The ninth clause refers to the qualifications of the voters and persons to be elected; which are similar to those given, in the first clause, for the petitioners. Other clauses relate to the registration of voters, to the appointment and duties of the clerk, to the sittings of the Council, and to the making of by-laws.

It may be observed that the knowledge of the particular trade connected with the subject in dispute, would be accurate to a degree to which the members of the French "*Conseils*" would often not pretend; since in place of a very small number of councils in the one town, there might be one for each trade. The "*Conseils*" in Paris are extensively resorted to; and the large majority of the cases are disposed of with great ease, or most of them at the preliminary examination by the body, or portion of the "*Conseil*," corresponding to the proposed Committee of Conciliation. But whether the facility with which masters can be brought before the courts by their workmen, leads to

difficulties in the masters' management, we are not quite sure; for, this much we know, there is an ever-continuing trouble in getting work done to the appointed time, and that when the master is reminded of his promise, he instantly adduces the workman's neglect, as though probability of such omission were so commonly understood as to have been of course taken into account by you.

Long and much as these Courts of Conciliation, and other methods of arbitration, have been striven for in this country, and important as is the adhesion to them of Lord St. Leonards, we cannot, as we have said, whilst recognizing their probable advantages, estimate them as likely to contribute more than in the second degree to improved relations of Capital and Labour. In that case what may we chiefly rely upon? The "old relation of master and man," says Mr. Hughes, "is gone hopelessly, whether we like it or not. The men will never be content until they have a share of profits, and some voice in the internal management of the workshops. Unless they can get these two rights, as they hold them to be, they will through much blundering struggle into co-operative societies for production as well as consumption. The masters must, in short, consent to become constitutional instead of absolute sovereigns, or they will have republican institutions rapidly springing up and shouldering them out." Therefore he wishes that masters in general "would follow the example of 'Messrs. Briggs & Son (Limited),' Messrs. Crossley, and others, and so win the battle by yielding, and lay down sure foundations for confidence and peace in their workshops, which would bring in their train the gratitude of the whole nation, and a trade such as the mind of man has never yet conceived." We quote these words because they represent what is just now the expressed opinion of such persons as those who are taking part in the meetings of working men and others, which are being held every Tuesday evening, at Exeter Hall, under the auspices of the Working Men's Club and Institute Union. At the first meeting, when the Duke of Argyll presided, "the Labour Question in connexion with Strikes and Co-operation" was treated of by the gentleman whose name has been just mentioned; and on last Tuesday evening, when Lord Lyttelton was in the chair, the secretary of the club, the Rev. Henry Solly, to whom all working men owe a debt of gratitude, explained under the title "Co-operation and Partnership between Masters and Men in a Yorkshire Colliery and Factory," the proposed and partly-matured scheme of Messrs. Briggs & Son, and showed lucidly the advantage that might accrue to capital itself through giving a share of profits to workmen, and by the enlisting of their full energies in work, and the advantage to both through that abandonment of strikes which seems consequent upon the new relation. Amongst the subjects for the ensuing meetings, is the question, on the 27th of next month, "Can Arbitration be successfully used in Disputes between Employers and Workmen?" to which Mr. J. M. Ludlow will speak, the Earl of Lichfield being named as chairman.

The importance of the change from absolute to constitutional government of the masters, as tending to the cessation of strikes, and to the advantage of employers and employed, has been dwelt upon by no less a person than Mr. John Stuart Mill, a man who, if we for once touch politics, we may say the electors of Westminster ought not to fail to send into Parliament. Mr. Mill in the chapter "On the probable Futurity of the Labouring Classes" in his "*Principles of Political Economy*" &c., of which work Messrs. Longman have just published a "*People's Edition*," has many passages, which coming from him, are of the greatest interest for our subject. Many of the facts collected in England and France were previously known to us.

Mr. Mill marks the existence of two conflicting theories respecting the social position desirable for manual labourers. "The one," he says, "may be called the theory of dependence and protection, the other that of self-dependence." The first, he continues, is "the ideal of the future in the minds of those whose dissatisfaction with the Present assumes the form of affection and regret towards the Past." But no times can be pointed out in any country, he says, in which the higher classes have performed a part even distantly resembling that assigned to them in the theory: all privileged classes have used their power in the interest of their own selfishness: the evil cannot be eradicated; and long before the superior classes could be

sufficiently improved, the inferior classes would be too much improved to be so governed. After speaking of the growth of intelligence in the working-classes, he says,—

“It is not to be expected that the division of the human race into two hereditary classes, employers and employes, can be permanently maintained. The relation is nearly as unsatisfactory to the payer of wages as to the receiver. If the rich regard the poor as, by a kind of natural law, their servants and dependents, the rich in their turn are regarded as a mere prey and pasture for the poor; the subject of demands and expectations wholly indefinite, increasing in extent with every concession made to them. The total absence of regard for justice or fairness in the relations between the two, is as marked on the side of the employed as on that of the employers. We look in vain among the working-classes in general for the just pride which will choose to give good work for good wages; for the most part, their sole endeavour is to receive as much, and return as little in the shape of service as possible. It will sooner or later become insupportable to the employing classes to live in close and hourly contact with persons whose interests and feelings are in hostility to them. Capitalists are almost as much interested as labourers, in placing the operations of industry on such a footing, that those who labour for them may feel the same interest in the work, which is felt by those who labour on their own account.”

And he says, that if improvement continue,—

“there can be little doubt that the status of hired labourers will gradually tend to confine itself to the description of workpeople whose low moral qualities render them unfit for anything more independent; and that the relation of masters and workpeople will be gradually superseded by partnership in one of two forms; in some cases, association of the labourers with the capitalist; in others, and perhaps finally in all, association of labourers among themselves.”

He gives instances of the first of these forms of association, including the case of the American ships trading to China, that in the Cornish mines, where the men are so remarkable for intelligence, cases mentioned by Mr. Babbage, in his “Economy of Machinery and Manufactures,” when pointing out the principle as capable of being extended to manufacturing interests, and several others.

We will pursue the argument in our next.

#### EXCAVATIONS AT OSTIA.

The excavations begun more than ten years ago, at Ostia, have been rewarded of late by the most interesting results, and are now being prosecuted by the labours of about sixty convicts, who inhabit the picturesque old castle, built by Sangallo in the latter years of the fifteenth century, within whose half-ruinous walls stands the wild little village that alone gives shelter to modern life, in the place of the antique city, on this desolate fever-stricken seacoast.

After a walk of about a mile along the uncultivated fields around this village, we reach a street of tombs leading to the threshold of a principal gateway, and lined by the substructures, walls of sepulchral chambers, several of which contain the usual rows of niches for cinerary urns, a few having remnants of mosaic pavement (in black and white), with designs, birds, a biga drawn by two horses, &c., or a simple ornamental pattern; and, in one instance, are such architectural details (for the tomb, singular), as a double doorway and large window with jambs, lintels, and framework of travertine. Beyond the ample threshold stone, sole remnant of the gateway, stand the ruins of a large mansion, supposed a military station or guard-house. We have hence in view a long perspective of paved street flanked with houses, now but low and roofless, among which lie strewn fragments of sculpture and of marble architecture; but no conspicuous front rises, no characteristically designed elevation attracts the eye. One more imposing ruin, however, is that of a palace, in whose chambers are pavements of geometric design in mosaic, and others of the richest coloured marbles inlaid in cubes.

A walk across the fields brings us to a more interesting ruin-group (opened shortly before our last visit), presenting several tombs, now roofless interiors and corridors lined with masonry, still firm and solid, partly in brick, partly in reticulated work of tufa,—the plan of this whole structure complicated,—several of its interiors containing files of niches in which the terra-cotta *otia*, for ashes, still occupy their places; and other large recesses are seen, evidently sarcophagi,—proof of the contemporaneous practices of interment and cremation; the former further attested, by numerous skulls, found here and elsewhere, among the Ostian sepulchres. Within one of these recesses, under a vaulting, is a painting of a banquet-scene, with large couch, table, garlands suspended above; but no guests introduced. In one chamber are figures

of animals, painted with some skill, on a stucco surface of deep red. These remains are far surpassed in interest by a superbly-decorated tomb, into whose vaulted interior we descend from the level below which it had been buried; measuring 12 ft. 8 in. by 11 ft. 3 in., with walls and vault entirely painted over,—the chief colours red and yellow,—the floor sloping upwards to a level centre occupied by a marble sarcophagus (now in a magazine of such relics at the village); ample niches, with their *otia* along a single file on the lateral walls; at the end wall, a kind of *adnicula*, with painted pilasters and cornices, containing four larger arched recesses, and surmounting of the vault, rich and graceful in style. Upon the ceiling a row of griffins and candelabra form a species of frieze, in white on a yellow ground; animals and a few human figures, much defaced, are here and there recognisable on the warm-tinted walls. A single funeral slash set into the masonry, near the entrance, gives the name of a child,—Sicia Semina, deceased in the second year of her age. Returning within the area of the city, and proceeding in the direction seaward, we reach the last and by far the most important group of buildings, which covers a considerable extent, divided into numerous interiors, now presenting a vast labyrinth, amidst whose complications it is most difficult to form anything like a ground-plan to the mind's eye, or to determine the specific appropriation of every part. One fact, however, is certain, and serves as guide for the apprehension of this great aggregate,—that we have here before us three systems, distinct, but in communication: a temple of *Mithra's*, with forecourt and other sacred parlours; the residence of the priesthood who here officiated; and *therma*, that may have belonged to the same sacerdotal body, no doubt wealthy and powerful whilst this once-fashionable Oriental worship prevailed under the Empire. These ruined structures are all alike roofless, divided either by partition walls at different heights, some reduced very low, or by massive brick pilasters, among which lie several shafts of marble, green-veined *Carystian* (*cipollino*), or other kinds. We first enter a spacious quadrangle, entirely paved with black and white mosaic, designed in a graceful ornamental pattern (without figures), like carpet-work. From this centre opens, to the left, a series of quadrangle chambers, various in size, at once recognizable as baths, all containing mosaic pavement; and two provided with terra-cotta flues, for admission of hot air from a hypocaust, into which we can look, stooping low, from a lower area of ruins still encumbered with soil and weeds.

The mosaics in these interiors are curious and varied; in one example (where a series of diamonds and bowties is adorned with a species of braid, like intertwining ribbons), coloured, the others, in black and white, their designs including several figures of spirited character,—athletes combating with the cestus, or holding the palm of victory; one in the act of crowning himself with a ponderous diadem-like wreath; a little Cupid mounted on a dolphin, which he drives with a long whip; a bull terminating in a monstrous dragon, &c. From these pavements one of the finest specimens in coloured mosaic has been recently transferred to the Vatican; the central of five panels, in its design presenting a beautiful group of birds and flowers, the subordinate detail consisting of foliage, meanders, &c.

Leaving these baths, we enter the principal court, an ample quadrangle surrounded by parallel chambers and the temple buildings; the pavement of this court presenting a very curious design in black and white mosaic, intended for a kind of plan of the city and its port; in the centre a rude representation of a lighthouse with flame at the summit; around this the moles and inclosures of a harbour; beyond, the wider extent of fortifications and gates round the city, whose streets are simply indicated by black and white squares in chess-board style. Off one side of this quadrangle opens a series of halls, oblong and parallel to each other, all in a very ruinous state, with the lower flight of a staircase nearly at the centre; one of these interiors containing mosaic pavement (geometric) and two square elevations, that probably (as seems indicated by the pipes carried through one side of each) served for fountains, as perhaps required for instructions in the Mithraic worship. At one extremity of this series, to the right, is the cella of the Mithraic temple, a narrow oblong, terminating on the western side in

a flight of six marble steps, on the lowest of which stands a small plain stone altar, with a cavity at the summit for libations, and the legible epigraph in front, *C. Calpurnius Hermænos antistes hujus loci fecit sua pecunia*. At each side apparently for communicating with the platform above the altar, are narrow corridors, lateral to the staircase, and now more ruinous than the other parts. On the floor are the words, inscribed in mosaic, repeated along two borders,—*Soli Invic. Mt. D.D.F. Agræus Colentis*. The several other chambers adjacent to this fane, now reduced to a state of scarce-intelligible ruin, are so connected with it that one may fairly suppose them to have served for its priesthood or other purposes pertaining to its rites. At some distance from these excavations stands the most conspicuous of the Ostian antiquities, the cella of a temple supposed (though without reliable evidence) to be that of Jupiter, and, at all events, one whose character must have been imposing, and art decorations splendid; its area ample; its walls of lateritic brickwork, still lofty and well preserved; though of the roof remains nothing, and the front has also vanished. Along the side opposite the entrance is a wide extent of massive stonework, in which we recognise the remnant of a large altar and platforms; the rich marble pavement (mentioned as extant several years ago, in Nibby's “*Contorni di Roma*”), has disappeared, all but an immense threshold-stone of fine African breccia; and in the midst open two yawning cavities, one filled with soil, the other allowing a glimpse into a dark subterranean. The posticum, on its outer side, is perforated with cavities at regular intervals, probably for the pivots by which a marble incrustation was fastened; and on the ground-floor, below that part of the cella where stood the altar, we enter by an arched ingress (lately opened) into the outer compartment of a system of crypts, where, under a high-lying vault, lie a profusion of marble fragments, some pertaining to richly-chiselled architecture, which we can only inspect in dim light admitted from the doorway. From this chamber is communication with the inner *penetrabilis* not yet cleared out, but soon to be so, from which further continuance of the works in this temple we may expect valuable results. Around the outer walls are portions of pavement, in very ample white marble slabs, numerous fragmentary shafts and cornices in the same material, the latter presenting fine examples of dental and egg-moulding. Seeing the extent of area over which these marble remnants are strewn, we may conclude they belonged to the sacred enclosure (*peribolus*), that must have been ample in plan, and majestic in architectonic character. It is evident from the elevation of ruin-masses, that a flight of steps must have led to the entrance of the cella, whose front was hexastyle, of the Corinthian order, as inferred from its remains; and the colonnade round the enclosing court seems to have been of smaller shafts in the same order. Gell gives the measurement of the whole area as about 270 Roman palms in length, by 120 in breadth. The wild solitude amidst which it stands enhances the effect of mournful grandeur in a ruin not otherwise of extraordinary character, as to either dimensions or artistic claims. The recent directing of the excavators' labours to this centre has been judicious; but we were sorry to hear of the removal of several great marble shafts from these interesting ruins, to “St. Peter's” as the custode reported, but we conclude, by mistake,—St. Paul's on the Ostian Way being, in all probability, the church for whose restorations they are destined. Besides the above-named, other noticeable discoveries on this site are the substructures of a granary and another public magazine, in whose spacious area are still seen files of enormous terra-cotta amphoræ, embedded in the ground up to their necks, mostly filled with clay, instead of the oil they were probably destined for. The wide-spawning arch of a ruinous gateway, seaward, forms one of the conspicuous features among these relics of a vanished city, once peopled, it is said, by 30,000 souls, but left to decay so early as the sixth century of our era.

As to the style of these Ostian ruins generally, we observe indications of a good, but rarely those of the best, period in Roman masonry; the *opus reticulatum* frequently seen, and quite compact; the brickwork, in some examples, with broad layers of cement, such as characterize the period of decline.

Soon are to be commenced other works on this site among the hitherto-neglected ruins of a

theatre, only a single arcade of which stands in intelligible form beside other vague piles of brickwork. Out of proper regard for the health of the poor *galotti* (condemned prisoners) the Ostian works are expended from the 10th of June till a period in the autumn. The deposit of antiques in the village contains sarcophagi, epitaphs, lamps, terra cotta ornaments of tombs, amphore, &c., the most valuable to be eventually transferred to Rome's Museums; the most remarkable among those objects still left here, is a recumbent female figure, headless, naked down to the waist, but for the rest draped, with a fine character of execution in the end, and in the drapery retaining the red tint, much faded, in which the whole of that portion has been painted.

Recently have been brought to Rome a fresco of Orpheus and Eurydice from the painted sepulchre above noticed; and a mosaic of a priest offering sacrifice at a flaming altar, now in the Lateran Museum. Another mosaic, covering a very large area, was transferred from Ostia to the Vatican some time ago, and is now laid in the hall where Podestà is painting a great series of frescoes to illustrate the dogmatic proclamation of the Immaculate Conception; this last, from the *therme pavements*, being an example of the geometric and decorative without figures or other design.

Apart from the interest of antiquities severally, there is, in the level uncultured waste, the serpentine windings of the Tiber between low banks and underwood, the frowning old castle, the fortified but desolate village (now three miles from the retreating sea), the aggregate of ruins strewn over the solitary, memory-haunted coast, at Ostia, a solemn mournfulness and strikingly marked character that impress and fascinate—disposing for such musings as would require poetic language for their just expression.

#### THE DANTE FESTIVAL, FLORENCE.

In the midst of the Piazza Santa Croce, rich with so many historic memories, has been inaugurated with the most brilliant success the statue of the divine poet Dante Alighieri. In 1857, when the Austrians were in Florence, a committee of twelve gentlemen determined on erecting a monument to Dante, and requested Enrico Pazzi, the sculptor, a native of Ravenna, to model a figure of the poet, giving to the features such an expression of indignation as would have been felt by the poet, had he been living, on witnessing a foreign rule in his native country. This committee subscribed a monthly sum towards carrying out their wishes. The model of the present statue was chosen from among many, but the then minister of the Grand Duke imperatively refused the completion of the work. A new order of things,—bringing liberty of action with it,—allowed not only the completion of the statue, but the arrangement for a centenary *fête* in honour of the poet, with the erection of his monumental statue. For this latter, large subscriptions have been raised, in which the king has liberally joined, together with many cities of Italy. The statue is of colossal dimensions, about 15 ft. in height, placed on a handsome pedestal, 20 ft. high; the standing figure, draped in the long cloak worn by the students of the time, the head covered with the well-known long Danteque drooping cap, the brow wreathed with laurels. The sculptor has idealised the poet, seized with just anger at the unmerited exile to which the accused factions that were bringing misery to his country had condemned him; and, at the same time, grieved because he saw no powerful hand outstretched to break the foreign yoke that held his country captive: his left hand closed, pressed to his side, as if to restrain the rage that agitates his breast. The right hand holds the book.

"That for the universe entire is open'd wide."

An eagle stands at his feet.

Opinions differ as to the merit of the statue. To my eye, there is a stiffness about the pose of the left arm and leg, which detracts from the beauty of the statue, otherwise of fine conception, though somewhat conventional. The pedestal is square, on an octagonal base. At each corner of the pedestal, a lion holding a shield, on which is inscribed one of the principal works of Dante,—that of the "Monarchia," surrounded with oak; that of the "Convito" (treatise on science), with olive; of the "Vulgare Eloquenza" (or the principal dialects of Italy), with various

flowers; the "Vita Nuova," with laurel; the pediment enriched with an ornamental *ciruel* of the arms of the cities of Italy, to signify the preconceived notion of a united Italy. These cities have contributed with money towards the erection of the monument. A deed of gift has been signed, by which the statue is presented by the committee to the municipality of Florence. One condition is made, that the former shall finish the statue, hurried to this state of completion for a particular day; the latter complete the pedestal, the reliefs of which, on each side, are not yet begun.

The monument was surrounded for the occasion with an elegant wooden amphitheatre, which, after leaving an open space around the statue of 8,000 feet, for the beautifully arranged dais and seat for the king, and for the group of deputies, &c., to receive the procession, afforded room for 18,000 persons. The whole was painted as stone work, with pilasters at certain distances holding shields emblazoned with the arms of some of the principal Italian cities. To enclose this amphitheatre is raised a handsome screen, enriched with thirty-eight bassi-relievi of subjects from the life of Dante, most admirably executed by Florentine artists, alternated with effigies (in frames of the thirteenth century style) of the most celebrated commentators, translators, and biographers of Dante. Between the bassi-reliefs and portraits are the emblazoned arms of the communities of Tuscany. Above the screen, as ornaments, are the arms of the principal municipalities of all Italy. On high staves wave the pennons of forty-eight of the chief Italian cities. At each corner of the piazza, are the flags of Venice, Rome, Florence, Ravenna.

After the arrival at Sta. Croce of the long procession, which had left the Piazza of San Spirito, on the south side of the Arno, and, crossing the beautiful Ponte di Trinità, had walked round the Duomo, and through the principal streets, and the thousands forming it had been placed in order around the enclosure so that one undivided line of banners edged the open space where stood the veiled statue, the king and his suite having arrived, the picture that was presented to the spectators was one not to be forgotten. Looking east was the beautiful façade of Sta. Croce. This façade, which was finished only as lately as 1863, from designs left by Cronaca, of brilliantly white marble, with its beautiful bas-reliefs, and the arms, in coloured marble and serpentine, of the donors towards its completion, of whom our countryman, Mr. Sloane, was the most liberal,—shone out in relief against the deep blue Italian sky. The wall of banners on each side, of all hues, and adorned with brilliant gilding,—those of Genoa being among the most gorgeous; the mass of military bands accompanying each representative of towns in a group before the façade; the small group, consisting of the king and his attendants, in uniform, opposite; then, when at a signal from the king the veil was withdrawn by the gonfaloniere, disclosing the statue of him whose memory all men present had come to honour, there arose such a burst of spontaneous enthusiasm as affected every one. The honours around the piazza were covered with brilliantly-coloured arras, and the windows filled with gaily dressed spectators. All was bright—all successful. Of course, as might be expected, politics were not forgotten,—the banners of Rome and Venice, borne by emigrants, had large hoes of black crape attached, and the long cheerings and aspirations for the liberty of the latter were heard again and again. The sculptor Pazzi received from the hands of the king the decoration of Saints Maurice and Lazarus. The Dante committee were introduced to the king. There was sung a *cantata* composed for the occasion; followed by reiterated cheers for the king; and thus finished the commencement of a *fête* intended to obliterate as much as possible the past unjust treatment of their patriot poet, and to bring together in friendly union those till now only united by annexation.

A tournament, in costumes of the thirteenth century, well arranged for the people, took place in the Casino, in the afternoon. In the evening the whole town was illuminated with white globe oil-lamps, giving a golden effect when, as in the case of the Pitti Palace, the façade of S. Miniato, the Duomo, Giotto's Campanile, the Palazzo Vecchio, the Bargello, the lines of the architecture were all illuminated. It may be remarked here that the erection of seven of the most striking edifices of Florence were undertaken during the life of Dante; namely, the Baptistery (as it now is), the Duomo, the Palazzo

dei Signori, the Bargello, San Spirito, Santa Croce, and Or' San Michele.

On Saturday the king opened the Dante Exhibition, and also a Medieval exhibition of choice objects from the rich collections of Florentine families. The former is rich in rare editions, manuscripts, illuminations, numerous portraits of Dante, modern pictures illustrative of his life. This and the Medieval collection deserve more space than can be now devoted to them. On the occasion of the opening of this exhibition, the king was presented by the Consiglio Provinciale with a sword of very beautiful design and workmanship, in wrought iron, executed by a young artisan,—Gnudi, of Pescia. On one side of the blade are the words, "Dante to the first King of Italy;" on the other, the lines from Dante's "Purgatorio," in which *Romo* appeals for release from her widowhood and misery. On the pomel of the sword are figures allegorical of "L'Inferno" and "Il Purgatorio." At the top of the handle, in allusion to "Il Paradiso," are figures of Dante and Beatrice. The king admired this memorial gift of the Dante Festa greatly,—and with justice. It will vie with many of the beautiful productions of the Middle Ages now exhibited in that glorious old Medieval palace, the Bargello.

Florence.

#### STREET ARCHITECTURE OF THE OLD TOWN OF EDINBURGH.\*

THE existence of secret chambers was by no means an unrequited occurrence in the old houses. The massive thickness of the walls and the great variety of outward form admitted of their existence that more readily, and it is not improbable that there are many such unknown to the present generation. The demolition of an old house in Todd's Close, in 1845, "brought to light a curious small concealed chamber on the first floor, lighted by a very narrow aperture looking into Nairn's Close. The entrance to it had been by a moveable panel, affording access to a narrow flight of steps ingeniously wound round the wall of a turnpike stair, and thereby effectually preventing any suspicion being excited by the appearance it made. The existence of this mysterious chamber was altogether unknown to the inhabitants, and all tradition had been lost as to the ancient occupants, to whom it doubtless afforded refuge."† In taking down the house of John Gourlay, in the Old Bank Close, a secret chamber was discovered placed between the ceiling of the first flat and the floor of the second. In the east wall of the Guise Chapel there is a staircase in the thickness of the wall, which gave access to a secret chamber beneath, in which there was a draw-well, with a surrounding stone parapet.

About thirty years ago, in the course of executing some alterations on that old house at the foot of the Canongate, the abode of the notorious Luckie Spence, celebrated in Allan Ramsay's poems, the workmen came upon a cavity in the solid wall, which contained the skeleton of a child wrapped in the mouldering remains of a linen cloth. A similar discovery was made in 1830 in the course of making some repairs on the royal apartments of the castle. A recess, 2 ft. 6 in. by 1 ft., was discovered in the wall, which is in a line with the crown room. It contained a very ancient oak coffin, within which were the remains of an infant, wrapped in embroidered silk and a woollen cloth. Both mysteries remain unsolved.

There was a curious old tenement, that of Provost Stewart, in the West Bow, so situated on the steep declivity that, while it presented a lofty façade to the south, on the north it was but one story high with attics. This house, according to Chambers, was full of concealed rooms and secret stairs. In one room "there was a little cabinet about 3 ft. high, which any one not acquainted with the mystery to be a cupboard. Nevertheless, under this modest, simple, and unassuming disguise, and interest than a trap-stair."‡ This stair communicated with the West Bow, and is said to have afforded to Prince Charles and some of his principal officers the means of escape from a body of soldiers sent to arrest them. In Lockhart's court there was a

\* See p. 326, ante.

† "Memorials of Edinburgh," vol. i., p. 149.

‡ "Chambers's Traditions," vol. i., p. 144.

profound underground dungeon, which was only accessible by a secret trap-door, opening through the floor of a small closet, the most remote of a suite of rooms extending along the southern and western sides of the court.

Garderobes are sometimes found in the thickness of the walls, entrance to them being obtained by a short passage from the jamb of the window. At other times the garderobe is boldly thrown out upon corbels from the face of the wall, as may be seen on the south and east sides of the castle and on Nisbet of Dirleton's house, in the Canongate. In the latter instance, indeed, the garderobe forms perhaps the most picturesque feature of the northern façade of that interesting mansion.

In houses erected in the fifteenth and beginning of the sixteenth centuries, the ceilings are frequently found highly decorated. They are commonly of wood, supported by solid beams placed parallel to one another, or divided into panels by moulded ribs, with bosses at the intersections, the bosses being carved with foliage or heraldic shields, and enriched with painting and gilding. Sometimes the panels are ornamented with scrolls bearing inscriptions, sometimes with beautiful arabesque work, and at others, again, with allegorical subjects and designs of flowers, foliage, and fruit; in others, again, there are armorial bearings highly blazoned with various colours. The ceiling of Queen Mary's bedroom, in Holyrood Palace, may be taken as the first example. It is divided by moulded ribs into square and hexagonal compartments, containing a variety of armorial bearings, among which may be mentioned a crown with a crowned lion above, enclosed in an ornamental border or wreath; a thistle and crown above a lion in defence, several crowns with the initials of Queen Mary, and one with those of her grandson. The central panel of the arched ceiling of the hall in General Dalrymple's mansion was occupied by a painting of the sun surrounded by golden rays on an azure ground, while the others were painted so as to represent the sky and clouds, with silver stars standing out in relief. In the small irregularly-shaped room in the castle in which James VI. was born, in the year 1566, the original oak ceiling still exists. The panels are ornamented alternately with the royal crowns I.R. and M.R., surmounted by the royal crown.\* I have already mentioned the two wagon-shaped ceilings in the Gnoise Palace; one of these was painted in arabesques and wreaths of foliage and flowers, surrounding panels which contained inscriptions in Gothic letters. One of these inscriptions was this:—

"Gif you wt syn afflieit be,  
Och yan say Chryst cum you to me,  
Swyth ye may, walk row thairin  
Embrace ye truth, abandon [sic]."

The other ceiling was ornamented with a great variety of emblematic devices and Latin mottoes, enclosed in ornamental borders, while the whole was richly coloured. Among those devices may be specified a hand holding a dagger in the midst of flames, with the motto "*Agere est pati fortia*," that of an ape crushing her offspring in the excessive fervency of her ombrance, and the words, "*Cæcus amor prolis*;" also that of a serpent among strawberry plants, and the motto, "*Latet anguis in herbâ*." Some fragments of this fine ceiling are still preserved in a private museum. In some of the other apartments of the same building the panels of the oak ceilings were found blazoned with the heraldic bearings of the Duke of Chateherault, of France, and of Guise, impaled with the Scottish lion. In the old stone land, at the head of Blythe's Close, there was accidentally discovered, more than twenty years ago, a very beautifully decorated arched wooden ceiling, which is thus described by Mr. Daniel Wilson. A large circular compartment in the centre contains the figure of our Saviour, with a radiance round his head, and his left hand resting on a royal orb. Within the encircling border are these words, in gilded Roman letters, on a rich blue ground, "*Ego sum via, veritas et vita. 14 Johne.*" The paintings in the larger compartment represent Jacobi's dream; Christ asleep in the storm; the Baptism of Christ; and the Vision of Death from the Apocalypse, surmounted by the symbols of the

Evangelists. The distant landscape of the Lake of Galilee in the second picture presents an amusing, though by no means unusual liberty, taken by the artist with his subject. It consists of a view of Edinburgh from the north, terminating with Salisbury Craigs on the left, and the old Castle on the right! This pictorial licence affords a clue as to the probable period of the work, which, as far as it can be trusted, indicates a later period than the Regency of Mary of Guise. The steeples of the Netherbow Port and the Old Weighhouse are introduced—the first of which was erected in the year 1606, and the latter taken down in 1660. The fifth picture, and the most curious of all, exhibits an allegorical representation, as we conceive, of the Christian life. A ship, of antique form, is seen in full sail, and bearing on its pennon and stern the common symbol, I.H.S. A crowned figure stands on the deck, looking towards a burning city in the distance, and above him the word V.Z.L. On the main-sail is inscribed *Curias*; and over the stern, which is in the fashion of an ancient galley, [*Sa pienza*]. Death appears as a skeleton riding on a dark horse, amid the waves immediately in front of the vessel, armed with a bow and arrow, which he is pointing at the figure in the ship; while a figure, similarly armed and mounted on a huge dragon, follows in its wake, entitled *Persecutio*; and above it a winged demon, over whom is the word *Diabolus*. In the midst of these perils, there is seen in the sky the Hebrew word *חיה*; and from this symbol of the Deity a hand issues, taking hold of a line attached to the stern of the vessel. The whole series is executed with great spirit, though now much injured by damp and decay. The broad borders between them are richly decorated with every variety of flowers, fruit, harpies, birds, and fancy devices, and divide the ceiling into irregular square and round compartments, with raised and gilded stars at their intersections. The fifth painting, of which we have endeavoured to convey some idea to the reader, possesses peculiar interest, as a specimen of early Scottish art. It embodies, though under different forms, the leading features of the immortal allegory, constructed by John Bunyan for the instruction of a later age. The Christian appears fleeing from the city of destruction; environed still by the perils of the way; yet guided, through all the malignant opposition of the powers of darkness, by the unerring hand of an overruling Providence. These paintings were concealed, as in similar examples, by a modern flat ceiling, the greater portion of which still remains, rendering it difficult to obtain a near view of them.\*

The council-room of the Canzio House still retains portions of a fine oak panelled ceiling, ornamented with heraldic bearings. The hall of John Knox's house is covered in with an oak roof, which is now partially concealed by a plaster one, probably of Charles II.'s time. The beams, which are of solid oak, and the planking of the floor above, are painted with ornamental devices, divided by fillets or bands. Portions are still preserved of a timber ceiling removed from one of the old *Templar lands* in the West Dow. In one of the panels is the motto,—"He yt Tholis [undergoes or suffers] over-cumms." A word en passant on the subject of the Templar lands. Passing through the Grassmarket one may observe a stone or iron cross, planted like a dagger, here upon this globe, and there upon that hartsian. This notified that the houses lay within the jurisdiction of the Knights Templar, an order possessed at one time of much landed property in Scotland. The tenants of these lands retained some peculiar and interesting privileges, as well as burdens, which were only abolished by the Act of 1746.

In the great hall of that lawyers' "receipt of custom," the Parliament House, the fine old open-timber oak roof still remains. It rests upon ornamented brackets, consisting chiefly of grotesquely sculptured heads, and is formed of dark oaken tie and hammer beams, with cross-braces. Small gilt hall pendants hang from the hammer-beams. The whole is so arranged as to give the outline of a circular arch. It was erected in the early part of the seventeenth century. The chapel in Heriot's Hospital has a beautifully embossed and painted arched ceiling. It is a recent restoration of the original ceiling, and is divided into compartments. The ribs are finely moulded, and spring from corbels, which represent angels holding scrolls.

It may be convenient, before passing to the

consideration of the stucco ceilings, which superseded those of wood, to glance at the style of ornamentation employed on the inner walls of houses of the sixteenth century. Towards the close of the previous century tapestry began to be disused, and its place to be supplied by wainscoting and stamped or gilded leather, which was imported chiefly from Spain. The wooden panels which formed the usual decoration of the lower part of the walls more commonly remain, and are usually richly carved. Like those of the ceilings, too, they are generally enriched by polychromatic ornamentation and gilding, although time's effacing fingers have done much to diminish the brilliancy of the original colouring. A common kind of ornamentation, although not so much so in Scotland as in the sister country, was that known by the name of the "linen pattern," from its being an imitation of the folds of a linen napkin. Sometimes the panels were filled with Arabesque designs, sometimes with scrolls, with or without inscriptions, sometimes with landscapes or portraits, and at others with armorial bearings. At the demolition of the new Council House it was found that the walls had originally been panelled in oak, the compartments containing a series of portraits. One only, unfortunately, of those panels has been preserved. It contains a representation of James V.'s widow, Mary of Guise, in a high-bordered lace cap and ruff, with a monogram, composing the word *Maria*, bordered into the back of the panel. There is still preserved some oak panelling, about 8 ft. in height, which was removed from the Gnoise Palace before its demolition in 1845. It is divided into four compartments by boldly-carved terminal figures, fine Arabesque carving occupying the compartments. In Sir John Smith's mansion, in Riddell's Close, Lawnmarket, there is some beautiful wood panelling in the principal apartment. The walls, doors, and shutters are all panelled in wood, each panel containing a different landscape. The painting is supposed to be the work of James Norrie, the celebrated house-decorator. In Trunk's Close there is part of an old house with a large hall, which contains some finely-carved oak panelling; and in a house built in Queen Mary's reign, which stands at the head of Pannure Close, there is a fine specimen of a carved panel, containing the Scottish lion, surrounded by a wreath of foliage.

The wooden ceilings, and the wainscoting on the walls, came in time to be superseded by plaster or stucco work, commonly called "pargeting," on which was stamped a great variety of patterns. Pendants not unfrequently took the place of bosses; and, as Gothic art gave place to the Roman or Italian, figures of Cupids and other Classical ornaments began to be introduced. A common ornament on the cornices of chambers, or immediately beneath them, was the heads of the Caesars. This style prevailed most, perhaps, during the reign of Charles II., and there are many fine examples of pargeted ceilings and walls dating from that time in the Old Town of Edinburgh.

That fine French mansion of the Earls of Moray, which is one of the most remarkable objects of interest in the Canongate, and which was built a few years before the visit of Charles I. to Scotland in 1633, possesses some fine examples of pargeting. It was shame, however, to pass by this fine old *maison de plaisance* with a mere notice of its walls and ceilings. The successive residence of the Countess of Home, who built it, of Oliver Cromwell, of the Marquis of Argyll, son of the great Marquis; again, of Cromwell, and of Lord Chancellor Seafield, it is rich in historic associations. Its northern façade forms part of the street of the Canongate; but to the south, and commanding a beautiful view of Arthur's Seat, and the mural ridge of Salisbury Craigs, is a large garden, with stately terraces of hewn stone, a fine fountain, interlacing trees, and that quaint old summer-house, surmounted by two greyhounds, the supporters of the arms of the House of Moray,\* in which the Parliamentary commissioners assembled to affix their signatures to the Treaty of Union between England and Scotland, but whence they were expelled or scared by the exasperated mob to do so in an obscure cellar, or *laigh house*, in the High-street. David Buchanan, writing some time between 1632 and 1651, says,—“On the south side of the Canongate, not far from the public cross are the gardens (with the mansion), of the Earl of Moray, which

\* On the wall of this apartment are the Scottish arms, and beneath them this inscription in black letter:—

"Lord Jesu Chryst, that crownit was with Thorne,  
Preserve the Birth, quibus Radigis heir is borne;  
And send His Souce succession, to Reigne still,  
Lang in this Realme, if that it be Thy will.  
Als grant, O Lord, quhat ever of Hir prosced,  
Be to Thy Honor and Fraiz, sobeit,  
19th Junij, 1586."

\* "Memorials of Edinburgh," vol. i., p. 156.

\* Though now converted in part into a greenhouse, this summer-house still retains much of its picturesque-ness.

are of such elegance, and cultivated with so much care, as to vie with those of warmer countries, and even, perhaps, of England itself. And here you may see how much the art and industry of man may avail in supplying the defects of nature. Scarcely any one would believe it possible to give so much beauty to a garden in this frigid clime." To return to the house itself. The street front, though solid-looking and picturesque, is not very highly ornamented. It has, however, good string-courses, and the windows are surmounted by various carved ornaments of Elizabethan character, while over the large centre window, impaled on a lozenge shield, are the lions rampant of Home and Dudley. The principal features of this façade are two substantial pillars, with very high pyramidal pinnacles flanking the gateway, which gives admission to the courtyard, and a massive stone balcony, carried on a uniform series of highly ornamented corbels. Upon the original balcony, of which this is a restoration, on the afternoon of Saturday, the 18th of May, 1650, a noble marriage party, consisting of Lord Low, afterwards Marquis of Argyll, his bride, Lady Mary Stuart (the Earl of Moray's eldest daughter), Lord Chancellor London, Lord Warriston, and the Countess of Haddington, was assembled. Assembled, and for what? To "feed their eyes,"—to use Lord Fountainhall's expression—upon the ignominy of their fallen enemy, the gallant Marquis of Montrose, who had been brought captive to Edinburgh that day. He had been received by the magistrates at the Watergate, where the sentence, which condemned him to die, was read over to him. He was then bound to a low cart, and preceded by the common doomsman, who was mounted on horseback, and by a number of other prisoners of less rank, bound two and two, and bareheaded, he took his way up the Canonigate. As the sad procession passed up the steep street, it passed beneath this balcony, crowded with the illustrious wedding party. And then Argyll's niece, the Countess of Haddington, with incredible meanness, forgetful alike of her sex and of her high birth, actually spat at the bound captive. But he bore the cowardly insult "with smile serene and high," and his ignominy though high-born enemies, shrank back abashed by the dignity of his demeanour. We read in "Nicholl's Diary" (p. 13) that his manner was "more becoming a bridegroom, nor a criminal going to the gallows."

The principal entrance to the mansion is by an arched passage, through the centre of the house. It contains two very handsome state apartments, one of which opens upon the stone balcony. The ceilings of these two apartments are wagon-shaped, and formed of elaborate stucco work, consisting of panelling, pendants, and a great variety of ornamental devices. That of the room, which looks into the Canonigate, is especially worthy of attention. It is profusely pargeted, and ornamented with winged cherubs; lions with crowns on their heads, dragons, salamanders, *fleurs-de-lis*, and thistles.

The drawing-room of the neighbouring mansion, Milton Lodge, built in the beginning of the 18th century by Fletcher of Milton, Lord Justice Clerk of Scotland, has its walls and ceiling beautifully decorated. The latter is richly pargeted with a cornice, finished with painting and gilding. On the walls is a series of landscapes and allegorical figures, divided by rich borders representing fruit and flowers. Among the borders are various figures, such as those of a cardinal, a monk, a priest, &c., in grotesque attitudes. It has been plausibly suggested that these curious figures, which seem as if they had been copied from some illuminated missal of the fourteenth century, were introduced to pleasure some whim of the Lord Justice Clerk. The decoration of this apartment, which commands an agreeable view of Arthur's Seat and the Royal Park, is generally ascribed to Francesco Zacherelli, an eminent artist who flourished in the early part of the eighteenth century. In evident imitation of this beautiful room is the drawing-room of the middle house on the north side of Brown-square, the residence of Sir Thomas Miller, Lord Glenlee, and the Lord President of the Court of Session, who died there in 1759. Another beautifully pargeted ceiling is that of one of the apartments of Sir John Smith, of Grotham's-honse, in Riddle's-close. In the centre of a wreath, composed of roses and thistles, are the royal crown, and the date 1678. The other compartments of the ceiling, circular, and polygonal, contain alternately the Scottish lion rampant, and the English lion passant gardant.

In the course of erecting George IV.'s Bridge, across the Cowgate, in 1829, Merchants' Court, built in a plain but massive style of architecture, was swept away. This was the residence of the celebrated Thomas Hamilton, first Earl of Haddington, and Lord president of the Court of Session, or *Tam o' the Cowgate*, as James VI. facetiously denominated his favourite. It contained some finely pargeted ceilings and handsome oak panelling. The principal apartment on the second floor, which gave upon the Cowgate, was a magnificent room, with a stucco ceiling, which was divided into square compartments, each of which contained a separate and distinct device. Pinkie House, which has already been incidentally mentioned, contains some very richly pargeted roofs. One room, in particular, a very lofty one, which is said to have been occupied by Prince Charles Edward, after his victory over Sir John Cope at Preston Pans, has beautifully decorated pendants. But the Painted Gallery, a fine hall, 120 ft. long, arched, and lighted by a fine oriel window, is the one most remarkable for its interior decorations, which are, however, of earlier date than the room just mentioned. On the panelling on the walls there is a number of groups and landscapes, round which frames are painted, with cords and nails, so as to represent hanging pictures. The roof is of wood, and is entirely covered with paintings and inscriptions. The subjects of the former are chiefly classical, and the latter are principally philosophical apothegms, intended apparently to play the part of the human skull at the ancient Egyptian banquets.

#### "THE TABARD," SOUTHWARK."

EVERY ONE has heard of "The Tabard." Such is the power of the poet! Five hundred years ago Geoffrey Chaucer put it in amber for posterity when he wrote,—

"Befell that in that season, on a day,  
In Southwarke at the Tabard, as I lay,  
Ready to wander on my Pilgrimage  
To Canterbury with devout courage,  
At night was come into that hosterie,  
Well nine and twenty in a compaigne;"—

and there it still remains, bright for the world. The thing has been protected by the word. It has had its changes; and on the 9th next it will be "Going! going!! gone!!!" under the hammer of Rushworth & Jarvis. The inn itself is now known as "The Talbot," some stupid landlord, about the year 1676, having put up a dog as a sign instead of the herald's sleeveless coat; so that it afterwards became necessary to write up on the hressumner above the gateway leading down to it, out of High-street, "This is the inn where Sir Jeffrey Chaucer and the nine-and-twenty pilgrims lay in their journey to Canterbury, anno 1383." The buildings of Chaucer's date have disappeared; but there is an old galleried structure, of the time of Elizabeth, at the bottom of the yard, used as offices by the Midland Railway Company, which bears on its face what was once a picture, and is marked out by an inscription as "the old Tabard." Change is everywhere around it. The town-hall formerly opposite the gateway has given place to a modern bank; new streets have been opened, new houses built; and so greatly has the value of land increased here, as elsewhere about London, that we may expect that, when the well-known old "hosterie" gets into other hands, it will disappear, and afford a site for some modern structure. Such is the natural course of events, and so it will be; and, however much we may desire for the sake of sentiment,—not a worthless thing,—to retain here and there remnants that tie us to the past, no valid word can be said against the removal in this case. We do hope, however, that, when this time comes, an inscription, properly shined, will be made, to tell all comers that here stood "The Tabard," immortalized by Chaucer.

#### NEW WING, ST. MARY'S HOSPITAL, PADDINGTON.

The ceremony of laying the first stone of the new wing was carried through very successfully on Tuesday last. The Prince of Wales, acting up to the traditions of the Family, was punctual; was received by a considerable assemblage in a fine marquee, tastefully decorated; and was attended by a number of distinguished persons. In the course of a reply to an address from the governors, His Royal Highness said,—"It must hereafter

be one of my most pleasing associations, as connected with the proceedings of this day, to have, as your governors propose, the new wing called after myself, and that two of the wards should receive the names of the Princess of Wales, and of my son. I trust, gentlemen, that neither they nor I will ever neglect the cause of the sick and the poor, and I join my prayers to yours in now invoking the blessing of the Almighty to prosper the undertaking."

It is unnecessary to speak of the cheers that followed this, and that were renewed when the Prince spread the mortar and struck the stone, the trowel and mallet being handed to him by the architect, Mr. W. Young, and the builder, Mr. Trollope, as representative of his firm.

The stone so laid is a fine block of Cheshire granite, weighing about two tons, and was given by Mr. Freeman. The silver trowel and mallet, made by Emmanuel, were the gift of Mr. Ernest Hart.

Afterwards some of the prettiest children of Tyburnia, mostly dressed alike, and who must have been under training with Mrs. Hope d'Egville or some other equally good mistress of "deportment," so well did they conduct themselves, filed by and handed each a purse to the Prince; and then mamma followed with beaver gifts, and showed that they, too, were well up in the "presentation curtsy." Besides these, we heard of several considerable donations, including a large sum from the Foresters, so that it may be hoped the governors will not be disappointed in the matter of funds. Some hearty cheers were given at the close for the committee of ladies, who had laboured most sedulously to cover everything with inscriptions and wreaths of evergreens and flowers, and well deserved the cheers were. The inscriptions, mostly apposite, were remarkably well formed, and the effect of the whole was very agreeable. Amongst the decorations, but less observed than it should have been, because of the position to which it was necessarily confined, was a graceful triente, by one of the ladies of the committee, to the memory of the late Prince Consort, Albert the Good, by whom the first stone of the original building was laid. This stone, showing in the external wall of the building within the marquee, was framed with leaves, and pointed out by an inscription; while above it was hung a portrait of the Prince, surmounted by a pyramidal form bearing his motto,—

#### "Treu und Erst."

Amidst the garlands and "wreathed smiles," and complimentary cheers, it may seem ungracious to talk of defects. The truth, however, ought not to be hidden even by flowers; and, truth to tell, we cannot avoid deploring that the new wards arc to repeat the error of the existing wards of the hospital. They will be modified to a certain extent, inasmuch as there will be two partitions down the centre of each, with a passage-way between; but they are to all intents and purposes double wards, that is, with four ranges of beds between the two external walls, an arrangement simply abominable. If we noticed rightly, too, these new wards are intended for "accidents." Is it too late for re-consideration? The surgeons attached to the hospital will be guilty of little less than a crime if they permit, without a protest, this evil arrangement to be carried out,—an arrangement that will inevitably increase their difficulties and cares, and lessen the chances of recovery. Such an arrangement is pointed to now by those who have fully studied the subject only as amongst the examples of what to avoid "in hospital planning."

#### PLAGUE IN A PIT VILLAGE.

WE are happy to be able to add, as a sequel to our account of the unsanitary condition of Raterliffe Terrace, a colliery village, on the northeast coast of Northumberland, that remedial works are now in progress. The lessee has built two new conveniences for the school, and one to the public-house, and has consented to build conveniences and ashpits about forty yards from the dwellings, in a line with the pigsties, at the rate of one of these twin necessities to every four houses. The drainage outfall, too, is to be carried a greater distance from the dwellings, and to be flushed at intervals. Unfortunately, however, our suggestion for an ample water supply is not to be carried into effect, the lessee preferring to organise a supply of water per cart from a spring at Ambic. This is to be sold to

the inhabitants of the pit village at a halfpenny a *skewful* (about four gallons), an arrangement which, while it reduces the cost to the provider, increases it to the consumer at a rate that threatens to prevent a sufficiently profuse use of this highly important sanitary agent. Neither have we gained all that we could wish in the matter of flagging and paving. A cartway is to be made behind the privies and ashpits, which will have the effect of reducing the traffic in front to some extent. We have, moreover, a new circumstance to deplore. The doctor who has ministered to the fever-stricken pitmen and their families has been dismissed, it is to be feared from a feeling that the information of the unsanitary state of the village was disseminated by him or his deputy; and that thus, as the lessee stated before the Board of Guardians, it got into the *Builder*. If lessees are to enforce secrecy upon the medical men they employ, there will be a new difficulty in the path of sanitary reformers. But in this case the medical officer is neither to praise nor to blame for the publicity the matter has attained. The Alwrick Board of Guardians, the police inspector of nuisances, the relieving officer of the Board of Guardians, the surveyor to the Alwrick Local Board of Health, and ourselves, share the honours of the agitation that has brought forth the partial amelioration quoted.

The Poor Law Board, whose attention has been drawn to the unsanitary state of things, consider it a case for the establishment of the Local Government Act.

#### BUILDINGS AND THEIR VEGETABLE PARASITES.

ALTHOUGH man calls into play all the known resources of science and art, to make his house as durable, perfect, and beautiful as possible; the present state of knowledge is wholly inadequate to preserve either the house or its inmates from the numberless insidious foes that begin the work of destruction the day the first stones and timbers of the house are laid. As soon as any building is erected, it seems as if all the powers of nature immediately set about its subversion; neither is the building alone in this, but its whole furniture and contents become the prey of various vegetable parasites, including among the victims even the master of the house himself. These parasites eventually succumb to the course of the second degree, so that in the others of time little or no trace is left of human habitations. Larger buildings and works of art of unusual size contrive to exist a little longer, partly owing to the difference of materials and construction, and often to accidental circumstances. It is the purpose of the present notice to consider only the vegetable parasites of houses, omitting altogether accidental causes of destruction, such as storms, earthquakes, floods, the chemical action of the atmosphere on wood, iron, and stone, and the members of the animal kingdom that delight to commit their ravages in our dwellings, such as rats and mice, and other animals,—birds, reptiles, and destructive insects.

The principal vegetable parasites of dwellings belong to the cryptogamic class, such as mosses, lichens, and fungi; principally the latter; although many flowering plants undoubtedly play their part, but generally after the way has been prepared for them by the lower members of the vegetable kingdom; for although such a plant as a wall-flower, stone-crop, or snap-dragon, could not grow on a newly-built stone wall, a lichen would soon be able to find a subsistence there, the moisture of the atmosphere being sufficient to cause the seeds to germinate, and keep the plants alive, and once there the extremes of heat and cold would have little or no effect, as lichens will survive the hottest summer and coldest winter. When secure on the stone, the work of disintegration begins; the tiny plant is sufficient to arrest small atoms of dust, &c., in the air, and by its own decay and renewal of its species, prepares a fitting *habitat* for a class of plant one stage higher, simply by partly crumbling away and loosening the cement, and allowing the tender root-fibres of other plants to penetrate the interstices of the stones, slates, tiles, or bricks, in search of nutriment and moisture: therefore every moss, lichen, or flowering plant that adds to the picturesque beauty of an ancient building is a parasite slowly but surely (with many allies) working the utter destruction of the building.

Perhaps the most dreaded parasite of the

wood-work (although by no means confined to the wood) is the dry-rot. Descriptions of the ravages of this fungus have frequently been published in the *Builder*, and therefore little need be said of it here (various specifics for its prevention were given in a recent number). Mention may, however, be made of the immense development of dry-rot in a railway tunnel in the North of England a few years ago, when it caused considerable discussion, and was considered of sufficient public interest to have its portrait published in one of the illustrated London papers. Professor Burnett, speaking of a house he rented, says, in four years, the parlours had to be twice re-wainscoted, and new stairs put in; but, after every precaution, the dry-rot ultimately became so developed that the house had to be *pulled down*. These instances might be multiplied *ad infinitum*; but we will pass to another plant of a higher order, viz., the mushroom-like fungus that so often grows under paving-stones, lifting them out of their beds and displacing them in various ways. There are few persons connected with building in any way but have seen the work of this fungus. It commonly occurs in damp kitchens and under the street pavements,—once to such an extent as to cause nearly the entire repaving of a town. But this, like the last species, has frequently been noticed in these columns, so that it is sufficient to mention it. There are many other species of destructive fungi, well known to botanists, that attack wood alone,—some that restrict themselves entirely to a particular sort of wood, as pine, oak, elm, maple, poplar, &c., and are never found away from their especial host. Other species confine themselves exclusively to plaster of walls and ceilings, and may be searched for in vain elsewhere; whilst a third is only found on the paper of walls, and extending to the books or any objects of paper in the house. Every portion of the building, outside and inside, is attacked by these plants, till at last its downfall is insured; and, after the house itself, it would be difficult to name a single article that is not open to an attack; for on such objects as iron, lead, and glass, they have been known to grow, instances of which are on record, and on the various poisonous metallic solutions. Another takes the carpets in hand, and a third the mats. Every article of food has its attendant plant,—all drinks, wine, beer, syrups, and even oil and vinegar, the clothing of man not being exempt. Various plants of this nature delight in the cellar as a *habitat*; and an instance is well known where a cask of wine was lifted by one species from the floor to the ceiling of the cellar, blocking up the entrance-door, the wine having leaked from the cask and developed itself into a monstrous fungus. Neither is wine in casks alone unfortunate, for wine in bottles has its parasite, that penetrates the cork and destroys the wine. Of the rapidity of their growth and development no one requires telling. One small plant that rapidly grows on bread possesses an historical interest. In a few hours it forms a brilliant blood-red stain; and various cases of its occurrence in Medieval times on the sacramental wafers are on record, causing astonishment and dismay among the clergy and worshippers. Its appearance is not rare on stale bread, and may soon be found if searched for.

That the master of the house himself, and his wife and children, and domestic animals, are afflicted with similar parasites to the ones that prey on his house and furniture, and food, is well known.

As a grim sequel to the dry-rot in the roof, the human subject is liable to a painful fungus on the head and beard, that mats the hairs together, causing exquisite pain. Even the disease known as scald head is shown to be of fungoid origin; or, to sum up, every part of the inside or outside of a man is as liable to an attack of these parasites as the house he lives in: bandages taken from wounds have been observed with the spawn of fungi attached; and, after being laid aside, instances are known where even the higher forms of mushroom-like fungi have rapidly developed themselves in a few hours. Scientific men have recently had under discussion the deadly "fungus foot" of India. This fungus attacks the heels of the natives, soon destroying the bones of the foot and part of the leg, the only cure, after the fungus has once appeared, being immediate amputation: its proper *habitat* is said to be probably damp earth; and it is suggested that the spores or seeds are absorbed by the skin, or introduced by a prick from a thorn or similar object, one spore (infinitely smaller than a grain of dust) being sufficient to introduce

the disease. Specimens have been forwarded to this country for examination, and attempts have been made to make the spores grow, but (at present) without success,—a result hardly to be regretted, when it is considered how large is the number of vegetable parasites we have already in this country peculiar to man and his house.

W. G. S.

#### THE HOLBORN VALLEY IMPROVEMENT.

At the last meeting of the Court of Common Council, a number of the inhabitants of the ward of Farringdon Without attended at the bar with a petition, which had been adopted at a public meeting, protesting against the plan in contemplation by the Corporation for raising Holborn-valley. The petitioners stated that they viewed with great dissatisfaction and alarm the rejection of a plan (by Mr. Abrahams) which had been submitted by their ward to the Improvement Committee of the Corporation, and the intention of the Corporation to execute the viaduct from Skinner-street to Ely-court, Holborn, which, they said, did not provide for a direct communication, between the high level and Farringdon-street (except for foot-passengers by means of staircases of 27 ft. high), thereby severing the two main arteries of traffic, and which, if so carried into effect, must occasion great loss and injury to the trade and property of Farringdon Ward. The plan submitted by the ward provided for direct communication between the high and low levels, and was one which should be adopted, inasmuch as it not only remedied all evils which the bridging over the Holborn-valley was intended to obviate, but, in addition, greatly improved Farringdon Market, making it easily accessible for traffic, and also the various streets and thoroughfares adjoining.

It was pointed out by Mr. Deputy Fry that the Corporation plan was adopted after anxious consultation with eminent engineers, and afterwards received the sanction of Parliament in all its great leading features; and the Court, by a large majority, declined, and we think wisely, to re-open the question. The plan recommended by the petitioners was considered by the committee, assisted by the City architect; and they rejected it on the grounds chiefly that it divided and narrowed Farringdon-street and Farringdon-road, and concentrated and crossed the traffic (which it has been a great object with the Corporation of late years to distribute) on the very centre of the proposed viaduct. Another objection to the plan of Mr. Abrahams is that it contemplates taking down the whole of the western side of Farringdon-street.

#### ARCHITECTURE AND ENGINEERING.

I HAD the pleasure of hearing an eloquent essay read by Mr. Ruskin recently, at a public meeting. The point which more particularly struck me as interesting to real builders, was the mode in which one out of many of our growing railway structures in the metropolis was gibbeted, so to speak, *in terrorem* by the lecturer.

Much was said, both in the essay and in the discussion that followed, as to the relation between architecture and engineering, and the line that should be drawn between the functions of the respective professions; and the general impression communicated was, that beauty fell within the province of the architect, while strength alone was the proper object of the engineer.

It did not seem to occur to any one present to suggest a very obvious distinction. The homes of mankind, the edifices needed by social life, whether for abode, for worship, for Government, or for amusement, are properly entrusted to the architect. To the engineer—military and civil, are committed, on the other hand, the defences and the communications of the country, that is to say, the fixed and permanent provisions for such communication, the actual material of transport forming a distinct charge, under its two principal branches of land and water communication.

If this be the true principle that divides engineering from architecture, it is clear that the rules of construction must materially differ for the two professions. In our habitations and in our public buildings, in which so much of human life is now necessarily spent, we require not merely shelter, but a sense of comfort, and

as far as is practicable, of pleasure. Adornment, therefore, has always been a very prominent part of architecture; and whether adornment take the form of the luxury of a modern clubhouse, or of the mystic teaching of a Gothic cathedral, it may and should be a genuine part of the structure created by the architect.

But the true beauty of the other class of structures consists in their scientific truth, in the best disposal of material—and of the best available material—to accomplish a given end. And it is where this is most distinctly the case that the taste, as well as the judgment, of the engineer is best displayed. The living tracery or rich emblazonment that has its fitting display in a palace or a cathedral, that is intended to last for centuries, would lose its significance if placed on the parapet of a bridge over which the passengers were whirled at the rate of forty miles an hour; and not only so, but as it would in this case be merely surplus weight, it would become positively offensive to the taste of the really scientific engineer.

If this be so, Mr. Ruskin will surely reconsider his eloquent remarks on one of the Thames railway bridges. The idea of such a bridge, as conceived by an engineer, is not, as stated by the lecturer, that of a bundle of iron bars seized and held together by a mighty grasp. The idea is that of a roadway, fitted to sustain great weights, propelled at great velocities, suspended over a navigable river, so as not to impede the navigation.

Now, such an idea may be well or ill carried out: we have examples of both. But it is not by the support of bronze angels with brazen wings, or of the claws of monstrous dragons, or the coils of a gigantic snake that this could be truly done. Such emblems, admirably adapted to architecture, would be here out of place; and if such a bridge could be constructed of a bundle of bars, as suggested by Mr. Ruskin, the very word eloquently used by him in its disparage, a gigantic nut would be the truest and therefore the most appropriate means of securing such a bundle.

The true defect, apart from any question of scientific construction, of the bridge in question is, that ornament has been attempted which is not structural. Not only in this, but in very many iron bridges on the railway in question, a large quantity of iron work has been introduced which forms no part of the true mechanical structure, and which is offensive to the educated eye, as representing so much money absolutely wasted. It is by the very attempt to produce an architectural effect by an engineering structure, and to do this, not by elegance of construction, as in the roof at Charing-cross, but by over-aid, and therefore false and incongruous ornamentation, that the Blackfriars Bridge really merits the reprobation bestowed upon it by the sure instinct of Mr. Ruskin.

TETON.

#### THE BUILDING TRADES.

**Wolverhampton.**—Some of the bricklayers have left the town for work elsewhere. Delegates from the masters and operative plasterers (who have hitherto worked under the same rules as the bricklayers) met at the Swan Hotel for the purpose of framing rules for the future regulation of that branch of the trade. Much to the credit of both sides, a mutual agreement was come to in a short space of time, the men accepting the rules which their fellow working men, the bricklayers, had refused. The operative painters have obtained two-thirds of what they asked for, and have resumed work at the increased wages of 26s. a week.

**Stafford.**—Differences which existed between the master builders, and the bricklayers and labourers of this town, have been amicably arranged, and the men have resumed work. It was arranged, after several interviews, that work should cease at six every day except Saturday, when it should terminate at one o'clock. The rate of wages was also fixed at 4s. 7d. a day for the first five days, and 3s. 1d. for Saturday, for bricklayers, during the summer season; and 2s. 2d. on Saturdays, and 3s. 2d. for other days for labourers. Work was resumed by the men, bye-laws and regulations for the rate of wages in the winter season, &c. having been in the meantime drawn up and signed by both masters and workmen.—We may here remark that the iron trade strike in North Staffordshire has at length come to an end; the men having decided to yield.

**Plymouth.**—The *Western Morning News* fears

that the worst must be anticipated as the result of the dispute between the masters and men in the building trades of Plymouth and its neighbourhood. The large contractors for fortifications, who had previously declared their intention to suspend their works, have been joined by almost the whole of the local builders, and will be similarly supported by the purveyors of building materials. There appears, so far as can be learned, to be no disposition on the part of any of the various bodies of men—masons, bricklayers, carpenters, stonecutters, or excavators—to accept the proposition of the employers. They rely on the central organisations to supply funds for carrying on the struggle.

**Warrington.**—The operative bricklayers of Warrington made a demand for an advance of 3s., and the joiners for one of 2s. per day, which the masters have been obliged to concede. There is a large amount of building now going on in the town.

**Stockport.**—The operative painters have struck for an advance of wages, the masters having refused to yield to the terms dictated. The men demand that in future the hours of work shall be 5½ hours per week, receiving the same rate of wages now paid, being equivalent to an advance of 3s. 6d. per week, or 1d. per hour.

**Bradford.**—The journeyman plasterers and plasterers' labourers at Bradford are on strike. Last year the men got an advance of 2s. per week all round; and, in addition, half a day holiday on Saturday. They now ask for another 2s. advance, and the labourers for 1s. The masters demur to this demand, chiefly because the notice of three months is not sufficient to enable them to provide in their contracts for such an advance, and also because the present rate is beyond the average of the whole country, and sensibly higher than in many places in the neighbourhood.

**Leeds.**—While the masons and plasterers of Leeds have settled their differences with the masters and returned to work, the carpenters, bricklayers, and labourers still remain out. The carpenters are now paid at the rate of 5½d. per hour, and they want 6d. per hour; the bricklayers now receive about 20s. a week, and they have asked for an increase to 32s.; and the labourers, who have now 4d. per hour, or about 1l. a week, desire an increase of 1d. an hour, making their wages 23s. 4d. per week.

**Huddersfield.**—The masons' strike at Huddersfield still continues, the point in dispute being how many apprentices must be employed in proportion to the number of journeymen.

**Paris.**—The working carpenters of Paris, who have been for some time on strike, now propose to refer their differences with their employers to nine arbitrators, of whom the masters may choose five; and in order to show their "esteem for the press," they earnestly desire that all the arbitrators may be selected from among writers in the leading Paris journals.

#### THE O'CONNELL MONUMENT COMPETITION.

The committee to whom the sixty designs sent in were submitted, have reported against all of them, and award no premiums. They recommend the general committee "to invite the competing artists either to modify their designs, or prepare new designs altogether, subject to the following conditions:—1st. If architectural features be introduced, then all architecture to be purely Classic, to be entirely subordinate to the statue, and no varieties of coloured stone to be introduced; and the whole erection (inclusive of statue, if crowned by any statue) not to exceed 40 ft. in height. 2nd. If the principal statue be in bronze, then the erection to be designed as an architectural pedestal, whatever its richness or extent. If marble, then a Classic covering canopy or cnpola, to protect it from above. 3rd. If subordinate figures be introduced, then these figures to be grouped, so as not to interfere with the unity of the whole, and all such figures to be wholly subordinate, and as few as possible in number."

**VITRIFIED PHOTOGRAPHS.**—Mr. F. Jombert, Porchester-terrace, W., has perfected a process of fixing by fire, in colours or otherwise, photographs on glass, of which he has had on private view several fine examples, having the quality of being equally perfect seen as transparencies or by reflected light.

#### THE MODEL HOUSES INDUSTRIAL EXHIBITION.

The prizes were delivered to successful exhibitors on the 19th instant, when Mr. Chas. Payne, the secretary, read a report, from which we obtain some facts.

The actual number of exhibitors was fifty-one: the number of articles exhibited was 142. During the time it remained open 930 persons paid for admission, whilst about 100 more were admitted without payment.

It is still, of course, too early to estimate the entire result of the exhibition: time is wanted for this purpose. The amount of good done is not to be measured only by the number of visitors, or by the number of articles exhibited, creditable as they were. The leisure hours of many have been well spent; the energies of many have been called out; the healthy ambition of many has been stirred; and the president and the committee are encouraged to believe that the tenants of the society's houses have seen in this exhibition fresh proof of the interest taken in the well-doing and happiness of the labouring classes.

The prizes were awarded by Professor and Mrs. Donaldson, Mr. John Hampden Fordham, and Miss Twining, to the amount of 70l., amongst forty-one exhibitors.

#### THE CHAIRMAN OF THE METROPOLITAN BOARD OF WORKS.

At the meeting of the Board held on the 19th inst., Mr. Dalton called the attention of the Board to the fact that Mr. John Thwaites, their chairman, had received the honour of knighthood from her Majesty, and in doing so said,—“As her Majesty has done our chairman the honour of conferring on him the degree of knighthood, which we all rejoice to see, I think it is a compliment conferred on the whole Board; and I trust that he may be blessed with health and strength to perform the duties of his office for many years to come.” Mr. Bidgood said this was doing honour to the right person at the right time. Mr. Savago proposed that Mr. Dalton's words be entered on the Minutes. Mr. Nicholas seconded the proposition, and the Board were unanimous on the same effect.

We cordially agree in the kindly feeling that was manifested on the occasion. Sir John Thwaites has performed and is performing the duties of his office in a manner that leaves no room for two opinions. His clear-headedness, his attention to the business of the Commission, his impartiality, and his ability, have been alike made evident; and, while we congratulate him on the proper recognition of his services that has been made, we express a very sincere hope, not alone for his own sake but for that of the Board, that he may long continue to preside as heretofore over its deliberations.

#### THE DUKE OF PORTLAND'S ESTATE, MARYLEBONE.

The surveyorship of this important estate, which has been filled for nearly half a century by the late Mr. Samuel Ware and his nephew, Mr. Charles N. Ware, last year became vacant by the retirement of the latter in consequence of a large accession of fortune by the death of his uncle, and the appointment has been conferred on Mr. Henry Baker, the district surveyor of St. Pancras, who was articles to the late Mr. Ware on entering his professional career. Our readers will observe, by Mr. Baker's advertisement, that the office for the estate business, which has been so long but so inconveniently located in the Adelphi, is now removed to his residence, No. 108, Gower-street.

Whilst on this subject we may add that it gives us much pleasure to witness, as we are "going along," the improvements that are in progress in Portland-place, Harley-street, and other parts of the estate: everywhere the buildings are being modernised as the leases fall in; a large expenditure is evidently invited rather than a high rent; and so, by judicious management and liberality to the lessees, the locality is able to hold its own, notwithstanding the attractions of its youthful rivals, Kensington and Tyburnia. The same may be said of the Marquis of Westminster's property, and it is but fair to acknowledge the merits of a system which alike contributes to the public and to private advantage.

## CONCERNING STAINED GLASS.

In your impression of the 13th instant you insert a few "Queries concerning Stained Glass," and appear desirous that they should lead to "some useful expression of views." I have given the subject of stained glass some serious attention, and therefore trust my following remarks may be found worthy of insertion in your pages; and although they may not be considered useful in themselves, yet they may prove so by leading to the expression of others more valuable. Bearing in mind the great demand upon your space, I shall endeavour to condense my remarks as much as possible. I shall take the queries seriatim.

1. "What is the object of stained glass: is it an effect of colour?"

Stained glass is obviously a decorative medium, and it is unquestionably the most splendid ornamental adjunct ever dedicated to the service of architecture. As a decorative medium it depends upon two things, *i.e.*, colour and form; and in a truly good work both must be present in equal degrees. Stained glass cannot be said to be an effect of colour only, or to depend for its beauty or value on colour alone. It is capable of displaying the greatest efforts of the artist, and of being made a genuine and perfect work of art. If it depended upon colour only, we should find perfection in a properly arranged mosaic window, for in it effect of colour can be developed to any extent; but we do not consider mosaic glass, however good, highly artistic, because it is mechanical in design and systematic in colour.

2. "What is good colour in stained glass: loud and flaring or quiet and cool?"

This query is not one which admits of a very definite answer, owing to the diversity of tastes and opinions regarding colour, and because in all cases the same class of colouring will not apply. The saying "circumstances alter cases," applies to stained glass as forcibly as to other things. I think, however, that we may safely say that good stained glass work should never be "loud and flaring," for those words imply the very richest colours associated inharmoniously. A rich effect, full of beauty and repose, may be obtained by the proper use of the most brilliant colours, at the disposal of the artist. That it requires much greater knowledge and taste to treat these rich colours than the low-toned tints and dingy neutrals now so much used, no one, I believe, will deny; but until they are adopted, and the requisite skill in their grouping acquired, we need not hope to rival the effect of ancient glass, or to do anything that cannot be pronounced "loud and flaring." At the present day there are too many colours and tints used, and some of these are very objectionable, such as hoar-green, brown-purple, claret, brown, neutral tint, &c. How can these dingy tints, which absorb all the light that attempts to pass through them hold their own when associated with such colours as ruby, blue, yellow, and green? or how can these last escape being pronounced loud and flaring when surrounded by tints which are positively discordant and dead? I believe if our artists would take one or two hints from ancient glass, and use fewer colours, and those well balanced and of similar intensity, we should soon have a marked improvement in stained glass—at least, as far as colouring is concerned. In stained glass, as in all branches of decorative art, a perfect uniformity of effect is required; this can only be obtained by the use of properly balanced colours properly distributed and arranged. I hold that a window may be composed of ruby, blue, yellow, green, purple, and grey glass (or white very sparingly used), and yet present a beautiful quiet bloom to the eye. The three windows of the twelfth century in Chartres Cathedral are constructed of these colours, and their effect is superb.

3. "Is it advisable to place figures coloured on broad spaces of white glass, as in perpendicular glass? Does not this get a quiet, cool effect?"

To the first question I unhesitatingly reply that it is not advisable to work figures in colour upon spaces of white glass; and to the latter question I must reply that I am convinced that such a practice is not well calculated to produce a cool, much less a quiet effect.

White glass should be used very sparingly in windows where positive or deep-toned colours are introduced, for the simple reason that, by admitting a direct and powerful light, it destroys the brilliancy and effect of all colours placed near it.

As an illustration of this, take two strips of rich blue glass of similar tint: place one across a pane of white glass in a common window, and place the other edge to edge between two pieces of rich ruby over another pane, so as to cover it. When this is done, it will be observed that the strips of blue glass appear quite different in tint, that over the white glass being dark and dead, while that which is in contact with the ruby appears in its proper tint, and full of brilliancy. Modern windows are more frequently destroyed by the practice of using large quantities of white glass along with rich-coloured glass than by any other means. In the fine twelfth and thirteenth century windows in Chartres, and in the superb glass of Bourges Cathedral, we find white glass used more sparingly than any colour.

4. "Ought canopies to be much coloured, or in simple white and black, to get quiet effect; and how drawn, with reference to next paragraph?"

5. "Ought geometrical diagrams to be drawn with absolute mechanical accuracy, or to be freely drawn?"

As the last query in your list alludes to the question of canopies, I shall add it to the above, and treat the three together.

7. "What is the difference between a thinly designed and richly-designed canopy?"

I am decidedly of the opinion that canopy work in glass is a great mistake, and that it is an artistic and clumsy way of filling up spaces over the heads of figures. Canopies are purely architectural features peculiar to stone and wood construction, and are, therefore, out of place in stained glass. If anything in the shape of canopy-work is used, it should be introduced in great moderation, and in colours to harmonise with the rest of the window. Some of the windows in the choir of Reims Cathedral present valuable studies in this respect.

The query No. 7 is somewhat difficult to answer in a few words; but I believe that a thinly designed canopy may be understood to signify that which is composed of representations of meagre tracery, wire-drawn pinnacles, impossible flying buttresses, &c.; while a richly-designed canopy may be understood to be one in which a proper conventional treatment, suitable to the material in which it is wrought, is more observed in the attempt to represent cast-iron Gothic, and in which the colouring is in perfect harmony with the rest of the composition. With regard to query No. 5, I am of opinion that canopies and all geometrical patterns should be drawn correctly, and at the same time the freedom of curves and other lines of beauty, which cannot be truly drawn by mere mechanical means, should be carefully studied and sought after. We are not called upon in any way to forego our skill in drawing, much less, at the present day, to copy the imperfections of old work. We have ample proof that the ancient artists did not draw haphazardly on purpose, or make crooked curves because they considered them more beautiful than true ones.

6. "How ought draperies to be drawn—thinly, or richly, &c. as Durer?"

In the treatment of draperies in stained glass, I am of opinion that severity and simplicity should in all cases be observed. Rich drapery demands a great amount of shading, and that is certain destruction to the brilliancy which is the greatest charm of stained glass.

The question of shading, as applied to glass, is one which demands careful consideration at the present time; for much modern work is rendered imperfect by the objectionable mode in which it is shaded.

The usual style of shading (called smudgo shading) which is produced by covering the surface of the glass with a thin graduated coating of brown enamel, resembling the soft chalk shading of lithography, is obviously a most dangerous mode, from the simple fact that it destroys the natural brilliancy of the glass. Smudgo shading is excessively tame and ineffective, and should not be used either for drapery or foliage. It is more suitable for the treatment of flesh because it takes away the overpowering glare of the white or flesh-tinted glass, and tends to unite it with the coloured glass around it. For drapery and foliage, or other ornamental features, line or hatched shading alone should be used. I allude to the style of shading found in fine old engravings, and to which they owe their great effect and brilliancy; it is composed of lines drawn in one direction, or crosshatched at an acute angle. If an old engraving be examined, it will be found that between the lines of the shading small spaces of the paper are left untouched; those

give the transparent and bright effect to the shadows. In stained glass a precisely similar result would be obtained by the adoption of line shading: the untouched portions of the glass between the lines, retaining their original transparency, would impart the brilliant scintillating effect required, and which cannot be secured by the use of smudgo-shading. There exists the same difference between glass line and smudgo-shaded as between line and mezzo-tint engraving.

G. A. AUDSLEY.

## SOUTH KENSINGTON NEW ROAD.

We see with surprise and regret that the Bill for the proposed new road has been rejected by the committee of the House of Commons to whom it was referred. It was proposed by the powers sought in the Bill to make a wide street, as we have mentioned, in the nature of a boulevard, from Sloane-street to South Kensington Museum, a distance of about five furlongs, and on either side to erect first-class mansions, the road itself being 150 ft. wide, with rows of trees planted on either side. There was no opposition from any landholder from one end of the contemplated road to the other. The vestries of Chelsea and Kensington, through whose parishes the road was to have been made, were in favour of the scheme; and it was stated in the committee that, of 800,000l. of property affected by the Bill, only 27,000l. were represented by the opponents to the measure. Nevertheless, on the opposition of a few lessees and occupiers of comparatively small houses about Brompton, and a few owners or occupiers of shops in the Brompton-road, the Act has been refused. The statements made were of such a character as never before weighed against a public advantage. In the event of any effort being made to get the Bill re-committed, it is to be hoped that the House of Commons will bear this fact in mind.

## PROVINCIAL NEWS.

Worcester.—The construction of the engine works at Sbrubhill is progressing rapidly, and will be completed by the fall of the year, according to the local *Herald*. Some hundreds of men are engaged upon the works. The principal façade is in the Italian style, and of red brick with white dressings. In the centre are two ornamental towers, and on either side in two rows will be ten windows, the top ones being segmental, and the lower semicircular-headed. Between the towers will be three large windows to correspond. The works are being carried out under the engineer of the company, Mr. E. Wilson, the superintendance of them being entrusted to Mr. Dixon.

Ipswich.—A new Gothic street pump and drinking-fountain combined has been erected by Mr. West, on the site of the old parish pump, at the entrance of St. Matthew's Church-lane. The cost, 15l., has been defrayed by subscription.

Birmingham.—The directors of the Masonic Hall and Club Company (Limited) hope to be able to have the first stone of the Masonic Hall laid about the month of July. Working drawings and specifications are now in course of preparation by Messrs. Naden & Holmes, the joint architects, under the supervision of a building sub-committee.

Leeds.—The White Cloth Hall will be demolished for the carrying out of the new branch and central station of the North-Eastern Railway Company, but a new hall will be erected on a portion of the site of the present General Infirmary, and the adjacent gardens. Other new buildings are contemplated upon the same site, including suites of offices and a large inn. Some improvements will also be made, including a new street between the present Coloured Cloth Hall and the New White Cloth Hall, with a ready means of access from one building to the other.

HYDRO-CARBON GAS.—Mr. W. Henderson, of Valparaiso, introduces dry steam to the retorts containing the coal or other substances, heated to their own intensity, preventing any reduction of the temperature during the process of making the gas: by this means he obtains an illuminating gas, consisting of a combination of the hydrogen of water with the volatile carbon of coals, cannels, and oleaginous substances. The chief feature is the use of retorts with false bottoms, beneath which the steam is admitted.

## JOSIAH WEDGWOOD.\*

HITHERTO it has been believed by some that Wedgwood was born in a mean hovel, surrounded by the rudest associations, and whilst yet a child consigned to the coarsest drudgery. The facts, as his new biographer, Miss Meteyard, finds, were essentially different. His father was a man in easy, if not in affluent, circumstances. His relatives Aaron Wedgwood and Dr. Thomas Wedgwood, junior, were persons of position in Burslem,

their native place. John and Thomas Wedgwood, the sons of Aaron, who commenced business in 1740, and in eighteen to twenty years from that date had acquired a fortune and built the handsomest house in Burslem, were, when Josiah Wedgwood was a child, active and intelligent young men, busy in improving their staple. A few years later, when they had erected their conspicuous dwelling, and earned comparative leisure, their hospitable hearth became a gathering-place for men of keen and active intelligence. Here Brindley, Thomas Gilbert, the Duke of Bridgewater's agent, John and Hugh Henshall, father and son, met to discuss the various plans, then afoot, for constructing and improving roads and flint mills, and the first surveys for canal navigation. Other of Josiah Wedgwood's relations held equally influential positions in their native place. Thomas and John Wedgwood were masters of their art. Prior to the advent of their young kinsman, they had done much to improve various descriptions of ware; especially white stone ware, in which they led the export trade of the district. Their englated specimens were excellent; and they were the first who by experiment ascertained the various qualities of the clays found in their neighbourhood. To them is due the introduction of pyrometrical beads, as tests in firing; and they had gradually learnt, by mischances in their own pot-work, the necessity of using only

Vase from Work by Count de Caylus.

water which was free from the soluble bicarbonate of lime.

Josiah Wedgwood was born in Chareyard House, Burslem, the residence and property of his parents, Thomas and Mary Wedgwood, in July, 1730. He was the last of a family of five or six children then under ten years of age, besides several older. There was nothing eventful in the childhood of Josiah,—scarcely

\* "The Life of Josiah Wedgwood." By Eliza Meteyard. Vol. I. London: Hurst & Blackett. 1865.

Ancient Tile Pavement from Prior Cruden's Chapel, Ely Cathedral.

even throughout his life indeed, if we except its one great feature, his skill and celebrity as a potter, and the conversion of it into a branch of the fine arts. Sprightly and yet grave, Josiah was a general favourite. Among his companions, he was distinguished for uncommon vivacity and humour. They were attached to him by his warm and generous temper; and his reputed sagacity marked him out as a leader in their boyish sports. It is handed down that he thus early betrayed his extraordinary eye for construction by his use of the scissors. Borrowing a pair, and with paper torn from a copy-book, he would cut out the most surprising things; as an army at combat, a fleet at sea, a house and garden, or a whole pot-work, and the shapes of the ware made in it. These cuttings when wetted were stuck the whole length of the sloping desks, to the exquisite delight of the scholars, but often to the real or affected wrath of the master. Josiah was apprenticed in 1744 to his eldest brother Thomas. It was then customary to place boys apprentice at an early age to almost every trade, more especially to that of a potter; because, if throwing were to be one of the branches taught, it necessitated that the learner should be very young, in order that the touch should be trained to an exquisite delicacy, and the muscles of the wrists so formed and strengthened as to insure altogether the utmost manipulative skill. This was beginning, in his own strong phrase, "at the lowest round of the ladder." With such an exquisite eye for proportion as he possessed, his skill in throwing or forming the vessel upon the potter's wheel soon became extraordinary, and rivalled that of the best workmen in the neighbourhood. Though subsequently diseased, he always maintained his marvellous skill in this direction; so that at the distance of forty years he could still give a practical example to his throwers; and, by merely poising a newly thrown vessel in his left hand, he would tell at a glance its defects or beauties. If it failed even minutely in its geometrical proportions, he would, before his leg was taken off, break it up with the stick which he then always carried, remarking as he did so, "This won't do for Josiah Wedgwood."

It was not until he had been some time an apprentice that his leg began to show symptoms of that disease which put an end to his practice as a thrower, and finally deprived him of the limb altogether. The disease in his leg, however, during his apprenticeship, appears to have been an advantage to him, as it led to his attention being turned to other branches of his trade, and also, no doubt, to a sedentary and studious habit of life. From the thrower's bench he was taken to the moulder's board, and to this period

probably belongs the specimen known as "Josiah Wedgwood's first teapot," still reverently preserved at Etruria. It is in the form of a tree-stump, with branched handle, spreading into leaves on the sides, and a rustic lid. Towards the close of his apprenticeship, young Wedgwood seems to have turned his attention to the improvement of the ordinary cream-ware, then manufactured in considerable quantities in Staffordshire. His master-brother, however, continually reproved him for his idle and unprofitable curiosity in trying new processes, and earnestly exhorted him to stick to the instructions of those

Vase in black Basaltes, by Wedgwood.

who knew, better than he did, what it was best to do. At the close of his apprenticeship, Josiah expressed a desire to become a partner with his brother; but that wise gentleman seems to have flattered himself that he knew better than to link his fortunes with those of such a young schemer as Josiah had already proved himself to be, and he therefore declined the proposal.

In 1751 or 1752, the young man took upon himself the management of Alder's pot-work, as

MANCHESTER

a sort of partner, at probably a very low salary. But it was soon seen that a master-hand had come amongst them. Even the blue scratched and common wares began to show a density of body, a clearness of glaze, and an improvement in form. The barbarous art which adorned them also betokened a change for the better. Sales increased; and as to productions of a higher class of ware, such as small articles for ornamental and useful purposes, they were something new to the works, and found ready purchasers in Birmingham, Manchester, and elsewhere. The cupidity of his employers was excited. They urged the young man to fresh exertions in this direction, without increasing his share in the profits; whilst personally he was hindered in many ways by their ignorance, interference, and by the absence of those necessities without which no improvement in an art or science can be carried onwards. As commonly the case with knaves, however, they mistook the character of the man they sought to overreach. Incapable himself of meanness, trickery, or profiting by others' loss, and already well aware that his art, like land in the care of the agriculturist, must have capital as well as labour bestowed upon it, if generous produce was to be expected, he revolted at length against their cupidity. The partnership was brought to an end, much more speedily than is generally supposed: it probably did not last more than a year.

A new partnership followed close upon the old one, and he who offered it was, this time, a very worthy man, named Thomas Wheildon, who made snuff-boxes for Birmingham hardwaremen, and knife-handles for Sheffield cutlers. Toys and chimney-piece ornaments, candlesticks, tea and coffee pots, table-plates, and various other articles, were also manufactured by Wheildon. Amongst his apprentices were Josiah Spode, in after years the famous potter, and William Greatbach, whose name personally, as well as by his descendants, was destined to be connected with Wedgwood's Staffordshire Etruria by a century's valuable services. Young Wedgwood's local fame, at the time of entering into partnership with Wheildon, must have been even then considerable; for one of the partnership agreements was, that he should practise, for the joint behoof, such secret processes as genius and experimental industry had made his, but this without the necessity of revealing to others what they were. The first result was a new kind of green ware, exquisitely modelled in perfect imitation of such natural objects as leaves and fruit. But its rarest speciality was its glazing. For glossiness and brilliancy of colour, nothing like it had as yet been seen. Everything made by the partners partook of Wedgwood's improvements. His personal intercourse with Birmingham, afterwards of great value to him, was then established. In the midst of enthusiastic and incessant labours, Mr. Wedgwood unfortunately injured his weak limb, and was laid up for months, a period which he devoted, however, to self-culture. During this interval many of his secret processes and mixtures were of necessity revealed to workmen, who soon spread them into use amongst the potteries, to the great improvement of the manufacture generally. The partnership with Wheildon expired in 1759, and was not renewed. Wheildon, an ambitious man, had already amassed money and was averse to further speculations of an uncertain nature. On the other hand, his young and ingenious partner saw, with precise eye, the capabilities of his art, could capital as well as taste be only brought to its aid. He had come forth from his sick chamber a stronger man intellectually, and meditation had given him a firmer hold as it were upon the laws and secrets of his art, and even before the expiry of his partnership he had begun to produce higher and more ornamental art works than heretofore.

In 1759, Wedgwood may be said to have commenced his independent career as a potter, having then begun business by himself in the Ivy House Works previously belonging to cousins of his own name. The manufacture of white ware, relief tiles, and small ornamental articles, was carried on at the new works. But Wedgwood saw clearly that it was not these classes of ware which would either open or secure a new and great market. What was wanting was a ware of a superior description, so excellent in all respects as to be suited to the tables of the upper classes; and which, when improvements and facility in production should enable the manufacturer to sell it at a cheaper rate, might reach those of the

middle classes. He had for a considerable period, as we have seen, turned his attention towards the improvement of the ordinary cream-coloured ware, manufactured at various pot-works in Burslem and its neighbourhood; but his experiments had been desultory,—rather directed to future purposes than immediate results. He now, however, concentrated all his energies for a period in this one direction. Every essential of body, glaze, form, and ornament was alike the object of his care; but through the various necessary processes his patience was often sorely tried, his repeated failures most disheartening. One kiln after another was pulled down in order to correct some defect, or effect some necessary improvement. His losses from this source alone were at this period very heavy, and the ware itself was often destroyed before he could bring his firing processes to the requisite degree of perfection. His chemical combinations often baffled him, and his experiments, both in body and glaze, would, after the greatest pains, turn out entire failures. Yet, unwearied and indomitable in spirit, he persevered, and success came. He had to invent, and, if not that, to improve, almost every tool, instrument, and apparatus, and to seek for smiths and machinists to work under his guidance. Lathes, wheelers, punchers, gravers, models, moulds, drying-pans, and many other things were all variously improved. He often passed the whole day at the bench beside his men, and in many cases instructed them individually. The first pattern of each original piece he almost always made himself; and, though no great draughtsman, the enamellers could work from his designs.

By the close of 1761, Mr. Wedgwood had brought his cream ware to a considerable degree of perfection. The body had a lightness hitherto unknown, the glaze an exquisite brilliancy, and its forms were entirely new. The proportion of native clay introduced into the body was probably but fractional. Dorset and Devon clays, with a due proportion of flint, were its chief components, and the glaze used was what was known as "Greathach's china glaze," but which Mr. Wedgwood subsequently greatly improved. Amongst its ingredients were red or white lead,—lead entering into all the glazes of the period under one form or another,—flint-glass, tin, and Isle of Wight sand.

The forms of the chief pieces, such as coppers, tarsens, snuff-boxes, and salt-cellars, were principally modelled from natural objects, as shells, leaves, and the hucks and seed-valves of plants. In his occasional journeys from home, Mr. Wedgwood lost no opportunity of seeking out, in shops and noted collections, for such specimens of Oriental and Dresden ware as might furnish him with new ideas as to form, colour, and manipulative skill, even if he could not obtain the privilege of modelling therefrom. And so far as he yet resorted to enamelling, the softest and most subdued colours were employed.

He opened an export and retail business in London by help of his brother, John Wedgwood; and at Liverpool by help of Thomas Bentley, who afterwards became his partner at Etruria.

An art was making its way in Liverpool, of which, as applied to the decoration of his improved cream-ware, Mr. Wedgwood soon found the great utility. This was the application to glazed earthenware of impressions taken upon paper from engraved copper plates; the ware, after printing, being passed through the muffle or enamelling oven to fix the colours. The discovery of this art had been made in 1752, or indeed previously, by Mr. John Sadler, a master printer of Liverpool, who, from observing some children stick waste prints, which he had given to them, upon broken pieces of earthenware they had brought from the pot-works near at hand, had conceived the idea of this new application of the printer's art. For a time he occupied himself with experiments, in which, after many fruitless trials, he succeeded. Taking heartily to their new trade, he and a partner, also a printer, prosecuted it with the utmost zeal. They printed plaques, tiles, mugs, teapots, and other earthenware for ordinary domestic use; and used various colours, but more generally cobalt blue, in imitation of Delft ware; the great object being to undersell the Dutch, who at this date imported tiles in vast quantities into the country for the purpose of ornamenting fireplaces. That this admirable discovery was likely to effect a perfect revolution in cheapening articles of ordinary earthenware was proved by the fact that the partners, "within the space of

six hours, printed upwards of 1,200 earthenware tiles of different colours and patterns, which, upon a moderate computation, was more than 100 good workmen could have done of the same patterns in the same space of time by the usual way of painting with the pencil."

The Brick-house, or Bell-house, works, once in the possession of a namesake of Wedgwood's, were leased by him about the year 1762, and there he carried on his business till his final removal from Burslem in 1773. In 1764 Wedgwood married, a step which, it seems, he never had cause to repent; and he afterwards purchased the estate of Ridge House, near Burslem, for 3,000*l.*, and thereon erected his celebrated works, which he named Etruria. He had previously taken an active lead with Brindley, the engineer, and Bentley, in carrying out the project of the Duke of Bridgewater's canal, which runs through Etruria. Before the erection of his works on this site, Wedgwood's fame was so fully established that he was taken in hand, not only by the nobility but by the royal family, for whom he made various choice specimens of his art.

While trying to induce Mr. Bentley to leave his business as a merchant—mainly in the pottery ware—at Liverpool, in 1766-7, and become a partner with him when the works at Etruria should be set agoing, he thus sketched out the precise objects which they should have in view as manufacturers:—

"The articles to begin the work will be—Root flowers of various sorts ornamental and plain. Essence pots, Bone pots, flowerpots, and Cornucopius.

Vases and ornaments of various sizes, colours, mixtures and forms, ad infinitum.

Then proceed to Toilet furniture, and such like & other ornaments with gold bent in.

Elegant Teacups must be made. Snuff and other boxes.

Fish, Fowl, and Beasts, with two legged Animals in various attitudes.

Ten thousand other substantial forms, that neither you nor I, nor anybody else, know anything of at present.

If all these things shall fail us, I hope our good genius will direct us in the choice of others."

Thus far Miss Meteyard, in her first volume, has carried the biography of her hero; and thus far only shall we go at present with it, since our sketch is a mere abstract transcript from her able and interesting, though somewhat diffuse volume. That she is a very fitting and capable biographer of the great potter is evident. She has a practical knowledge of pottery, and for fifteen years has had the work in view. She has had abundance of materials, in the shape of family papers and private correspondence, placed at her disposal by members of the Wedgwood family, by Mr. C. Darwin, F.R.S., Mr. Joseph Mayer, and others; and the volume, which is first-rate as to paper and print, is full of engravings illustrative of the text. We print four of them as examples, representing a picture cameo; the ancient pavement in Cruden's Chapel, Ely Cathedral; and two vases, one of the latter being from an early Wedgwood in Mr. Roger Smith's collection, and the other from Count de Caylus's work, and which is given by Miss Meteyard as having influenced the one produced by Wedgwood. The biography is preceded by an introductory sketch of the art of pottery in England; and the second and completing volume, the author tells us, in her preface, "will be a perfect shrine of the masterpieces of Wedgwood's art." From this preface we may take, as a conclusion, a quotation in reference to the use of terra cotta by architects:—

"He wished to induce the architects of his day, amongst them the brothers Adams, who built the Adelphi, and Sir William Chambers, to introduce terra-cotta ornaments and bas-reliefs into the pedes and other parts of houses and buildings. But, like his friend Erasmus Darwin, he was greater than his time, and the architects would not listen. Let us, therefore, in this day realise the dreams of the great master, and at this point take up his art. Whilst nature is eternal and ever prolific, imitation is unworthy of the artist. As the men of science purify the atmosphere of our cities and towns, as assuredly they will, let our public buildings become in the best sense, palaces of art, and the interior of our houses shrines of simple taste in ornament and colour. Wall-mings of terra-cotta would do away with the barbarous taste of the paperhanger and upholsterer, and floors of exquisite tile-work would serve to border the warm embracing carpet. Here would be work enough for the potter and the artist; and in the quality of colour and the purity of design we might rival antiquity, whilst true to the spirit of our generation."

#### MEMORIAL HALL, MANCHESTER.

This building, now approaching completion, occupies the angle of the new Albert-square, in a new open "place" of considerable size, in course of formation in Manchester, and in the centre of which the Prince Consort Memorial is being erected by the same architect.

The hall is a building chiefly appropriated to

collegiate purposes, and has been erected by subscription, by the Unitarians, in commemoration of the ejected clergy of 1662.

The basement and ground-stories are to be let as offices, or warehouse, having separate entrances from the side street. The first-floor contains a large lecture-hall, a library, rooms for professors and students, porter's house, and sundry minor rooms. The top floor is entirely occupied by a lofty lecture-hall, capable of accommodating from 700 to 800 persons.

The hall has been erected from the designs of Mr. Thos. Worthington, architect, by Messrs. Bowden, Edwards, & Forster, contractors.

#### PAPER-STAINING.

The reports for 1864 of the inspectors of factories contain many interesting particulars respecting factory labour. Of paper staining it is said:—

The operations in a paper-staining establishment are very similar to those carried on in a calico printwork. The printing is either by block, when it is done by manual labour, or by the cylinder, which is moved by power. At Over Darwen (near Manchester), at Manchester, and at Leeds, a large number of children are employed, and steam power is used in connexion with machinery.

In paper-staining works the block printers, always men, are paid by the piece, and the men pay the boys they require to assist them; but the boys employed in connexion with the printing by cylinders, which are moved by steam power, are engaged and paid by the principal; and Mr. Potter, of Over Darwen, having full control over the latter class of boys, applied to them as strictly as if they had been under the Factory Act the half-time system, by which each child under thirteen years of age attended school daily for three hours.

In the metropolis there are important paper-staining works, but conducted upon an entirely different system from those in the north. At some it has been the custom for work to begin at 7 a.m., and others not till 8 a.m.: the boys are generally required to go earlier to light the fires and sweep the shops, &c., and they are an older class of boys than those employed in the north. The chief objection in London to the Act is the necessity to commence at 6 a.m.: the men have been so long accustomed to begin late and to continue to work late, and to make overtime, that they do not readily fall into a more regular system; but the masters all acknowledge that the regularity which must be observed under the factory regulations would be of immense advantage to them, with this proviso, if the same amount of work can be produced. This (says one inspector) I do not doubt. Where men are employed at piece work, and can work pretty well as they like, either diligently or lazily, a portion of a protracted day's work is passed in unnecessary idleness. But when work must cease at 6 p.m., I know from experience that the working hours are hours of work, and that the time formerly passed in procrastinating and idling, is occupied with vigour and intelligence and with equal results at the end of the week.

#### VALUE OF LAND ABOUT LIVERPOOL.

LAST week an inquest commenced at St. George's Hall, Liverpool, before Mr. W. Aston, the sheriff's assessor, and a jury of merchants and others, to assess the value of a quantity of land, as well as the amount of depreciation, belonging to Mr. Edward Griffin, near Mossley-hill, Allerton, through whose estate the Edge-hill and Garston branches of the London and North-Western Company pass. Mr. Griffin's claim upon the company for the land actually taken, as well as compulsory sale, depreciation, and severance, was between 14,000l. and 15,000l. Messrs. John Cunningham, Young, Scourfield, Leyland, & Williams, had been summoned on behalf of the claimant; and Messrs. S. Holme, Pierson, Bulshaw, Shelmerdine, and other gentlemen, on behalf of the railway company. Mr. Leofric Temple stated the case for the claimant, and called witnesses who stated that the approach to a very large portion of the estate had been almost cut off, 70 acres being severed on one side of the line, and 80 acres on the other. Mr. John Cunningham thought Mr. Griffin was entitled to 11,753l.; Mr. Owen Williams, 3,582l.; Mr. John Scourfield, builder and valuer,

13,991l. In cross-examination by Mr. Lloyd, this witness said the entire estate was worth from 750l. to 800l. an acre, which would be from 130,000l. to 140,000l. He believed a person could not do better just now than buy land five or six miles from Liverpool and hold it for some time. It must increase in value. He had had 3s. per yard offered for land further from Liverpool than this, and he had refused it. The company called rebutting testimony, and the jury awarded 6,750l., being 3,742l. 3s. for the land actually taken, and the balance for depreciation in value through severance of the remainder.

#### THE PREMIUMS OF THE ARCHITECTURAL INSTITUTE OF SCOTLAND.

THE Institute, last year, offered prizes under the four heads after mentioned; and the council, on the 6th of March last, appointed Messrs. Cousin, Paterson, Dick Peddie, MacGibbon, and Maclean (Mr. Cousin, convener), a committee to judge in the competition, and to determine the subjects of competition for the following year. The subjects of competition and the awards were the following:—

1. For the best Geometrical Drawing, by apprentices of not more than three years' standing.

Three sets of drawings were submitted for examination. The committee considered that the drawings of Daniel Macnabon, apprentice to Mr. John Lessels, architect, Edinburgh, and William Addis, apprentice to Mr. D. Bryce, architect, George-street, Edinburgh, were equal in point of merit, and awarded a book to each.

2. For the best Perspective Line Drawing raised from the Plan.

Six drawings were submitted, and the committee considered the drawings of Andrew Dewart, apprentice to Mr. Robert Paterson, architect, Edinburgh, and Alexander Sutherland, apprentice to Mr. D. MacGibbon, architect, Edinburgh, equal in merit, and awarded a book to each.

3. For the best Drawings of a small portion of any Ecclesiastical Building, measured and drawn from the originals.

Three sets of drawings were submitted. The committee awarded a book to David Home, apprentice to Messrs. Lightbody & Gorrie, architects, Edinburgh; but they think it right to observe that the drawings of Elgin Cathedral, by Robert Wishart, South Gully-street, Elgin, deserve favourable mention for the great pains and labour which have been bestowed upon them.

4. For the best Original Design.—Subject, a Presbyterian church.

Six sets of drawings were submitted. The committee had considerable difficulty in making a selection, as none of the competitors had strictly complied with the conditions as to style and otherwise. The committee considered that on the whole the drawings of William Urquhart, in the office of Messrs. Paterson & Shields, architects, Edinburgh, were the most meritorious, and awarded him a book.

As an encouragement to the young men, the council have resolved to present each of the competitors under the several above heads, with a copy of last year's 'Illustrations of Scottish Buildings.'

#### "SPECIFICATIONS AND MYSTIFICATIONS."

UNDER this title we have received a long letter signed "A Builder," asking, chiefly, "whether an architect when he hands to a builder a specification and drawings does not pledge himself that the specification is a clear description, and that the drawings are such as can be worked to; and whether he, and not the builder, be responsible for their correctness?" also complaining of treatment received in working under such instructions. Builders should see that the specifications and drawings are clear before they sign contracts. In the present case, if "A Builder's" statements are correct, the law will protect him.

#### LLOYD'S PROVING HOUSE.

As will be remembered by readers of the parliamentary debates, about a fortnight ago the President of the Board of Trade stated that, unless the testing machine of Lloyd's Register were altered, it would not be licensed. But out of regard for such a considerable body as Lloyd's, the Board of Trade have determined to obtain the best opinions on the matter. We understand that the Board have thus requested Sir William Armstrong, Mr. W. Fairbairn, Mr. Hick, Mr. Bolton, as also Mr. Hawkshaw, Mr. Penn, and Mr. F. A. Paget, of London, to examine the machine in order to fully report on its presumed deficiencies.

INSTITUTION OF CIVIL ENGINEERS.—The President's annual *conversazione* is fixed to be held at the house of the Institution on Tuesday evening next.

#### STAINED GLASS.

*Gloucester Cathedral.*—The memorial window to Dean Plumtree has been placed in the east cloister of this cathedral. The artist is Mr. Hardman, of Birmingham, who, we believe, has furnished the whole of the windows in this part of the cathedral, with one exception. In each of the eight principal lights of the new window is a figure, bearing a scroll. The first four are prophets, the others are female figures. The text is:—"For unto us a child is born," &c. The windows in this cloister form a connected series. The second (to Dean Plumtree) contains the prophecy referring to the birth of the Saviour, just quoted; the fourth (to Dean Rice), the Nativity; the fifth (to the Rev. T. Evans), the Saviour taken by his Parents to the Temple, and discoursing with the Doctors; the seventh (to the Rev. Dr. Classon), the Baptism of the Saviour and his Preaching; the eighth (to Dean Luxmore), the Saviour's admonition to the disciples to become as little children, and his exhortation, "Suffer little children to come unto me;" and the ninth (to Archbishop Wetherell), the Temptation.

*Glannaire (R.C.) Church, County Cork.*—The Roman Catholic Church at Glannaire has lately been enriched by the addition of two stained windows of unusually large dimensions. The windows are semicircular at the top, and contain, in one the "Transfiguration," and in the other, "The Agony in the Garden." The figures are nearly life-size, and that of our Saviour, in the "Transfiguration," is placed within an aureole, radiated, and surrounded with stars and conventional clouds. A broad worked border forms a framing to the picture, intended to harmonize with the massive simplicity of the style of the building, which is Norman. The executants were Messrs. Edmondson & Son, of Manchester.

*Mullingar Church (county Westmeath, Ireland).* The Hopkins memorial window consists of a series of foliage which is thus explained:—The oak, denoting strength; the lily, purity; the passion-flower, endurance; and the vine, faith. The artists were Messrs. O'Connor, of London.

#### FROM SCOTLAND.

*Kelso.*—The foundation stone of a new Free Church at Kelso has been laid by the Hon. Lord Ardmillan. The site of the new building is in Roxburgh-street. The erection is in progress. The design is by Mr. Pilkington, of Edinburgh, and is one of those fan-shaped designs which that architect has recently introduced in Scotland. It somewhat resembles in its general features the Barclay Free Church, Edinburgh. The church will be seated to accommodate 750 persons. Two kinds of stone are to be used in the construction of the building,—a yellow, from Fairloans Quarries, and a grey stone from a quarry near Coldstream. Red stone will also be used, to a limited extent, to render the contrast of colour more effective. The cost of the building is estimated at between 4,000l. and 5,000l. The main building, it is expected, will be so far completed in August next as to permit of the entry of the congregation; but the tower and spire will probably not be finished till a year later.

#### NEW UNION WORKHOUSE, MORPETH.

FOR the last twenty years the guardians of the Morpeth Union have had it in contemplation to build a new workhouse. From motives of economy, possibly, in the first instance, when unions were established, a house was purchased, which, with additions and alterations, has hitherto served the purpose; and, owing to the increase in the union and the utter impossibility of proper classification being kept up in so irregular a structure, this has been condemned by the Poor Law Board. Several sets of designs have been procured, from time to time, within these twenty years; none of which, however, have fulfilled the required conditions. Meanwhile, the want of accommodation in the house led to the giving of out-door relief on a large scale. Last autumn the guardians consulted Mr. F. R. Wilson, Anwick, whose designs for a new classified workhouse were approved by the Poor Law Board. The purchase of an adjoining site, to admit of extension, having taken place, and the necessary formalities having been ob-

served, the building of the new house is to be proceeded with immediately. The design comprises accommodation for 150 inmates, besides vagrants; and provides inspection wards, male and female vagrant wards, a hospital, &c.

#### THE AGE OF ROLLING STOCK.

At the meeting of the Institution of Civil Engineers, on the 18th inst., in a paper "On the Maintenance of Railway Rolling Stock," by Mr. Edward Fletcher, the author, said he, was of opinion that with regard to the ultimate age, or life, of rolling stock, the improved rolling stock of the present day, built of carefully-selected and well-seasoned timber, and materials of the best quality—superior as it was in all respects to that built twenty years ago—might be fully calculated to have a life of from twenty-five to thirty years; assuming always that the stock was of such a character that it would not be necessary to break it up on any other ground than that of decay. It was also to be remarked that, on all large railways, the quantity of rolling stock was always increasing, the result of which was to keep down the average age of the stock; and having a large amount of new stock, on which there was little expenditure for some years, the per centage of outlay was proportionately diminished. Making allowances on these points, the conclusion was arrived at, that carriage stock might be fully maintained by an outlay of about 12 per cent. on its cost, wagon stock by an outlay of 6½ per cent., and locomotive stock by an outlay of 12½ per cent. The chaldron wagon stock, which was peculiar to the north of England, generally had cast-iron wheels, was without springs, and was subject to great breakage by inclined planes and other hard usage; so that, whereas the general wagon stock only cost 6½ per cent. on its first cost for maintenance, the chaldron wagon stock cost 17½ per cent. This stock was by degrees being replaced by 8-ton wagons of superior construction. An 8-ton coal wagon would cost 90*l.*, and three chaldron wagons, to carry the same quantity of coals, 75*l.*; but the cost of maintenance in the first case would be only 5*l.* 10*s.*, whilst in the second it would amount to 13*l.*, showing that the superior wagon was the cheaper one of the two. The number of locomotive engines belonging to the North Eastern Railway Company at the end of 1864 was 504, and their average age was 12·48 years. Assuming that the duration, or life, of an engine was twenty-five years, then the company should have been rebuilding at the rate of twenty engines annually, to be paid for out of revenue, in order to keep the stock up to its original value; but the table showed that for the last five years an average of only eleven engines had been rebuilt, including under this head only those which were entirely new, and of a different class when rebuilt. But taking into account the engines of the same class which had been so treated, the total number reconstructed had been twenty per annum. The principal part of the engines so altered during the thirteen years from 1852 to 1864 were those which were old when they came into the possession of the company.

#### ACCIDENTS.

Near the end of the South Wharf-road to Bishop's-road Bridge, Paddington, a road which is unmade has been made by the Great Western Railway Company, and it is about 6 ft. below the level of the ground on the right hand side. There is of course a retaining wall alongside the pavement. Above the level of the ground so retained rises a parapet 3 ft. in height, and composed of 9-in. brickwork. About 130 ft. of this wall have been built for ten years. The ground which it bounds is in the occupation of the Lilleshall Company, and they had a quantity of coals contiguous to the wall for the extent of more than 100 ft. Captain Newberry, of the Madras Infantry, and others, were walking along the pavement when 95 ft. of the parapet, and 40 or 50 tons of the coal fell out and hurried him and another man. The retaining wall did not fall out. At the inquest on the body of Captain Newberry, who died from his injuries, the jury expressed a very strong opinion that the parapet was of a construction entirely too slight to support anything like the weight of coals stacked against it. The evidence showed clearly that the deceased had died in consequence of the

parapet and coals having fallen upon him. Several witnesses were examined as to whether the street was used as a public thoroughfare. They agreed that it was, but it was stated that the railway company had on some occasions blocked it up. The inquest was adjourned.—An accident lately occurred at Chatham dock-yard while the workmen in the metal mills were engaged in casting a large metal cleaver, or wedge-shaped prow, for the *Lord Warden*, weighing several tons. The molten metal had been run into the mould, when, in consequence of the air not having been properly exhausted, the whole exploded, scattering the heated metal about in various directions. One of the workmen was seriously injured, the red hot metal falling completely over him, and inflicting horrible injuries.

#### BUILDERS' CHARGE FOR TENDERS.

At the Shoreditch County Court, before Mr. Charles Coleman, the deputy-judge, on Tuesday, was tried the case of *Parsons, a builder, of Acton, v. Hawkes, a publican, of Bethnal-green*, the action being brought to recover 15*l.* 14*s.*, expenses incurred in tendering for certain work required by the defendant.

Mr. Horace Earle, for the plaintiff, in opening the case, said it was a very popular subject among the building trade, where surveyors called upon builders to send in tenders for contracts, and the Court would be asked by plaintiff to award him the sum of 15*l.* 14*s.* rather, peculiar circumstances. A surveyor, named Harris, employed by the defendant, sent out invitations to a number of builders, and amongst them plaintiff, to tender for the erection of a certain building, and Mr. Hawkes, defendant's was the lowest tender; but it was not accepted; and he was therefore, in accordance with a custom of the trade, entitled to charge for the expenses he had incurred in taking out quantities and pricing the various items.

The Judge asked if this custom would be proved. Mr. Thos. Angell, for the defendant, submitted that a custom must be proved to be universal before it could be set up in a court of law.

The Judge entirely disagreed with this view, and put it to Mr. Angell whether he was in a position to call witnesses to prove that no such custom existed.

Mr. Angell admitted that it was rather for plaintiff to prove that it did not exist.

Mr. Earle would prove by witnesses that the custom was acknowledged and acted upon in the trade, and would, in addition, hand in a letter which plaintiff had received from defendant's surveyor, offering to pay 4*s.* Mr. Angell did not dispute that letter, and was willing to pay the 4*s.* at once.

Mr. Earle could not accept it, because he should show that 2 per cent. was the regular charge, and he said that Mr. Earle thought 2 per cent. prodigious, and said that it had been proved before him that a general charge for taking out quantities was 4 to 4 per cent. However, perhaps plaintiff had better call witnesses.

Plaintiff's son deposed that the amount of plaintiff's tender was 770*l.*, and it was not accepted, though the lowest. He was in consequence entitled to charge 2 per cent. By his Honour—Plaintiff, as a builder, was employed to charge this, although he did not do the work tendered for. Never knew so low a percentage as a quarter charged for taking out quantities. The surveyor employed by the plaintiff charged 1½ per cent. Plaintiff stated, that when he received the invitation to tender he employed a surveyor to take out the quantities, and it was the custom in the trade to charge the person doing this to the person requiring the work in the event of the lowest tender not being accepted.

Mr. Henry Parsons, son of the plaintiff, said he was a surveyor, and had taken out the quantities in this matter. Witness charged 1½ per cent., or 11*l.* 12*s.* 6*d.* Cross-examined—Had received 5*l.* on account.

Mr. Green, a builder, of twenty-five years' standing, said the custom of paying the lowest tender expenses, when not accepted, was acted upon in the trade. Cross-examined—In a case which occurred in witness, he tendered 307*l.* for some work at Paddington. He was the lowest, but his tender was not accepted, upon which he claimed 30*l.* from the person who had his tender accepted. That builder declined to pay the money, and then witness demanded that he should be allowed to take the work. His request was complied with, and he was now doing it.

Mr. Winter, a builder, of Croydon, corroborated the last witness as to the custom.

Mr. Smith, a surveyor, of thirty-four years' standing, stated that it was the custom to pay the builder his expenses for taking out the quantities and pricing the items, when he, as the lowest tenderer, was not accepted. Mr. Angell (this being the plaintiff's case) submitted that this was either a question of custom or contract. If it was a custom, then there was nothing to prevent a man sending in a ridiculously low tender, which he knew could not be accepted, for the mere purpose of claiming the expenses.

The Judge said that, in that event, the person requiring the work would have his action against the contractor, if upon an acceptance of the tender it should not be carried out.

Mr. Harris, defendant's surveyor, said that when he sent out the tenders he stated upon them, "the parties did not bind themselves to accept the lowest tender." This was done by the War Office and other places. Cross-examined—Witness wrote the letter offering to pay the 4*s.* on behalf of the builder whose tender was accepted. When the party requiring the work stated that he would not be bound to accept the lowest tender, it was not the custom to pay the lowest tenderer for taking out the quantities and pricing the items.

The Judge ruled that a custom to pay something was not only proved by the evidence of the plaintiff and his witnesses, but actually borne out by the letter from Mr. Harris, offering the 4*s.* He considered 2 per cent. prodigious, but would find a verdict for 11*l.* Verdict for plaintiff for 11*l.*, with costs.

#### AN IRON CHURCH, MILE-END.

St. Augustine's Mission Church and Schools, in Greenfield-street, one of the most densely populated and poorest parts of Mile-end, was opened, on Thursday, the 18th. It is an iron building, containing two floors, and is believed to be the first two-story iron building of the kind erected in the metropolis. The upper floor consists of the chapel portion of the building. It has a vestry, chancel (with chancel screen), &c., and will accommodate about 200 persons. The lower floor (which is quite separate and distinct from the upper part of the building) is used for the purpose of a school, and will accommodate upwards of 200 children, exclusive of the necessary space required for the usual desk and class accommodation. The total cost of the building, including the gasfittings, bell, fixtures, &c., will be from 650*l.* to 700*l.* The works have been carried out under the direction of Mr. S. W. Iron, architect.

#### "A NEW STYLE."

##### MANCHESTER ARCHITECTURAL ASSOCIATION.

An ordinary meeting of this Association was held, on Friday evening, May 19th, Mr. W. H. Fisher in the chair. After the transaction of business, the chairman called upon Mr. G. S. Aitkin to read his paper, entitled, "The Creation of a New Style."

The essayist, following in the first place the course of analogy, endeavoured to show, from the history of past styles, the certainty of the future creation of a British style of architecture.

Having next considered the current objections to such a probability, the writer went on to show from the present system of practice in architectural styles that the natural issue could be none other than a distinctive national architecture.

To strengthen this inference the principles of Gothic and Classic construction and decoration were considered in the following words:—"In Classic there existed command over height; in Gothic, over width: reverse the process and the result is in favour of Gothic: in the first, the width must be a fixed quantity, the height made proportional to it; in the second the height must be the determined dimension, and the width accommodated to it. To further demonstrate this, let us assume in the Classic height to be the normal dimension; then as the beam—the principle of construction—is only of limited capacity, it is possible that this height may be so great as to render its use, with any regard to proportion, impossible. In the Gothic, on the other hand, if width be taken as the materialer dimension, then a width may be assumed so great that, to secure a well-proportioned section, the piers and abutments may require to be of colossal and, therefore, of inartistic dimensions. In Classic the beam is at fault; in Gothic the pier; or rather, it should be said, in the one the pier is too perfect; in the other, the arch: they do not perfectly balance themselves with their respective complements. Classic has, therefore, command over height in its perfect pier; Gothic over width in its perfect arch.

What, then, is the inference? Naturally this: conjoin these two properties and they will form a new and perfect basis of construction.

§ This much for construction: our next stage is decoration and its character. Our two standards of style are the offspring of mind in different phases of development, affected by religion, circumstances, and climate; the earliest subtle and refined; the later, bold and rich.

In the one the multiplicity of the straight line necessitated delicacy of moulding and severity of enrichment; in the other, the frequency of the curve demanded boldness, roundness, and depth.

Moreover, as climate and temperament had much to do in forming these architectures, so did they affect their ornamentation, reducing it to harmony with the construction it decorated. As we have in the two the extremes of decoration, the natural and the artificial, our ornament of the future must lie somewhere between them.

... We neither want the naturalism of the one nor the idealism of the other. As it is not right, in the one case, for the designer to practically assert the absence of mind in an exact and unassimilated copyism, so neither is it lawful, on the other hand, for nature to be sacrificed on the altar of idealism."

The essayist proceeded to show the practical advantage a British style would have in a perfect adaptation to modern requirements, and concluded by deprecating any search for a new style from the mere sensational desire for change.

A discussion ensued, but, owing to the length of the paper, had to be curtailed, and adjourned till the next ordinary meeting, when the business of the session will be closed.

#### GATES AND BARS IN BELGRAVIA.

WE find, with great satisfaction, that the Marquis of Westminster has withdrawn his authority for keeping up gates and bars on his estate, including Wilton-place, Upper Belgrave-street, Eaton-square, &c., and opens them for every description of traffic. It is to be hoped the example will speedily be followed by other landowners in London.

#### INDOOR ARCHITECTURE.

GREATLY is it to be hoped that Professor Kerr will some day supplement his book by saying something on the not quite exhausted and worn-out subject of *internal fenestration*; that is, fenestration studied with regard to effect within, which, strange to say, has been all along ignored and overlooked. In like manner as a person who could tell us all about prehistoric men could not, perhaps, tell us anything whatever about his own grandfather, so those who are seemingly quite familiar with the history of the rude domestic architecture of those heated if not exactly blissful Mediæval times,—from which, by the bye, we keep drifting away further and further every day,—are ignorant of modern arrangements, or else look at them through a very delusive medium.

Except by one writer, it has not been remarked that the application of what was originally a pointed style to domestic and other secular buildings, led, almost of sheer necessity, to the gradual lowering of the arched head of windows until it became lower and lower, and ultimately degenerated—as some, perhaps, would call it—into an insipid straight line. Yet that same adoption of the square-headed windows of the latest Tador or Elizabethan style may be said to form the turning-point between expiring Mediævalism and nascent modernism in architecture. Therefore, I think it would have been as well, or even better, had Mr. Kerr made that same "turning-point" his own starting-point. At this time of day we do not so much need to be lectured about bygone my-grandmother's matters as, if it be possible, to be plainly instructed in the art of planning or laying out "a gentleman's house" with regard to much more than the convenience of poorly butlers and pampered flunkeys.

Nothing is said, for instance, of the changes—and they may mostly be called improvements—which have taken place in the fittings-up of rooms as compared with those of the same class in the olden Elizabethan time; for we need go no further back than that, or to when

"Fair tapestried walls and filthy rush-straw floors"

showed the unsaintly cardinal's love of tasteless pomp. By way of an *instar omnium* as to omissions in the history of domestic architecture, it strikes me as somewhat remarkable, that no one should have thought it worth while to inform us when looking-glasses, since grown to colossal dimensions, first began to be applied as decorative furniture. It may, perhaps, be objected that all matters of that kind are out of the architect's province; and so, indeed, they seem to be: he is looked upon as the mere planner—the provider of mere rectangular rooms and their bare walls, and to leave all the rest to the undisciplined decorator and the tradesman upholsterer, surrendering up to them the putting in of those finishing touches which are not to be safely confided to any one but the architect himself,—that is, supposing him to be an artist also. Judging by appearances, little more seems to be now thought of or expected, from the architect, than regard to external unassumingness as to style. By no means few are the publications which profess to show designs, or, more properly speaking, patterns, for villas; but among them all there is not a single one that takes any account of interior fitting-up and furnishing, although some judicious advice and instruction on such points might tend to promote the cause

of good taste; nor would it be at all out of place in anything on the subject of a gentleman's house. Well, if a promising theme has hitherto been left untouched, so much the better for him who shall now for the first time take it up; that is, if also capable of treating it worthily, and with *con amore* relish.

Properly executed, the history of furniture, &c., would form not the least interesting chapter in the history of civilization. With this remark I throw down my pen; for were I to proceed I should be much nearer the beginning than the end of what, for my own convenience sake, I make the end of this say.

ART-LOVER.

#### BRITISH MISTAKES RESPECTING THE STAR-SPANGLED BANNER OF THE GREAT REPUBLIC.

THERE is a locality in "York," not far from that dreary-looking building "The Tombs," which is called "The Five Points," indicating, no doubt, the exact number of the spurs upon each of the stars which so fluently dot the national flag of the United States. No one is keenly alive to the fact as your "cute Yankee" that we are not so knowing in this "winkle" as we ought to be; and I have heard the very urchins before the picture-shops in the Broadway criticise our artists wildly for their ignorance in giving the stars more or less points than they should have. *Punch*, our notorious court-jester, is very true in this respect, and therefore cannot be ridiculed; but his clever contemporary, *Fun*, has only recently made one of his "leaders" the subject of another mistake of this kind, in giving the national stars only four points; whilst the *Illustrated News*, a most intellectual authority, goes beyond that; for, on one of the banners intended to illustrate the funeral paraphernalia of President Lincoln, it gives as many as six points to a star. A blunder of this kind actually occurred in the fabrication of the silk handkerchiefs which were adopted as the national colours of the combatants on the encounter between Sayers and Heenan, indicating how little we know of the fact.

Henceforth, then, it is wise to know that such is the case,—that no star intended to convey to us the nationality of the States can be legitimate without the five points; and that *ought* to be a consideration to the satirist who has most of the *starring* business on his hands.

ALEXANDER HAY.

#### "CHURCHES FROM A MOULD."

SR,—In your journal of April 22, "Cast Work" complains that five churches have been built from a model plan; if so, is it not a proof of its superior merit, and is it not far better to multiply buildings intended for a similar use on the basis of a good design, than, for the sake of variety, to erect such ugly, dismal, cold, monastic-looking structures as one is doomed so often to meet with?

As "Cast Work's" critique may possibly be designed to have a two-fold meaning, allow me to state that the Crediton committee did not apply to the English Chapel Building Society for plans, but to Mr. Thomas Oliver, who had built a church at Middlesboro', of which an illustrated description had been published in the "Year Book," and which was thought very suitable for the site, &c. A correspondence was entered into with Mr. Oliver, and the result was that he prepared the plans. The building has been carried out under the inspection of Mr. F. Cross, of Exeter, and has elicited the approval of all who have seen it.

I may as well add that while the English Chapel Building Society are ever ready to assist those about to build, by the loan of plans, they also state, "In the event of any one of them being selected, the architect who prepared such design will prepare the working drawings," whence it is clear no capital is made out of a premeditated design.

T. H.

#### RATS, MICE, FLIES, WASPS, AND OTHER SIMILAR ANNOTANCES.

SEVERAL years ago I read, in a French scientific periodical, that chloride of lime would rid a house of all these nuisances. I treasured up the information until opportunity offered for testing its value, and this occurred some four years since. I took an old country house infested with rats, mice, and flies (no Norfolk Howards, though). I stuffed every rat and mouse hole with the chloride. I threw it on the quarry floors of the dairy and cellars. I kept saucers of it under the chests of drawers, or some other convenient piece of furniture; in every nursery, bed, or dressing room. An ornamental glass vase held a quantity at the foot of each stair-

Stables, cowsheds, pigsties, all had their dose, and the result was glorious. I thoroughly ranted my enemies, and if the rats, mere impudent than all the rest, did make renewed attacks upon the dairy, in about twelve months, when probably from repeated cleansing and flushing all traces of the chloride had vanished, a handful of fresh again ranted them and left me master of my own premises.

Last year was a great one for wasps: they wouldn't face the chloride; though, in the dining-room, in which we had none,—as its smell, to me most refreshing and wholesome, is not approved by all persons,—we had perpetual warfare. Upon N. H.s, as before stated, I am happy in not having required to experiment, but I have no doubt what the result would be, judging from the effect upon most other insect life.

And all this comfort for eightpence. Only let housewives beware that they place not the chloride in their china pantries, or in too close proximity to bright steel wares, or the result will be that their gilded china will be reduced to plain, and their bright steel fenders to rusty iron in no time. EDWARD PAYNE.

Aylesbury House, Warwickshire.

#### REMEDY FOR DOMESTIC INSECTS.

IN the *Builder* of the 13th instant I noticed your article upon one of the "plagues of housewives," viz., the insect known by the not unpleasant name of the "bug," which infests homes and dwellings, especially those of the poorer classes. The nuisance is often tolerated so long as personal comfort is not interfered with.

The remedy you propose may be, and doubtless is, a good one; but I can mention one which is readily applied, is cleaner than some of the greasy substances usually employed, and about the efficacy of which there can be no doubt. Purchase, at any oil or colour warehouse, a pennyworth or two pennyworth of the liquid known as "oil of tar," and with a small brush or strong feather, apply it to the parts where the insects are known to be or likely to secrete themselves, and it will immediately destroy them, and effectually prevent their location in that place. If housewives would brush the joints and holes of their bedsteads, &c., once a year with the liquid, no insects will approach those parts, and as it is absorbed readily by the wood, the bedsteads could be put up again the same day.

A capital opportunity occurs when a house is being renovated of applying the tar to all the crevices, and around doors, windows, skirting, &c., before any paint is put on.

Too much of the tar should not be applied at one time if the room is daily occupied, as the tar has decidedly an odoriferous nature: the smell, however, is far from being injurious, but is of a healthy, purifying nature; and no inconvenience will arise if used in small quantities.

I am told, if a ring be drawn with a brush dipped in the tar, and some insects placed within the circle, they will never approach it, but perish rather than attempt to cross the barrier.

GATA.

#### SCHOOL-BUILDING NEWS.

*Bristol*.—The foundation stone of the proposed new school-rooms in connexion with Old Market-street Wesleyan Chapel has been laid. The school will be 100 ft. long and 25 ft. wide, and two stories high, comprising three rooms. It is expected it will be ready for use in August next. It is intended at the same time to renovate and beautify the chapel; and the cost of both will be about 1,800*l.*, of which 1,500*l.* have been obtained.

*Haughley*.—New parochial schools have been erected and opened at the east end of the churchyard for boys and girls, at the sole expense of the Rev. W. H. Crawford, of Haughley Park. The buildings have been erected by Mr. Betts.

*Salford*.—New Wesleyan schools have been erected and opened in Regent-road. The schools are intended also to be used as a chapel. The site cost 500*l.*; the shell of the building, 1,200*l.*; the gas, heating, and other extras, 400*l.* The schools consist of two large school-rooms and six class-rooms. The larger school-room on the upper floor is capable of accommodating 400 pupils; and the smaller, on the ground floor, 100. Towards the cost of the building, about 850*l.* are in the treasurer's hands.

## CHURCH-BUILDING NEWS.

**Hampstead.**—All Souls' Church, Hampstead, has been consecrated by the Bishop of London. It has been constructed, and endowed, with but some slight assistance in the purchase of the site, at the sole expense of the Rev. H. R. Wadmore, the present incumbent. The church is built with brick, with coloured bands and arches, the aisle and chancel arches being relieved with bands of red brick, while serpentine shafts are used in the latter. The total length, including a semi-circular apse, is 104 ft. and the width 42 ft., inside dimensions. At present one aisle only is erected. There is a gallery over the west end lobby entrance, and a vestry and chantry over at the north-east end of the aisle. The church will accommodate 596 persons. Some of the carving and other decorations to the walls require to be completed, and some colour and stained-glass windows added. Messrs. Scrivener & White were the contractors. Provision for warming by hot water has been made by Mr. Dove, of Tunbridge. The gas-fittings were supplied by Mr. Hewlitt. The total cost of the church will be about 3,900l. Messrs. Wadmore & Baker were the architects.

**Kempsey (Worcester).**—Kempsey Church, which has been under the hands of the restorer during the last twelve months, has been re-opened. The fabric has been restored: Mr. Christian, the architect to the Ecclesiastical Commissioners, being employed in the work. The builder was Mr. Griffiths, of Eldersfield, near Tewkesbury. The cost of the work was 4,000l., towards which the principal contributor was Mrs. Royds, of Brighton, who gave 1,000l.

**Upton-on-Severn.**—It has been decided as to what kind of chapel should be erected on the ground chosen for the new cemetery in Buryfield, near the railway station, and that the design sent in by Mr. G. R. Clarke, of London, should be accepted. The building will be commenced as soon as a satisfactory tender has been received.

**Bebington (Cheshire).**—The foundation-stone of a church at New Ferry, Bebington, has been laid. Nearly 2,000l. have been subscribed. The cost of erecting the church is estimated at 2,500l. The building is designed to accommodate 550 persons, and will be fitted with open seats. The interior will be divided into a nave, north and south aisles, chancel and chancel aisle. The principal entrance will be through a porch at the south end, and there is to be a bell-turret at the west end. Trammere stone will be the material principally used, with Stourton dressings. The Gothic style has been adopted by the architect, Mr. E. Haycock, of Shrewsbury, and provision is made for the extension of the building. Mr. Richard Lloyd, of Shrewsbury, is the contractor, and it is expected that the church will be completed about the end of the present year.

**Nottingham.**—A new peal of bells has just been fitted up by Messrs. Taylor, of Loughborough, in the tower of All Saints' Church, and forms a portion of Mr. Windley's gift to the town. The peal is of eight, the largest, or tenor bell, weighing 17 cwt. 11 lb. They are in the key of E natural. The chamber for the ringers is large and lofty, and is placed at a considerable elevation above the roof of the church. It is reached by a long and narrow flight of stairs at the south end of the tower. The windows in the bell tower are fitted with louvres of slate, which give free passage to the sound; while above, there is no impediment to free resonance—the hollow spire acting much the same part as the sound-board in an organ or pianoforte, though, of course, on a much larger scale.

**Norwich.**—The plans for the restoration of St. Giles's Church having been submitted to the Bishop of Norwich and Archdeacon Hankinson, and received their cordial approval, the contract has been taken by Messrs. Lacey & Atkins, at the sum of 2,900l. The architect's estimate somewhat exceeded this sum. About 2,400l. have been already collected. The architect, who has prepared the design and under whose superintendence it is to be carried out, is Mr. R. M. Phipson, who has at this time, it is said, between twenty and thirty churches in Norfolk and Suffolk alone now under his charge. There appears to be reason to think that the foundations of the east wall have been come upon when sinking graves, and that they were about 35 ft. from the nave. It has, therefore, been settled to make the new chancel this length between the clear inside walls. The style of the nave and aisles is Perpendicular. The new chancel, however, will be decorated.

On the south side will be three bays, each containing a three-light window, and below the centre one a chancel door. On the north there will be no windows, as it will be occupied by an organ-chamber and vestry, the former opening with arches into the church, and the latter having an outside door, to enable the clergyman to enter without passing across the chancel. The east window will be a large four-light one. The roof will be open, of oak, and covered with lead. Internally it will be divided into six bays, with arched braces springing from carved stone corbels. There will be two steps at the altar, and one into the chancel from the nave. At the wish of the incumbent, who has given 1,000l. towards the work, the children will occupy all the seats in the chancel, and these seats will be made moveable. The present pews, pulpit, desk, and gallery, will be swept away, and the whole church thrown open, and benched with open oak benches. The west arch will then be seen to full advantage, and the large west window opening will have its present wood mullions removed and filled in with new stone tracery mullions. All the north and south windows will also be scroved in a similar manner, and the whole, together with those in the chancel, glazed with cathedral glass. The west tower doorway will be restored and made one of the principal entrances to the church, the comparatively modern north doorway being done away with. The belfry windows of the tower, now blocked up, are to be opened and glazed, and the upper ones restored. Five of the tower buttresses, now unsound, as well as the parapet, are to be rebuilt. The roofs of the nave and aisle are to be restored and reroofed, and the internal arches and other stonework cleaned of all whitewash and paint. The porch and west doors are to be of oak, ornamented with tracery and carving. The chancel will be paved with Milton's encaustic tiles, and the passages in the nave and aisles will be laid with the same material.

**Staveley (near Kendal, Westmoreland).**—The parish church has been rebuilt at a cost of 1,500l. The accommodation is for 300. The church is in the simple Early English style of the thirteenth century, and was designed by Mr. J. S. Crowther (of Manchester), and consists of nave, chancel, organ chamber, and vestry. The chancel is lighted on the north side by three simple lancet windows. The east window is a triplet, the centre light of which is trefoiled. The walls are 3 ft. 3 in. thickness, the angles formed of freestone quoins. The vestry, with a low lean-to roof, and the organ-chamber, are placed on the south side of the chancel from the ground sloping to the south. The chancel is separated from the nave by an arch, the span of which is the full width of the church. The nave is lighted by complete lancets in the north and south side walls, one of which is filled by a stained-glass window, put in by Miss Taylor to the memory of her father and mother. The west end is lighted by two lancets, having trefoiled cusped heads. The nave roof consists of framing, and is divided, like the walls, into five bays by principals. The nave is seated with plain open benches, stained and varnished. Mr. Harrison, of Windermere, did the woodwork; and the walls were Messrs. Bowness & Davis, of Staveley.

*The "Flint Implements" from Drift not Authentic; being a Reply to the Geological Evidences of the Antiquity of Man.* By N. WHITLEY. London: Longman & Co.

THE assertion that the flint implements from the glacial drift are not authentic is not new, it may be recollected; for even some of those gentlemen who now fully believe in their authenticity were at first strong deniers of it. Mr. Whitley, however, believes that he has discovered that flint has a natural tendency to split up not only into oblong and sharp-edged pieces, but actually into arrow-headed or almond-shaped forms. The multitude of more or less complete forms of this kind which occur in so many places, he thinks, cannot be explained on the idea of human design; and he cannot imagine what use naked savages, living in an ice-bound and eternal arctic winter, where there could be no trees for canoes, would have for such "tools" as the axe-headed forms are supposed to have been. It is not for us, but for such advocates of the opposite view as Sir Charles Lyell and others, to controvert Mr. Whitley's ingenious

arguments and assertions; but, in a critical light, we may remark that there appear to us to be some untenable hypotheses, and various errors and fallacies, in them which will no doubt be dealt with by his opponents. How does he know that the people of the glacial era were naked savages? Is it likely? Why does he take for granted that the glacial era had no summers, or that these summers were not as intense, on the one hand, as the winters were on the other? The present arctic region is evidently the remnant of that vastly extended envelope of ice which covered great part of the northern hemisphere of the globe, in what is called the glacial era; and we know that the great cause still in operation to the production of the present arctic and juxta-arctic winters is the turning of the hemisphere away from the sun, or, in popular parlance, the departure of the sun out of the hemisphere, while his return into the hemisphere is the great cause of the conversion of that winter into a summer. Since the winters of the glacial era were so intense and extended, it is reasonable to conclude that the cause still in operation must have then been more potent and extensive in its kind, or, in other words, that the sun must have departed farther out of the hemisphere in the winters; and if so, he must have returned farther into the hemisphere in the summers; so that the arctic winters must have alternated with tropical summers in what we now call the temperate regions; and accordingly, from time immemorial, the obliquity of the ecliptic has been steadily and continually diminishing; or, in ancient times, it was greater than it now is; and although astronomers, admittedly without sufficient data, have concluded that this variation must be very limited, they will no doubt be better instructed, shortly, by evidences of an astro-geological nature which are accumulating against them in this respect. We do not see, then, why the inhabitants of the glacial era in now temperate latitudes could not have quite sufficient use for hatchets even in the vegetative kingdom; but might not even the cutting up of such "monsters of the deep" as whales, and the fashioning of bone, walrusbone, and such like substances, have afforded quite enough use for hatchets, independent altogether of the cutting of trees or brushwood? As to the natural tendency of flint to split up into oblong and sharp-edged fragments, this might have been the very reason why such a substance was chosen or preferred for the fashioning of arrow-heads out of it; and as to the multitude of such forms, of more or less perfect and imperfect finish, that have been already found, we must consider that arrow-heads, at such a period, were probably the shot which men fired with, both in their wars and in the chase. Suppose that, some thousands of years hence, many stores of shot were to turn up, especially in the lead-bearing districts, what sort of argument would it be to maintain that their multitude, and the fact that lead, when melted and suddenly thrown from a height, into water, naturally assumed a spherical form, proved that these stores of shot were not of human formation? The fact that Mr. Whitley himself admits that "the most perfect of the almond-shaped flints of St. Acheul, from their regularity of outline and marks of fine chipping on the surface, if viewed apart from others, appear to evince design," vitally damages his own argument; for if even one such shape be of human design his argument is worthless. The multitude of imperfect shapes would only then go to show that the difficulties contended with were great by comparison with the success. Of course, to complete his case, Mr. Whitley contends that these more perfect arrow-head forms were probably also natural productions. This we must say, that some at least of those stone implements of the drift which we have seen were undoubtedly of human formation; and we cannot see any rational force in Mr. Whitley's singular remark that the "roughly-fractured flints could have been applied to no use whatever, and if they were of no use to man, he could have no object in designing them." We fear this question is not to be decided by arguments such as this.

## VARIORUM.

"Suggestions on Town Sewage and its Application to Land by Gravitation." By L. H. Spooner. London: Hardwicke, 1865. This pamphlet gives the results of an experiment of long standing at Mansfield, in the utilization of sewage. So long ago as 1816 the late Duke of Portland put the sewage of Mansfield to that of Sutton-in-Ashfield to use by means of an

intercepting apparatus about a mile below Mansfield, and ever since this sewage has been yielding highly profitable results, which long ago repaid all outlay and converted a very poor and sterile tract of land and peat, of literally no value, into land worth 11L. to 12L. per annum an acre, and yielding a return of 24 per cent. upon the capital invested, which it repaid years ago, leaving nothing but profit for the past, the present, and the future, so far as regards capital expended. "One of the most valuable features of this example," remarks Mr. Spooner, "is the evidence it affords, at the present day, that the process is not an exhausting one. There is no depression in produce value: the 300 acres of the Duke of Portland's water meadows, and 103 acres subsequently irrigated from the same stream by the late Earl Manvers, have gone on from their formation to the present time, yielding every year a large amount of grass for mowing green, of hay, of heef, mutton, and wool, upon land which, if left to itself, would be all but sterile. This irrigation commences at a distance of 2½ miles from Mansfield, and extends for 5½ miles along the course of a narrow valley; and in this distance all these water that the town yields has flown upon, and been drained through, some one or more of these meadows, has parted with its impurities, has returned to the river as pure as all ordinary streams are which flow from land only. Such is the use that one small stream, aided by the sewage of a comparatively speaking small country town, can be made to produce by judicious employment of gravitation."—"Remarks and Suggestions on Cotton Packing in Egypt." By E. T. Bellhouse, Mcm. Inst. M.E. Printed for private presentation. Mr. Bellhouse, of the Eagle Foundry and Iron Works at Manchester, gives here some useful suggestions on a subject of great importance to us as a cotton manufacturing people; for it is to be hoped that everything will be done to foster and improve the production and the preparation of cotton in Egypt for our market, so that we shall never again risk the possibility of cotton famines while our American consins are fighting like Kilkenny cats, to their mutual destruction.—Given 128 pages, filled by Mr. G. H. Lewes, "George Eliot," Mr. A. Trollope, Sir John Herschel, and others, and the result, it may be predicted, whether called the *Fortnightly Review*, or anything else, will be well worth 2s. This is certainly so in the case of the Review in question, which takes for model the *Revue des Deux Mondes*, and gives all signed articles; admitting diversity of views. The paper on the "Ironmasters' Trade-Union," by the way, is a very one-sided view of the late outlook, in condemnation of the masters.

### Miscellaneous.

**THE HIGH-LEVEL RAILWAY BRIDGE ACROSS THE SEVERN.**—The report of the referees upon this undertaking has been issued. The engineers, Messrs. Fowler & Fulton, propose that the railway shall be increased to 120 ft. above mean-tide level, instead of 115 ft., and that the span of the main opening of the bridge shall be 600 ft., which is as wide as the Thames at Southwark.

**THE DISTRICT SURVEYOR OF PADDINGTON.**—Our friend, Mr. George Gutch, completed, on the 15th inst., his fortieth year of office as district surveyor of Paddington, and we hope that, like his predecessor, he may live to see his half-century out, should he care to work so long. Ever since the passing of the old Building Act, now ninety-one years ago, this important district has been held only by old Crunden (who lived to the age of ninety-four), and by Mr. Gutch. Great are the changes in Paddington which Mr. Gutch has witnessed if not created.

**BOOTLACES.**—Sir: Being able from experience to testify to the truth of your correspondent's remarks upon the inconvenience of bootlaces, &c., permit me to offer a suggestion of what I have tried and found to answer. For a fastening I use the ordinary metal loop and stud, applied in the same manner as buttons to hoots, are only to keep the loop in its place I use a lapnet with a spring such as is used to spring-side hoots. Thus a neat, supporting, and ventilating hoot is provided that can be easily and quickly fastened, without the trouble of buttons, and the danger of laces.—W. E. B.

**FALLING-OFF IN THE RAINFALL OF ENGLAND.**—It would appear that, notwithstanding the concentration of very dry summers by very wet ones, of late years, Mr. G. J. Symons considers that he has made a discovery which is enough to cause us all disquietude. By collating records of the rainfall in England during the last fifty years, he has ascertained that the fall has, on the whole, decreased throughout the country, in some parts by a tenth of the average annual amount, and in others by a twentieth. Year by year this decrease goes on, and, as Mr. Symons says, it has become a matter of national importance. In some counties it amounts to thirteen per cent. Ireland, which might well spare a little of its rain, has been least affected by the change. It is a question for meteorologists to discuss whether, in the words of Mr. Symons, we are experiencing "a temporary fluctuation, and not the inauguration of a regularly decreasing supply." The *Builder* drew attention to the diminution of rainfall some years ago.

**DISCOVERIES AT CLONMACNOISE.**—In the course of some repairs at the Seven Churches of Clonmacnoise, by the Kilkenny Archeological Society, under the direction of the Rev. Charles Vignoles and the Rev. James Graves, excavations were made at the west end of the Church of the Nuns, a remarkable building erected by the celebrated Queen Devorgoil, in 1180. Traces of a western entrance to this church have been always apparent, but now, according to the *Carlou Sentinel*, there have been found the jambs and side mouldings of a magnificent doorway of four orders, with almost, if not all, the carved vousoirs of the arch. It is confidently hoped that every stone may be recovered, and that this fine specimen of ancient Irish art will rise from its place of burial nearly as perfect as when it came from the cunning hands of Queen Devorgoil's master masons. It is proposed to rebuild the grand choir arch of this church, the carved stones having nearly all been preserved. This is being effected by a special subscription.

**THE SAILORS' HOME AT LONDON DOCKS.**—The new building just completed to increase the efficiency of this valuable institution has been opened by the Prince of Wales. The chief stone of the seaman's church adjoining was laid by the Prince Consort. Previously to the inauguration of the new Home, an address was read by Admiral Sir W. Bowles, in which he quoted statistics to show the need for the present institution in the accommodation. Since 1835 the Home had accommodated 158,525 sailors, including many of her Majesty's navy,—134,885 belonging to the United Kingdom and to her Majesty's possessions abroad, and 23,640 to the various foreign countries with which England had maritime and commercial intercourse. Out of an aggregate sum of 1,263,893L. lodged by the sailors in the bank of the Home, 711,560L. had been drawn out; 459,610L. had been re-invested to friends and relations; and 46,400L. invested in the Home and Board of Trade Savings' Banks. The original buildings contained 328 sleeping-berths, and this addition would afford 174, so that they could now accommodate 502 persons.

**A NEW HOTEL FOR SOUTHSEA.**—The foundation stone of "the Southsea Beach Mansion," situated at St. Helen's, has been laid. The "Mansion" will be created from the designs and under the superintendence of Mr. Whitcherell, of London, the architect of the Grand Hotel at Brighton, Clarence Hotel at Dover, and other establishments of a like character, and will be completed in time for the summer season of 1866. It will be arranged as a hotel and boarding-house, and will comprise, on the ground floor, a gentlemen's coffee-room and ladies' coffee-room; on the first and second floors, reading-room, saloons and bed-rooms for invalids; saloons, sitting-rooms, and bed-rooms which are planned that families may occupy them *en suite*. The third and fourth floors will be for bed-rooms. The "Mansion" will be so constructed that it may, if desired, be subdivided into three distinct buildings, and occupied as several superior boarding-houses or mansions, as at Brighton. The structure will contain 140 rooms, including eighty-five bed-rooms. The design is of a plain Italian character, with bay windows and balconies, with the sea view. The contract has been taken by Messrs. Simms & Marten, of London. This building is being erected by a limited company, called the Southsea Beach Mansion Company.

**EXETER DIOCESAN ARCHITECTURAL SOCIETY.** At the meeting, on the 18th inst., Mr. H. S. Ellis read a paper as to a figure of St. Peter, at the corner of North-street, which figure he thinks may formerly have occupied the principal canopy of the bishop's throne in the cathedral.

**THE SANITARY PROGRESS AT LIVERPOOL.**—The state of the health of this town has given the health committee much anxiety for some time past, and the council, amongst other measures, have just authorised the purchase of the plant requisite for performing scavenging and night-soil work within the borough, at an estimated cost of 6,300L.; and have empowered the borough engineer to employ men at scavenging, at wages varying from 13s. 6d. to 15s. per week.

**A WORKMEN'S HALL IN DUBLIN.**—The foundation stone of a Workmen's Hall has been laid in Dublin, by the Lord Mayor, in presence of a vast assemblage. The object of the movement, which originated some years since amongst a number of ladies, is to erect a place in Lower Kevin-street, in which the working classes will be provided with good and wholesome food at a moderate charge, and afforded, at the same time, such opportunities after their day's toil, for mental improvement as will induce them to cease frequenting public-houses.

**COST OF A SURVEY.**—At a meeting of the Whitehaven Trustees last week, it was stated that Mr. Rendel claims, on account of his wet-dock plans, &c., 1,916L. A previous payment of 500L. added to this, runs up his bill to 2,416L. The *Whitehaven Herald* says:—"The set-off is 0, and less than nothing, when we consider what has been lost by all the bungling and delay in the matter. But to these 2,416L. there fall to be added the amounts paid to the late Mr. Rendel. The credit of the harbor is gone. Not a meeting is held but money lent is called in, and new loans to meet the demand cannot be raised. Trustees themselves evidently have as little faith as the public in these dock schemes, for we do not hear of any of them hastening to the rescue."

**PARLIAMENTARY ITEMS.**—In reference to the breakwater at Alderley, Mr. Peel stated, in reply to a question in the Commons, that during recent storms, the masonry walls of the breakwater had breached in two places, of considerable length, 2 ft. below the level of the sea at low-water. The cost of the repairs had been estimated at 15,000L., but the cost to the public would not be so much, as the contractor was liable for any damage till the breakwater was completed, except in the case of damage arising from great storms, in which case he was liable to pay one half.—The Public Offices (Site and Approaches) Bill has been read a second time in the House of Commons. Lord Stanley of Alderley said, that most of the land required was now in the hands of the Government.—The India Office (Site and Approaches) Bill has also been read a second time in the Commons.

**HAYMARKET THEATRE.**—As only two scenes are needed for the three acts which compose "Brother Sam," the new piece provided to display the capabilities of Mr. Sothorn, Mr. Compton, and Mr. Buckstone, extra care has been bestowed on them, and we have a very perfectly fitted interior, showing the drawing-room and parlour, opening one into the other, of Mr. Trimhush's house at Scarborough, and an equally good exterior of the same house in its garden, with sea and cliff in the distance. The practised author of the piece, Mr. John Oxenford, has wisely avoided making it a sequel, or in any way a part of the "American Consins," beyond developing the character of *Brother Sam* as conveyed to the British public in that wonderfully successful piece. *Sam* is a much "cuter fellow than his brother, — a cool, off-hand, sponging, but not bad-hearted sort of fop, sustained from beginning to end in the most perfect and finished manner by Mr. Sothorn. The entire difference in the conception and mode of displaying the two characters was forcibly shown, and was recognized by the house with loud applause, when *Sam*, at the close, receives a telegram from Dmdreary, and reads it in imitation of him. Mr. Buckstone and Mr. Compton are both very funny. The plot is simple, and not wholly new; but the piece is exceedingly well written, with much epigrammatic point and sharpness, and proved completely successful.

**WORCESTER CATHEDRAL TOWER.**—The steps necessary to be taken for the repair and strengthening of Worcester Cathedral tower, in order to render it suitable and safe for the reception of the proposed clock and bells, will shortly be commenced. A scaffold is in course of erection. This is in itself an undertaking of considerable magnitude, as the tower is 44 ft. square and 196 ft. in height.

**A NEW FACT IN THE LIFE OF GAINSBOROUGH, THE PAINTER.**—So little is known of Gainsborough, that the discovery of a new fact in his life is always an agreeable addition to our knowledge of his doings. This new fact Mr. Tom Taylor supplies in his recent "Life of Sir Joshua Reynolds." We shall give it in Mr. Taylor's own words:—"Among the Royal Academy Records for this year [1775], I find a motion carried in the council for omitting from its lists the name of Mr. Gainsborough, he having declined to accept any office in the Academy, and never attending. His name was, however, restored to the council by the general meeting." Let us observe on this, that as one of the twelve "apostles in art" whom the Academy has had among its many members, the name of Gainsborough stands preeminently high. Was the reason for Gainsborough's "never attending" a growing jealousy of Sir Joshua? Perhaps Mr. Fulcher, Gainsborough's latest biographer, can tell us.

**MR. HOWISON AND THE NORTHERN ARCHITECTURAL ASSOCIATION.**—The position of Mr. Howison, the surveyor of the county of Northumberland, in reference to the Walbottle Dean Bridge, came up for discussion at a meeting of the Northern Architectural Association, held in the Old Castle, last week. The committee of the Association had visited the bridge, and in accordance with the verbal reports given in by some of the members, a resolution was drawn up for presentation to Mr. Howison, stating that the Association were of opinion that the want of stability in the bridge has been caused as much by the defective execution of the work by the builder, as by any fault of the plan itself. The resolution recommended that, with a view of preventing further failures of this kind, the county surveyor have the assistance of a clerk of works, and expressed the hope that the magistrates would not accept Mr. Howison's resignation.

**THE IMPROVEMENTS IN NEWGATE-STREET AND THE PROPOSED NEW POST-OFFICE SITE.**—Notwithstanding that some little difficulty has occurred between the Corporation and the authorities of the Post-office as to the purchase of certain ground in Newgate-street, for which the Commissioners of Sewers had agreed to pay 3,000*l.* (the houses being numbered 71 and 72, Newgate-street), we are in a position to state, says the *Morning Advertiser*, that the Post-office authorities have agreed to confine themselves to the erection of the official buildings on the western side of St. Martin's-le-Grand to the line agreed upon by the Corporation, so that a most commodious approach from Cheapside and Aldersgate will be secured to the public, the Post-office purchasing the freehold acquired upon certain equitable conditions provided for under the provisions of the 13th section of the "Post-office Additional Site Act, 1865," to which the opposition of the court will be at once withdrawn.

**FEARFUL DEATH OF A "STEEPLE JACK."**—For some time past a man named John McCann has been employed to repair chimneys, &c., in the black country. A stack at the iron-works of Messrs. Williams, Wednesbury Oak, required repairing, and McCann was employed to do the work. He had affixed his apparatus, and after a visit to a public-house, he ascended and went through certain foolhardy antics on the top of the chimney. Again descending, he again repaired to the public-house, and, after staying there an hour, reascended unobserved, it is said, and was soon afterwards seen lying asleep across the apex of the stack. In another hour he was seen to roll from his perilous head. He fell upon the roof of the building below, and was picked up in a mutilated condition on the floor of the works, having broken through the roof and some rafters beneath it. He was conveyed to the South Staffordshire Hospital, where he died. Deceased's father earned his bread in a manner equally hazardous with that of his son; and it is stated that the father's death was similar to the son's.

**BURSTING OF A SEWER ON THE NORTH LONDON RAILWAY.**—On Tuesday afternoon, during the heavy thunder and lightning storm, and sewer which passed under the North London Railway, between the Kingsland and Stoke Newington stations, burst in consequence of the great rush of water, and flooded the line for a considerable distance. It appeared that the crown of the arch of the sewer under about the centre of the permanent way yielded, and, so great was the pressure, that the water shot up in a body as if out of the main, and rushed along the line.

**ACCIDENT AT THE NEW STATION OF THE NORTH LONDON RAILWAY.**—On Wednesday night considerable alarm was caused in the neighbourhood of Bishopgate-street, London-wall, and Fishery-circus, by a crash which shook the entire locality adjacent to the spot where it occurred. Very shortly afterwards it was discovered that the noise was caused by the falling of a considerable portion of the ironwork forming the semicircular arches and girder supports of the double roofing in course of erection at the new station for the North London Railway terminus at Liverpool-street. It appears that several portions of the ironwork had been placed *in situ* safely, but whilst the workmen were engaged in raising other portions of the work, through some cause the derrick used for hoisting the iron arched slipped.

**CLEAN AND TIDY HOUSES.**—An effort to promote cleanliness amongst the poorer inhabitants of the city, has been made in the parish of St. James, Bristol. About six weeks ago, four prizes were offered to the residents of Eugene-street and courts, and four to those of Black-friars and courts, for the cleanest and tidiest of rooms. The first prize in each street was 10*s.*; second, 5*s.*; third, 3*s.*; fourth, 2*s.* There were 22 competitors, and during the six weeks of inspection, 132 visits were paid to the houses of these people. Of the 132 calls made, 55 were marked clean and tidy; 31 were marked tidy, but not clean; 18 clean, but not tidy; 8 dirty. No one was reported dirty after the second visit. The prizes were distributed at the house of Mr. Nunn, King-square (who originated the movement, and gave all the prizes); and, through the kindness of the Rev. W. Bruce, the unsuccessful candidates were presented with a quarter of a pound of tea each.

TENDERS

For house, &c., at Teddington. Mr. J. T. Jackman, architect. Quantities by Mr. W. R. Ingleton and Mr. J. G. Smither:—  
 Jackman ..... £2,000 0 0  
 Wiles ..... 1,793 0 0  
 Sharpling & Cole ..... 1,797 0 0  
 Adamson & Sons ..... 1,955 0 0  
 Bruden ..... 1,491 10 0

For the erection of the Dominican Priory, at Carisbrook, Isle of Wight. Mr. Gilbert Blount, architect:—  
 Bird ..... £14,718 0 0  
 Wheeler ..... 13,254 10 0  
 Stevens ..... 10,545 0 0  
 Mender ..... 10,900 0 0

For alterations and additions to the King's Arms Tavern, Kennington-lane, for Mr. Hancock:—  
 Simpson ..... £2,204 0 0  
 White ..... 2,369 0 0  
 Jelf, Brothers ..... 2,251 0 0  
 Kilby ..... 2,137 0 0

For the erection of auction-rooms, &c., Park-lane, Piccadilly, for the Park-lane Company (limited), Mr. Gasling, architect:—  
 Piper & Wheeler ..... £3,232 0 0  
 King & Sons ..... 2,198 0 0  
 Nixon ..... 2,077 0 0  
 Jackson ..... 2,038 0 0

For proposed alterations, at the King's Head Tavern, Margaret-street, Cavendish-square, Mr. J. Bird, architect:—  
 Tracey & Son ..... £615 0 0  
 Brown ..... 595 0 0  
 Rows ..... 539 0 0  
 Williams ..... 487 0 0  
 Henshaw ..... 463 0 0

For dwelling-house and offices, to be erected at Bramley Hill, near Croydon, for Mr. A. B. Cowdell. Mr. R. Corby Baxter, architect. Quantities supplied by Mr. F. Warburton Street:—  
 Rawlings ..... £3,987 0 0  
 F'Anson ..... 2,745 0 0  
 Colls & Co. .... 2,732 0 0  
 Keddel (accepted) ..... 2,647 0 0

For St. Clement's Schools, Barsbury. Mr. Ridge, architect:—  
 Philis ..... £2,926 0 0  
 Carter & Sons ..... 2,865 0 0  
 Foster ..... 2,630 0 0  
 Dove, Brothers ..... 2,595 0 0  
 Keyes & Head ..... 2,553 0 0  
 Glenn, Brothers ..... 2,560 0 0  
 Williams ..... 2,625 0 0  
 Brown & Robinson ..... 2,460 0 0  
 Scrivener & White ..... 2,437 0 0

For stabling, near Trinity Church, Ryde, for the Rev. A. J. Wade. Mr. F. Newman, architect. Quantities supplied:—  
 Sibley ..... £290 0 0  
 Denham & Saunders ..... 287 0 0  
 Saunders & Parson ..... 287 0 0

For house, and china and glass warehouses, Union-street, Ryde, for Mr. W. Henshall. Mr. F. Newman, architect. Quantities supplied:—  
 Langdon ..... £1,965 0 0  
 Smith ..... 879 0 0

# The Builder.

VOL. XXIII.—No. 1165.

Literature illustrative of the Catacombs of Rome.

**B**ELOW the surface of the Campagna around Rome, it is ascertained that from 800 to 900 miles of subterranean corridors, interspersed with chambers excavated in other forms, extend their marvellous ramifications; and between six and seven millions are the number assumed for the Christian dead here deposited by those sharing their faith during primitive ages.\* In much the greater part it may be deemed certain that these hypogees were formed for Christian uses, worship, instruction, and interment, before the period of the first converted emperor; but it is also indisputably proved that they continued in use for devotional purposes, and received many of their pictorial decorations long afterwards; likewise that the work of excavating was still in progress till the beginning of the fifth century. The idea that they ever served for the habitation of numbers, during Pagan per-

secution, is shown to be erroneous, as, in fact, materially impossible, owing to the very formation of their far-stretching labyrinths, small low chapels, and story above story of narrow passages. We read, indeed, of the martyrdom of saintly bishops, while in the very act of officiating at their humble altars; of several among the earliest Roman pontiffs who, during extreme peril, took refuge in these abysses. Alexander I. (A.D. 109—19), Stephen I. (253-57), Sixtus II., Cajus (of the two latter one at least put to death in these subterranean sanctuaries, A.D. 258), Tiberius, and Boniface I. Pope Cajus is said to have actually lived for eight years in catacombs, from which he only came out to suffer martyrdom. With Mr. Northcote (whose admirable work is a *vade mecum* for this range of antiquities) we may conclude that not the multitude of the faithful, but the Roman pontiffs, or others especially sought after by persecuting officials, were at any time resident for long periods in these retreats (*Vide* "The Roman Catacombs," ch. ii.) In no part do we see anything like the preparation for dwelling-places, or for any other purposes save worship and interment; yet an epitaph, by St. Damasus, in the Callixtan Catacombs, implies the fact that at some period these cemeteries were indeed inhabited:—

*"Hic habitasse prius sanctos cognoscere debet."*

Damasus, however (elected to the Papacy 366), cannot be cited as a contemporary witness to the periods of persecution. Turning to dates much later than these periods, we read of Pope Tiberius taking refuge, A.D. 352, in the cemetery called after St. Agnes, from the outrages and insolence of the then ascendant Arian sect; of Pope Boniface I., so late as between the years 418—422, passing some time in a similar retreat, in order to withdraw from the faction bent on supporting his rival Eulalius. True it

\* Father Marchi, who makes this conjecture, adds that he considers it to fall short of, rather than exceed, the truth.

is, however, that the evidence as to the occasional habitation of these subterranean is too conclusive to be set aside without rejecting much that is contemporaneous, or nearly such, in "Acts of Martyrs," and other received authorities. Of Pope St. Urban we read (in the "Acts of St. Cecilia"), *latebat in sacrorum martyrum monumentis;* of St. Hippolytus ("Acts of St. Stephen," A.D. 259), "*vitam solitariam agebat in cryptis.*" Baronius states that the same pope "used to celebrate masses and hold councils in the crypts of the martyrs;" and an epitaph to St. Alexander, found in the Callixtan catacombs, contains the line,—"*O tempora infauata quibus inter sacra et vota ne in cavernis quidam salvati possumus!*" In one terrific persecution, a multitude of Christians were put to death in some catacombs on the Salarian Way, by order of the Emperor Numerianus, a vast mound of sand and stones being heaped up against the entrance, leaving all those victims hurried alive, of which martyrdom was found affecting proof ages afterwards, not only in the bones of the dead, but in several silver cruets they had taken into those subterranean for the Eucharistic celebrations. An impressive circumstance accompanied the martyrdom of Pope Stephen. The ministers of death rushed into the subterranean chapel, found him officiating at its altar, and, as if struck with sudden awe, waited till the rite was over before they slew him in his episcopal chair! It is ascertained that many catacombs were not left open, even in the actual extent to which they had been excavated, during the entire period of their most frequent use; for, as their sepulchres became gradually filled by the dead, corridors, thus rendered no longer serviceable, used to be blocked up with soil brought hack to its original place, in order thus both to separate the living from the dead, and to avoid the necessity of leaving material accumulated outside, whilst concealment of all such underground retreats was an object necessarily in view. Granular tufa, which, with lithoid tufa and pozzolana, forms the material of the volcanic strata throughout the region around Rome, is the sole substance (easily worked, but quite unsuitable for building), in which the catacombs are excavated, except only those of St. Pontians, outside the Porta Portese, and of St. Valentine, on the Flaminian Way, which are opened in a soil entirely of marine and fluvial deposits, shells, fossils, &c. Exaggerations must also be rejected in many cases respecting the immense number of martyrs here entombed,—the 174,000 still boasted of, and revered in relics kept at the St. Sebastian Basilica, as all reposing in the catacombs entered below that church,—one of those misrepresentations of history, or rather legend, too often provoking scepticism, or sarcasm, in popular report at Rome. From the ninth century till a comparatively advanced period in modern ages, these hypogees were left unexplored, perhaps almost entirely inaccessible, and for the most part forgotten. Mediæval writers usually ignored their existence. That strange compilation, so curious in its fantastic suggestions and blindness to historic fact, the "Mirabilia Urbis Romæ" (written probably in the twelfth century, first published in Rome about 1471), enumerates, indeed, twenty-one catacombs; Flavio Biondo, writing in the fifteenth century, under Eugenius IV., mentions those of St. Callixtus alone; Onofrio Pamino, in the sixteenth century, reckons thirty-nine; Baronius, at date not much later than the former writer, raises the number to forty-three; but recent illustrators of the subject have shown the existence of no fewer than sixty distinct systems among these hypogees, not hitherto made permeable in more than about one-third their extent to modern explorers. Those of St. Priscilla, opened in an estate on the Salarian Way, belonging to that matron, mother of the Christian Senator Pudens (who received St. Peter at his house in Rome);

also those of SS. Nereus and Achilleus near the Appian Way, have been referred to an antiquity correspondent with the apostolic age; and, if those called after St. Callixtus had really been formed long anterior to that Pope's election, A.D. 210 (*vide* Northcote), we may place those only second in chronologic order. That several catacombs continued in use as cemeteries long after the first imperial conversion, is evident from the fact that Constantine's daughter ordered the embellishment and enlargement of those called after St. Agnes (on the Nomentan Way), which became in consequence more than ever frequented,—so to say, fashionable,—as a place of interment during the fourth century. And this circumstance of their history is manifest in the characteristics of the same catacombs; the superior regularity and spaciousness of their corridors; the more laboured execution, but inferior style of several among their paintings. Other facts relevant to the story of later vicissitudes may be cited: Pope Damasus (*vide* Baronius, anno 384) ordered a *platanica* (pavement of inlaid marbles) for that part of the Callixtan catacombs in which, for a certain time, had lain the bodies of St. Peter and St. Paul after the attempt to remove them further to Constantinople. Pope John III. (560-73), who shod for a time, according to Anastasius, in the catacombs of SS. Tiburtinus and Valerian, ordered all such of these hypogees as had suffered from barbarian spoliation to be repaired; also provided that a regular supply of bread, wine, and lights should be furnished from the Lateran Basilica for the celebrations still kept up on Sundays at the altars of these underground sanctuaries. Towards the end of the sixth century, St. Gregory "the Great" indicated several catacombs among places of assemblage for the faithful on the days of the Lenten "Stations," organized by him with much solemnity and great concourse of worshippers, at the several parish churches and basilicas. The evidences of art may be cited also, to prove comparative modernness of origin in decorative details; at least the *nimbus* around the heads of many figures indicates a date subsequent to the fourth century; and in the Callixtan catacombs the figures of St. Cecilia (strangely attired in cumbersome finery, jewelled head-dress, and necklaces), of the sainted popes Urban and Cornelius, besides a large and sternly-expressive head of the Saviour, presenting marked characteristics of the Byzantine school, suggest origin certainly not earlier than the sixth or seventh century, if not so late as the eighth century.

The practice of frequenting these cemeteries, for prayer or for visiting the tombs of martyrs, continued in prevalence till the ninth century, nor had entirely ceased even in the thirteenth century, as we may conclude, if admitting the testimony adduced by Agincourt, who finds proof of its continuance under Honorius III. (1217-27). Yet the process of transporting the bodies and epitaphs of martyrs from these resting-places to the city, for safer and more honoured interment, had begun under Pope Paul I. (757-67), who took such precaution against the pious frauds of the Longobards, whilst their forces were investing Rome, led by Astolphus,—a king who seems to have been particularly bent upon relic-stealing, so devout in this respect were the armed invaders of the Papal territory. At later Mediæval periods the catacombs fell into oblivion, till their ingresses became, for the most part, unknown even to the clergy of Rome; and one of the earliest records of their being visited before the sixteenth century is in the names still seen scratched beside the date 1490, of Raynuzio Farnese (father of Paul III.) and the companions who descended with him, in the Callixtan catacombs. Not till late in the next century, in the time of Sixtus V., was the attention of *securus* directed to new lights from science and the study of antiquity towards this

field of research, subsequently to which revival excavations were carried on at intervals from 1592 to 1623. Most important and fruitful in results were the labours of the indefatigable Bosio, who found access to and explored the labyrinthine recesses of many long-forgotten catacombs, and used, in those on the Appian Way, to spend whole days and nights, provided with provisions, tapers, and twine, for laying lines. After such patient toils, pursued enthusiastically for thirty-three years, he died (1600) without completing the work projected for transmitting their fruit to posterity. Its first publication was in 1632, under the title, "Roma Sotterranea," compiled from Bosio's MSS. by Severano (an Oratorian priest); and a few years subsequently another Oratorian, Arrighi, brought out, with additions, a translation of the same into Latin. Next followed (1702) the "Inscriptiones Antiquæ" of Fabretti, official custode to the catacombs. Another contribution, "Cimiteri dei Santi Martiri," by Boldetti, the fruit of thirty years' labours (1720) surpassed all hitherto produced on this subject alike in vivacity of description, extensive knowledge, and well-sustained argument. Only next in merit and authority is the "Sculpture e Pitture Sacre" ("Sacred Sculptures and Paintings taken from the Cemeteries of Rome"), by Bottari, 1737-54, an illustrated work evincing thorough acquaintance with its theme. The "Manners of the Primitive Christians" by the Dominican Mamachi, certainly one of the most valuable archaeological works ever printed in Rome (1752), though not dedicated to this particular range, comprises a general review of catacomb monuments, together with all others of sacred character that throw light on the usages or ideas of the early Church. Most interesting, though incomplete, is the contribution of the Jesuit father, Marchi, "Architettura della Roma Sotterranea Cristiana" (1844), or "Monuments of Primitive Christian Art in the Metropolis of Christianity," which the writer only lived to carry to the close of one volume, comprising several sections, dedicated to the constructive and topographic part,—this serial publication having been suspended long before his death, owing to the general defection of subscribers, by whose assistance he had been enabled to continue it, after that year '48, so fatal to the interests of his religious order. The great merit of his argument, in throwing light on its theme, is, that it entirely sets at rest the question of a supposed connexion between the Christian catacombs and Pagan *arenaria*; and establishes that in no one instance were the former a mere continuance or enlargement of the latter, as neither could the quality of soil in which they are excavated have served for any purpose of building, nor their plan and dimensions have permitted the extracting of material for such object.

The lithoid tufa so much used for antique Roman structures, and so enduring, is not found in any of these cemeteries; and the *pozzolana* for which the Romans worked those caverns, still numerous in this neighbourhood, called *arenaria*, is far too soft and friable for that regular distribution of corridors lined with tiers of sepulchral deposits, of altars and chapels with their sacred ornaments, which form the distinctive features in all catacombs. One could not, indeed, desire clearer refutation of the theory respecting the identity of the two formations than that which meets the eye in the St. Agnes's catacombs,—ascending from the lower, the story originally formed for Christian purposes, in which we enter the Pagan *arenaria* above those corridors for sacred uses, the former totally distinct in plan and different in the dimensions of their winding passages, as requisite for extracting the fine *pozzolana* sand. Marchi handled over all the drawings prepared for two volumes on the paintings and sculptures in these hypogæe to Padre Carucci, the well-known and learned archaeologist of the same religious order. And, *en passant*, we cannot help noticing, as another valuable illustration to the same range of sacred antiquities, the work by the latter, "Vetri ornati" (glasses adorned with figures in gold, from the cemeteries of the primitive Christians), with engravings of 818 tazze, on all which are groups or heads, designed and gilt by a peculiar process on glass. As to the use of these, Carucci differs from Buonarroti and other authorities, who assume all such vessels to have served for sacramental purposes, the Jesuit father referring many of them to a remoter period than formerly assumed—to the second and third, instead of exclusively to the fourth century, as was the conclusion of previous

writers. Among the figured designs on these glasses are several of great interest and significance, St. Peter and Paul frequently appearing side by side, usually as busts, and with not the slightest indication of superiority in one over the other apostle,—rather, indeed, a perfect parity in honours and deserts, as implied in the single crown suspended, in some instances, over the heads of both, or in the simultaneous crowning of both by the hand of the Saviour, whose figure is seen hovering above. Between these two apostles is often placed the Virgin, or some other female saint, especially Agnes, admitted to like honour; and in certain examples, either Mary or another female, in attitude of prayer, appears on larger scale than the apostles to convey idea of *relative*, not of course, absolute honour; and very probably (as, indeed, is Carucci's inference) expressing the still loftier ideal of the Church, personified in the prayerful Mother, as the great earthly Intercessor, supported by the chief witnesses to Divine doctrine. It may be assumed that the origin *in art* of that supreme dignity assigned to the Virgin Mother (a source of so many and such anti-evangelic superstitions in practice) may be referred simply to this tendency of idealizing, not so much her person as her position, amidst hierarchic grouping,—thus to personify the intercessory office, the link formed by prayer between simple-minded faith and theologic infallibility. Mary also appears on others of these tazze, standing between two trees, or between two columns, on which are perching birds, the symbols of the healed spirit, or of the resurrection; and in one instance only do we see the nimbus round her head—proof that this representation at least must be of comparatively late origin. Among other noticeable and uncommon subjects are, "Daniel giving a cask to the Dragon," from the book, "Bel and the Dragon," considered by Protestants apocryphal (found also among the reliefs on Christian sarcophagi); and, striking evidence to the strength of the influence from that Pagan art still overshadowing the new faith in its attempts at similar modes of expression! Dædalus and Minerva superintending groups of labourers at different tasks; Cupid and Psyche (no doubt admitted in appreciation of the profound meanings that illumine that beautiful fable); Achilles, the three Graces, here introduced with some intended mystic sense not so intelligible. This comparatively gay and mundane class of subjects seems to accord with the appropriation conjectured by Carucci, as to certain among these tazze, *not* to the sacramental solemnity, but to various festive and *gravo* occasions in domestic life,—the nuptials, the names-giving, the baptism, and funeral, besides the relatively-sacred banquet of the *Agape*, that primitive blending of the fraternal feast with the Eucharistic rite and communion, later suppressed by councils because of the grievous abuses supervening, which we see frequently represented in catacomb paintings, and always with the symbolic viands,—the lamb, the fish, and loaves marked with a cross, spread before the small companies of the faithful, who are generally seated round a *sigma* (semi-circular table) at that solemn entertainment.

Resuming our cursory notice of the literature illustrative of Rome's catacombs, we have now to consider the last and most precious addition,—a yet incipient work, which may be expected, in its completeness, to supply the fullest and profoundest investigation of its subject,—De Rossi's "Suterranean and Christian Rome," published by order of the Pope, the first volume of an extensive undertaking hitherto executed with all the ability and erudition to be looked for in a writer of such eminence. A voluminous introduction is dedicated to the history of researches carried out in the catacombs from the fourteenth to the nineteenth century, and an analysis of the *Roma Sotterranea* of Bosio. To this follow three sections, forming the remainder of an ample volume in folio: 1st. Christian cemeteries in general, considered as to their antiquity and the legalized proprietorship of them under Pagan emperors. 2nd. Documents and evidence for which the writer has ransacked all the principal libraries in Europe, affording proofs to the genuine basis on which the student may rely in respect to the history and topography of these Roman hypogæe. 3rd. An analytic description of this vast Christian necropolis, especially dwelling upon their most artistically-characterised and celebrated type in the catacombs called after St. Callixtus. At a general

view De Rossi assigns four epochs to the story of these cemeteries, commencing from apostolic times, and successively extending over the third century, the period of the newly-attained freedom and peace officinally granted to the church through Constantine (A.D. 312), and the fifth century, with which begins the abandonment and decay of all such ancient sanctuaries, impaired by the rude shocks of barbarian invasion, devastated by Goths and Lombards, till at last, towards the close of the ninth century they fell into neglect or oblivion. Another section, compiled with much knowledge and carefulness, at the end of this volume, is a "geologic and architectonic analysis," by Ernesto de Rossi, the author's brother, who has pursued most patient studies on the interior disposal and the soil in which these subterranean are laid out and excavated; this part being provided with plans, that further enrich a work illustrated, moreover, by forty chromolithographic engravings from the principal paintings, sculptures, and epigraphs referable to earliest antiquity among such objects in these Cities of the Dead.

We may probably carry on the subject a little further.

#### THE PREVENTION OF STRIKES.\*

The chief instances of application of the principle of co-operation in the building trades, are to be found in France. Somewhere about three-and-twenty years ago, M. Leclaire, the house-painter, whose experiments in connexion with painters' work have been often mentioned by us, described in a pamphlet the system adopted in his establishment, and gave the reasons that led him to establish it. At present, the concern is a partnership, consisting of M. Leclaire himself, M. Defournaux, and the *Société de Secours Mutuels*, of which all persons in the establishment are members. Each of these three partners has 100,000 francs in the concern, M. Leclaire having advanced to the Society as much as was necessary to make up for an original insufficiency in its funds. On the part of the Society, the partnership is limited; on the part of M. Leclaire and M. Defournaux it is unlimited. The profits are divided. The Society has an excellent library; and lectures are delivered. M. Leclaire and M. Defournaux receive each 6,000 francs (240*l.*) as wages of superintendence. Of the annual profits they receive half, though owing two-thirds of the capital. The remaining half belongs to the *employés* and work-people; two-fifths of it are paid to the Society; and the other three-fifths are divided amongst the general body. M. Leclaire, however, now reserves to himself the right of deciding who shall share in the distribution, and to what amount, only binding himself never to retain any part, and to bestow on the Provident Society whatever has not been awarded to individuals. It is further provided that in case of the retirement of both the private partners, the goodwill and plant shall become, without payment, the property of the Society. The reasons that led M. Leclaire to adopt his original system, which was the same in principle as his present, are given at too great length in his pamphlet to be reproduced here. They may be found in a number of *Chambers's Journal* of the year 1845. Amongst them he mentions the incessant vexation in the losses arising from the misconduct of workmen.

In his first year, the men who worked 800 days made each 300 francs (12*l.*) as the profit, or beyond the wages, which were four francs a day. Improvement in the habits and demeanour of the workmen was immediately manifest. M. Chevalier, in 1848, stated, on the authority of M. Leclaire, "that the increased zeal of the workpeople continued to be a full compensation to him, even in a pecuniary sense, for the share of profit which he renounced in their favour; and in 1857, M. Villiamé gave similar testimony. The passing of the Limited Liability Act first made similar associations possible in this country. Before alluding to them, it should be mentioned that of successful associations of operatives alone, there are in Paris upwards of a hundred; so that the experiments of 1848, for which M. Louis Blanc has been so much condemned, have not been wholly valueless. The chief of these associations is that of the masons. Its amount of business done from 1852 to 1858, both years inclusive, has increased from 45,530 francs in the former year, to 1,231,461 francs in the latter, and its profits from 1,000 francs to 130,000 francs.

\* See p. 365, ante.

It lately paid 56 per cent. as the dividend of the year, on the capital. Mr. Villiamm remarks that intemperance greatly decreases amongst the members of the different associations, as well as everything of the nature of coarseness and rudeness.

Mr. Mill and all who have studied the subject, expect a great increase in the productiveness of industry, from the advance of the co-operative movement. Mr. Mill thinks it is scarcely possible to rate too highly the benefit from placing the laborers so that it would be their interest to do the most, instead of the least possible, for their remuneration; but that this would be as nothing compared with the revolution in society that would accompany the benefit of the particular kind, and which would include the healing of the feud between capital and labour.

We have here before us particulars of the two undertakings on the limited liability and co-operative principle, to which the chief interest in the subject now attaches. The Company of "John Crossley & Sons, Limited," was founded in 1864, with a capital of 1,650,000*l.* The original proprietors retain four-fifths of the share-capital; and manage the business without salary. The shares are of 15*l.* The primary object of the formation was to give parties associated with the business an opportunity of co-operating with the original sole proprietors; and in the allotment of shares, a decided preference was given to applications from those employed on the premises, where a *bona fide* investment, and not a mere speculation, was intended. The proprietors took the step, believing it would add to the strength and good working of the business. The Company of "Henry Briggs, Son, & Co., Limited," for working the collieries of Whitwood and Methley Junction, near Normanton, is stated, in the prospectus, as projected by Messrs. Briggs,—

with the primary view of securing the co-operation of all those connected with the collieries, either as managers and workpeople, or as customers, in the earnest hope of thus effecting a satisfactory solution of the difficult problem now so largely occupying the attention of political economists and philanthropists, namely the best mode of associating capital and labour, and of preventing the occurrence of those trade-disputes which so frequently disturb the social relations of our country. . . . The members of the existing firm will retain in their own hands two-thirds of the share-capital; and in allotting the remaining one-third, a decided preference will be given to applications for shares:—*First*—From the officials and operatives employed in the business; and *Secondly*—From the purchasers of the produce of the collieries.—Surplus shares will be allotted among general applicants in order, however, so to associate capital and labour still more intimately, the Founders of the Company will recommend to the shareholders, that whenever the profit accruing from the business, after the usual reserves for redemption of capital and other legitimate allowances) exceed 10 per cent. on the capital embarked, all those employed by the Company, whether as managers or agents at fixed salaries, or as workpeople, shall receive one half of such excess profit, as a bonus, to be distributed amongst them in proportion to their respective earnings during the year in which such profit shall have accrued. The selection of the mode of appropriation thus recommended, would it is believed, add so great an element of success to the undertaking, as to increase rather than diminish the dividend to the shareholders. The following are anticipated *First*—The attainment of a direct incentive to every worker, whether a shareholder or not, not only to do his own duty, but to see that his fellow-workmen do not neglect theirs; *Secondly*—The prevention of causes of dispute between the employers and employed; *Thirdly*—The attainment of direct advantage to the operatives as well as the shareholders, from the adoption of improved modes of working, either by machinery or otherwise; and *Fourthly*—The securing of a permanently settled and superior class of workmen. The attainment of these advantages is especially desirable in coal-mining operations: nearly 70 per cent. of the current expenditure being absorbed in wages for work which, from its nature, must necessarily be under imperfect supervision.

The acting partners of the present firm are to retain the management, consulting the directors from time to time. The founders of the company will make arrangements for the gradual payment of the calls, by any of their workpeople, by weekly instalments. The capital is to be 135,000*l.*, in 9,000 shares of 15*l.* each; but it is not intended to call up more than 90,000*l.*, or 10*l.* per share.

The feature which distinguishes the last mentioned company from that of "John Crossley & Sons, Limited," is the bonus.

We have referred to the Bill to amend the law of partnership. It was required to make some of the arrangements above detailed feasible. It enacts that if a man lend money to a trader, he shall not be deemed a partner merely because he receives a share of the profits in lieu of interest; though in case of bankruptcy of the concern, he cannot receive any portion of his principal or his interest till other creditors are satisfied; and that if a clerk or servant receive a share of the profits instead of salary, he is not thereby made a partner,—also that a widow, or child, of a deceased partner, receiving a portion

of the profits by way of annuity, shall not be deemed a partner. It has been remarked concerning the clause which permits a clerk or servant to receive profits without becoming a partner, that, whenever the system is introduced, a strike will become impossible, and that the master will find in the system the surest guarantee for the effectual co-operation of his men. The firm of Crossley & Co. had to be formed into the company with limited liability, to allow the servants to have an interest in the business given them.

The shares in the Colliery Company have not been taken up so readily as was hoped for. This is attributed to the exertions in opposition, from delegates of the trade's union. Messrs. Briggs claim to be establishing a union on a wider basis, which shall take in master as well as men. They, in the position of the master, will take 10 per cent. as their wages for management; the men will take their wages; and the profits will be divided.

As Mr. Solly told his hearers, at the meeting to which we have already alluded, when he gave the particulars of Messrs. Briggs's scheme, wealth comes from three sources, Labour, Skill, and Capital. They are not permanently opposed; though for a time they may be apparently opposed. But benefit to the workmen is long delayed, excepting where there is co-operation. For some men, indeed, co-operation may be yet untried; for these, the old position of servant will remain open, for some time, if not always. As the employer flourishes, the demand for labour increases; whilst the tendency of dishonesty on the part of the servant, is to impoverish the employer. Mr. Holyoake, at the Exeter Hall meeting, said the reason why Messrs. Briggs's shares were slowly taken, was simply that the workmen did not understand the position offered them: they had never been so treated before. A letter read from Mr. Mill spoke of the old plan of fixed wages as doomed, now that the capitalists themselves gave it up.

Can there be difficulty in applying the principles which have guided Messrs. Crossley and Messrs. Briggs in the foundation of their companies, to similar foundation of companies in the building-trades? Strikes have not supplied the remedy to any state of things complained of; the success of arbitration is uncertain; but co-operation of one kind at least, comes before us with argument in favour of it from workmen and master, from political economist and philanthropist. By the endeavour of the workmen to dictate terms, all parties come out losers: by the co-operative arrangement, the masters gain, by the abandonment of strikes, and by the elevation of their workmen, as much profit as that which they seem to concede.

#### THE REGULATION AND CONSTRUCTION OF THEATRES AND OTHER PLACES OF PUBLIC AMUSEMENT.

THE Bill now in the House of Commons, to amend the law relating to theatres and other places of public amusement, should receive the immediate attention of those who have had occasion particularly to consider the structural causes of the many lamentable accidents that have occurred, and who have seen reason for alarm at the danger which there is each night, of a calamity of the most serious character arising from one or other of two or three defects of the planning and construction of this class of buildings. The whole subject is one that we have been working upon for many years,—sometimes predicting the very disasters that have occurred; but any beneficial results of our exertions have been more than counterbalanced by the great increase of places where the provisions for egress from the building, are inadequate to a greater degree even than those of the theatres. Of course we need not say that places of public amusement are not the only buildings in which there is risk of a great disaster from the occurrence of fire, or from panic. Almost universally in buildings of public resort, the means of egress are insufficient in number, are not sufficiently distributed, and are otherwise badly planned; and staircases, in planning, are not even, as at the very least they ought to be, such as would be found in a first-class mansion, where stairs are not generally so crowded that a person descending is unable to choose the spot on which to place his foot. An architect might be expected to be able to plan a staircase suited to the requirements in any building; but it is

clear that special study is required of all the details of the provisions for safe egress from particular kinds of buildings, and that the attention to them is not in practice encouraged by the proprietors or managers of places of public amusement, or plainly demanded by the voice of the public.

Almost the worst staircase for safe descent with which we are acquainted, is that from the meeting-room of the Institute of British Architects.

Though skill in planning will do much, and is essential in every case, it will not allow of the best disposition of stairs, or the desired number of ways, if the site be closely shut in, and the number of persons dictated as for the auditory of the theatre, or other place, be such as to require curtailing of the total space appropriated to egress. Much, therefore, as we dislike to have the freedom of architects interfered with, we see that stringent enactments are called for; and these may strengthen the hands of those who would make the desired provisions, if permitted.

The Act of King George II. relates to public places for dancing, music, or entertainment of the like kind, in London, and within twenty miles thereof; and the aim of the proposed Act is stated to be to empower granting of licences for places for public entertainments of a higher kind, and to confer the powers on justices throughout Great Britain (why not Ireland also?) "and to secure that due provision be made in the construction and arrangement of places of public entertainment for the safety, in case of fire or other accident, of persons resorting thereto," and also to amend in certain particulars the laws relating to performances. By the second clause, a licence is not to be granted unless the justices or magistrates are satisfied that the place is constructed or arranged in conformity with rules which are given in a schedule; and any place licensed before the passing of the Act, is not to be deemed licensed "for the public performance" of stage plays, unless the authorities mentioned "are satisfied as aforesaid." This would have made it appear that any theatres might be closed; but clause 4 reserves the power of the Lord Chamberlain "of justices under any other Act." Other clauses repeal the section of the Act of George II. which relates to the inscription over the door, or refer to the application of the Lord Chamberlain's powers of licensing, and to the universities, to copyright, to interpretation of the term "stage-play," and other matters.

We have already given the rules of the schedule, but omitting the fourth, which originally was not correctly printed. These rules, with the exception of the sixth, provide for nothing more than a certain width of passages in proportion to the number of persons accommodated, and for these being kept free for egress. The sixth clause requires that all gas-lights within two feet of any inflammable substance shall be guarded with wirework or other means of security against communication of fire. This clause would not be likely to meet the danger which now exists from the vicinity of gas-lights to wood-work. There is great reason to believe that, from the desecation, it is in many of these cases only a question of time whether the wood-work catch fire or not.

The width for halls and corridors, private box-lobbies being excepted, is to be not less than 5 ft.; and for each hundred persons over five hundred to be accommodated in the part of the building to which the hall or corridor leads, there is to be 1 ft. more in width. In each part of the building there is to be doorway-access of at least 6 ft. for five hundred persons there to be accommodated, and 1 ft. in addition for each additional one hundred. This would make the doorways wider than the passages leading from them,—a curious provision, and difficult to observe in actual planning. The intention obviously is that the clear opening, the door being thrown back, should not be less than the width of the passage. No internal doorway, even a box-doorway, is to be less than 3 ft. in width. All doors are to open outwards; all halls and corridors are to be maintained free and clear, and unobstructed with barriers, in the direction of egress; and all gangways in those parts of the building where the public are placed, are to be kept clear of seats and other obstructions to free ingress and egress, and are to be used for passage only.

The 5 ft. width of these rules, for corridors, is less than that provided in the Charing Cross Hotel, indeed considerably less than that of the corridors of the principal floor; but the box-

doorways might be less than 3 ft. without disadvantage. Our object in noticing the Bill, is to draw the attention of our readers to it before it gets into Committee. Unquestionably there are great omissions in the Bill in points to which we have at various times called attention. There is nothing that would tend to check the evil,—for such it unquestionably is,—of the erection of theatres on sites that are not isolated, and thus to stop the danger of the communication of fire to adjoining buildings, and to permit of that distribution of the ways of ingress and egress which is of as much importance as dimensions, to the safety of the audience, and to non-obstruction of street-traffic. Provisions in the building, against fire, excepting by the sixth rule, have not been thought of; and the stage may still continue to be lighted in a manner which endangers the lives of those engaged in the performance. But the capital omission is that of staircases, which, for anything to the contrary in the Act, would continue to be constructed with well-holes, winders, narrow treads to the steps, insufficient hand-rails, and all the defects that we have so long striven against. The same staircase or corridor, might still, as in some theatres, serve more than one part of the house, thus involving meeting currents. And there appears to be no immediate prospect of the adoption of a better system than that which allows a crowd to congregate at each doorway, obstructing the public footway, and to become on the opening of the door, a surging mass of individuals, "good humoured," as the newspapers say of every crowd, but very dangerous to one another's lives and limbs.

It is always difficult to decide, when an insufficient measure is proposed, whether progress is best served by the temporary acceptance of it, or the entire rejection. In this case, we could wish that the attention of the profession were directed to the means of rendering unnecessary a choice of alternatives. Legislation has become imperative; and it should be assisted by those who will themselves be subject to the rules and provisions. The only question is, whether it should not go to the placing all buildings of public resort under professional control, similar to that in the principle or intention of the Buildings' Act, but at the same time providing most efficiently against such alterations of arrangements originally good, as have been made in the case of Drury-lane Theatre. There can be few members of our profession uninformed as to what should be done; but an architect cannot provide an exit where there is no street; nor can he apportion space to staircases and passages which his employer will consider unnecessary or effecting a diminution of apparent or immediate receipts.

#### PORTRAIT MINIATURES AT THE BROMPTON MUSEUM.

A VERY remarkable and beautiful collection of portrait miniatures has been brought together with the aid of the committee appointed by the Committee of Privy Council, and are well exhibited in the new gallery upstairs. They are 3,081 in number, and include 16 by Holbein, 24 by Nicholas Hilliard, and 54 by Samuel Cooper. A very full and interesting catalogue has been prepared, mainly by the hands of the Rev. Jas. Beck, M.A., and Mr. R. H. Soden Smith, M.A., who, with Mr. R. F. Sketchley, a member of the committee acting as secretary for the special exhibition, have taken a main share in the formation of the collection. The catalogue will include an introductory notice by Mr. Samuel Redgrave, and we cannot do better than give our readers a foretaste of this:—

"The Miniature Art of England possesses this distinguished peculiarity—that, while no native painter had attained excellence in life-sized oil portraits before the time of Vandyck, we have in Miniature Art, a succession of eminent 'painters in little,' commencing with Nicholas Hilliard in the reign of Queen Elizabeth, and continued by John Hoskins, the two Olivera, father and son, down to the inimitable Samuel Cooper, in the reign of Charles I.

The works of these men became the treasures of their own and of succeeding generations. Unlike the larger portraits of their foreign competitors, which, in the troubled days that ensued, were exposed to all the mutations of our great families, the miniature was mostly a cherished decoration worn about the person and easily concealed. Many have thus descended

to us, inestimable both for their art and as the sole recollections of several of England's most distinguished men, while others, despoiled in times of need of their jewelled settings, have been lost or destroyed.

Miniature painting appears to have naturally arisen in the development of the ancient misal painter's practice, and in its first stages to have been connected with the ornamental art of the goldsmith and the jeweller. The miniaturist began by using the opaque colours of the misal painter, and like him he introduced gold to heighten the effect of his dresses and ornaments; but as the art progressed we find him treating the face, and then other parts of his work, with transparent colour. The earliest miniatures were drawn on vellum or on thin cardboard. The artists we have mentioned, to whom should be added Thomas Flatman, a poet as well as a painter, practised in this manner. Soon after, the art of painting with vitrifiable colours added great lustre and brilliancy to the miniaturist's skill; and later, probably in the reign of James II., ivory was substituted for paper or vellum, giving the means of more delicate completion, and, by its creamy whiteness, increased beauty of colour.

The art of enamelling is of great antiquity and uncertain origin. The *encreust enamels* of Limoges were mostly applied to utensils for the church, and were the admiration of the thirteenth century. Benvenuto Cellini used this process to heighten the perfection of his works in silver and gold, and the goldsmiths of Germany employed it with success in reproducing the designs of Hans Holbein. About the beginning of the fifteenth century, by an improved process, *painted enamels* became applicable to miniature portraits, an art which was certainly derived from France, but was not brought to much perfection till towards the middle of the seventeenth century.

In 1632 a goldsmith, named Jean Toutin, who was skilled in the use of transparent enamels, produced a variety of colours, which, when used upon a thin ground of white enamel, vitrified in the furnace without any change of tint. These colours were applied in the same manner as water colours used on vellum or ivory; they were the materials of the first miniaturists, and a few years later they enabled the great Jean Petitot to carry the art to its highest excellence. They consisted of metallic oxides with fluxes of vitrifiable substances, chiefly silica and borax, both fusible at a heat capable of being resisted by the metal ground, whether gold or copper, on which they are to be used; it is also essential that these materials should be of a character to adhere firmly to the ground; should possess the transparency or opacity required to give finish to the artist's work, and maintain after fusion a clear smooth vitreous surface.

The colour produced results either simply from the colouring material used, or from the chemical combination of that material with the flux. The delicacy of the whole process will appear surprising when the brilliancy of colour and the minute beauty and perfection of finish attainable in the enamelled miniature are considered; and that the work, when completed, unites these qualities with its imperishable character.

There is, however, another class of artists whom we now term miniaturists, who practised towards the latter half of the seventeenth century. They were by education engravers, and both drew from the life, and engraved the subjects of their portraits, as is recorded on their plates '*ad vivum*.' In this manner David Loggan, his pupil Robert White, and Thomas Forster, attained great excellence. Their works formed the portrait frontispieces of the books of that time, and were among the first book illustrations. Dryden writes of a would-be poet,—

'And at the front of all his senseless plays  
Makes David Loggan crown his head with bays.'

And the impressions of the plates of these artists, as well as their highly-wrought drawings, were then, and continue to be, highly prized by collectors.

Such was the art of our first miniature painters,—commencing on card or vellum, then using the newly-discovered enamel process, and lastly, ivory, as the means of higher perfection, and contemporary with this the drawing in plumbago, as it was then called.

When portrait art in England degenerated after the death of Vandyck, and Lely and Kneller were followed by Jervis and Hudson, miniature painting fell into the same debasement. One of the sons of Petitot, and of the same Christian

name, settled in London at this time, and practised miniature enamel. Charles Boit also came to our metropolis, and painted in enamel under the patronage of Queen Anne. But the art languished in their hands till Christian F. Zincke, founding his style, it is true, after Kneller, and somewhat the pupil of Boit, painted in enamel with great industry and success. Commencing with the beginning of the eighteenth century, he was for many years without a rival, and his works are justly admired for their beauty of execution and correct drawing.

When at length the portrait painter's art received a new impulse from the noble works of Reynolds and Gainsborough, a new school of miniaturists grew up, and the art again shone lustreously in the works of Jeremiah Meyer, Nathaniel Hone, Richard Cosway, Samuel Shelley, Richard Collins, John Smart, and a number of other talented men, who, far from lacking employment, were beset by fashion; and beauty was decked with lockets, brooches, and bracelets, in which the painter's work vies with the precious materials of the jewellers. Under such encouragement another generation of miniaturists succeeded, and the art in modern days culminated with Henry Edridge, Henry Bone, Andrew Robertson, Alfred Chalou, Sir William Ross, and some few eminent men who have survived it,—for, strange to say, miniature painting, which had during nearly three centuries been practised by so many great artists, suddenly collapsed before the cheap mechanical processes of photography, and is now almost lost.

The value of the exhibition would have been increased if the miniatures had been arranged chronologically or personally, but the necessity of keeping together the collections lent by individuals, and other obstacles, appear to have prevented this. We should be glad if we could hope that the exhibition of the fine specimens of miniature portraits here to be found will lead to the revival of an art which the sun has for the present destroyed.

#### CONDITION OF THE SILK WEAVING TRADE.

THE state of this business in Spitalfields is as deplorable as it can well be, and the accounts from Coventry are not yet very satisfactory. Persons engaged in the mechanical and other parts of this business have attributed the distress produced by the want of employment, the lowness of prices, &c., to various causes. Some blame the late Mr. Cobden's policy, and would have a prohibition laid on all foreign manufactured silks, and mention other reasons which are quite as little to be depended on; and in England, it is generally believed by the artisans that in France their brother labourers in this trade are in a high state of prosperity, while they are in almost a starving condition. Such, however, is not the case; for from Lyons, the great centre of the French silk trade, the accounts come worse and worse.

The Paris correspondent of the *Morning Star*, quoting from the *Avenir National*, says that the writer, M. Horn, a man well known in the literary circles of the French capital, has been sent to Lyons to study the question of *chomage*. In a first article this gentleman reports that the exportation of silks, which amounted in 1861 to 33,000,000 francs, in 1864 amounted to 384,000,000 francs: this is an increase of nearly twelve times the amount; and the question to be solved is, why, notwithstanding this enormous increase of the production and foreign demand for this kind of labour, there should be a *chomage*. We trust that the investigations of M. Horn will throw light upon this very important subject, and show us how it is that, under the circumstances, there should be at Lyons, especially amongst the silk-workers, such a sad extent of want and destitution. M. Horn says, that there are in that city at the present moment 20,000 unemployed frames, the total number which are usually at work being 30,000; so that, for each loom that is at work, there are two standing still. And these 20,000 idle looms represent 16,000 families, or 64,000 individuals. And this estimate of the number of persons who are without employment and in a starving condition, seems to us to be below the actual number; for, including the father and mother, there is only an allowance of two children made in each family.

A subscription has been opened for the relief of those artisans who are placed in such a miser-

able condition, but M. Horn states that this only amounts to 167,000 francs (less than 7,000L), or a sum which is not equal to half-a-crown for each distressed person. This is a matter for the consideration of the fair ladies, not only of Paris, but elsewhere, who flatter gaily in the hand-work of those artisans, and who might afford relief; but it is to other and more permanent means that the silk-workers of Bethnal-green, Coventry, Lyons, and other places must look for effectual relief; and the way to effect this is in the first instance to discover, beyond dispute, the cause of the evil; and we trust M. Horn will not rest in his exertions until he has achieved satisfactory results.

In connection with the present state of the labour market, and the working of free-trade principles, it is certain that, with the evidently great advantages, there are also important matters for anxiety. In both town and country, there is in England an extent of poverty which we do believe has not yet been rightly estimated. House rent and several of the necessities of life have increased in price; and while the increase of the circulating medium, in the shape of the precious metals, bank-notes, bills of exchange, and many other securities, is going on to a tremendous extent, the wages of the agricultural and many other labourers stand without change. Capital, not in certain of the aristocratic families only, as was shown in the *Builder* not long since, has already grown, and is still growing, in a manner which would have been considered fabulous a century or so ago. In the hands of leading manufacturers, colossal fortunes are being gathered together. We trust, however, that we shall not have in our country to lament the evil which results from the rich man growing richer, and the poor man poorer, an evil which has at various periods of history wrought mischief to nations. The strikes, many of them on a large scale, which are occurring in the mining districts, amongst those engaged in the working of metals, not only in the mines, but also in other parts of their manufactures, in brickmaking, and the other branches of the building trades, and the numerous disputes which are happening in so many parts, between masters and men, indicate the large extent of the disturbance which there is just now in the English labour market.

By patient forbearance, and by the display of mutual good feeling, and an extension of the knowledge of those laws which since the most ancient periods of our history up to the present day, have governed the disposal of labour, many of the difficulties which at the present time seem so hard of arrangement will be disposed of; but the transition state in which we are at present, and the solving of a great problem which is being wrought before our eyes, form a subject for the serious consideration of those who are interested in the welfare and progress of the great and varied branches of British industry.

THE WEST LONDON INDUSTRIAL EXHIBITION.

The following remarks are not intended as a criticism upon the merits of particular objects in this exhibition, but rather as general observations as to what are and should be the chief aims of exhibitions of this character, and how far they have been carried out in the present instance.

There are more reasons than one why an exhibition of this description, is calculated to do much good. Firstly, the sight of such numerous examples of what untiring patience and perseverance can achieve, even under circumstances in many cases most disheartening, and in some, at first sight, apparently overwhelming, cannot fail to encourage many who have not brought these qualities sufficiently to bear upon the task they may have taken in hand, and who consequently have not struggled so successfully as others against the disadvantages of their position. It cannot fail to cheer them on to turn to their work with renewed vigour, when they see others emerging uninjured—nay, even strengthened, from a severer test than any they themselves have borne: and if such an exhibition be not without its good effects on a mere spectator, much more must it inspire and animate the man who has had a hand in the work itself, however humble his part may have been, and however insignificant its apparent importance;

yet if he has only executed it with honest pains and zealous devotion, he may well feel proud of his efforts, since he has been promoting the fundamental object of the exhibition itself.

For assuredly the promoters of this exhibition must have sought to direct their efforts in an especial manner to the calling forth that general and individual enthusiasm which, where present, leads all other things in its train, and the want of which nothing else can supply. The opportunities which exhibitions of this nature afford for the development of these qualities is what we would point out as their greatest excellence. The old saying of "A fair field and no favour," has a charm for every man who is able and willing to work. By availing himself of the opportunities afforded by these exhibitions, he will be certain to feel encouraged by the thought that his labours are not without a definite object, and that his work, when accomplished, will be noticed by men ready to give him due credit for whatever merit it possesses. Such a man will evince a praiseworthy feeling of emulation in contending for the palm of excellence in some particular subject. Should he succeed in carrying it off, he will be justly rewarded by his own happy feelings and the kind sympathy of his friends; while failure, if he be manly and right-minded, will not render him slow to derive benefit and instruction from studying his opponent's masterpiece, and marking his own shortcomings, with a view to their correction. This brings us to another proof of the benefit of these exhibitions. They teach a man the real value of his work. Totally disregarding the estimation, be it high or low, in which he may hold it himself, the *vox populi* stamps it with a mark, whether of approval or condemnation; and in so doing, it is an agent for much good; here stripping one of the self-conceit and narrow-mindedness which have grown upon him—perhaps through his never having met a superior in his particular path; here encouraging another whom diffidence and mistrust of his own powers might have withheld from future success. Lastly, the opportunities afforded every man of seeing in juxtaposition the productions of various callings, and of observing how much patience and skill is required in other branches of labour than his own, cannot fail to give him a higher and more liberal tone, and to knit together the whole guild of craftsmen in a closer bond of mutual respect and good will.

The arrangement of the objects is, for the most part, satisfactory. We would, however, point out one important neglect in this latter respect. While the objects exhibited are very properly classified under different headings, and while such of them as are at all similar in their nature or purpose are, as a general rule, conveniently grouped together, the numbering is utterly without order. This necessitates much trouble to the visitor in referring to the catalogue, besides effectually hindering him from going straight to any particular object which he may be especially desirous of examining. The plan of classifying each object under one of eight distinct headings has enabled us, with a little trouble, to compile the following rather interesting statistics. There are,—

Of amateur productions .....	(A) nearly 70
Architectural, marine, and ornamental models .....	(B) nearly 60
Artistic objects .....	(C) about 230
Inventions and novel contrivances .....	(D) about 60
Ladies' work of all kinds .....	(E) about 100
Mechanical objects .....	(F) over 40
Miscellaneous objects .....	(G) about 150
Professional workmanship .....	(H) about 370

The large excess of objects of professional workmanship over those by amateurs,—that is, over those by men who exhibit the produce of labour spent on objects not coming within the scope of their every-day employment,—enables us to see that the majority of exhibitors are desirous of making the exhibition practically useful to themselves in their different callings; and this, we think, should be the chief purpose of the exhibition. We do not forget that there are some exhibitors, such as servants, cobblers, &c., whose occupation offers no motive for the expenditure of voluntary labour on its account, and whose spare time is consequently devoted to subjects with which they are professionally unacquainted. These remarks, of course, will not apply to those whose works display artistic skill or invention: qualities like these will always elicit original productions, and when met with should be carefully recognised and appreciated. But it nevertheless becomes a question whether the object of the exhibition would not be more effectually answered by the exclusion of all such

articles as do not by their intrinsic merit, irrespective of all other circumstances connected with them, deserve admission.

As at first stated, we shall not attempt a criticism of even those objects which stand forth most prominently at the head of each distinct branch of labour. Our object is to offer an observation as to the art, or rather the want of art, displayed. This exhibition, like others to which we have before alluded, though affording innumerable proofs of unwearied industry, is lamentably deficient in evidences of art. There are here results of arduous labour which call for very great respect, and cannot but strike a blow to the heart of many an idler, and send him home with an inward determination that he will at least work. But with this very industry there is often linked a want of taste, which goes far to modify the praise which the display of perseverance and mechanical skill would have otherwise called forth. We find that the so-called "Artistic Objects," number as many as 230. But a little investigation will soon prove that the term is wholly misapplied to many of those it includes. For instance, reference to the catalogue shows us that No. 802 is described as "An Original Drawing in Water-colours;" No. 672 as "A Picture of Pictures." Both are marked C; the letter used to denote artistic objects; and yet of genuine art there are no traces whatever in either. They are elaborate and excellent imitations; in the one case of a confused mass of papers, &c., in the other of pictures, scattered promiscuously over a surface. Several exhibitors have chosen the same subject, and though all the specimens are good, yet that of J. J. Pickworth, No. 511, is perhaps the best. No other so well exemplifies the extreme care and pains-taking enduring patience which the subject requires. So far it reflects great credit on its exhibitor, and probably as an exercise for bringing out his powers will have been of much use to him in his calling. But art demands far other powers than are shown forth here. She requires some share of fancy, thought, and creative power in her followers. And we, therefore, earnestly protest against the mistaken notion which so totally misapprehends her requirements, and debases the standard requisite to enter her ranks. A still more forcible illustration of the want of taste of which we speak, is exemplified in the choice of such a subject as "A Card-table after a Dispute." This is a table inlaid most laboriously with various woods, to represent cards lying about in disorder on its surface, some face downwards, some upwards, others torn. There are spectacles, counters, and, in fact, everything which imagination can suggest, to add to the illusion, all inlaid in wood. But the thing represented is in itself suggestive of unpleasant thoughts, and this makes us the more strongly deprecate the outlay of time and patience spent in depicting it. Were a man to grasp a handful of sand, and declare his determination to count every grain of it, and should he, by dint of untiring patience and scrupulous care, at length succeed in his object, who would not regret the prostitution of qualities so estimable in themselves to an object so devoid of use or purpose? And yet in the case last quoted the failing is even greater, for here the result is not only useless, but absolutely painful.

It is with much pleasure that we now turn to notice a work which, while it even surpasses those previously mentioned in labour and mechanical skill, tempers and directs these qualities with much artistic thought and taste. We refer to the sideboard carved by Gerard Robinson, in illustration of the old ballad of "Chevy Chase." Were the centre and principal carving of this copied in a painting, it would not fail to interest and please, both from the skill displayed in its composition, and the intense life and animation which breathe forth from it. But, to our mind, the oaken wood in which it is wrought gives it a look and flavour of antiquity which, by its extreme suitability to the subject, fully outweighs the disadvantages of want of colour. We dwell especially upon the life and animation of the carving in this sideboard, since these are qualities seldom met with even on canvass, and particularly to be admired in carving. For the laborious process of manipulation in this latter art hinders the artist from developing his ideas with any speed, or from instantaneously representing his glowing conceptions; and, the knowledge that an error once made is irretrievable, forces him to carry on his work with the utmost caution. In the present instance the artist, overcoming these difficulties, has depicted scenes

from the hunt and battle with wonderful spirit. In the former, deer seem to be really fleeing for their lives from the dogs, which hunt them, full of the lust of prey. We almost fancy we hear the snorting of the horses, and the shouts of their riders, as they come dashing through the wood behind. In the latter, there are the archers in the background; while, in front, we see knights fighting in single combat with the most terrible earnestness; bodies lying about in the rigid sleep of death; women bewailing the loss of the "house-bands" of their home. And, besides all this, the sideboard is eminently adapted for a sideboard. It would equally puzzle the spectator whether to admire it more for the beauty of the general design, or the finish and grace of each particular part; because, though inviting and satisfying the strictest scrutiny, each minor detail is throughout made subordinate to the harmony of the whole. Here, then, we have two examples; the first of much bad taste, the last of much good. In the former, when once the eye, which has been attracted by its startling novelty, has satisfied its curiosity, it will turn away with a sense of weariness and indifference; but when it falls upon the latter, it will find plentiful and lasting pasture to feed on,—as beauty of form, a story to unravel, different emotions to be traced. Of course, the important distinction between these objects is, that the one aims not only at pleasing the eye, but also the mind, through the eye; whereas, the aim of the other,—even were it far better carried out than it is,—could hardly be more than to delight the eye, and the eye alone. But even here it fails, and that because it does not pay attention to the unalterable rule that this pleasure ought to be excited through the beautiful, not through the eccentric,—through the divinity of beauty, not the phantasm of eccentricity.

If those whose contributions here bear unmistakable evidence that they prize the qualities of labour and industry far beyond all others, could be induced to ask themselves whether there be not something even higher than these, valuable as they are, and would henceforth make very sure that they are not spending their toil on an unworthy object,—if they would only be led to think more of *thought* and less of mechanical skill; these remarks will not have been without result.

#### WORKS OF THE ARCHITECTURAL PUBLICATION SOCIETY.

We have not, for some time, noticed the publications of this Society. The recurrence, however, of the annual meeting, as reported elsewhere, has induced us to look up the parts lately published, and to offer a few comments on the material put forth in them by the committee. In 1863 was issued the larger half of the articles comprised in the letter G. Amongst them it will be well to notice those of more prominent interest, and those which will, at the same time, fully prove the great area of knowledge included in the "Dictionary of Architecture." Such are "Gable;" the three architects "Gabriel;" the "Gaertners;" "Gallery," with a list of the sizes of those of most importance erected late in the Mediæval period, and those of the Elizabethan era, to which it is a pity the dates, or approximate dates, of the buildings have not been placed; the six architects "Galli Bibiena," rendering it necessary to be somewhat cautious that the right one is named when a special work is quoted; "Galvanic Action" and "Galvanized Iron," two very important subjects; "Galway Marble," the city of "Gand," or Ghent, as we in England call it from the Flemish; the architect "Gandon," and the three "Gandys," clever men, all of them; "Garnet-hinge;" "Gas," with a useful short historical account of its introduction, also including the contingent articles of "Gas-burner," "Gas (effects of)," especially in destroying leather bindings; "Gas-fittings;" "Gas-meter;" and that other description of the subject, "Gas (noxious)," arising from cesspools and decomposing substances. The article "Gement" we copy at once, as a lesson to those who endeavour to decipher old manuscripts without being able to avoid errors, thus deceiving other literary men. It will likewise serve to show the care of the revisers, one of whom, we understand, went twice to the Herald's College to verify the quotation. It is as follows:—"GEMENT, a word said to be used in a MS. of the time of Henry VII., in the Herald's College, describing the hall at Richmond Palace: the *Antiquarian Reposi-*

*tory*, 4to., London, 1808, ii., 315\*, as copied in Hunt, "Tudor Arch.," 4to., London, 1836, p. 94, quotes, the "rof is of tumber,—after the most new invencon and crafte of the prospicit of gement;" but upon inspecting the MS., the words are found very illegible,—"gement" is written "g'ment" and the word following is "crafte." The passage may be read, therefore, with greater probability, "and pure nase of geometrical crafte.—A. A." Then we may point to "Genova," or Genoa; the architect and everything-else-professor, Sir Balthazar "Gerbier," of whom, considering the period in which he lived, his intimacy with important personages, and his active life, we are surprised that no one has yet undertaken his memoir, large materials for which are noticed in this article, though it is, of course, not immediately confined to his architectural constructions; "German Architecture;" "Ghetto," the derivation of which word appears to be unknown; the three architects, "Giamberti," popularly known as San Gallo; and a full account of "Gibbs," the fashionable architect in the last century. Some readers interested in this subject may remember that last year we inserted a communication from an esteemed correspondent, now no more, being a query as to the architect of the celebrated house called Canons, in Middlesex, so generally attributed to James, of Greenwich, and we notice in this account of Gibbs the original of the reply which attributed the design to him, for the first time. Fra "Giocondo," the learned commentator on Vitruvius, in 1511, and celebrated at Paris as an engineer or bridge-builder, has an account which appears to have been written with much care and research. The various kinds of "Girder" are noticed; the names of the designers of them, and the dates of their creation; a very long and complete account of "Glass," treated historically and constructively, even to its decay; with "Glazier," and "Glazing;" then "Gloucester" city; "Glue;" "Goodwill" in valuations; "Graining;" and with the commencement of the article "Granary" the Part in question is completed.

The succeeding portion, dated in December of last year, but issued early in this year, commences with the conclusion of the article "Granary," noticing Doyère's system of silos, lately put forth, which is an imitation of the ancient method of storing grain in excavations, or pits sunk in the ground; "Grand Stand" for a race-course; an elaborate series of articles on the different varieties of "Granite," contributed apparently by the several owners of quarries, and containing much new and valuable information respecting that material, and the mode of working it, with notices of the ancient and foreign granites; "Greek Architecture" is of course not forgotten; nor useful "Greenhedge" timber; "Grisaille Class," the "Groined Vaulting," which would be much to short, except that it is explanatory only; "Grottoes," "Grottesque;" "Ground-rent" in valuations; the *Roques* architects "Guarini;" "Gulloche," carefully distinguishing it from the more common term *fret*, which it is often called; "Gully-hole;" the architect-hisop, if we may so designate him, "Gundulphus," about whose professional capacity much has been lately written by Messrs. Ferry, Parker, and Papworth, and continued herein by another esteemed contributor; a curiously detailed description of the employment of the "Gutta" used in the Doric order; "Gutter," the three architects "Gwilt;" the Royal Academician architect "Gwynn," greatly abridged apparently from the unique detailed account of him which appeared in our pages in 1863; "Gymnasium," ancient and modern; and "Gypsum," finishes the letter; but the Part is continued with much of the letter II, where "Haberies" explains another mis-reading of old manuscripts; the Emperor "Hadrianus," treated as an architect, which is, perhaps, more than he deserves, considering he put another architect, Apollodorus, to death; the three architects "Hakewill," of the family of the present brothers of that name; the familiar name of William "Halfpenny," architect and carpenter, whose many editions of his many works dating in the last century, must have assisted materially in depreciating correct taste in architecture; "Halifax Stone" "Hall," with a long and carefully prepared list of such buildings, not including, however, those devoted to music, which we see will be the subject of a separate article. Surely, a larger number of foreign halls might have been obtained, but we can also imagine the great additional amount of labour

it would have required, and so rest satisfied with what is given; we also notice that many of them vary from the customary dimensions, but as several are marked, "not checked," we presume a very large amount of care has been bestowed in the preparation of the list to verify those given. The city of "Hamburg;" "Hamilhill Stone;" a few of the better known architects, bearing the name of "Hamilton;" "Hammer Beam Roof," the origin of which term, it appears, has not been ascertained, although it has been traced in Nicholson's "Dictionary" to the period of 1819; some of the multitudinous "Hans" von some place or other; "Hardening Timber;" "Harmony" in all its relations of colour, form, and proportion. The Greek term "Harmus," which is—but we refer the student to the work itself for the explanation, as it would be easier to say what it is—not; a very carefully drawn up memoir of the architect "Hawkmore," as it is here spelt from the signature to his will of 1730, placing him in a very different light to the usually received meagre description of his works as a pupil of Wren, an assistant to his master and to Vanbrugh, and the designer of five of the great stone churches in London, besides numerous buildings of importance elsewhere. "Heart Wood;" "Heat," "Hebrew Architecture," and the last article we will notice, "Heddington Stone," so largely used at Oxford, completes the Part.

As may be gathered from these somewhat lengthy notices, great care has been devoted throughout these publications to obtaining fresh and reliable information, not merely in reprinting the hackneyed accounts of former writers. We would advise all our readers, whether amateurs or professionals, whenever they may be in doubt as to where information is to be found on a subject connected with architecture, to first try this Dictionary, for that step will save them a vast amount of unnecessary labour and time. The work should command a much larger list of subscribers, and it would then proceed more rapidly, and each subscriber would get more for his money.

We will now turn to the one Part of "Illustrations" issued during the same period, and dated March, 1864. These comprise drawings for the articles in the work above mentioned, and are irrespective of woodcuts, a larger number of which we see have been introduced with advantage into the last Part of text. The twelve plates comprise the subject "Fortress," a square old tower-like structure, called Palazzo Valdamina, at Alghamo; a very interesting work of its details; two plates to illustrate many of the varieties from existing examples of "Girder," "Girder roof," and "Girder bridge," in timber and iron, and both combined; two plates to the article "Granary," giving some of the large constructed examples, and one on Doyère's system, as above mentioned; two coloured plates of "Grisaille glass," from drawings made expressly for the work, by the late Charles Winston, esq., and which were very kindly and liberally superintended by him during their execution at Mr. Brooks's establishment. They are wonderful representations of the effect of such glass, and show an accurate knowledge of the manner of the crude drawing of the period; "Half timber house," from Lisieux; "Lantern," from Coutances, in a view, with plans and sections; the "Loggia," or Palazzo della Loggia, at Brascia, a very grand and yet picturesque work of the Italian school; a host of knockers, and other details of "Metal work;" these with two external Staircases, at Stamboul and at Viterbo, complete the material comprised on the twelve plates, which continue to exhibit great attention in selection and arrangement, and a fair amount of care and skill by the lithographers employed.

We perceive from the report that another Part of text will shortly be ready, while another Part of illustrations has somewhat progressed. We will only further notice that those who may feel interested to assist the undertaking, will find in the last Part of text, a list of terms, to be included in the following sheets, and another list of the subjects or articles, for which drawings are required for the illustrations, so that there is no excuse for saying that it is not known what would be useful to the Society. The honorary secretary stated at the annual meeting that, from a calculation he had made, founded on the progress of the work, compared with the list of terms printed previously to the commencement of it, the Dictionary would be fully half done on the completion of the letter II, to be issued in the next Part, a statement on which we may congratulate the Society.

## ART AND MR. RUSKIN.

STR.—You have been good enough to allow me on several occasions lately, to remark on the present state and probable future of art and architecture, and on the means now in fashion to work out of our now universal system of blind and thoughtless reproduction of the forms and methods of the past by routine and manufacture. You have yourself all along battled this, and I am convinced that nothing short of a perpetual keeping up of the struggle will ever bring about even a commencement of a change: will you therefore allow me space for only a very few lines on the very important lecture lately read by Mr. Ruskin? It is, as it seems to me, the most significant contribution on this subject of the future of art and art education yet written; with Mr. Scott's last paper: they both together are wholly right or wholly wrong. I think they are wrong,—wholly wrong,—as guides for the future.

I doubt not that it must have struck you and others that this paper of Mr. Ruskin's differs in no slight degree from all he has yet put forth to the world, and indeed would seem to be a sort of general rejection and abandonment of what he has now been for more than a quarter of a century urging on the public and on art students. It differs, too, in this, that it is the first time Mr. Ruskin has lectured to a purely professional audience. He has now for the first time lectured architects face to face. The outside world may, therefore, we ask, "What does he say to them, and through them to us," about the past, present, and future of art? I can, of course, only ask you for space for a few remarks on one or two of his multitude of art texts in it, *i.e.*, one or two of them indicative of a policy out of many. I ask of your readers a little careful attention to facts.

Mr. Ruskin says, "We have absolutely as a nation," now at this present time, "no motives but vanity and the love of money" to actuate and guide us; but—and this is the foundational text of his address—in the past, in *archaic* times, "there was no fame of artists," never any credit to be got by the exercise of the artistic faculties. "The artist lived in an atmosphere of perpetual, wholesome, inevitable eclipse." Is this true? If it be, then we must all allow that the whole nature of humanity must have since then entirely changed, and that man is no longer the same sort of being that he was. I ask attention to this, because if Mr. Ruskin is in error here, all he has said fails to solve the difficulty which he cannot help seeing, and there must be something beyond which he does not and cannot see. But first for facts.

Some years since, under the auspices of the Camden Society, a little MS. history, now in the British Museum, was republished and translated, being a portion of "The Life and Doings of one Jocelin, of Brakelond," a monk of St. Edmundsbury, dated from A.D. 1173 to 1202, *i.e.*, the latter end of the twelfth century; and, it will be admitted, sufficiently "archaic." During these thirty years, have we not only the doings of the writer and his thoughts, but, as well, those of his abbot, fragments of the histories of his brother monks, the *servants* of the monastery, the master of the ritual, what they said and did, and the very modes of finding timber and materials for new buildings, and a detailed account of the supply of funds for the expenses of the house and church; and, what is more perhaps to our present purpose, what the writer and his abbot and brethren thought about things. I respectfully ask Mr. Ruskin to procure the book,—it may be got for a shilling,—and give it an attentive reading. It is a perfect insight into the life and ways of twelfth-century men, living and graphic as need be. In it he will find that, so far from love of wealth being absent from the minds of people, the abbot found it necessary to prohibit his monks from borrowing money, each one for himself, and storing it up; and, when timber for a new building could not be got at as easily as desired, the said Abbot Sampson himself headed his men, and saw to the cutting of it down and its carriage. Human nature has not changed. Again, not to lengthen this, when some new buildings were finally completed, and some incredulity seems to have been expressed as to their size and grandeur, the writer, in his enthusiasm and vanity, says to all comers, "If you will not believe, open your eyes and see," and when the "shrine" itself has some additions made to it in "pure gold," Jocelin defies the "world" to show or produce the like. Such was his vanity, and

the vanity of those in whose time he lived. What does Mr. Ruskin mean? Let him open his eyes and see, and *hear*, too, the abbot's motto, ever on his lips,—"*I will not abate a jot of my glory*"—*i.e.*, as master.

It is not, therefore, as I take it, the *vanity* of artists or their *love of wealth* which now a days stands in the way, any more than it did in the twelfth century, of honest and true art action and the production of objects of fine art. To my mind it is precisely the reverse; the true reason, to my thinking, is—and it is this which I want Mr. Ruskin to attentively consider—that all those to a man, in these days, who work out our art, are not and cannot be actuated by either the one or the other of those powerful human feelings and aspirations. They who actually indicate and do the work are never credited with it; the "vanity" is not for them, but for some one else, running about, it may be, from job to job, gathering up all the "vanity," but who himself personally does nothing whatever as an artist. Has not Mr. Ruskin supplied the text for a future course of art action, but read it unfortunately backwards? The artists,—that is, the executive artists, of that "archaic" day did not live in a perpetual, wholesome, inevitable eclipse; but as this worthy monk will show him in a perpetual, wholesome, and inevitable notice and personal recognition, as far possible as the art-power of the time admitted, and as the onlookers saw. Artists must, I think, read again Mr. Ruskin's lecture; but it must be backwards. What is in solemn truth now wanted in the world of art, and by artists, is not that vanity should be crushed out, but that every artist, whether draughtsman or workman, shall have his fair supply of "vanity;" and that it shall cease to be, as it now is, the sole privilege of a few, and, what is still worse, capable of being taken from those who may have earned it for nothing. Truly it is not much; for, as the work is, such is the vanity to be got out of it. It is, as Mr. Scott says, "starving" work!

I must not go on, I fear. I will but notice, if you will kindly allow it, one more text in this lecture. "The meanest man can imitate." I have seen Mr. Ruskin stand over a pupil, I will not say for how long, in the vain effort to get a dead leaf copied on paper, and fail after all. You cannot deceive Mr. Ruskin when his instinct is on the watch. He got the leaf on paper at last, but he was compelled to drop it there *himself*, without "idealism," without "composition," without "enchanted memory." In my own poor way I have tried to get a leaf simply copied, not on paper, where it is of no use, but in stone, and succeeded but miserably enough. I posterized the workman neither with "idealism," "composition," nor "enchantment," nor did I trust to his memory. The leaf was our difficulty. This is all Sir Joshua and his lectures over again. I cannot help saying that I think Mr. Ruskin owed more to his audience than to repeat such nonsense as this, and that he should have given *architecture* for the first time some PRACTICAL consideration, and should have inquired of the Institute how "architecture" is brought into actual being, and what the successive stages are from and between the "design" and the "building and its enrichment." It is here that the problem and great art secret of the future will be found to lie hid. I ask Mr. Ruskin to forget his books and his Gothic—to own he did not write this lecture—to look at simple facts as they are—and at the three ways of bringing into being an art work or a building—the sketcher, *i.e.* the architect—his clerk who draws out and makes it practical and workable—and finally, but not least, the workman who executes, and whose handwriting or scrawl it really is which Mr. Ruskin is looking at when he imagines so vainly it is the handwriting of a master. C. BRUCE ALLEN.

## STATE OF THE STATUES.

LONDON owes you thanks for caring for its public statues. Does any historian record so extraordinary an event as the cleansing of them? Does the oldest inhabitant recollect any such occurrence? Can any of the great landlords, or the Government, or the local authorities, show accounts proving the performance of so interesting and needful a ceremony? *Achilles*, in Hyde Park, has recently been cleaned; but there are three *bronze statues* almost daily under my notice which sadly want a helping-hand. 1st, *William Pitt*, the heaven-born minister, standing appropriately in Hanover-square, surely deserves

relief. But there he stands, black as ever his most desperate opponents could have made him, protesting against the infernal garb he is forced to wear, insisting that his character is fair as the skies of May, and demanding consideration from the representatives of the stanch English king, whose throne he so effectually supported, and who stood by him in all his diffident undertakings in defence of the liberty and constitution of this country. 2nd, *H.R.H. the Duke of Kent*, that good, kind, and excellent prince, whose virtues are daily bearing fruit in the illustrious reign of our most gracious Queen. I look back through many years to childish walks in Portland-place, and to the repugnance I then felt to this great black image: asking, as other children now ask, why it was made *black*? But this is not alone a child's question; it concerns us all. Why should we not be permitted to see the beautiful work of the artist? Why should it be veiled in soot for ever? Sometimes, indeed, a glimpse is afforded: but no thanks to man for it. Jack Frost occasionally delights in showing off the countenance and the drapery, by his imitable touches of white. But a few hours dispel the vision; black resumes its dismal sway, and forbids veneration or respect. 3rd, *Lord George Bentinck* was set up in Cavendish-square by a large party of admirers, many of them grateful for his determined advocacy of *protection*; others sympathising heartily with his sporting character. When placed there, his fame was resplendent as the lustrous bronze. It is since been eclipsed by the increasing glory of *free trade*? Or are his friends ashamed of him, and of the cause he so stoutly defended? Surely nothing else can have tarnished it; but now, alas! he is black as the heroes of the last century. *Mud* was cast upon him five or six years ago. Was this an act of malice by some opponent in politics, or by some loser on the turf? There it sticks; and had the poor man been set in the pillory, he could scarcely have exhibited more signs of disgrace.

Now, all this is discredit. Art is now the talk and pretence for large outlay. Ambitious men aspire to direct public taste; but who cares for our statues? London possesses many of them. Why not educate the eye of the child and the wayfarer, by presenting clean works of art to view, rather than horrify the public, year after year, by the spectacle of human forms of colossal dimensions, shrouded in the blackness and darkness of dirt. C. H. H.

## EGYPTIAN ANTIQUITIES AND ENGLISH TOURISTS.

IN an article by M. Renan in the *Revue des Deux Mondes*, on the antiquities of Egypt and the excavations now in progress, he makes the following statement:—

"The worst enemies of Egyptian antiquities have been the English or American travellers, systematically protected in all their misdeeds by their consuls. The names of these idiots will go down to posterity because they have taken pains to write them themselves on the most celebrated monuments and over the most delicate designs. It is thus that the invaluable pictures of the grottoes of Beni-Hassan have almost entirely disappeared; the most beautiful tombs of Biban-el-Molouk are odiously defaced, and a precious portion of the sculptures of Deir-el-Bahari was stolen some days after M. Mariette had exposed it. The wise principle that the antiquities are the property of Government has been proclaimed: a watch is established over them; but what if a brutal stranger, despising all law, defies the guardian, bursts the door of the monument, if there be one, breaks everything at his leisure, and if the guardian so much as touches him, complains to his consul, who causes the unhappy native to be beaten? The process of destruction, however, has of late years diminished. This is proved by the fact that the natives who profited by the stupid curiosity of travellers, have fallen back on the manufacture of false antiquities. We have seen some of these establishments, and we feel disposed to encourage them. The apocryphal objects produced suffice to supply the tourist, and cannot injure true science."

Mr. C. H. Wilson, of Glasgow, sends us an indignant and very proper protest against the partiality of M. Renan, which leads him to limit his condemnation to English and American travellers. Mr. Wilson says,—

When in Egypt, I saw, on nearly every monument on the Nile, in letters of white chalk, 16 inches high, and scrawled over "delicate designs," the name of a French 'idiot,' who called himself the Countess do something, who had thus conveyed her name 'to posterity'; but I should hardly have thought, on account of this particular 'idiot,' of accusing the whole body of French travellers of being enemies of Egyptian antiquities. I venture to say, without fear of contradiction, that M. Renan found

nowhere, on these antiquities, an English name of the same social rank. On the Pylon of the temple at Philæ, there is a long French inscription of many lines, *cut into the stone*, by 'Castex, sculpteur,' commemorating the pursuit of the Memloeks to this part of Egypt by French troops; and as some insane leyalist has obliterated the name of Napoleon in part of the inscription, another Frenchman has printed in oil paint, 'A page of history ought to be respected.' Can M. Renan point to any 'English or American' inscription upon any Egyptian monument to compare with this? Has M. Renan no words of condemnation for the Romans who formed part of a scientific commission to examine Egyptian antiquities some years ago, and who, with execrably bad taste, have disfigured the beautiful columns of the abrine of Isis at Philæ by inscriptions in black paint, the letters being at least 6 inches in height? Amongst the thousands of English and Americans who have travelled in Egypt, including no doubt a legion of snobs, no one has approached the snobbery of this inscription, or has so seriously injured any Egyptian monument. The shock given by these inscriptions, which thus coarsely invade the antique sanctity of Philæ, can only be appreciated by those who have been surprised by them, on visiting the monuments there. But, on the other hand, M. Renan may quote the Anglo-Saxon names in enormous letters, and in black paint, which so hideously disfigure the column 'of Pompey' at Alexandria, evidently the work of daring and foolish sailors, whether English or American it is impossible to say; or he may point to the names on the summit of the Great Pyramid, or to those scrawled in white chalk on the top of the temple at Dendera. Do some travellers carry white chalk in their pockets? These are disgraceful enough, and amongst them predominate the names of two Glasgow 'idiots,' in letters a foot high; but they are written on the plain masonry, and nowhere that I can recollect upon works of art. Nor were the perpetrators people of rank, or even savans. At Bibin-el-Molook, 'The Gates of the Kings,' tombs of the kings at Thebes, I certainly saw many English names, but written in pencil on broken parts of the rocks, and in small characters. I cannot recall any on the works of art. Some were the names of very celebrated travellers, who never could have written them where they could do any harm, and which give a certain sanction to the practice, whilst its antiquity is illustrated in the most interesting manner on venerable monuments in the Valley of the Nile, on which the names of old Greek and Roman travellers, the 'idiots' of their time, are found inscribed. It is perhaps impossible, if it is desirable, to prevent a practice common to all nations in all times, but the partial and one-sided criticism of M. Renan may do good if it leads all travellers to indulge the propensity in a harmless manner.

#### BILLINGSGATE MARKET: A SUGGESTION.

SINCE the erection of this fishmarket a great change has taken place in all that respects the supply, the demand, and the transmuted interests of dealers resident within our continuously spreading town and suburbs. The river was formerly the medium whereby fish was delivered from barges; and the moored craft were used to store cargoes, more especially oysters, until the recurring market-day again cleared the hold. Such, however, has been the increase of population, and the spread, in a westward direction, of interminable ranges of houses, that while Tooley-street stands out two miles from the centre eastward, the market, which barely sufficed at the period of its foundation, is too small for the enormous traffic of the times. The greatest sources of demand lie far afield in the western, north-western, and south-western directions, and the fish salesmen and vendors have to drive farther to attend markets at four or five o'clock, a.m. But the greatest change of attendant circumstances is in the supply of the commodity, four-fifths parts whereof are now forwarded by railways from all the lines which, starting from the ports or fishing stations, converge in the grand central terminus at Farringdon-street.

These two hexameters, which have not markets equal to those of the City, and many possess fish, meat, and vegetable markets of greater extent and far superior in constructive provisions to those of the metropolis. It is needless to refer to Leadenhall and Newgate

Markets, which are to be supplemented by that projected and planned for Smithfield. Like the meat markets generally through all parts of the town, these central and ancient markets are not only too limited, but most unfavourably constructed for the conservancy of viands for any population; therefore the adaptation of Smithfield to the purpose will not only be a great convenience, but an additional security for the storage of meat, and for the public health, which so much depends upon the quality of their food.

If upon all these grounds the removal of the meat-market is desirable, a change of Billingsgate to a more central position, such as Farringdon-road, the new centre of railway traffic, is still more needed. A large, open, and yet unappropriated site is available there; it is more easily accessible by the dealers, the fish-salmon, and the public; besides that, the deposit of supplies by rail would render the transit less expensive. Proper shambles, with water-supply and extensive storage-cellars, offices, assembly and reception rooms, and all the requisite appendages of a great improved market, might be provided at a reasonable rate, while the present market, hedging in and constricting, as it does, the Custom House, the shipping wharfs, and the Tooley-street stores, might be disposed of at an enhanced value.

This is a question which properly belongs to the Corporation, therefore private enterprise cannot attempt competition in the matter. The attempt to establish Hungerford Market was abortive because the site was too far westward, and it was undertaken at a time when nearly all the fish supplies came by water; now all the circumstances are changed, and the opportunity occurs, before the vacant ground is appropriated, of raising a market that might do credit to the City, and vastly improve two most important localities; and also give liberty to the present stunted accommodation for wharfage of the increasing passenger-trade by steam-vessels to London Bridge. For these purposes, coupled with the needed extension of the Custom House, and the liberation of the Pool, which is now blockaded at this most important and terminal portion of the quay, the site of Billingsgate is of almost unappreciable value; and the surplus, beyond its cost or value when these shambles were erected, would pay for the new and extended site. It ought to be kept in view that hundreds of vans and carts assemble there both to carry in and to remove the never-failing supplies of this perishable commodity; and that hundreds of dealers drive thither, thus embarrassing a neighbourhood unprovided with stabling or sheds. Therefore provision should be made in this respect at any new locality; for without it great inconvenience must be sustained by dealers as well as householders in the vicinage: this is much felt at present, as the situation close to London Bridge is full of stores, and is approachable by the narrowest defiles of the old City.

#### THE ALTAR TO THE NYMPHS, ALNWICK CASTLE.

EARL STANHOPE, in his recent address as President to the Society of Antiquaries, said, when speaking of the late Duke of Northumberland, "It was in accordance with the same tastes and studies that the Duke formed, in his magnificent castle at Alnwick, two museums; the one to comprise the antiquities which he had brought from Egypt, and the other devoted to the antiquities of Britain, and especially to some of the moveable objects derived from the Roman Wall. Among the latter there is now probably the most remarkable of all, an altar to the Nymphs, which was found at the ancient out-post of Habitancum, the modern Rivingham, that same spot commemorated as the birthplace of Bertram in the *Rokeby* of Sir Walter Scott. The altar in question is well described and elucidated by Dr. Bruce, at page 414, in his 'History of the Roman Wall,' but at the time he wrote, namely, in 1852, the altar was not, as now, in any museum, but held a place in the garden of Spencer Trevelyan, esq., of Long Witton. The inscription upon it is as follows:—

*'Somnio premonites miles hanc ponere iussit  
Aram que Fabio nupta est Nymphis venerandis.'*

These two hexameters, besides that they are not free from false quantities, will be found not a little difficult to construe or to understand. Lord Macaulay, to whom I showed the lines, was, I remember, greatly interested in them, and discussed them with me on more than one

occasion. He was by no means satisfied with either of the two interpretations which Dr. Bruce in his History suggests. It appeared to him, as I confess it appeared to me also, that the passage is best explained by the ellipse, on account of the metre, of *Puellæ* or some equivalent word. In that case the meaning, somewhat different from that which in either of his suppositions Dr. Bruce assigns, would be to the following effect: 'A soldier, warned in a dream by the maiden who is married to Fabius, directed the erection of this altar to the nymphs to whom worship is due.'"

#### ON MECHANICAL CONTRIVANCES FOR THE SIGHT, AND HOW TO PRESERVE IT.

I HAVE no doubt but that, some day, we shall have spectacles whereby a man will be reading his manuscript from the desk and yet looking at his audience at the same time. Such an invention as this must come, if it has not arrived already. The opticians of the present generation will reap a fair harvest of income from the fact that people now-a-days have so very much reading. Formerly, from a want of learning, people retained their sight more vigorously than we do at present, because they did not abuse it. Paraffine oil and gas-light, and long nights of romance reading, will soon impair the visual organs even of youth. No doubt but the oil-lamp, which used to be, gave the eye also great fatigue in reading, though it had not a fraction of the temptations it has now. A magnifying glass somewhat the size of the pages generally read would be useful in keeping the eyes unimpaired, together with shades, to check the intensity of light thrown upon them. The glass ought to be square, and raised to its focus from the surface of the book just enough to enlarge the print. This would be most acceptable to the young, and as essential to them as a good pair of spectacles would be to the aged. It ought to be cheap, too, because cheapness means popularity. Our eyes, then, those delightful lenses that serve us in the wise discrimination of the beautiful, ought to be treated more than the gems and "koh-i-noors" of the wealthy; and the more we attend to and study their mechanism, the longer will they fulfil the office of the "good and faithful servant." A. H.

SOCIAL SCIENCE ASSOCIATION.—The ninth annual meeting of the National Association for the Promotion of Social Science will be held at Sheffield, under the presidency of Lord Brougham, from the 4th to the 11th of October next.

ARCHÆOLOGY ABROAD.

NEAR Senlis, 33 miles from Paris, some Roman remains lately discovered are being laid bare by the exertions of the Archæological Society. As far as they have gone several courts, chambers, and doorways have been brought to light by the excavations. The funds of the Society not being very extensive are unable to satisfy the demand of the landed proprietor, which is exorbitant. He has evidently no affection for the relics of bygone ages, having threatened that he will, if not promptly settled with, fill up the excavations as he wants to sow his crops, &c.

According to the *Courrier de Lyon* an archæological discovery of some interest has been lately made on the Gay property at Fourvères. It consists of the ground-floor of a Roman mansion with hypocaust, bath chambers, cisterns, &c. In one of the walls surrounding the building is a niche, encircled with fresco paintings on a red ground, and supposed to have been the sanctuary of the *Lares*.

At thirty-five kilomètres S.E. from Constantine, in Algeria, on the slopes giving rise to the streams of Bou-Mezoug, not far from the Batna road, and in a country called by the natives *Mordjet-el-Gourzi*, within a radius of more than three leagues, on the mountainous portion as well as on the plain, all the country surrounding these sources is covered with monuments of Celtic form, such as dolmens, demi-dolmens, cromlechs, menhirs, alleys, and tumuli. Féraud, interpreter of the African army, who has been unremitting in the prosecution of these researches, says he never counted them, but that he examined more than a thousand during the three days that the exploring lasted. These monuments are not only scattered in great numbers over a small space, but are connected together, so that, while each monument is a complexity in itself, it also forms portion of a greater general system. Mr. Bertrand, who has studied Celtic remains all over Europe, remarks that in one case, a tumulus surrounded by several circles of stones or cromlechs, and surmounted by a great table or dolmen, is exactly similar to those he observed in Denmark. Several of the tumuli, of which the stone circles mark the bases, have been opened in the environs of Constantine, contained bodies, unburied, frequently with the arms crossed and the knees bent up so as to touch the chin. This is precisely the position of the skeletons in the stone age of Denmark. It is worthy of remark that while the latter are of the stone age and those of Gaul of the bronze age, the Constantine remains are of the iron age.

SOUTH KENSINGTON NEW ROAD BILL.

THE rejection of this Bill by the Committee of the House of Commons has been the subject of correspondence in the press, and an important preliminary meeting of the resident gentry has been held at the South Kensington Hotel, Queen's-gate-terrace—Mr. Charles Buxton, M.P., in the chair—to take into consideration the propriety of applying to Parliament for the recommitment of the Bill. The resolutions were unanimously supported by an influential body of gentlemen, including the following:—Sir Ralph Howard, bart., Colonel Sir Thomas Troubridge, bart., Lord William Lennox, Admiral Bethune, Rear-Admiral Buckle, the Hon. Captain Mande; R.N., Mr. F. H. Atterbury, Captain Walrond Clarke, Mr. C. J. Frauke, Mr. F. H. P. Wetherall, Mr. G. S. Dale, Mr. John Stapleton, and Mr. W. W. Lawrence. The resolutions were as follows:—Moved by Sir Ralph Howard, bart., and seconded by Admiral Bethune:—"Resolved, that in the opinion of this meeting the construction of the proposed new road or street from Cadogan-place to the South Kensington Museum would be of great local and public advantage, and that the project meets with their cordial approval, and in the opinion of the meeting is well deserving of public support." Moved by Colonel Sir Thomas Troubridge, bart., and seconded by Mr. William Douglas:—"Resolved, that this meeting is of opinion that it is desirable that the promoters of the undertaking should make an application to the House of Commons for a recommitment of the Bill during the present session." Moved by the Hon. Captain Mande, R.N., and seconded by Rear-Admiral Buckle:—"Resolved, that a vote of thanks be tendered to Mr. Charles Buxton, M.P., the chairman, for his able conduct in the chair."

VALUERS' TENDERS.

THE guardians of the Halifax Union advertised for tenders for the valuation of property in the Union that may be requisite during the ensuing twelve months, for the purpose of parochial assessment. The following is a list of the tenders, showing the rates per cent. on the rateable value of property on which it was proposed to take the valuations:—

	s.	d.	per cent.
Robertshaw & Barry, Lightcliffe	100	0	0
Hippesholme	40	0	0
J. Nicholson, Halifax	33	0	0
Corbett & Raby, Manchester	30	0	0
Hepworth & Halliwell, Brighouse	20	0	0
James Powell, Harrogate	20	0	0
B. W. Jackson, Halifax	20	0	0
Stevenson & Utley, Halifax	20	0	0
Butler, Cleckheaton	20	0	0
J. Booth, Halifax	15	0	0
Kershaw, Halifax	15	0	0
R. Horsfall, Halifax	12	6	0

and the last-named Tender has been accepted.

THE DANTE EXHIBITION.

THE Dantesque Exhibition, in the lower rooms of the Bargello,—on the wall of one of which, formerly used as a chapel, the portrait of Dante, by Giotto, was brought to light from under coats of whitewash in 1841,—consisted of invaluable manuscripts of different editions of Dante's works, produced during the five centuries after his birth, among which, one engraved on vellum (considered nique), beautifully illuminated copies, documents relating to Dante and personages mentioned by him in his works, all brought from the Florentine archives and from those of other Italian towns, as well as from the libraries of private individuals,—formed a source of deeper interest to the Danteologist than the casual inspector, and required more time than the glances obtained in a crowd during the three days when all were exhibited. The part belonging to Florence still remains for the student to pore over; the others have been returned to their owners. Every portrait of the poet attainable was also there; modern pictures, engravings, ivories, sculptures, photographs, medals,—in fact, every artistic object relative to Dante.

The Medæval exhibition was hastily arranged, the collection gathered together in a fortnight. In a city like Florence, the cradle of the most beautiful of Medæval art, more might have been expected; but all that is seen is very beautiful and interesting. Two rooms are devoted to ancient armour, among which are to be seen some of the wonderful specimens of fine steel armour, inlaid with graved gold ornament; that of a Gundagni, of the sixteenth century, the richest; another, of the fifteenth, of steel, with figures in relief; shields, of marvellously artistic design and execution; saddles, of finely-carved ivory, of the fifteenth century; a collection of finely-mounted daggers, of work from the fourteenth to the seventeenth century. Then there is a cabinet of Chinese small enamelled vases, encrusted with gold. The Exhibition is rich in beautiful panels; fifteen out chests, the fronts painted with historical subjects, the lids and stands handsomely gilded.

The principal room contains specimens (lent by the king) of the finest majolica known,—those also of the later kind, with elegant arabesques surrounding small gem-like cameos,—gorgeous wine-coolers, elegant tazze, marvels of art, two cases of carved ivory objects, and one of amber, manufactured into every conceivable object of ornament. The specimens of Limoges enamel are some of the finest seen. One, supposed to be by Mariano, 1530, for delicacy of design and execution, and brilliancy of colour, cannot be surpassed. An early thirteenth century specimen of Niello, an inch in diameter,—subject, an emblem of Christ, with many figures, very perfect,—it is the centre of a brass patina. Among the bronzes, a Medusa, by Benvenuto Cellini, and bust of Alexander de Medici, are the most interesting. A lovely female head in terra cotta, by Leonardo da Vinci, is amongst the most choice objects.

There is a fine selection of precious seals. That of the Republic, with the Heracles, in bas relief; episcopal rings of Pius II. and of Pius III. The numismatic contributions are very valuable and numerous. There are antique reliquaries, crucifixes in ivory, rivaling Guercino's on canvass, for expression and feeling; jaspers of ivory, of silver, and coral of carved wood, in design so beautiful one would wish to send them as examples to our modern workmen. A green enamelled watch,

with gold figures in high relief, of high finish, formerly belonging to Voltaire, is among the objects of interest: Mr. Spence has sent a rough of sixteenth century valuables.

Gorgeously painted and gilded chests, an old bedstead in excellent preservation, such as we see in Andrea del Sarto's pictures; tapestry lines the walls—subjects from the old masters. A Luca della Robbia, and cabinets of old bronzes, and gems of all kinds, are there.

The want of a catalogue is much felt, the names of the contributors alone in most cases being attached, without any explanation. The king has expressed a wish that the present collection shall form a nucleus for a permanent Exhibition of Medæval Art, and it is to be earnestly hoped the wish may be complied with, and that the numerous treasures now hidden in Italian private collections, may be displayed to not only the Florentine public, but the many foreigners visiting the new capital of Italy.

LABOURERS' COTTAGES.

THE "necessa questio" of economically constructed labourers' cottages seems further from solution than ever; if we may judge from the list of tenders that have been obtained for carrying out the last prize design of the Society of Arts, published in the *Builder* of December 31, 1864. That design was estimated to cost 200l., the pair of cottages; but the lowest builder's tender, according to the list afterwards given, amounts to 397l. 13s. 4d.

Annexed is a design, prepared for the last Society of Arts' competition, but which unfortunately did not come under the notice of the Society, from having been delayed in transit. Now, as my pair of cottages were estimated by myself to cost 200l., including architect's commission and supervision; and as, moreover, I have now before me a builder's tender, offering to execute the pair for 180l., which I obtained at the time and now forward; I hope I may be allowed, "without prejudice," to allude to one or two features of the design.

On the ground-floor I have a living-room, 13 ft. by 11 ft.; a scullery, 9 ft. by 8 ft.; a pantry (not a closet in a room), 4 ft. by 5 ft.; a coal or fuel place; good entrance-porch; staircase (entirely to itself), 6 ft. by 7 ft.; and a store closet.

In the prize design there are no fewer than four doors in the scullery, which is without a fireplace, and the boiler is placed close to the door of the living-room. There are two doors in the living-room; indeed, both these rooms form a complete thoroughfare to and from the yard, and W. C. at back, and the stairs and chamber at front. That this arrangement is adopted for economical reasons I am at a loss to understand.

In my design I provide a good staircase, approachable from every room in the house separately. None of the rooms are passages from one part of the house or premises to another. I have only one entrance to the living-room and one to the scullery, both opening into the entrance passage, into which also the pantry opens; and in the same passage or lobby is the foot of the staircase.

On the chamber-floor I have three bed-rooms, respectively 11 ft. by 9 ft. 3 in., 12 ft. by 8 ft. 6 in., and 6 ft. by 8 ft. In the latter is a cheaply-constructed but efficient bath, and over it a cistern, which collects the whole rainfall of the roof. Town water might, of course, be laid on to this cistern in localities where it is desirable or available. The pitch of roof I have given is just sufficient for utility. It gives more cubical internal space, and at the same time is less costly than the high-pitched roof shown in the prize design (and by some fatality generally adopted), as will be readily seen. I have also avoided that eternal central gutter, with its cost and its insufferable nuisance; and all the down conductors of rainwater I employ consist of an overflow pipe from the cistern to a water-hut in the yard, and a small pipe and tap to the sink in the scullery.

I will not now enter into further detail on the subject; but, if there be any certainty in figures, or trust in "the sons of men" in the shape of builders, I have yet to be convinced that my design cannot be creditably carried out, including cost of supervision, for 200l. the pair of cottages.

Mr. Sinclair says in his letter,—“Any one can build a good labourer's cottage: the difficulty is to build one for little money.” Granted. But I am convinced that 40l. or 50l. less than the

FRONT ELEVATION

SECTION

GROUND PLAN

SCALE OF FEET

## LABOURERS' COTTAGES.

sum named by Mr. Sinclair would provide for the labourer with a small family a home that, as far as comfort and sanitary arrangements go, might be to him as good as a mansion.

In my letter to the Committee of the Society of Arts accompanying my design, I find the following passage:—"In considering this design I have endeavoured to secure to the labourer the greatest possible amount of comfort with the means at disposal; and am quite convinced that this can be satisfactorily accomplished without cost to the proprietor which shall at all militate from an adequate return for original outlay."

JAMES KENDALL, Architect.

#### MEDIEVAL DOMESTIC ARCHITECTURE OF GERMANY.

No country in Europe offers so many examples of domestic architecture of the Middle Ages as Germany. The names of Frankfort, Nuremberg, Ratishon, and Prague are familiar to all who take an interest in Gothic architecture; and there are many less visited towns, such as Warzburg, Bamberg, Landshut, and Ochsenfurth,

which are nearly, if not quite, as interesting as their better-known and more important neighbours.

The architecture of Nuremberg has constantly been illustrated and described, and perhaps no town in Europe is so thoroughly Medieval; its houses, however, are not of great antiquity, few, if any, of them being of earlier date than the fifteenth century.

Ratishon, perhaps, contains the earliest examples of Medieval domestic architecture in existence. Many of its houses possess Romanesque and First Pointed windows (see example, fig. 1), vaulting, staircases, &c. The windows are often peculiarly beautiful; they generally consist of two or three bead-moulded arches, resting upon slender shafts, which are quite detached from the wooden casements. Sometimes a little tracery is introduced into the heads of the lights, as in fig. 2. The "Goliath's Haus" is the finest and most perfect thirteenth century house in existence. The doorways have generally been replaced at a later date. Fig. 3 is a good example of a late doorway. The shops, hasements, and passages are generally vaulted, and are not infrequently ornamented with bosses and carved corbels.

Landshut is a town which carries one back to the sixteenth century: its principal street, which is nearly a mile long, contains scarcely a single modern building. Every house has a gable: the material used is brick, except for the windows, which are either stone or wood. The fronts are generally covered with plaster, which in many instances still retains vestiges of decorations. A vaulted arcade runs along the east side of the street. No town that I have ever seen contains so much vaulting as Landshut. Even the shops, stables, and beer-cellars have vaulted ceilings worthy of the aisles of a cathedral. Fig. 4 is a good example of a Landshut gable.

Fig. 5 is a house of very peculiar design in the Cathedral-place at Frankfort: it is probably a work of the fifteenth century. The hattlement is treated in a very striking way. There are houses of very similar design to be found in the "Kvaunmarkt," "Römer-platz," and on the Quay. The slaughter-house at Frankfort is a curious example of Medieval architecture, and well worthy of notice. Unfortunately modern "improvements" are making sad havoc amongst specimens of the domestic architecture of Frankfort, and soon few vestiges of antiquity will be left in this city.

MEDIEVAL DOMESTIC ARCHITECTURE OF GERMANY.

LIFE AND DEATH IN LONDON AND PARIS.

THE fact mentioned in the *Builder* of the 22nd of April, that there has been a reduction in the mortality of Paris during the years 1860, 1861, 1862, and 1863, and that in the same period there has been an increase in the mortality of London, is a matter which requires our most serious and careful attention; for, amongst other reasons, there are still some who argue that sanitary improvements are of but little avail; and this number will be increased if it is shown that the large expenditure which has been made in the London district fails, in the matter of health and the duration of life, to enable us to compete in this way with the neighbouring capital. We will, therefore, jot down a few points on which we should have clear information before coming to positive conclusions respecting the value of the sanitary measures that have been brought into use; for there are important causes of excessive death which do not depend altogether upon the neglect of drainage, although that will always be one main point on which the inhabitants of towns, villages, manorials, and dwelling-places of all kinds, must rely for health. We require particulars, so that by contrast and comparison we may be able to test the causes by which the health of the two capitals is affected by means independent of the general system of drainage which may be in use.

The medical treatment of the sick poor is, according to the manner in which it is managed, the means of either saving or losing a considerable number of lives. In London there is great improvement required in this respect. The subdivision of the metropolis into parishes, the workings of so many contending interests, the manner in which medical relief-orders are dispensed by relieving officers, particularly in poor and crowded districts, and other matters connected with this department of the management of a great city, to which the *Builder* has before at different times referred in detail, materially affect the death-rate.

From different reliable authorities as to the manner in which the sick poor of Paris are treated, it would seem to be better than with us. The management there, not only in this way, but also in the visitation and relief of the helpless poor, is on a broad and comprehensive plan, which prevents those painful cases of neglect that are so often followed by the sacrifice of lives which might otherwise be saved; and we should know what percentage of deaths may be fairly set against London in this respect.

It is likely, also, that in Paris there is a saving in consequence of the plan which is used regarding the very large number of infant children who are either unclaimed or little cared for, but who are gathered up and provided for by the State, and sent, for the purpose of being reared, to rural places, where their condition is inspected, and where there is a better chance of life than there is in the crowded and polluted alleys, and in the wretched tenements and bad air of a great city. Even the size of a city, and the number of people that are gathered on a particular space, are the cause of death. In the comparison of the death-rates of Paris and London we should have not only notes of the extent of space which is crowded beyond a certain limit, but also the general allowance of space for the dwellers in each capital.

Under an imperial rule, when it is guided by an intelligence such as that which now reigns in France, there are many advantages in the way in which sanitary and social improvements can be carried out. We all know how difficult it is to move the municipal bodies, the Parliament, &c., to carry out measures which are known to be absolutely necessary. In Paris, the changes which have been made by direction of the Emperor Napoleon in the dwellings of the industrious portions of the community, although they cause present inconvenience and increased rent, will eventually produce good. Even now the position of affairs will be of advantage to the Parisian death-rate. In London, the state in which immense masses of the people live is one of terrible confusion and antagonism to health. Morality, even decency, is far too often impossible; and there are parishes with a population of from 150,000 to 200,000, in which thousands of people—men, women, and children—live in tenement dwellings left in the sanitary care of only two, three, and, in some rare instances, four inspectors of health, who are appointed by the boards of guardians,—gentlemen who

in many instances have a direct pecuniary interest in preventing the necessary outlay of money on this kind of household property. We want an estimate of the number of deaths in the thousand occurring in the metropolis which can be fairly attributed to this cause alone.

To intemperance and its after effects, both as regard men and women, and children, who are either affected in infancy by the administration of strong drinks, or by the effect which their use has upon the constitution of children whose parents have been addicted to them, there are more deaths to be attributed in London than in Paris.

The population of London is about twice the number of that of Paris, and we should know the proportions in each city which the struggling poor bear to those who are rightly supplied with all the necessities of life; and also the numbers in each place who are employed in trades affecting the duration of life; or who work in situations which are unfavourable to the duration of life or the preservation of health.

In parts of London, vast populations are placed in the most evil sanitary conditions. The people are under-fed, ill-clad, and live in and are surrounded by an atmosphere of filth which surely performs deadly work.

The dirty state of the streets of our metropolis has been so recently referred to in the *Builder*, that we will not at present say more on the matter, except to remind our readers of the neglect of scavenging, both in the muddy months and in those when the dry polluted dust finds its way into the lungs of every wayfarer, and which, by entering houses and shops, does not allow those who are indoors to escape. Paris is better than London in this respect; and, as a sure consequence, we must give to the last-named place an extra number of deaths.

The quality of the food used by the families of the industrial and poorer classes in a great capital, is a most important consideration; and in London there is certainly a great want of proper inspection, not only of some of the markets, but also of the shops of many of the tradesmen who deal in the necessities of life for the use of the poorer part of the community. Is this better managed in Paris? We fancy that the extra quantity of vegetable diet used in Paris will be less dangerous to health than the various kinds of butcher's meat and fish which, in diseased and often in putrid conditions, are allowed to be disguised in so many forms and offered with the object of tempting the hungry to hny.

When considering the effect of the improved drainage of London, we should bear in mind that there is here an immense quantity of work of this kind to be executed. Hundreds of cesspools still exist in situations where human life is the most exposed to their bad influence; and besides, the main drainage, so far as regards health, has not been brought yet into operation. It is our duty to use every exertion to hasten the Parisians in the healthiness of our capital, and we hope that the "good day is coming" when our rivalry with France will be in matters of sanitary science and its application, to preserve the bodily health and add to the duration of the lives of the people. In this way, and in the improvement of the arts and fine manufactures, and in the advancement of the social conditions, the intelligence and comfort of the dwellers in each land, we hope that the contest between England and France will be more severe and in earnest than the struggles which are recorded in the history of past times.

A. & B.

COLOUR THE FIRST QUALITY IN STAINED GLASS.

SIR,—You have invited the expression of opinions upon the queries concerning stained glass, which were contained in your number of the 13th ult. I have just read these questions, and as an enthusiast on the subject, perhaps a few remarks of mine on the two first may not be uninteresting to some of your readers.

I consider that the primary effect of stained glass most decidedly is one of colour: a window may be badly drawn, but if the colours are well arranged and harmonized, and the glass good, the effect must be to a certain extent pleasing. On the other hand, no beauty of drawing can compensate the eye for the glare of brilliant colours mixed without regard to contrast. Again, there is a something in the nature of glass which points out to us, that to colour in the first place we must be indebted for the pro-

duction of effect. As a medium for paint glass cannot compete with canvass; but what painter can imitate the depth of tone in a piece of thick, grey blue glass; or can his palette produce anything to match the brilliancy and richness of a piece of ruby glass. Certainly not, and therefore it is by its powers of colour that stained glass should appeal to us first. Look at ancient windows: it cannot be said that it is to their drawing they owe their charm entirely, but rather it is to the correct taste with which the colours are blended, and to the tone the glass has received from age. Now, why should not this be done equally well at the present day? Surely there are many artists now living who can make designs quite as fine as those of our ancestors; and although age has a certain effect upon glass, as upon port wine, which cannot be copied exactly on new, still the use of a thick coarse glass almost entirely obviates that.

I do not wish to underrate the value of good drawing in glass-staining, but I am sorry to see a taste arising for windows which do not owe their value to the especial beauties of glass, and its characteristic feature as opposed to paint, viz, that it is seen by transmitted, not reflected, light, but which depends upon the skill of the artist in forming a pretty picture, a mere imitation fresco or oil painting. Take, for instance, the new windows in Glasgow Cathedral. No one can deny that they are beautiful pictures; but, in my opinion, they should have been painted on canvass, or on the walls of the building. Where can we find in them the beautiful pieces of glass into which you may look and imagine you are gazing into an unfathomable depth tinted with the colour you are admiring? Where are the tiny bits in which the light seems to linger and rest before passing through? Such things should always be found in a good window; but in those I am referring to, although we have the pleasing effect of good drawing and colouring as in a picture, we have none of those peculiar charms of colour which, so to speak, form the glory of stained glass. I lately visited Glasgow with a friend, for the purpose of closely examining those windows. At my companion's first glance at one of them he exclaimed, "How lovely!" "It is, indeed," I answered, but my reply referred to the loves of two sparrows I observed on a neighbouring building, through the medium of one of the Apostles, clothes and all. The fact is, the glass, being the common thin glass from Munich, is too poor and weak ever to make a good window; and the designers have, perhaps for that reason, by the use of enamels and all the skill of the painter's art, produced pictures, quite ignoring those splendid effects which glass, and glass alone, can give us.

As to your second question, I think there can be little difference of opinion that good colouring must not be loud and glaring, under any circumstances, and this applies more particularly to glass. Of course, the position of a window should have some consideration before determining the warmth or coolness of its tone; but I think, as a rule, it is better to have a window a little too cool than a little too warm. If rather too quiet in its colouring, it will be found to improve upon acquaintance, and the eye will become more reconciled to it in time; but if too warm and loud the strain upon the eye seems to render it more critical, and we think we liked the design best at first. Glass can now be so readily obtained, of every tint under the sun, that perhaps it has caused us to be too profuse in our varieties of colour, without employing a proportionate amount of skill in blending them. To approach perfection in stained-glass, we must have colouring rich and gorgeous without being hot, bright without being glaring, and soft without being dull; and lastly, good drawing. To do this, we must first have completely coloured and finished designs, drawn by talented artists; and have such designs carried out on thick glass, so as to produce those effects of colour without which stained-glass is unworthy of its name. J. H.

DRINKING FOUNTAIN MOVEMENT.—Mr. Munro has nearly completed a drinking-fountain and its surmounting statue of a Naiad, which is of Carrara marble, and 7 ft. in height. This work will shortly be placed in Berkeley-square, opposite the residence of the late Lord Lansdowne, the donor. The base of the work is of red granite, the action of the figure that of holding a brimming urn.

#### A PLEA FOR ST. MICHAEL'S CHURCH, ST. ALBAN'S.

COME, sir, and see once more our little church, "rich with the spoils of Time," of St. Michael in St. Alban's. We have unroofed it, and gutted it, and unpeeled it, and unchurchwardened it, and un-Batty-Langleyed it, and are letting, wisely we all think, George Gilbert Scott have his own way. Yes, sir, St. Alban's *revisited* will well repay all who love genius, all who study antiquity, and all who build. The noble portrait-statue of the Great Francis Bacon is now to be seen to rare advantage. And, what all lovers of the great Lord Chancellor will be pleased to hear, the grave-stone—the blue-logger that covers the body of Bacon's faithful follower—is to be seen, I believe for the first time by the oldest inhabitant in St. Alban's. "With reverence look." I have deciphered, and with Layard-difficulty, these words:—

"HERE LYETH THE BODY OF"  
THOMAS MEANTYS."

What the rest of the inscription was we may gather from Chauncy and from Clutterbuck. This Sir Thomas Meantys erected the monumental statue of Francis Bacon. Meantys set it up, but who the sculptor was no research has been able to detect. I suspect Sir Francis's half-brother, Sir Nathaniel, was the sculptor: he was a painter (see Walpole) and his monumental bust in the church of Culford in Suffolk, decorated with palette and pencils, is, in my opinion (and I have seen it), the anticipatory monumental-tomb of his own hands.

Church-restoration cannot go on—any more than Chancellors of the Exchequer can go on—without "ways and means." Our hudget of subscriptions is not very large, but we ask, receive, and are hopeful. We want to preserve and restore the church that contains all that is mortal of "the greatest, wisest, meanest of mankind." We have faith in our architect, and every confidence in the vicar and patron of our most interesting church.

By giving publicity to this letter, carrying no great name with it—but asking in a mighty name—you can importantly strengthen and help the work we have in hand. Were I good at "begging-letters," I would re-write this. Let the name in which I ask conceal or excuse every imperfection.

PETER CUNNINGHAM.

#### A HOUSE PAINTER ON THE LABOUR QUESTION.

WE are asked by a number of working men to publish the observations made by John Brien, operative house-painter, at the first meeting of the Working Men's Club Union, held at Exeter Hall recently, as already mentioned by us, and willingly comply. The speaker said,—“Words cannot express my feelings of gratitude to the noblemen who are present to take part in this debate with working men; but social distinctions must be banished to-night, and all must stand on this platform as men engaged in the moral fight of intellect against intellect; not for the purpose of obtaining a party triumph, but to elicit that which is beneficial to all men, *truth*. The three ingredients that compose the wealth of a nation are land, labour, and capital; and its distribution is as follows:—One portion falls to the proprietors of the soil; another to the owners of capital or tools, including food, which sets labour in motion, and which is, in fact, nothing but the stored-up results of labour; and the last falls to the share of the labourer, and is the remuneration for his toil. The two last portions fall to the employer and the workman, and the proportion in which they are to be allotted is a constant source of struggle between these two parties,—the one, the employer, endeavouring to get the largest amount of work at the lowest rate of wages; and the workman endeavouring to get the highest wages, and to spare his bones as much as possible. If I use strong language, I trust you will consider it directed against the system, and not to employers of labour. Perhaps I read political economy different to some persons; but I conceive that the writings of the father of the English economists, Dr. Adam Smith, clearly prove that the interests of the employer and employed are not identical; and, so long as the two classes exist, there must of necessity be antagonism of interests, and neither courts of arbitration nor of conciliation will prevent strikes; for, as working men advance in intelligence, wages will become more

distasteful to them, seeing that it is only a slight remove from the chattel-slavery our forefathers laboured under; and the only solution of the phrase, "a fair day's wages for a fair day's work," is the whole of the profits to the workman when he combines capital with his labour. Under the present system, strikes take place in America, with its democratic institutions; in Australia; and also under imperial rule on the other side of the water. I am firmly convinced the remedy is co-operation; and, when the working men know its benefits, the franchiso will not be far distant. During the late strike of carpenters in the Midland Counties a house was in course of erection, and the bricklayers, having got up to the first story, could not proceed further without the aid of the carpenters to lay the floor. Now, what did the master carpenter do? Why, he obtained the assistance of the other master carpenters in the town, and they set to work and laid the floor in the presence of the men who were out on strike, and the bricklayers then proceeded with the erection of the house. Now, if these operative carpenters understood the principles of co-operation, they would have said to each other, "These master carpenters have combined labour with capital, and done without us. Now, if we practise temperance, economy, and forethought, to obtain capital, and combine it with our labour, we can then do without master carpenters."

#### ACCIDENTS.

AS the workmen employed upon the Thames Embankment were pushing a truck loaded with cement along a wooden stage, almost in front of the residence of the Duke of Buccleuch, the stage suddenly gave way, and seven men were precipitated to the bottom in the midst of slush and mud. One man became so embedded that it occupied five hours before his body was drawn to the surface. He was then quite dead. It is said that the stage contained 100 tons of ballast upon it at the time of the accident, that it was manifestly insufficient to bear any further weight, and that it broke down about a week before, and then buried an engine in the mud. Since this accident a stage at Waterloo-bridge has given way beneath the weight of an engine. Some workmen were seriously injured.

One man has died from the effects of injuries received in the accident at the Liverpool-street Railway-station of the North London line. The intended station is being erected by Messrs. William Cubitt & Co. The building itself forms a parallelogram, the area of which occupies about three acres and a half of ground. The western elevation faces Liverpool-street, reaching from Broad-street-buildings, on the south, to Bloomfield-street, on the north, abutting itself upon the Ophthalmic Infirmary, at the corner of Elder-street. The eastern elevation is near to Sun-street, Bishopsgate, the lineal measurement from which point to the back wall of the western offices being several hundred feet. Before this large extent of intermediate ground upon arches is the level of the new line of railway, and here the roof is being spanned, of a semicircular construction, sustained upon intermediate pillars, thus forming a vast expanse of double roofing overhead, the fall of which caused the accident. The exact manner in which the occurrence was caused is ascertained to have been the yielding of one of the lightly-tested wrought-iron tie-rods, which, by giving way, brought with it several of the girders and the major part of the springing iron arches which were fixed in their places. The brick walls gave no appearance of yielding, and none of the general scaffolding has given way. The timber used in scaffolding—supports alone throughout the building is of the value of at least £2,000.

Two bridges on the Castleary branch of the Caledonian Railway have been swept away by the flooding of a stream which runs under the line at Culmermauld Bank.

At Ipswich, a granary-floor has fallen, at the premises of Messrs. Harpham, Palmer, & Harpham, iron merchants, on the Quay. The corn merchants hire the top part of the premises, over Messrs. Harpham's shop, as a warehouse for grain. The barley fell bodily through to the next floor, which it also carried before it into Messrs. Harpham's shop, which was filled with the grain. A man was severely injured. This is the third accident of the kind which has happened on these premises within a few years.

#### STATISTICS OF MAGNESIUM.

THE light emitted by a wire one-thousandth of an inch in diameter, is equal to that of seventy-four stearine candles of five to the pound: 3 ft. of it are burned per minute, or a quarter of an ounce per hour, the cost of which, at the present price, would be about 2s. 6d. Seventy-four stearine candles would, however, in the same time, consume 2lb. of stearine, which would cost 2s.: 40·4 cubic feet of 12-candle coal gas would be required to produce the same effect, and would cost about 2d. The dearthness of magnesium arises from the dearthness of sodium required in obtaining it. Sodium is now 10s. per lb., and one pound, under the most favourable circumstances, would be required for a pound of magnesium. But increased demand will, no doubt, cheapen sodium, and in other ways also render the production of magnesium more economical. Already the Magnesium Metal Company have reduced the price of magnesium more than fifty per cent. Magnesium gives off 265 times less heat than gas. Gas and candles vitiate the air by the production of watery vapour and carbonic acid: magnesium is free from this objection, but it has an inconvenience of its own: a large quantity of calcined magnesium is thrown off as a fine powder, which soon renders the atmosphere of a room intolerable. This is also objectionable in photography, though used only for very short periods. For ordinary purposes it would render some peculiar mode of ventilation, or purification yet to be discovered, indispensable. Perhaps the smoke might be conducted through water and then condensed. At best magnesium can be only an imperfect substitute for sunlight: its light has been found to be only the 1·525th of that of the sun on a bright November day; but, at the same time, its chemical effect was ascertained to be the 1·36th of that of the sun.

#### THE ARCHITECTURAL ASSOCIATION.

THE usual meeting of members was held on Friday evening (the 26th ult.) at the House in Conduit-street. The chair was occupied by Mr. J. H. Christian, the president.

Mr. F. Jameson was elected a member of the Association.

Mr. J. Denon, on behalf of the committee, brought under notice the necessity of greater punctuality being observed in the payment of subscriptions by the members; and, pursuant to notice, moved an alteration in Rule 3, to the effect that at the close of any session the name of any member more than one session in arrears should be posted up in the room of meeting, and that it should be within the discretion of the committee to strike off the roll of members any who should be two years in arrears with their subscriptions. The motion was, after a short discussion, carried *unanimously*.

Mr. J. D. Mathews, Hon. Secretary, read a letter which had been received from Mr. Foster, Secretary to the Society of Arts, acknowledging the receipt of the protest of the Association with reference to the award of prizes for cottage designs, which he said would be laid before the council of that body.

The Chairman said, the Association had much reason to be grateful to Mr. Bazalgette and Mr. Poulton for their kindness in allowing their members to visit the works of the Thames Embankment. He could say for himself that he was much pleased with what he had seen, and that he had not previously been aware of the interesting nature of the works with which the names of those gentlemen were associated.

A member inquired whether any further facilities to visit the works would be afforded to such of the members as had been unable to inspect them on the occasion referred to by the chairman.

The Chairman said, that they were received with the utmost kindness and politeness by the engineers of the Metropolitan Board of Works, and that he had no doubt all reasonable facilities for inspection would be afforded those members who might hereafter desire to witness the progress of the undertaking.

Mr. H. Daughy said, that the visit to the embankment had been paid at his suggestion, and that he had reason to believe that the engineers of the Board would be happy to meet the views of the Association to any reasonable extent. The works were of an extremely novel and interesting character, and he recommended that in a few weeks hence another visit of

inspection should be paid, when the visitors would be enabled to trace the progress not only of the embankment *per se*, but also of the railway, the great sewer, and the hoveyard or roadway, all of which were being carried on contemporaneously.

Mr. Mathews stated that arrangements were in progress for a visit to St. Alban's Abbey, on the 3rd of June.

The Chairman recommended as many of the members as could spare the time to join the expedition, which he ventured to predict would be most interesting, and would well repay the trouble of a visit. He had no doubt but that on making application to the proper authorities the members would be enabled to see many portions of the church, interesting to students of architecture, which might not be generally open to the public.

A member suggested that a visit might also be paid to Hatfield House, the residence of the Marquess of Salisbury, which he stated was perhaps the finest specimen of Elizabethan architecture within reasonable distance of the metropolis, and which happily had not undergone the process of "restoration." He believed that the Marquess of Salisbury would give permission to view it if the necessary application were made to him.

Mr. C. L. Eastlake then read a paper on "Nuremberg."

At the conclusion, a member expressed his surprise that so few students visited the south of Germany, as there were other towns fully as interesting as Nuremberg which deserved attention. Nuremberg was easy of access, and the expense of getting there was not great. He suggested that other papers should be read before the Association upon some of these towns.

Mr. Edis understood that the object of Mr. Eastlake was not so much to recommend the details of the architecture in Nuremberg as to point out a town in which cunningly devised falsities had been wrought in stone. As architectural examples, however, judging from the character of the sketches exhibited that evening, he thought they ought to be avoided. He considered that it would benefit them as students better to visit other towns where the Gothic was of a purer character.

Mr. Eastlake said the town of Nuremberg was well worthy of a visit for sketching, studying, and measuring.

The Chairman thought it was of great advantage for a student to visit a town so thoroughly Gothic in feeling. The picturesqueness of Nuremberg was most marked, and the peculiarities of the large roofs was much to be admired. The immense area of the skyline broken up to the high roofs of the buildings made the town marvellously picturesque and beautiful.

Mr. Ridge observed that the houses at Nuremberg appeared to be painted in a much more artistic manner than they were in England. This was produced by the houses being relieved against another in a series of tints of which the prevailing colours were green, buff, and a central green. They were rarely repainted—certainly not once in every three years, as was the case in this country.

Mr. Blashill thought that the longer an architect lived the more difficulties he had to meet, in dealing with London buildings. Flatted paint (like that of the Nuremberg houses) would not do for the metropolis; indeed, he would recommend the use of paint for anything but wood and iron work.

AFTER some further discussion, a vote of thanks was passed to Mr. Eastlake for his paper.

It was announced that the next object for the design would be "interior perspective," and that on the 9th inst. Mr. J. W. Fenfold would read a paper on "Metropolitan Improvements."

is shown of 388*l.* 0*s.* 11*d.*, and an expenditure of 147*l.* 5*s.* 8*d.*, leaving a balance of 240*l.* 15*s.* 3*d.* to be appropriated to the production of the publications.

The "expense account" shows that the amount expended on completing the stock of the early years has been 145*l.* 0*s.* 6*d.*, of which amount one-third, 48*l.* 0*s.* 10*d.*, has been charged to each of the fifteenth and sixteenth years, and the balance will be charged to the seventeenth year. Of the cash balance, 350*l.* have been placed on deposit account, with the Union Bank of London, in the name of the treasurer.

The Chairman, in moving the adoption of the report, and referring to the balance-sheets, observed, that from what he had seen, the society seemed to have well husbanded an amount of subscription which, considering the object at stake, was not at all creditable to the art-loving people of England. He then proceeded,—When I look at what that work is—the copiousness and beauty of its illustrations, the large area over which it moves,—the area, in fact, of all architecture,—without party, without partiality, and without prejudice,—I must say that I think this society has undertaken a work far greater and much more onerous than most institutions of this size could have dared; and has carried it through with a success which is perfectly exceptional. If we look at the life of Dr. Johnson, we see how his gigantic intellect almost broke down under the wearying work of lexicography, and his was the simplest of all dictionaries, namely, the Dictionary of a Language. Looking, again, at the Dictionary of the French Academy, how year after year was consumed in the work undertaken by that great Royal Institution; and looking, again, at our different encyclopedias, and how much trouble, how much finding and finding, and going back again and rewriting, are involved in every encyclopedic that has yet been produced,—what a contrast is presented when we look at the Dictionary of Architecture that is now being prepared by this society. Of course, I do not mean to say that it is perfect; I do not pretend to say that it will equal the next edition, which may be produced early in the next century, when, I hope, we shall see our friend Mr. Cates in vigorous and robust health, though, of course, of maturer years, but ready to carry that out as he has carried this out. I say again, as I said before, that it is not creditable that a work of the sort should be supported by such an infinitesimally small number of the men and of the societies we know feel an interest in art. I beg leave to propose, not only from the chair, but from the heart, "That the report and balance-sheets now read be received and adopted, and printed and circulated as usual."

Professor Donaldson seconded the motion, and in doing so suggested to the committee that they might with propriety consider whether some means could not be adopted for the purpose of securing a more rapid issue of the Dictionary. He believed the plan of advertising for articles had been tried, and he felt that something ought to be done, if possible, to get on a little more rapidly towards the completion of the work, which, if delayed for another ten years would, he was afraid, dishearten people from subscribing to it. They were very much indebted to those getting up the work for the amount of labour they bestowed upon it; but he ventured to suggest that some of the articles might very well be shortened, and that the scientific and historical parts of the different subjects were sometimes too largely treated upon, while the artistic part was, perhaps, in some degree, neglected.

Mr. Sydney Smirke, the treasurer, said it must be borne in mind that the low state of the funds was a great cause of delay in the preparation of the Dictionary.

Mr. Horace Jones fully concurred in the observations made by Professor Donaldson. What the Treasurer had said was no doubt of great importance, but he could not help feeling that in these days of mercantile and commercial enterprise, arrangements could be made with some energetic publisher for the purpose of completing the Dictionary. If the Dictionary were not finished for the next ten years, the early numbers would by that time have become obsolete.

Mr. Newton declared that the object which they had always had in view was to make the work as far as possible perfect. The work had hitherto been done by two or three people, and it could not have been in better hands, because it had been with them a labour of love;

but he was afraid that if they paid for assistance, and did not get men to act on the same principles as those who were now conducting the work, the scheme would altogether fail.

Mr. Cates said that they had now gone through more than half the list of terms that was prepared in the first instance as an index to the Dictionary; and, according to the progress already made, they would only require five years and a half subscriptions from the completion of the publications for 1862, to enable them to complete the text of the Dictionary. There was much truth in what the Treasurer had said with regard to the funds; but the progress of the work was also retarded, to a very considerable extent, by the great care taken in the production of the text. There was great difficulty connected with what had been said about asking a publisher to take the work in hand. In his own opinion, the only course open to them to realize the wishes expressed, was to get some one with an earnest interest in the art to advance them money upon the security of their stock, which was a very good security, and thus enable Mr. W. Papworth to call in, under his own supervision, assistance of paid contributors; and in this way the work might be got on with more rapidly.

Votes of thanks to the committee and officers, Mr. O. Hansard, Mr. W. Papworth, and Mr. Cates, were then unanimously passed; and Mr. Horace Jones was elected a member of the committee.

THE BUILDERS' BENEVOLENT INSTITUTION.

A GENERAL meeting of the subscribers to this charitable Institution, was held at the London Tavern, Bishopsgate-street, on Thursday, 25th ult., to elect four pensioners on the funds, viz.—three males and one female, from a list of candidates of eight males and three females. The president, Mr. Thomas C. Lucas, occupied the chair.

The Chairman said, they had met together for the purpose of electing four pensioners on the funds of their Institution, from a list of candidates which was now before them. He was present with a mingled feeling of pleasure and regret—pleasure in carrying out a portion of the object they had in view, and regret that their funds would not permit them to return all the candidates who had presented themselves for election. The Society was a progressive one. It had progressed to a certain extent, but more slowly than its friends desired. He trusted, therefore, that the builders of London and the suburbs would come forward and support that Institution, on which many of their poorer brethren mainly depended; and if they could not afford their five guineas, they might subscribe their one guinea, or even their 10*s.* 6*d.* The building trade was one of a peculiar character. It was full of vicissitudes, and the prosperous man of this year might, through unforeseen misfortune, the next year become a candidate for the benefits of the Society. He would congratulate those who must be successful on this occasion, and offer his sympathy to those who would be less fortunate, trusting that on the next occasion there would be more elected. He was of opinion that if the builders generally contributed, every one of the candidates would be elected on their first application. With the day's election there would be twenty-one males and nineteen females on their funds.

The poll was then proceeded with, and during the absence of the scrutineers,—

Mr. Joseph Bird who had taken the chair, owing to the departure of Mr. Lucas on a pressing appointment, informed the meeting that between 300 and 400 votes only had been recorded, so that 10,000 or 12,000 votes had not been made use of. He mentioned that in order that the candidates at the next election should be more diligent, and use greater energy in calling upon their friends. He was quite sure, that where subscribers paid for a certain object, they did not like their votes to be lost. He hoped what he had stated would act beneficially.

On the return of the scrutineers, Messrs. Cozens and Stirling, the following were announced as the successful candidates:—Thomas Martin, aged 78, carpenter, unable to work through debility and the infirmities of old age. William Terry, aged 78, painter, plumber, &c.: his distress arose from great losses in business and old age. Thomas Birch, aged 73, carpenter: his distress was caused by severe accidents, loss of trade, and inability to labour. Sophia A. Crane,

MEETING OF THE ARCHITECTURAL PUBLICATION SOCIETY.

The annual general meeting of subscribers was held May 26th, at the House, in Conduit-street, Mr. A. J. B. Beresford Hope in the chair. The Secretary, Mr. Arthur Cates, read the report and balance-sheets for the past year, which show, for the fifteenth year, 1862, a total receipt of 478*l.* 10*s.* 4*d.*, and an expenditure of 228*l.*, leaving a balance of 145*l.* 8*s.* 4*d.* available to complete the publications for that year, and for the sixteenth year, 1863-65, a total receipt

aged 72, widow of a builder: her only means of support are 8l. per annum, and a residence in Balls Pond Almshouses.

The fortunate candidates having returned thanks, the usual complimentary votes terminated the proceedings.

#### THE BUILDING TRADES MOVEMENT.

**London.**—The workmen are again agitating for an advance in wages. The stonemasons—the originators of the movement—allege that the increased and increasing cost of house and room rent, the high price of butcher's meat and other provisions, the general prosperity of the trade, and the fact that in nearly all the provincial towns the wages of the building operatives have been advanced 2s. to 3s. per week, entitles them to an advance of 6d. per day. A memorial asking for that advance was accordingly presented to the masters.

**Plymouth.**—The men on strike at Plymouth have resumed work, and withdrawn the "rules" objected to by their employers.

**Stockport.**—The operative painters are still on "strike"—not, however, as was erroneously alleged, for a reduction of the hours of labour, but for an advance of wages from 5j. 4. to 6d. per hour, equal to 3s. 6d. per week of 56 hours. There is some prospect of a prompt and satisfactory settlement of the dispute, one or two of the masters having already consented to pay the advance.

**Bradford.**—The plasterers' labourers still continue on strike. The masters have offered the shilling advance in wages which is asked, on the condition that the men find their own tools, as the practice is in Leeds, Manchester, and other large towns; but these terms have been refused, and there is no sign of an agreement being come to at present. The strike of the plasterers has terminated by the masters yielding the advance of 2s. per week sought, the second advance of 2s., and a half-day holiday on Saturday in addition, since 1863. The wages of the men range now from 25s. to 28s. per week.

**Middlesborough.**—The joiners have struck work for an advance of 1s. per week in their wages. Some short time ago, they made a demand on the masters for 2s. advance and half-a-day's holiday, and the masters met this by granting 1s. advance and the half-day. When the men got this, they gave notice for the other shilling, since which they have now got it, the masters being unable from press of work to resist their application. The wages of the town are now 28s. per week, with half-a-day's holiday on Saturdays.

**Stockton-upon-Tees.**—The joiners' strike has terminated with the advance in wages, but not the half-day's holiday, except in a few instances.

#### THE OFFICE OF WORKS.

On the vote of 24,148l. for the salaries and expenses of this office, Mr. Cowper, in reply to questions as to Mr. Pennethorne's salary of 1,500l., and other emoluments, said that the professional fees for the work performed by that gentleman would amount to a much larger sum than he at present received. The extensive purchases of land on the site of the new Foreign-office and of the land between Bridge-street and New Palace-yard had been conducted by him, upon whom had also developed a great deal of business connected with Battersea Park and other metropolitan improvements. It was necessary that there should be some professional man connected with the Department to whom application could be made for advice, and Mr. Pennethorne was a very able man, of great experience. The agreement with him was, that he should give his services as surveyor and consulting architect, but when he was employed to furnish designs, or act as an architect in erecting new buildings, then he must have his five per cent. like other architects. In former days the Office of Works had three architects, who received a per centage—3 per cent., he believed—for their labours, and the office was bound to employ those architects in every work which was erected. It was, however, thought that it would be an immense advantage that the office should not be restricted to any particular architect. Mr. Pennethorne had no absolute claim to be employed on any new work. It was deemed better to appeal to the profession at large. Mr. Pennethorne was the surveyor who surveyed and

negotiated the purchase of property that might be required, and Mr. Hunt (whose salary is 1,000l. a year) was consulting surveyor in the office, giving his advice on matters referred to him. The political head of the department required a professional man like Mr. Hunt to give him his advice on matters coming within his special knowledge and experience.

As to the cause of delay in laying before the Chancellor of the Exchequer the materials necessary for him to form an opinion in respect to the estimate required for the new buildings at Kensington designed by Captain Fowke, Mr. Cowper said that the building was intended for the natural history collections of the British Museum. It was thought right to give the officers of the Museum an opportunity of considering the plans. Accordingly, Captain Fowke's plans were sent to the trustees at the end of last year. They were anxious to give them full consideration, and they had only lately expressed an opinion, which was not however final, as they had referred the plans to a sub-committee. When the trustees had made up their minds the Government would resume its action.

As to the proposed road between Piccadilly and Park-lane, Mr. Cowper said that the Office of Works was concerned in the scheme, because a portion of the park was proposed to be taken. He said he had no objection to the scheme, although he did not think it the best. It was true that there was some difference between the Commissioner of Woods and himself as to the propriety of making the street, but no expense was caused thereby to either department. The best plan would be the widening of Park-lane, but such a proposal must originate with the Metropolitan Board of Works, and he had not heard yet whether the Board had decided on adopting the best plan, or only the second best.

In reply to a question as to whether it was the intention of Government to erect at Brompton the buildings designed by Captain Fowke for the Natural History Collection, Mr. Cowper said it was the intention of the Government to make a proposal, but he thought it better not to go now into the question what that proposal might be. No step had been taken which would in the slightest degree prevent full and ample consideration of the subject.

#### OUTLOOK v. LOCKOUT.

Str.—In reading over your leading article of last week about "strikes," and what are commonly called "lockouts," I observe that you have adopted another form of the latter word, namely, "outlooks." This certainly appears to be a more pronounceable word than the one in ordinary use, and one which I should feel inclined to adopt myself, did I know a "reason why." Therefore, I should feel obliged, with very lively thanks to your readers, if not trespassing too much on your kindness, if you would impart the useful information.—Q.

[Our only reason for deviating from the vulgar custom with regard to this word was a desire to conform to the settled analogy of the English language, and to avoid giving countenance to the establishment of another glaring irregularity in addition to the host which already disfigure our orthography. It is a well-known rule in the formation of compound nouns substantive from a verb and preposition, that in the compound word the preposition is placed first and the verb last, although in their simple state the reverse holds good.

Thus, from *let out* we have *outlet*; from *set out, outset*; from *cast out, outcast*; from *pour out, outpour*; from *cast off, outcast*; from *set off, offset*; from *pour down, downpour*; and numerous other words, which no doubt will suggest themselves to our correspondent. There may be a few words, such as *look-out*, which are not yet brought under the general rule; but as this word hardly admits of a plural, the incongruity is not so striking as *lookouts* would be. Nevertheless, we do not despair of seeing this word rectified, in time, in accordance with general analogy. It is only necessary that the example should be set by a few writers of credit, and then such barbarisms as *lockouts* and *lookouts* would disappear from our language altogether.—Ed.]

A PUBLIC PARK FOR CHESTER.—It is stated that the Marquis of Westminster is preparing land for a public park and recreation grounds, as a gift to the citizens of Chester.

#### PROVINCIAL NEWS.

**Wellington.**—The contract for the erection of the new covered market at Wellington has been given to Messrs. Treasner & Son, of Shrewsbury and Newport, whose tender, 6,178l., was the lowest of five sent in. The erections, although not so large as at first contemplated, will embrace a covered market, with shops and stalls for butchers' meat, fish, poultry, butter, vegetables, fruit, &c., with a detached building in the rear, with room for unloading, for use as a potato market. The work will be carried out under the inspection of the architect, Mr. Bidlake, of Wolverhampton.

**Rochdale.**—The local general purposes committee have determined to suggest to the Town Council, at their next meeting, the advisability of altering the interior plans of the new Town-hall, by adding a large hall for an Exchange, at a cost of about 7,000l. In order to accomplish this, fewer corridors will be inserted in the new plans. An Exchange has been long wanted in Rochdale.

**Endcliffe (Sheffield).**—The large mansion which Mr. John Brown, J.P., is erecting at Endcliffe, on the site of the old hall, is fast approaching completion; and is, in fact, in so far advanced a state that the architects (Messrs. Flockton & Abbott) issued invitations to view the building, which were made use of by a numerous party. A large sum of money has been expended on it. The hall stands upon the site of the former residence of Mr. Henry Wilkinson; and it is just two years since the sale of the old hall to Mr. Brown was completed. The contractors had to remove the whole of the then existing building; to remove the old and excavate new foundations; to level the grounds in some parts and raise them in others, in order to open out the prospect from the front of the plateau house. The hall stands upon a sort of plateau just below the Rammoor road, and commands extensive views to the south-east, south, and west; and it is a conspicuous object from the Tharageath road. The site is in the centre of about 40 acres of land, which has been laid out in gardens and ornamental grounds, planned by Mr. Flockton, after the Italian model. A large conservatory, with a lofty dome, and pinciers, vinerias, &c., are placed on the western side of the grounds, and behind these is an extensive kitchen garden. The general style of the hall is Italian. Above the entrance porch are groups of figures by Wyon, representing the Seasons; and the pediment of the south front, above Mr. Brown's bedroom, supports two figures by Papworth, emblematic of Labour and Art. The south is the principal front. The whole house is fitted with Breguet's patent electrical bells; which are so numerous that twenty or thirty wires pass beneath the flooring of some of the rooms. These wires concentrate on the landing outside Mr. Brown's bedroom; and, by touching an ivory knob there, they can communicate with any of the servants of the house, or with the lodge-keeper at the entrance to the estate. The stoves have been supplied from Roscoe-place and Chantry Works, and the chimney-pieces by Mr. Hadfield. The kitchen stoves are by Langden & Co. The stone carving has been executed by Messrs. Mawer & Ingle, of Leeds. The modelling for the ornamental ceilings has been produced by Mr. Green, of Sheffield, from the designs of Mr. Flockton. The outside shutters to the principal windows are a Belgian invention. They are made of iron, and slide into the wall by means of a rack and pinion. These shutters either make the window secure at night, or can be used as sun-blinds, as the *louveres* can be regulated to any angle. The Messrs. Craven have been the contractors for the masonry and joinery. The carpentry has been executed by Mr. W. Gibson, of Ecclesall; the external plumbers' work by Mr. Bisset, and the internal plumbing and the glazing by Mr. Pitt. The plasterers' work has been done by Messrs. Craven, under the superintendence of Mr. Large. The vinerias, the lower terraces, and the lodges have been built by Mr. Wado; the stables by Messrs. Craven. Messrs. Ellis have fitted up the warming apparatus, iron-work, &c., for the conservatories, saloon, and vinerias. The decoration of the rooms was entrusted to Messrs. Rodgers.

**Newcastle-upon-Tyne.**—The new county court, situated between the Assembly Rooms and the Savings' Bank, in Westgate-street, has been opened for business. The entire cost of the building is about 10,000l. and its erection has

style of the edifice is to be French Gothic, and it will possess a tower and spire, and accommodate for a congregation of 450 persons. Messrs. Pritchard & Son, of York and Darlington, are the architects, and Mr. Alderman Weatherley the contractor.

**Hayton (Cumberland).**—The foundation stone of a new church has been laid at Hayton, Aspatia. The church will be built by subscription, and will cost about 1,100*l.* The architect is Mr. Travers, of Manchester; the contractor for the mason work is Mr. H. Grave, of Aspatia; and for the joiner work, Mr. J. Tremble, of Aspatia. Mr. J. T. Hayton, of Oughterside, has been chosen by the committee to superintend the erection. The style of architecture is chiefly a combination of Norman and Gothic. The building will be of red stone, and though there will be no spire, there will be an ornamental bell-tower. The inside dimensions of the nave are 54 ft. by 25 ft. 6 in., and the chancel 27 ft. 6 in. by 21 ft. The church will be built to accommodate about 220, and the district assigned to it are the townships of Hayton, Mela, Oughterside, and Allerby, containing in the whole a population of 1,095.

#### DISSENTING CHURCH-BUILDING NEWS.

**Weybridge (Surrey).**—The new Congregational church here has been opened. The style is Decorated, and the plan is cruciform, and measures across the nave 32 ft. 6 in., and 48 ft. 6 in. across one transept. The length of the church, including the apse, is 69 ft., and the height from floor to ceiling is 27 ft. 6 in. The whole of the outside walls are built in stone, from the neighbourhood of Godalming, in rough random-work. The quoins are in Bath stone. The interior is finished with brick, with rough stucco, and jointed. The entrance to the body of the church is through the base of the tower, which at the same time forms a porch. From the tower springs a spire which rises from the ground to the height of 84 ft., and is surmounted by a vane, which carries it up to the height of 90 ft. The lower part of the main timbers of the roof is exposed to view, and is wrought, stained, and varnished. All the principal windows are filled in with stained glass, supplied by Messrs. Ward & Hughes, of London. The church is lighted by a number of star pendants, and all the gasfitter's work has been done by Mr. Rothwell, of London. It is warmed by hot water, by Mr. Smith, of London. There is accommodation for 330 persons at present, but when the other transept is finished it will accommodate 390. The total cost of the church, including warming, lighting, boundary fencing, stained glass, and architect's commission, will be a little over 2,100*l.*, exclusive of site, which cost about 200*l.* Mr. John Tarring, of London, is the architect; and Mr. Sanders, also of London, is the builder.

**Banbury.**—The new Wesleyan chapel in Banbury has been opened. The architect was Mr. Woodhouse, of Bolton, Lancashire. The work has been executed by Mr. A. Kimherley, of Banbury, the original contract price being 3,400*l.*, exclusive of the spire, which was estimated to cost about 300*l.* The actual cost has, it is said, run up, including sundry extras, to between 5,000*l.* and 6,000*l.* The material of the chapel is of Brackley and Bath stone. The interior is calculated to seat from 1,100 to 1,200 hearers, the free sittings being about 200. The pulpit built by Mr. Kimherley is of carved oak, upon a base of stone, the communion-table with its enclosed railing being immediately in front of it. The pillars at the main entrances to the chapel are of red Mansfield stone. The roof is an open one, and the galleries are supported on cast-iron pillars. The windows have a stained edging, while over the pulpit is one of more deeply stained glass.

**Sharnbrook.**—The foundation stone of the enlargement of the old Baptist chapel has been laid. The total expense of the enlargement is estimated at about 600*l.* The contractors are Messrs. Gostick & Tysoe, and the architect Mr. J. Usher, of Bedford.

**Gamblesby.**—The new Wesleyan chapel, erected on the site of the old meeting-house, has been completed. The design is of the Gothic period. Mr. Richardson, of the North-Eastern Railway, drew the plans. Messrs. Tensdale, of Gamblesby, were the contractors for the stonework; Mr. Brown, of Ousby, for the joiner work; and Messrs. Scott, of Penrith, for the plastering and painting. The pews are open, and stained a dark oak colour. At the east end of the build-

ing is a large stained window; and from a centre of the ceiling is suspended a chandelier, upon which are fixed large paraffin lamps. Attached to the chapel is a school-room, underneath which is a heating apparatus.

**Fen Drayton (Cambridgeshire).**—The foundation stone of the new Wesleyan chapel at Fen Drayton has been laid. The site occupies about one rood, and is given by Mr. W. Cooper. Mr. Hutchinson, of Huntingdon, is the architect; and Messrs. Danting & Saint are the contractors. The chapel is to be in the Gothic style, with a tower and a spire, about 100 ft. high. It will cost about 1,200*l.*, and will be complete, it is expected, about the latter end of August.

#### Books Received.

*Notes on the South Lancashire Dialect.* By J. A. PICTON, F.S.A. Liverpool, 1865.

THESE notes are reprinted from the Transactions of the Literary and Philosophical Society of Liverpool. They contain an interesting analysis of the various elements, or ingredients, and sources, of the Lancashire dialect, from its Cymric or Celtic nucleus, emanating from the adjoining high lands, to its Angle, Saxon, Jute, and other successive superfections from extrinsic sources.

Perhaps a time is coming when the relationships of the languages of mountainous, high level, or highland countries, will show that these are in general more ancient and purer than the low level languages—not so much on account of the inhabitants having been driven, as aborigines, from the low lands by invaders, but from the mere fact that the high lands were inhabited by human beings at a time when the low lands were under water. We have already pointed attention to the probability of this with reference to the philological affinities of the Sub-Himalayas and the Caucasus, and in allusion to the intrusion of the Aryan race between the Tamulian of the high land of Southern India and the coeval races of these same Sub-Himalayan high lands. Something quite analogous appears to have occurred on a small scale in the Lancashire low land between the Cambrian and the Cambrian, the Welsh and North English high lands, anciently—aboriginally—inhabited by the Celtic or Cymric races, no doubt, at a time when the Cambrian and Lancashire high lands were islands, and Lancashire lay between them under the sea. It was into that intermediate and less ancient land that the Celtic (first) and then the Teutonic, or the Angles, and Saxons, the Danes, and others, intruded, while still the primitive lands remained the great centres of the primitive or Celtic inhabitants, who could not therefore be said to have been driven into these highlands by the intruding races. As we have before said, a great philological and ethnological light is probably about to dawn in this direction on the ancient history of mankind; although first our suggestion may possibly be scoffed at by shallow thinkers, whose mental force lies solely in scoffing; and, when the suggestion has been fully adopted, then we shall be jeered at for claiming it as our own. This has frequently been the fate of the *Builder's* innumerable pioneering suggestions.

As Mr. Picton remarks, "by many educated persons dialects are considered as mere vulgar corruptions of the current language of the country, equivalent to the cant or slang phrases which obtain currency from time to time in particular classes of society in our great towns. This is an error which it is very desirable to eradicate." The fact is that it is mainly among the provincial dialects that the purer forms of the old English language are to be found. Of course, these now look antiquated and moonish, and are not admissible into refined modern society. Yet, as observed by Mr. Picton, this is not so with reference to "broad Scotch." It must be recollected, however, that broad Scotch is not merely a dialect of the English language, but is itself the language of a once separate and independent coeval nation, not of a mere province or county of England; and it might as well (or much rather) be expected that "the American language," as a Yankee called it, should be inadmissible to polite society in England, as that the Scottish should. As for the Scottish language, however, ranking coevally with the English, it ought no more to be called even old English than old English Scottish. The two countries, as we have said, were coeval and independent, though both always spoke the

same language essentially; for the Scottish language, though as old as old English, is essentially the same. It is rapidly becoming modernized, however, under English auspices.

*The Holy Sepulchre and the Temple of Jerusalem.* By JAMES FERGUSSON, F.R.S. London: Murray, 1865.

It will suffice to mention that we have in this volume the two lectures delivered by Mr. Fergusson in the Royal Institution, Albemarle-street, on the 21st of February, 1862, and March 3rd, 1865. Outlines of these have been already given in our pages, where indeed some of Mr. Fergusson's views were originally set forth. Investigations during eighteen years that have elapsed since the publication of his "Essay on the Ancient Topography of Jerusalem," have in no way altered his opinion that the building known as the Dome of the Rock at Jerusalem (wrongly called the Mosque of Omar) is the identical church which Constantine built over what he believed to be the Sepulchre of Christ. The volume before us gives a complete statement of the argument, contains a considerable number of engraved illustrations, and is altogether a very interesting work.

#### VARIORUM.

"The Quadrature of the Circle; or, the true ratio between the Diameter and Circumference geometrically and mathematically demonstrated." By James Smith. London: Simpkin, Marshall, & Co. 1865." Mr. Smith must be a highly practical man, since he is chairman of the Liverpool Local Marine Board, and member of the Mersey Docks and Harbour Board; nevertheless he here deals *en amore* with what we cannot but still think is a very impracticable and undemonstrable question. It is Mr. Smith's belief that he "can produce geometrical figures by the score in demonstration of the truth of the theory, that eight circumferences are exactly equal to twenty-five diameters in every circle." We respect Mr. Smith's ingenuity, but we are not convinced, although we see nothing to sneer at in his endeavours.—The *Calcutta Engineer's Journal* gives, in the number for April, as usual, several articles from our pages, and with our perfect goodwill. Articles that cost us much money are reprinted not merely all over the country, but all over the world; and, so far from offering any objection, provided the source be acknowledged, we see it with gratification. In the number of the *Calcutta Engineer's Journal* already referred to, we see, however, the following—

"Amongst our selections will be found an article signed 'Rejoinders,' taken from the *Builder*; we have not inserted this on account of any merit of the article, but because it refers entirely to this country. We will ourselves say a few words on the system of building on wells."

A less gracious acknowledgment we have not met with for some time.

#### Miscellanea.

**INSTITUTION OF CIVIL ENGINEERS.**—The Annual *Conversazione* of the President of this Institution—Mr. John Robinson McClean, F.R.A.S.—took place on Tuesday evening last. The company numbered upwards of seven hundred. The arrangements were in charge of Mr. Charles Manby, F.R.S., honorary secretary, and Mr. James Forrest, the secretary, and were very effective and satisfactory. Amongst the objects exhibited was a large number of excellent pictures.

**EAST LONDON INDUSTRIAL EXHIBITION.**—This exhibition will be held in St. Mary's Schools, Whitechapel, from the 12th of July to the 2nd of August, both inclusive. The musical arrangements are under the direction of Mr. J. Prondman, the conductor of the International Reformatory Exhibition. The Board of Trade have already licensed the Exhibition. There is to be another Exhibition of a speculative character in the east of London, from which it should be carefully distinguished. The East London Working Classes' Industrial Exhibition, to be held in St. Mary's Schools, Whitechapel, is under the patronage and guarantee of the Marquis of Westminster, the Earls of Shaftesbury and Macclesfield, Lord Bury, the Chancellor of the Exchequer, and various other influential gentlemen.

**SMOKE PREVENTION.**—The Mersey Steel and Iron Works have applied for leave to lay a gas conduit 20 ft. under the surface of the street, and leading into their works. The object of this change is to smelt their iron with gas instead of coal, and so to completely abate the smoke nuisance.

**ARCHAEOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.**—At the last meeting of this society, it was arranged that the annual meeting for this year should be held at Dorchester, on Tuesday, August 1, to Tuesday, the 8th, inclusive, and the local committee and presidents of sections were nominated.

**SEWAGE UTILISATION BILL.**—On the motion of Lord Ravensworth, in the House of Lords, the following were agreed to as the select committee on this Bill.—Earl of Derby, Earl of Arundel, Viscount Strathallan, Viscount Torrington, Viscount Bressley, Lord Palmerston, Earl of Cork, Lord Redesdale, Earl of Longford, Lord Ravensworth, Lord Essex, and Lord Ebury.

**DURHAM ARCHITECTURAL SOCIETY.**—The first meeting for the season of the Architectural and Archaeological Society of Durham and Northumberland was held in Hartlepool and neighbourhood. The members who attended visited a number of places, paying particular attention to the old church of Hartlepool. A paper was read by Mr. Longstaffe, on "The History of the Church and Town," after which the members dined together, under the presidency of the Rev. Greenwell, of Durham.

**ALLEGED RISK IN OPENING SAFES AFTER FIRES.**—At the late conflagration in Richmond, United States, according to the *New York Daily News*, a curious incident occurred. Some weeks ten days after the fire, the iron safe of the *Enquirer* office was opened; when, immediately on the admission of the air, the books and papers were ignited and consumed. Such was also the case in all other safes which were not in brick walls. In these latter the contents were unharmed. The *Enquirer* safe, at the time it was opened, was cold externally to the touch.

**PROPOSED ART EXHIBITION AT ALTON TOWERS.**—At a recent meeting of the London Committee, held at the residence of Viscount Ingestre, M.P., the prospectus of the Local Committee, with amendments and additions, was adopted; and it was decided that the opening of the exhibition should take place, if possible, on Wednesday, July 5. The general management of the exhibition is to be entrusted to Mr. C. B. Mason, of the South Kensington Museum. The committee will very shortly receive articles for the exhibition. Special trains will be run frequently during the exhibition to Alton from all parts of the country.

**EMERALINE LIFTING MACHINE.**—An interesting experiment of M. Eybert's newly-invented submerine lifting machine, the *Narval*, was just taken place on the crater lake of Geneva, on the mountains of the Puy-de-Dôme. The machine of the huge machine having been tested, the apparatus was made to collapse and sink to the bottom of the lake. A diver then came down and attached to it large masses of iron weighing 60 tons. The machine was then inflated, and slowly rose to the surface to its immense burden. A report addressed to the Minister of Public Works by the prefect is a testimony to the perfect success of the experiment.

**DAMAGE IN UNDERPINNING WALL.**—In the case of Common Pleas, a case *Williams v. King*, was tried in which the defendant was a builder, who had been employed to build a house adjoining one belonging to the plaintiff. It was necessary to underpin the plaintiff's wall, and in the course of this operation the plaintiff's house sustained damage. Subsequent upon this, an action was brought, and the jury awarded him 20*l.* Mr. Philbrick, who gave for a rule for a nonsuit. The Act 19 Vic., c. 122, s. 108, said that no action should be brought against any district surveyor "or other person" for anything intended to be done under the provisions of this Act unless a month's notice of action were first given. It was submitted to the court that the defendant was entitled to notice of action under the provisions, and that such notice not having been given the plaintiff must be nonsuited. *Granted.*

**BURNING OF A THEATRE IN STOCKHOLM.**—A Stockholm letter states that the Park Theatre of that city was entirely destroyed by fire on the night of the 22nd. The building being constructed almost entirely of wood, all the efforts of the firemen to arrest the progress of the flames were fruitless.

**IRON RAILWAY CARRIAGES.**—The Chicago and St. Louis Railroad Company have received one or two iron passenger-coaches. This car is sixty-seated, in point of appearance not excelled by any passenger-coach in the north-west. It is constructed entirely of iron, with the exception of doors and windows and inside linings.

**MIRAGE.**—On the 26th ult., in the morning, the wind being S.S.E. the summit of the cliffs of Hastings were distinctly visible from the port of Dieppe, the distance being about 47 miles. The phenomenon of mirage is not of very rare occurrence in this portion of the Channel, the inhabitants of Hastings and Eastbourne having been often favoured with a view of Dieppe by the aid of Nature's great "refractor."

**THE ATLANTIC TELEGRAPH CABLE.**—The new telegraphic cable, destined once more to connect England with America, has been completed. For a year past, the machinery of Messrs. Glass & Elliott, of Greenwich, has been busily at work, and the directors of the company invited a number of gentlemen to witness the ceremony of twisting the last foot and inch of the 2,300 miles of rope, after which the completion was of course celebrated by eating and drinking, at an entertainment which took place in the Ship Tavern, Mr. J. Pender, M.P., in the chair.

**EXHIBITION OF INSECTS.**—The Central Society of Agriculture of France has proposed an exhibition, not of husbandry, nor of horses, cattle, or dogs, but of insects. The programme of the animals to be displayed is thus set forth:—First class.—Useful insects: 1. Insects used for the production of silk; 2. For the production of honey and wax; 3. Tinctorial insects; 4. Edible insects; 5. Those employed in medicine. Second class.—Noxious insects:—Those injurious to cereals, the vine, other crops and industrial plants, kitchen gardens, plants furnishing food for animals, fruit-trees, forest-trees, and timber wood; parasitic animals of man and the inferior animals, &c., *et hoc genus omne.*

**THE CATASTROPHE AT THE GREAT WESTERN RAILWAY.**—The coroner's jury, in this case, after hearing a mass of evidence, returned the following special verdict:—"That the deceased, Henry Charles Leblanc Newberry, was accidentally killed by the fall of a wall and a stack of coals, on the premises of the Great Western Railway Company, in the occupation of the Lilleshall Coal Company, and the jury impanelled having recorded a verdict of accidental death, desire to give their opinion that the conduct of the Lilleshall Coal Company has been utterly reckless with regard to the stacking of coals against the wall that fell on the deceased, and they also think that the officers of the Great Western Railway Company were highly culpable in not protecting the public from the danger of the falling of a wall which they knew to have been in a dangerous state for several days before its fall."

**VALUE OF HOUSE PROPERTY.**—The following were amongst the sales on the 30th ult., at the Guildhall Coffeehouse, by Messrs. Driver, Leasehold two mansions, being Nos. 42 and 75, Onslow-square, Brompton, producing 300*l.* per annum, term 86 years, from 1849; ground-rent, 17*l.* per annum—4,710*l.* Leasehold seven residences and premises, being Nos. 1 to 6 and 12, Summer-place, Onslow-square, Brompton, producing 638*l.* 10*s.* per annum, term 85 years from 1850; ground-rent, 35*l.* per annum—9,300*l.* Leasehold ten residences and premises, being Nos. 1 to 10, Summer-terrace, Brompton, producing 825*l.* per annum, term 86 years from 1849; ground-rent, 50*l.* per annum—12,330*l.* Leasehold mansion, being No. 17, Southwick-crescent, Hyde Park, let at 292*l.* per annum, term 96 years from 1840; ground-rent, 2*l.* per annum—4,570*l.* At Garraway's, by Messrs. Edwin Fox & Bondfield.—The beneficial interest in the lease of the professional residence, No. 45, Threadneedle-street, term 21 years from 1863, at a rent of 90*l.* per annum—2,000*l.* Leasehold house, being No. 18, Canterbury-road, Ball's Pond, let at 28*l.*, term 99 years from 1852; ground-rent, 3*l.* 5*s.* per annum—

**COPPER.**—The demand is languid; the smelters are now selling tough at 89*l.* per ton; best selected at 92*l.* per ton; manufactured, 96*l.* per ton.—*Ryland's Circular.*

**RESTORATION OF THE PALACE AT BRUNSWICK.**—The Chamber of Brunswick has just met in an extraordinary sitting to consider a proposal for the rebuilding of the ducal palace. A sum of nearly a million thalers was voted almost unanimously for the purpose.

**WELDING STEEL AND CAST OR MALLEABLE IRON.**—Mr. William Carson Corsan, of Sheffield, has provisionally specified the use of a composition, consisting of borax, fifty parts; Calais sand, thirty parts; emery, ten parts; and manganese, ten parts, in the welding of steel and cast or malleable iron; but he does not restrict himself to these precise proportions.

**METROPOLITAN BOARD OF WORKS.**—The subject of the proposed gratuities of 6,000*l.* to the engineer, and 4,000*l.* among his assistants, was taken into consideration at last week's meeting of the Board, who decided, by a majority of 18 to 4, that the recommendation of the committee was excessive in amount, and the proposal premature; and that the subject be postponed until the works are nearer completion.

**THE LOCAL GOVERNMENT ACT, 1858.**—At a meeting of the West Hove Improvement Commissioners, held on Tuesday, a resolution was unanimously adopted, and without discussion, to apply the above Act to the district over which the said commissioners have jurisdiction, so that the whole of Hove parish beyond the Brunswick-square district, excepting some agricultural land, is now under the Local Government Act.

**DEMOLITION OF THE PIAZZA OF ST. LAWRENCE, READING.**—The local Board of Health having decided to remove the piazza on the south side of the Church of St. Lawrence, and also the projecting aisle known as "Knoollys Aisle," the resolution as to the piazza was at once carried into effect, and the old land-mark was destroyed before even a protest could be made against the resolution. The piazza was erected in February, 1619, at a cost of 100*l.*, by John Blagravo. The aisle, also, proposed to be demolished, was raised in 1637 by Sir F. Knoollys.

**SANITARY MATTERS IN IRELAND.**—At a meeting of the Belfast Board of Guardians, a member stated that he had visited Boyd's-court, in the middle of a dense and rich population, fifty yards from Donegal-place, and the like of it he never saw. He never saw human beings in such an awful place. They were without light. There was not a bed in the place, and they had nothing but wood shavings to sleep upon. He had to hold his nose the whole time he was in it. The people of Belfast should be ashamed of themselves,—talking of their missionary operations, and sending thousands of miles to catch a stray Laplander when there was such work for them at their own doors.—The churchwardens and officers of health appointed for the parish of Down in accordance with the provisions of the 69th George III., chap. 41, have issued a notice calling the attention of the parishioners to sections of the Act relating to nuisances; and stating that it is the intention of the officers of health to enforce the law without delay, in order to prevent contagious diseases.

**ARTISTS' BENEVOLENT FUND.**—The 56th anniversary of this excellent Fund took place on Saturday evening at the Freemasons' Tavern—Lord Bury, M.P., in the chair. The artists have two funds for the benefit of distressed members of the profession. One is the Artists' General Benevolent, which, like the present one, has been established more than half a century, from the funds of which relief is afforded to distressed meritorious artists generally. In the case, however, of the Artists' Benevolent Fund the benefits are strictly confined to those artists and their widows or orphans who have by their subscriptions or donations established a claim upon the fund. The one is founded on the provident principle; the other is purely benevolent. During the last year fifty widows of artists have participated in the benefits of this charity, and a large amount of relief had been afforded to deserving recipients of its funds. At the dinner, of which about 100 gentlemen partook, it was announced that her Majesty had, for the twenty-seventh time, presented her annual donation of 100 guineas.

SCARBOROUGH.—Two almshouses at Scarborough have been sold by auction, by order of the Charity Commissioners, who intend to erect new almshouses on some less costly site, and to give the poor the advantage of the surplus. The commissioners stipulated that the old inscription stone over the entrance of the hospital should be handed over to them for insertion in the wall of the new building, or otherwise. The inscription is as follows:—"These hospitals were built by Elisha Troat for two widows to live in, who died Sept. 19th, 1697." The property was purchased on behalf of the Local Board, who contemplate widening and greatly improving that part of St. Thomas-street in which this property is situated.

FAILURE OF GRANITE CASEMATE FORTIFICATIONS.—Recent experiments at Shoeburyness, it seems, show that granite is not only unsuited for resisting shot, but is a most dangerous material for those who are behind it. Two invent guns which go off at the wrong end, and wound the gunners, and we erect fortifications which are more dangerous to the defenders than to the assailants. What the course of the War Office will now be it would be idle to conjecture, but the regret must be universal that the fortifications at the entrance to the Thames, about Portsmouth, around the Isle of Wight, and generally round the south and west coast, should have approached so near completion on what must now be regarded as an erroneous principle.

DISCOVERY OF CANNEL COAL IN NEW SOUTH WALES.—The *Journal of Gas Lighting* says,—"Advices have been received, by the last overland mail, of the discovery, about 80 miles from Sydney, near a line of railway now in course of construction, of a workable seam of cannel coal, which surpasses the hitherto unrivalled Bog-head in richness. Its yield per ton is reported to be 17,600 cubic feet of gas of thirty-one candle illuminating power, and 745 specific gravity. The discovery must exercise great influence on gas-lighting in Australia, the East Indies, China, California, and South America, by enabling the gas-works of those countries to use their inferior local coals, and bring up the quality of their gas to a satisfactory illuminating power by the addition of a small quantity of Australian cannel."

THE IRON TRADE.—The following quotations are from *Raydon's Circular*, May 27th.—South Staffordshire pigs.—Common forge, 2l. 15s. to 3l.; better class, 3l. 2s. 6d. to 3l. 5s.; common melting pigs, 2l. 17s. 6d. to 3l. 2s. 6d.; better class, 3l. 10s. to 4l.; best makes, 4l. 5s.; cold blast, 4l. 15s. to 5l.; refined metal, 4l. 10s. Manufactured iron.—Marked bars, 8l. 10s.; hoops, 9l. 10s.; sheets, singles, 10l.; doubles, 11l. 10s.; latens, 13l.; angles, 8l. 5s. to 9l.; gas strips, 8l. to 8l. 10s. The commoner makes of our district in bars are being quoted at 7l. 5s. to 8l. at works; puddled bars, 6l. to 6l. 5s.; scrap bars, 6l. 10s. to 7l., according to quality. North Staffordshire: bars, 7l. 10s. to 7l. 15s.; best, 8l.; best steel, 8l. 10s.; best angle iron, 8l. 10s.; best T iron, 9l.; best plates, 9l. 10s.; Welsh bars, 6l. 10s. to 6l. 15s.; Welsh rails, 7l. 2s. 6d. to 7l. 5s. at works. These prices are quoted as "at works," unless when otherwise specially mentioned.

STEAM OMNIBUSES.—An omnibus drawn by a steam engine has commenced running regularly on the high road between Nantes and Niort. The road from Nantes to Niort presents several rather steep hills, which the engine with its omnibus, according to *Galigan*, ascends and descends with the utmost facility and safety. The engine, called the *Avenir*, weighs about 7 tons, with its provision of water and coals: it is 16 ft. 5 in. long, and 6 ft. 11 in. wide.

THE VICTORIA RAILWAY STATION, MANCHESTER. At Victoria Station the alterations are on a gigantic scale, and must involve a vast expenditure. The works are rapidly progressing. The station, large as, in its new shape, it will be, is capable of still further extension, as the wants of the public may require it. Its appearance, too, will be greatly improved. The new triangular roof is 60 ft. high, and we believe it was erected 12 ft. higher than was intended, owing to the extensive alterations made by the London and North-Western Company in their part of the station, some time ago. All the platforms at the Victoria Station are being raised to the level of the carriages, and new waiting-rooms and booking offices have necessarily been erected to accommodate the sub-divided traffic. The Salford Station is being remodelled and enlarged.

THE LIVERPOOL WHOLESALE MARKET QUESTION. At a recent meeting of the markets committee, Mr. Samselson proposed the adoption of a site near St. John's Market, which would give 10,840 square yards, at an estimated cost of 87,875l.; or, excluding corporation property, 80,000l. Mr. Fairhurst moved an amendment, to the effect that the site be at the North Haymarket, with an area of 13,000 square yards, at a cost of about 56,000l. The amendment was lost by 6 to 4. The meeting then adjourned, the original resolution not being put, as a further amendment is to be moved upon it.

TENDERS

For the erection of warehouses, Tower Royal, Cannon-street West, for Mr. J. Jacobs, Mr. M. S. Joseph, architect:—

Read & Son	£2,028 0 0
Lawrence & Son	1,883 0 0
Ashby & Horner	1,870 0 0
Hill & Keddell	1,849 0 0
Hardman & Sandon	1,830 0 0
Conder	1,817 0 0
King & Son	1,751 0 0
Axford & Sons	1,708 0 0
Brown & Robinson	1,647 0 0
Newman & Mann	1,688 0 0

For police offices and prison cells (except the warming and ventilating) for the Corporation of Sheffield, Messrs. Picketon & Abbott, architects:—

Byron	£8,800 0 0
Gosnell	8,675 0 0
Wade	8,570 0 0
Craven Brothers	8,480 0 0
Neill (accepted)	6,840 0 0

For a house for Mr. Robert Frazer, at Mistle, Essex. Mr. R. Barnes, architect:—

Saunders	£1,185 0 0
Girling	1,111 0 0
Hollis (accepted with modifications)	1,095 0 0

For additions to seed stores, in the King's-road, Reading, for Messrs. Sutton, Messrs. Wm. & S. T. Brown, architects. Quantities supplied:—

Searle	£1,164 0 0
Sheppard	1,169 0 0
Strong	1,154 0 0
Matthews	1,148 0 0
Dunn	1,147 0 0
Wheeler Brothers	1,136 0 0
Woodroffe	1,098 0 0
Strong	1,098 0 0
Barnicot (accepted)	1,099 0 0

For new school for British School Committee, at Redhill, Mr. Williamson, architect. The first two took out their own quantities; the others were supplied by Mr. Mathews:—

Cook	£773 0 0
Wesley	741 0 0
Hicksworth	839 0 0
Thornton	710 0 0
Sheppard & Room (accepted)	710 0 0

For building new warehouse and workshops, Newman-street, Oxford-street, for Mr. Crisp, Mr. J. B. Benwell, architect:—

Green	£610 0 0
Hyde	690 0 0
Southall & Watson	672 0 0
Tracey & Son	651 0 0

For new church at Wickham-road, Denford, Kent. Mr. F. Mearns, architect. Quantities by Mr. W. F. Meakin:—

Stone & Pierce	£13,562 0 0
Ryder	13,383 0 0
Sharlington & Cole	13,383 0 0
Dover	13,193 0 0
Sawyer	12,770 0 0
Myers & Son	12,662 0 0
Howard	12,463 0 0
Jackson & Shaw	12,350 0 0
Longmire & Barge	12,180 0 0
Stimms & Martin	11,560 0 0

For the chapels, registrar's houses, and lodges at the new cemeteries for Ashton-under-Lyne and Dukinfield. Messrs. Paull & Ayllis, architects:—

Eaton	£8,331 0 0
Storrs	7,879 10 0
Thompson	7,254 0 0
Horsman	7,052 19 11
Robinson	7,000 0 0
Barton (accepted)	7,000 0 0

For Christ Church Schools, Battersea, exclusive of teachers' residences. Mr. E. C. Robins, architect:—

Jackson & Shaw	£2,893 0 0
Sharlington & Cole	2,838 0 0
Fincher & Martyn	2,817 0 0
Brass	2,730 0 0
Maeers	2,719 0 0
Newman & Mann	2,702 0 0
Allen	2,700 0 0
Scrivenner & White	2,651 0 0
Nicholson	2,635 0 0
Bass	2,468 0 0
Lathey Brothers (accepted)	2,423 0 0

For new class-rooms, St. Stephen's Schools, Paddington. Messrs. Francis, architects:—

Myers & Son	£994 0 0
Colls & Son	925 0 0
Cowland	881 0 0
Hill & Sons	825 0 0
Reyes & Head	799 0 0
Higgs	799 0 0
Kelly	759 0 0
Fish	758 0 0

For parsonage-house, Christ Church, Battersea. Mr. Bennet Kays, architect. Quantities supplied:—

Jackson & Shaw	£2,150 0 0
Nicholson & Sons	2,145 0 0
Sharlington & Cole	2,085 0 0
Scrivenner & White	2,043 0 0
Fincher & Martyn	2,025 0 0
Allen	1,978 0 0
Lathey	1,943 0 0
Bass	1,880 0 0
Maeers	1,870 0 0
Brass	1,815 0 0
Newman & Mann (accepted)	1,783 0 0

For house and shop, Plough-lane, Battersea, for Mr. John Smith, Mr. Charles Boves, architect:—

Lathey Brothers	£333 0 0
Goldbolt	352 0 0
Lacy	335 0 0

For teachers' residences, Christ Church Schools, Battersea. Mr. E. C. Robins, architect. Quantities by Mr. Richman:—

Jackson & Shaw	£1,075 0 0
Allen	1,063 0 0
Fincher & Martyn	1,063 0 0
Sharlington & Cole	1,033 0 0
Brass	973 0 0
Nicholson & Son	968 0 0
Newman & Mann	948 0 0
Maeers	948 0 0
Bass	913 0 0
Scrivenner & White	901 0 0
Lathey Brothers (accepted)	891 0 0

For new buildings, Bishopsgate-street Within, for the City Offices Company, Limited. Works to level of ground-floor. Messrs. France, architects:—

Brown & Robinson	£11,131 0 0
Higgs	10,967 0 0
Reyes & Head	10,577 0 0
Hardman & Sandon	10,487 0 0
Hill & Keddell	9,990 0 0
Brass & Co.	9,970 0 0
Henshaw	9,845 0 0
Hill & Sons	9,630 0 0
Piper & Wheeler	9,667 0 0
Myers & Son	9,579 0 0
Myers & Son	9,430 0 0
Collis Son	9,430 0 0
King & Son	9,376 0 0

For additions, alterations, and repairs at the Jewish Free Schools, Bell-lane, Spitalfields, Messrs. Tiltott Chamberlain, architects. Quantities supplied:—

Nicholson	£13,576 0 0
Hill & Keddell	13,328 0 0
Myers & Son	13,296 0 0
Brass	13,294 0 0
Ashby & Horner	12,851 0 0
Patrick & Son	12,975 0 0
Piper & Wheeler	12,777 0 0
Lawrence & Sons	12,181 0 0
Ashby & Sons	11,782 0 0
Priceland (accepted)	11,782 0 0

For five attached cottages, Avenue, Denmark-street, Camberwell. Mr. J. Thomas, architect. Quantities supplied:—

Dennis	£1,780 0 0
Colls & Co.	1,772 0 0
Soper	1,735 0 0
Hill & Keddell	1,534 15 0
Pearce	1,565 0 0
Thompson	1,565 0 0
Minard	1,298 0 0
Pescott	1,280 0 0
Brashear	1,150 0 0
Wastrop (accepted)	1,067 0 0

For sundry buildings and additions to house and homestead at the Manor Farm Old Windsor, for the Commissioners of Her Majesty's Woods and Forests:—

Sargut	£2,230 0 0
Jenkins	2,217 14 0
Cowland	2,181 0 0
Ondes (accepted)	2,169 0 0

For "The Albert Wing," Royal Asylum of St. Ann's, City. Mr. J. Thomas, architect. Messrs. Wimbale & Taylor, architects:—

Hill	£6,065 0 0
Allen	4,934 0 0
Killy	4,773 0 0
Hardman & Sandon	4,628 0 0
Colls & Son	4,532 0 0
Adamson & Son	4,441 0 0
Sawyer	4,389 0 0
Hart	4,295 0 0
Stone & Pearce	4,206 0 0
Wills	4,200 0 0
Guland & Thompson	4,150 0 0

For alterations to No. 11, Warton-street, Oxford-street, for Messrs. Garrett & Whitaker. Mr. F. F. Holsworth, architect:—

# The Builder.

VOL. XXIII.—No. 1166.

[Portrait Miniatures in South Kensington Museum.

Y bringing together, in a fire-proof building, and in London, the much-prized treasures — heirlooms — tied down with legal restrictions, and accompanied with all the fears of fire and injuries and losses of every kind that unwillingness can suggest, with all their little omissions, a noble "exhibition of portrait miniatures" has been provided and may be studied at South Kensington. Many thanks to her Majesty's Committee of Council on Education, thanks to the sixty-nine gentlemen of the Committee, thanks to Mr. Secretary Cole (C.B.), and thanks to the cataloguers.

The collection was ordered and set about in the March of last year, and it is now open to the

world, with three thousand and eighty-one examples — many marvelous, many excellent, very many interesting, some mysterious, and not a few of very little moment. Still, we are glad to see them together, just as they are, and in so central a spot as Brompton.

The catalogue before us is a very handsomely-printed octavo volume, of three hundred and more pages, and has, as we have already mentioned, a short "Introductory Notice," by Mr. Samuel Redgrave, partly quoted in our last.

The compilation and publication of a full and satisfactory catalogue of a "loan" that is a temporary exhibition of works of art (a splendid annual) is no easy matter. The certainty that thousands on thousands will gaze with wonder, admiration, and ignorance on the portrait miniatures they see, was not properly before the minds of the House of Commons, the other night, when they were talking about the exhibition. It is true that neither Lord Palmerston nor Mr. Gladstone, on one side, nor Lord Derby nor Mr. Disraeli, on the other, need be told about Sir William Temple or Josiah Wedgwood, Hobbes the philosopher, or Hampden the patriot. True, also, that there are thousands of schoolboys who are well up in English and foreign biography; but still, there are tens of thousands more than pleased, and to be pleased, with this Government exhibition who would find their instruction and delight more complete had the catalogue been even more full than it is; — if the character of the persons represented (as weighed by really great names) had been appended to the numbers in it. We remember, in our hoyish days, an actually well-educated lady (*out* of the art, it will be seen, of recognising likenesses) mistaking the busts of blind old Homer and ringleted Virgilius Maro for blind King George III. and the Princess Charlotte. "Whom is that meant for?" said Lady K. to Sir Henry, at a Royal Academy exhibition. "Why, my dear, Lord Fitz — to be sure." And what was my lady's reply? "And so it is; — and how very like." My lady had

never recognised the likeness had she not been told.

Before proceeding further in what we have to say about this great *Miniature* Exhibition, we would say one word touching the use throughout the catalogue of the title or distinction of "Miniaturist." Holbein and Hilliard, Isaac and Peter Oliver, John Hoskins and Samuel Cooper, Christian Frederic Zincke and Henry Bone, nearer our own time, would not have known what the calling or profession meant. John Hoskins, one of the greatest of the several names we have mentioned, signs his will as "John Hoskins, Limner;" and the illustrious Sir David Wilkie, who died in 1841, was "Limner" to the Queen for Scotland. We trust that "miniaturist" will not take dictionary root in "the Queen's English."

That mighty master in miniature Isaac Oliver leaves in his will (he died in 1617) to his famous son Peter, "all my drawings and *lymning* pictures, he they histories, stories, or anything of *lymning* whatsoever."\* And while Isaac and Peter Oliver engage our attention, let us state for the information of the Committee of Council on Education, future editors of Walpole, and future catalogue compilers, with kindest intent, that Peter Oliver died in 1648, not in 1660. His will, dated 13th of December, 1647, may be seen for a shilling in Doctors' Commons, where it was proved on the 15th of December, 1648.

There are many portrait-miniatures in well-known collections in England that are not (very rich, we repeat, as it is) in this Kensington garnering. We find nothing here from Burleigh House (the Marquis of Exeter's); — nothing here from Hatfield House (the Marquis of Salisbury's) — the wealthy in works-of-art representations of the two great Cecils of the reigns of Elizabeth and James; — nothing from the Vere, Cavendish, Bentinck, and Harley collections at Welbeck (the Duke of Portland's); — nothing from Hamilton Palace (Duke Hamilton's); — nothing from Longleat (the Marquis of Bath's); — nothing from Ham House, in Surrey, the seat of the Earl of Dysart, where we have seen the finest and largest John Hoskins we have ever seen; though we were at the Manchester Exhibition, and saw the Welbeck and Balstrode collections formed with so much judgment and liberality by three *Harleys* of three generations: (1) the Lord High Treasurer Oxford; (2) his son (Vertue's friend in art; Oldys's friend in literature, and still much more), Edward Earl of Oxford, a magnificent and munificent collector; and (3) his daughter, Margaret Cavendish Harley, the Duchess of Portland, whose name is inseparably connected with art in the precious "Portland Vase" of antiquity and all time. What we have said, however, is not by any means intended to reflect on those who have gathered together the Brompton exhibition, for they have worked well; but to show the amount of this description of wealth to be found in England.

It seems strange that in an art so exquisitely delicate as miniature painting, women have not excelled. One would have thought that the delicate fingers and lustrous eyes that make such marvellous work with needlesfuls of coloured silks and threads, would be able to supply "a Queen of Beauty" on the reverse of a queen of hearts in a pack of playing-cards. Few have heard, or will ever hear, of Mary Beale, of the seventeenth century; of Frances Reynolds (Sir Joshua's sister), in the eighteenth century; or of Maria Cosway or Mary Ann Knight, in the nineteenth century. Staring into handsome men's faces, to transfer their lineaments to canvass or cardboard, is not altogether becoming

Miss in her teens; or the lady who, when asked in a court of law how old she was then (when the transaction took place), replied with sweet reluctant delay, and "said a smile to a tear" kind of look — "She did not know how *old* she was *then*; but she knew (her modesty still on the increase) how *young* she was *now*." This was up to the mark of Mrs. Mary Anne Clarke's reply (in the Duke of York case) to Mr. John Wilson Croker. Pride and paint, Dryden says, in his famous epistle to Sir Godfrey Kneller, were the main causes of the fall of Eve. It is true, he afterwards omitted four lines, in which the cause is so characteristically told by the great poet.

The seeming wonder we have expressed that *ladies* have not taken to limning or miniature painting, is strengthened by a practice which we find, from the collection of miniatures under review, more customary than we thought it. Many early *limnings* are drawn and coloured on the backs of playing cards. Miss Arabella Fernor's painted face, in beautiful *miniature* art, on the hack of the queen of hearts, and Lord Petre's patched and powdered face, of a like skill, on the hack of the knave of diamonds, would command good money "quotations" under the King-street hammer of Messrs. Christie, Manson, & Woods.

We were to "place" Mr. Redgrave's "miniaturists" in the order of their several merits, we should be inclined to rank them somewhat in this way; and we have our judgment on more examples than are to be found in the present collection, admirable as it is: —

In colours, on card or ivory.	{ Hans Holbein. Nicholas Hilliard. Isaac Oliver. Samuel Cooper. Peter Oliver. John Hoskins. Thomas Flatman. Sir William Ross.
In enamel.	{ Pettit. Zincke. Henry Bone, R.A.
In pencil, uncoloured.	{ Robert White. William Faithorne. David Loggan. George Vertue.
In chalks or crayons.	{ Samuel Cooper. Archibald Skirving.

We purposely omit the living.

As pictures of saints are known by their emblems, so many of the nameless miniatures in this and other collections might be identified by the mottoes they bear. Let us illustrate our position. Supposing there was in the Kensington collection a fine miniature of the age of Charles I., like the great Marquis of Montrose, and so called but upon insufficient authority: all doubt would be at an end if the miniature bore the emblem of two rocks with a chasm between, a lion mounted on a pinnacle, and the motto "Nil Medum;" for such a seal was used by the gallant Graham, as we know by existing letters in his own handwriting. Again, could we find in the collection a miniature said to represent Dr. Donne, the divine and poet, "in a melancholy posture," and with a motto about it, "De Tristitia ista libera me," we should reduce all doubt to certainty, for we know, on indisputable authority, that Donne gave his portrait to the poet Earl of Ancrum with such a motto. Again, should we see a contemporary miniature believed to be Sir Philip Sydney, and like the known portraits of him, we should have full confirmation of its being so, beyond cavil, if it carried the motto "Sine refluxu," alluding to the Caspian Sea, which neither ebbs nor flows. Other instances might be given in great numbers; and here let us observe, that among the Trustees of our National Portrait Gallery a first-rate herald and a first-rate genealogist are sadly wanting, men like Garter-King-at-Arms and Mr. John Gough Nichols.

Several portrait limnings or miniatures in

\* See the will of Isaac Oliver, first printed in 1863, by the Camden Society, in "Wills from Doctors' Commons," edited by John Bruce. George Vertue drew up a catalogue in January, 1742, of "The Right Honourable the Countess of Oxford's Miniatures, Enamels and Limned Pictures, in one of the cabinets near the door." It is still in MS.

early MSS. on vellum and on paper are of all-absorbing interest to Englishmen. Such (foremost above all) is the whole-length of Geoffrey Chaucer, the father of English poetry, among the Harleian MSS. in the British Museum, most admirably copied with its colours by Henry Shaw into one of his many capital contributions to the history of Mediæval art. Oocleve, the poet, was the scholar of Chaucer and the artist. Such, too (if we could fully believe in it) is the William Caxton, the father of English printing, among the Lambeth Palace MSS.—believed in by Vertue and Horace Walpole, but very much doubted as "Caxton" by an accomplished English antiquary, the late Thomas Hudson Turner, who, in several conversations we had with him on the subject, was more than a Dis-senter—an Unbeliever. An Act of Parliament alone (such as was passed in the Soane Museum case, respecting the Hogarth for South Kensington) could have removed these for a time to Kensington; but we own to a hankering wish, shared in by many, to have seen them there.

"A minute" of the Right Honourable the Lords Commissioners of her Majesty's Most Honourable Privy Council on Education, under whose careful auspices this "Special Exhibition" has been brought together, could move Lambeth and Whitehall to Kensington without any risk, to the gratification of an innocent and instruction-loving desire.

Here we must close for the present. Three thousand and eighty-one miniatures are not to be fully examined, passed judgment upon, and written about in a hurry.

#### ARCHITECTURAL NOTES OF TRAVELLERS.

Much valuable information connected with architecture and its history lies hurried in books of travels of a kind that seldom meet the eye of the professional architect; books addressed to the general reader, and calculated to kill time agreeably, with a slightly narrative of the ordinary incidents of travel,—books, in short, which the busy architect, in the pursuit of an active profession, has not the time even to glance at. And yet the authors of such books are often persons of cultivated taste in art, who seldom fail to record their impressions of any remarkable monuments they meet with; not unfrequently describing works of art which lie out of the beaten track of legitimate artistic toning, and which in many cases are not referred to in any existing works of a professedly artistic character.

Many such light hooks of travels that have recently issued from the press present to us, in the midst of slight gossiping chit-chat, very valuable information, *en passant*, connected with little known and often very remarkable monuments of art, every particular connected with which, however slightly hinted at, is full of interest as coming from the actual observation of a recent visitor, on the spot. A new hook of travels in Albania and Dalmatia, though only claiming to be a slight journal kept during a summer trip of a few weeks, is yet full of glimpses, and something more than mere glimpses, into the ancient architecture of a region which is brim-full of architectural interest of a kind that is very little known.\* With the exception of various notices of the remains of Domitian's palace at Spalato (almost invariably written *Spalatro*), the whole region lying between the northern boundary of Greece proper and the course of the Danube is nearly a *terra incognita* to the modern student of art history. And yet it comprises within its limits the whole of ancient Macedonia, and was, during the Greek and Roman periods, quite a focus of European civilization. Under the dominion of Rome, it was the link which connected the eastern and western divisions of the vast empire. It was a region studded over with Greek cities, which became greater and richer under the Roman dominion, as being directly in the line of overland communication with the Roman east. It was at the most important

part of this Roman line of overland route, on the banks of the Bosphorus, that Constantine determined to transform the small Greek city of Byzantium into a vast midway emporium, that should, from its position as the link of the east and west, become the centre of the vast empire that comprised both Europe and Asia within the circuit of its dominion. After this foundation of Constantinople, and the subsequent separation of the vast Romanised world into the empires of the East and West, Greece and the regions immediately to the north, as far as the Danube, became the European centre of the arts of the Eastern empire, as Syria had been under the Greek dynasties, in the East. It was, then, under the sway of the Eastern emperors that Byzantium, under its new name of that Early Christian art which we term Byzantine; and an endless number of churches and monasteries erected in that interesting style sprang up in every part of these European provinces of the Eastern emperors. From the fifth to the fifteenth century, a period of a thousand years, this state of things continued, though for the last half of that period undergoing gradual declension and decay. And then came the overwhelming conquests of the Turks, the fall of Constantinople in 1453, and the absorption of all the fine region in question into the gloomy darkness of the Turkish empire; since which time, four centuries of oblivion have, as it were, utterly effaced both the Classic and Byzantine glories of Macedonia, Thessaly, Epirus, and all the surrounding provinces as far as the Adriatic, from the pages of artistic record.

It is only within the last few years that light has been let in upon some portions of this interesting region. The still lamented M. Papesti, who made a charming series of drawings of the churches and monasteries of Mount Athos, with their curious Byzantine frescoes still fresh and bright upon their glistening golden grounds, was one of the pioneers in this direction. Since then, the Macedonian exploration, under the authority of the French Government, has added greatly to our knowledge of the noble remains of art still existing in these provinces, and the grand marble doors from a Macedonian tomb, with the bronze hinges still perfect, now in the Louvre, are sufficient to show what brilliant results other expeditions of the kind may be expected to bring to light of Messrs. Texier & Pullan's book we have recently spoken.

Other less artistic and scientific travellers have since been aiding and assisting in obtaining further glimpses into this vast *camera obscura* of hidden art; and although architects may not deem such knowledge of a sufficiently accurate nature to be professionally valuable, they should recollect what we often owe to travellers who make no pretension to being either artistic or scientific explorers. To M. Butte, for instance, simply a consular agent in the interests of French commerce, we owe the first revelations of Assyrian art on a grand scale; and to an English traveller, neither architect, painter, nor professional servant, we owe the still greater discoveries, in the same field, that have enriched our national museum with a noble series of monuments of a grandiose style of art hitherto unknown to us. When first the continental drawings of Prout, Stanfield, and Roberts, so strongly arrested public attention as exhibiting architectural forms and combinations, often entirely fresh to those who only knew our North-western Gothic, and the set styles of the "five orders," a certain class of architects, when it was proposed to them that they might get ideas from them, replied that, in a professional point of view, such representations were utterly useless, as being the work of persons unacquainted with the technicalities of the art. Happily, this line-and-rule school of architects has passed, or is rapidly passing away. The art is fast casting off its mechanical and technical trammels (perhaps too recklessly), and its professors are ready to receive, at the full value, every grain of proffered information.

Among the chief objects of architectural interest, described in the book of travels above referred to, is the Cathedral of Parenzo, now an insignificant place, nearly opposite Venice, on the Dalmatian coast of the Adriatic. When it was a city of some importance, during the early years of the Eastern Empire, and during the reign of Justin I., the present cathedral was built. Justin had interested himself greatly in church matters, and succeeded in reconciling the Greek and Roman churches after a long and acrimonious schism; and it was during this period of eccle-

siastical activity that several of the Byzantine churches of Macedonia and the adjoining provinces were erected, and among others it would seem the Cathedral of Parenzo; for, as our traveller was informed, it was finished in the year 526, the last year of the reign of Justin I., and the year before the accession of Justinian. This would make it older than the enrius and celebrated Byzantine Church of Santa Fosca, on the island of Torcello, in the Venetian Lagoon, and place it in the purest and most interesting period of Byzantine art. Justinian continued the efforts of his predecessor to re-establish the unanimity of the church, and to extend the influences of the Christian religion. He constructed twenty-five churches in Constantinople, besides entirely rebuilding the celebrated Church of St. Sophia, on a scale of such splendor, that on contemplating the completion of his own work in the magnificent Christian temple which had arisen under his immediate direction, it is recorded (as every one knows), that he could not forbear exclaiming, "Glory be to God, I have vanquished thee, O Solomon!" This was the most vigorous and brilliant period of that Greco-Gothic style that sprang from the union of two distinct theories of art which met and mingled in the Eastern capital of the Roman empire. It was the epoch of the full development of the distinctive features of that kind of architectural composition which we term Byzantine. Taking into consideration the splendor and important scale of the Cathedral of Parenzo, one might almost feel inclined to dispute the date appended to it at Parenzo, and assign it to the reign of Justinian, more especially as the details of the capitals and other portions of the ornamentation appear to be very closely similar to those of St. Sophia. This, however, need only alter the date some twenty years, and that given may, in fact, belong to its commencement in the reign of Justin, at whose death it may have been left incomplete, and have been finished a few years later by the famous artists of Justinian.

The traveller describes the building as a basilica with atrium, a two-aisled nave, and one chapel; a modern transept and some other chapels having been added at later periods, and in very inferior styles. "At the east end is a rounded apse, as glorious in its mosaics as that of Santa Sophia." Every part of the wall and roof is, indeed, covered with mosaic, as we are informed, and especial admiration is expressed for a group of nine saints and angels surrounding the Virgin and Child, on a gold ground. Heads of saints adorn the spaces between all the arches, and they are said to be very beautiful. To about 10 ft. high the walls are inlaid with whole shells of mother-of-pearl, set into dark brown stone, which "looks like a rich piece of Damascus furniture," and though in principle this kind of decoration is a somewhat rude device, it is said to be effective, and even beautiful. The entire floor is composed of coarse mosaic, in curious Byzantine patterns; but, exclaims the traveller, "one can scarcely look at anything after the wall mosaics, except the capitals of the columns." The columns themselves are of polished brown marble, and the capitals, exactly in the style of those of Santa Sophia, but perhaps a little bolder in treatment. Their design forms a perfect lacwork of flowers, birds, and foliage, most elaborately and deeply undercut, and all the features made out clearly and gracefully with the greatest life and spirit, yet with no idly superfluous work. "Not a single line thrown away!" exclaims the fascinated spectator, expressing a hope at the same time that ere long this series of capitals may be photographed, as exquisite gems of Byzantine art.

The Baldachin is described as very fine, and of exceedingly curious workmanship, the ancient hangings not being its least interesting and beautiful feature. Of later date is a beautiful Renaissance altar-front, entirely of silver gilt; and of the original date are the remains of a porch and cloister, of which, unfortunately, only a few columns remain. The author's account of the cathedral coincides with the expression of a firm conviction that it is well worth the time, expense, and trouble of a special journey from England to see it.

The account of the visit to Pola, a little lower on the coast, is not without a few remarks of architectural interest. The well-known amphitheatre is, of course, dwelt upon. Its vastness, indeed, strikes all travellers who have seen it; and Sir Humphrey Davy describes in his best manner the grandeur of the monument as he saw it, at sunset, with the rays of yellow light

\* "The Eastern Shores of the Adriatic." By the Viscountess Strangford.

streaming through its arches. There is no attempt at architectural ornament in this vast structure; but the masonry is beautiful, and the immense stones, blocks of coarse white marble, of which it is built, are fitted to each other without mortar.

At Fiume, a fine brown marble is noted, which might become a valuable commercial staple, as it is very abundant, easily taking a high polish, and its rich nut brown is described as being of unequalled richness. There is also abundance of a good yellow marble; and a valuable material for making compost should not be overlooked by our enterprising cement manufacturers. This material is obtained from Santorini, and at the time of our traveller's visit one of the quarries was crowded with vessels laden with it. So important and valuable is this material, that a commission from our Royal Engineers has, it seems, just been sent out to examine into its qualities, and study the methods of working it; so that our men of commercial enterprise, if not wishing to be left behind, should lose no time in seeing into the matter.

The castle of Tersatto, near Fiume, is, at a distance, a very remarkable object, from its commanding position. It was bought by the late Field Marshal Count Nugent, who wasted great sums of money upon it without producing any other effect than that of a vast "Castle Rackrent." The only thing he completed was a kind of temple, in a bastard Grecian style, over a dungeon which he prepared for his own sepulchre, and where his remains now lie. In some sheds about the castle are a number of fragments of ancient sculpture discovered in the neighbourhood. They are without special interest, except as showing how rich the whole country is in artistic remains, especially of the Roman period.

The small city of Zara, nearly opposite to Ancona, on the Italian coast, has some architectural attractions worth referring to. It was once in possession of the Venetians, and a trace of their possession is found in the ancient gates of the city, which, though Venetianized on one side, still remain Roman on the other. Among other relics of the Venetian occupation, in the shape of architecture, are the handsome gate, called Porta di Terra-firma, a work of Michaeli, erected in 1543; and a handsome loggia, of true Italian style, in the Piazza dei Signori, close to which is a solitary Corinthian column, of fine character, the last remnant of a Roman temple.

The cathedral of Fiume is mentioned as a fine building, in the severe Lombardic style of the thirteenth century, said to have been erected by the French and Venetian Crusaders, who made this place a permanent station on their way to the East. The west façade is covered with arcade-work, with two fine rose-windows and three deeply-recessed doors. The capitals of the columns of the nave are, it appears, some of them of the severest Lombardic block style, while others are of a very florid bastard Corinthian. A remarkably beautiful triforium of white marble runs round the nave, and balustrades of the yellow marble, previously referred to, inclose the chapels. The stalls are remarkably rich, and each is surmounted by a small gilt figure holding a scroll, containing the name of the stall. The crypt is also very fine, and in a curious style. On the whole, the edifice appears well worthy of careful architectural study; and there are other remarkable churches in the place. Sebenico is another of these little Dalmatian cities which calls out the traveller's evident love of art. There is a fine loggia on the principal piazza; but the great attraction to the architect would be the cathedral, though of comparatively late date, having been commenced in 1415, and finished in 1555. The western façade, which is very rich, in the transition style of the period, has lost many of the statues which originally adorned it; but its fine rose-windows, one of twelve and one of twenty-four lights, are in remarkably perfect condition. The interior is described as being very grand in general effect, and many of its details appear to be curious. All round the top there is a gallery, adorned with "square white marble triple columns with very elegant flower-mouldings." It would be interesting to know more about this peculiar feature, and the details of its arrangement. From the centre of the edifice springs a lofty dome, the drum of which is pierced with what are described as *Conquero windows*. Each chapel of the choir is said to be inclosed by a range of white marble colonnettes; while the stalls, also sculp-

tured in fine white marble, do not appear to be remarkable, except for the beauty of their material. The baptistery is said to be a Medieval copy of that of Constantine at Rome. There are many existing relics of the former importance of the cities of this region, especially during the period of Venetian supremacy. One of the old nobles of Sebenico, for instance, has a fine picture by Andrea Schiavone, who was a native of the place, and also a fine picture by Tintoretto, now much injured; and he possesses also an exquisite piece of artistic chasing in metal, a splendid dagger, which formerly belonged to Matthias Corvius, King of Hungary.

But the most interesting church in Dalmatia, speaking archaeologically as well as technically, is that of Trau. It is one of the most perfect examples in existence of the true Lombardic Romanesque, and was commenced in 1213. The exterior has all the massive solidity of aspect of the best specimens of the style, but it is well enriched with good ornament, which prevents the effect from being heavy. At the east end is a group of the usual semicircular apses, and at the west end a porch or arcade along the whole front, which, from its proportions and execution, produces the finest possible effect. From the centre of the western façade rises a campanile of two stories, which is described as exceeding beauty, somewhat Oriental in style, having some of the Moresque characteristics which pervade some of the Gothic work of the Spanish architects of the same period. The great western entrance is described as excessively rich in sculpture, the mouldings of the doorway being profusely enriched with magnificently-executed borders; and what are described as "the flat surfaces at the sides," are also covered with the "closest sculpture." Large figures of crouching Turks are made to play the part of Gothic caryatides in this entrance, while statues of Adam and Eve, whose history is sculptured in compartments around, are supported on the backs of winged lions of St. Mark; and, finally, the vanings of the porch are enriched with "rope-mouldings," springing from "spiral columns." It would seem that this western doorway as well deserves a photograph as the capitals at Parenzo, over which the traveller's enthusiasm was so much excited. At the end of the porch is a baptistery, which appears also to have its curious and distinctive features. The interior of this church of Trau also merits a more detailed description than it was the purpose of our present traveller to bestow upon it. Its alabaster columns and good sculpture, and its curious stalls richly carved in black oak, appear to be very remarkable features. Then there is the rich white marble pulpit, and the singular baldachin over the tomb of William, the son of Baldwin, the crusading emperor of Constantinople. The south transept appears to be of very singular and unusual character. The walls are divided into seventeen compartments, in each of which is sculptured a small Cupid-like figure holding a torch; while the ceiling or roof is formed, in a most singular manner, of diaper pattern produced by the heads of cherubim, in the midst of which is the figure of the Almighty, a kind of device very common in illuminated missals of the thirteenth and fourteenth centuries, in which the heads are generally painted in shades of rich vermillion, or in ultramarine, heightened in the high lights with gold; but, although this kind of device is common enough in missal painting of the thirteenth century, there is scarcely no other example of its reproduction in sculpture. The capitals of the main columns appear to be composed of figures of the same kind as those in the wall compartments; but the author's notion about their being possibly intended for *Cypriads*, and the whole transept to be a sort of *temple of Hymen*, causes the narrative to blossom out into facetia, which greatly obscure the meaning of the description. This church possesses some gold and silver work of very high character, and it is sufficiently evident that altogether it is well worth a pilgrimage to Dalmatia to examine, especially as Parenzo, and other places which we have still to glance at, lie close at hand, and may be seen during the same journey.

In the Gulf of Salona, a little lower down the coast, the convent of Palndi should be visited, on account of the curiously-sculptured pavement of the pretty little church; and two illuminated volumes in the library should not be forgotten, as very gorgeous but somewhat coarse examples of a late phase of that beautiful art.

At Lesina, still lower down the coast, a number

of interesting specimens of Venetian architecture of the true type will well repay a visit, some of the examples being exceedingly good, especially a loggia by San Michele. But the gems of Lesina are the two exquisite campanile towers of the Byzantine church.

The picturesque Ragusa, it would seem, would make a delightful artistic centre from which to make excursions, and is, in addition, full of interesting objects for the student of art. The ancient Dogana, or custom-house, is a very beautiful building, in the palatial style of the greatest age of Venice, but having Ragusan peculiarities of its own well worthy of architectural study. The town-hall is said to resemble the Ducal Palace at Venice, and to be almost as fine a building; the six huge capitals of the colonnade being perhaps even richer and more beautiful than any of those of the famous palace of the Doges, but perhaps more Byzantine in style and treatment,—the one representing *Asclepius* reading in his study, surrounded with various implements of the healing art, being a perfect marvel of intricacy and finish. The interior is in many respects as full of architectural interest as the exterior, and the staircase, with its noble rail of richly floriated ironwork, calls for special attention; while other specimens of the same art, in which the Ragusans appear to have been very skillful, may be seen in the clock tower, *Torre dell' Orologio*, close by. The bronze well-covers which abound are also very remarkable, and marble fountains, semi-Oriental in style, invite study, and appear to be full of useful hints to the architectural student. The Renaissance cathedral is described as very inferior to the Byzantine churches of Dalmatia, but the rich gold work encasing many of the relics, is said to be of truly marvellous beauty. We are told that much remains to be learnt concerning the beauty of the gold and silver work of Dalmatia, Hungary, and all the Slave countries. The gold jewellery of the peasantry shows that the taste still exists, though in many instances the peculiarly wrought gold beads and earrings are heir-looms, which have been in the same family for centuries. The gate of the relic chapel is a specimen of delicate bronze work, which seems to surpass all the other specimens of Ragusan skill in metal working.

Cattaro is the next point of artistic interest touched at, and every one of the picturesque narrow streets of the place seems to be quite a little school of Byzantine art. "Scarcely a dozen yards of any one of them can be passed," we are told, "without lighting upon some delicious little morsels of Byzantine architecture," and the handsome Venetian-built sea gate is a very fine monument. The façade of the cathedral is also worthy of close examination. Over the porch is a beautifully designed gallery, from which the bishop gives his blessing to the assembled people; and above it is a beautiful rose-window, with sixteen richly trefoiled lights; while the "soffit" of the great entrance, and all its mouldings, are very richly sculptured. There is also a Romanesque church of good style. In the neighbouring inlets along the coast here, the artificial colours of architecture may be studied with good effect. Some of the cottages and villas,—many of them constructed in very characteristic styles,—are all highly coloured, in pink, yellow, or even sky blue, and the effect is often very happily successful.

A trip inland to Joanina or Janina and its neighbourhood, will, it seems, repay the traveller in the shape of a profusion of ancient frescoes in the monastic churches of Nisi, of various ages, their gold grounds glistening in the "dim religious light" with a singular and impressive effect, imparting a peculiar kind of splendour. But the most remarkable thing at Joanina is an altar, stretches all across the church from wall to wall between the nave and chancel, according to the Greek arrangement. It is about 40 ft. long and 18 ft. high. Its material is walnut wood, and the piercings and carvings are of the greatest elaboration and delicacy. It is divided into elegantly proportioned panels, containing figures of saints, and further enriched with bouquets and borders of fruit in high relief, which partially conceal the figures of angels and beads of cherubim carved in lower relief beneath the foliage. Other screens of the same kind, it is said, are to be found in many of the Greek islands, especially at Mitylene, all of which should be hunted out and photographed on a large scale, before decay, or more to be feared innovations, destroy or disfigure them. An English traveller, it appears,

has recently offered a very large sum of money for the Janina screen, but it seems that the ill-paid and worse fed ecclesiastics feared to clinch the bargain. At all events, if the work be equal to the expectations raised by the present account of it, casts might be made, from which a *fac-simile* of the work could be erected in plaster at the South Kensington Museum.

Enough has been shown to demonstrate that no region could offer greater temptations for an architectural tour of professional character than the coast of Dalmatia, whence it is quite evident that a series of architectural examples of great beauty, and frequently of great novelty of character, might be gleaned with small trouble or exertion.

A railway trip to Vienna may now be rapidly accomplished with but few interruptions, and that would be a good *point d'appui* from which to visit the opposite shores of the Adriatic. Small steamers are once or twice a week making trips along the coast, and stopping at the various ports of the islands as well as those of the mainland. In short, what may be termed an architectural trip might so easily be made to that tempting region, so rich in a class of Christian architecture hitherto very imperfectly studied, especially in its more Oriental aspect, that it is to be hoped the prospect will prove irresistible to some architect, who might doubly repay the expenses of his trip by a book on the subject of Dalmatian art, illustrated with a rich series of good working drawings, sufficiently large and accurate to serve as hints to our stay-at-home students.

#### FAMOUS SEATS.

The subjective association of people with their accustomed places leads us to look upon various objects with interest which would, perhaps, have little charm for us but for this relationship. After the houses in which celebrities have lived, and the clothes or trinkets they have worn, we seem to feel this association of idea in its greatest intensity when we look upon their vacant seats. Beranger gave expression to this feeling in his "Songs of the People," when he caused the village crowd to exclaim, as his "old and hoary dame" related her reminiscences of Napoleon's visit to her house,—

"Mother, and was that the chair?  
Mother, was he seated there?"

As might be expected, we have several chairs and seats preserved as relics of departed celebrities, although their number is not so large as we could wish. A gallery of famous seats would be at once instructive and attractive in the now frequent exhibitions. We throw out the hint for the benefit of those concerned in organizing the most recently proposed of these.

Applying the theory of development to furniture, the first stage of a seat is a stool; the second, a chair; the third, a throne; the highest, a canopied throne raised on a dais. Perhaps, the three-legged stool was the precursor of the four-legged one; but, whether this was the case, or *vice versa*, we are never likely to ascertain. We can see, however, how the addition of a back to a stool made it into a chair; and the further addition of arms developed it into an arm-chair; and the adoption of a large scale and costly materials exalted it into a throne.

We need not trust entirely to the illuminations of Saxon MSS. for information concerning early seats, for we have actual examples. There are Saxon friestols, or stone seats of peace, preserved at Hexham, Beverley, and Sprouburgh. The last of these three is but little known, but an illustration of it may be seen in a little volume recently published by the Rev. Scott F. Sturtees, entitled "Waifs and Strays of North Humber History." Besides these stone seats we have an early wooden chair preserved in Jarrow, which is said to have been used by the Venerable Bede. This consists of a seat, having three planks, reaching from the ground to a convenient height, to form the back and sides. The boards forming the sides are sloped away from the front of the seat till they die into the top of the back. Although there is nothing distinctly indicative of Saxon workmanship about this seat, there is nothing that negatives the assumption of its great antiquity.

The Glastonbury chair has a reputation of interest. It was the property of Horace Walpole for some time, and formed one of the attractions among his curiosities at Strawberry Hill. At the

dispersion of those objects at the memorable sale, it was bought by Mr. Smyth Pigott, of Brookley Hall, Somersetshire, for 75*l*. It was again sold in October, 1849, to Mr. Brackenridge, of Cleveland, this time fetching only 49*l*. The following is the account of it given in the catalogue of the sale in which it changed hands:—

"351. A very ancient chair of oak which came out of Glastonbury Abbey; on it are carved these sentences:—'Johannes Arturus, Monachus, Glastonie—Salvet enim Deus De Pacem Domine, Sit laus Deo.' This chair, from its authenticity, shape, and extreme comfort, has been repeatedly copied, particularly for the late Earl Bathurst. It belonged to Sir Robert Walpole, and was purchased by Mr. Pigott, at Strawberry Hill sale."

Another famous seat is preserved at Dunmow, an illustration of which is given by Dr. Chambers in "The Book of Days." It is used in the ceremonies attending the award of the fitch of bacon to contented couples.

At Bedford, in the vestry of the new Baptist chapel, erected on the site of the "old meeting," is preserved a chair for the sake of its owner, John Bunyan, the enrapt writer of the "Pilgrim's Progress." This is illustrated in "Pilgrimages to English Shrines," by Mrs. S. C. Hall.

The coronation chair in Westminster Abbey, in its intimate association with our successive kings and queens, may be called the seat of honour. We have so recently given an account of it in our notice of Mr. Scott's "Gleanings in Westminster Abbey," that we need do no more than mention it in this list. Holyrood, too, has chairs of regal association. The Woolsock is another famous seat; although, perhaps, not available for the exhibition we have suggested. Ducking-stools would be, however, a curious branch of the subject. These were terrible realities in their day; and our museums possess several forms of them. As a contrast to the scolding, screaming dames, and the noisy scene of the execution of the ducking sentence, it is composing to remember that some famous seats have had a reputation only, but no existence; Miss Eliza Cook's "Old Arm-chair" being a case in point. Where, for instance, could our collectors look for the "seat of the scorners," or the "stool of repentance?" And that others have had both reputation and existence, but the former only survives, as in Canuto's chair, from which he bade the waves retire. Sedan-chairs would be a further appropriate variety. The chairing of members of Parliament is intended, perhaps, as a simple honour only; but it is interesting to trace the observance of a similar mode of showing respect to Rome, where the Pope is always carried on men's shoulders in a gorgeous chair, on ceremonious occasions; and to take the two facts together, and see an adaptation of a rare custom to every-day convenience in the sedan-chair. To be invited to take the chair, and be the chairman at a public meeting, is another form of the same intention to pay respect.

We leave the suggestion of collecting all our identifiable and historical chairs that are available for the purpose into one group, with a catalogue of a few scattered curiosities not available:—The Queen's Bench, London; King Arthur's Seat, Edinburgh; Cedar Idris, North Wales; the civic chair; and a country-seat.

#### THE LATE MR. WILLIAM DENHOLM KENNEDY.

It has been observed, more than once, that the world which receives delight from the productions of men of genius, little wots of the anguish that sometimes attends upon the work, or of the amount of effort wasted that there is behind the presented scene. If anything could be wanting to urge the Government, the nation, and the Royal Academy, to terminate the unsatisfactory state of things which is represented by the arrangement of the works of art in the galleries in Trafalgar-square, and the rejection of pictures that are of great merit, it would be afforded by the relation of facts such as from time to time come to light. Each year we hear of an increased number rejected, of works that, it is not disputed, as well deserved place as those which are exhibited; whilst also we see a considerable portion of the pictures placed where no picture can be appreciated, or so that their exhibition is productive of as much pain as advantage to their authors. Not long since, an artist of great excellence, Müller, dying, spoke of the treatment which he felt he had received at the hands of the Academy, and to which his death was ascribed; and last week there was another

melancholy instance of effects that may be produced through the condition of affairs administered to the best of the means and ability of the Academy, acting upon a peculiarly sensitive mind, such as is often that of an artist.

In the present exhibition of the Academy, in the North Room, numbered 588, and placed next the ceiling, where it is impossible to discover the beauty which we believe the work has, is a picture to which is attached the title in the catalogue,—"The Land of Poetry and Song," together with the quotation,—

"Ah, monarchs! could ye taste the mirth ye mar,  
Not in the toils of glory would ye fret;  
The hours dull drum would sleep, and man be happy yet."

It is the last principal exhibited work of one, William Denholm Kennedy, who might be ranked with some of the first of English painters, or those who have been the brightest ornaments of the Academy, whose chief honours in the schools he gained. He lived to feel himself neglected and passed over; for, though more than once within one vote of his election as an A.R.A., he never gained that distinction—perhaps because he was too proud to solicit it; and anxiety about the reception or treatment of the work which we have named, and some mortification at the actual result, acting upon a diseased frame, and coupled with grief at a severe bereavement, have sufficed to terminate his life. He had himself observed that his anxiety on the subject of his picture would "kill" him; and when the exhibition opened, and it was seen where the picture was hung, his friends made the same remark, and dreaded answering his inquiries. He was found dead on Friday morning, the 2d inst., at his rooms in Soho-square; and though the inquest has shown that the disease from which he had suffered might have been the primary cause of his death, it is probable that had the system of the Academy allowed better acknowledgment of his talents, his life would have been prolonged and his end have been somewhat different. The writer of these lines met him two evenings previously to the last sad event; and another friend was with him on the evening before his death, when he appeared well, as he had for some weeks. He had been painting on the day before the death of his decease.

His principal works represent Italian scenes, and combine great beauty of landscape-painting with a treatment of figures resembling that of Etty, with whom he was a favourite, and in some measure a pupil, and from whom he derived great love of colour. During the last few years his pictures have not been so conspicuous in Trafalgar-square, as were his earlier works; and some of them were wanting in finish; but one who knew him well, and has the capacity for appreciating a good picture, says that he never painted better than during the two years of his illness. He produced a multitude of small works that never went to the Exhibition. One dealer, we believe, sold in two years, 2,000*l*. worth of them. In one side of his character he might be said to resemble James Barry; and the neglected state of his rooms helped to keep up the idea of a similarity. For several years he had not visited the galleries of the Academy. With his intimate friends, however, by whom he was sincerely esteemed, he was remarkable for great kindness and sociability; coupled with a charming politeness "of the old school;" as he also was for humour and anecdote. A certain fraternity to which he belonged will miss him.

He was born in Dumfries on the 16th of June, 1813. Thus, at his death, he had very nearly completed his 52nd year. He received his early instruction in drawing, at the Edinburgh School of Art; came to London about the year 1830, where he became a student of the Academy; and at length gained the gold medal, and afterwards the travelling studentship. He went abroad, with Mr. Elmore, we believe, and was in Rome about the year 1830. He had exhibited previously to this time. A list of his works would perhaps be beyond the scope of our pages; but we may mention, as amongst the number, a picture to which were appended the words, "The last of all the birds was he," &c.; "The Italian Goat-herd,"—a very fine work; but injured lately through his having been induced to paint out the principal figure;—"Sir Guyon and the Palmer;" "Gil Blas;"—"I must say that Italy's a pleasant place to me;" and "The Wardens" of which works, the two last are still amongst his effects. At one time he assisted Mr. Willemont with designs. The windows of the Church

of St. Stephen, Walbrook, are from his cartoons. He was a clever *connoisseur* of engravings; of which he had a choice collection. One of his pictures is now in the collection at the Crystal Palace.

His brother, Colonel J. D. Kennedy, who had served in India, died about a fortnight ago; and this loss, together with the peculiarly distressing disease, dropsy, from which he suffered, were, rather than any treatment of the Academy, the causes of his death. Still, so far as this case may be illustrative of the sad effects of the indecisive position in which the Academy is, or is left by the Government, it deserves to be recorded here. What is quite clear, is that no picture that deserves to be hung, should be placed where it cannot be seen, or where otherwise its effect may be falsified. The position of sculpture, as well as architecture, is too obviously discreditable to the Academy, or the country, to require present remark.

HENRY DE YEVELEY,

ONE OF THE ARCHITECTS OF WESTMINSTER HALL.\*

The biography of English artists in general during the Middle Ages has been a subject greatly neglected, to the prejudice of our national Europe; and the names and works of our Mediaeval architects have shared in the common fate.

In the illustrated edition of Walpole's "Anecdotes of Painting," &c., 1828, the editor, Mr. Dallaway, has given (at vol. i., p. 208) brief notices of some half dozen "eminent master-masons" of the fourteenth and fifteenth centuries; but among them is not to be found the name of Henry de Yeveley; and yet this architect was master-mason to three successive kings of England, and to Westminster Abbey; and records are still extant that he was employed in many important works, particularly in the remodelling of the great hall at Westminster during the reign of Richard II., and in the erection of that monarch's tomb.

Walpole it may be presumed discredited, or at least he ignored, the statements of an earlier writer, that Henry Yevell knit for the king the London Charter House; King's Hall, at Cambridge; and Queenborough Castle; and that he rebuilt St. Stephen's Chapel, at Westminster. ("Constitutions of Freemasonry," edited by James Anderson, M.A., 1738). And in the earlier edition of the same "Constitutions" (by J. T. Desaguliers, 1723), Henry Yeveley had mentioned (p. 31) as "the king's freemason or general surveyor of his buildings, employed in building several abbeys, and St. Stephen's Chapel, at Westminster."

Preston says he was one of the five deputies appointed by Edward III. to inspect the proceedings of the fraternity of masons.

Some of these statements are indeed probably guess-work. St. Stephen's Chapel was begun about 1330; Queenborough Castle is attributed to the celebrated William of Wykeham.

Some slight notices of Yeveley might have found its way into Walpole's work, either from the collection of Rymer, or from the more popular "Survey of London," by Stowe, where his interment in the church of St. Magnus, near London Bridge, is mentioned, and he is designated as freemason to Edward III., Richard II., and Henry IV. Stowe says "his monument remaineth," but he does not describe it further, nor give the epitaph, of which no copy appears to be extant, the original having probably perished in the Great Fire of 1666. Strype, in his edition of Stowe, added a few brief notes from Yeveley's will; and this has now been recovered from the Hustings rolls.

The name of Yevele is evidently local, and it was probably derived from the town in Somersetshire now called Yeovil,—this being one of the many ancient forms under which that place appears. But of Yeveley's immediate parentage or family nothing has hitherto been discovered.

Henry de Yeveley, mason, was director of the king's works at Westminster as early as 1365, if not before; and during the 364 days from September 28, anno regni 39, to September in the following year, he received the wages of 1s. a day.† At the same date he supplied 7,000 Flanders tiles, for pavements, at 6s. 8d. the 1,000; and six mowells of plaster of Paris, at 12s. the mowcell.‡

\* By Mr. John Gough Nichols, F.S.A. Written for the London and Middlesex Archaeological Society.  
† Brailley's "Westminster Palace," 1836, p. 196.  
‡ Ibid., p. 199.

In 1366, the name of Henry de Yefee occurs as supplying some of the stone required for the works at Rochester Castle. Thirteen tons of Stapleton freestone were purchased of him at 8s. a ton; and thirty-two tons of Thomas Fitz-John.\*

In 1370, Henry de Yeveley, mason, was employed to retain masons to be sent in the king's galleys over the sea, and was paid the sum of 5l. 12s. 6d. on that account.†

On the 1st July, 1376, at the requisition of Master Henry Yeveley, then tenant of the manor of Langton, in Purbeck, an inquisition was granted of the record in Chancery of the liberties of that manor, as determined by *quo warranto* before the king's justices at Sherbourn, in 6 Edw. I.‡ It was doubtless as a merchant in stone that Yeveley had become interested in that locality.

In 1381, Master Henry Yevele was employed to engage thirty stone-cutters (*latomos*) for the king's service.§

In the same year he designed the south aisle, then undertaken to be added to the church of Saint Dunstan's, in Thames-street, at the expense of John Lord Colham. The indenture of agreement is still preserved in the British Museum. It was made on the eve of Christmas, 5 Rich. II., between that nobleman and Nicholas Tyertoun, mason, and the aisle was to be erected *solom la devyse Mestre Henry Yeveleye*, as his name is written upon that occasion,|| at the cost of 25 marks.

In the same year, at Michaelmas, he had received from Lord Colham the designation of *Mason et Citoyen de Londres* the sum of 20l., due to Thomas Wrewek, mason, for the works going on at Cowling Castle, near the junction of the Thames with the Medway; and by another still more interesting document, dated the 23rd July in the following year, we find that he was employed to measure the work done at the same castle by William Sharnale, which amounted to the cost of 456l., of which 270l. 10s. 4d. was that day paid.¶

In 1383-4, by letters patent, dated 20 Feb., 7 Rich. II., under the designation of *Henricus Yevele latomos*, he was confirmed in the possession of two shops and four shillings yearly rent, in the parish of St. Martin Oteswiche, formerly the property of Master Excestre, and which he had recently purchased of John Tottenham, carpenter. This confirmation was considered necessary because he feared that he might easily lose the property through the procurement of certain rivals, who had endeavoured to cause it, by false colours, to be seized as an escheat to the crown. The king's favour in the matter was conceded in consideration of the great labours which the said Henry daily sustained in the royal service.\*\*

By an indenture dated 20 April, 7 Rich. II. (1383), between Henri Yevele, citizen and mason of London, of the one part, and William Palmere, citizen and horse-dealer (*merchant des chevaux*), of the same city, and Isabella his wife, of the other, the former party gave to the latter a yearly rent of 40s., issuing from his lands and tenements in the parish of St. Martin Oteswiche, on condition, that if Margaret, the wife of Henry, should survive her husband, and ask her dower of a tenement with four shops, together with 4s. of quit-rent issuing from the tenements one belonging to John Tudenham, carpenter, which the said William and Isabella held for their lives, of the grant and lease of the said Henry, by the service of 20s. per annum, then the said annuity should be in force, but otherwise void.††

In 11 Rich. II., "Master Yeveley" was chief mason of the new work then in progress at the

\* Fabric Roll, from 11 June, 40 Edw. III. to 11 Jan., 42 Edw. III. Printed in the "Archæologia Cantiana," ii. 112.

† Issue Roll of Thomas de Brantingham, bishop of Exeter and treasurer, 4 Edw. III., as edited by Fred. Devon, 1835, p. 3. Yevele and the workmen are all called "plasterers" by Mr. Devon; but their designation in the original is doubtless *cementarii*. The *comentarius* was a builder in stone; and *latomos*, or *latomas*, a stone-carver or cutter; but probably in many cases either term was used for masons without discrimination.

Church of Westminster, and received for his fee 100s. a year, and 15s. for his dress and furs. Henry Zyevely is also named as chief mason in 17-18 Rich. II.\*

At the latter date he was a party to two very remarkable engagements, which are preserved in the collection of Rymer.

The one, dated on the 18th March, 18 Ric. II. (1395), is an indenture for making, well and faithfully, all the *table* of the walls of the Great Hall within the Palace of Westminster, on one side and the other: raising them for 2 ft. of assise, and inserting twenty-six *souses*, or corbels, of Caen stone. The parties to this agreement were the king on one part, and Richard Washbourn and John Swalwe, masons, on the other; and the work was to be done according to the purport of a form and model made by the advice of Master Henri Zeveley, and delivered to the said masons by Watkin Waldon, his warden. These terms—*selonc le purport d'une fourme de moule faite par conseil de mestre Henri Zeveley*, surely raise him to the dignity of an architect, and invest him with the credit of having designed some of the more conspicuous features of Westminster Hall.† The same observation may be made with regard to the word *devyse* already quoted from the document relating to St. Dunstan's-in-the-East. In both cases other masons were employed under his direction.

The *souses*, or corbels, in the hall were clearly introduced for the support of the grand roof, which has been so much an object of the admiration of subsequent ages. We have no authority, however, to attribute the merit of the timber work to Yeveley. In the division of labour which was then prevalent,‡ it is probably due to the master carpenter, and the name of Nicholas Walton is found in that capacity.

Another indenture, dated on the 1st April (within a fortnight of the preceding), relates to the "tomb of fine marble" still remaining in Westminster Abbey, which was then undertaken to commemorate the reigning sovereign and his queen, Anne, daughter of the Emperor of Germany, recently deceased. It was made between the king on one part, and Henri Yevele and Stephen Lote, citizens and masons of London, on the other. (This Stephen Lote was afterwards an executor of Yeveley's will.) The tomb was to be made after a pattern remaining with the said masons, under the seal of the treasurer of England, to occupy in length all the space between the pillars where the said queen was interred, and to be raised to the same height as the tomb of King Edward III. It was to be finished by the Feast of St. Michael, in the year 1397, at the price of 250l.§

Yeveley died in 1400, and by his will, dated 25th May (1 Hen. IV.), enrolled in the Court of Hustings at Guildhall, by John Clifford, mason, and Martin Seman, clerk, his executors, he left his body to be buried in the chapel of St. Mary, within the church of St. Magnus, where his tomb was then already built.¶

He appoints as executors his wife Katherine, John Clifford, mason; Stephen Lote, mason; Richard Parker, his cousin; and Martin Seman, clerk; and as overseer, John Warner, alderman.||

\* "Fabric Rolls," appended to "Cleanings from Westminster Abbey," by George Gilbert Scott, R.A., F.S.A. 1861. Appendix, p. 26.

† Rymer, *Fœdera*, &c., vii. 794. The name is there misprinted *Zeveley*. See an abstract of the same document in Brailley's "Westminster Palace," p. 437.

‡ Some interesting papers on these subjects, by Mr. Wyatt Papworth, will be found in the Transactions of the Royal Institute of British Architects; see that on "Superintendents, &c.," 1860, January 23, p. 38; and that on "Master Masons," 1861, December 2, p. 37-60; with the Index to both papers.

§ This indenture is printed in Rymer's collection, vol. vii., p. 795. "Memorandum quod xxviii die Augusti anno R. Ric. secundi xviii dominus Johannes Innocent clericus liberavit in thesaurarium alteram partem cujusdam indenturae facte inter dominum Regem ex una parte et magistrum Henricum Yevele et Stephanum Lotelote, nos altera parte, pro una tumba marmoræ faciendam et reparanda pro Anna super Regina Angliæ at pro dicto domino Rege." At the same time agreement was made for the royal effigies which were to be executed by Nicholas Broker and Geoffrey Best, copiers-myths of London. (Paigrove, *Calendar*, &c., of the Exchequer, 1836, ii. 50.) Payments to Yeveley and Lote on account of the tomb occur in Devon's Extracts from the Issue Rolls, 1397, pp. 232, 264. On the subject of this monument, and particularly its heraldic devices, see a memoir by the present writer in the "Archæologia," vol. xxix. pp. 32-59.

|| Hustings Roll, 1 Hen. IV., memb. 3.

MURAL PAINTINGS.—Mr. Cave Thomas has been commissioned to paint the Twelve Apostles for the new church of the Russian Embassy, of which we gave a view some time ago.

## THE DWELLINGS OF THE RURAL LABOURERS.

In the face of the evidence which has been given of the inconvenient and unwholesome conditions of the dwellings in which the real workers of the land have been forced to live, without any adequate alterations or improvements, it seems to be wonderful that even in these days of intelligence there are to be found, in both Houses of Parliament, men who are, however, for the most part owners of the land, who should get up in their places and argue that the tillers of the soil have had justice done to them, either as regards the state of their houses, or the number of houses which are provided for them on the respective estates on which they have often been employed from early youth to old age.

While ago we gave in the *Builder* the result of an inquiry which we made in Aylesbury, and some of the surrounding parts; and although the descriptions of the places which met the view in those parts are very much under-coloured, they betrayed a state of things which at the time we showed to be disgraceful. All who have looked into the matter must feel surprised that persons can be found in our great legislative assembly who, in consequence of having been so long familiar with the abuse, or it may be from certain interested motives, will say that the present state of the cottages, and the working of the Poor-law, as at present established, are just to the large and important multitude who form the agricultural classes throughout England.

We will not just now go beyond the district to which we have referred, but in connexion with this we will state our firm belief, founded upon personal and long observation elsewhere, that in eight out of ten of the old cottages of the Aylesbury district there are provisions neither for the health, the morality, nor even the decencies of families, in the space which is allotted: especially in the sleeping apartments there is no chance of a proper degree of health.

When making inquiries in the neighbourhood of Aylesbury, we met, at morning and evening, bands of labourers, consisting of men, women, boys, &c., going from and to the fields in which they worked—a distance of three, four, and more miles from where they were forced to seek lodgings in Aylesbury. We did not listen to the reports of the labourers themselves; but by the actual observation, and from the reports, of persons of various stations of life, we have no doubt whatever that both the homes and feeding of the children of the workers in the fields are, notwithstanding the fresh air, which is so nearly at hand, deficient and injurious; and the children are so pale and bloated, so thin and ill nourished, that in the metropolis we look in vain for similar conditions and appearances, except in some of those parts of Bethnal-green and Spitalfields to which we have so often and with pain directed attention.

Mr. Henley, and others of the House of Commons, have attempted to throw doubt on Dr. Hunter's recent report on the sanitary and social condition of parts of Oxfordshire, where Mr. Henley has large estates. If there is to any amount the existence of a reason for this doubt, by all means let us have the matter set right, beyond the chance of any mistake, by further inquiry made by able and independent persons. We believe, however, that Dr. Hunter has been careful to keep within the bounds of truth in this respect, and not expose his cause to failure by a particle of exaggeration.

Mr. James E. T. Rogers writes, as to the report on the parish of Headington, which has been said by Mr. Henley to be inaccurate,—“I may say, from my personal knowledge, that Dr. Hunter's statement, as regards the condition of Headington parish, falls short of a true description, and that the miseries which the resident labourers endure in their wretched cottages are aggravated by the fact that many of the agricultural labourers are forced to earn their living in a parish where a judicious owner has been careful not to supply house-room for those who work upon his estate.”

This gentleman remarks, that it is not surprising that the general body of the rate-payers welcome the prospect of an equitable system. From a parliamentary paper (No. 491, 1861), which gives a return of the sums levied for the relief of the poor in all the parishes of England and Wales during the year 1856, much useful information may be gathered respecting the variable incidence of the

poor-rates upon property. For instance, Ramsden, a township in Witney Union, appears to have paid 9s. 9d. in the pound; Enford, 6s. 3d.; Crawley, 5s. 3d.; Witney, 5s. 11d.; while the fortunate parishes of Holwell paid 2d.; Yelford, 1d.; and Brighthampton 4d. Again, in the Thames Union, which contains Mr. Henley's estate, Adwell paid 1d.; Ascott, 1d.; Basington, 2d.; Wapsgrave, 4d.; Thornley, 4d.; Long Crendon, however, paid 4s. 5d.; Sydenham, 4s. 6d.; Ashton Rowant, 4s. 2d.; Tewknor, 4s. 10d.; Thame, 4s. 1d.; Mr. Henley's parish, Waterfory, paid 1s. 2d.; the average contributions being 2s. 11d.; and these anomalies are to be paralleled in many other instances; but surely there has been sufficient here to show that in the country, as is the case in the towns, the inequalities of the poor-rates must act as a preventive of improvement in the lodging of the poorer and the industrious classes. A change in this way will press hardly on those who now pay less than the average share of relief of the poor: for instance, Mr. Rogers estimates that, taking Mr. Henley's amount paid in 1856 at 147l. as an average, his payment on the union system of rating would in time come to 369l., or thereabouts. This is, however, a question which must not be looked at from a money point of view; for the rich proprietors of the soil have a duty to perform to the labourer; and in the end they will surely—if conscientious scruples be left altogether out of the question—and the actual advantage of doing right in the accounts with their bankers.

## A LONDON THOROUGHFARE AT HOLIDAY TIME.

THE working classes of London never gave themselves up to a holiday with more unanimity than they did last Monday. It is a sight which gladdens the heart, even in the pent-up parts of this vast city, to see the sun breaking with intense splendour through the grey haze, which its soon dispelled; and, as the morning passes, the great light rolls on his course without a cloud to dim his brightness. Although, from our point of view, the scene is a commonplace one, which every day's looking at has rendered familiar, it has on this Monday holiday a new appearance. The grey coal-colour of the shadows; the distinct contrast of the warm yellow, yet greyish sunlight; the startling effect of the light and shadow, and the chaste, yet marvellously powerful arrangements of colour, are useful lessons for the painter, and remind us of the pictures Canaletto drew, which combine so much of the truthful effect of photography, although produced so long before this discovery was made. Notwithstanding that this is a holiday, Smithfield Market is busy, and country carts, the horses decked with ribbons and flowers, and the rustics in their picturesque dresses, bring loads of fresh green grass and hay to London. As the morning advances, crowds of boys and youths go towards the fishing-places, and numbers of well-dressed people, some in comfortable-looking family groups, wend their way to the railway stations for the purpose of catching the early trains, which are to wait them to distant friends and to pleasant places. The very first omnibuses are loaded inside and outside, and carts, and even costermongers' barrows, roll along; the donkeys and other beasts of burden, and the unnatural human load which they are forced to carry, are ornamented with ribbons and streams of coloured paper. Then so many vans, drawn by three and four horses, pass along, that it is puzzling to discover where the space to keep them all when not needed is to be found. Brass hands are on the roofs of many of these, but the other parts are occupied by the very cream of our industrious classes. From various directions the riflemen are going to their places of muster; and it is pleasant to notice the improvement which the drill and exercise have had on the appearance and the style of walking and general bearing of the volunteers. Up to about twelve o'clock the numbers of people on pleasure bent continue to increase, until the roadway presents an exciting scene; and on the footpath, the lines of wayfarers move in continuous streams. And it is a delightful sight to see these thousands, the chief part of whom are of the working classes, presenting a scene which cannot well be equalled. Some are going to the excursion trains,—to Brighton, Dover, Southampton, &c.; others to the Zoology, and Gardens, where, in the course of the day, there are nearly 30,000 visitors; some to Kensington, to

the British Museum,—but here, we fear, that the numbers who go are not so large as they should be. Others through the Crystal Palace, the East-end and other parks. Never did we see on a holiday before so many people who were perfectly well conducted and sober. Up to about four or five o'clock the thoroughfares continued to be crammed, and then for a couple of hours they presented a deserted appearance, until the women and children from the surrounding parts began to wander home; and up to midnight the jovial sounds of the holiday folks were heard, telling us that many thousands of Londoners had had the advantage of spending a delightful day and breathing fresh air, freeing their minds from cobwebs and their lungs from carbon.

## CONTINENTAL NEWS.

*Italy.*—To the list of buildings recently restored in Rome, we may now add the curious old church of San Nicolò in Carcere. This church was originally raised upon very extensive substructures of ancient date, these being the foundations and basements of no less than three distinct temples which here cross or are heaped upon one another. The Carcere, or prisons, shown and described to strangers as a dungeon built by the Decemvir Appius Claudius, is evidently nothing more than a part of one of these temples. The church was long closed, as utterly dilapidated and unfit for service, but has now been restored at the Pope's expense. Neither marble nor gilding has been spared, and the whole sum expended on its restoration is 65,000 scudi (about 14,000*l.*). Two interesting discoveries were lately made on the property of Prince Torlonia, not far from Rome. One was a statue of Æsculapius, the other a Muse. Both are in marble, about one and a quarter life size, and are described as well preserved. They have been added to the Prince's collection.—At Milan an English company is engaged in making the improvements of which we have before now spoken. Amongst other schemes a large block of handsome buildings on the Cathedral square, and also the new gallery, “Vittorio Emanuele.” Thus, whilst Paris, Vienna, and other continental cities, are cutting streets through crowded, unclean quarters, the Italian cities are not slow to imitate the example. Florence is in course of utter transformation, in order to convert the seat of the Medici, and of the Grand Dukes of Tuscany, into the capital of Italy; and Milan is not behindhand. The cathedral and Scala squares will both be considerably enlarged, and an entirely new street is to be formed, and named after the first king of Italy. Mr. G. E. Seymour is chairman of this company, and Signor Giuseppe Mengoni, of Bologna, the architect. The Gallo-German Protestant congregation has erected a new place of worship. The cost of this church, which amounted to close upon 200,000 francs, was raised by the congregation, assisted by friends at home. Mr. Engelmann, of Stuttgart, was the architect, and the style is Venetian-Gothic.

*Worms.*—Upwards of 15,000*l.* has been collected for a monument to Martin Luther, and the committee, aided by the advice of the Grand Ducal Chamber of Agriculture,—we cannot imagine what they can know about it,—and the architect, have resolved to erect the monument on the Promenade, near the cathedral.

*Göttingen.*—The University in this Hanoverian town is supposed to educate some 1,500 young men, but although founded upwards of a hundred years ago,\* it is not until this year that a specially academic building has been erected. Hitherto students had to walk from one professor's house to another, whereby one quarter of the hour set apart for any particular lecture was invariably lost. The students in chemistry alone formed an exception, their Laboratory and Anatomical Museum being new well ventilated buildings. The new building is situated near the Botanical Gardens, a part of these having been ceded for the purpose, and presents a frontage of 200 ft., with receding wings. In the centre is a handsome vestibule and staircase, and the passages right and left lead to twenty lecture-rooms, of various sizes, each accommodating from twenty to 200 hearers. The total cost barely exceeded 12,000*l.*, but then labour is exceedingly cheap in this neighbourhood, and the

\* The “Schola Georgia Augusta” was founded in 1737, by our George II., King of Great Britain and Hanover.

stone near at hand, this being partly tuffa, partly sandstone. Medallions represent the busts of learned local celebrities, whilst near the entrance are the full-length figures of King George II., Duke Julius of Brunswick, Leibnitz, and Munchhausen, first curator of the University. The architect was Mr. Doeltz, from whose designs much has of late been built in Göttingen.

THE NEW BOULEVARDS AT VIENNA.

VIENNA, like most Continental cities, has a day especially set apart for a display of all that is now and fashionable in "Vanity Fair." Paris has its *Mardi Gras* in the Bois, Berlin its day in the Thiergarten, and Vienna scrupulously keeps the 1st of May in the Prater. The newest shape in carriages, the last "sweet thing in bonnets," the most correct cut of coat à l'Anglais, is then to be seen, walking, riding, or driving up and down, much the same as the *habits* of our Row,—only with this difference, that on these occasions the scene continues all day. Some ninety years ago the Emperor Joseph II. gave to the city a new park, known as the Augarten, and the day on which he attended in person and declared the park open for the recreation of the people, has since been kept as a public holiday. On that day, and for tens of years after, the 1st of May brought its *Corso* in the Augarten; but fashion changes all things, and gradually the scene became transferred to the Prater, another park on the banks of the Danube, and, *par excellence*, the Hyde Park of Vienna. This year, however, the old fashion was revived on the occasion of the inauguration, by the emperor, of the new quarters of the city on the site of the old fortifications. For many years the narrow limits of the old line of bastions, curtains, and ditches, which surrounded the city, had become very inconvenient; and it was universally agreed that "something must be done." In 1858, the emperor sanctioned the extension of the city proper, and ordered the demolition of the fortifications; and now, after seven years, this task has at length been completed, and a handsome Rue de Ceinture now takes the place of the old moat, opening up large tracts of ground for handsome and commodious buildings, of which we have before now given particulars. Already a whole town has arisen; and, though many plots have yet to be filled, this part of Vienna bids fair to become the fashionable quarter for the future. Where practicable, the massive walls of the bastions have been removed; but, in the course of time, many houses,—whole streets, in fact,—have been built up against the old walls; and, as the destruction of the walls would involve the demolition of all these houses, they have been suffered to remain for the present. This is mainly the case in front of the barracks, the Coburg-Cohary Palace, and the Palace of the Archduke Charles; so also from the Hofburg, or Imperial Palace, to the Francis Gate. To the north of this a large square, the Rudolf's Platz, and eight enormous blocks of buildings, have been raised, divided from the boulevards by prettily laid-out gardens and walks. Eastwards this new extension is bounded by the palace of Count Wickenburg, opposite to which a site is reserved for the new exchange. Thence, along the Danube Canal, past the Ferdinand Bridge as far as the River Wien and the Radetzky Bridge, a handsome road has been formed, and will ere long be skirted by houses. From the bridge of Aspern, along the Horticultural Gardens as far as the Kärntner Thor, many handsome mansions have been constructed, partly by archdukes and the old Austrian aristocracy, partly by merchant princes and wealthy manufacturers. Amongst the latter is the house of Mr. Henry Drasche, a great tile and terra-cotta maker. The designs are by Mr. Hansen, and the interiors are finished in the most sumptuous manner. The style of these houses is chiefly French Renaissance, with pilasters and steep, high-pitched Mansard roofs. Here the new opera is in course of erection, and, indeed, is almost finished. It will be one of the largest as well as one of the handsomest theatres in Europe; and so it ought to be, for the costs have already reached a fabulous sum. Next to this group come the "Imperial Gardens," and beyond, two sites are reserved for a new museum and the barracks of the Guards. Further on comes the People's Garden and the parade; and beyond these more sites have been formed, but are as yet unoccupied. At the junction of the Teinfalt Strasse and these new boulevards an-

other theatre is one day to be erected. Opposite to this the new Schiller statue is to be placed, but both theatre and statue appear at present to be only "in the clouds." The boulevards which we have described were formally opened by the Emperor on the 1st of May. Dr. Andreas Zelinka, the burgo-master of Vienna, approached the Imperial carriage, and read an address, thanking the Emperor for the permission to extend the city, and briefly pointing out the manner in which that extension had been carried out by the committee. His Majesty, in reply, expressed his satisfaction at the result; and added that, in commemoration of the event, the new aqueducts now in course of construction for the better supply of water should be made over as a gift to the city.

FLORENCE.

A CORRESPONDENT writes to us from the new capital.—"They are going to set about building iron and wood houses for 3,000 persons outside one of the gates here. Some one has been sent to London to pick up the most useful hints on the subject. The old walls are to be taken down; the gates left; new railroads begun; workmen, engineers, builders, architects,—all are rushing in. Where they are all to be stowed, in little Florence, is an enigma. The new part of Florence, if begun at once, cannot be finished for two years. The bones of Dante have been just found, they say! The Ravenna Dante *fito* was postponed till the 16th of June, so as not to interfere with the *fites* here. Preparing for the former, the bones were found. The find seems almost *too appropos*. You will have read about the capture of Mr. Aynsley and friend. I know the spot where they were stopped perfectly. Returning from Postum, our carriage was stopped by a number of men, apparently laborers, at that very place. They asked me to buy some coins they had found. I opened my purse, and told them I had only a small piece left; for, except that, I had given all for bread for the wretched half-starved poor at Postum. I gave the piece for an old coin, and we passed on. A lady friend, and her maid, and myself, were inside; the coachman, and a man from the hotel, out. Lucky escape for us."

THE CONVERSION OF SEWAGE TO MANURE AT CHALONS.

M. CHODZKO, ancient professor of chemistry at the College of Fribourg, in Switzerland, after a long series of labours discovered some years ago the means of converting these sewage matters of towns into an inodorous compound, containing all the essential elements of a complete manure, which he called atmospheric manure, from the fumigation employed. This compound when completely prepared is in the state of a coarse powder, without any disagreeable odour, of a brownish colour, easily to be distinguished at first sight, and is the lightest of all prepared manures, the specific gravity being only 0.450 (water being 1.0), and, consequently, well adapted for cheap carriage. It contains, according to the analysis of M. Hôte, of the Conservatoire des Arts et Métiers, in Paris,—

Azotated organic matter	... 53.53
Ammonia (quite formed)	... 0.65
Phosphoric acid	... 4.48
(Corresponding to 9.70 of phosphate of lime.)	
Silex and sand	... 4.50
Lime	... 4.07
Water	... 17.75
(The azote being 4.20.)	

Comparing this with the analysis given by the same chemist of the "poudrette," or dried sewage, as prepared at Bondy, we have,—

Poudrette 1.20 to 1.40 per cent. of azote.
Chodzko's manure 4.20 do. do.

This plan of disinfecting sewage, and converting it into a complete manure, may be thus described. First, a saturated solution of coarse sulphate of magnesia and sulphate of iron in equal parts is made with water or liquid refuse: five or six litres of this mixture suffice ordinarily to disinfect a cubic metre of matter, but that depends upon the state of its decomposition and its density. After the application of this solution to the sewage, a small quantity, a saturated solution of bicarbonate of potash, is then added, in order to destroy all traces of acid re-action, and also  $\frac{3}{10}$  part of a mixture of tar and

benzine, or some empyreumatic oil. This latter part of the treatment serves to destroy any remaining odour, and the preparation is then ready for the second process. This consists in pouring the sewage matter thus treated over piles of faggots, the water evaporating very rapidly, owing to its minute subdivision, while the solid particles and salts adhere to the twigs.\* While this is going on, and the liquid is falling from branch to branch of the fascines, a fumigating furnace, placed below, diffuses through the mass the fumes of sulphurous acid gas resulting from the burning of sulphur and hydrochloric acid produced by the action of sulphuric acid on common salt: the first decomposes the sulph-hydrates, and the latter completes the fixture of the ammonia. Repeating the watering of the fascines once or twice a day according to the season, at the end of a fortnight or three weeks in summer, and six weeks in winter, the faggots will be sufficiently charged with the solid extract or manure to be allowed to dry perfectly. In a few days they will be ready for the operation of heating or thrashing—a very simple method carried out on one of the floors of the building. The extract is then collected and placed in sacks as ready for use.

Owing to the favourable reports on the above process made by M. Belgrand, engineer-in-chief of the waterworks and sewers of Paris, and by M. Boussingault, member of the Institute, and professor of chemistry at the Conservatoire des Arts et Métiers, the Emperor was induced to place the disinfection of the Chalons camp into the hands of M. Chodzko. The establishment constructed consists principally of a building the ground floor of which is laid out in offices and dwellings for M. Chodzko and his engineer, M. Lankasky, with their families. Immediately above these are disposed three stories of lofts, constituting the building of graduation, filled with the faggots ranged in two series of columns, a vacant space being left between the series furnished with a planked flooring at each story on which the faggots are heated. Very little liquid ever arrives at the bottom of the building: any small quantity that may happen to do so is drained off by a pipe into a vessel placed to receive it.

Several farmers and agriculturists residing in the neighbourhood, constantly use this manure, some in the liquid and some in the solid state. One of them, M. Secondé-Baromet, at Prosmes, made an experimental comparison, by sowing beetroot in two plots of ground, one manured with the poudrette from Reims, the other with Chodzko's patent manure. The result was that in less than ten weeks on the land manured by the first-named, the produce was equal to twice the expenditure, while on the latter the return was five times the outlay.

M. Belgrand, municipal engineer, of Paris, states, in a report, that the poudrette takes twenty months, on an average, to complete, and has lost all its ammonia, whereas the manure above described is formed in about a month, and all the gases are preserved. The price of Chodzko's compound is about 5s. per ton. The cost of a complete establishment for a town of 50,000 inhabitants, is estimated at 24,000*l.*; and the working expenses, including the interest of the capital for one year, 12,800*l.* The receipts are calculated to be 23,360 cubic yards of sewage matter removed from the houses (paid by the inhabitants), at 5s. per cubic yard, 5,840*l.*; 3,708 tons prepared manure, sold at 5*l.*, 18,540*l.*; total receipts for a year, 24,380*l.* Deducting the expenses (12,800*l.*), there remain 11,580*l.* net profit on the capital, or at the rate of 48.25 per cent. In case of the town being drained so as to deliver the sewage at the works, the item paid by the town would disappear, but a gain of the expense otherwise incurred, of cartage and sixty horses, would add a benefit of about 3,000*l.* per annum, thus leaving the net profit at 8,740*l.*, or 36.40 per cent. as a minimum.

NEWTON IN MACKERFIELD SURVEYORSHIP.

UPWARDS of fifty candidates offered themselves for the above office, from whom the commissioners selected four to attend personally. Ultimately Mr. R. Brierley, for several years assistant to Mr. B. P. Coxon, C.E., borough engineer of Warrington, was elected to the office.

\* This stercoritic process of obtaining salts from solutions is very common in the salt works on the Continent. Very often cords are used instead of faggots.

RENDCOMB.—Plan of Principal Floor.

MONUMENT TO LORD AND LADY SUDELEY.

MR. LOUGH has just now completed a remarkably fine double monument to the memory of the First Lord Sudeley, and his wife, Henrietta Susanna. It takes the shape of a fourteenth century altar-tomb, on which lie the effigies of the individuals commemorated, the whole being raised on two wide steps. The sides of the tomb are panelled, and bear shields properly blazoned. At each angle is a finely-sculptured statuette of an angel; and between these, on each side, are two figures of the Evangelists. The tomb and steps are of Sicilian marble, the figures of Carrara marble. An inscription on metal, in the cornice around the tomb, tells us it is erected:—

"In memory of Charles Hanbury Tracy, 1st Baron Sudeley, of Toddington, in the County of Gloucester, and of Greyknog, in the County of Montgomery, Lord Lieut. of Montgomeryshire. Born Dec. 28th, 1777. Married, Dec. 29th, 1798. Died, Feb. 10th, 1838. Also in memory of Henrietta Susanna, his wife, daughter and heiress of Henry 8th and last Viscount Tracy. Born, Nov. 30th, 1771. Died, June 5th, 1839."

This is rubricated, and with the shields gives the only colour added to the monument, beyond the gentle difference observable in the two marbles used.

The principal figures are most admirably executed, and the whole is worthy of the deserved high reputation of the sculptor,—one of the very, very few amongst us who have devoted themselves to ideal sculpture.

The monument is to be set up in a chapel about to be erected specially for it at Toddington.

RENDCOMB.

RENDCOMB is a small village between Cirencester and Cheltenham, not far from the source of the Thames, though the stream is here called the River Churn, a name it retains till it becomes the Isis. The village and surrounding property belonged to the Gnisio family till a few years ago, when they passed into the possession of Sir Francis H. Goldsmid, bart., the present member for Reading. A natural terrace, high up on the side of the hills which enclose the valley, has been enlarged, to form a site sufficiently broad for the new house, with the gardens and terraces that are to surround it. The old house stood near the new site; but it was pulled down, being much out of repair and possessing no feature of interest.

Above the house the hills are covered with woods; to the west is a beautiful park, full of old oak-trees; and at the foot of a steep descent to the valley is a sheet of ornamental water, fed by the River Churn. The house consists of an entrance-hall, a library, two drawing-rooms, and a dining-room, on the ground-floor, which are arranged so as to command the best views of the entrance; the domestic offices are at the back of the house, and are screened from the garden by a conservatory. The dimensions of the rooms can be seen by a reference to the plan. The bedroom floor is divided into smites of bed and dressing rooms. The stables will be approached by a new road to the east, which passes in front of one of the largest wych-elm trees in England, the branches covering a circular space of about 110 ft. in diameter. The architect of the build-

ing is Mr. P. C. Hardwick: the contractors are Messrs. Cubitt & Co.; and we understand the cost of the house will be rather more than 40,000*l.*

ESSAY ON DWELLINGS FOR THE WORKING CLASSES.—The adjudicators on the essays sent in to compete for the prize of 10*l.* offered by the Liverpool Health Committee for the best essay on the above subject, have awarded it to that signed "A Workman," as the most practical, the writer's name being Edward Reid, of No. 9, Nicholson-street, Netherfield-road North, Liverpool.

KENDOCKE; A MANSION NOW BEING ERECTED FOR SIR H. FRANCIS GOLDSMID, BART., M.P.—MR. P. C. HARVEY, ARCHTCT.

**THE ARCHITECTURAL PROFESSORSHIP, UNIVERSITY COLLEGE, LONDON.**

On Saturday last, at a session of the Council, Mr. Hayter Lewis was appointed Professor of Architecture in the College, from the close of the present session, on the resignation of Dr. Donaldson, who, retiring by reason of long service, will assume the title of Emeritus Professor.

The testimonials submitted to the Council by Mr. Lewis were of the most remarkable character, and could have left them little alternative. Mr. Lewis succeeds a most accomplished, energetic, and excellent man,—a man not merely with a head, but a heart. When we say that we believe the credit gained for the position will not suffer in Mr. Lewis's hands, we pay him the highest compliment in our power.

**THE ELECTION OF DISTRICT SURVEYOR FOR MILLE-END OLD TOWN.**

The following candidates presented themselves before the Metropolitan Board of Works, on the 2nd inst.:—E. Adams, A. Baker, W. Baker, Sidney Godwin, — Hovenden, J. Houle, J. Hindson, J. W. Papworth, E. Paraire, A. Peebles, E. W. Power, H. S. Legg, C. A. Long, Geo. Saunders, J. Tolley, F. Wallen. The following six were then selected by vote:—W. Baker, Sidney Godwin, H. S. Legg, C. A. Long, A. Peebles, J. Tolley; from whom Mr. H. S. Legg was ultimately elected to fill the office.

**COTTAGES FOR THE WORKING CLASSES.**

The Lower Norwood Co-operative Building Company, Limited, are putting up some cottages for the working classes on the Elm Grove Estate there. They have three pairs already occupied, and are about to build two more pairs. Each pair includes four separate lettings, with separate entrance, of living-room, kitchen, and bedroom. The following tenders have been recently sent in for the erection of two pairs of these cottages:—

Street .....	£790	0	0
Wallis .....	758	5	0
Perks .....	700	0	0
Fenley .....	700	0	0
Barwell .....	650	0	0
Ward (accepted) .....	660	0	0

**SANITARY MATTERS.**

SOME notes on sanitary requirements, on fever and overcrowding, excessive mortality, and so on, now before us, we shall here string loosely together into one more or less connected whole.

It is to be hoped that in the new Parliament, shortly to open, the present state of the mortified dwellings of the metropolis may meet with special attention. The urgent necessity for this is every day becoming more and more apparent. The overcrowding is increasing, notwithstanding partial endeavours to prevent it; and so great is the demand for apartments in some localities, that rents have been considerably advanced; and even at the increased rates it is not easy for persons who have families of children to find a shelter. Besides the demolition of a far greater number of dwellings than would have been thought possible a few years ago, there are other causes for this: one of these is the enormous increase of the number of persons employed in connexion with the railway stations, large manufactories, &c.; and, according to present arrangements, it is thought necessary for even these men to find a dwelling near to their work.

In the Caledonian-road, in numerous instances, the apartments above the shops are let, in floors, for about 20l. a year for each floor; but few of the shopkeepers will let those parts of their premises to persons who have young children. The houses are of spacious enough proportions; and, if the drainage be all right, with good management they would be healthy enough places. Nevertheless, there has been much sickness and death in some of those houses. A majority of the cases have been from fever, of several types, and we are therefore inclined to think that there are derangements of drainage in this now bustling thoroughfare, especially at the end near King's Cross. In Alhion-street, where the houses are not large, 7s. 6d. are charged for an unfurnished first-floor; and in another street in this locality, which is

not so good as that named, a house situated in anything but an agreeable position, being over an archway, and in the immediate vicinity of a cow-shed and other unwholesome matters, rents at 6s. 6d. a week per floor. In other places 6s. a week are charged for apartments which might formerly have been had for 5s. or 5s. 3d. a week. The frequent consequence is, that many who had been in the occupation of two rooms have been driven into one; and the over-crowding is hence increased to an extent which leads to discomfort and mischief. The houses in which this increase of rental has taken place are, for the most part, property of a well-built kind, in a fair state of repair, although the rooms are in every way quite unfit for separate families. In the poorest neighbourhoods we have not heard of any material change in the matter of rent; but there can be no doubt that over-crowding is there increasing from other causes to a considerable extent; and it would probably be found, on inquiry, that the increase of fever which has of late prevailed in the metropolis must be attributed, in some degree, to this circumstance. In the City, however, and to a less extent in some other parts of the metropolis, the houses of the very poor are carefully inspected, and measures taken to improve their bad condition; and in places where fever, small-pox, and other pestilential disorders have been raging, the people have been turned out at a very short notice by a magistrate's order. Proceedings of this sort are actually a kindness to those who are forced to live in such situations; but, unfortunately, there is great difficulty in getting accommodation elsewhere. We have heard sad complaints in connexion with this: respectable women wander about for days in search of apartments before they can find anything likely to suit, or persons willing to let to those who have children. This is one of the puzzling parts of the important subject of providing proper homes for the industrious and poorer classes of the metropolis. There can be no doubt that the matter to which we now refer is a phase of the question which gives those who have thought carefully of the matter, cause for much anxiety. If, however, the overcrowding is allowed to increase, we shall be in constant danger of the outbreak of some pestilence, which would be a terrible punishment for delay and neglect. But without driving out families from overcrowded dwellings to that considerable extent which some anticipate, there is a great deal to be done by the enforcement of sanitary provisions. The landlords of this kind of property should be compelled to do their duty; and this, as our readers know, is not done at present. It is to such points as this that the attention of Parliament should be directed; and inquiry would show that there is more need of interference in this way than most people are aware of.

There is also, requiring to be better seen to, inspection of workrooms and workshops. In the small ill-ventilated and unwholesome underground apartment to which we recently referred, wherein from twenty-three to twenty-five persons work, manslaughter still goes on, although the parties interested have been apprised that this room is not fit for five persons to work in. It appears that the law cannot touch such arrangements at present; and certainly all that has been done in this way is of but little use. With the machinery which is at present at work, the condition of these places will not be understood: those whose shops are in good order will court inquiry, but parties who encourage ill conditions will to the utmost defy inquiry.

The fever dens in St. Luke's have recently turned up into public notice by the bearing of a coroner's inquest respecting the death of a woman who had fever, and seems to have died from starvation and neglect, superadded to prostration from the fever. Twenty persons lived in the house, and all had the fever excepting one person. The family of deceased consisted of five children. They all lived in one room, for which they paid 2s. 6d. a week rent. The deceased and two of the little boys, who used to earn something, were thrown out of employment by the fever, and they were all in

great distress. A lodger said that she never saw anything in the place for deceased to eat. Once she thought her a farthing's worth of milk and moistened her lips with it to revive her!

That standing reproach to the metropolis, the sanitary condition of Bethnal-green, has also again been dragged into notice by another of those terrible coroner's inquests which lay bare the dreadful condition of the London poor. The deceased was a man of seventy, whose earnings lately had only averaged about 5s. per week, and out of that he had paid 1s. per week for rent for a wretched place. There was no furniture, with a heap of dirt in the corner of the room. The window, however, was broken to admit air. Dr. G. Haycock said the place was not fit for human habitation. There were bad smells, the walls were dilapidated, and the place was deficient of cleanliness. He ordered chloride of lime to purify the atmosphere of the room. Dr. Lechley said that he visited the house, and found that the walls were in a very filthy state, and had not been cleaned out for years. There was a large accumulation in the cellar under the room where the deceased lived. The whole house and back premises required active sanitary measures carried out. The condition of the place was calculated to injure the vital powers of persons exposed to the influence of the atmosphere. The deceased had no doubt been subjected to the foul condition of the room where he lived, which was scarcely 7 ft. square. The water-butt at the back was very small, and inadequate for the number of inmates. The wife said, in answer to the coroner, that the deceased brought home on the last Saturday 1s. 6d., out of which she purchased two cold faggots for 1½d., a pennyworth of coals, and a similar quantity of tea and sugar. They had animal food once a week, and they had to sell all their goods, and slept upon the floor. Since the death of the deceased she had notice to quit. The jury returned the following verdict:— "That the deceased died from extravasation of blood on the brain from natural causes, and the jurors do further say that there was great neglect in the sanitary condition of the neighbourhood in which the deceased resided."

Our strictures on the sanitary condition of Shrewsbury are being fully justified by what has since transpired. Such is the present state of matters in a sanitary view, that a memorial was lately sent to Government, signed by twenty-nine ratepayers, stating that "the mortality of the borough had now reached the almost unprecedented and startling average of 32 in each 1,000 of the population," and that the memorialists felt "convinced that this high rate of mortality has been greatly aggravated by the culpable indifference of the municipal authorities to all sanitary improvements and precautions; by neglecting to carry out a proper system of sewerage; and by their still permitting a considerable number of the worst description of slaughter-houses and pigsties to remain, breeding death and disease in the very centre of the most crowded districts of the town, notwithstanding these insufferable nuisances had been most strongly reported against by Mr. Fowler in 1847, Mr. Ranger in 1853, and by Mr. Rawlinson, during his visit in 1864, since which latter period small-pox, scarlatina, and typhus fever have been fearfully prevalent. The prevalence of nuisances in the most crowded districts will be understood (continue the memorialists) from Mr. Rawlinson's expressions with reference to the slaughter-houses in the most important street in the town.—'If you want to see a state of things which exists in no other civilized town in England, for God's sake go to Pride Hill!'" The memorialists therefore most urgently memorialize the Government to direct a special-entire inspector to visit the borough for the purpose of making an inquiry and examination into its unhealthy condition, and to take such other measures as may seem best calculated to ensure, with the least possible delay, the provisions of the Health of Towns Act being applied to the borough.

As the local Chronicle in an able leader on this subject remarks, the present alarming increase of mortality in Shrewsbury is not a merely temporary or upstart one, but has been gradually and persistently on the increase for many years. With the attention of the Privy Council fixed upon the borough, however, and under the guidance of a vigilant sanitary watchman such as the *Shrewsbury Chronicle*, it is to be hoped that the reproach will be ere long wiped out, and that Shrewsbury will become,

\* Some weeks ago we directed attention to the bad drainage of houses near the bottom of the Caledonian-road. The parish sanitary officers have since interfered, and an order has been given to do away with the cesspools, and attend to the state of the drainage of these houses, but the work is not complete: the cesspools still remain.

what it is so capable of being, one of the healthiest of our county towns. The Privy Council, we may add, have already moved in the matter by asking the Corporation what they have got to say to it, and the Corporation have set their town clerk to prepare "an explanation in reply to the communication from the Secretary of State."

The fever so prevalent in a Rochdale work-house has led to a panic among the nurses, who have all fled, leaving the patients without proper attendance. The master finds a difficulty in getting nurses on any terms, but has at last prevailed on a pensioner, who had long served in India, and two females, out-door recipients, to assist, should be obtained the sanction of the Board. The chairman and guardians gave full discretionary power to the master to meet the emergency.

#### THE CONSECRATION OF A JEWISH SYNAGOGUE AT SOUTHAMPTON.

The synagogue in Southampton has been consecrated and opened for divine service. It is erected on the Maddison estate in Albion-place, and is built in the Italian style from designs furnished by Mr. H. H. Collins, of London, architect. A portico leads to a vestibule, paved with Minton's coloured tiles, having on the right a staircase leading to the ladies' gallery and a committee-room, to which are attached several convenient offices. This gallery, the seating of which is of stained deal, and varnished stop chamfered octagonal paneling, with a front of ironwork picked out in bronze and blue, is supported by two iron columns, with ornamental bands, the capitals being enriched with vine leaves and grapes. The body of the synagogue has open pews of stained and varnished deal, with boxes for the books of each worshipper. Pillars springing from the reading desk, the sides of which are of open ironwork of the same pattern as in the gallery, support six gas standard. The sanctuary, approached by three steps, is octagonally recessed and unframed with a colonnade, the entablature being supported by a pillar and a pilaster on each side, of imitation marble, the capitals of which are picked out in gold and cream colour. Over the arch is a scroll containing, in Hebrew, "Know before whom thou standest." The lining of the ark is of amber damask, and the veil of Gobelin tapestry. A pendant lamp for the continual light was presented by the architect. Messrs. Defries, of London, who supplied the gas fittings, presented a pair of triple standard lights. The synagogue is lighted by eight semicircular-headed windows of netted glass, with coloured borderings, containing a running flower. The roof is supported by beams, standing on ten ornamented trusses, and is divided into twelve panels, in imitation of alaid cabinet work, four of which are filled with papier maché ventilators communicating with an exterior shaft. A hot-water apparatus placed under the reading-desk communicates with a system of warming, and to give more perfect ventilation the window-heads open at pleasure. A water-tank in the roof insures a supply in case of fire. The edifice will seat about a hundred persons. It was built by Mr. James Bailey, of Southampton, and the cost has been upwards of 1,200*l.*, exclusive of the site. A stone in the outer wall near the entrance states that the synagogue was erected 5625,—1854.

#### THE WAGES QUESTION.

**Taunton.**—The carpenters and joiners of Taunton, who are in the receipt of 1*l.* per week, intend to strike for an advance of 4*s.* per week, on the ground that provisions and house-rent are as high there as in larger towns, and that they have not the means forthcoming to meet their common necessities.

**Rotherham.**—The notice of the operative carpenters and joiners of Rotherham to their employers, asking for an advance of 2*s.* per week, has been effective. The employers, as a body, have agreed to the request, and the standard wages of the town will now be 26*s.* per week.

**Leeds.**—There is no alteration in the position of the dispute here. The masters offer an advance of 3*d.* per hour to the bricklayers and carpenters, and this the operatives refuse to accept.

**Darlington.**—The joiners are on strike in consequence of being refused an extra hour on

Monday mornings. They have demanded the half-day's holiday on Saturday, and an increase in their wages of 1*s.* per week, both of which requests have been complied with by the masters; but they wish to commence work at seven o'clock on Monday mornings, instead of at six, as at present.

**Miscellaneous.**—A strike of a curious nature has occurred among the ironworkers of Worcestershire. They have issued a notice that, in consequence of the high price of meat, they have resolved not to buy any for a month. It appears that they hope by this means to force the hutchers to lower their price.—The National Conference of Miners, held at Bloomfield, Staffordshire, has been brought to a close after a long discussion on strikes, outlocks, and the assistance which should be given to men on strike. The substance of the debate and the form of the resolution adopted, are best summed up in the phrase used at the meeting that "strikes are most injurious to all parties," but that the Association could not always refuse to support them.

#### PROVINCIAL NEWS.

**Harwich.**—The Great Eastern Hotel has been opened. This first-class building has been erected by the Great Eastern Railway Company, for the accommodation of their passengers to and from the Continent, and for visitors. The hotel faces the passenger pier. The style of the building, which occupies an area of 24,000 ft. in Italian. The frontage is about 120 ft. long, and 67 ft. high; and has four stories, exclusive of the basement, which rises at least 4 ft. above the ground-line. The most notable apartment is the dining or coffee room, occupying the north-east end of the building, and which is 60 ft. by 40 ft., and lofty in proportion. The enrichments of the ceiling, cornices, and panelling are of an elaborate description. At the back part next the corridor, and also from the roof, the room is lighted by embossed glass windows, and six lofty windows in the front. The ceiling is panelled, and in each of the nine panels is a bronze gasolier. The decorator was Mr. Schmidt, of London. There are two billiard-rooms, public and private, the latter being on the first floor. On this floor the Royal Harwich Yacht Club is accommodated with a club-room. There are two bars; one for the hotel, and a second for company who may have no desire to enter the hotel. The architect was Mr. T. Allom, of London; builders, Messrs. Lucas, Brothers, of London and Lowestoft. The works have been carried out under their superintendence, Mr. W. R. Lacey, Mr. R. W. Darken, of Colchester, was clerk of the works.

**Aldeburgh.**—"The White Lion Hotel" is about to be extensively increased by the Aldeburgh Hotel Company (Limited), whose prospectus has just been issued, with a nominal capital of 25,000*l.*, divided into 2,500 shares. The greater portion of the capital has already been subscribed in London. The designs are by Messrs. Elmsley, Franey, & Haddon, of London, architects.

**Croydon.**—The foundation stone of a new work-house for Croydon has been laid. There will be compartments for 110 old men, 25 able-bodied men, and 45 partially able-bodied; total number of men, 180. The accommodation for females will also be on the same scale: old women, 100; able-bodied women, 25; partially able-bodied, 25; total number of women, 150. This accommodation will be provided for 330 persons. There is to be a large dining-hall in the centre of the building, over which will be the chapel. The residence of the master is to be near the tower, and the stores and workshops at the rear of the building. Mr. J. Bernay is the architect; Mr. H. Hart, the builder.

**Weston-super-Mare (Somerset).**—A new banking-house, with shop and dwelling-house adjoining, are about to be erected here from designs by Mr. W. B. Gingell, of Bristol, architect. The site has been cleared, and the new premises will occupy a good situation in High-street, with returns in South Parade and in West-street. The general contract has been taken by Mr. John Perry, of this town.

**Wellington.**—The contract for the erection of the new markets has been given to Messrs. Trow & Sons, of Wednesbury, contractors, on terms which are stated to be highly satisfactory to the directors. The works will be commenced forthwith.

**Sheffield.**—The proposed enlargement of the Cutlers' Hall is about to be at once proceeded with. A meeting of the Building Committee

has been held, to examine and let the contracts for the work. Mr. G. Wade, and Mr. Bradley, of Sheffield, builders, each sent in a tender for the whole of the work, amounting to 5,715*l.* Their tenders were the lowest, and the committee decided to give them the contract jointly. The cost of the alterations will be larger than was originally contemplated, 800*l.* having been paid for land to complete the site. Over 4,000*l.* have, however, already been promised.

**Leeds.**—A first-class hotel is about to be built by the Great Northern Railway Company at the central station, Leeds. The architects are Messrs. M. G. Hadfield & Son, of Sheffield. It is expected that the works will be very shortly commenced. The estimated cost, including fittings, is 22,500*l.*, and it will probably require twelve or fifteen months for its erection.

**Sunderland.**—A new temperance-hall is about to be built in Sunderland, at the north end of Toward-road, and close to the New Park, for which a site has been secured. It is proposed to have a lecture-room to contain 2,500 people, with smaller rooms, for committee and other meetings. The cost is roughly estimated at 4,000*l.*

**Carlisle.**—During the past twelve months, says the local *Journal*, there has been in course of erection at the Holme Head a second large mill in connexion with the works of Messrs. Ferguson, in which it is intended to carry on the manufacture of their fabrics from the raw material to the finish. The new works have just been opened under auspicious circumstances. The steam is raised from six boilers, which supply the whole concern, and the machinery is set in motion by two 60-horse power steam-engines. The mill is capable of holding about 23,000 spindles, and the sheds will accommodate about 350 power-looms. The engines were built by the Fairhair Engineering Company. The stonework of the building was done by Messrs. C. & J. Armstrong, Messrs. Wright & Son, and Mr. Milburn; joiner work, Mr. Court; plastering, Messrs. Johnston, Brothers; the shafting and gearing, Messrs. Blaylock & Pratchitt; the remainder of the iron-work, Messrs. Porter, Clarke, Lees & Graham, and John Hind; painting and glazing, Messrs. Sles & Morgan; plumbing, Messrs. Irving & Lowthian; and the slating, by Mr. T. Nanson.

#### FROM SCOTLAND.

**Edinburgh.**—In the Council Chamber, the Lord Provost has proposed that a grand exhibition, similar to the Dublin one, shall be opened in Edinburgh. His lordship is of opinion that the exhibition should be a national rather than an international one, and that it should be held in 1868.

**Dumfries.**—The committee of the Town Council and Kirk-session and Congregation, having advertised for plans for a church, the cost not to exceed 4,000*l.*, thirty-one plans were lodged, most of them in the Gothic style. Five of them were marked for further selection, and the committee have since reduced the list to three, and have requested the architects, Mr. John Starforth, Edinburgh; Mr. Robert Edgar, London; and Mr. James Barbour, Dumfries, to prepare detailed estimates, in order to test whether their plans can be executed at the stipulated cost. The committee, however, reserve power to reconsider any of the other plans, should they see cause.

**Grangemouth.**—The foundation-stone of the new Established Church has been laid, with Masonic honours. The new church is being built from designs by Mr. A. Black, of Falkirk, architect, and is in the Early English style. It will include sittings for upwards of 400, and space is left for a gallery.

**Queensferry.**—One of the most extensive projects of the day is that of Mr. Bonch for crossing the Firth of Forth by a viaduct upwards of two miles long. The four openings for the navigation are each 500 ft. wide, and 125 ft. high. The viaduct consists, in addition, of nineteen openings of 100 ft., ten of 150 ft., ten of 175 ft., and seventeen of 200 ft. The piers are intended to be of stone to above high-water mark, and the upper portion of open ironwork. The estimate for the viaduct is 560,000*l.* Another work of a like character, a high-level bridge over the next northern Firth—the Tay, has been withdrawn by the promoters, the estimate, 180,000*l.* having been found insufficient. This work had two openings for navigation, in separate portions of the viaduct, each of 300 ft. span, and the one 100 ft. and the other 70 ft. high,

with seventy-nine other openings of various widths, the total length being about 1 1/2 miles. **Nairn.**—It is proposed to form a joint-stock company in Nairn for the erection of a new town-hall. There are two plans, one by Dr. Grigor, and another by Mr. Chumas, architect. The estimated cost of the proposed building is £1,000.

**Elgin.**—The opening of the Combination Poomoon for Morayshire, at Bishopmill, has now been sanctioned by the Board of Supervision. Last summer the foundation-stone was laid by Mr. Alexander Stewart, builder, Peterhead, contractor for the mason-work of the house. The other contractors all belonged to Elgin. Contractor Brander had the wrought-work; R. Stewart, the plaster-work; J. Gordon, the plumber-work; F. Wilson, the slater-work; and the plans and specifications were the work of Mr. Alex. Reid, architect, who engaged Mr. Malloch as his inspector. The stones for the building were principally obtained from the Bishopmill quarries, wrought by Mr. Eric Anderson. When the walls were about 3 ft. or so above the foundation, a thick coating of asphalt was laid upon them, to stop the damp from rising. The extreme length of the main building is 200 ft., the breadth of it about 70 ft., and the height to the eaves is about 26 ft. The main building is two stories high. The form of the building may be said to be that of a transept. A range of office houses, 200 ft. in length, lies back from, and runs parallel to, the main building, and the kitchen connects the two. It and the office houses are only one story in height. There are thirty-three apartments in the main building, and in the clock range twelve.

REMOVAL OF THE SMOKE NUISANCE.

SCIENCE has overcome the evil of noxious vapours from alkali works: the sewage question is nearly solved. I think it time to grapple with the smoke nuisance from houses in towns. As a beginning, I beg to suggest a plan.—A glowing fire will consume any quantity of smoke, soot, &c. There are many such furnaces in all parts of London capable of being used for the purpose. I would draw the smoke from the chimney-stack through a large tube, and by the aid of the patent blast fan force it through the fire. A two-horse gas steam-engine would serve for a small parish. The force to be lowered at night; every fireplace to be fitted with a tamper to regulate the draught; connecting pipes could be attached to draw noxious gases from houses, factories, sewers, &c.

I feel assured every difficulty can be surmounted, and the only wonder will be that it was not brought into practice before.

R. T.

The suggestion is an old one, but may be usefully kept in view.

COMPENSATION CASES.

**Bradford Street Improvements.**—Last week the case, the Corporation and Mr. Abraham Bower, was heard before the Under-Sheriff (Mr. William Gray, of York), and a special jury. Mr. Abraham Bower, who resides at Elm-crofts, near Ripon, and is a magistrate, is the owner of a large block of buildings known as Bower's buildings, situated at the junction of Tyrel-street and Chapel-lane, and of other buildings situated at the corner of Manchester-road. The property is required by the corporation in making a new street from the south-west end of Market-street to the principal street in the town) to Manchester-road. The claimant and his witnesses contended that the property could fairly let for 857l. After deducting 6 1/2 per cent. for repairs, insurance, &c., they proposed to capitalise the net profits, at 27l. 2s. 7d., at twenty years' purchase, and to add 20 per cent. for compulsory work, making the total claim 19,500l. The town clerk, however, contended that, according to the experience of claimant's own witnesses, sixteen shillings per cent. purchase for similar property was the almost universal rule. He objected also that the rentals being placed at so high a figure, did show that the deduction for leakage was a proper one. The town clerk also contended that 10 per cent. for the compulsory taking would be a proper compensation to Mr. Bower. The Under-Sheriff having summed up, the jury, after being present from the court about half an hour, awarded 19,500l.

A LARGE GIRDER.

SOME considerable works are being executed, and are now nearly completed, at the London and Westminster Bank, Lothbury, under the direction of Mr. E. N. Clifton, architect. The alterations there being made will give the bank a room the largest in London without columns. Mr. Shaw has built a wrought-iron box girder, 86 ft. span, and 96 ft. long, to carry all the back buildings of the bank, which, with skylights, will weigh from 400 to 500 tons distributed. The girder is 8 ft. deep, and the top and bottom flanges are 2 ft. 6 in. wide. This girder had to be built in its place, on a stage, and the whole of the riveting had to be done there. The total weight of this girder itself is about 70 tons.

ANCIENT LIGHTS AND CITY IMPROVEMENTS.

In the Vice-Chancellor's Court, a suit, Stokes v. The City Offices Company (Limited), for an injunction to restrain the defendants from obstructing the plaintiff's ancient lights, has just been decided by Sir W. Page Wood.

The plaintiffs are wholesale ironmongers, at Nos. 11 and 12, Clement's-lane, and the defendants are an office-building company. Clement's-lane is only 20 ft. in width, and the ancient houses in the rear of a height of 35 ft. from the ground, the plaintiffs' premises, which have been built nearly 100 years, being of this height, exclusive of the sloping high-pitched roof of the period. Property purchased by the defendants was of the same height. They pulled down these houses, and commenced building houses 59 ft. in height. To this the plaintiffs objected, on the score of injury to their ancient lights, and on finding their remonstrances productive of an unsatisfactory result, these proceedings were instituted.

The plaintiffs proved that their business returns were 100,000l. a year, and that a direct light was of the utmost importance to them in their business, to enable purchasers properly to examine the character of the iron, and more especially of the steel goods which they dealt in. It was also proved, that if the buildings question were erected only a general or diffused light would be obtained, which would be valueless for all practical purposes.

The defendants argued that the erection of buildings such as they were about to erect would raise the value of the plaintiffs' property; and they also dwelt on the fact, that suits of this nature were a bar to all public improvements in large towns like London.

The Vice-Chancellor said, it had been aptly remarked, that the encouragement of suits of this description enabled individuals to prevent public improvements, and condemned large and otherwise improving towns to a low style of building. There was a great deal of truth in this; but it was a question for the legislature,—certainly one well deserving their consideration. It was for them to say whether they would pass a general act, by which improvements in towns might be made, either by submitting matters in dispute to a jury, or sanctioning other arrangements; but it was essentially a question for the legislature. No house or land could be compulsorily taken by a railway company without first obtaining the sanction of the legislature. The legislature had made light and air, after twenty years' enjoyment, property by Act of Parliament. The injunction would, therefore, be granted, with liberty, however, for the defendants to apply to a judge in chambers with respect to any future scheme they might select in respect of any future buildings, in conformity with the terms of the injunction. At present he thought it desirable to say nothing about the expense of any application, as he was unwilling to encourage litigious opposition.

HOLBORN VALLEY.

Sir,—The plan brought forward by Mr. Abraham for the Holborn Valley Improvement, and adopted by the Ward of Farringdon-street Without, and discussed by the Court of Common Council, is a copy, in all its best features, from the plan I sent in at the competition. Being put aside, I published it, and distributed a few copies. I gave one to Mr. Abraham, on whom I called in order to explain it. I found he had a pet plan of his own, one for a double viaduct, with a sunk road between. He could not then understand my plan; now he has adopted it. Adding a sunk road and a few other objectionable features, he brings it forward with his name attached; the plan he has no more right to than I have to the wares in his shop. C. J. RICHARDSON.

"SPECIFICATIONS AND MYSTIFICATIONS."

Sir,—In reply to "A Builder's" question, "Who is the proper party to me?" my opinion is that, as the architect is the paid agent of his client, he is responsible only to him, and not to the builder. All his acts are, therefore, (so far as the builder is concerned), the acts of his client, and any losses through his unskillfulness or through ambiguities or mistakes in the specification, must be visited on the head of the principal, who, in his turn, has his remedy against the architect.

In reply to "A Builder's" former query, who is responsible that "the specification" is not "a mystification?" I think there can be no doubt that the architect is, as it is he who puts forth the document bearing the appellation "a specification," the undoubted meaning of which is "a clear description," and if it be not a clear description of the works to which it refers, he is guilty (to use a mild term) of gross misrepresentation, and commits a fraud not only on the builder, but on his client. A SUFFERER FROM "MYSTIFICATION."

EXHIBITION AT PORTSMOUTH.—An industrial exhibition is about to be established at Portsmouth,

CHURCH-BUILDING NEWS.

**Coltishall (Norfolk).**—The church of Coltishall, one of the oldest of the 1,100 churches in the diocese, has been restored and re-opened. The church, previously to restoration, was somewhat dilapidated. The gallery at the west end effectually blocked up the tower arch with its west window, but it has now been thrown open. The whole of the interior fittings, including the gallery, have been removed, and the nave and roof are slightly repaired. The roof-screen is repaired. The communion-rails, chancel benches, reading-desk, and pulpit, are of oak, the latter bearing foliated cusps, in the Decorated style of architecture. The sedilia are repaired, the piscina is re-opened, and the old Norman font removed to a position opposite the west door; while the pews have given way to open deal benches, with oak ends and carvings, and a boarded floor. The south aisle has been re-roofed with new oak, and the exterior covered with lead, with freestone cornices. This aisle has also been lengthened, so as to give room for an organ-chamber, which now opens with an arch into the chancel. The whole of the old stonework of the nave and south aisle have been replaced by new, and the window at the east end has been restored. The windows in the porch had been bricked up, but have now been re-opened and glazed with cathedral glass, of a greyish tint, with which the other windows have been similarly filled, relieved by small panes of stained glass. In a small lancet window in the chancel some painted glass has also been inserted. The interior walls are plastered with rough stucco, and the stonework has been cleaned, as have also the pillars. The floors of the nave and aisles have been laid with Peak Staffordshire tiles, the floor within the communion-rails being of Minton's encaustic tiles. The lower part of the walls are plastered with Parian cement, relieved from the stucco ornamental work by a border of Minton's encaustic tiles. In the course of the restoration, on the north side of the nave, a mural painting was discovered; but as its design was nearly obliterated, it was again covered up with plaster. In the west wall of the nave a new circular window, with geometrical tracery, has been inserted, with the view, while maintaining the character of the architecture, of giving additional light to the west end of the choir. The windows, which are all of the Decorated style of architecture, have been restored, and the eastern gable has been surmounted by a stone cross, with new intrinsecos to the south aisle. The tower, which is improved, is of a later style of architecture, being transitional. Mr. Kitton, of Norwich, was the architect employed, and Mr. Cornish, of North Walsham, the contractor; the glazing and plumbing work being done by Mr. E. Horner, of Coltishall. The churchyard has been enlarged, the ground (being about a quarter of an acre) being given by Mr. R. P. Kemp. The total cost of the restoration is 1,000l.

**Hitchin.**—The church of the Holy Saviour, erected by the Rev. G. Gainsford, at his own expense, on the east side of the Radcliffe-road, about midway between the railway-station and the town, has just been consecrated. The church will accommodate about 400 persons. The style of architecture is the Early Decorated, from designs by Mr. W. Butterfield, of London, architect, and contains chancel, cancel-aisles, nave, north and south aisles, organ chamber, and vestry. The material used throughout the church is red brick, with Bath stone dressings. In the interior the dressings are ornamented with incised patterns filled in with black cement. The roof is open and of stained deal. The entrances are by the north and south doors to the nave, and by a south door to the chancel. The aisles are paved with Minton's encaustic tiles. The chancel is fitted with oak stalls, which are appropriated to the choir. The nave and aisles have deal seats stained and varnished, and unappropriated. The pulpit is of oak on Bath stone base. The west end of the building is surmounted by a bell-turret, containing three bells, manufactured by Messrs. Warner & Co., of London. The cost of building amounted to about 2,900l. The contractors were Messrs. W. & H. Butterfield, of Hitchin; and the sub-contractors, Mr. W. Seymour, carpenter, of Hitchin, Mr. Franklin, painter and glazier, of Hitchin, and Mr. Hinton, stonemason, of Bedford.

**Wolverhampton.**—The chief stone of a new church has been laid at Whitmore Reans. The edifice is to be named St. Andrew's. It will be 112 ft. long by 63 ft. wide, and will have a spire

130 ft. high. It is not intended at present to build more than the nave and two aisles. The total cost of the building, when completed, will be 2,800l. The style is Early English, in the trapezoidal form. Mr. H. Lovatt is the builder. The locomotive works of the Great Western Railway Company, on the Stafford-road, has increased the population at the north end of North-road, Stafford-street, and Waterloo-road, some 2,000 in number, and new terraces there are occupied as soon as they are built. The want of church accommodation in that locality has been recognised by many of the Great Western Railway proprietors, who have subscribed more than 600l. towards the expense of putting up a church at the north end of the Waterloo-road, where it joins the North and Stafford Roads.

**Waters Upton (Salop).**—The new parish church of this village has been formally consecrated. For a number of years past the old church had been in a state of great dilapidation. In last year the old building was taken down and plans for a more commodious church obtained. These were furnished by Mr. G. E. Street, of London. The work has been carried out, and at length completed, by Mr. Cobb, of Newport, builder. The new church is built of stone from the quarry in the village, is in the Early English style, and consists of a nave, chancel, and vestry. The roof is open timbered, of unstained deal, and tiled without. The west end of the nave is surmounted by a bell-gable, with a small spire. The pavement within is of encaustic tiles in pattern. The church will accommodate 150 persons, and nearly the whole of the seats are free. The total cost of the building is about 1,800l.

**Hereford.**—The interior of the parish church of St. John the Baptist, the Ladye chapel of the cathedral, has recently been undergoing a refitment, and to commemorate the completion of this work—or at least so much of it as was necessary to make it available for parochial use—special services were held there on Ascension-day. The woodwork has been carried out by Mr. Merrick, of this city. New oaken seats, for the clergy and choir, have been put up; a new altar-table of the same wood, which will shortly be further embellished with carvings, has been supplied. The sittings are all new, and are free and unappropriated.

**Coatham Mundeville.**—A chapel-of-ease, to be hereafter consecrated, has been opened at Coatham Mundeville, in the parish of Haughton-le-Skerne, near Darlington. It is a small structure, erected from the designs of Mr. Witbers, architect, and consists of a nave 40 ft. by 18 ft., and chancel, with apsidal end, 20 ft. by 18 ft., with vestry on south side of chancel. The walls are built of local brick, both inside and out; the roof timbers to nave being visible, and the chancel roof panelled. A constructional screen, with tie-beam, divides the nave and chancel, which latter is fitted with stalls and subellia, the nave being seated with chairs. The three windows of the apse are filled with glass by Lavers & Barrand. Externally, a spirelet breaks the long line of roof at the junction of the nave and chancel, being 40 ft. to the cross on the same. The church seats 100 people, and the cost was about 500l. Mr. Hodgson, of Darlington, was the builder employed.

#### DISSENTING CHURCH-BUILDING NEWS.

**Newport (Monmouth).**—The Tabernacle chapel, Commercial-street, has been re-opened, after undergoing considerable renovations. The old pews on the ground-floor were removed; the plastering of the walls and ceiling renewed; and the latter being exceedingly low, the roof was raised bodily 2 ft. 6 in. higher. The old side windows were walled up, and the old front taken down and removed. The interior has been partially remodelled and improved. A group of six coffered and moulded panels of wood framing, filled with embossed glass, having a rose-coloured star in diaper pattern thereon, has been inserted in the ceiling, and through these a soft light is admitted from strong clear glass skylights in the line of roof. The sides of all the coffers are filled with panels of perforated zinc, through which ventilation is secured. A new organ gallery—parabolic in form, and lighted by an arcade—has been constructed at the back of the pulpit. The ground-floor has been refitted with partly enclosed pews, having sloping seats and backs, stained and varnished. The galleries and seats have been re-arranged, and new stairs

with enclosed lobbies constructed to them. The pillars formerly supporting the galleries have been replaced by columns, with trellis capitals. The interior generally has been painted various tones of grey, relieved by cream colour, and a little gold, and the columns are finished violet, steel colour, with copper bronze caps. The whole is lighted by a combination of standardis, starlights, and brackets. The exterior now presents a new Bath stone front, of Romanesque character, having grouped and arched windows, with foliated capitals, and finished above the cornice, with an open arcaded parapet. Mr. B. Lawrence, of Newport, was the architect, and superintended the whole of the works. Mr. G. Jones was the builder; and the decorations were executed by Mr. J. Pricc. The whole of the works will cost about 1,100l.

**Tarporley (Cheshire).**—A new Baptist chapel is about to be erected here. The edifice, which will be at the south entrance to the town, will be in the Gothic style, and will be 56 ft. long by 23 ft. wide, with an ornamental Gothic entrance springing from two arches, supported upon granite pillars. The exterior will be of brick-work with stone dressings. In the interior there will be open benches. The roof will be formed of circular ribs on principals, with circular ceiling. In the front elevation there will be three tracery windows. At each angle of the front will be a small enriched pinnacle. The centre gable will be surmounted by a small turret. The building will be heated by a hot water apparatus, and lighted with two sun-lights. It will accommodate upwards of 300 persons. The architect is Mr. J. Jones, of Eaton, near Tarporley, and Mr. R. Beckett, of Hartford, is the contractor; the contract being 803l.

**Cardiff.**—The new "Bethany chapel," which has been erected partly on the site of the old and partly covering the graveyard attached to the chapel, has been opened for divine service. The new building has a Doric appearance, and is executed with Newbridge stone and Bath stone dressings. The front is about 50 ft. wide, having the entrance door at the centre, and two smaller ones leading to the galleries on each side. The length of the building is 70 ft., and the interior is divided by pillars, supporting arches into three aisles, the pulpit being placed in a niche covered with a dome, nearly opposite the principal entrance. The accommodation, including the gallery, which extends round three sides of the building, will afford sittings for about 1,000 persons. The architects were Messrs. Hartland & Sons, and the builders Messrs. James & Price; the contract being for 2,800l. The total cost of the building was 2,800l.

**Newcastle-on-Tyne.**—The foundation stone of a new Wesleyan chapel, in Park-road, Scotswood-road, has been laid. Park-road is one of the new streets which have recently sprung up at the west end of the town, and on the east and south is surrounded by the newly-built streets, radiating from Scotswood-road to Sir William Armstrong's factory, at Elswick. The chapel is in the Italian style. The front elevation and sides will be faced with coloured bricks, and stone will be used in the windows, door, and cornices. The fenestration will have carving to the windows, &c. The ground floor will accommodate about 460 persons, the whole to have open benches of Memel red wood, stained and varnished. Underneath the chapel will be a school-room, three class-rooms, with all necessary conveniences; apparatus-room, with boilers, fitted up for ten parties, and apparatus for heating the chapel, &c. At the back will be the chapel-keeper's house, and the minister's vestry. The committee accepted an estimate from Mr. Walter Scott, the contractor, without competition, his estimate being within that of the architect. The total cost, including ground, will be 3,000l. Mr. Matthew Thompson, of Newcastle-on-Tyne, is the architect.

**Worcester.**—At a recent meeting of the Building Committee of the Presbyterian Church, tenders for the church to be erected in Salt-lane were considered. They were as follows:—McCann & Everill, Malvern, 4,100l.; Trow & Sons, Wednesbury, 3,983l. 0s. 3d.; Osborne & Co., Malvern, 3,945l.; Wood & Sons, Worcester, 3,936l.; Haigh & Co., Kidderminster, 3,864l.; Ife, Stourbridge, 3,718l. 10s.; Jones & Sons, Gloucester, 3,600l. Messrs. Wood's were accepted. The works will be somewhat more costly than was anticipated when the plan of Mr. Bidlake, of Wolverhampton, the architect, was adopted, the total amount to be expended, including the cost of the site, approaching near to 5,000l.

#### STAINED GLASS.

**St. Matthew's, Spring-gardens.**—A new east window and reredos have just been placed in this church, from the designs of Mr. Stephen Salter, jun., architect. The window has been executed by Messrs. Lavers & Barrand, and contains three large subjects, viz., the Nativity, the Crucifixion, and the Ascension, surrounded by the emblems of the Passion. The window is erected as a memorial to many former members of the congregation. The reredos is composed of different coloured marbles, the centre being a pure white statuary cross, with super altar and a cornice of alabaster. The marble work was executed by Messrs. Burko & Co.

**Coalville Church.**—The altar window in Coalville Church has been filled by the incumbent with a stained glass memorial of his wife and daughter. The window is a triplet, the centre 13 ft. 7 in. high, by 2 ft. 3 in. wide; the sides each 10 ft. 1 in. by 2 ft. wide. The style of the church is Early English, and the stained glass is in keeping with the architecture. The window is so divided as to introduce the Ascension in the three upper compartments, and on the lower our Lord bearing his Cross, the divisional line being so arranged with canopy work as to separate the subjects. Canopy work also fills in the top of the window over the Ascension, which contains thirteen figures, all 3 ft. 6 in. high. The whole was executed by Mr. C. A. Gibbs, of London.

**Bidford Church.**—Within the last twelve months the chancel of the parish church of St. Lawrence has been undergoing extensive repairs and improvements. Under the east window has been erected a carved reredos of Hampton stone, in accordance with a design supplied by Mr. H. J. Ingram, of Cheltenham, architect, under whose superintendence the work has been executed. Among the proposed improvements (provided sufficient funds could be obtained) was the erection of a new east window of stained glass, and sufficient success was speedily achieved in obtaining subscriptions to warrant the commencement of the work, and its final accomplishment has just been celebrated. The new window consists of three lights. The subject occupying the centre light is the Ascension of our Lord, which is arranged in a long or oval-shaped medallion, the figure of our Lord occupying (as a matter of course) the upper portion, while the apostles are grouped below, in various attitudes, expressive of amazement and adoration. On the right of our Lord is seen his mother, while from the ground behind her springs the lily. The two side lights are composed of ornamental work; the medallions therein, to correspond with the subject in the centre light, being filled with scrolls ensigned with texts of Scripture, in Old English characters, and combined with enrichments, whose leading features are the fruitful vine. The stonework above the three principal lights is composed of a circle, inclosing a double emblem of the Trinity counterchanged. In each of the three larger compartments, in the upper part of the window, is the figure of an angel, each with arms extended and holding a scroll. The new stonework and the painted glass have both been supplied by Messrs. Cox & Son, of London, who have likewise executed several windows and other works for Bidford Church.

**Algoa Bay.**—Thirty-five stained-glass windows have been designed by Mr. Barnct, of Leith, for a new Roman Catholic Church at Port Elizabeth, Algoa Bay. The windows are all gifts by members of the congregation, principally Irish.

#### Books Received.

*The Coal Question.* By W. S. JEVONS, M.A. London and Cambridge: Macmillan & Co. 1865.

The interesting and most questionable of the probable exhaustion of our coal mines is here considered. The author endeavours to prove that should the consumption increase for rather more than a century at the same rate as now, the average depth of our coal mines would be 4,000 ft., and the average price of coal much higher than the highest price now paid for the finest kinds of coal; hence he infers that we cannot long continue our present rate of progress. Further, he is of opinion not only that our coal is exhaustible, but that there is no prospect of any adequate substitute for it. Nor can the

omical use of coal, he thinks, reduce its consumption. On the contrary, "by rendering its employment more profitable, the present demand for coal is increased and the advantage is more strongly thrown upon the side of those who will in the future have the cheapest supplies. We cannot even make up for a future want of coal by importation from other countries, that, it appears, there is no reasonable prospect of any relief from a future want of the main agent of industry. We must lose that which substitutes our peculiar energy; for, considering how greatly our manufactures and navigation depend upon coal, and how vast is our consumption of it compared with other nations, it cannot be supposed we shall do, without coal, more than a fraction of what we do with it." As for restrictive legislation, it may mar, but probably not mend or correct, the natural course of industrial development. Such is a general outline of the more important of Mr. Jevon's very bright nor cheering arguments and conclusions.

*The Lady Ina, and other Poems.* By the author of "Blythe House." London: Virtue, Brothers, & Co. 1865.

The circumstance that two or three of the smaller works in this very charming little volume,—for example, "The Lighthouse," and "England's Loss,"—appeared originally in our pages, makes for it a claim on our attention, amply justified by its own merits. It contains, in addition to the longer poem that gives its name to the volume, forty-three pieces, all marked with taste, elegance, and feeling,—healthful and enabling. We select for quotation an acrostic, not being by any means an example of the best part of the book, but because its teaching may not be thrown away, and the subject of it, Mr. H. Wild, was well known to many of our readers in connection with the erection of the "Crystal Palace" of 1851. The subsequent early death of that gentleman, lamented, as the author justly observes, even beyond the circle of its immediate friends, gives keen point to the kindly warning:—

"ENTREATY.

Careless of censure or of praise,  
Hedless alike of smile or frown,  
A lone thou' art trod this upward course,  
Rearing a name of good renown,  
Lest not Ambition's towering height  
Neglect too much thy eager thought;  
S' it shows some brief moments on thy way:

S as Earth no spot with beauty fraught?  
E ach blossom that in thy way aids  
A s worthless, in youth's summer day,  
R ising to mind in after years,  
D raws bitter tears in Life's decay;

Words of consoling left unspoken,—  
I utent on Fortune's glittering prize;—  
L ove turned aside or rashly broken;  
D ark, phantom-like, such thoughts will rise."

to give an idea of the author's descriptive power and accuracy of observation, which are remarkable, we are tempted to quote from the first story this truthful and striking word-picture of

A CHURCH.

"Join'd to the tower, but in less rigid style,  
Was built the church, an ornamental pile,  
Whose high-pitch'd roofs such varied lines combined—  
Rich pinnacles and gables—which inclined  
The eager eye to wander on, and trace  
The thousand beauties scatter'd o'er its face.  
The fond supporting buttresses, which press  
Against the walls with tender lovingness,  
Casting dark shadows into each recess;  
Heightning by contrast their own airiness.  
The slender shafts, where window-arches rest—  
So slight, yet with sufficient strength impress'd—  
Wearing with grace rich crowns of forest leaves,  
That mocking stone lightly around them weaves,  
The portal, with its cluster'd columns grouped  
In closer masses, and its mouldings scooped  
Into deep lines that darker shadows gave,  
And framed—as 'twere, a picture—the broad nave  
That spread within the opened door and showed  
Rich wealth of beauty, lavishly bestowed.  
The polished pillars gracefully upreared  
The pointed arches, which, in turn, appeared  
With ease aloft the fretted roof to raise,  
Whose vaults oft echoed with glad hymns of praise:  
The deep pierced windows, with their slender  
Threads  
Of iron-wrought mullions; and their traciced  
heads  
Fill'd in with tinted glass, which but obscured  
Earth's tannell, while the light from Heaven  
pours  
In streams of glory through each colour'd pane  
And soothed away the soul from thoughts profane."

to volume is dedicated by special permission of Henry Wadsworth Longfellow, who, with the modesty that belongs to genius, had asked, that the wording of the dedication might be "simplified so as to bring it nearer to the level of my

poor deserts, though farther from your good opinion."

The acceptance of the dedication of the book by Longfellow is of itself sufficient assurance of the worth of the work, and leaves little occasion for praise. The fervour and tenderness of some of the pieces are remarkable; and we most cordially recommend the volume to all who can appreciate and find delight in poetry.

VARIORUM.

THE current *Art Journal* is, of course, mainly devoted to the Exhibitions of the season. Mr. Ruskin, in his paper, treats eloquently of Rembrandt and of etching; and Thomas Hood is the subject of a graphic and touching memoir, by Mr. S. C. Hall.—The June number of the *Ecclesiologist* contains two excellent large lithographed views of the Church of the Resurrection (Anglican), in the Rue des Drapiers, Brussels.

—*London Society*, for the month, is very amusing. It was a good notion to treat of "Fellows"—members of societies;—but the engraved types are manifestly not characteristic. —*The Art Student*, in announcing that the *Fine Arts Quarterly Review* had expired, says if friends are apathetic and artists indifferent, they, too, "must retreat from the field, wearied and disheartened by vain efforts and wasted time, labour, and money."—The current number of the *Social Science Review* contains the remarkable lecture on Missions to the Zulus, in Natal, recently delivered by Dr. Colenso at the Marylebone Literary Institution, a lecture that will probably supply his opponents with fresh grounds of objection.—*The American Gas-Light Journal*, when published under that title, quoted largely from our columns, and uniformly acknowledged the source. Now that it is called the *Mining and Petroleum Standard*, under other hands, a different and less satisfactory system is pursued. Thus, in the current number now before us, we find three extracts from our columns, but not one of them is acknowledged.

Miscellanea.

THE WORKMAN QUESTION.—On Tuesday afternoon Mr. Edwin Chadwick commenced a course of three lectures, at the Royal Institution, on what he terms "the wage classes" of England.

THE LATE SIR CHARLES BARRY.—The statue of the late Sir Charles Barry, executed by Mr. Foley, and intended to be placed in the Westminster Palace, is now finished, and in the course of a few days will be placed in the assigned spot on the staircase.

PROVIDENT INSTITUTION OF BUILDERS' FOREMEN AND CLERKS OF WORKS.—That it may not be overlooked, we mention that the anniversary dinner, on behalf of the funds of the above institution, will take place at the London Tavern, on Tuesday next, the 13th inst. Mr. G. G. Scott, R.A., will take the chair.

THE LONDON GUILDHALL RESTORATIONS.—The common council have agreed, by a majority of 40 in a court of 96, to a recommendation of the Guildhall Restoration Committee to expend a further sum, not exceeding 9,330*l.*, on additional restorations and improvements, besides providing 6,000*l.* odd for other works already agreed to be executed. Other improvements are contemplated, amounting, with those already decided on, to 15,348*l.* Upwards of 39,300*l.* have now been voted for these works. The roof is nearly finished, and the interior will be done with by the end of the present month.

THE SEWERAGE WORKS OF RIO DE JANEIRO, IN BRAZIL.—The works of the second section of the City Improvements Company are progressing rapidly, eleven miles of main drains having been laid; and the whole works were expected to be completed within about eighteen months. The first section is working to the satisfaction of the householders. It is calculated that when all the sections are at work, upwards of 10,000 blacks can be dispensed with, whose services are needed under the present system, and thus that number of effective men will be set free for other purposes, for which it is to be hoped they will all be required. The Italian Minister at Rio appointed a Commission, composed of scientific officers of an Italian corvette, to examine into the working of the system of sewerage employed in Rio (including the disinfecting works at Gloria), as the same system is to be adopted at Naples.

NOTES FROM HOUSE OF COMMONS.—The Hyde Park Gate Estate Bill has been read a second time. The majority for the second reading was 83 to 47.—The General Post Office (Additional Site) Bill has also been read a second time.

EAST LONDON WORKING MEN'S INDUSTRIAL EXHIBITION.—It is proposed to hold this Exhibition in the month of July next, at St. Mary's School, Whitechapel, as we have already said, and that it is in no way connected with the one now held at the Beaman Institution. The tender of Messrs. Wood, of Mile-end, has been accepted for the counters, gallery, and other fittings, by Mr. Wigginton, the honorary architect, on behalf of the committee. A large amount of space, we are told, has been applied for.

OPENING OF THE NEW ZEALAND EXHIBITION.—From Otago newspapers just received we learn that the opening of the first New Zealand Exhibition took place at Dunedin, in the province of Otago, on the 12th of January last. The ceremony was performed by Mr. J. Hyde Harris, the superintendent of the province, in the unavoidable absence of Sir George Grey, the governor. The building has been erected at the cost of the province. The Exhibition itself, although confessedly very incomplete at the time of the opening, held promise of great improvement, and the articles and productions exhibited, both colonial and others, were exceedingly creditable to so young a colony.

THE PROPOSED TOWN-HALL AND EXCHANGE FOR ROCHEDALE.—At the last monthly meeting of the town council a resolution was put to the effect that the amended plans of the proposed town-hall, now made to include accommodation for an exchange, be accepted, and the committee instructed to obtain estimates of the cost of construction, and report to the council. The chairman said the architect had intimated that some 7,000*l.* additional would be required to complete the plans in the form in which they now appeared, in addition to the 20,000*l.* for the town-hall alone, and besides the foundations, which are to cost 5,000*l.* The estimate for furniture and fittings is 8,000*l.*, which will bring the whole cost up to 40,000*l.* The resolution was carried by 18 to 13.

NEW ODD-FELLOWS' LODGE, NORTH SHIELDS. On the 5th, the ceremony of laying the foundation stone of a new hall for the members of the Royal British Flag Lodge of the Independent Order of Odd-Fellows, M.U., took place in North Shields, amid great rejoicings. The proposed erection will consist of a building of brick with stone facings. It will have a frontage of 50 ft., and will be two stories in height. The ground-floor will consist of two shops, underneath which will be commodious cellars, the hall-keeper's rooms, &c. Above the shops will be the hall, the dimensions of which will be about 50 ft. by 30 ft. Annexed to the hall will be a suite of committee-rooms, retiring-rooms, and other conveniences. The architect is Mr. Thomas Forrest, a member of the lodge. The contract for the erection of the hall is not yet let.

THE CRIMEAN MEMORIAL AT NETLEY.—The cross erected in the grounds of the Royal Victoria Military Hospital at Netley by subscription among the medical officers of the British army to the memory of their comrades who fell during the Crimean war, is now completed. Being 56 ft. in height, it forms an object of interest from the Southampton Water. It was designed by Mr. T. H. Lewis, of London, architect, and is built in the style of the beginning of the thirteenth century. The principal part of the erection is of Portland stone. It is close to the river front of the grounds, and about midway between the hospital and the officers' quarters. A series of four steps, having appropriate divisional pillars at the angles, support the base, which is about 5 ft. high, and from which spring a series of arches forming an octagonal arcade, supported by eight coupled columns of polished Derbyshire marble. Under this arcade, eight tablets record the object of the memorial and the names of the officers. These tablets are surmounted by a smaller arcade, also of an octagonal form, and enriched by columns of polished Derbyshire marble, supporting four niches, containing figures illustrating the relief offered to the sick, wounded, and dying. A column springs from this sum, surmounted by a large cross. If R.I. the Prince of Wales, it may be remembered, laid the foundation-stone in August last. The builders were Messrs. Myers, of London.

**SEWAGE AND ESSEX RECLAMATION BILL.**—At the meeting of the Metropolitan Board of Works held last week, the chairman said he was sure that the members of the Board would be pleased to learn that the Sewage and Essex Reclamation Bill had been read a third time in the House of Lords, and it must afford to them an additional satisfaction to know that His Royal Highness the Prince of Wales had registered his first vote in favour of that Bill.

**SALE OF JARROW IRON WORKS.**—We understand that the extensive iron works of Messrs. Palmer, Brothers, at Jarrow, have been sold, and are about to pass into the hands of a company conducted on the principle of limited liability. The capital is 2,000,000*l.*, and the shares, the whole of which, we believe, have already been taken up, are 5,000*l.* each. The purchasers are the same parties who some time ago bought the works of Messrs. Bolckow & Vaughan, at Middlesbrough. The Messrs. Palmer, of course, will retain an interest in the Jarrow Works in the new form which they are about to assume.—*Newcastle Chronicle.*

**A BRIDGE OVER THE MERSEY.**—The Mersey Dock Board have had before them the preliminary plan of the proposed bridge across the Mersey, to extend from Canning-street (about the central point of the docks on the Liverpool side) to Birkenhead. The idea is, that the bridge shall be supported on three columns, each column to be 150 ft. above high-water mark, while another column will be placed on the river margin. The chairman of the Board thought that it would be scarcely possible to construct such a bridge without interfering with the navigation of the river, but the scheme was referred to the Works Committee for consideration.

**THE SOCIETY OF ARTS' EXAMINATIONS.**—H.R.H. the Prince Consort's prize of twenty-five guineas has been awarded to Thomas Healey, twenty-five, of the Burnley Mechanics' Institution, book-keeper, who has obtained the following first-class certificates—1862, arithmetic, first-class certificate; English history, first-class certificate, with second prize. 1863, book-keeping, first-class certificate. 1864, algebra, first-class certificate, with first prize; mensuration, first-class certificate, with second prize; chemistry, first-class certificate, with second prize. 1865, music, first-class certificate, with first prize; animal physiology, first-class certificate, with first prize. For free-hand drawing no prizes were awarded. For geometrical drawing, the first, prize, 5*l.*, went to Edwin Alexander Merry, twenty, Bristol Trade School, architect's clerk; and the second prize, 3*l.*, to John Sargeant, twenty, Slough Mechanics' Institution, carpenter.

**MEMORIALS AND MONUMENTS.**—The mayor of Tenby has received an official communication from Sir Charles Phipps, stating that Prince Arthur will represent her Majesty at the inauguration of the Welsh memorial to the Prince Consort at Tenby. It is believed that the inauguration will take place about the 15th of July.—A stained-glass window has been placed in St. John's Church, Eton, as a memorial of the Prince Consort and the other founders of the church. The memorial consists of six lights, and will occupy the east window of the edifice, facing High-street. The lower part of the compartments of the window, which is about 30 ft. high and 14 ft. in width, is devoted to scenes in the "Passion" of our Lord, wherein St. John was conspicuous, while the upper is occupied by subjects depicting the "Resurrection," the decorative tracery at the top of the memorial representing the Saviour receiving the "Just," who have risen. About 500*l.* will cover the cost of the memorial, which will be defrayed by the subscriptions. The window has been executed by the Messrs. O'Connor, of London.—Lord Harris writes to say that the Canning Monument Committee have obtained permission to place a full-sized statue of Lord Canning in Westminster Abbey, near to that of his father, and Mr. Foley has been instructed to furnish designs.—The committee for erecting a memorial of the late Field-Marshal Lord Seaton have resolved that Mr. Adams shall be employed to execute a bronze statue of not less than 5 ft. in height. A model of a statue has been prepared by the sculptor. The committee confidently rely on obtaining the full means of executing the work and placing it at Doverport on the Government Parade, where a site has been obtained from the Secretary at War.

**A MONSTER CASTING.**—On Wednesday, at the works of the Bolton Iron and Steel Company, Bolton, Mr. J. Ireland undertook the casting of the largest anvil block yet made in England. The block, when finished, is estimated to weigh 210 tons. It was run out of two cupolas, the whole process occupying about eight hours, and being most successful in every respect.

**FAILURE OF NEW BRIDGE AT NEWPORT, ISLE OF WIGHT.**—The commissioners of the local highways having ordered a committee to report on the present state of the new bridge at Wootton, the committee met on the spot, for the better ascertaining the nature of the foundations on which it was erected, but they assembled when it was exactly high water! and not an inch of the abutments was discernible; consequently they adjourned. Having met again at the bridge, the architect's statement was read, by which it appeared that, in sinking for the foundations, he had come across a stratum of yellow clay, which he supposed was quite capable of bearing anything he could possibly put upon it; but, after erecting the bridge, he discovered that there was a mud formation of considerable depth under the clay, and the bridge began to sink in consequence to such an extent as to be considered dangerous. He, however, now proposed the taking down a portion at a time, so as not to interfere with the public traffic, and rebuilding the arch of the bridge, the cost of which he estimated at 300*l.*, and the contractor had offered to complete the work for 350*l.* There were no difficulties of any serious import to encounter, and the original tender of 2,035*l.*, including all the extras, would not be exceeded beyond 400*l.* or 450*l.* The committee resolved to consult Mr. Alfred Giles, the engineer for constructing the Southampton Docks, in conjunction with their own architect.

**THE AGRICULTURAL EXHIBITION AT COLOGNE.**—This exhibition has been opened, and is considered to be a success. It was started by the Flora Horticultural Society. There are 1,370 exhibitors registered in the catalogue, many of them reckoning their contributions by the dozen. Leaving the meadow land inclosed for the occasion, the garden of the Flora Horticultural Society is entered. With an imposing background of terrace, conservatory, and fountains, it presents a fine view, even in the infancy of the grounds. The conservatory more especially, —a miniature imitation of Sydenham Palace,—is quite large and tasteful enough to serve as a point d'appui for the eye, and render the vista a thing beautiful in itself, independent of the horticultural surroundings. By blending the architectural effect of solid masses of masonry with the light and transparent beauty of crystal and glass, the society is said to have produced a building equal to anything of the kind.

**AS TO AN ADVERTISEMENT.**—Our attention has been called to a recent advertisement in our pages wherein Mr. S. Trickett cautions the trade against a person calling himself Stredder, who, he is informed, is representing himself as S. Trickett's agent or representative. Mr. Stredder now requests us to say, that there is no foundation for the charge made in the advertisement; that he has never had any thing to do with Mr. Trickett, and never represented him in any business transaction whatever.

# The Builder.

VOL. XXIII.—No. 1167.

The Late Sir Joseph Paxton.

THE claims of Sir Joseph Paxton to biographic notice in the pages of the *Builder*, along with architects, would in 1851 have been estimated by our profession as but slight; but time which has moderated some of the pretensions advanced in his behalf, in inflated language, by the newspapers, rather than at

all by himself, has permitted of a higher as well as of a more just appreciation by architects, of his abilities in connexion with the pursuit and practice of architecture. Absurdly as he had assigned to him place with Wren for the estimate of posterity, and regrettable as it was to see that misconception of our art, and of the qualifications required for the profession of an architect, which allowed Paxton to be ranked equal with Barry, there is no doubt that he who mainly conceived the effect of the Sydenham nave, deserves a place in the company of architects, if not as one of them. It may be not the highest art-architecture that he brought into use: he may have been entirely wrong in his anticipations,—for, these in common with the public, he seemed to have,—that the “ferro-vitreous,” or iron-and-glass, system of architecture would displace every other even, for dwelling-houses; but his merits, we think, well earned the place which he well accord to him, after due consideration of those which he had and those he had not. It may be considered seemly to follow the custom of saying nothing but what is good of the dead; but it is in our belief better, with a view to real and lasting fame, to leave on record only the particular good that posterity justly can endorse.

Sir Joseph Paxton died at his residence, Roek Hills, near the Crystal Palace, Sydenham, on the 8th inst. He was in his 62nd year. His remains were to be laid in the churchyard of Edonsor, near Chatsworth, in Derbyshire, on Thursday, this week. He was born on August 3rd, 1803, at Milton-Bryant, near Woburn, in Bedfordshire, and was the seventh son of William Paxton, yeoman, of that place. He was educated at Woburn Free School. When very young he went to work as a gardener at the seat of Sir Gregory Page Turner, Battlesden, in Bedfordshire, where his elder brother, who is yet living, then was, and where a new mansion designed by Sir Joseph's son-in-law, Mr. George Henry Stokes, architect, is just now being built for Sir Edward Page Turner. Here young Paxton received about 15s., or 16s., a week. Subsequently he was at Kensington, we believe at the gardens of Messrs. Lee & Kennedy. Persons still resident in that neighbourhood call him to mind as making himself generally useful with a wheelbarrow. But he soon got to the Horticultural Gardens, Chiswick, where he and Dr. Lindley, both young men, were resident at the same time. There he attracted the attention of the late Duke of Devonshire. The duke, a great lover of horticulture, arboriculture, and the fine arts, was pleased with Paxton's taste in making up *bouquets* for him, and with his manner of rendering slight services, and became in the habit of inquiring for Paxton whenever he the

duke, visited the gardens. Soon afterwards, or when as it appears Paxton was not more than about 24 years of age, there being a vacancy at Chatsworth, the duke invited him there; and he eventually occupied a very important position, not merely as head-gardener, at Chatsworth, but as an adviser of the duke in the most important affairs connected with his several estates. About the time of his removal, or in the year 1827, he married the third daughter of Mr. Thomas Bown, of Hurst-Bridge House, Matlock, Derbyshire. Though there were a land-steward and a house-steward at Chatsworth, the present writer recollects, about the year 1838, or when Paxton would have been with the duke about eleven years, and would be about 35 years of age, hearing him spoken of by one who was in the best position for knowing, as the man who above all others had the duke's confidence: in fact, it was said that he could “do anything with the duke.” At that time the great conservatory was in progress. It was built to contain large palm-trees, and was regarded as a wonder of horticultural-building; in which however it was not Paxton's first essay, on the estate, any more than was it the first progenitor of the building of 1851,—though sometimes it has been thus regarded.

Mr. Paxton became the duke's house-steward in the year 1840.

During the period of the building of the conservatory, he resided with his family in a large house near to the extensive gardens and forcing-houses, which are in the park, at some little distance from Chatsworth House itself. Attached to the latter are other gardens and grounds, and an arboratum, as well as cascades, fountains, and “temples,” dating probably from the time of the building of the original portion of the house, a fine Italian work by Talman. These waterworks of course suggested those of Sydenham. In one place the water flows down a long and steep flight of steps from a “temple” at the summit. This cascade, and all the architectural features connected with it, are better in character, though on a smaller scale, than the cascades and “water-temples” at Sydenham. About the time we speak of, Sir Jeffrey Wyatville had just completed his extensive additions to, and modifications of, the original house. They included galleries for the extensive collections of sculpture, and other works of art, which the duke had brought together, chiefly from Italy, and also a very effective feature of the exterior, a terrace-garden, with its flower-beds in geometric patterns, and with balustrading and other architectural accessories. His position with the duke obviously led him to take the greatest interest in all these architectural works and fine-art collections. In fact, without the Duke of Devonshire, and the lesson of Chatsworth, there would have been no Crystal Palace at Sydenham. The arrangements at the latter building, indeed, for the disposition of sculpture, as designed, may be considered a step in advance of those at Chatsworth,—albeit *sculptors* are not universally of opinion that their works are best placed with foliage and flowers as accessories or background. Paxton, however, was of that opinion; and to be convinced that he was right, nothing more would be required, we think, than a visit to the Chatsworth sculpture-gallery, stocked though it be with the finest of Canova's works, after having seen the arrangement of the sculpture in a garden, as ordinarily at the Exposition in Paris, at the Palais de l'Industrie; which method adopted was of later date than the Crystal Palace, and was probably suggested by the disposition of the works in the latter building. Sir Edward Bulwer Lytton, in one of his novels, has some apt remarks on the inferior effect of sculpture in galleries exclusively devoted to it, to that of sculpture placed in libraries, or with the furniture of ordinary apartments.

The duke's taste for horticulture must have been of the greatest service to Paxton in furnishing him with means of rendering himself famous in that branch of his acquirements. To do justice to his services to horticulture and botany,—and, we must add, cottage-gardening,—would require a distinct article, which may perhaps he looked for more fittingly in one of the periodicals devoted to those subjects, than in the pages of a journal like our own,—even not forgetting that landscape-gardening is truly an art with which the architect must be acquainted, and a matter which is not merely important to the effect of a building, but almost to be regarded as essential thereto. But we ought to mention as amongst his literary works, a “Treatise on the Cultivation of the Dahlia,” in 1838; and amongst others, or to which his name has been attached as editor, the “Magazine of Botany,” commenced in 1840, and of which the sixteenth and last volume appeared in 1852; “The Flower Garden,” with the joint editorship of Dr. Lindley, commenced in 1851, and brought to an end in 1853; the “Botanical Dictionary,” of which there have been several editions, the latest in 1853; the “Horticultural Register,” and the “Cottager's Calendar.” There was considerable resemblance between the subjects of Paxton's attention, and those to which London devoted himself; though the literary works of the latter must be considered of much greater importance to the architect specially than were Paxton's. Paxton's name however is more likely than London's, to remain identified with important designs that were actually carried into effect. Neither can be said to have gone much nearer to the professional ideal of the true artist-architect, than may be comprised in the appreciation and skilful direction of the abilities of others; but both had great knowledge of, or aptitude in, matters of construction.

It is difficult for the architect who has gone through a regular course of pupillage, and whose comprehension of the requirements of study is now expanding every day, and who would fain reach the inevitable speciality of practice only subsequently to his grasp of the widest area of attainments, to realize to himself the possibility of approaching the profession of an architect by way of the practice, empirically in many cases, of the speciality. The fact however is that structures required for horticultural purposes are produced chiefly under the direction of gardeners; moreover, many of those who, not being landscape-gardeners, have no claim to rank as artists, acquire great skill in contrivance of the buildings that often happen to be connected in position with conservatories; which last, themselves indeed, require the exercise of much ingenuity in their mechanical appliances. In Paxton's case, the ingenuity must have been peculiarly called for by the variety, as well as the extent, of the horticultural buildings that were under his care. The duke seems to have collected plants from every quarter of the globe; and the gardener had to provide each with its fitting domicile. One of these plants, now almost to be regarded as naturalized, was the Victoria Regia. It is impossible to omit mention of it, even in a biography addressed chiefly to persons interested in architecture; and the study of the plant, no less than the provision of its place of abode, really belonged to the gestation of the Exhibition building itself. Paxton was proud of his success with the Victoria Regia, which first flowered in 1849. In the paper descriptive of his design for the Exhibition building, read at the Society of Arts on November 13, 1850, he exhibited a leaf of the plant, 5 ft. in diameter, and the growth of five days. He pointed out that the underside of the leaf was a beautiful example of “natural engineering,” in the “cantilevers” radiating from the centre, where they were nearly 2 in. deep, “with large bottom flanges and very

thin middle ribs, and with cross-girders between each pair to keep the middle ribs from buckling; their depth gradually decreasing towards the circumference, where they also ramified. This, at least, was observation of the character fitted to form an architect, and might be compared in truth with that of Wren, of the shell whose strengthening novel kept unharmed its form when dashed against the rocks, and suggested to the great architect, as Cockerell loved to tell, the arrangement of the spire of St. Bride's.

Paxton arrived at the solution of each question, on the Baconian principle, that is, by the way of experiment. The experiments may be said to have commenced immediately upon his arrival at Chatsworth; and whatever the value, architecturally, of the building of 1851, they should be mentioned as having led up to it, and thus conducted to the success of the Exhibition of that year. They were begun in the year 1828. The pine-house, built in 1833, was the first in which the ridge-and-furrow roof was employed. In that case, the roof was contrived on the system of numerous short spans, the ridges and valleys transverse to the longitudinal axis of the plan; whilst the valleys or rafters were inclined. The object of all was that the glass might be more nearly at right angles to the slanting and weak, though valuable, rays of the morning and evening sun, than that in the "lean-to," or simple double-slope roof. This was followed by a greenhouse in 1834, and a "curvilinear" hothouse in 1836. In this last, the Victoria Regia first bloomed, or fifteen years later. The great conservatory was commenced in 1837. In 1840, in a conservatory at Darley Dale, Mr. Paxton first employed the ridge-and-furrow-roof with the spans on a level, that is, with the ribs, valleys, or gutters, neither curvilinear nor inclined as in the former cases, but borne horizontally by an arrangement of trussing to them. The proprietor of the building wrote in 1850 to Mr. Paxton, saying that he used this conservatory as his family sitting-room. Then followed the new Victoria Regia house, spoken of in 1850, as a perfect type, on a small scale, of the Exhibition building. In the last or greatly magnified work, it must be recollected that the lines of the valleys, or gutters, were parallel with, instead of transverse to, the longitudinal axis of the building: thus their ends had to be carried by cross-girders, which were themselves carried by the columns. Upon the cross-girders were large trough-gutters.

This statement of particulars of the growth of the ridge-and-furrow method of roofing, which was a main feature of the building of 1851, is derived from the paper before referred to; but there have been other claimants to priority of authorship of that system, and also as regards the "Paxton-gutter," of which more has to be said. What there is less immediate difficulty about, is in according to Paxton the merit of the invention of a particular machine for making sash-bars, which was of the greatest service in the rapid achievement of the building of 1851. This machine had been the subject of communications by him, to the Society of Arts, in March, 1840, and was rewarded with their silver medal. The invention was made during the construction of the great conservatory at Chatsworth, with a view to abridging the amount of labour in sash-bars, that would have been required. In the first state, the machine was merely one for grooving; but it was afterwards improved so as to make the bar complete. It saved the labour of twenty men for one year, or an amount of about 1,200*l.* and the length of bars made by it was about 40 miles. In the improved form, the machine was first used in August, 1838. The sash-bars in the conservatory were precisely similar to those in the Exhibition building; that is to say, they had grooves sunk at the sides, so that glass and bars would have to be fixed alternately, instead of in the way of bedding the glass upon the bars after the latter had been all laid.

We now approach the period of Paxton's association with the chief feature of the display of 1851. It is important that the origin and nature of the connexion should be distinctly stated. A new generation has sprung up since the year of the first Great International Exhibition; and even at the time, facts were so much distorted, that what they really were was known to few persons amongst the general public. From 1851 to the present time, nothing has appeared more clear to those whose conclusions are simply whatever happen to be those of the newspapers, than that the whole combined architectural and

engineering profession failed to solve a problem duly presented; and that it thus brought the undertaking to the verge of failure. Without diminishing the credit due to Sir Joseph Paxton, we have to oppose to these notions "the inexorable logic of facts." And we may observe in passing, that whilst it is admitted that professions are apt to get into the state of requiring the valuable contributions which they receive from without, it is none the less exceedingly unsafe to prefer, as to a large extent the public seem to do, the man who has not had, to the man who has had, the education and training for the particular profession, be it medicine, engineering, or architecture. If Paxton's attainments were those of an architect or engineer, surely to him should be attached some share of the blame, if there were any anywhere applicable, for not having come forward before the danger of shipwreck was felt. If they were not such attainments, and yet were those required at the juncture, then certain writers, who would reproach the public, are called upon to show this curious position, to wit that the best mode of arriving at skill in a profession is not to acquire the special knowledge for it. Paxton's sagacity in matters of engineering was considerable; he was quite competent to originate most ingenious contrivances; and he had an intuitive perception of what would be good construction; still, his attainments fell short of those of an architect or engineer; and he could not, as we believe (even given his previous experience in that class of buildings), have accomplished an enduring work in the form of the building of 1851, or even the building as it was, without the aid of the architects and engineers who ably co-operated,—or rather, who took the entire work into their hands. As regards the Sydenham building, however, he appears to have maintained a much more important position; everything was directed by or submitted to him; and, in particular, the construction of the principal-ribs, by which the arched form of roof, the whole length of the nave, as well as to each of the transepts, became possible, without external buttresses, was his idea; though there was assistance from others in the drawings, calculations, and supervision.

But as to the building of 1851, points brought out in the discussion at the Institution of Civil Engineers, in January of that year, after Mr. M. Digby Wyatt's paper on the construction of the building, should not be forgotten; and there is no reason to doubt that the representations then made, led to the extra strength given to the structure in certain places, as well as that the additions were required. In "The Practical Mechanic's Journal Record of the Great Exhibition, 1862," Mr. R. Mallet has gone very carefully into the question of the sufficiency of the method of construction in the building of 1851, and in the Crystal Palace, Sydenham. In the former building he had found, on a summer's day, certain columns two inches "out of plumb" in the first range in height only; he shows the uselessness of the wooden keys and wedges for the objects for which they were introduced; he reminds us that M. Barrault found the expansion in the building of the Palais de l'Industrie sufficient to fracture glass and produce leakage; and lastly, he comes to the question of the effect of wind, which had been the subject of some important remarks by the Astronomer Royal. He says that, fortunately, during the whole period of the existence of the original building, London was not visited with a single really severe gale. At Sydenham, the building has greatly increased stability, in the major portion of it at least; and, from 1851 to the time of his writing, he says, "London has never been visited by one of those 'first-class' tornadoes that about twice in a century sweep over our temperate regions." Yet he observes that a wing representing best the construction of 1851, has been blown down; and he predicts that, "should London ever be visited with such a cyclone as that which swept over a large portion of these islands in 1839," and the storm strike "broadside on" upon the Sydenham building, "strengthened though it is, its towering beauty and precious contents will be too probably be left one commingled mass of ruin and rubbish." Thus he comes to the conclusion that "the unbroken columnar and girder structure is neither safe nor durable."

Such conclusions, not confined to Mr. Mallet, it is strictly just to mention, in order that there may be a right estimate of the merits of the *ferris-rotundus* system of construction, or "archi-

lecture," or that variety of it to which, as exhibited in the Hyde Park and Sydenham buildings, the name of Paxton has been attached. We resume our narrative, which has been already anticipated in parts.

In the course of the elaborate preparations for the Exhibition of 1851, there was one matter, that of the building, that was too long left uncommenced. We suppose every difficulty was expected to be overcome through those who were at first the contractors for everything, the Messrs. Munday; but due warning, was given that there would be by no means superabundance of time. The Royal Commission itself was not appointed till January 1850. Sir Charles (then Mr.) Barry was upon it, as was the president of the Institution of Civil Engineers, but not the president of the Institute of Architects. Mr. Richard Turner, who constructed the conservatory at Kew, had previously exhibited a model of a structure which he suggested, and which was designed by his son, Mr. T. Turner, an architect. The main building, in the design, was described in the *Builder* of January 26th, 1850, as "in truth, an enormous greenhouse, 1,020 ft. long," and having five domes of iron and glass. It was proposed to be a permanent structure, eventually to be used for concerts, "winter-garden," and the like purposes. In February, 1850, it was said by us:—"Arrangements should be immediately come to as to the building; there is not a week to spare." The Commissioners then were expecting the building to be completed by the 1st of January, 1851. In the beginning of February, 1850, however, a committee for matters connected with the intended building had been appointed. It consisted of the Duke of Buccleuch, the Earl of Ellesmere, Messrs. Barry, Cockerell, and Donaldson, architects; and Messrs. Cubitt, Stephenson, and Brunel, engineers. Early in March, they took what at least is a common course with committees similarly placed, and desiring not to show favour. They issued an invitation for suggestions to be sent to them; and though they offered no pecuniary reward, the usual result followed: they were responded to sufficiently to find their judgment troubled by number of the projects sent. Could the eminent professional men on the Committee have gone to work themselves, they would probably have adopted the right course. As might have been expected, and as indeed they themselves seemed to have contemplated as possible, they in effect rejected all the suggestions; and they proceeded to the preparation of a design of their own.

It may be well to observe that their original paper of particulars contained a careful statement of rules and conditions, and general requirements. Attention was directed to distribution of parts, mode of access, and internal arrangements and contrivances, as going to constitute the convenience and fitness of such a building as that to be erected on the site which by this time had been pointed out in Hyde Park. The conditions included one for fire-proof construction; and amongst the requirements were "means of classification," or according with the four divisions, or sections, that had been determined upon. Each of the stipulations ultimately was sacrificed; and a building was erected into which wood largely entered, and one which left classification entirely to the arrangement of stalls and fittings.

Designs, in number two hundred and forty, according to Mr. Wyatt, were received about the first week of April. An exhibition at the Institution of Civil Engineers, shortly afterwards, showed, as we well recollect, that the aim at classification had operated largely in giving the character to designs. Some of the plans proceeded upon the datum of stalls arranged parallel with one another, and with transverse passages at considerable distances; others made the stalls radiating; other plans showed four distinct buildings; and some had these buildings in parallel lines, with interspaces. There were designs that might have suggested the glass-case or conservatory method of meeting the requirements, and others the railway-shed method. The committee could make no use of the designs, after awarding "honourable mentions" further than in arriving, with the aid of them, at certain views, which in June they sought to embody in the design of their own.

Amongst these views were the "advisability" of constructing the building, "as far as possible, in such a form as to be available, with least sacrifice of labour and material, for other pur-

poses, so soon as its original one shall have been fulfilled, thus insuring a minimum of cost." And it would appear from the description of construction adopted, that they contemplated a permanent building. One of the "points of excellence" which they explained themselves as endeavouring to attain, was "some striking feature" to exemplify the state of the science of construction; and this was to be attained by a dome of 200 ft. in diameter. Here, it was thought, Mr. Brunel had been at work; and on one occasion subsequently, he spoke of the whole design as his. There was no engineer for whose talents architects, his contemporaries, had greater admiration; there was none whose grandiosity of character and practice, they would have been less in the position, or less disposed, to imitate. We cannot say much for the dome; but the plan, besides having special reference to the intended classification, had the stalls or cases distinctly marked as to be placed all at right angles to a central passage. It is evident that some consideration of the arrangement of stalls, would have tended to facilitate ultimately examination of the articles and works displayed. In fact, the committee had been right on several important points. Time, however, had so much advanced by the beginning of July, that it became evident that brick walls, which the committee proposed, were a mistake. An outcry was raised against placing the building in Hyde Park; and about the same time, many persons were determined rather to sacrifice the whole undertaking, than to allow one of the few trees which there were in that part of the park where the building was to stand, to be cut down.

The Committee had on the 12th of June invited tenders for their design; and several were received on the 10th of July. It was the original intention of the Committee when they asked for the suggestions from architects, to invite by a second public notice, more precise designs accompanied by tenders. But their subsequent course in making a design themselves, and issuing the data upon which tenders could be based, and for which materials they charged five guineas to each person, did away with the first expressed intention. Yet, when inviting the tenders for their own matured design, they intimated that "Tenders for methods of construction other than those shown upon the drawings, and described in the specifications, would be entertained, but on condition only of their being accompanied by working-drawings and specifications, and fully-priced bills of quantities." This seemed to involve injustice to those who had originally been induced to submit designs. We shall see in the sequel, how the curious posture of affairs was attained. Any competent person, after study of the 240 suggestions, and examination of the design of the Committee, might have been in a position to produce, if not one intrinsically better, one more exactly hitting requirements of the moment. The apparent intention, as said in the *Builder* at the time, was not that designers should again enter the field, but that practical men should be able to suggest ways of doing the same thing cheaper and better than the methods shown on the drawings. However, one of the tenders, that of Messrs. Fox & Henderson, was accompanied by an entirely fresh design, which had been made by Mr. Paxton. It was immediately caught at, as means quite at hand for escaping from a difficulty. It differed considerably from the design that was ultimately carried into effect; though in each, the idea was the simple inclosing and covering the objects exhibited, in a completely lighted case,—the arrangement of the objects and the circulation of the crowds, being left to hazard, or the chances of the contending claims of exhibitors. We have adverted to the fact that more than one suggestion of the green-house sort of building had been previously made. In April, in the *Westminster and Foreign Quarterly Review*, Mr. W. B. Adams had written, that the structure should be like "a great metropolitan conservatory, the materials of which should be chiefly iron and glass;" and that the building should be permanent for purposes of "a conservatory and winter-garden." The real merit of Paxton's suggestion consisted in its being accompanied by proof of the success, for certain purposes, of the methods of construction to which we have referred as adopted at Chatsworth, and which Mr. Donaldson went to examine, and in the applicability of all the resources of machinery. A view of the exterior, which appeared in the *Illustrated London News* about this time, shows that the original design

consisted of three stories, each upper one set-in from the sides, and the end-elevations taking the character of a pyramid of three steps. The description showed that the trees, if not removed, were to pass through the glass. The idea of fire-proof construction was so far abandoned, that the whole of the roofing and guttering, a considerable portion of the upright encasement, many of the supports, and portions of the trellis-girders, were eventually of wood.

Immediately upon the acceptance of Mr. Paxton's suggestions, the design underwent considerable modifications. The most important of these was the addition of the transept, and lastly of the arched roof to that part of the building. There was considerable difficulty at the time, in settling to whom should be ascribed the credit of what was certainly a very fine feature of the internal effect. Mr. Henderson was said to have had some hand in it, and Mr. Barry also, at least as to the roof. Mr. Barry was largely concerned in a modification of the details, which was made with a view to some decorative effect therefrom. The transept grew partly from the desire of breaking the length of the building, and partly from that of preserving the larger trees, since gone. However, the arched roof itself was claimed for Paxton, by his friends, when the Exhibition was open; and upon a sheet of blotting-paper, framed, and exhibited in the Stationery Court, the visitor was told to see the first conception of the whole design, and the delineation of the arched form as part thereof. We must say that the sketch was so exceedingly vague, that it was difficult to make much of it; still there was something like the end of a semicircular roof. There is more to say, however, than can be given in one article.

THE GOLDEN AND IMMUTABLE MEAN,  
THE MEASURE OF THE SCIENTIFIC  
IDEAL OF THE GOOD AND THE BEAUTIFUL.

"There is a mean in all things, and a certain measure wherein the good and beautiful consist, and out of which they never can depart."—*Dryden*.

The following outline of a science of formative ethics had its origin in an early desire to establish the principles of taste on a scientific basis; but the inquiry, which was at first limited to a special branch of study, gradually extended to a survey of the whole phenomena of the solar system; and it can hardly be too forcibly impressed upon the attention of the student of nature that there is scarcely any phenomenon which can be fully and completely explained without a union of several, perhaps of all the sciences. The great phenomena of astronomy, perhaps, may be considered exceptions; but this is merely because the scale is so vast, and those agents whose sphere of action is limited to a more immediate perception by sense, become merged into oneness by the vast distance. Hence it is hardly possible to arrive at the knowledge of a law of any degree of generality in any branch of science but immediately furnishes us with a means of extending our knowledge of innumerable others, the most remote from the point we set out from; so that, when once embarked in any physical research, it is impossible for any one to predict where it may ultimately lead him.

The objects of my former and present lectures are, to demonstrate that the fundamental form of phenomena is quantitative; to prove, by the testimony of the most eminent mathematicians and astronomers, that the mean sometimes called the golden is the immutable law of rectitude in the solar system, and, consequently, the metrical expression of the scientific ideal of the good and the beautiful. To expound the great remedial, curative principle, the law of compensation, by which the divinely appointed mean of well-being is preserved, by which erring nature is rectified and restored to its moral form; to found upon the premises of the immutable mean and the law of compensation, a formative science by which man and all being under his dominion may be conformed to the standard of rectitude.

The comprehension of the Divine purpose revealed by phenomena is the comprehension of

\* "The antique world, in his first dawning youth,  
Found no defect in his Creator's grace,  
But with glad thanks, and unreprieved truth,  
The gifts of sovereign bounty did embrace;  
Like angel's life was then man's happy race:  
But later age's pride, like corn-fed steed,  
Abused her plenty and let sinners excrete  
To all licentious lust and gan exceed  
The measure of her means and natural first need."  
*Ætære Queens, canto vii., s. 16.*

art in its widest signification,—of that Will by which faith, science, politics, social life, the pen, the pencil, and the chief minister, either consciously or unconsciously, to one appointed end. The theory of the Divine governance of nature set forth in formative ethics is founded upon the evidence of science. Truths, common to what at first sight appear independent and disconnected branches of inquiry, have been appropriated and systematized, revealing in the process dominant principles of such sublime simplicity, that the mind rests satisfied that it has discerned the truth.

The progress of science and art is always from the vague and complex, to the definite and simple; astrology and alchemy gradually grew to be astronomy and chemistry; the multiplicity of incident and minuteness of detail of the early painters gave place to the simplicity of conception and treatment of maturer intellects. But, to the growing, I will not say dull mental constitution, with its vague expectations and aspirations, this ultimate simplicity of science and art is unsatisfactory and disappointing; it looks for something more recondite and complex, and often spurns the truth which lies at its very feet. For men are born intellectually blind, and have to stumble and whine in the mazes of confusion, complication, and misconception, before their mind's eyes are permitted to behold nature amplified by the full light of truth. It is for these reasons that the intellectual cost of destroying fallacies and expounding nature is so often undervalued, and that the Columbus of a new world of ideas is frequently neglected and unthanked; for, the work once accomplished, appears to have been of such easy attainment, that every one supposes he might have done the same.

It is many years since the theory of formative ethics was conceived. Its verification and elaboration have at times interfered with and prevented an undivided attention to my profession, but the labour has been a pleasant one. If with a very common weakness I over-estimate its importance, you will know what deductions to make on this account. But sincerely believing as I do my subject to be a most important one, I venture to predict that when what is now attempted shall be perfected, and raised to the dignity of a science, and becomes a part of elementary education, the energies of mankind, no longer dissipated by vague philosophies, will be concentrated upon the practical duties of life; for it will be perceived that the immutable mean is the ultimate term of scientific inquiry beyond which lies the region of faith. When it is seen, too, that the law of rectitude is eternally fixed—must ever remain intact in the aggregate, though nature be convulsed to the utmost by error,—it will be an important and aiding testimony to creative design; and, being capable of mathematical demonstration, will be accepted wherever reason dawn as the basis of moral science and goal of human progress. Moreover, when the science of formative ethics, founded on the premise of the immutable mean, shall be discerned to be in harmony with, and recognised by, Christianity,\* it will prove no unimportant means, not only of re-forming, but of increasing the power, and extending the bounds of Christendom.

In my introductory lecture last season, I endeavoured to show that the subtle ambiguity of words is one of the great barriers to unity of thought. That the word "truth," for instance, constantly thwarts just conclusions by gliding imperceptibly from one of its significations to another; and that the imposing, and at first thought, perplexing question,—what is truth? is in a great measure divested of its obscurity, and the gate to its solution opened so soon as what is really meant is correctly expressed. The question should be,—not what is truth? but—what is right in nature? for all the incidents of being are as facts, truths; but being also, as facts, either right or wrong, it is the province and highest aim of science to determine the law of rectitude. For to know this law is to know the law of highest generality, the supreme law; the law of God manifest in nature, which is the basis of moral science; the law which gives true critical powers of discrimination, a forecast of the future, in brief wisdom! I endeavoured to show that this law, ascertained and enunciated, is the criterion by which the aberrations of nature may be estimated and rectified: hence

\* "Let your moderation be known unto all men."  
"He that striveth for the mastery is temperate in all things."  
"Be not excessive towards any."

the Old and New Testaments, comprehending such a law, predict a new earth, a world conformed and restored by moral ideas and forces to its moral form. I then touched upon the nature of scientific progress, and pointed out the fact that it is always towards the exactness of numerical statement, and that man can produce no effect upon nature, can fully appropriate none of her powers, if he be not conversant with general relations according to measure and number;\* that this must necessarily be the case if the fundamental form of sensation be force in space and time, if the fundamental form of phenomena be quantitative,† which are demonstrable truths; that upon this theory all sciences will ultimately be considered branches of metrology, and all phenomenal differences as definite proportional differences, having corresponding metrical expressions,—consequences which are necessarily dependent not only on these facts, but the popular hypothesis, that heat, light, electricity, &c., the imponderables, as they are called, are only modes of motion.

Having decided the exact quantitative statement of the law of rectitude to be the most important object of scientific attainment, the calculations of the most eminent mathematicians and astronomers were interrogated with reference to the planetary law of rectitude, for the law of rectitude in the larger phenomena of nature. Their evidence on this point, which was then cited at some considerable length, may be briefly recapitulated, viz.—That, notwithstanding all the variations, fluctuations, or aberrations which can possibly take place in the solar system, the general balance of its parts will always be preserved, and every departure from a mean state periodically compensated; that all the changes which the mutual action of the planets on each other can produce are periodical,—that is to say, increasing to a certain extent, and that never a very great one; and then again decreasing, so that the system can never be destroyed or subverted by the mutual action of its parts, but keeps constantly oscillating, as it were, round a certain mean state from which it can never deviate to any ruinous extent. The researches of Laplace and Lagrange in particular have demonstrated the absolute immutability of the mean distance of each planet from the sun, and, consequently, of its periodic time.‡ Here, then, was glorious testimony drawn from the depths of space to the law of rectitude reigning in the solar system, an astronomical revelation of the law we sought, of that immutable mean against which all the powers of aberration will never prevail; and whoever may hitherto have been tossed to and fro by the unstable waves of opinion, may here grasp a principle of certitude, the immovable rock and foundation of moral science. For could any principle but that of rectitude be unchangeably, eternally fixed?

It is a remarkable circumstance, and some slight collateral testimony to the truth of the theory I am expounding, that the records of astronomy were searched with a presentiment of the laws they would disclose, as by a careful study of phenomena more immediately my province, and of the limits of the variation of ratios, I believed I had detected a universal moral law presiding over the near and the remote terrestrial and planetary phenomena, viz., that every aberration from a mean state of any system of being must be compensated at some time or other by one of an equal but opposite kind, i.e., in excess by one in defect, and vice versa, or that system will remain permanently injured and unbalanced. This is precisely the law of compensation by which the mean of the planetary system is maintained, a principle which was at first surmised was found to be abundantly confirmed by facts gathered from a variety of sources, astronomical, meteorological, political, ethical, æsthetic; from man's physical nature, animal and vegetable life. If the mean, then, be the ordained immutable measure of well-being in nature, as the cumulative evidence from all these various

\* "Measure is that which perfecteth all things, because everything is for some end; neither can that thing be available to any end which is not proportionate thereto; and to proportion excesses as well as defects are opposite."—Hooker.

† This has recently been announced as the secret of Hegel.

‡ "Temp'ring goodly well Their contrary dislike with loved means, Did place them all in order, and compel To keep themselves within their sundry reigns, Together link'd with adamantine chains."—Spenser.

§ "So every scope turn'd to immoderate use, Turns to restraint."—Shakespeare.

sources confirms, it must be the measure of ideal rectitude, of the good\* and the beautiful.

It may now perhaps be perceived how phenomena apparently the most remote are linked together by a common quantitative basis and the same general laws; how everything that is right in the planetary system, in the conduct of life or in art, must be in conformity to the same immutable moral principle; and that all aberrations or departures from the divinely-established mean or mid-point of rectitude must be rectified or compensated by the same means. This enables us to comprehend the inevitable penalties of extreme action, the necessary reaction, the fitful oscillations which the eternal principle of right in nature demands till compensation be effected; and that it is the duty of man as a responsible agent to avoid and prevent to his utmost departures from the golden mean.

The mean, then, being the quantitative expression of rectitude in the solar system, is also the expression of the ultimate term of natural development, that desirable state in which the ideally good and beautiful will be realised; and, to judge from the past history of the system, the geology of this planet, and the history of the human race, there are abundant evidences that the perturbations, fluctuations, aberrations, or, in other words, the convulsions of nature, are becoming less and less, and that the whole process of being is towards this balanced mean state. All our sources of evidence, then, unmistakably point one way, and proclaim the object of the Creator's formative design, which we, as stewards and doers of His will, are bound to promote in the development of the earth, of its animate being; above all, in the formation of man, intellectually and physically: this is the key to the conception and design of a science of formative ethics. And in observing that nature in its largest physical aspects is being moulded to rectitude by an unseen will and power, we are naturally led to look forward through the vista of the future to a period in the history of man, when, from a universal perception of the purpose of the divine will, the moral intellect will have conformed and moulded the human body to rectitude,—to a period when beauty will be rennited to goodness. I am aware that this part of my theory, viz., that goodness rectifies the body, does appear, on a superficial glance, to be negatived by the facts of every-day experience. It has been said, indeed, in reference to my views on this subject, "that I have to deal with an ugly snail; that the plainest looking men in England were lately three persons most conspicuous for every kind of excellence, moral, intellectual, and religious;" how then would my theory "account for such a singular phenomenon?" Nevertheless, I believe I can perfectly reconcile this fact to the theory, for it should be recollected, that excessive and defective exercise of the intellectual or physical powers and functions are the two great deforming influences. Now the present imperfect state of society, with its ignorance upon many subjects necessary to its improvement, often exacts the devotion and extreme mental exercise of good men to develop truths of the utmost importance to its future well-being. Thus it is that the physical beauty of the best and wisest men is often marred, and their more perfect natures sacrificed, for the ultimate benefit and redemption, in some form or other, of the human race. But notwithstanding the deep wounds and scars of thought which score their features, those ponderous brows and sunken eyes, which sometimes mar the external aspect of great and good men, it is ugliness very different from that of thousands in our galls, which is ungraced, unsummed by goodness. But this part of the subject will receive ampler investigation in another place; meantime, however, as a preparative for the full acceptance of the theory advocated, take up the converse position, or that moral goodness tends to deform and degrade physical nature in the aggregate, and see whether this hypothesis commends itself to your understandings.

You will perhaps exclaim, "This immutable mean, of which so much is made, is recognised by every body in trite and commonplace proverbs; it is as old!" You are right: it is and has been acknowledged under the familiar appellation of

\* Goodness answers to the theological virtue Charity, and admits of no excess but error: the desire of power in excess caused the angels to fall; the desire of knowledge in excess caused man to fall; but in charity there is no excess, neither can angel or man come in danger by it.—Bacon.

the golden mean by millions of the human race. You are right, too, that "It is as old." Shall I finish your sentence?—as nature, as time. It is set forth in the Proverbs of Solomon; it is the natural basis of ethics recognised by Christianity. Under the title of "immutable" it was the great doctrine of Confucius; it was recognised in an aphorism of Thales; it is the basis of Aristotle's ethics; it has been deeply graven and enshrined in verse by the great classic poets, and more recently by Spenser,\* Shakespeare, Dryden, and Pope. But, except in the Scriptures, it has and could have had acceptance but in a very limited sense; for those observations and calculations which put its truth and universality beyond guess and surmise, are but of yesterday. In fact, the yet numerous objectors to the mean being the principle of beauty, and the few who can be found to grasp the theory logically dependent upon the central premise, leads me to believe that the mean has been, and is, popularly recognised only through that hazy dawn with which all great truths rise on the understanding. Indeed, a high authority in art has, within a few years, dismissed in one of his works the mean as the principle of beauty as absurd, because, if true, beauty would then be the average of deformity; but this is no greater absurdity than that truth is evolved from averages of error, which is unquestionably true, in confirmation of which we have the greatest scientific set against artistic authority. The following quotation is from a well-known treatise on astronomy: "The quantitative or exact method pursued by modern science is pre-eminently distinguished by the attainment and correction of mean values. The useful and valuable property of the average of a great many observations, that it brings us nearer the truth than any single observation can be relied on as doing, renders it the most constant resource in all inquiries where accuracy is desired. And it is surprising what a rapid effect in equalising fluctuations and destroying deviations, a moderate multiplication of observations has." Thus in obtaining the average proportions of any race or species of living being, the opposite deformities in excess and defect (fluctuations and deviations) neutralize each other, and yield the mean average or standard proportions of the race or species; otherwise it would inhere in excess or defect, which is absurd. And here I should desire to impress a very important consideration, viz., that the theory of the mean being the measure of perfection and beauty is the theory of probability, which ought to have acceptance in the absence of direct testimony, unless it be more reasonable to put out our lamp because we have not the light of the sun; and the great diversity of opinion existing on the subject shows that there is no popularly-recognised ground of certitude, no recognised doctrine. But when the testimony of the most eminent mathematicians and astronomers, above all of the Scriptures, is brought to bear witness to the mean being the immutable or governing law of creative being, we have the certainty and sunlight desired, and the theory is no longer probably but certainly true. †

W. CAVE THOMAS.

#### BAMBOROUGH CHURCH.

THE recent death of the venerable father of Grace Darling, and his burial by the side of his brave and tender-hearted daughter, has caused Bamborough Church to be brought prominently into notice. As it is a fabric of more than average architectural interest, and misleadingly described in the local gazetteer as "a plain neat edifice, dedicated to St. Aidan," and in the

\* "But Temperance, said he, with golden squire Betwixt them both can measure out a measure; Neither to melt in pleasure's whorl desire, Nor flye in hartlesse grief and doleful tere; Thrice happy man, who fares them both attwene!"—*Faerie Queene*, b. ii., c. 1, s. 58.

† "Love moderately, long love doth so; Too fast invites, as tardy as too slow."—*Shakespeare*.

"Austerity severe and cold, Or wild excess, Wine voluptuous quaff'd from gold, Not happiness. They true enjoyment find alone Who steer between A torrid and a frigid zone, A temperate mean, Avoid extremes, and shun the fault of such Who still are pleas'd too little or too much."—*Pope*.

† The quantitative theory was illustrated by an instrument which the lecturer has designed, and entitled "The Balance of Nature," upon which he promises at some future time to demonstrate the theory of harmonic ratios applicable to the fine arts.

Daily Telegraph as a "little village church," we give a few details. It is a large Transitional cruciform church, built at that period when the Early English style was being developed into the Decorated, standing in a spacious, grassy, but bleak, churchyard, on an elevated site removed by the length of the village from the seashore, having north and south aisles to the nave, and a low square tower at the west end. From the church to the famous castle, or to the shore, down the wide, gravel-pathed, scrupulously clean and neat village of small houses and one-storied cottages, built on either side of a long piece of ground thickly planted with young trees, the distance is about that of four long stonethrows. Standing in the churchyard, you look up to the castle on the stupendous rock at the other extremity of the village as you would look up to the clouds; and the church, compared with the edifice, certainly appears to be of less commanding proportions than it really is; but we have only to concentrate our attention upon it, and pace its length, to arrive at a correct appreciation of its dimensions. The nave and chancel, with the tower, measure 161 ft. long; the transepts 90 ft. wide. Still lingering in the churchyard, before entering the edifice to look at the white lighthouse on the rock in the glittering sea, now so well known, the eye presently falls upon a canopied monument rising high above the grass and nettles, on which reposes the figure of a female with an orb in her hand. This was erected to the memory of Grace Darling, by public subscription. Her real tomb is several paces from it, among the lowly grave-stones of her kindred. The churchyard is not so far from the sea but that the sand from the shore is borne in eddies round it, and sometimes deposited on it in great quantities. There is a proof of this in the fact that the ancient crypt was completely buried in sand, and, until a few years ago, quite lost to sight and memory alike. This subterranean feature consists of two chapels, the one being about twice the width of the other; the length nearly the same, the smaller one having at its west end traces of steps that gave ascent to the chancel above. The large chapel measures 12 ft. 2½ in. by 21 ft. 5 in.; the smaller one is 5 ft. 6 in. in width, and the same length as the other, from which, however, the steps would make some redemption. The east ends of both are formed by the east wall of the chancel; and both chapels are lighted by narrow splayed slits looking into the paved trench made round the chancel, several feet deep, when the crypt was newly formed. The masonry is in excellent preservation, and proves, in various details,—such as a cusped trefoil-headed piscina, and shoulder-heads to the inside of the window-splays,—that crypt and church were built at the same time. There is an exterior entrance to the principal chapel on the same level as its base, likewise in good preservation, owing doubtless to its long concealment and conservation by the sand-drifts mentioned. Thus, as in the newly-found Saxon crypt at Hexham, there was a descent from the church and exit into the open air, or *vice versa*. A curiously-low doorway, to pass through which it is necessary to stoop very considerably, affords communication between the two chapels. Seeing the importance of Bamboorough in Saxon times, antiquaries would have rejoiced to find this long-buried crypt to be of Saxon workmanship; but it is not so. We must look elsewhere for the site of the edifice in which Aidan and his contemporaries and successors preached, with quickened pulse, the duties imposed upon us by the bright example and luminous exhortation of the Founder of our faith. As there is nothing left of the Saxon castle which the brave Ida defended till she saw her husband in the hands of the Norman Rufus, with the pincers ready to put out his eyes unless she surrendered, except the draw-well—still full of reverberations of these old times, as we may hear when the *cicerone* drops a stone into its depths,—it would be unlikely that the fabric of the church should have been handed down. At all events, there is no fragment of it here. The roof of the principal chapel is divided into two bays.

The principal entrance to the church is in the large double aisle on the south side. No sooner has the foot stepped through it than a pleasing effect is produced upon the eye by the spaciousness and antiquity of the interior, as revealed in the views between the massive arcades dividing the nave from the aisles. The columns supporting these are stout cylindrical pillars, with plain moulded caps, of transitional character; the arcades are pointed. Coming into view of the

chancel, the effect becomes richer. This is lighted on the south side by lancets, most of which are filled with stained-glass of deep brilliant hues, grouped in couples, having an arched panel between each group. The east end is lighted by three lancets; the north side by two couples of lancets. It is seated with stalls, leaving for the sanctuary exactly that portion of the chancel which is occupied below by the crypt. The aisle and transept on the south side of the nave have three-light windows, except at the westernmost end of the former, where there is a lancet; that on the north side by double-lights, except at the north end of the transept, where a treble-light corresponds with that at the southern transept, and in the case of a curiously narrow splayed light at the east side of the same transept, which is of similar width to the slits mentioned as lighting the crypt. At the west end there are two double lights; and a single one lights the vestry built against the north side of the tower. We have said the stained-glass is of deep brilliant hue. Unfortunately, that is all that can be said of it. It was bought second-hand not long since, and bears no relationship to the general design of the fabric, nor to the intensely interesting history of the Early Church in this district, nor even to the loving bravery of the lighthouse-keeper's daughter. The chancel is nearly as long as the nave; the one measuring 60 ft. by 25 ft., the other, without the tower, 68 ft. by 30 ft.

Many will be glad to hear that Grace Darling's brother now fills the situation once occupied by her father. The lighthouse is a marvel of cleanliness and neatness. After climbing from the boat up an ascent of rocks covered with seaweed, through which Mr. Darling has cleared a precipitous path, the pebble-paved and enclosed yard of the lighthouse, where everything that is not painted red is painted white, appears strikingly different from terra-firma objects. The spiral staircase conducts the visitor past room after room, all scrupulously neat, and decorated with marine curiosities, till it terminates in the glass chamber containing the revolving lights. These are triplets of moderator lamps, each having a reflector of surpassing brilliancy behind it. The three lights appear as one from a distance, and as the revolution of the machinery takes these out of sight before the next three come into view, that intermittent effect is produced that makes it distinguishable from any other. Not a smut or a flyspot is perceptible on any part of the brilliant gear; nor indeed a mark of any kind, except one dent in a reflector that the keeper vainly endeavours to efface: a bird bewildered in a long-ago storm had dashed its breast through the glass walls and fell dead in its dearly-sought shelter. The rocks or islets that make this part of the sea so dangerous for navigation, are the breeding places of myriads of cormorants and other large sea-birds, which, as boats approach them, flap their wings, and with fierce noises object in a most unmistakable manner to any one landing. The island nearest to the shore, with the lighthouse upon it, known as the near light, has a pele tower upon it of Edwardian architecture. The largest chamber on the principal floor has a small recess in it, which, from the opening in the masonry, appears to have been a confessional; it has lately been rendered habitable, and is now in use as a marine seat. St. Cuthbert's Chapel, upon the same island, has also been put into repair, and furnished with some old carved oak fittings brought from the mainland, and divine service is occasionally performed in it in the summer months. The memory of the two vigorous ascetic ecclesiastics, St. Aidan and St. Cuthbert, with that of their first regal convert, the good St. Oswald, is still green on this part of the coast.

Bamboorough appears to have been as much knocked about by the Danes and Normans as Sebastopol was by the English and French. And the poetic faculty of Mediaeval times seems to have idealised some such tragedy as that of the "thru red line" at Balaclava in the ancient Northumbrian poem, "The Laidley Worm of Spindleston Heughs," the long loathsome horror doubtless representing an armed and hostile force.

OPENING OF A PUBLIC PARK AT BINGLEY.—A public park has been opened at Bingley, amidst great demonstrations of rejoicing. The site of the park is at Brown Hill, on the left side of the Aire, and it consists of eighteen acres of ground, ornamentally laid out. The park bears the name of the Prince of Wales.

CHRIST'S HOSPITAL.

A COMMOTION lately made on the proposed removal of the Charter House from its ancient site to the country induces a return to the question mooted several years back in the *Builder*, advising a similar change for the still more important and equally ancient foundation of the Blue-coat School. Both are richly endowed and magnificent institutions, established for the education of the children of distressed but reputable parents; the Charter House having forty resident free scholars, and some sixty decayed pensioners; while Christ's Hospital nurtures, clothes, and educates 1,300 boys, the complement maintained for many years on its foundation. These children are taken in between the ages of eight or ten years, and are wholly sustained within the establishment, first in childhood at the infant school in Hertfordshire, and afterwards until completely educated; when for good scholars and successful aspirants there are exhibitions at Oxford and Cambridge, and livings in the Church.

It may be that in the lapse of ages, as the value of the estates and possessions of either have become enormously enhanced, and as the sites which were at first suburban have both been circumvented by the great and still growing metropolis, that the benevolent intentions of the founders of, and contributors to, these God-like charities have not been fully carried out; and that, in fact, we find therein, not the children of decayed or distressed tradesmen, or of reduced gentlemen, but the sons of independent families; yet still these institutions are to some extent eleemosynary; and, if the sphere of their utility could be enlarged, as most undoubtedly it could be by a transfer from the centre of the busiest of cities to the country or the suburbs of London, surely there can be no reason for the retention of the original localities, which are now as inappropriate to the objects of education and health as they were formerly well chosen.

Between Giltspur-street on the west, and King Edward-street on the east, and from Newgate-street on the south, the busiest thoroughfares of the City, and Bartholomew's Hospital on the north, a large space divided into several squares, with a magnificent hall, a church, and numerous extensive buildings, affords an asylum and playgrounds for over 800 boys. This is the largest school in England, educating as many as any four of our most celebrated metropolitan seminaries. It occupies, in proportion to its numbers, a large site; and the position it stands on has now attained a value that could never have been contemplated by the royal founder, Edward VI. Surrounded by prisons, hospitals, railways, markets, and busy thoroughfares, the space is needed for civic and national buildings of importance; and, as it has been prejudicial to educational purposes, and to the health and morality of the scholars, its removal to one of the Hospital estates in Middlesex, or one of the home counties, would enable the governors to increase the numbers at least 100 more, and, at the same time, to erect more extensive and appropriate buildings, with a park, gardens, and premises tributary to the bodily health, mental culture, and gratification of the pupils.

Many of the governors (800 in number) and principals of the institution are favourable to a change to the country,—the question having been under discussion some six years back. Since then, the completion of two railways, and the foundation of the great meat-market in Smithfield, make such a change more requisite, and on all accounts more desirable. But the Corporation has a paramount influence, as the lord mayor, the aldermen, and twelve common councilmen are governors *ex officio*; and they also have each of them the privilege of one presentation to the school every year; while the other royal and noble governors are entitled to one in turn only. Besides that, there are other deferences paid to the Corporation by the school, which is received annually at the Mansion House, when every boy is treated to a bun and a shilling!

It would be vain to expect that so large a body of distinguished governors would interfere in the management of the school, although each one contributes 500*l.* on election; still in a question of such vital importance, wherein the education, health, and nurture of 1,300 youths are concerned, it is worth a little consideration, and one attendance at a Board meeting, to settle the point of transfer or otherwise.

Seeing that a glorious national college of

1,500 students might be the result of a well-managed change to one of the home-county estates of the school, a day devoted to the object would be well spent if at the same time some little alteration were made in the ancient costume which is still so absurdly retained. It is needless to point out the absurdity as well as the inconvenience of a long yellow cloth petticoat, under a long blue coat; of antiquated light knee-breeches and yellow (clouted) woollen stockings in summer; and the hare head! No-thing could be more ungainly, awkward, or perhaps more unhealthy.

A uniform of a modern kind would be more grateful to the public than the old monastic costume.—“*nimum ne crede colori*,”—it matters not what colour they choose, but the fashions forms are more consistent with modern tastes, and most certainly more conservative of health and comfort, and favourable to free exercise.

As the estates of the institution now realize 70,000*l.* a year, the additional income sure to be derived from the sale of the City grounds, the buildings, and Mr. Shaw's noble hall, offers a fair incentive to re-open the question of transfer to the country;—these remarks being offered as *addenda* to former articles in the *Builder*.

#### IMPROVEMENTS IN THE MANUFACTURE OF GLASS.

On the 15th ult., M. J. Pelouze presented a memoir to the Academy of Sciences of Paris, on the action of metalloids upon glass, and the presence of alkaline sulphates in all the glasses of commerce.

It has been known for a very long time that glass is coloured yellow by charcoal and by sulphur, but the effects of other metalloids had not been ascertained. The experiments conducted by M. Pelouze, in the Siemens' furnaces of the Saint Gobain works, were as follows:—

**Charcoal Glass.**—To colour glass yellow by charcoal, he took the following composition (called A):—White sand, 250 parts; calcareous spar, 50 parts; carbonate of soda (of 85 degrees), 100 parts; wood charcoal, 2 parts. After a lapse of a few hours, the glass being melted and refined, the crucible was taken from the fire and cooled. It contained a mass of homogeneous glass, of a deep yellow colour.

**Sulphurized Glass.**—This preparation is the same as the last, and the colour identical with that obtained by charcoal. Owing to the volatility and combustibility of sulphur, 6 grammes of sulphur are equal in effect to 2 grammes of charcoal.

**Silicium Glass.**—The following composition was taken:—White sand, 250 grammes; carbonate of soda (at 90 degrees), 100 grammes; calcareous spar, 50 grammes; silicium, 2.50 grammes. This gave a yellow glass impossible to be distinguished from the two former.

**Boron Glass.**—Same mixture as the last, the silicium being replaced by 2 grammes of boron. This gave a glass of a fine yellow colour similar to the others above mentioned.\*

**Phosphorus Glass.**—Amorphous and pulverulent phosphorus, mixed in considerable proportion with the composition A, gave no colour whatever to the glass. All his efforts to obtain a positive result failed, in consequence, no doubt, of the entire vaporization or combustion of the phosphorus; but when the composition A was acted upon by phosphate of lime (prepared by the process of M. Paul Thénard), weighing from 5 to 6 grammes, the phosphorus ceased to be volatile, and furnished a yellow glass exactly similar to the rest mentioned.

**Aluminium Glass.**—The presence of even a very small portion of aluminium in the composition renders the glass most difficult to be fused or refined. When, after much time and pains, this is accomplished, the result is a yellow glass, as in the other cases. He thus sums up, as giving a yellow colour to the white glass of commerce, among the metalloids, carbon, sulphur, silicium, boron, and phosphorus; among the metals, aluminium. M. Pelouze was of opinion at first that this constantly identical colour was due to the presence of silicium, the only one of these substances which necessarily entered into the composition of glass; but experiments soon demonstrated that he should search elsewhere for an interpretation of these singular phenomena.

\* The silicium and boron, obtained through the kindness of M. H. Deville, were beautifully crystallized, and of remarkable purity.

Hydrogen, thoroughly purified, colours glass yellow at a red heat. If this gas be passed through a porcelain tube containing a platinum dish filled with fragments of glass, the latter, raised to a temperature not very elevated and then cooled in the current of hydrogen, gives a yellow colour, less fine and less intense than that produced by carbon, boron, &c., yet well defined. It is surprising that this reaction is not generally known, for reductions by hydrogen gas in glass tubes are of frequent occurrence in laboratories. The reduction of the silicium by hydrogen appearing impossible, especially at low temperatures, M. Pelouze attributed this coloration of the glass to the presence of alkaline sulphates, of which every glass of commerce contains notable quantities, and therefore turned his experiments in this direction. In melting the composition A with some hundredth parts of its weight of sulphate of soda, and submitting it to a current of hydrogen, he obtained a glass of an exceedingly deep yellow colour, in which were easily recognisable the odour, taste, and all the properties of an alkaline sulphuret.

The most distinguished chemists who have analysed glass not having noticed the presence of sulphur, he proceeded very cautiously with his experiments in ascertaining the presence and proportions of sulphates in glass of commerce. For this purpose were examined mirror, window, table, Bohemian, and bottle glass, also a specimen of ancient glass brought by him from Pompeii in 1863. The mirror glass gave different quantities of sulphate of soda, varying from 1 to 3 per cent. The fusion, refining, and annealing of this sort of glass take in general from eighteen to twenty-four hours. After exposure to the same temperature for 120 hours, the glass contained still 7 per 1,000 of sulphate. The Pompeian glass gave a quantity of sulphate of harytes corresponding to 2 per 100 of sulphate of soda. The Bohemian furnished 2.2 per cent. of sulphate of potash. The other glasses gave from 1 to 3 per cent. of sulphate of soda. It is well known that glass-makers employ two fluxes, sulphate and carbonate of soda. As this last salt rarely exceeds 85 degrees, or at most attains 90 degrees, it contains constantly considerable proportions of the sulphate of soda. To obtain, therefore, glass totally free from the sulphate, a carbonate should be used which is free from it also, and operations should be carried on in the manufacture by aid of a carbonate of soda hitherto unknown, at least in glass-making, marking 92.5°. No such glass exists in commerce. It would be undoubtedly less alterable and more homogeneous than those hitherto known, and capable of rendering great services to the arts and sciences, especially to optics. With a view of proving that the colorization of glass, being due to the presence of sulphate of soda, when acted upon by charcoal, silicium, boron, &c., does not take place when the sulphate is absent, he took the following composition:—White sand, 250 grammes; carbonate of soda, pure and dry, 100 grms.; carbonate of lime, pure, 50 grms.; starch charcoal, 2 grms. The glass obtained was well melted, well refined, and perfectly white. The same result took place when the charcoal was replaced by boron, silicium, or hydrogen; but as soon as even half a hundredth part of sulphate was added, a light yellow colour was the consequence. Pure glass, then (made with carbonate of soda free from sulphate), is coloured yellow by sulphur, or an alkaline or earthy sulphuret.

Instead of preparing for commerce yellow glass by the aid of carbon, it can be obtained directly with sulphuret of calcium; but it must be recollected that the sulphate contained in the carbonate of soda acts as a combustible, and wastes a corresponding quantity of the sulphuret. It is, then, only when the sulphate has been destroyed that the excess of the sulphuret colours the glass.

The following combinations were fused:—  
A. White sand, 250 grammes; carbonate of soda at 90 degrees, 100 grammes; carbonate of lime, 50; sulphuret of lime, 20 to 10 per cent.\* This gave a very deep yellow-coloured glass, hardly translucent.

B. Same combination, with 10 grammes of sulphuret of calcium, or 2.5 per cent. It obtained a glass of a lighter yellow than one would have expected.

C. Same mixture, with 1.25 per cent. of sul-

\* Prepared by calcining at a red heat, a mixture of 250 grammes of wood charcoal, and 4 kilograms of gypsum. The sulphuret still contained a certain quantity of sulphate.

phuret of calcium. This glass was completely colourless.

D. Same combination, with 5.5 grammes of sulphuret.

E. Same, with 6 grammes of sulphuret of calcium. Glass of not a very deep yellow, similar to crystals of native sulphur.

The extreme point of decoloration corresponds to 5.500 grammes of sulphuret of calcium, or about  $\frac{1}{2}$  per 10 of the vitrifiable compound, and the yellow colour does not commence to appear until the quantity of sulphuret exceeds this last proportion. Also, in the compound B, where 20 grammes of sulphuret were employed, 14.5 grammes only entered into the colouring of the glass, 5.5 having disappeared by oxidation. With these data one can readily prepare a combination to produce the required shade of yellow. The proportions given by M. Pelouze, on a practical scale, are 270 kilogrammes of sand, 100 kilogrammes of carbonate of soda at 90 degrees, 50 kilogrammes of marble, 12 kilogrammes of sulphuret of calcium.

#### THE NATIONAL AND PORTRAIT GALLERIES.

On the vote for 13,336*l.*, to complete the sum of 23,336*l.* for the expenses of the National Gallery, including the purchase of pictures, being moved in committee of supply in the House of Commons, Mr. Cowper said an estimate of the cost which would be incurred by the enlargement of the National Gallery was in preparation. This estimate would be for the purchase of the ground in the rear of the National Gallery. Nothing could be done at present beyond the purchase of the land. The vestry were willing to dispose of their property, provided they received such a sum as would enable them to erect another workhouse in the suburbs, and a casual ward and parochial office within the parish. The trustees of Archbishop Denison's school were also willing to part with their property, provided means were given them of obtaining another school within the parish, and a similar arrangement could be made with the parochial school. It would, therefore, be his duty to bring in a Bill for the purchase of these properties; and the land thus purchased could be used from time to time as the enlargement of the gallery was required. A proposition had been made to the Royal Academy, informing them that if they pleased to apply for a site at Burlington House, the Government would be prepared to grant it to them; but there was not yet time to ascertain the intentions of the Academy, and a considerable time must elapse before they could obtain another building. Many of the persons for whom the national collections were kept could not, from their daily vocations, see them during the day. Therefore he agreed that, as far as it was feasible and safe, the public exhibitions should be opened in the evening. If a building were erected from the commencement with a view to using it at night, it would be made fireproof, and gas could be introduced in such a way as to cause the smallest amount of danger. He did not think, however, that it could be so arranged in the present building, and he could not but think that the pictures would run great risk if gas were introduced into it.

Sir W. Fraser urged the importance of increasing the Gallery, as an incentive to individuals to bequeath their pictures to the public.

A supplementary estimate has been presented to Parliament, asking for 20,000*l.* for the purchase of a site for the enlargement of the National Gallery. The total estimate of the sum that may be required to acquire possession of the land and premises between the National Gallery and Hemming's-row is 100,000*l.*

On the proposal that 1,650*l.* should be voted for the British Historical Portrait Gallery, Mr. Cowper said the portraits are at present only in a temporary place of accommodation; they can only be very imperfectly seen, and it is a source of anxiety that they cannot be better exhibited. It is intended to find a proper place for these portraits in the new gallery that is to be erected in connexion with the National Gallery. He would call the attention of those who manage the exhibition to the expediency of rendering the hours of viewing the exhibition more convenient to the public.

SOUTH KENSINGTON MUSEUM.—During Whitson week 30,471 persons visited the Museum.

## ON METROPOLITAN IMPROVEMENTS.\*

It has of late years been the fashion to sneer at the attempts made in this country to carry out such improvements as have become necessary from time to time in our metropolis, and to draw unfavourable comparisons between what is done here and what is done on the Continent under similar circumstances, and especially with regard to the magnificent works which have been carried out in the capital and provincial towns of France, under the auspices of the present Emperor.

New, although we do not enjoy the advantages of a paternal government, to guide and preserve us in the right path, like our neighbours across the Channel, and our civil improvements, taken one by one, will perhaps hardly bear a comparison with theirs, either in grandeur of conception or in the rapidity and spirit with which they are carried out; still a glance at the extent and conditions of our metropolis some sixty years ago, will soon convince us that a very large aggregate amount of work has been done (some of it, no doubt, wretchedly conceived and badly executed), but which on the whole will bear a very favourable comparison with what has been accomplished in the same time in any part of the Continent.

Let us take a map of London at the time we are speaking of. This is one entitled "The Stranger's Guide to London and Westminster, exhibiting all the latest Improvements up to the present time," published in 1806. We shall find that, practically, the City was bounded on the north by the New-road,—Gower-street ended in a market garden,—and it was a pleasant walk by Bagnigge Wells, the Merlin's Cave, and the New River reservoirs, to the Angel at Islington. Parties to Primrose Hill could stroll through Marylebone Park Farm (belonging to the Crown), and stop to refresh themselves at the Jew's Harp, if they desired anything more potent than the ems-and-whey they would obtain at the adjacent farm-house. The inhabitants of Westminster might walk across Tothill Fields to the river, and be ferried over to Vauxhall Gardens; or if they wished a quicker walk, might turn to the right, through the Five Fields belonging to Earl Grosvenor, and passing the large reservoirs of the Chelsea Water-Works, go by the Royal Hospital on to Chelsea Common. Westminster, Blackfriars, and London were the only bridges below Battersea. The access from London Bridge to the Royal Exchange was by way of the narrow Fish Street-hill and Lombard-street; while we can only hope that very few people were obliged to attempt the difficult passage from the Bank to Finsbury-square, up Coleman-street and Little Moorfields. Regent-street did not exist; and the Royal Mews, at Charing Cross, however convenient it may have been for the Prince Regent at Carlton House (close by), must have seriously impeded the traffic at the junction of the leading thoroughfares of the Strand, Whitehall, and Charing Cross. The possibility rather than the probability of being whirled through the air at the pace of ten or twelve miles an hour by steam on a railway was only then beginning to haunt the dreams of a few enthusiasts; and Londoners journeyed seven or eight miles out of town to be astonished at the marvel of a long string of coal trucks drawn by two or three horses along the Surrey Iron Railway, just then completed, to connect the river Thames at Wandsworth with the inland towns of Mitcham and Croydon.

Until within the last ten or twelve years, however, it has been tolerably easy for any one whose attention was directed to these matters, by business or inclination, to keep pretty well informed on the subject; but since then, such rapid and important changes have taken place, and others of still more consequence are in contemplation, that the difficulty of obtaining, or rather of retaining, the information has much increased, while the necessity for its acquisition, in a professional point of view, is daily becoming more obvious and pressing. It is now a matter of every day occurrence for an architect to be called on to advise on the eligibility of a building estate, or as to the site of a new building and the effect which the opening up of some new street or railway, or the contemplated diversion of a line of traffic, may have on the business or the objects for which it is proposed to be erected; besides the many other incidents of an architect's ordinary practice, in which the knowledge of the present or prospective value of property

plays so important a part. Looking on the subject from this professional point of view, I have thought it might be of some advantage if I were to lay before the members of the Association a brief outline of some of the most important works which have been executed during the present century, and include in my survey some others which are already in progress or on the eve of being commenced. With the object I have just indicated in view, I propose to confine myself chiefly to a consideration of those undertakings which have been set on foot for the purpose of affording new or increased facilities of intercommunication between different parts of the metropolis; the principal points we shall have to notice, therefore, will be bridges, streets, and railways.

Now, any one who has not thought much on the subject, as he walks down Regent-street, or along Cannon-street, and sees the line of splendid shops or ranges of lofty warehouses, knows very well that if he wishes to buy or rent premises, either in one street or the other, a price will be asked amounting almost to a fortune, or to a handsome yearly income for a man of moderate expectations; and the idea may occur to him, what a fine speculation it must be to get an Act of Parliament, and open up a new street like this! But he would think it strange, when he came to inquire more closely, and was told that the actual net loss on carrying out a new street is equal to one-half or two-thirds of the money expended, and that that proportion of his capital would be utterly sunk and lost. Cannon-street, which was only half a street, has, I believe, turned out the least loss of any recently executed, and it entailed a loss of 40 per cent. The leases of houses in Regent-street might have been bought, after they were built, at prices equal now only to the rents which they realize per annum. This arises from several causes, the principal being the fact that a new street is generally made through a densely-populated locality; and the area occupied by so many small houses, all of which have to be paid for by heavy compensation, is thrown into the improved width of roadway, which does not return a direct equivalent profit in the increased value of the frontages thereto. Again, it is a long time before a new street takes with the public or the shopkeepers. The slow progress of New Oxford-street towards respectability is a case in point; and, at the present time, it has hardly got into the position it ought to occupy as a leading thoroughfare. It is obvious, therefore, that the ways and means for accomplishing any of these undertakings are of the utmost importance; and to this subject we will devote a few preliminary observations, as the sources from whence such funds are derived must of necessity exercise an important influence, both on the character of the projects themselves, and on the rapidity and manner in which they are carried out.

First, then, it is well known, I have no doubt, to all, that the revenue of the estates belonging to the Crown is made over to the executive Government in return for what is called the civil list, or Parliamentary allowance to the Sovereign. These estates are vested in commissioners during the life of the reigning Sovereign, the reversionary interest of the estates being reserved for his successor. These estates themselves are therefore kept intact, the commissioners dealing with the revenue as may be deemed advisable in the interest of the State. It is with a portion of this revenue, aided by grants and loans from the Consolidated Fund, that many of the improvements at the West-end, where the Crown has valuable estates, has been effected; the two-fold object of accommodation to the public and increase of value to the reversion of the estates being for the most part kept in view.

Next, perhaps, we should mention the corporation of the city of London, who have a large revenue derivable from property in their possession, and a great proportion of this is annually devoted to improvements from which no direct profit accrues to them. They have also been intrusted, from time to time, with the administration of large funds which have been raised with the sanction of the legislature for making new streets and other works, such as London Bridge and approaches, the Royal Exchange approaches, and others of equal importance. The chief source of the revenue which they have thus administered is the well-known coal-tax. This duty consists of 1s. 3d. per ton on all coals brought within a radius of about 20 miles of the City, and was originally granted in the time of William and Mary, for the relief of the orphans

and other creditors of the city of London, and has been continued from time to time by various Acts of Parliament, which point out the specific purposes to which it is to be applied. Now the coal tax produces 240,000*l.*, and in 1836 it was about half that amount. The commissioners of sewers, also, of the city of London have a separate fund raised by taxation, out of which they are constantly hit by his improving existing streets and setting back projecting houses whenever an eligible opportunity presents itself for so doing. There are also the local Boards, and the Metropolitan Board, who have certain powers of taxation, and now generally administer the funds derived from public sources for most of the important civic undertakings. A further source of revenue in years new gone by, was the profit derived from the State lotteries; and with it Westminster Bridge and the improvements at Snow-hill were partly executed. The profits were between 300,000*l.* and 400,000*l.* per annum. This was rather too good a sum to lose on the score of morality; and the committee, if they did not actually recommend, very strongly suggested that there would be no harm in raising by way of lottery (or, as some of the witnesses put it, availing themselves of voluntary taxation), a sum of about 120,000*l.* per annum, to be appropriated to improvements from which the public themselves would derive the benefit.

*Bridges.*—Facilities for crossing the river are perhaps the most important to a city like London. Bridges, therefore, seem to claim our first attention; and first among these comes London Bridge. We are all familiar with the aspect of old London Bridge, as it appears in old prints and engravings. There is a very good view of it in the Vernon Gallery, with its houses, gateway, mills, chapels, and narrow arches. The Great Fire of London, in 1666, destroyed most of the buildings, and damaged the bridge; they were, however, restored in a great measure, and so remained till about 1754; when an Act was obtained for clearing off the houses, throwing two of the arches into one, and otherwise improving the bridge. This was done on designs by Sir Robert Taylor and Mr. Dance; and as it stood after this, the bridge consisted of nineteen arches of various spans, the water-way at low water being only about 231 ft., while the space occupied by the piers and starlings was 700 ft. This of course was a serious obstruction to the traffic; and at length, after having been only sat upon and reported upon by various committees, an Act of Parliament was obtained in the year 1823 for the erection of a new bridge. This was commenced in 1824, from the designs of Mr. Rennie, and opened on the 1st of August, 1831. The bridge is built of stone, and now consists of five arches, with a water-way of 690 ft., and a space occupied by piers of 92 ft. only. The cost of the bridge was about 426,000*l.*, which was raised principally from the Bridge House Estates, belonging to the Corporation.

The Act of Parliament for the construction of Blackfriars Bridge, which was originally called the Pitt Bridge, was obtained in 1756, under powers given to the corporation of the city of London, who were empowered to raise a sum of 30,000*l.* per annum by tolls, to pay off part of the expense. Out of a large number of designs, among which were some by Smeaton, Chambers, Dance, and others, that by Mr. R. Mylne was eventually selected. It was commenced in 1760, and completely opened in 1770. It was built of stone, and consisted of nine arches, leaving a water-way of 788 ft. The cost of the bridge and approaches was about 265,000*l.*; of this amount about 166,000*l.* may be put to the expense of the bridge itself. However, from some inherent defect in the foundations, the arches sank; and between the years 1832 and 1843, 165,000*l.* were spent in repairs; and since that time it has been a source of constant expense to the corporation. The parapets were taken off and replaced by wood; and within the last year or two the Corporation obtained a number of designs, and the new bridge, which is to be somewhat similar to that of Westminster, is now being erected, under the superintendence of Mr. Joseph Cubitt.

Westminster Bridge was commenced in 1739, from the designs by Labeleye, and finished in 1750; about 300,000*l.* were expended. It consisted of fifteen arches, leaving a water-way of 820 ft. This bridge also, like Blackfriars, seems to have been a constant source of annoyance and expense. Even during its building, in 1747, one of the arches failed, and had to be made good at a large expense. The whole structure became so bad that, as we all know, it was

\* From a paper by Mr. Penfold read at elsewhere mentioned.

taken down and replaced by the present structure from the designs of Mr. Page, which was commenced about 1855. There are seven main arches and two or three smaller ones. The bridge is nearly twice as wide as the old bridge, being 85 ft. against 44 ft. of the old. The bridge was erected in halves, the old remaining while half of the new was building: this delayed the completion. The cost was about 316,000*l.*, besides the approaches.

In 1809 the Strand Bridge Company was incorporated, and they were empowered to raise 500,000*l.* in shares, and a further sum of 300,000*l.* on mortgage. Further powers were obtained in 1816, and the name was changed to Waterloo. The bridge was commenced in 1811, from the designs of Mr. John Rennie, and opened in 1817. It consists of nine arches, with a water-way of 1,080 ft. The original estimate for the bridge alone was 680,000*l.*; and it deserves to be recorded, to the credit of Mr. Rennie, in a work of such magnitude and so much uncertainty, that the estimate was not exceeded by more than 5,000*l.* The total cost of bridge and approaches, with expenses, was 1,030,852*l.*, which was raised by shares, annuities, and bonds. The company met with great opposition from the City; and Mr. Mylne, their engineer, stated before the committee of the House of Commons that it would be impossible to build a bridge on the site; and, if built, it could not stand. It, however, has survived to the present time, and seems likely to last still longer; while Mr. Mylne's bridge is fast disappearing from the face of the earth. Whatever advantage this bridge may have been to the public, the shareholders have not derived much profit; and although, since the opening of the Waterloo Station, the traffic has increased, some years ago the 100*l.* shares might have been obtained for about 3*l.*; and the clerk to the company, in evidence before a committee in 1836, on a question of opening the bridge free of toll, said that the then market value of the whole property—shares, annuities, and bonds—was 303,811*l.*, or about 700,000*l.* less than the cost.

Southwark Bridge, an iron bridge, was also designed by Mr. Rennie. It has three arches, with a water-way of 660 ft.; it was commenced in 1814, and opened in 1819. The expenditure of capital for the bridge and approaches, and other expenses, was 666,486*l.*; of this, 186,000*l.* were paid for purchase of property, 278,000*l.* for masonry to bridge, 143,000*l.* for iron work to bridge and approaches, and 60,000*l.* for miscellaneous charges. About 150,000*l.* were raised by preference shares, at 5 per cent., and the holders of these are the only proprietors who have received any dividend, and these only at the rate of 2 or 3 per cent. The 100*l.* shares might have been bought at 2*l.* or 3*l.*

Vauxhall Bridge is also a cast-iron bridge; it was designed by Mr. James Walker, and carried out by him, though Mr. Rennie and Sir James Benthams seem to have had some hand in it. It was commenced in 1811, and opened in 1816. It has nine arches; and the cost was about 300,000*l.*

Lambeth Bridge was erected by a private company. It is on the suspension principle, being of wire cable. The bridge has three spans, each of 280 ft.: the piers are cast-iron cylinders, the same as Hungerford. There is a carriage-way and footpaths, the total width being 32 ft. The works cost about 28,000*l.*, the whole cost for land, &c., being 40,000*l.*

Chelsea Bridge, which connects Battersea Park with Pimlico and Chelsea, is a suspension-bridge. The width of the river at this point is 737 ft., which is crossed by three spans, the central one being 352 ft. between the piers. The roadway is 32 ft. in width; the footways overhang, and are each 7 ft. 6 in. wide. The four towers which support the chains are of iron, except about 15 ft. at the top, which are of copper partly gilt. The bridge and the embankment in connexion, are from the designs of Mr. Thomas Page.

*Streets.*—The first, perhaps, that claims our attention is that of Regent-street, and the works connected with it. The immediate cause of its being undertaken was the desire of the Commissioners of Woods and Forests to improve the Marylebone Park Farm, belonging to the Crown, and the lease of which had just expired; and also (through the influence of the Prince Regent) to form a good means of communication from Carlton House to this estate, where it was proposed that a residence for him should be erected. There was a competition, with a premium of 1,000*l.*, for laying out the proposed park and

forming the necessary communications; but the result does not seem to have been satisfactory; and in the event a plan, which was a combination of the designs of Messrs. Leverton & Chawner and Mr. Nash, was adopted. This was about 1813; and, in a few years, the Regent's Park, as we now see it, was fenced in and planted, and the terraces built. The net cost of laying out the Regent's Park was about 20,000*l.* This was paid out of the revenue of the Crown estates. Regent-street was opened some time in the year 1819. The total cost of forming the street, for compensations, and other expenses, seems to have been about 1,406,000*l.*, and the expense of the sewer 60,800*l.* besides. Of this amount, 515,000*l.* were paid out of Crown revenues, and 800,000*l.* out of the Consolidated Fund.

As the improvements in Regent-street drew near their completion, those in the neighbourhood of Charing-cross were commenced, and comprised the extension of Pall-mall into the Strand, by cutting off a part of the churchyard of St. Martin's, clearing away the King's-mews, and the formation of Trafalgar-square, and widening the Strand and St. Martin's-lane at their junction with the extension of Pall-mall. Up to the year 1835 these improvements had cost about 1,500,000*l.*, principally defrayed out of the revenues of the Crown lands, and carried out under the superintendance of Mr. Nash.

In the meantime considerable improvements had been going on in the City. London Bridge I have already alluded to; and, in connexion therewith, the street from the Mansion House to the bridge, now called King William-street, was carried out, as also the continuation of that thoroughfare to Finsbury and the New-road to the present Princes-street and Moorgate-way. These works were carried out under the superintendance of Sir Robert Smirke and Mr. Montague, the City surveyor. King William-street cost about 212,000*l.*; Moorgate-street about 156,000*l.*; the approaches on the Surrey side about 300,000*l.*; and other matters in connexion made the total cost about one million, and this burden was laid on the coal-tax. St. Thomas's Hospital, the hurning of the Royal Exchange also, and its re-erection, necessitated great improvements in the neighbourhood of the Bank and Mansion House; and these were also paid for out of the coal-tax fund. Some new openings in connexion with Waterloo Bridge were also carried out at this time.

In 1836, a committee of the House of Commons was appointed, of which Alderman Wood was chairman, to inquire into a variety of schemes connected with London and Westminster, among which were the improvement of Skinner-street and Snow-hill by a viaduct; a new street from St. Paul's to Bricklayer's Bridge; from Farringdon-street to Clerkenwell; from the Post Office to the Bank; Westminster Abbey to Pimlico; Finsbury-square to Whitechapel Church; St. George's Church to Blackfriars Bridge and Waterloo Bridge; and opening Waterloo Bridge and Southwark Bridge free. Mr. Donaldson, Mr. Montague, Mr. Cottingham, and others, gave evidence, and submitted plans. In 1838, the committee were again engaged on the same subject, and they recommended Cranbourne-street, Endell-street, New Oxford-street, and Spitalfields, for some of which plans had been prepared by Mr. Nash.

In 1814 and 1845, Cranbourne-street, New Oxford-street, and Spitalfields-street were opened, at an expense of about 841,000*l.* These were carried out under the superintendance of Mr. Pennethorne.

The improvements in Westminster, and notably Victoria-street, were entrusted to commissioners, who were incorporated by the Westminster Improvement Act, 1815. This, however, did not work very satisfactorily, and an Act was required nearly every following year up to 1852 and 1853, giving powers to raise various sums of money amounting to something like 250,000*l.* The commissioners also obtained powers to lend money to builders, which they did to the amount of about 400,000*l.* They also issued a large number of bonds without sufficient security; these got in the market, and became depreciated in value; the creditors interfered, and there was the usual crop of Chancery suits. And in the years 1859 and 1860, Acts were obtained for reconstructing the commission on a new basis, and making arrangements for paying off the creditors, Mr. Tite having been persuaded to take a leading part in the new constitution.

Canon-street had also been opened in the mean time, at an expense of about 300,000*l.* paid chiefly by the Corporation of the City.

The Act for the new street in Southwark was obtained in 1857. The works were commenced in 1861, and the whole of the street was thrown open to the public on the 1st of January, 1864. The street is about two-thirds of a mile long, and the estimated cost was 519,424*l.*, including about 9,000*l.* for sewer. Instead of the sewer, a subway was carried out at an expense of about 25,000*l.*, including which the total cost of the street has been 557,051*l.*, a result creditable to Mr. Marshall, who carried it out; and, it is anticipated, that of this amount about 267,000*l.* will be recovered by sale of land, &c.

Almost every engineer and architect who has taken any leading part in such matters, from the days of Sir C. Wren downwards, has been pressing on the notice of the authorities the necessity of embanking the Thames. Almost every committee has reported on the subject and earnestly recommended its adoption. John Martin, the painter, made great efforts, extending over twenty-five years, to get a design he had made carried into effect. In 1842 a commission, with the late Duke of Newcastle for chairman, was appointed, and many designs were laid before them; but nothing was done except here and there in connexion with other works, and by private individuals, according to a line laid down by Messrs. Walker & Burgess; and it was not till 1861, after the Metropolitan Board of Works had been empowered to carry out the main drainage, and the inhabitants of the Strand, along which the low-level sewer was to be carried, became alarmed at the prospect of being enclosed in a hoarding for a year or two, that any serious steps were taken to carry out this long-contemplated scheme. In this year, another commission was appointed, who took evidence and received a large number of designs, one by Mr. Shields, being the basis of that now proposed to be carried out. The commission recommended the Embankment, and a new street from Blackfriars to the Mansion House. An Act was then passed, providing funds for the Embankment, by continuing the Coal and Wine Duties till 1872. The necessary plans were then prepared, and, after much opposition from the Duke of Buccleuch and others on the question of carriage traffic, the Thames Embankment Act was passed in 1862.

This Act authorises the construction of an embankment, with a roadway 100 ft. wide, and the necessary junctions of existing streets therewith. The width of the Embankment varies from 450 ft., near Buckingham-street, to 130 ft. by Somerset House. The works were commenced at the end of 1863, and two contracts are let; one from Westminster to Waterloo, by Mr. Furness, at 520,000*l.*; and the other, from Waterloo to near the Temple, by Messrs. Ritson, at 229,000*l.*; this includes the Embankment sewer and subway.

The Act for the Thames Embankment did not include the powers for the new street to the Mansion House, the Act for which was obtained in 1863 by the Metropolitan Board, after some sparring with the City authorities, who wished to have the administration of the funds and the honour of carrying out the work.

The railway will pass up the middle of this street, which is not yet commenced. The street will have a subway.

In revenge for slight put upon them in giving to the Metropolitan Board the works of the new street within their boundary, the Corporation applied for, and obtained, last session, the Act for the Holborn Valley Improvement.

#### SANITARY WARNINGS DISREGARDED.

THE occurrence, in Nichol-street, Bethnal-green, of yet another of those dreadful plague-warnings which are following each other up, in rapid and still more rapid succession, like a ghastly procession of evil-foreboding skeletons, suggests to us that this same Nichol-street was distinguished in "Another Blow for Life," as a fitting example of all that is vile and death-dealing in the horrid metropolitan district which is now making itself so notorious before the public. In alluding, at page 12, to the operation of the Local Management Act, and the mistaken idea that the district surveyors under the Building Act, whose duties are entirely structural, were responsible for neglects occurring under the Local Government Act, the author says:—

"For the most part, therefore, the Act is nugatory,—we had nearly written, with Hood, Newgatory,—excepting where, as in Islington, and some other parishes, the inspector of nuisances, or other qualified person, obtains

the proof of occupancy, calls on the district surveyor for a report as to the structural deficiency only, and carries the case before a magistrate, in accordance with the Act. *This should be done in ethical-green, and scores of miserable deans would be put up.* It is no answer to say the inhabitants prefer to live, or (more truly) to die, in such rooms rather than meet the difficulty of finding a better chamber, which might not be allowed to do so. Suicide is not permitted; still less suicide that leads to the death of others not desiring to die, and to the pauperising of a still larger number, who must be maintained by the more sensible and provident."

One of the worst examples, that of a room (underground) in Nichol-street, No. 59, is then described and illustrated by engravings. The author then proceeds to remark on the "frightful picture of what met the sight in an upper room of a neighbouring house," and reiterates the immediate object which he had in view in drawing such special attention to Nichol-street, Bethnal-green,—an object

"which is special and precise,—to call for a sufficient water supply; the periodical removal, at short intervals, of all refuse; and the enforcement of the law in respect of the occupancy of underground dwellings."

It is now much more than twelve months since these desiderata were so earnestly called for; but we regret to observe, from the report now to be given from the daily newspapers, that Nichol-street, Bethnal-green, is no better, in respect to filth and want of water, at least than it then was.

An investigation respecting the cause of the death of Frances Hoag, aged 48 years, has been held at Bethnal-green.

It appeared from the evidence that the deceased lived with her married daughter in a room at No. 12, Old Nichol-street. There were five rooms in the house, each of which let for £30 a year. At the time of her death eight persons in all lived in it. The sanitary state of the place was described as being dreadfully bad: the stench was abominable and awful. The yard was wet. A month or two back there had been water laid on for four or five weeks at a stretch. The wells had not been cleaned or repaired for an indefinite period, and the cesspool had been cleaned out. The parish doctor, Mr. Heycock, was called in to be consulted, he pronounced her to be dying from fever, and she died in half an hour afterwards. Her son-in-law had the fever too, and his wife had to be removed to the hospital.

Sarah Ann Raybeck, a lodger in the house, said that while they were without water they continually complained to the landlady, Mrs. Hurst, who lived next door, but she only said, "You must do as I do—do without; get it where you can." Witness told the landlady that the deceased was dead, and in an hour he came down with a man, who put two bags of lime and gravel, &c., into the cesspool to fill it up. The man told her to tell any one that might come that the nightman had carted the soil away; but none of it had been removed; it was only kept up. He left in the evening before the job was finished. When he came back in the morning, witness's husband put his head out of window and said, "You are too late; the coroner appears to have been here and seen every thing." The next day he said, "You don't see that?" and went away, leaving the place as the jury found it.

Dr. Letheby, professor of chemistry at the London Hospital, said that he inspected the premises in question, and he had been informed, after the death of the deceased, that the water had been laid on for a considerable distance. In close proximity to the closet was the water-but, which was uncovered and open to the reception of filth, and to the water coming from the closet. The neighbouring houses and Shepherd's-curt, in the rear of them, were in the same condition, the privies overflowing with soil, the water-butts open, &c. He had rarely seen places in a worse condition.

The Coroner, in summing up, said that the state of the dwellings and neighbourhood in question was disgraceful. It was disrespectful to the landlady, a man holding an exalted position in the Kingdom, to have part of his income drawn from property in such a condition; and then there came the middleman, who made his money by grinding the poor. The next parties to blame were the sanitary officers of the parish, who permitted such most dangerous nuisances to exist.

A Juror asked who the freeholder was? said he believed the Marquis of Chandos.

The Jury, after a long deliberation, returned the following special verdict:—"That deceased died from typhoid fever, accelerated by the sanitary condition of the neighbourhood and premises in which she died; and they consider that such condition is dangerous to human life, and shows great neglect on the part of the freeholder, as well as the landlady, of the premises, and also on the part of the sanitary and medical officers of the parish; and from the evidence it appears that there is not a sufficient number of sanitary officers for the inspection of so large a parish."

The accounts given in this report of the stato of the street are as like as possible to much that was said of it and of the district which it was shown so fully to represent, in our pages long ago.

The serious increase in the mortality of Shrewsbury of late years is still engaging the attention of the local papers. One of these, called the *Journal*, appears to be an exponent of the dirt interest, which is very active, like the dirt itself, in Shrewsbury. The *Chronicle*, on the other hand, gives convincing proofs of "the connexion between dirt and death" as "one of those stern facts which few will be prepared to deny." A heavy responsibility rests with the

local press of a town in respect to its line of conduct as to sanitary matters. We have always been grateful to the *Shrewsbury Chronicle* for the proper spirit in which it received on somewhat severe strictures on the state of the town in our leading articles of 10th and 17th August, 1861. In reprinting these the editor said:—

"While on this subject, we may allude to an article in our sixth page from the columns of the *Builder*, wherein the writer draws a frightful picture of the sanitary state of the town. It is evident he has sought out some of the worst places,—which are, however, quite as horrible as he has described them; and, taking them under their most repulsive aspect, has presented such a picture as ought to induce our Improvement Commissioners to inquire from their inspector if such things really exist."

That they "really exist," the inhabitants of Shrewsbury, and we are glad to perceive, are now convinced; and, should Sir George Grey be also convinced, in spite of the "explanation" of the corporation, there is now a strong hope of speedy sanitary amendment and consequent diminished mortality. As we remarked in our leader of 17th August, 1861:—

"One man can do but little; Holophr could not control the result of the battle of Shrewsbury. To accomplish a decrease of the death-rate there must be accord and determination; in other words, a long pull, and a strong wall, and a pull altogether. It is to be hoped the men of Shrewsbury will go in and do it."

It has been urged by Dr. Lankester that mortuaries for the dead, to prevent the necessity for poor people living and even sleeping with their dead before burial, should be established; and a correspondent of the *Morning Post* draws attention to the fact that the Vicar of Heston suggested the same thing "some months since." The suggestion is a good one, and ought to be realized without loss of time; but, had the *Post* correspondent been a reader of the *Builder* some years since—nay, a good many years since—he would have known that the desirability of establishing mortuaries for the dead was then repeatedly urged in our pages.

NORTHUMBERLAND STREET SCHOOLS, IN THE PARISH OF ALL SAINTS, POPLAR.

The establishment of these schools is mainly owing to the energy and exertions of the Rev. T. W. Nowell, the rector of Poplar. The first stone of the new buildings was laid on Monday, the 21st of November, by Mrs. Money Wigram, in the presence of the Lord Bishop of London, and an influential body both of clergy and laity.

The schools are being erected in the midst of the densely-populated parish of Poplar, and comprise accommodation for about 900 boys, girls, and infants, together with class-rooms and two complete teachers' residences.

The external construction is of stock bricks, with red bricks in window-arches, and in parallel bands on the wall face. The internal face of the schools and class-rooms is also worked fair, with red brick courses every 2 ft. The ground-floor is appropriated for the boys and infants, and their class-rooms; the upper floor for the girls and the two residences.

The contract for the buildings has been taken by Mr. W. Howard, of Chandos-street, Covent-garden, for 3,687l., to whom, also, will probably be entrusted the erection of a church in the same parish, about to be built in the East-India Dock-road.

The architects, both for the schools and the church, are Messrs. Francis, of Upper Bedford-place, London.

CHORLTON UNION HOSPITAL, NEAR MANCHESTER.

The hospital of which a plan is given on the adjoining page is now in course of erection at Withington, about five miles from Manchester, for the guardians of the Chorlton Union,—a union said to be one of the largest, if not the largest, in the Kingdom. The population of the district has increased enormously during the last five or six years; and the great rapidity in the growth of pauperism has induced the guardians to undertake the important works which are now in progress.

Some years ago the guardians erected a large workhouse; but the hospital part of the building has long been found utterly inadequate to meet the requirements of the union, the inmates being frightfully overcrowded, and all kinds of infectious diseases being of necessity indiscriminately mingled in the wards. The absolute necessity of a change led a few of the guardians

to study the subject very carefully, and the result of their inquiries was a determination to erect a new hospital, on the pavilion principle, on a plot of land at the back of the workhouse buildings, and to appropriate the present hospital as lunatic wards.

The plan we illustrate, which gives accommodation for 500 beds, is only a part of the ultimate scheme which will embrace eight pavilions, and it is probable that very shortly the three other blocks will be proceeded with. Mr. Thomas Worthington, of Manchester, is the architect to the guardians, and the contract for the execution of the works has been taken by Messrs. Warburton. The architect tells us that he has largely availed himself of the articles and suggestions made in the columns of the *Builder*, and of the valuable works of Miss Nightingale and Mr. Robertson, on hospital construction. He has also visited many of the most important hospitals in Brussels, Paris, Bordeaux, and other places, previously to preparing his plans.

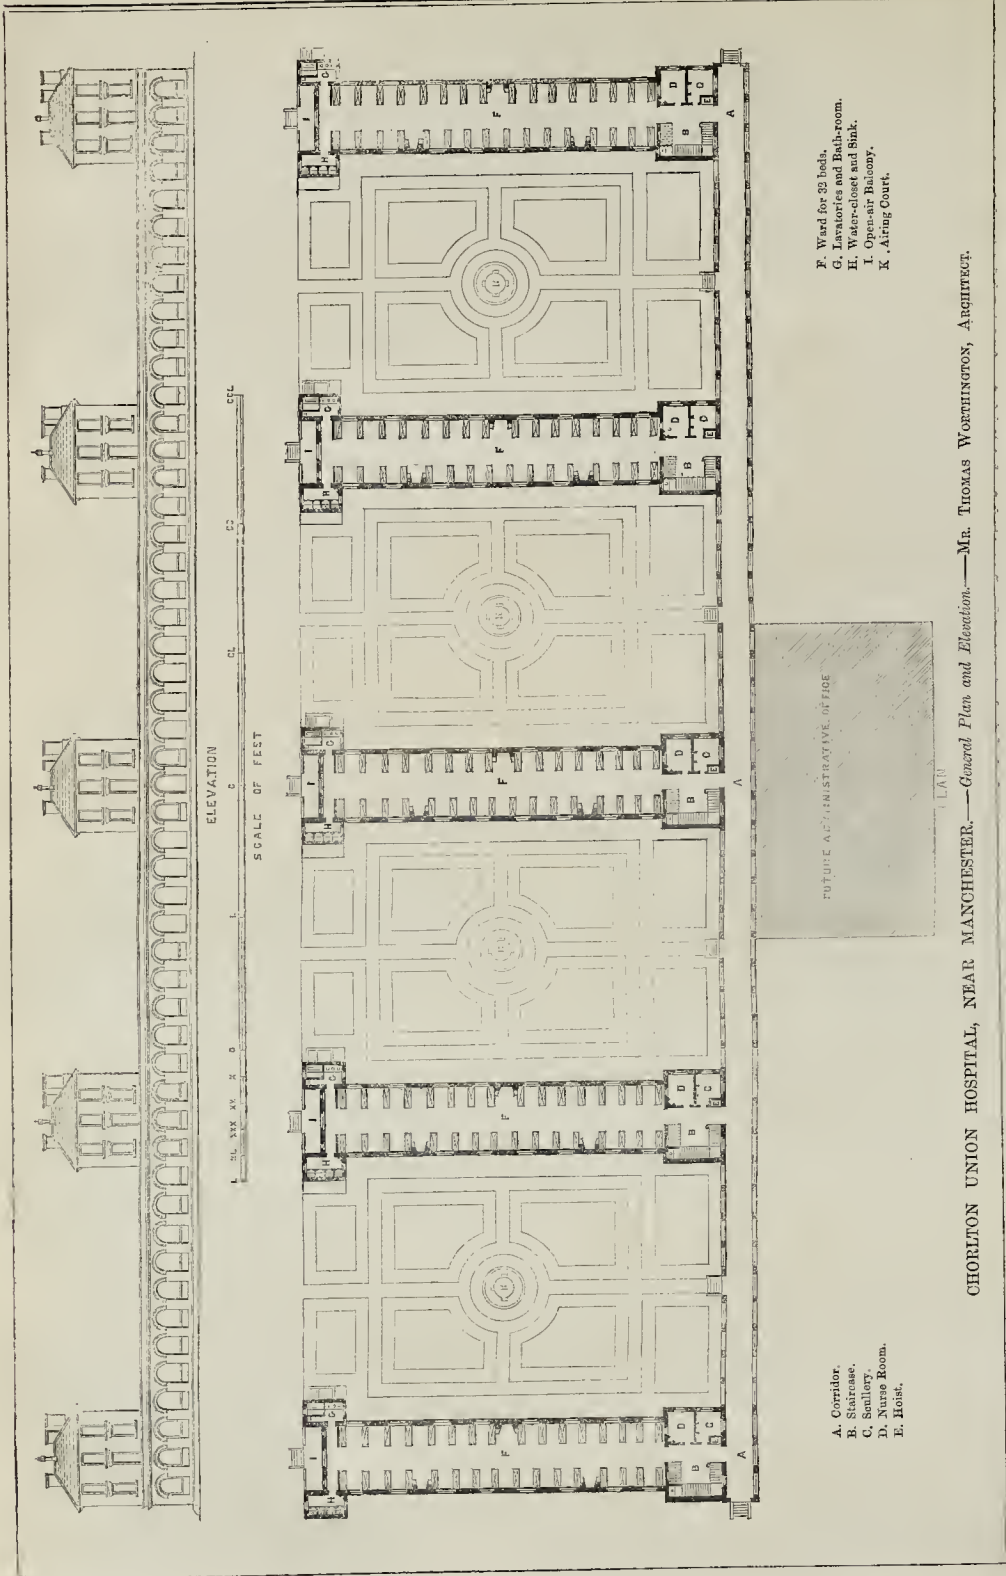

The buildings were commenced last spring, and it is expected will be completed in the course of the present summer. They consist of five pavilions connected by a long arcade corridor. Each pavilion is 124 ft. long by 24 ft. wide, containing three floors, and ninety-six beds for patients, in addition to the small rooms for the nurses, adjoining the wards. The height of the wards is respectively as follows:—Ground floor, 14 ft. 6 in.; first floor, 14 ft.; top floor, average of about 15 ft. The wards are entirely warmed by open fires, three in each ward, each 5 ft. wide and 4 ft. 6 in. high. They project about 3 ft. into the wards, and it is intended to surround them entirely with firebrick, the coal being confined simply by light iron bars. The windows are 4 ft. 8 in. wide, in three divisions; the two lower portions opening like an ordinary sash, and the top part being pivoted; while a small portion of the top of each window is provided with a narrow passage for air the full width of the window, but guarded by a sloping iron frame covered with fine wire gauze, so arranged as to distribute the air, and give it a direction towards the centre of each ward. These windows reach from 2 ft. 9 in. above the floor to within a few inches of the ceiling. Each patient will have an air-space equal to about 1,350 cubic feet, which is very considerably greater than the regulation quantity defined by the Poor-law Board.

The arrangement of the latrines and bath-rooms has been the subject of very careful consideration. It will be observed that the position of the windows in the latrine department admits of a current of air being constantly kept up between the wards and the W.C.s. The bath-room and lavatories are in the opposite projection, and in the angle of this wing are the dust-rooms and foul linen shoots; the former being of iron with hoppers on each floor, and discharging into a small sunk pit outside the building; the latter having its outlet into a ventilated chamber in the basement. A large ventilating trunk is provided to carry off the foul air from these flues terminating in a revolving ventilator. Between the two wings containing the latrines and the bath-rooms, on each floor, is an open-air balcony with a large sash-window, opening so that a full-grown man may walk out without stooping. This window reaches, like the others, to the ceiling, and over the door at the opposite end of the ward is a louvred window, also reaching to the ceiling, worked by a lever and rod, so that a rapid change may be made in the air of the wards by opening these windows at the two extremities, when the air may from special causes have become foul or oppressive. The balcony looks over a wide extent of green fields, and it is hoped will prove a feature of value to convalescent patients.

A point of the greatest importance is the distance between the pavilions, and this, after much discussion, has been fixed at 100 ft., or more than twice the distance between the pavilions at the great hospital at Bordeaux. At the Hospital Lariboisière, Paris, the distance is 65 ft.; at the new Herbert Hospital, Woolwich, 64 ft.; at St. Jean, Brussels, barely half that distance. This interval, it is believed, will allow of a sufficient circulation of air round the several buildings, and as the country about is open and used chiefly for agricultural purposes, it is anticipated that the wards cannot fail to be well supplied with pure fresh air.

The administrative buildings will be placed in the centre of the corridor, and hoists will be provided in the staircase of each pavilion to raise the food to the several floors.

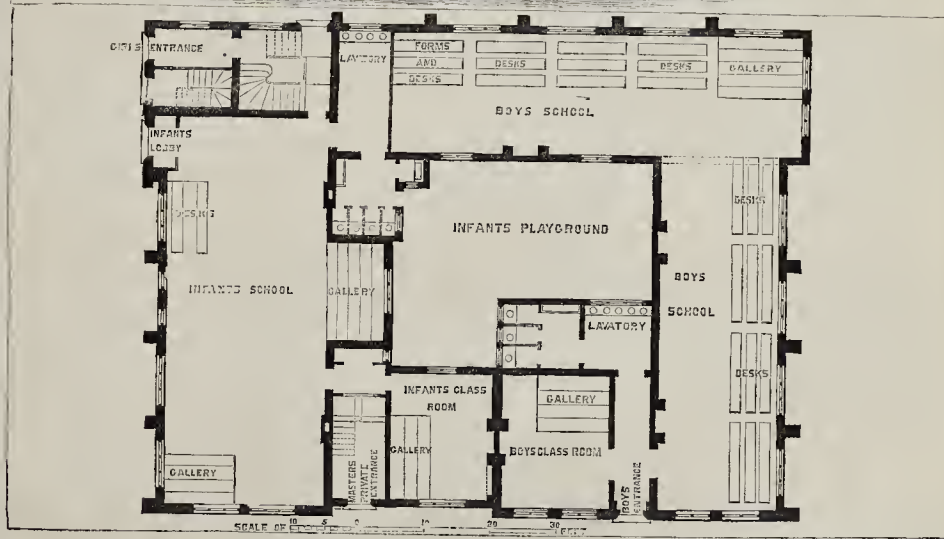

CHORLTON UNION HOSPITAL, NEAR MANCHESTER.—General Plan and Elevation.—Mr. THOMAS WORTHINGTON, ARCHITECT.

NORTHUMBERLAND STREET SCHOOLS, POPLAR.—MESSRS. FRANCIS, ARCHITECTS.

Plan.

## DISCOVERY OF THE BONES OF DANTE.

DANTE ALIGHIERI, as is well known, ended his days at Ravenna, whither he had retired after his unjust banishment from Florence.

In Ravenna he was the guest of Guido da Polenta, the then Lord of that State; and there, though roaming to return to his native city, he gave himself up to his poetical studies. But Venice began to wage war with Guido, his host; and the latter besought Dante to undertake an embassy to that powerful belligerent State, to attempt to bring her to reasonable terms of peace. He failed to accomplish the end of his mission. The Venetians forbade his return to Ravenna by sea; and, after a fatiguing journey over the marshy pestiferous lands of the east coast of Italy, and sad at heart at the ill success of his negotiations, he fell ill of a fever, and died, September 14th, 1321.

"Guido da Polenta," says Boccaccio, "had the body of the poet laid on a bier, decked with poetical adornments, and this was borne on the shoulders of grave citizens to the Convent of the Frati Minori of Ravenna with due honours; and, in the stone urn or coffer (*arca lapidea*), he caused it *pro tem.* to repose, intending to honour the remains of his friend with a sepulchre more beautiful than any before seen."

What the vicissitudes of fortune prevented Guido da Polenta from doing was effected by Bernardo Bembo, protonotary of the republic of Venice, at Ravenna, in 1483. The insignificant tomb gave place to one of coloured marbles and ornamental sculpture. The original inscription, by Giovanni del Virgilio, a poet of Bologna and friend of Dante, was omitted, and instead, on the right of the chapel, where the ashes of the poet reposed, appeared the still traceable inscription recording the erection of the tomb by Bernardo Bembo. This tomb was surmounted by a half-figure of Dante, by Pietro Lombardi.

In 1692, Cardinal Corsi, legate of Ravenna, again undertook the required restorations and some additions; and in memory of this placed, on the left of the chapel, an inscription relating his deed.

Finally, in 1780, the tomb was again restored, by Cardinal Gonzaga, who took from the left wall of the chapel the inscription of Cardinal Corsi, caused one to be placed in its stead written by Morelli, with an allusion to the restorer Gonzaga introduced in it, and as such the monument has remained to the present day.

In order not to interfere with the late centenary *fetes* in Florence, Ravenna postponed hers until the end of the present month, as we mentioned last week.

There stand behind the monument four arches (bricked up) of an ancient chapel called Braccioforte. It was at first intended to remove them, to give greater space around the monument, but finding they were of as early a date as the ninth century, it was proposed that the arches should be opened only. On the 27th of last month, while removing the bricks from the arches, the workmen discovered, about 60 centimetres from the ground, firmly walled in, a box of pinewood, 80 c. by 30 c., and 31 c. in height, containing, as said the telegram bringing the news to Florence, "the veritable bones of Dante." Inside the box is written:—

"DANTIS OSSA,  
A Me Fra Antonio Santi,  
Hic posita anno 1677, die 18 Octobris."

On the outside,—

"DANTIS OSSA,  
Deuper revisa, 3 Janii, 1677."

The discovery, as may be imagined, has occupied exclusively the attention of all interested in it, in the old city of Ravenna.

At a council held on the 31st, it was decided that the marble tomb of Dante should be opened, to ascertain what it contained. A commission appointed by the Government here, with Otlo Vannucci at its head, proceeded to Ravenna, to be present at the opening of the tomb. This was publicly done on the 7th, and two bones of a hand and one of a foot, with a few dried laurel-leaves, alone were found in it. The authenticity of the bones found hidden by the monk is considered confirmed.

Numerous are the conjectures and reports respecting the reason of this concealment. The date agrees with a struggle made to put down everything anti-Papal, and the revered bones of Dante, whose verses of bitter acrimony against Papal abuses were passing from mouth to mouth, might have been feared as a rallying subject,

have been threatened to be removed, and have been hidden by this monk in consequence. Others imagine they were intended to be taken to Florence. Their absence could not have been known in 1780, or Gonzaga would not have lavished any care on the preservation of the monument. The records of his family, as of those of Corsi, will be searched for any light to be thrown on the mystery. In the mean time, the wooden box is to be encased in a strong iron one; and after the *fetes*, at which the bones, jealously guarded and covered with glass, are to be shown publicly, they are to be placed in the monument.

We regret to have to record an act of modern Vandalism that has occurred, since the discovery which has attracted persons from all parts of Italy. To the restorations of Gonzaga—done by Morigia, a native of Ravenna—the arms of the cardinal have been twice added. These, within the last ten days, have been destroyed, and a threat implied that a two-headed eagle, also found among the sculpture, shall be crased also. These hot-headed iconoclasts forget, or are ignorant of the fact, that the Venetian protonotary and the cardinals Corsi and Gonzaga were alone willing and active in preserving the monument of the Florentine exiled poet, and also of the fiercest Ghibelline who over lived and wrote.

Florence.

## RESTORATION, CONSERVATIVE AND DESTRUCTIVE.

THE ECCLESIOLOGICAL SOCIETY.

THE twenty-sixth annual meeting of this Society was held on Thursday evening last, at the House in Conduit-street.

The chair was occupied by the Rev. William Scott (chairman of committees), who observed that he had been suddenly called upon to preside, in consequence of the absence of the president, Mr. A. J. B. Beresford Hope, who was prevented from attending in consequence of the sudden death of his brother-in-law, Lord Cranbourne, which took place most unexpectedly that afternoon. Referring to the operations of the Society generally, Mr. Scott observed that when they looked back to the state of church architecture six-and-twenty years since, and contrasted it with the improved tone of the present day, he thought they had great reason to congratulate themselves upon the progress that had been made. A badly designed church was nowadays very rare, and such was the rage for re-edification, that the Society had rather to curb excessive zeal than to stimulate the negligent or apathetic.

The Rev. B. Webb read the report of the Society for the last twelve months.

On the motion of Sir C. Anderson, it was received and adopted.

The Rev. Mr. Cox called attention to the propriety of having a choral festival in either Westminster Abbey or St. Paul's Cathedral.

The Rev. H. L. Jenner said there was a choral festival at Canterbury, which proposed to hold a festival at one or other of the great metropolitan churches.

The Treasurer's report was received, and the office-bearers of the Society appointed for the next year. Archdeacon Freeman was also elected vice-president of the Society.

The formal business having been disposed of, The Chairman called upon Mr. Parker, of Oxford, to report his experiences in a recent visit to Rome.

Mr. Parker expressed his regret that he had nothing favourable to report. The intentions of his Holiness the Pope were no doubt good, and he was a most estimable and amiable person; but unfortunately for ecclesiological art, he was surrounded by as ignorant and conceited a set of architects as could be got together in any part of the world. The restorations now going on in Rome reminded one of the buildings put up by churchwardens during the reign of George III. Christian art of every description was being destroyed wholesale, including the beautiful frescoes of the twelfth and thirteenth centuries, the like of which were not to be found anywhere out of Rome. In fact, the advisers of the Pope deprecated as modern all art of a later date than the fifteenth century. There were in Rome two distinct periods of art: the first, the removal from the pagan era; and the second, the millennium of the Christian era: but it was not until about the fourteenth century that the Romans had any style of their

own. He regretted to observe that the wonderful works contrived through three generations by the Cosmeti family were either wholly neglected or willfully destroyed. The modern architects of Rome prided themselves upon following in the steps of Vitruvius, forgetting altogether that Vitruvius built heathen temples and not Christian churches. He regretted to say that, among other demolitions which were threatened, was the destruction of the wonderful mosaic pictures of the fourteenth century in the church of St. John Lateran. These were about to be destroyed, in order that the choir might be enlarged. He feared that unless some earnest protest could be addressed to the Papal Government, every vestige of early Christian art would be lost to Rome.

A member inquired whether an archaeological society had not been established in Rome.

Mr. Parker replied, that such a society had been formed, and that it had been supported by several learned persons, including many ecclesiastics of the Roman Church, and among them Monsignor Talbot (now Cardinal Talbot), who filled the office of vice-president. Unfortunately, however, he (Mr. Parker) was so unhappy as to fall foul of the Pope, although he had not the faintest intention of giving offence. It seemed that, wishing to visit the lower church of St. Pudenzia, he applied to the abbot for leave to make certain excavations at his own expense in order to assist his studies, the body of the church being filled up with rubbish and earth which had been thrown through the windows. His application was favourably entertained by the department of the Government to which the subject belonged, and a resolution was passed by three to one giving him the necessary permission. However, when the matter was brought before the Pope, he declined to sign the order, having been prejudiced against him by reports that he had been seen "poking about" all the churches in Rome making discoveries. The Pope was angry when he was told that he (Mr. Parker) had made a discovery of the lower church of St. Pudenzia, declaring that it was no discovery at all. In this respect, however, his Holiness was right, because the fact of the church being there was stated by Baronius, although when at Rome he (Mr. Parker) had not had an opportunity of consulting that authority. He regretted, however, for the sake of archæology, that the Pope had taken offence at his very harmless proceedings, for he stopped his lectures after two had been delivered.

Sir C. Anderson brought under notice certain restorations at the cathedral of Lincoln. He did not think that the present mode of conducting the works there was quite conservative. The stone of which the cathedral was built was a very good oolite, similar to that at Peterborough and Ely, and in his opinion there was no reason whatever for scraping it, simply because it had become necessary to replace decayed stones here and there. At the minister at Beverley, good Yorkshire common sense came to the rescue, and new stones were put in the place of the old ones without any of the scraping process. The scraping to which he referred gave a very spotty appearance to the south and west fronts of Lincoln Cathedral.

The Chairman said the remarks of Sir Charles Anderson reminded him of two effigies of the Courtenay family in Exeter Cathedral, which were chipped away to such an extent that they might be said to be diminished and not restored.

Mr. Street observed, with respect to restorations, that the best thing would be to leave matters as much as possible as they were in 1550. If they were tooling away the stone at Lincoln Cathedral in the manner described, all he could say was that the sooner the dean and chapter were caught and toolled in the same manner, the better it would be for the church. While upon this subject he ventured to recommend the paper issued by the Royal Institute of British Architects, which was the result of much consideration by architects of experience, and was intended to convey instruction to restorers generally, in order to prevent them from doing mischief. A notable case of "tooling away" came under his notice a short time since. When removing the jamb of a window, set up in 1790, he came upon a jamb of fifteenth century work, and upon removing it another was found beneath it of thirteenth century work. Ultimately he was enabled to find enough stones to reconstruct an eastern triplet of the original design. As a general rule, therefore, he would recommend restorers to let well enough alone, and not to destroy things simply because in

their opinion they were old and unsightly. It was, he thought, sad to see the destruction of screens which was going on in several places, simply because the bishop or the archdeacon thought them too high. Some people who did not know better made war upon the screens because they thought it was desirable to see one clean sweep of everything in the church, from the door to the altar. The over-restoration of monuments and mural paintings was also much to be deprecated, and he thought it would be better to leave those things as they were rather than to attempt their restoration in an ignorant or thoughtless manner. Indeed, he did not think we had any right to restore sculpture at all. He had himself on one occasion fished up a Crusader out of a farmyard. He found him short of a leg, but he put him up as he found him, and he believed very few people would detect the fact that he was minus a limb. At Worcester Cathedral he was minded to find that they were tooling away the buttresses by an inch or so, which he regarded as a great mistake, as he generally found that in cases where the weather-face (so to speak) was removed the subsequent decay became much more rapid. Patching and repairing work which would last three or five centuries was greatly to be deprecated, but some people would continue to do so until nothing of the original remained.

The Rev. Mr. Williams said he could not agree with Sir Charles Anderson with reference to the "tooling" going on at Lincoln Cathedral. He had examined the work very carefully, and he could not see that any tooling had been done in order to get up a new surface on the work. They had used soap and water, certainly, and a rough scraper, but the sculpture had not been restored, while the ashlar had been preserved as much as possible. It struck him, however, as singular that when the restorations were made in the beginning of the present century, sandstone, brought all the way from Yorkshire, should have been used for the shafts when there was plenty of the original oolite of which the cathedral was built ready at hand. At King's College, Cambridge, the stone presented very much the appearance of that which had been treated as described by Sir Charles Anderson, but it had been carefully washed and repaired here and there when necessary. Mr. Williams subsequently introduced to the meeting Count De Vogué, the Syrian traveller, and invited him to describe the state of the churches which he had examined in that portion of the East.

Count de Vogué observed that he was indebted to the work of the gentleman who had last spoken for much valuable assistance in his researches in Syria. Should the Christians ever again get possession of the country, the restoration of the churches to their original state would be a matter of little difficulty, for as a general rule they were still (owing to the climate and apathy in the matter of "restoration") in very good preservation. The Count then described the church of St. Simon Stylites, between Aleppo and Antioch, which he said was a cruciform building, containing, in fact, four churches, with a large open space in the centre. It was built in the fifth century, and was one of the most interesting churches in Asia.

After some further discussion, in the course of which the Chairman, referring to the mutilated crusader discovered by Mr. Street, threw out a hint as to whether strict conservatism had not been kept in view in the retention of the statue of his Majesty George II. in Leicester-square, the proceedings terminated.

THE APPROACHING HANDEL FESTIVAL.

THE approaching Festival at the Crystal Palace promises to be very satisfactory. The rehearsal will take place on Friday, the 23rd instant. This will include both solos and choruses, and the pieces selected will present great variety, the object being to make the rehearsal day an epitome of the three days of the Festival. The first day of the Festival will be Monday, the 26th, the "Messiah" the second, on Wednesday, the 28th, will comprise a selection from Handel's best known and most popular works; and the third, on Friday, the 30th, will be "Israel in Egypt." The selection on the 28th will present many attractive features. Amongst other pieces it will comprise a selection from "Saul," commencing with "Hov excellent," and including the choros, with Carillon's accompaniment,

"Welcome, welcome, mighty king," the choros, "Envy, eldest born of Hell" (which created so much sensation at the last Festival), and the famous "Dead March." This day's performance will also include the Nightingale Choros from "Solomon," "May no rash intruder," and, as the 28th instant is the anniversary of her Majesty's coronation, the great anthem, "Zadok the Priest," written for the coronation of George II. in 1727, will be appropriately introduced. A selection from "Judas Maccabæus" will also be given, concluding with the popular chorus, "See, the conquering hero comes." Mdlle. Adeline Patti will sing "Let the bright seraphim" (trumpet obligato, Mr. Harper), and "From mighty kings." Besides "Sound an alarm" Mr. Sims Reeves will sing the great song in "Joshua," and Madame Sainon-Doby, Mr. Santley, and other well-known artists will take part in this and the other performances.

Some alterations in the construction of the great orchestra are said to facilitate bearing very much. It is proposed, too, to place large screens on each side of the great transept, transforming it into an inclosed concert-hall. Thus an old suggestion of the *Builder* is about to be realized.

The concert last Saturday was very satisfactory and edifying; Mdlle. Lucca, in particular, ran away with her audience completely, and was forced to sing everything twice.

The gardens are more bare of flowers just now than we should like to see them, and all the vases scattered about have been emptied of their floral contents, to the detriment of the general effect. The gardens must not be neglected.

THE LANGHAM HOTEL, PORTLAND PLACE.

THE Langham Hotel, built by Messrs. Lucas, under the superintendence of Messrs. Giles & Murray, architects, was opened formally on Saturday, the 10th inst., when H. R. H. the Prince of Wales honoured the directors with his presence. The decorations were designed by Mr. Owen Jones, and carried out by Messrs. Graham & Jackson, who have supplied all the furniture. In our volume for 1863 (pp. 531, 532, and 533) will be found a view of the building and plan of the principal floor. We content ourselves, further, on the present occasion, with a detailed account of the kitchen arrangements.

THE KITCHEN OF THE LANGHAM HOTEL.

THIS kitchen is understood to be the largest in London, its dimensions being 54 ft. long by 48 ft. wide; and the scullery adjoining being 37 ft. by 19 ft. All around the walls are recesses, formed in various parts, in which the cooking apparatus is fixed. The first which attracts the eye on entering is the large roasting range, which is 8 ft. wide and 7 ft. high: the roasting-jack over this is driven by hydraulic power, having provision for cooking at least fifty or sixty joints at one time, and is very complete in its details. Passing thence, we come to a very extraordinary and spirited piece of work, consisting of a series of stoves in a semicircular form, fitted completely round the bay-window at the end of the kitchen: they are 30 ft. in diameter, and are for the preparation of the higher class of viands, under the special control of the *chef*. They include a large hot-plate, with an oven for soufflés, entrées, &c.; several charcoal stoves; gas steaming-stoves, constructed so that they cannot possibly smoke; a large *bainmarie*, for keeping sauces hot, heated by steam; and another gas-stove for the large stockpot, which is kept at work during the whole night, in preparation for the next day's soups. Passing on, we come to the fish-cooking department, where we have the means for frying, broiling, and boiling any quantity that may be required: one large copper pan, heated by steam, is specially reserved for salmon and turbot, the largest of which can be placed whole in this apparatus.

In the stoves for cooking chops and steaks, the fires have all the draught striking downwards, to prevent the meat being smoked and blackened. On the opposite side is the large pastry-oven, and just at the back is the pastry-room, cool and well-ventilated.

Opposite to the large bow window is the serving window, whence all the viands are dispatched to the upper floors by means of an

hydraulic lift; but before they leave the kitchen they are all brought to a serving table placed near, to be entered by the clerk in his book. This table, which is of bright polished iron, is 16 ft. long by 4 ft. wide, heated from end to end by steam and fitted with two *bainmaries*, one for soups and one for sauces, so that every dish leaves the kitchen perfectly hot: there are a whole series of hot closets besides, for heating plates and dishes, all fitted with steam chambers and pipes.

Passing into the scullery, we find a range of steamers for cooking potatoes, boiling beans, puddings, rounds of beef, &c., the excess steam being carried by a flue to the top of the building, and then we have a large hot-plate for cooking all sorts of vegetables. On the opposite side are sets of troughs fitted with hot and cold water for preparing the vegetables, washing up plates and dishes, &c. Another department for the scouring of the stew-pans, where the water is kept hot all day long, the large troughs and pans being fitted with steam jackets. In the centre of the scullery is a large closet heated by steam, and a table.

The grand table in the kitchen is 20 ft. long by 6 ft. wide, and has the top made of elm 6 in. thick. Some idea may be formed of the quantity of materials used in fitting up this kitchen when we state, that the total weight of the iron of which the cooking apparatus is constructed is upwards of twelve tons; and there is a complete system of underground pipes by which all the waste steam is collected and made to heat a tank holding 500 gallons, supplying hot water to all parts. The length of iron pipes used in the kitchen alone for steam, hot, cold, and waste water, exclusive of gas, is upwards of 3,000 ft. The fittings were all designed and manufactured by Messrs. Adams & Son, of the Haymarket, and erected by them in the building.

PARIS.

TWO new thoroughfares, the Boulevard des Amandiers and the Avenue Lacée are in course of construction in the east of Paris: these, starting from points widely distant asunder, intersect at the Eleventh Arrondissement, at a point not far from the Abattoir Monilmontant.

The Avenue Lacée owes its name to General Lacée, killed at the battle of Gantzbourg, in the Austerlitz (1805) campaign. It commences at the Pont d'Austerlitz, at Bercy, and follows the axis of the bridge, cutting across the Rues de Bercy and de Lyon, the Avenue Danmésnil, and passing under the Vincennes Railway by a bridge of considerable span; here it enters the densely peopled quarter of the Faubourg Saint-Antoine, through the mass of cabinet-makers' workshops where are manufactured the luxurious articles of Parisian furniture which find their way all over the world. In the passage of this avenue an ancient wall-fountain at the angle formed by the Rues Basfroi and de Chronoux, has been made to disappear, having shared the fate of most of the old Paris fountains, now replaced by *bornes fontaines*. This, built under Louis XV., was one of the usual type of the period,—a brass mask, delivering the water from its mouth, enclosed in a semicircular niche surmounted by a triangular pediment. It is worth knowing, that the most ancient fountain of this nature now existing in Paris, is that at the corner of the Rue Maubouc, not far from the Hôtel de Ville: it was erected at the beginning of the fourteenth century.

The works of the new terminus of the Northern Line of France are nearly completed. Covering an area of 30,000 square metres (nearly 7½ acres), the building is composed of five principal parts; in the centre the great hall, on the left the departure saloons, and beyond that the lobbies; on the right the arrival saloons and the covered carriage sheds. This last portion cannot be commenced till after the demolition of the ancient station and the temporary installation of the service in the new buildings. The lateral façade adjoining the right pavilion consists in a series of arches resembling the system adopted for the great hall, and affording to the public ready access to the several arrival departments.

Four great thoroughfares are in progress to complete the group of new streets on the slopes of Chaillot. The Avenues de l'Alma, de Josephine, de Jena, and de l'Empereur. This latter is the most important as it may be considered the prolongation of the Cours la Reine (that magnificent drive from the Place de la Concorde along

the river side towards Passy) as far as the Porte de la Muette, one of the central entrances to the Bois de Boulogne, and consequently the nearest road from the Tuileries or Paris proper to the ornamental waters and the Pré Catelan. In this unbroken drive, as it will be when finished, the length is six English miles. The first three miles from the Porte de Pantin, along the Route de Metz and the Rue de Lafayette, as far as the New Opera House, are in one single straight line. No finer opening exists in Paris than the Rue Lafayette for ready communication between the whole of the North of Europe (for the Northern terminus is in it) and the rest of the metropolis.

#### HINTS IN CONNEXION WITH LOCAL INDUSTRIAL EXHIBITIONS.

If the Prince Consort had been alive at the present day, he would have felt great pleasure in the development of these institutions, which give promise of being permanent, not only in the metropolis, but also in the provincial towns of Great Britain. Throughout the civilized world; in the capitals of England, Scotland, and Ireland; in Paris, and elsewhere on the Continent, "Great Exhibitions," held at periods long between each, seem now to have become less frequently but as firmly established as the Christmas feasting at the festive season of the year.

The general result of all this development is satisfactory. In the first instance, it shows that there is a strong feeling in favour of gatherings of this description, that have been the means of originating and developing ideas; of enabling manufacturers to form companies, which will show the merits of their goods; and in these great gatherings there is a source of pleasure, either in one department or another, for all kinds of visitors. Many other important advantages might be mentioned, and not the least of these is the rise of the local Industrial Exhibitions in the London districts and elsewhere. There is, if we may judge from the present indication, a prospect of the opening of exhibitions of this kind in villages and districts, where there is only a small amount of population.

When looking with anxiety at the practical working of these exhibitions, we have noticed several hopeful results which lead us to expect better things in future. Amongst these may be mentioned the advantages which arise from persons of different classes meeting together, if only for a short interval; but in nearly every case the working men, whose benefit is chiefly sought for in connexion with these gatherings of themselves, and the articles of their own manufacture, have been too much pushed out of the management and working of these exhibitions, the award of the prizes, &c.; and many of the best men of this class, whose manners, general intelligence, and right feeling, entitle them to fitly take their places of management on committees of this description, feel that, in too many instances, they have been overlooked for the sake of the appointment of persons who seek to distinguish themselves. There is nothing so unpleasant to us as to say what may be hurtful to the feelings of any one, or to give expression to ideas which may seem to reflect upon well-intended, and, to a large extent, useful, endeavours; but, in the end, plain truth, is of far more advantage than meretric and unmeaning praise. We have, therefore, somewhat unwillingly, said this much, and will also again express a strong opinion that, so far as the advantage of individuals is concerned, and as a means of advancing the reputation and pecuniary position of those who have displayed the articles produced by their skill and appliance, the results have not been at all satisfactory.

There are many reasons for this undesirable result, some of which may be arranged as follows:—

1. The neglect of exhibitors to endeavour to distinguish themselves in the branches of their own line of industry.
2. The expenditure of a large amount of labour on articles which have no particular use.
3. There is also the thought that, in the present state of the law of patents and copyright, ingenious inventions, &c., may be appropriated by other than their owners.
4. In the large towns, in the metropolis especially, there is a want of the opportunity of men meeting together who are engaged in simi-

lar branches of labour after the regular hours of work have passed, for the purpose of comparing their knowledge and endeavouring to direct their attention to the best means of advancing themselves and giving interest to those exhibitions.

There are many other considerations which come to mind; but, while thinking of these, we should not lose sight of the fact that these exhibitions are still but in their infancy, and allowance should be made for all the difficulties usually associated with new experiments. We must, however, mention that the committees will, for the purpose of ensuring future success, do well to change much of the present plan of arrangement and selection; for we doubt much the wisdom of the management which gives a prominent place and prizes to such matters as the pen-and-ink drawing which has so strangely roused the fear and anger of the Bank of England authorities, although, to many who have not given consideration to the higher principles and practices of the fine arts the production of a Chinese imitation such as this seems surprising.

However creditable to the patience and even the hand-skill of the producer, this is not one of those things which are likely to advance the welfare of Industrial Exhibitions. To many who do not know the mechanism for some of the stages of engraving on metals, drawing on wood, lithography, &c., the execution of the group referred to would seem to be one of much greater difficulty than it is. By means of tracing-paper, good transfer-paper, a finely-sharpened and firmly-leaded pencil, pens with the requisite varieties of point, and a well-mounted and closely-grained sheet of drawing-paper, a neat and steady-handed person, without artistic ability, might readily produce that which many persons would consider wonderful.

None can be more glad to see the useful development of art in any of its branches than we are, and in the present instance we do not write for the purpose of damaging the fame which the producer of the pen-and-ink drawing has gained; but it is our duty to look at such matters as this from a broad point of view, and in this case consider in what way industrial exhibitions may be benefited by the encouragement of works of this kind.

We trust that the time is not far distant when it will be a curiosity to find in England a workman who is deficient in the rudiments of education, and who cannot also perform at least the simple process of outline delineation of objects; but in the manner in which the generality of the Industrial Exhibitions are at present managed, it is not clear in what way this desirable end either has been or can be advanced.

In connexion with the schools of industrial art which have, under the management of the South Kensington directors, been established throughout the country, there are facilities for not only the display, but also the teaching of this mechanical art in its higher branches. There are also the various exhibitions in both town and country, in which artistic works of real merit are likely to obtain a fair amount of notice; and in many directions there are at present opportunities for fostering art when germs of the right kind have been shown to exist. It therefore appears that attempts of pictorial art, and having no application to the improvement of designs for the general forms, ornamentation, or coloring, of articles of manufacture, should be considered with particular care by committees having the kind of knowledge which will enable the members duly to appreciate such attempts; and in one department there should be gathered together all matters of delineation of value for the general purposes of art manufactures. Here might be displayed rare efforts of neglected genius which may be found in painting and sculpture.

But, as it appears clearly to us, in the Industrial Exhibitions, committees should not give special encouragement to such matters as bank-note imitation, or to pictures, simply because they have been executed by a pork-hutcher or a general-postman.

Even in an artistic way, there is much to be done in connexion with these local exhibitions. Take picture-frames for instance; and let us see the workmen's ideas respecting them, and show not only their actual work in this way, but also display models and sketches. There are, also, the panels of cabinets, doors, &c., of rooms, or the cornices of ceilings, for which we should have designs. Let us see who can

fashion us the most graceful and useful door-knocker, or bell-handle, or scraper; who can give us the best idea for an iron railing, or a street lamp; and let our tin-plate worker, or tailor, continue to find delight in his sketching; but let him also, if he lives in London, take occasional holidays, or go on certain gas-light evenings and see at the South Kensington Museum how articles in his way have been fashioned and wrought formerly, not only here, but in Germany and elsewhere; and let us have his views, not only on paper, but also in tin or cloth. Our tailor might, perhaps improve his cut by examining the engravings of costume, which he will find ready access to in the print-room. There is great reform still needed in the style of men's wearing apparel; and hints for this purpose might be got in these places.

In the Great Exhibitions, it has been complained, the employers obtained all the credit, and the men were deprived of what was fairly their due. In the local exhibitions this is not the case, except in as far as the employment of large capital gives facilities for the completion of articles at reduced prices; and in the way of finish, in all parts by the subdivision of labour; but, in the designing and working of many things the men have now afforded to them rare opportunities of distinction. Workmen who have for long been employed in the manufacture of articles of general use, have peculiar and often valuable views in connexion with them, and these it is most desirable to get gathered together. There is also the ornamental painter's work, in the imitation of woods, marbles, &c., the fashioning of letters, and other things which appertain to this trade. All these, and in the same way the results of the choice labour of other handicraftsmen, should be systematically arranged, not only with a view to distinctness, but also so that they might be readily studied by all interested in them.

Up to the present date the local Industrial Exhibitions cannot be said to have been fairly got into working order; but one principle in connexion with them should be, the reward of utility rather than of what has no especial use; and that the workman who, with ingenuity and skill, applies either ancient or modern devices, should, in such displays as these, be rewarded and meet with praise, rather than the amateur artist who spends time in the execution of matters which will neither raise him to the rank of a Royal Academician, nor assist him in any department of art industry.

There is much more to be said in connexion with this most important subject, but we will just now only remark further, that in the Industrial Exhibitions it might be found of great use to afford space for the selected works of boys and girls of the age of from twelve to fifteen years. By this means, some would be likely to discover the right bent of his or her talent, and get it launched into the proper current for its successful progress.

#### THE SHEFFIELD SCHOOL OF ART.

The annual *convocation* has taken place in the Arundel street building. The visitors, owing to the changed season for holding the meeting, were much fewer than usual. Mr. Roehuck, M.P., and Mr. Tom Taylor, were among the present. Mr. Taylor, who distributed the prizes, said, in the course of his address,—If I were asked, as an outsider, whether the reproach of indifference to the claims of art still attach to your town, I should naturally answer, in answer to the contrast between the lugubrious trio of 1841, that party in a parlour,—all silent and damp,—with this brilliant assemblage, gathered within a spacious, commodious, and elegant school-building; these classes, attended by 250 students in all degrees of art, from its elementary rudiments up to the most elaborate branches of design; these proud records of achievements of local and national honours achieved and prizes won; the rapid increase in those honours for the last three years, shown in a constantly rising influx of medals from seven to nineteen, till this year it stands at thirty-five,—a spring tide,—thirty being the maximum for any one school fixed by the regulations of the central department. Yet, when I come down to Sheffield, I do not find the local supporters of your School of Design hopeful, nor those employers, as a rule, enthusiastic in its support, highly impressed with its value, or sanguine as to its success. The former tell me that the reduction in the amount of Government aid hitherto given to

this school is, as they fear, likely to be seriously prejudicial, if not absolutely fatal to it; and this is, I am sorry to learn, very much the case with all the schools at the great centres of manufacturing industry throughout the three kingdoms,—at Manchester and Birmingham, at Stoke-upon-Trent and Newcastle-upon-Tyne, at Glasgow and Dundee, at Cork and Limerick. If we look at art as applicable to industrial production, it is evident from all, that a man honestly seeking information on the subject, can see, hear, and read, that the local sense of the value of art is not as yet efficient to make schools of art self-supporting either by means of fees or subscriptions. The ladies of Sheffield show their sense of the value of sound education in art by attending these classes; but the sons of your manufacturers, those to whom knowledge of the principles of art is, we would suppose, essential to the superiority of their wares, and the rise of their reputation in the great market of the world, do not enter as students here. The manufacturers themselves, I am told, are lukewarm: they do not, it is said, see any direct benefit from the school: nay, I hear of some who actually punish their apprentices by not allowing them to attend the classes of this school; of others who do not scruple to say that they consider it an injury to themselves to educate a class of skilled designers, as they can now obtain over their competitors by securing the services of a solitary designer. When employers are thus short-sighted, have we any right to wonder or complain of labourers or apprentices that they do not see very far; that the artisans or apprentices who attend these schools are apt to show a mistaken sense of the object and value of the instruction given; that they want to be set at once to learn what will be immediately useful to them in their crafts and trades, and are vexed and disappointed, and apt to give up the school in disgust, if they do not get this special instruction at once?

Mr. Roebuck said,—There are things about and around us which no other age has seen. We travel now faster than men ever travelled before. We have compelled the power of nature to our use in a way that mankind never beheld before. But Mr. Taylor says the spirit of heaviness is wanting. Now, I do not think that, altogether. I will take rather a warlike instrument—a rifle turned out from the armoury of Whitworth or Armstrong. Is it not a beautiful thing to look at? It is simple: it is designed to do its work with the least possible trouble; it is light and strong. What do you want more? I say that there is a spirit of beauty, but it requires an eye to see it; but that spirit of beauty, I think, does reign, ay, in the midst of England. I like to see men like my learned friend, who belongs to literature, coming down to give his assistance to the manufacturing power of England. It is a distinction which belongs to our age. We have had all the bright stars of literature—Shakespeare, Milton, Bacon, and Spenser,—and when I mention those names, I am sure my hon. friend will rather be anxious to be numbered amongst them; but they never aided mechanically art in England. I see this great advantage, when we can compel men like my friend to come down here among us—working artisans—to aid us with that spirit of beauty which ought to live amongst us.

THE COMING ELECTIONS.

It is unfortunately the case that, in the House of Lords, and the House of Commons also, there are but a very small number who have bestowed much attention upon the promotion of those social and sanitary improvements upon which the lives and health of a large part of the industrious and poorer classes of the country depend. In the House of Lords, the Earl of Shaftesbury,—whose personal labours have been attended with so much good,—finds it to be no easy matter to get a dozen noble lords to attend to matters on which so much depends. It would therefore be a great advantage if, in the approaching elections, we could get into the Commons House a few more men who would pledge themselves to bestow special attention to the life and death question. Twenty additional men who could be depended upon in this respect would, by their cohesion and energy, have much effect on others. During the canvass which will be made, and the meetings which will soon be held throughout the land, it would be well for those who are convinced of the necessity which there is for more

vigorous action in sanitary matters to ask candidates to pledge themselves to support, or, if needful, bring forward measures upon which the condition of the dwellers in both town and country so much depends. Out of about 600 members who will be returned, it would be easy by this means to gain a number of new men, who would with advantage join those whose exertions are well known to have been productive of much good.

NATURE AND ART.

Let never man, from Nature think  
The sciences to part:  
Creation is in every link  
The prototype of art.

Earth is the fav'rite work of God,  
By wisdom spher'd in air;  
For man design'd, from sea to sod,  
Inimitably fair.

Ate not the caves on Edin's shore,  
Where tempests chafe and weep,  
And music hails the changing floor,  
The temples of the deep?

The circle of the showery sky  
O'er the sun's radiant march,  
Who shall its holy name deny?  
Mercy's memorial arch.

The blending branches of the grove,  
The vast stones piled in haste,  
The roaring streams, and cliffs above,  
Disruption's giant waste.

Primeval bridges of the earth,  
Ere art arose were they,  
The silent tutors of its birth,  
And masters in decay.

By Nature summon'd to aspire  
While scarcely art was known,  
The rocky cave, the mountain's spire,  
Was modell'd forth in stone.

The solid majesty of mass  
In mystic Egypt shrined,  
The ponderous skill of ornate class,  
Growth of the Roman mind.

The hauteens harmony of line  
By subtle Hellens proved  
The holy splendour of design,  
By Gothic prelates loved.

The sumptuous dignity and grace  
By Arab fancy wrought,  
The multiples of form and space  
The Asian's laboured thought.

All sprang from Nature, grave or gay,  
By one unerring law:  
The technic elements portray  
How each creation saw.

From henceforth let not creed or caste  
Man and his teacher part:  
The future is reared past,  
And Nature nurtures art.

W. R. COOPER.

Working Men's College.

PROVIDENT INSTITUTION OF BUILDERS' FOREMEN AND CLERKS OF WORKS.

The anniversary dinner of this institution took place on Tuesday evening last, at the London Tavern. Mr. Digby Wyatt presided. The usual loyal toasts having been proposed by the chairman, and duly honoured,

Mr. Taylor proposed "The Royal Institute of British Architects." Without the aid of that association neither he, nor those whom he addressed, would be able to pursue their callings as they now did. It consisted of a class of gentlemen whose ability and energy they all appreciated, and without the exercise of whose ability so many fine buildings would not be seen as are now rising in many parts of the metropolis. The members of the Provident Institution owed them much, and he was therefore confident that the toast would be well received. He asked them to associate with it "The Institution of Civil Engineers." They, also, by their talent and industry, had carved out a great deal of work for those whom the Provident Institution represented; and he was sure they would acknowledge the obligation by heartily drinking the toast he proposed.

The toast, which was coupled with the name of Mr. Burnell, was drunk with applause.

Mr. Burnell returned thanks. He said that both the Institutions,—the subject of the toast,—felt deeply the extent to which they were under an obligation to the Associated Foremen and Clerks of Works, for the co-operation which they extended to them, and the zeal and ability which they displayed in carrying out the important and onerous duties confided to them.

The Chairman said the next toast was one which he was sure would be cordially received. It was the health of "Builders, Contractors, and Merchants." He, representing professional men, and many of those whom he addressed representing the executive body, occupied two positions, between which stood the class which he called upon them to honour. They ministered to professional men, and to their employes, and each class derived advantage from them. Independently of that consideration, they had a special claim upon members of the Provident Institution, as that part of its funds which was derived from supplementary sources came from them. Their occupations demanded intellect, courage, energy, and enterprise, and those qualities he had found to be displayed by them in a remarkable degree. They were to a great extent the strength and stiffness of the nation, and therefore he had no hesitation in calling on those present to drink their health.

The toast was duly honoured.

Mr. Patman briefly responded.

The Chairman said he now came to the toast of the evening, before speaking to which he should express his sincere regret at the absence of Mr. Gilbert Scott, who was to have presided, and at the cause which rendered his absence unavoidable. Mr. Scott had the interest of the Institution entirely at heart, and had written him a long letter, stating the grounds on which he would have advocated its claims to continued and increased support. He had a great regard for the respectable body of which it consisted, and wished every prosperity to it, owing to the useful purposes for which it was founded. The president of the Royal Institute of British Architects had also requested him to express his regret at being obliged to be absent, and his sympathy with the objects of the Provident Institution. The toast he had to propose was, "Prosperity to the Institution;" and that prosperity was a thing that ought to be earnestly wished for by all right-minded persons, because the class whom it especially benefited was one that must be greatly respected. No man in a country which thrives by labour could look with a cold heart upon the best representatives of labour. Those whom the Institution included were picked from the working classes for their superior ability, and for the display of intellectual and other faculties which distinguished them from others, and they rose step by step until they were enabled to express the thought and conception of the professional man. They occupied a responsible position, and their labour was all essential for the success of the building art, an art which ministered to the well being of the vast body to whom it gave employment. The class which benefited by the Institution was one which demanded respect also for its providence. The very fact that they had associated themselves for improvement for educational purposes, for fitting themselves for the better discharge of the duties they have to fulfil, and for making provision for those accidents and mischances which might overtake them, proved them to be a thoughtful and a provident body. They had now, he was happy to say, only thirteen pensioners upon their books, and they had gathered together a sum of 3,000*l.* in order to establish the Institution upon a permanent basis. The Institution rested upon the first principle of humanity, namely, that of mutual assistance, the assistance of the weak, who were stricken down; extended to them by the strong and sturdy, who were happily enabled to hold on their way in the path of life. It was much to the credit of the Institution that its funds were solely directed to the purposes of charity. The subscriptions and donations which they received are not devoted to any extent to personal ends, but are sedulously applied to or set aside for the objects for which they were given. He spoke with diffidence of the class which composed the Provident Institution, for he could not but remember, that throughout his life they had taught him much. From builders' foremen and clerks of works much of the most valuable information he possessed had

been derived. Professional men were indebted to them for the all-important assistance they received from them; and as the march of mind went on, and the building art progressed, so would their duties become more onerous and their position more important. They now occupied posts of trust of no ordinary kind, and the providence which enabled them to look forward to a reasonable provision for themselves and those who were dear to them, was calculated to keep them in the straight path, and was thus a benefit to the entire community. He therefore sincerely and hopefully called upon them to give their cordial and practical support to the Provident Institution of Builders' Foremen and Clerks of Works.

The toast was coupled with the names of the governor and officers of the Institution, and was drunk with enthusiasm.

Mr. Henry Lee, governor of the Institution, responded.

The health of the chairman was subsequently drunk with all the honours.

During the evening a selection of music was performed, under the direction of Mr. Fielding. The vocalists were Miss Rose Hersee, Miss Eyles, Mr. Fielding, Mr. Shoubridge, Mr. Ransford, and Mr. Montem Smith.

#### THE ARCHITECTURAL ASSOCIATION.

The usual meeting of the members was held on Friday, the 9th inst., at the House, in Conduit-street.

The chair was taken by Mr. J. H. Christian, the president.

Mr. J. D. Mathews (honorary secretary) read the list of names suggested by the committee as office-bearers for the ensuing year, on which a conversation ensued.

The Chairman, referring to the recent visit of the members of the Association to St. Alban's Abbey, said he regretted extremely not being present on the occasion, but that he was compelled at the last moment to forego what would have been an agreeable admixture of business and pleasure for an engagement of a purely business nature. He moved a vote of thanks to the Rev. Dr. Nicholson, for the facilities which he had afforded the members for inspecting the abbey.

The motion having been agreed to,

Mr. Mathews read a letter which had been received from Mr. Bazalgette, engineer of the Metropolitan Board of Works, stating the pleasure it would afford him at all times to allow the members of the Association to view the various public works under his charge. Mr. Mathews also announced that the annual dinner of the Association would be held on the 27th inst., and that they hoped before the session terminated to be able to visit either Montagu House, Whitehall, or the New India Office.

Mr. L. W. Ridge inquired how it was that the lectures at the Institute were so badly attended. Various reasons had been suggested to him, to which he would not more particularly refer except to say that occasions had occurred on which the persons who attended in the hope of hearing a lecture were informed that no lecture would be delivered.

A member said that no sufficient notice was given of the lectures, and that no intimation was given beforehand of the subjects.

Mr. Blashill said he had only attended one of the lectures, and that was an extremely valuable one in its way; but that, had he known what it was to be, he would not have attended it, because it ought to have been printed, so that it might have been studied with profit elsewhere.

The Chairman said, as he understood it, the lectures were not to be regarded as complete in themselves, but were intended more as suggestions to students as to the line of study they ought to adopt.

Mr. Mathews observed that the lecture he had attended contained an enumeration of about fifty books—a circumstance which, so far from encouraging, was likely to deter a student. He believed that the members of the Association would have attended the lectures in greater numbers if the inducements held out had been greater. Moreover, on some occasions, when the members did attend on appointed evenings, they were informed that there would be no lecture, which was very like making fools of them.

Mr. Plunthe suggested whether the non-attendance at the lectures might not be accounted for by the circumstance that the

members of the Association did not intend to go up for examination.

The Chairman said he was sorry to hear that gentlemen were likely to be sent back from the examinations simply because they did not altogether like the manner in which the Association had been treated by the Institute. It would be like biting off their noses to be revenged on their faces. He recommended them by all means to go in for the examinations; for if they lost the present opportunity, they might find that after they got into practice no time would be afforded for going up. With regard to the Institute, he confessed, for his own part, that he was far from satisfied with the manner in which the memorial of the Association had been treated by that body, and he recommended that some further correspondence or communication should be opened on the subject. He had reason to believe that they had now some friends in the council of the Institute who would get a hearing for their memorial; for it was quite clear that when it was presented last session, it had been received, but not taken into consideration. There was another subject on which he desired to throw out a suggestion, and that was, that greater anxiety should be evinced in future by the members to take part in the discussions of the Association. Possibly the forthcoming dinner might do something towards removing the reticence of which he complained; as the more the members knew of each other, the less difficulty they would have in speaking on the subjects which they were called together to discuss. He hoped, therefore, that there would be a good attendance at the dinner.

The Chairman stated that as the meeting on the 23rd inst. would be the last of the session, he hoped that members in arrears of their subscriptions would pay up, in order to prevent the unpleasant necessity of posting up their names as defaulters.

Mr. J. W. Penfold then read a paper on "Metropolitan Improvements."

The subject for the next class of design will be, "Interior Perspective;" and on the 23rd inst. Mr. E. C. Turner will read a paper on "Organ Cases."

#### A NEW FIELD FOR LANDSCAPE-PAINTERS.

SINCE the French Emperor's visit to his Algerian province, the accounts of its rare and picturesque beauty are coming from many pens,—and most tempting some of them are,—for, besides the historic interest of the locality, the picturesque charms of the scenery appear to be remarkable. On this point Mrs. Rogers, in a book which she has recently written, says: "A warm genial spring seems really to have set in. To-day we discovered one of the most romantic walks we have yet found in our roivings;—in a short, or rather direct, cut to the Bouzareah, through gorges and glens, ascents and descents equally steep, and with views of exquisite beauty, a gurgling stream descending from its mountain-source—flowing over a grey rocky bed—amidst rich foliage of overhanging banks, transported us in fancy, as we stood on the narrow bridge by which it was spanned, to some of the lovely dales of Derbyshire, till some dark, glossy, richly-laden orange-tree dispelled the illusion; and then a sudden opening outspread before us, as with the enchanter's wand, one of the beautiful bays around Torquay, till the cactus and the aloe, and the mosque-like building surmounting the grey stone slope, recalled us to Africa. Cork-trees were in the hollow; and ascending the old Roman road, if such a narrow overgrown path ever really were so, we noticed on the opposite side of the ravine the picturesque effect of an orchard of fig-trees denuded of leaves, and, with multitudinous stems and twigs so white as to appear pasted against the bright green background, they looked like huge branches of white coral. The fields are now covered with the sweet jonquil and the purple iris; but hitherto we have searched the hedges in vain for the snow-drop or the primrose. The mignonette is finer than ours; but the daisy, although larger than those met with in Great Britain, has not the crimson tint; the hawthorn has whitened the hedges and scented the air, and strange flowers are peeping up in anticipation of the floral glory of the summer. Exquisite views meet the eye on the right hand and on the left, and from the heights the scenery is very grand: on one hand are the dark frowning chains of the Atlas, and

on the right the view stretches towards Gilbraltar, which was, however, far beyond our ken; but we saw Sidl Ferruch,—the landing-place of the Gallic conquerors,—part of the western plain of the Metidjah, and all those promontories, and inlets, and havens so dear to a painter's eye, especially when bathed in the lustre of the setting sun as we saw them now. Turning from the left we again caught the blue sea calmly rippling on in front of the Hessian dey and the Hammah, encircling in the embrace of Cape Matifon, which one could hardly believe to be about fifteen miles from Algiers; the snow-tinged hills keeping stately guard around, on every side opened out a series of pictures. Why do not more of our R.A. artists come out here? Do they really know that it is but four days from London? Above all, how richly would he their trouble repaid. Poor Mr. Egg, R.A., indeed, came here, but in an advanced stage of consumption, and only to find a grave. His widow is here at the present time, having undertaken the long journey, all alone, for the purpose of erecting a tomb to his memory."

Some of the Roman remains seem to exist in the most perfect condition. In England the incessant changes, the perishable nature of the climate, &c., have destroyed much that the conquerors left of their handiwork; but in Algiers, houses are to be found perfect in all parts, in which the most elegant ornamentation and the various appliances for luxury and comfort are still to be seen.

#### BRITISH STAINED GLASS.

IN continuation of the articles on this subject in your last two numbers, allow me to submit some remarks on the most noticeable defects of modern British glass, and on what appears to me to be their natural remedy. I should premise, however, that all the defects which I shall mention may not be found in all the stained glass of British manufacture; but, more or less, the remarks apply to every specimen I have yet seen.

1st. Our stained-glass artists, as a rule, use too much blue.

2nd. That blue is often of a very bad quality, being either semi-opaque, or otherwise objectionable in tone, and much inferior to the beautiful colour used by the artists of Munich, Dresden, and other Continental manufactories.

3rd. Too much white glass is used; and this, with the objectionable blue, gives a hard, harsh, and cold aspect to all the window.

4th. The outlines are very frequently spoiled, and the effect disturbed by blotches of coloured drapery cutting the figures horizontally or obliquely, and causing it to be a matter of no slight difficulty and considerable ingenuity to trace each figure from head to foot. Another objection connected with this is, that often every object is equally emphasized, and consequently figures or accessories intended to be in the background appear on the same plane as those in front, and so add to the confusion.

5th. Flesh is painted too white, or a dirty yellow.

6th. Want of concentration of effect: equally light parts are distributed in the most meaningless and random manner all over the window, especially in large subjects.

7th. Too many colours are used in almost equal proportions.

The preceding are, I believe, the chief defects in the manipulative part of our British glass; but the faults in the conception and design are more heinous. Not to mention the absurd imitation of the worst parts of Mediæval work practised by some manufacturers, nor that puerile conceit which gives a metallic stiffness to the draperies and figures, and calls it "Mediæval spirit" and "feeling," there are sillinesses perpetrated in the name of Religious Art which are only a ludicrous parody of art: expression is in many cases totally ignored; and on faces which are intended to represent divine or glorified beings, the meaningless everlasting stare of the wax doll is substituted. Most of the works give evidence of a very desultory training on the part of the artists: the aim seems to be neither high nor very decided, and the designs smack more of the manufacturer than the artist.

The stained-glass makers may object that they could not get a sufficient remuneration for their labour were they to study their designs more fully; but works of merit will command their own price in this as in everything else; and if the British glass were equal to that of

Munich, no one in this country would refuse to give home talent the preference. But, compared with Munich, Dresden, and some other Continental glass, our own is lamentably behind; and, notwithstanding "J. H.'s" perhaps truthful sneer at the thinness of the Munich glass in Glasgow Cathedral, I know nothing that would lead more to raise our own art than the zealous study of the magnificent windows in that building: faulty some of them may be, but they have at least the merit of telling their story boldly, simply, and without affectation; and it would be difficult to surpass the broad, rich, and luminous draperies, the quiet brilliancy of the skies, and the grand, dignified, and thoughtful heads, which are their leading characteristics. Next to studying under the masters who produced these works, the studying of the works themselves would be, I believe, the surest way to the attainment of those excellences which are as yet unknown in British stained glass.

Your correspondent "J. H." gives it as his opinion that a cool tone should be preferred in stained glass; I fancy that a warm mellow light is the most agreeable—at least, in a building such as a cathedral, where the cool grey of the stone wants something to enrich it. I had the advantage of comparing the effects of the warm and cool treatments in two windows which stand side by side in the crypt of Glasgow Cathedral: one is from Dresden (I think); and though only a single lancet light, is the most beautiful piece of colour I have seen. The subject is "Christ and St. Peter on the Sea;" and—so far as I can recollect—a fine red and a delicate straw-colour are used for the draperies; the border is formed by a small gem-like design, in which green, relieved by red, predominates. The whole effect is exquisitely rich, soft, and warm; and it is with an inward shiver that we step from their light into that of a "very cool" St. James of British manufacture, in which blue drapery, "cool flesh," and neutral colour have a disagreeable pre-eminence.

In conclusion let me say, that if I have written somewhat harshly of our infant school of stained glass, it is because I feel that our country—with a school of painting which owns no modern superior, and with sculptures almost rivalling the antique—ought not to be behind in anything which demands harmony of colour and beauty of form.

J. MOYR SMITH.

TRAPS TO RAINWATER PIPES.

In a season of drought the traps at the foot of rainwater stack-pipes frequently become quite dry, and if there are dormer windows in the roof, the gases from the drains are drawn off by the stack-pipes, and flow into the windows, and from the attic rooms find their way into the whole house. With a high house it is not an easy matter at all times to let water into the dry traps. Last summer I thought upon a very simple plan which answers admirably, and gives no trouble. About 2 feet from the ground I had a hole made in the stack-pipe, and inserted a plug with a screw thread upon it, and with a square head. Whenever it is required to fill the traps the plug is withdrawn, and water poured in from a common watering-pot. Deodorizing fluids can by this means easily be sent into the traps, and into the drains. The plan is simple, and although very efficacious, is not in any way costly.

WALTER FERGUS, M.D.  
Medical Officer of Marlborough College.

\*.\* Particulars were given in our pages not long ago of an improvement in rainwater-pipes, with a view to the remedy of the evil complained of by Dr. Fergus.

HOW MAKE STONE IMPERVIOUS?

SIR,—I have just been called upon to remedy some defects at a parsonage-house, built four years ago. The house stands on an elevated site, facing south-west, and in wet weather the rain penetrates quite through the window jambs and spondrels over, which are of freestone, nowhere exceeding 8 inches in thickness.

Can any of your readers inform me of a method of rendering the stone impervious to rain, without altering its appearance externally? Oil paint would have the desired effect, but would spoil the appearance of the stone. The occupier has tried oil colours internally, but without success, although he says the stone was perfectly dry when painted.

W. B.

SENSE IN DESIGN.

WHEN architects adopt the Antique or Mediaeval as their models, I wish they would reflect a little on the reasons for different materials being used together. For instance, the iron bars through open-work wooden gates were only used to draw them together, and so strengthen them; but now we often see the iron bars added for ornament where they could be of no use.

As an instance of this, I inclose you a rough sketch of the gate of what appears to be a very costly entrance, lately erected near Belfast. The gate is of very massive pierced woodwork; but those handsome twisted iron rods, with fleur-de-lis ends, are quite out of place, for no one could screw them in with that twist in the upper part of them; and if not of use to strengthen the gate, they should not be there.

Pardon these free remarks from an AMATEUR.

RAILWAY MANAGEMENT.

THE late accident on the Great Western Railway, near Shrewsbury, is another proof of the great defect in the present system of starting long and heavy trains without sufficient break power.

Put forty carriages together filled with passengers, with a break at each end, and start them up a heavy incline, and the chances are, one of the coupling-irons breaks, and thirty of the carriages run back, which the hindmost break will not hold; the same as occurred some time ago with an excursion train filled with school-children, out of Birmingham. Do the same thing with forty carriages as the Great Western did a short time since, and send them down a heavy incline, like the one at Holloway, and the chances are that they run into King's Cross, and into the Pancras-road.

Do the same thing with forty carriages as the Great Western have now done, and send them down a heavy incline, with rails out of repair at the bottom, and the chances are that the carriages run down at full speed, and smash up. Whereas, if the train had been an ordinary train, and passed slowly over the rails which were temporarily laid, the chances are they would have gone all safe. But it is of no use the press writing; it is of no use even for her Most Gracious Majesty to write. Your paper was the first to point out, in the case of Mr. Briggs's murder, that such might be remedied by having glass partitions in the carriages, and it was taken up by the other papers; but nothing has been done. Passengers' lives are reckoned up in the working expenses; and nothing will be done till a law is passed making all railway carriages and trains come under inspection, the same as all other public conveyances; the same as cabs, omnibuses, and steamboats; and duly licensed, as fit and proper, and to carry so many and no more; and that every train with ten carriages shall have a break and guard at each end; and every increase of ten carriages over that number shall have an extra break, with an extra guard; and that a train shall not consist of more than a certain number of carriages. Also, that every railway train shall be compelled to run two trucks, either empty or full of goods, next the engine, so as to receive the concussion in case of accident.

Railway companies do nothing unless compelled by Act of Parliament; and that they will try and evade, the same as they did with the closed carriages of the Government trains, by having wooden shutters and a skylight in the roof. But, under proper inspection, the same as cabs, and enforced by a heavy fine, we might then travel with comfort and safety.

L.

OBITUARY.

The late Mr. Lightly, Architect. — A very amiable, clever, and manning young architect has just now been called to a better scene.—Mr. William Lightly, the coadjutor with Mr. P. Anson in the restoration of the Dutch Church, Austin Friars, of which we gave a view a few weeks ago. Mr. Lightly, who was a pupil of Mr. P. Anson, had acted for some time as the Honorary Secretary of the Architectural Photographic Society, and had lately commenced to edit a volume of Photographic Views, the first few parts of which that have already appeared were noticed in our pages. Decline was the cause, we believe, of his regretted premature decease. He was a Fellow of the Institute of Architects.

GREAT MUNDEN CHURCH, HERTFORDSHIRE.

THROUGH the exertions of the Rev. C. W. Maude, the rector, and the liberality of the few holders of property in the parish of Great Munden, near Ware, funds have been raised to do some of the works much needed at the church. The building dates from the Norman time, and has some remnants of the architecture of that period in the shape of a north doorway and part of the chancel arch. It has been altered in various ways, and, with the exception of the chancel, which was repaired a few years ago, is in a miserable condition. It is proposed to reset the nave, put on a new roof, and restore the stone-work generally. Tenders are now being invited. Messrs. G. & H. Godwin are the architects.

THE SEWERAGE OF KINGSTON-ON-THAMES.

THE Conservators of the Thames sought to obtain an injunction to restrain the Corporation of Kingston from discharging the sewage of that town into the Thames under a new scheme of drainage, by which the existing cesspools are to be discontinued and one main intersecting sewer constructed with an outfall into the river a little below Kingston Bridge. The case made by the information and evidence in support was in effect that the increased quantity of sewage would in time cause an offensive deposit in the river, pollute the water for bathing, boating, fishing, or drinking purposes, be injurious to human health, and so interfere with the enjoyment of the public in the use of the river as to create a public nuisance.

The Vice-Chancellor, in giving judgment, after admitting that such a nuisance might be so committed as to authorise an injunction to stop the works, was of opinion that the existence of such a nuisance had not been proved on that occasion. Further than this, some means of defeating or deodorizing the sewage might be applied before the nuisance actually arose. Was he, then, to stop the works of the defendants on a mere case of prospective apprehended nuisance? The Court would have full power to deal with the matter when any case of actual nuisance arose, and the proper course would be to dismiss the information, such dismissal being prefaced by a declaration that the Court was of opinion that the evidence did not establish the existence of any nuisance in respect of the works executed or intended by the defendants, or any case for the interference of the Court. The order would be without prejudice to any future proceedings on the part of the Attorney-General in case the works should occasion a nuisance; and under the circumstances, it was not a case for giving costs.

THE SEWERAGE OF GREAT CROSBY.

THE ratepayers of Great Crosby, Liverpool, at their meeting on the 9th, had before them a plan for drainage of the district, by Mr. Clarke, their surveyor, supported by Mr. Thorburn, of Birkenhead; and a plan by Messrs. Roade & Goodison, strongly supported in opposition to the first, by Mr. James Nowlands, of Liverpool. Mr. Nowlands said he estimated the first would cost 8,500l., Messrs. Roade & Goodison's 5,100l. After considerable discussion Mr. Clarke's plan was adopted.

THE SMOKE NUISANCE.

SIR,—In your last impression there is an article, signed "R. T.," on the subject of the removal of the smoke nuisance. Your correspondent, in his suggestion, seems to have overlooked the now established fact, that by passing smoke over a red-hot fire it is not the smoke itself that is consumed, but merely that portion of it called soot. The noxious vapours, such as crescents, sulphuric and carbonic acids, &c., that also form part of the smoke, are still allowed to escape into the atmosphere, and really do more harm than by being combined with the soot, which partly neutralises the bad effect these gases would otherwise have.

The only effectual method is to prevent any smoke at all from going into the atmosphere. This can be effected by a very simple apparatus which I have invented, but which I hope you will excuse me from describing, merely saying that it was pronounced by one of our eminent engineers—Capt. Grant (the inventor of the army position and cooling apparatus)—to be "the simplest and most effective apparatus he had seen." I took it, some time since, to Lord Palmerston, who expressed himself highly pleased with it, and said, that although he could not help me with it himself, he would do what he could to enforce the law in regard to its use, if I could have it brought out. It would require a much larger sum to give it a fair trial than I have at my command.

W. H.

## THE BUILDING TRADES MOVEMENT.

**Wolverhampton.**—The strike of the bricklayers still continues, and there are no apparent signs of an adjustment of the difference. On Thursday before last there were only 25 bricklayers left in the town, out of 180. At a meeting of the masters they resolved on a series of rules under which they would engage bricklayers. These rules, with few and unimportant regulations, simply embodied the terms which they had offered the men at their conference, and which the men then rejected, and which those that remain in Wolverhampton say they are equally determined to reject now. They offer 5½d. per hour as wages. These rules refer also to the labourers, who are offered 3½d. per hour. They demand 4d. an hour; and it is estimated that perhaps 100 are at work at that price. The result of there being little or no bricklaying is that the plasterers and carpenters are getting worked out and reduced to forced idleness.

**Brafford.**—The masons' labourers now are out on strike. The number of hours of labour at present is 503 hours per week, a reduction having recently been yielded, and the men are now seeking an advance also of 1s. per week, making the wages 20s. per week, instead of 19s. A strike on the part of the operative joiners, for an advance of wages, also seems inevitable.

**Leeds.**—The strike in the Leeds building trade was terminated by a friendly arrangement of the matters in dispute. The men will receive an advance of wages, but the hour system, which the bricklayers have strongly opposed, is to be adopted both by the joiners and bricklayers, and the bricklayers' labourers. The two former are advanced a halfpenny per hour, and the latter a farthing, the wages for joiners being now 6d. per hour, and for bricklayers 6½d.

**Darlington.**—The painters are on strike: they demand an advance of 2s. per week, summer and winter; and to leave work at one o'clock on Saturday, instead of four, as previously. The brickmakers have given notice that they will strike, unless the half of Saturday be allowed them.

**Middlesex.**—The Middlesex ironmasters have, in answer to a requisition from their employees, agreed to give them a half-holiday in the week, the works to close in future at one o'clock on Saturday afternoons, instead of four, as heretofore. The privilege has been granted for six months. If at the end of that time the masters see that the men have not abused the privilege, it will be granted altogether. The men's wages will continue the same.

## COMPENSATION CASES.

**The Holborn Valley Improvement.**—At the Lord Mayor's Court last week, before the Recorder and a special jury, there came on for hearing a compensation claim in respect of the Holborn Valley, made by Messrs. Lloyd, tobaccoists on Holborn-hill, against the Corporation of the City of London, for their premises and business. Several witnesses were called in support of the claim, which was for about 12,000l. A sum of 3,153l. was agreed upon for the leasehold interest in the property, and the principal question was as to the business and the removal of the stock to new premises near Gray's-in-road. The receipts were about 25,000l. a year, and the gross profits from 9 to 40 per cent. on a certain class of goods. The stock would be deteriorated by the removal. It was proposed to give evidence as to a fair sum for such a business, but the court declined to receive such evidence, and Mr. Cronin and other valuers in attendance were not called. A conference took place, which ended in a settlement for a sum of 7,550l., including the value of the leasehold property.

**Marson v. The Metropolitan Railway Company.** In this case at the Sheriff's Court, before Mr. Humphreys, the claim was 8,195l., and made by Mr. Marson, as the freeholder of the Cobham's Head, Coppice-row, Clerkenwell. It was supported by Mr. Cronin and other gentlemen on the ground that the house had been closed for some years, and if it had not been closed the premium for the place would have been 4,500l. On the present occasion witnesses for the company were examined. It was denied that the works of the company had caused the house to be closed. There had been some little damage done to the property, but the extent was about 100l. The house was very old, and the best course would be to pull it down and build another. Mr. Jay, the contractor, was called. He was answerable

for damage, and he had paid the amount and done the repairs. He purchased the lease and had not opened it as it had only two years to run, and the expense would have been considerable. The coroner, in placing the case before the jury, said the question was whether the injury done to the property was by the works of the company. The house had been closed by Mr. Jay and not by the company. No doubt it had lost its prestige by being closed, but the question was whether the company were liable to the extent alleged. No doubt they were liable for the structural damage done by their works, but that was only to an extent of about 100l. Witnesses had been called on both sides, and it was admitted by all that the house had better be rebuilt. The question was whether the works of the company had done the damage. The house was an old one, and had been closed by Mr. Jay, who had purchased the lease. The jury would consider the evidence as presented on both sides, and say what in their opinion the claimant ought to recover. The jury retired for some time, and on their return assessed the compensation at 500l.

An unprejudiced correspondent who was present, writes to us to ask whether Mr. Jay did not in reality represent the company?

**Wall's v. Robson v. The London, Chatham, and Dover Railway.**—At the Lord Mayor's Court, this compensation case was investigated by the Recorder and a special jury. The claim was for a freehold house and land, 48, Ludgate-hill, the premises having been pulled down on account of the bridge on the north side. The claim was for 10,000l. The rental was valued at 450l. a year, at twenty-two years' purchase. Mr. Bovill, Q.C., who appeared for the claimants, took occasion to allude to the state of the law on railway compensations, and complained that there were many extra expenses which were not allowed on taxation, and it was an additional reason why jurors should give ample compensations. Until the Legislature interfered there would be no remedy. Mr. Lloyd, for the company, called several witnesses to show that the value was under 6,000l., and the rental only 250l. a year. The jury, after a long investigation, awarded 7,550l.

## Books Received.

*The Grammar of Ornament.* By OWEN JONES. Illustrated by Examples from various Styles of Ornament. London: published by Day & Son.

WHEN the costly folio edition of "The Grammar of Ornament" was first published, we expressed strongly our admiration of the work, and offered our congratulations and thanks to Mr. Owen Jones for the manner in which he had carried out the idea. The book was at once accepted, as well supplying a want, and is now out of print, notwithstanding the large price at which it was necessarily published. The company which has since been formed to carry on Messrs. Day's business have now wisely issued a new and cheaper edition,—an edition not made cheaper by any curtailment or diminution in worth, but by a reduction of the size of the plates; and the cost is thus brought down so as to place the book within the reach of a much larger number of persons than was the case before. The publishers only speak the truth when they say that,—"The 'Grammar of Ornament' has not only been adopted as a class-book in all the Government schools in this country, but also by the principal schools of the Continent, where the importance to art of this invaluable collection, and of the principles explained in the text, by which Mr. Owen Jones has sought to guide the student to its use, has been fully recognised and honoured."

The several plates have been proportionally reduced by the photographic process, through the care of Mr. Francis Bedford, who so skilfully conveyed to stone the original drawings of the folio edition. In some cases, where the general scale of reduction was unavoidable, the examples forming a plate in the original have been retained to a larger scale, and spread over two plates; thus giving, on the 112 plates of the present edition the whole of the material contained in the 101 folio plates of the original work. Without the aid of photography and other mechanical appliances, the perfect reduction we now have could not have been obtained but at a cost that would have prevented the publication.

The text, with all its woodcuts, is complete as in the folio edition, and consists as before, of twenty chapters, treating of,—The Ornament of various Savage Tribes, with 3 plates; of Egypt, 9; of Nineveh and Persia, 3; of Greece, 8; of Pompeii, 4; of Rome, 3; of Byzantium, 4; of the Arabs, 3; of the Turks, 3; of the Moors, 8; Ornaments from Persian MSS., 6; from the Indian Exhibitions of 1851 and 1855, 9; the Ornament of the Hindos, 3; of the Chinese, 4; of the Celtic Races, 3; of the Middle Ages, 9; of the Period of the Renaissance, 10; of the Elizabethan Period, 3; of the Italians, 6; a series of Leaves drawn from Nature as Models of Ornament, 10; and Illuminated Title-page.

The author has endeavoured in these several chapters to define the apparent origin and trace the development of the several styles of ornament. He then proceeds to ascertain the laws which govern their composition; both those which are general to all styles and those which are peculiar to each.

Of course there are points in the various essays accompanying the illustrations of the different styles with which we do not agree. Take the following observation, for example, on which we happen to stumble in the chapter on Greek Ornament:—"In the well-known honeysuckle ornament it is difficult to recognise any attempt at imitation, but rather an appreciation of the principle on which the flower grows; and, indeed, on examining the paintings on the vases, we are rather tempted to believe that the various forms of the leaves of a Greek flower have been generated by the brush of the painter: according as the hand is turned upwards or downwards in the formation of the leaf would the character be given, and it is more likely that the slight resemblance to the honeysuckle may have been an after-recognition than that the natural flower should have ever served as the model." Now, the resemblance is anything but "slight," and that the original flower did originally serve as the model we feel no doubt; but the fact obviously is, that the ornament was in constant use by the Assyrians, and was carried on and immensely improved upon by the Greeks, owing nothing of its origin to the brush of the painter. However, we are not now to review the book. We would simply say that "The Grammar of Ornament" is a work of great value, and we applaud and recommend for a wide circulation the new and cheaper edition that has just been published.

*Elementary Drawing Copy-Books, for the Use of Children, from Four Years old and upwards, in Schools and Families.* Compiled by a Student certificated by the Department as an Art-Teacher. London: Chapman & Hall.

THESE copy-books are seven in number, and are intended to be used in the same manner as the ordinary writing copy-books; that is, the copy, being set at the side of the page, is to be copied on that same page, either below or on a line with the copy. Books 1 and 2 consist of horizontal, perpendicular, oblique, and curved lines, as letters; 3, geometrical figures and ornaments; 4, objects; 5, leaves; 6 and 7, birds, beasts, &c. Simple instructions are given on the covers. The price is small. We have no doubt they would be found useful, not merely for children, but by adults who may wish to obtain some facility in copying objects. With good will and perseverance considerable progress might thus be made.

## VARIORUM.

**Hardwick's Science Gossip.** London: Hardwick. No. 6, for June, contains chat on various subjects in zoology, entomology, botany, microscopy, geology, piscatology, &c.; and sustains its position and its interest as a monthly medium of interchange and gossip for students and lovers of nature.—A Report on the Condition of Journeyman Bakers of London, by the Standing Committee of the Department of Economy and Trade of the National Association for the Promotion of Social Science, has been issued by the society, at 1, Adam-street, Adelphi, London. It states that much good has been done by the new Act, although it cannot directly reach the subject of adult labour and night-work. Bakehouses were found by the inspectors to be frequently in a foul state most unpleasant to think of, and which, we should fancy, must greatly promote the interests of machine-making bread companies. The journeyman bakers of London appear to be looking a little more closely to their own interests than the poor fellows have heretofore done. An amalgamated union of operative

bakers has been formed, for the purpose of obtaining an abridgement of the hours of labour and the abolition of night-work. They have a small room in 13, Rolls-buildings, Fetter-lane, which they are now desirous of extending, as they find it inadequate for public meetings, and they are unwilling to resort to the general hut most pernicious practice of workmen meeting in public-houses. We hope some good Samaritans will help them towards the very commendable object which they have in view. They also aim at having a home for young men from the country to lodge in till received under the roof of a master, so keeping them also out of the lowest public-houses, to which they are now generally obliged to resort.

Miscellaneous.

THE THEATRES BILL.—MR. LOCKE'S Bill has been abandoned.

MADLE ROSA BONHEUR.—This distinguished artist has received the Cross of the Legion of Honour. It is the first time it has been bestowed on a woman unconnected with the army.

CAUTION AS TO THE CONSTRUCTION OF "LIFTS." At the Grosvenor Hotel on the 12th inst., the beam which suspended the machinery of the lift gave way, and the ascending-room, with persons in it, was precipitated to the bottom. One of the porters was killed by the counter-weight falling on him, and a gentleman's servant had his leg fractured.

MONUMENT IN THE CITY OF LONDON AND TOWER HAMLETS CEMETERY.—A monument has been erected to the memory of the infant daughter of Mr. Josh. Westwood, Tredegar House, Bow, after the manner of an Eleanor's Cross. The height is about 30 ft., and the whole is built of selected Portland stone. It is inclosed by an iron fence. The floors are laid with Milton's ornamental tiles. The architect was Mr. John Moxon, of Bow.

THE WORKING MEN'S COLLEGE.—Great want of room is felt. The drawing-class, one of the largest and most efficient of all, has to complain of a most unwholesome atmosphere, and of want of space for their regular work. Every other is similarly crippled in proportion to the numbers which frequent it. So the council are driven to the necessity, which they have always avoided as much as possible, of begging help from the public generally. They hope that they may set up a building suitable for their present purposes, and capable of further enlargement, at the expense of 1,000l. For this object they now seek subscriptions.

CONVERSAZIONE OF THE SOCIETY OF ARTS.—This society held a *conversazione* at South Kensington on Wednesday evening, which was most numerously attended. Mr. W. Hawes, as chairman, received the visitors. The new Raffaele Room and Sheepsheads Gallery were open; and these, as well as the rooms containing the exhibition of miniatures, were thronged. Two hands were in attendance—that of the Coldstream Guards and that of the Royal Artillery. One of these was stationed in the Cartoon Gallery, and the other in the new North Room, near to which refreshments were served. The miniatures appeared to be objects of especial attraction. The arrangements reflect credit on Mr. Le Neve Foster, Mr. Davenport, and the officials of the South Kensington Museum, by whom they were made. The evening was one of unmingled satisfaction.

ART-SCHOOLS AND THE COMMITTEE OF COUNCIL ON EDUCATION.—There has recently been issued the copy of a minute of the Committee of Council on Education relative to the art-schools. On the 1st instant the consideration of the memorial from various schools of art was resumed, and the Council agreed to modify the arrangements, consenting to resume the payments of building grants and grants for examples, but declining to revert to the system of payment by certificates. They do not consider that the art-teachers come within the provisions of the Superannuation Act, 22 Vict., c. 26; but they will increase the amount of the payments proposed in the schedule appended to the minute of February 9, in the hope that certificated art-teachers will earn payments equivalent to the value of their certificates. This schedule referred to is cancelled, and another, which is given in the return, is substituted for it.

STOPPAGE OF THE NATIONAL WALLACE MONUMENT WORKS AT STIRLING.—The tower has reached the height of 155 ft. but funds are wanting, and the committee have resolved to suspend building operations, and dispose of the plant and materials for the purpose of liquidating existing obligations.

LAYING THE FOUNDATION STONE OF THE HARTLEPOOL RESERVOIRS.—On Thursday last week, the ceremony of laying the foundation stone of the new reservoirs in connexion with the Hartlepool Gas and Water Company was laid. The reservoirs are situated near the village of Hart, at an elevation of 170 ft. above the level of the sea. They are capable of containing 25,000,000 gallons of water, and are supplied by a spring which is estimated to fill the reservoirs in twelve hours. The supposed cost of the works is 12,000l.

GALWAY.—The Atlantic Sawing, Planing, and Moulding Mill, recently erected by the firm of Messrs. Cloberty & Semple, has been set agoing. The mill is a large edifice. The machinery is turned by a turbine wheel of 40-horse power. There are six different machines entirely distinct from each other, viz.—A planing and moulding machine, a large saw-bench, a small saw-bench, log frame, a deal frame, and a band-saw. The machinery was supplied by Messrs. Robinson & Son, of Rochdale.

THE ART EXHIBITION AT ALTON TOWERS.—An Art Exhibition will be opened at the commencement of July, at Alton Towers, Staffordshire, the seat of Earl Shrewsbury, as we have already announced. The purpose is to aid the funds for the erection of the Wedgwood Memorial, Burslem, a building intended to be "an experiment of Ceramic Architecture on a bold principle," and it is proposed that it shall continue open for about three months. A gallery of modern architecture is to form a portion of the Exhibition, and offers of drawings from architects are being invited.

DOWLING'S "METRIC TABLES."—We are glad to see that Mr. Charles H. Dowling's "Metric Tables" (Lockwood & Co.), for converting British into metric measures and weights, and *vice versa*, have been well approved in France. The *Moniteur* a short time since said,—"This work was completely wanting; having, at every instant, to convert into French measures English measures of every sort, and obliged to trust to the insufficient tables of our almanacs, we often felt discouraged. Thanks to Mr. Dowling, we shall never more be at a loss."

THE BONAPARTE MONUMENT IN CORSICA.—Prince Napoleon presided over the inauguration of the grand monument raised at Ajaccio to the memory of Napoleon Bonaparte and his family. The Emperor is on horseback, surrounded by his four brothers, and all are dressed in Roman costumes. The equestrian statue is nearly 10 ft. high, and the others are about 7 ft. each. The base is raised more than 12 ft. above the level of the soil. The statues are cast in bronze furnished from cannon taken in the late Italian campaign; but two winged Victories, placed in the basement, are of marble. The entire monument is about 100 ft. in length and 25 ft. in height. The general arrangements were made by M. Viollet le Duc, and the sculpture was executed by MM. Barry, sen., Thomas, Jean Petit, Maillet, and Duhray.

FIELD-LANE RAGGED SCHOOLS AND NIGHT REFUGES FOR THE HOMELESS POOR.—On Tuesday last, the ceremony of laying the foundation-stone of a new building, for an increased and more efficient accommodation of the Field-lane Ragged Schools and Refuges, was performed by the Earl of Shaftesbury. The site of the new building is in Vine-street. It will command a frontage in Saffron-hill opposite the Italian Catholic church, and a still larger frontage in Vine-street itself, now called Hatton-wall. The building will consist of three main divisions—first, night refuges for men and women; second, a home for female servants; and, third, the ragged schools. In the night refuges there are waiting-rooms, lavatories, baths, and dormitories for 80 men and 90 women, with separate entrances. The servants' home will have living-rooms and sleeping-rooms; and the schools will consist of one large room 40ft. by 40ft., and capable of being divided into three departments for girls, boys, and infants. Mr. F. W. Porter is the architect, and Mr. W. Higgs the contractor. The tenders for the erection of the building will be found in another page.

ASSESSMENT OF THE BANK OF ENGLAND.—The *City Press* says the Bank of England has been assessed at the gross annual value of 47,000l. by the Assessment Committee of the City of London Union. The former assessment was something like a fourth of that sum; but the increased amount is considered by the committee to be strictly fair and equitable. We understand that the Bank authorities have given notice of appeal. Under the Union Assessment Committee Act, the rateable value of property in the City has been equalized. The disparity between the amount at which premises were previously assessed and the present value has in many instances been very great.

AN IMPROVEMENT IN IRON.—An improvement in iron, increasing greatly its tensile strength, is claimed by Mr. J. D. Williams, of Pittsburg. Tested at Fort Pitt, a specimen of wrought iron made by him was subjected to a strain of 166,900 lb. per square inch, without breaking, which is nearly twice the endurance of any iron ever tested, and is much greater than that of cast steel. The process of imparting this unexampled tenacity of strength to iron adds only two dollars per ton to its cost. If after facts justify this test, it will add nearly 150 per cent. to the strength of steam boilers, the thickness of plate being the same. Chains of equal tractile strength can be made of less than half the iron now used. For suspension bridges it will be invaluable. The improvement is chemical in its nature, and is applied in the boiling furnace. The iron of which the piece which was tested was made was principally anthracite pig, with a small quantity of charcoal iron.—*New York Paper.*

SASH WINDOWS.—A writer in *Notes and Queries* says,—"Your correspondent, 'A. A.' proves the use of this word as apparently rare in May, 1710. A reply to his note suggested that that term was derived from the Old English word *sasse*, a sluice; and *sas*, the Dutch, also for a sluice; the common French term for such a window being *à la guillotine*. The following note is, I venture to suggest, a very little, if at all, known assertion of the introduction of the window into France from England, and opens the question whether the invention was a Dutch or German one, and brought over with paint for house work, and sundry other building inventions, by the Dutch with William III. :—

"De Lorge: We had the good fortune here to find the marshall himself. He showed us his great *sash windows* how easily they might be lifted up and down, and stand at any height; which contrivance, he said, he had out of England, by a small model brought on purpose from thence, there being nothing of this sort in windows in France before; the house was but building," and was situate near Montmartre.—*Lister, "Journey to Paris,"* 8vo. London, 1699.

NEW IRON BRIDGE.—There has just been completed, in the yard of the Regent's Canal Ironworks Company, an iron bridge, which is the largest yet constructed on a system invented by Mr. A. Sedley. The *Society of Arts Journal* says,—"The structure in question has been made to the order of the Indian Government, and is designed to be erected in India. The leading feature of the new principle is that, without the necessity of any subaqueous works, or the erection of any intermediate towers or piers, the bridge can be built to cross in a single span any river or chasm up to an extreme width of 500 yards, or 1,500 ft. The bridge just finished is of 75 ft. span and 14 ft. wide; its total weight is 22 tons, including the roadway, and it will support a nominal strain of four tons per sectional inch, but really a greater weight. Two great cantilevers, or wedge-shaped girders, are built up piece by piece till they are projected from opposite sides of the chasm or river which is to be bridged over, and extended till they approach within a distance something less than a third of the whole span. Across this space a central girder is thrown, which, while it completes the continuity of the bridge, acts, when fixed in position and riveted down, as the key-stone, so to speak. The wedge-shaped girders which project from either side of the stream are at their wide ends embedded and built into massive piers of masonry on the shores. The base of the wedge is fixed by iron tugs, in an upright position; the central arm of the girder supports the actual roadway of the bridge; the lower arm, stretching to the point of the girder, becomes a bracket support; and the upper arm passing over the summit of the upright end, which makes the thick end of the wedge, is extended backwards as a tension-bar, and anchored firmly in the earth, thus giving suspensory support to the central arm, which attains a perfect rigidity."

**METROPOLITAN RAILWAY.**—The number of passengers conveyed on the Metropolitan Railway on Whit Monday was 83,410. This is the largest number conveyed in one day since the opening of the line.

**INTERESTING TO ANTIQUARIES.**—The Rev. E. Kell lately exhibited at a meeting of the Literary and Photographical Society, Southampton, some curious specimens of ancient Roman workmanship, recently dug up from the site of an old Roman station near Andover. There have been great disputes as to the site of Vindomis, some antiquaries fixing it at Basingstoke and others at Silchester. Mr. Kell considers the site near Andover to be the true one. He has just discovered the site of a Medieval glass manufactory in Western Hampshire.

**BLASTING.**—A notable result of gunpowder blasting has been witnessed at the Calciferous Granite Works, belonging to the Trefry estate, situated about one mile from Per station. The granite rock operated upon measured 56 ft. in length, 55 ft. in width, and 16 ft. in height. The hole was bored near the centre of the rock, about 16 ft. in depth, and charged with about 30 lb. of the "patent safety blasting powder," from South Down. The result was that the quantity of rock fairly disengaged is 3,520 tons. Scarcely any noise was made by the blast, although the rock was rent in the form of T, from top to bottom, and lifted as by a lever from its bed.

**THE PUBLIC BUILDINGS OF WOLVERHAMPTON.**—The Town Council have resolved to pull down the buildings at present used for the public offices in North-street, and erect a Town-hall, Sessions-house, Police-court, Police-barracks, Vestry-room, and Overseers' Offices, and other requisite public offices; and a committee already appointed are to "procure plans and estimates for such new buildings, and submit the same, with their opinion thereon, to the Council; such committee, in their advertisements for designs, being empowered to offer a premium of 100l. for the design which shall ultimately be selected as the best in the order of merit, and 50l. for the second best; the first premium to merge in the usual commission, in case of the author being employed to carry out the works." The contemplated cost will be about 12,000l., exclusive of sale of premises.

**METROPOLITAN FREE DRINKING FOUNTAINS.**—In the poor and densely-populated parish of Shoreditch there were forty-five miles of streets and only one public drinking-fountain; and at the London Fields, where large numbers of the poorer classes are in the habit of assembling on Sundays and holidays, there was much need of a drinking-fountain. The committee of the Metropolitan Free Drinking Fountains Association have therefore erected two fountains in Shoreditch and one at the London Fields. The Fields fountain has now been opened. The first Shoreditch fountain also has been opened. A site was granted by the vestry at the corner of Chapel-street. This fountain is the ninety-first which has been erected in the metropolis by this Association, who greatly require the means of going on with their useful work, their funds being now completely exhausted.

**THE METROPOLITAN BOARD OF WORKS.**—At the usual weekly meeting, the Board opened tenders from persons desirous of contracting for carrying out the works of the Falcon Brook covering and diversion. There were six tenders—viz., from Mr. Buston, for 39,400l.; Mr. W. Moxon, 35,400l.; Messrs. Hill & Keddell, 37,850l.; Mr. Detbie, 39,430l.; Mr. T. Wainwright, 36,000l.; and Mr. Rixon, for 36,857l. The tender of Mr. W. Moxon for 35,400l. was accepted. The engineer reported the quantities of filling-in material supplied to the Thames Embankment, from the 9th December last to the 7th instant, to be as follows:—On No. 1 contract, 30,780 cubic yards of land stuff, and 86,109 cubic yards of river-dredged material; on No. 2 contract, 6,864 cubic yards of land, and 9,299 cubic yards of river-dredged material; total quantity from both sources, 132,882 cubic yards. In reference to Park-lane, the chairman observed, that the works proposed in the Bill which the Board promoted, involved an expenditure of 12,000l. or 15,000l., whilst the widening of Park-lane proper (as proposed by the Parliamentary Bill which was lost in committee during the session) would have involved an expenditure of at least 150,000l. He considered it most important and necessary for the convenience of the public that that greatly overcrowded district should be relieved of its enormous traffic.

**GAS.**—The Harwich and the Woodbridge gas and coke companies have each declared a dividend of 8 per cent. per annum. The Market Harborough Gas Company have agreed to reduce the price of their gas from 5s. 6d. to 5s. The Melrose Gas Company have announced a dividend of 7½ per cent. per annum, and a reduction of 1s. 3d. in price.—Mr. Jaques, from the London Equitable Gas Company, has been appointed engineer to the Borough Gasworks, at a salary of 300l., in the room of Mr. Leslie, C.E., who is now with the Crystal Palace Gas Company.

**THE METROPOLITAN HOUSELESS POOR ACT.**—The Act of Parliament to make perpetual the Metropolitan Houseless Poor Act, which received the Royal assent on Friday, has just been issued. The provisions in the former Act as to the period for relief are repealed. The Poor Law Board are to have the wards and other places of reception provided by the Act inspected, and may revoke and renew the certificate, and an allowance may be made by the Board for providing wards instead of a sum in respect to each pauper. "Any constable of the city of London, may personally conduct any destitute wayfarer, wanderer, foundling, or other destitute person, not having committed or being charged with any offence punishable by law within the knowledge of such constable, to any wards or other places of reception approved by the Poor Law Board under the said Act or this Act, and every such wayfarer, wanderer, or foundling shall, if there be room in such wards or other places of reception, be temporarily relieved therein." The wards are to be opened for the relief of destitute persons between six in the evening and eight in the morning between October and March, and from eight o'clock in the evening till eight o'clock in the morning between April and September inclusive.

**A HOME FOR APPRENTICES.**—Mr. Hartley, of the Westminster Marble Works, in Earl-street, London, has founded a home for boys, who are taken as apprentices, and placed in a small house, in which a person resides connected with the works, who acts as a master; his wife is the superintending matron; and the control of these lads is placed in their hands. They are called in the morning to go to their work; they return at stated times to their meals, which are always ready for them. After the work is over there are books and newspapers for them to read, or occupation is found in writing and drawing. They are allowed full liberty of ingress and egress, being fined, however, if not in by a stated time, which varies according to the season, and they are allowed a small sum a week for pocket-money. They are thus placed in a position which must have a very material effect in qualifying them to fulfil their duties properly when arrived at manhood. The boys are taken at about thirteen or fourteen years old, and retained until twenty-one, at which age they ought to be able to take care of themselves, and make room for others. This institution is said to have been found exceedingly advantageous, not only as an industrial school, but to the master who has founded it; for, on a comparison made by Mr. Hartley of the loss sustained by him during a year, taking twelve boys of the Home and twelve apprentices living at their own homes, he found that the loss by absence amounted in the whole to but 11s. 3d. from the college boys; whereas, from the apprentices living with their parents, the loss on the same account exceeded 40l. during the same period.

**TENDERS**

For haunting-stables, farm buildings, and cottages, for Mr. S. T. Cooper, Bulwell Hall, near Nottingham. Mr. S. D. Walker, architect:—  
A. & R. Dennett & Co. (accepted) 22,250 0 0

For sundry additions and alterations to the residence of Mr. Samuel Smith, Woodberry Down, Stoke Newington, London. Mr. E. D. Walker, architect:—  
Dorus ..... 22,333 0 0  
Higgs ..... 2,237 0 0  
Dawson ..... 2,100 0 0  
Sewell & Son ..... 2,092 0 0  
Wright ..... 1,725 0 0  
Simpson & Lynam ..... 1,720 0 0  
\* Accepted, with modifications.

For alterations and additions to 153, High-street, Camden-town. Mr. Thomas T. Green, architect. Quantities supplied:—  
Manley & Rogers ..... 8313 0 0  
Scrivener & White ..... 808 0 0  
Stevenson ..... 800 0 0  
Palmer ..... 793 0 0

For the Girls' Orphanage, at Bitchingly. Mr. E. W. Pugin, architect:—  
Smith & Son ..... 23,900 0 0

For the Boys' Orphanage, at Hellingly. Mr. E. W. Pugin, architect:—  
Wilson ..... 211,868 0 0

For additions to a house at Wimbledon, for Mr. R. J. McCabe, Messrs. C. W. & S. W. Lee, architects:—  
Patrick & Son ..... 21,129 0 0  
W. & L. Avis' ..... 1,052 0 0  
\* Revised tender of 980l. accepted.

For house, stabling, garden-walls, and entrance-gates, at Ravenscourt Park, Hammer-smith, for Mr. L. Spain. Mr. J. Crawley, architect. Quantities supplied:—  
Bywater ..... 23,247 0 0  
Galsworthy ..... 2,888 0 0  
Hayward ..... 2,798 0 0  
Futman & Fotheringham ..... 2,300 0 0  
Cowland ..... 2,680 0 0  
Scrivener & White ..... 2,500 0 0  
Simpson & Son ..... 2,444 0 0  
Scott ..... 2,442 0 0  
Smith & Son ..... 2,390 0 0

For building Field-lane Ragged Schools. Mr. E. W. Porter, architect:—  
Building. Fittings. Total.  
Holland & Hamon ..... 25,050 ..... 21,400 ..... 46,450  
Jackson & Shier ..... 9,100 ..... 1,400 ..... 10,500  
Manfield & Sons ..... 8,900 ..... 1,400 ..... 10,300  
I'Anson ..... 8,550 ..... 1,400 ..... 9,950  
Patman & G. Herringham ..... 8,794 ..... 1,403 ..... 10,197  
Sawyer & Sons ..... 8,585 ..... 1,569 ..... 10,155  
Hayward ..... 8,572 ..... 1,455 ..... 10,027  
Coleman ..... 8,200 ..... 1,623 ..... 9,823  
Henshaw ..... 8,422 ..... 1,562 ..... 9,984  
Higgs ..... 7,960 ..... 1,830 ..... 9,790

For building three houses, at Peckham-rye. Mr. H. Jarvis, architect:—  
Collis & Son ..... 23,173 0 0  
Jerrant ..... 3,084 0 0  
Marland & Son ..... 3,015 0 0  
Wholey, Brothers ..... 2,500 0 0  
Piper & Wheeler ..... 2,925 0 0  
Henshaw (accepted) ..... 2,834 0 0  
Kynoch ..... 2,625 0 0

For the proposed restoration of Sherfield Church, Berks. Mr. W. H. Woodman, architect. Quantities supplied:—  
Budden ..... 21,305 0 0  
Pritchard ..... 1,280 0 0  
Woodroffe ..... 1,260 0 0  
Thomas ..... 870 0 0

For twenty-three houses, at Wimbledon, for the Rev. Alfred Peache, Mr. James G. Snaith, architect:—  
Mitchell (accepted) ..... 44,795 0 0

For alterations to No. 220, Vauxhall Bridge-road. Mr. James G. Snaith, surveyor to the estate:—  
Cornish (accepted) ..... 4,222 0 0

For building new Barr-mills, at West-end, Southampton, for Mr. Charles Bowes, architect:—  
Ball ..... 21,787 0 0  
Stevens (accepted) ..... 1,639 0 0  
Saunders ..... 1,157 0 0

For alterations, Ratcliff Workhouse. Mr. W. R. Kinipple, architect. Quantities not supplied:—  
Macers ..... 2,970 0 0  
Stans & Pritchard ..... 923 0 0  
Ramsey ..... 881 0 0  
Kelly ..... 817 0 0  
Johnson ..... 783 0 0  
Curtis (accepted) ..... 750 0 0

For a pair of semi-detached residences, Hornsey-ryse. Mr. J. W. Reed, architect. Quantities supplied:—  
Kilgus ..... 42,735 0 0  
White ..... 2,258 0 0  
Lambel ..... 2,230 0 0  
Smith ..... 2,200 0 0  
Carlton ..... 2,155 0 0  
Ramsey ..... 2,180 0 0  
Hawkes ..... 2,080 0 0

For erecting a beer-house and cottage adjoining, at Basingstoke, for Mr. Gardener. Mr. W. Smith, Architect:—  
Muselwhite & Sons ..... 2,454 0 0  
G. Charlton ..... 400 0 0  
Litchfield ..... 388 15 0  
Pritchard ..... 350 0 0  
Adams ..... 290 0 0  
F. Charlton ..... 290 0 0

For erecting three cottages, for Mr. Hoehley, Basingstoke, Hants. Mr. W. Smith, architect:—

# The Builder.

VOL. XXIII.—No. 1168.

Architecture  
and Engineering in  
India.\*

THE revival of architectural taste which has sprung up in England within the last twenty years is slowly but gradually spreading to India; and within the last few years more than one handsome church, railway-station, or other public building which would do no discredit to any European capital. This improvement certainly has not come before it was wanted. Until lately we did not shine in designing public or private buildings at home: witness the heterogeneous rows of suburban villas in the neighbourhood of London, or the unmitigated monotony and ugliness of many of our modern streets. But we certainly surpassed ourselves in India, and succeeded in inventing a style of building (irreverently known as the Military Board style), which for ugliness beat everything that ever was constructed by man.

\* Who does not know the sense of desolation that comes over one at first sight of some of our Indian cantonments," says Major Medley; "the straight and dusty roads, the rows of glaring white rectangular barracks, the barn-like church, differing only from a barrack in the presence of a square tower and classical (1) portico; the Roman Catholic chapel ditto, only smaller and with bright green doors all round."

"Then the houses, evidently built after the model of the barracks, unless when the genius of the builder had displayed itself in a profusion of bright colours on the external walls, arranged in such startling contrast that the dark borders were very apt to shy at passing it."

"If we go inside, matters are not much better. High bare white-washed walls, a barn-like roof, with perhaps a dirty ceiling cloth shaking in the wind; a dilapidated plaster floor, and square holes cut in the walls doing duty as doors and windows. One exception alone is there to this puritanical simplicity, in the fire-place, which is evidently an offspring of the genius of the native mason, and consists of a grotesque mass of ornaments which would perhaps be more effective if unobscured by the smoke from the ill-constructed chimney."

The general reason assigned for such a state of things is,—1st. The requirements of the climate; 2nd. The necessity of economy. But the cogency of either argument must be altogether denied. There can be no doubt that a thoroughly airy and well ventilated building may be made just as ornamental as one which is adapted for a cold climate only; and that a small amount of money expended in judicious ornamentation will scarcely affect the total cost of the building. The real reason has been undoubtedly a want of taste and knowledge, and now that such deficiencies are beginning to disappear, it is hoped and believed that the beginning of an improved state of things has arrived. It must be allowed that the true principles of

architectural construction for buildings in the East, which are to be used by men habituated to an entirely different climate, have not as yet been discovered.

"A mosque," remarks Major Medley, "has a pleasant temperature both in winter and summer, while a Gothic church in India is, as a rule, either very hot or very cold. I do not say that Gothic churches are unsuitable to India, but only that they are so as we now build them. In the same way, many of our houses with lofty rooms, numerous openings and thin walls, are far less cool and pleasant than native houses, low and badly ventilated as they are, with thick walls and few doorways. I do not say that we ought to live in native houses, but simply that we have not as yet hit upon the right way of constructing our own."

Tending of architecture as distinct from mere building, it is an art, not a science, and therefore does not fall under exact rules of instruction; one consequence of architecture stands still and copies. We make better roads and bridges now than in the fifteenth century, but we have hardly got beyond copying their churches; and until there is a reformation in this respect, it is hopeless to expect that we shall have an architecture adapted to the peculiar circumstances of Anglo-India."

As to the style of dwellings in the Upper Provinces of India, it is doubted whether the present style is not radically unsuitable to the climate.

"In a hot and damp country, especially if near the sea coast, numerous doors are certainly required by which the cool breezes may sweep through the house; and hence verandahs are necessary to shade the doors from the direct glare of the sun. But where, as in Upper India, it is necessary during the fierce dry heat of April, May, and June, to exclude the hot air altogether, by night as well as by day, the fewer doors there are the better; and ventilation should be secured through the roof. In the cold weather, the paucity of doors would add much to the comfort of the house, and verandahs might perhaps be altogether dispensed with. The thin walls which now get so thoroughly baked that they continue to radiate heat by night and day for months together, should be made twice their present thickness, or, better still, might be double. Upper-storied buildings are perhaps more suitable to Lower than Upper India, unless the upper rooms are used solely as dormitories; but constructions of expense will generally bar their adoption. In many parts of the country, perhaps the old Eastern style of building round an open quadrangle in the centre might be adopted with advantage. This open court, paved with marble or stone, filled with fragrant shrubs, and with a fountain and tank in the centre, is characteristic of most of the dwellings of the wealthy throughout Syria and other Eastern countries, and is, indeed, common enough in native houses in India. Perhaps some one will work the idea into a tangible shape."

He protests against the indiscriminate use of plaster so generally applied to buildings of all kinds in India. In most cases it is simply used to conceal bad masonry, and every plastered building looks shabby in a few months after being constructed. It is expensive and adds no strength to the work. Brick masonry, if well executed, as he observes, has a beauty of its own, and with well-made bricks, well bonded, and with fine joints, there can be no meaning whatever in hiding the material. Some excellent specimens of brick masonry have been lately erected \* in Upper India, but improvement is required in the manufacture of bricks before this kind of work can be executed to the best advantage.

Will somebody, he asks, invent a new material for roofs in India?

"Slates we have not, except in one or two out-of-the-way localities. Galvanized iron we cannot get. Tiles get broken and look ugly, and are leaky. The ordinary flat terrace-roof leaks also, and is very heavy. A trussed roof with a very slight pitch (say 10 degrees), and covered with flat bricks and lime terraces, is about the best we know, but is very far from being what it should be."

But floors are worse. A lime floor looks very well when just finished, and for a private house answers its purpose fairly; but for a building like a barrack it is soon cut up, is unhealthy (the dusty particles flying about engender ophthalmia), and it is impossible to repair it satisfactorily. A plank floor is expensive, perishable, and warps from the extreme changes of the climate. The best floors hitherto made are those of flat brick or brick-on-edge. But why should not this method be improved upon in public and private buildings? Excellent coloured and glazed tiles are made in the Punjab and other parts of India. The glaze is objectionable as making the floor slippery and apt to chip or wear off, but why not use the unglazed encaustic tile now employed so largely in England by Minton and other manufacturers? The requisite materials exist, it

\* The new Government School-house at Unrisur, built by the Municipal Engineer, Mr. W. Gordon, and the new Lahore Railway Station, are instanced as excellent specimens.

appears, in plenty throughout India, and nothing is wanted but the requisite skill and capital. One other material may be named for floors, viz.,—plaster of Paris, which abounds in some parts of India, as for instance, the Debra Doon. It is well adapted for floors, as well as cornices, and other interior parts of buildings, and is capable of being made into highly ornamental forms.

In India the architect and engineer are generally one, and he is also the constructor as well as designer. The requirements of the climate necessitate modes of construction differing from those in England, but until lately our Indian engineering architects have not managed to combine coolness and ventilation with much architectural beauty. A reform in this respect is, however, in progress. Major Medley says,—

"We are at least erecting handsome buildings, and attention is being directed towards cooling them effectually. The difficulties are great, but with all drawbacks, many fine public buildings have been completed, many more are being constructed and projected, and churches, railway stations, and Government offices are rising fast, which would do no discredit to any capital."

Some specialities of construction which are common to most Indian buildings attract the attention of the new comer. Except in the Presidency towns, they have no upper story, partly from considerations of expense, and partly because the upper rooms get very hot during the dry months. The roofs are either thatched or tiled, or else are flat and covered with brick and lime plaster. The thick beams supporting the roof are, as a rule, left exposed below. The room walls are very rarely papered, being usually plastered and whitewashed. Wooden floors would be too perishable and dear, so floors of flat tiles or of lime plaster are substituted. Doors are numerous, and are invariably double, opening in the middle. Verandahs all round a house are considered indispensable.

In many of the most important and interesting branches of engineering, little has been done as yet in India: in drainage, water supply, and gas-lighting, they are now only making a commencement even in the Presidency towns. A fine scheme is, however, in progress for the drainage of Calcutta; and a similar project will shortly be submitted for Madras, while the drainage and conservancy of native towns and European cantonments are engaging much attention.

In the improvement of the great rivers for inland navigation, little or nothing has been done, but many navigable canals are at work in Madras and Bengal, and others are in progress. In Bengal, inundations from the sea and rivers have also given practice in the important subject of embankments; and the Hidgee Sea Dyke, when completed, will, it is said, be a noble work.

Of military engineering not much is said. Like the Romans of old we encamp our Indian troops in the open instead of shutting them up in forts. The arsenals are for the most part inside old native forts, slightly improved, and except Fort William and the outposts on the north-west frontier, there is scarcely a single fort of modern construction in the country.

In India the Government is the constructor and maintainer of nearly every public work throughout the country. Not merely works which specially appertain to an immense military establishment, but every road, bridge, church, court-house, jail, &c., has to be built from imperial funds, and through Government officers. Nor can even the railways be excepted, for though the capital employed is not its own, yet the controlling power possessed by Government is so great,\* that not the smallest work can be undertaken, nor the salary of the least official paid, without its written authority.

Every effort is being made to introduce the contract system, and it is generally in vogue in

\* This arises from the guarantee system.

\* "Professional Papers on Indian Engineering." Vol. I., 1863-64. Edited by Major J. G. Medley, R.E.; A.I.C.E., Principal, Thomason College, Roorkie. Printed and published at the Thomason College Press, Roorkie, Calcutta: Thacker, Spink, & Co. 1864.

the Presidency towns, and on most of the great railway works; but over the whole country the vast mass of the Government work is done by daily paid labour, and the extra work thereby thrown upon an engineer may be easily conceived.

In many parts of the country there is no organization of labour whatever, and when works have to be executed, the engineer has to collect and train his workmen, to make arrangements for carriage, to make his own bricks, burn his own lime, cut his own timber, and in a word superintend a hundred petty details, which in a civilized country are undertaken by a hundred different men, each skilled in his own peculiar business.

Of the workmen themselves, much good is reported. If well managed, they are as a rule both intelligent and teachable. Excellent masons, carpenters, and smiths abound in the country. The machinery in the various railway workshops is managed by natives under European superintendence, though there are no native engine-drivers as yet.

The most striking thing to the engineer fresh from England, is the total absence of the ordinary mechanical appliances for executing work. Vast earthworks are still made by the help of the *phowah*, or native spade, and baskets carried on the heads of women and children. Wheelbarrows are scarcely ever seen; horse carts still more rarely. For getting water out of foundations, &c., pumps are coming into use, but in general the primitive native modes of baling, or the *Churus* (leather bag), or Persian wheel worked by bullocks, are still employed. Bricks and tiles are almost invariably hand-made, and the pug-mill is unknown: the saw-pit is never used. The principal reason for this is the comparative cheapness of labour, but if the rate of labour increases for a few years longer, as it has done for some time past, the introduction of more elaborate appliances will become essential.

At present, except the railway workshops, and those established at Roorkee, there is no steam machinery in the country, unless at the Presidency towns. Machines driven by wind power are also unknown, it is difficult to say why. Of the enormous water power available on the numerous canals and rivers, very little is utilized.

In Central India and the hilly districts all over the Indian continent, many varieties of excellent building stone exist, and are abundantly used. In the great plains of Bengal, Hindustan, and the Punjab, however, brick is the only available material. The English sized bricks, or those of a still larger size, are now coming into general use. The native bricks are very small, excellently burnt, laid with little attention to bond, and with a profuse expenditure of mortar. Bricks are burnt with wood fuel, in kilns of several kinds, or in stacks like English clamps, with dried cow-dung instead of coal.

Excellent lime is everywhere abundant, produced either from limestone *in situ*, or the boulders found in hill torrents, or the knukur found in the plains. It is mixed with various substances for mortars, of which pit-sand and soapstone (pounded brick) are the chief ingredients. For very strong or fine mortars, coarse sugar and egg-shells are sometimes added.

A great variety of fine timber is found in India, generally brought from the forests in the hills, among which may be noticed *Saul*, a dark, heavy, straight and strong wood, and *Deodar*, nearly the same as the cedar of Lebanon; the former used in the North-West Provinces, the latter in the Punjab for every kind of building purpose. Both of these are found in the hills alone, at an elevation of from 2,000 to 5,000 ft.: the trees are cut down and thrown into the rivers, and when these rise the logs are floated down to the plains. In West and South India *teak* is in general use. It abounds in the forests of Burmah, being one of the most valuable productions of that province. *Toon*, an inferior sort of mahogany, is extensively used for furniture; *Sissoo* or *Sheesham*, and some of the varieties of acacia, are hard, heavy, crooked woods, used for strength and toughness.

Iron ores of fine quality are abundant in many parts of India, but from the want of fuel and carriage are little worked, and English iron is generally used. Government have made, and are now making, several praiseworthy attempts to develop the manufacture of iron.

The greatest works as yet executed in India, belong, as in England, to the railways. Indeed, there are none in the world more interesting or important than the Bhoré Ghât incline, of which we have more than one given particulars in the *Builder*, or than the Soane and the Jumna

bridges, and other works little inferior to them which might be enumerated. The East Indian Railway, 1,000 miles long from Calcutta to Delhi, with the branch to Jubulpore now under construction, is probably the longest line in the world owned by a single company, as it is certainly one of the greatest triumphs of engineering. The Great Indian Peninsula, and other lines, though inferior in length, are some of them, at least, of equal engineering interest.

With them may be classed the great roads, though the system, like that of the railways, is still far from complete.

«The Grand Trunk Road from Calcutta to Lahore, 1,300 miles in length, comprises every variety of construction, from the heavy gradients through the Rajmahal hills, to the massive and level embankments between the Jumna and the Sutlej. The Lahore and Peshawar road, a continuation of the Trunk line, 270 miles long, and now rapidly approaching completion, may challenge comparison with any in the world; while, in the formidable extent of drainage crossed by it, it probably stands alone. Of others, the Hindustan and Tibet road when finished, may take its place by the side of any of the famous Alpine roads; while the great Deccan road, the Assam road, and many others still in hand are works of considerable magnitude.»

It is, however, in the great irrigation works that have been, or are being, constructed in India, that the peculiarities of Indian engineering are more especially to be sought; for, except in Italy, these works have no counterpart in Europe. The Ganges canal, 600 miles long with its branches, and pouring its waters over a million of acres through 3,000 miles of distributing channels; the East and West Jumna canals, 200 and 500 miles long, respectively; the Baree Doab canal, also 200 miles in length; are works of which any country may be proud, and in the principles and construction of which engineers have to learn much which they cannot be taught in England. An entirely separate class of works are the great weirs and tanks of Madras, whereof the works on the Godavary are the finest examples, and which are also purely Indian specialities.

Of the Solani aqueduct, by which the Ganges canal is carried across the valley of the Solani river, we have already given an account in the *Builder*; but the subject is one of so much interest to the profession, from the magnitude and peculiarity of the work, that we cannot refrain from here inserting the brief description of it given by the editor of the work under notice, with reference to a lithographed photograph of it which appears as a frontispiece.

«The Solani Aqueduct, by which the Ganges Canal is carried across the valley of the Solani river, consists of an earthen embankment or platform, raised to an average height of 16½ ft. above the country, having a base of 356 ft. in width, and a breadth at top of 200 ft. On this platform the banks of the canal are formed, 30 ft. in width at top and 12 ft. in depth. These banks are protected from the action of the water by lines of masonry retaining walls formed in steps extending along their entire length, or for nearly 21 miles north of the Solani.»

The river itself is crossed by a masonry aqueduct, which is not merely the largest work of the kind in India, but one of the most remarkable for its dimensions in the world. Its total length is 620 ft.; its clear waterway 750 ft., in fifteen arches of 50 ft. span, each. The breadth of each arch is 162 ft.; its thickness is 5 ft., its form is that of a segment of a circle, with a rise of 8 ft. The piers rest upon blocks of masonry, sunk 20 ft. deep in the bed of the river, being cubes of 20 ft. side, pierced with four wells each, and undersunk in the usual manner. These foundations, throughout the whole structure, are secured by every device that knowledge or experience could suggest; and the quantity of masonry sunk beneath the surface is scarcely less than visible above it. The piers are 10 ft. thick at the spring of the arches and 12½ ft. in height. The total height of the structure above the valley of the river is 38 ft. It is not, therefore, an imposing work when viewed from below, in consequence of this deficiency of elevation; but when viewed from above, and when its immense breadth is observed, with its line of masonry channel, nearly three miles in length, the effect is most striking.

The water-way of the canal is formed in two separate channels, each 85 ft. in width. The side-walls are 8 ft. thick and 12 ft. deep, the depth of water being 10 ft. A continuation of the earthen aqueduct, about three-quarters of a mile in length, connects the masonry work with the high bank at Koorkee, and brings the canal to the termination of the difficult portion of its course.

This great work was designed by Sir Evelyn C. Cautley, and chiefly executed by Capt. (now Lieut.-Col.) A. G. Goddard, R.E. It occupied seven years in construction, and cost Rs. 32,57,000.\*

Among the numerous illustrations in this interesting volume there is a photograph of Trinity Church, Sealkote, designed and built by Lieut.-Col. J. H. Maxwell, R.E., at a cost, to the Indian Government, of 41,000 Rs., besides subscriptions to an unknown amount. The spire cost a further sum of 8,830 Rs., and was completed in 1861.

Engravings are given of the design for Cawnpore Memorial Church. This edifice was in progress when the volume under notice was published. Competitive designs were called for in 1861, the cost of the building being limited to 1,20,000 rupees. The design of Mr. Walter Granville, C.E., consulting architect to the

Government of India, was selected. This design is founded on the round-arched Lombard and Romanesque styles of architecture, with introductions from the later Italian Pointed style, in accordance with a suggestion of the Government of the North-Western Provinces of India.

The architect, in his descriptive remarks, says:—

«It is proposed to build the walls of the church of red pressed bricks, faced in part outside with Chunar stone in dark grey bands; inside, the walls are to be faced solely with stone. The roof is groined in stone in the simplest manner. The corbices, arches, and columns are to be also of Chunar stone. The flooring is also of stone, with a pattern of grey Chinese marble. It is not intended to have any plastering either externally or internally. It is argued that this church especially should be a memorial church, *ore perennia*, and as such typical of our enduring grandeur.»

The dimensions of the church are as follows:—

	Feet.	Inches.
Extreme length inside .....	141	0
Extreme width inside .....	59	6
Height of church .....	49	0
Width of nave .....	25	6
Depth of chancel .....	42	0

The church is capable of affording sittings for 500 persons on the ground floor. In the gallery at the west end, over the vestibule, 100 more persons can be seated. The organ is placed in the gallery of the south transept, and there is a corresponding gallery in the north transept; these will seat, if required, 100 more persons; this giving accommodation in all for 700 persons.

The method by which the church is lighted and ventilated and secured against the intensity of glare, forms one of the chief objects of the design. In this bright climate light should be admitted with caution, and there is this advantage that it produces a shadow effect or a dim recessed light, which is highly favourable to architectural grandeur. The principal light is obtained from a considerable elevation immediately above the lower passages or aisles. It is admitted, *first*, through a series of small pointed arches pierced in the outer walls of an upper arcade built over the passages below; *second*, through a series of similar arches left in the inner walls of the church. This double arrangement for admitting light will tone down the rays of the sun and obviate any inconceivable glare, while it effectually prevents the rays from falling directly on the people occupying the seats on the floor of the church. By leaving all the openings free from glass, a free current of air is afforded for the ventilation of the church.

So far the design differs from any known church; but whilst I have departed from the usual plan of northern churches in this particular, on account of the climate, I have adhered to the orthodox plan of a church appointed for celebrating the rites and ceremonies of the United Church of England and Ireland. I have moreover endeavoured to give to the exterior and interior at least an Oriental stamp, by the introduction of coloured bands which, so far as I remember, had their origin in the East among the Tartar tribes, and were introduced by them into every country they occupied.†

The architect's estimate amounted to 1,17,700 Rs., but subsequent experience showed that the estimate was insufficient, and it was raised to 1,51,131 Rs., which sum was sanctioned by Government. An improvement has at any rate been initiated in India, and not before it was called for.

#### THE LATE SIR JOSEPH PAXTON.\*

ACCORDING to Montesquieu, the success of most things depends upon the knowing how much time will be wanted in order to succeed. («*Le succès de la plupart des choses dépend de savoir combien il faut de temps pour réussir.*»—*Pensées Diverses.*) In such a case as that of the building for the Exhibition of 1851, as we have seen, the time being fixed, the success is dependent upon the selection of means and appliances with reference to the time, and upon a certain tact in the rejection, consistently with safety to life, of numerous details. It is dependent also upon tact to select, if not upon the good fortune of having, agents to whom matters of supervision, and if need be contrivance, can be delegated. Ability of the particular sort finds its best illustration in the career of Napoleon. Ordinarily it neither renders the less necessary, but rather the reverse, genius, so called,—which is the accumulation of the results of thought and study, just as capital is the accumulation of the earnings from labour,—nor dispenses with the necessity of fresh and increasing exertion of the personal kind. It is a peculiar gift,—that which secures the co-operation and aid of numerous hands and minds. Probably there is involved with it the readiness to accord credit to others, when due. Both the gift and the disposition were features of Sir Joseph Paxton's character; and probably were he now living, it would be easy, with his aid, to determine the exact share of merit due to him for what would have been the architect's work in the design of the building of 1851, as well as in that of the Crystal Palace. That he himself thought he had, for one of these buildings at least, accomplished the greater part of what is ordinarily architect's duty, is possible. Architects

\* See p. 421, ante.

will know that he did not personally accomplish so much in the former case; but his name is not therefore unworthy of honourable record in association with the first International Exhibition.

It is clear to us, and indeed we have already shown, that the building of 1851 was accomplished only by a course of proceeding that could not be recommended for imitation, and by omission of what would be in every other case an architect's duty. At least, the work was accomplished with a deficiency of control over expenditure, such as it is hardly possible to conceive could be allowed to occur again, or now that Government is claiming to set example of having precise estimates before building. It was argued publicly, at the time, by the present Sir Charles Fox, that the building could not have been completed had the work been supervised in the ordinary way by an architect,—thus showing that in the contractor's opinion, there was no one performing what would have been the ordinary duties of architect. And that there had been no such authority, was afterwards testified to by the fact that, although there had been a contract, a large sum of money had to be allowed to the contractors, not as justly claimable for extras, but as *bonus*. Paxton saw that there was a difficulty; but neither did he, not being an architect, succeed, as stated, where the whole profession had failed; nor did he then acquit himself of the duties of architect. We have seen that the idea of an iron and glass building had occurred to others; he renewed the suggestion at a happy moment for his fame; and had the mechanical appliances at hand, by which alone success was possible. A man better acquainted with the nature of the steps that are usually preparatory to commencement of such a work, would have been likely to hesitate, and might in the end have not done so well. But no one would contend that the course that was taken as to the building of 1851 should be repeated.

Paxton himself gave a history of his design at the Derby Mechanics' Institution on the 8th of October, 1850. He said that his first idea of sending in a design, occurred to him while conversing with a friend on the subject of the construction of the new House of Commons. Paxton said he thought a blunder would be made, and that he had a notion in his head. He went to the Executive Committee of the Exhibition, whether it was too late to send a design, whether they were so far committed to the design of the building committee as to be precluded from receiving another. The answer was, "Certainly not; the specifications will be out in a fortnight; but there is no reason why a clause should not be introduced allowing of the reception of another design." Without taking into account the behaviour to the profession, it must be observed that had legal proceedings been adopted by each of the builders who had been made to incur expenses on a basis that was removed, the executive would have been rightly treated. Mr. Paxton replied,—“Well, if you will introduce such a clause, I will go home, and in nine days hence, I will bring you my plans all complete.” No doubt, he is reported to have said, the executive thought him a conceited fellow, and that what he had told them was nearer akin to romance than to common sense. The interview with the executive took place on Friday, the 11th of June. Paxton did not go straight home, but first to the Britannia Bridge to see the third tube placed. On his return to Derby he had to attend a board-meeting; but his mind was occupied with his design; and then it was that he made the sketch on blotting-paper. The report of what he said, at Derby, continues,—“He was sorry he had not the original with him; but the fact was Mrs. Paxton had taken possession of it, and if they were at all anxious to see it, the only possible way of gratifying their desire was by sending for her to the meeting.” He sat up all the night of the board-meeting; and, by the aid of his friend Mr. Barlow, he was enabled to complete the whole of the plans by the Saturday in the following week, on which day he left Rowsley for London. On arriving at Derby, he met Mr. Robert Stephenson, a member of the building-committee, who was also going to London. Mr. Stephenson examined the drawings, and at length said the design was just the thing, and that he only wished it had been submitted in time. Mr. Stephenson, however, laid the drawings before the committee. The idea was at first “pooched;” but the committee “did in the end reject the abortion of a child of their own, and

unanimously recommend his bantling,” the design having been in the interim published.

Mr. Paxton was soon afterwards consulted by Yorkshire manufacturers and others with reference to the application of his system to covering large areas; and Mr. Batty proposed to him to make a design for the Hippodrome then intended to be erected, but which eventually took a different form.

From the date, at least, of the acceptance of his design, the credit due for the Exhibition building must be considered as largely shared in by others. In the preparation of the working-drawings, Sir Charles (then Mr.) Fox, who was one of the contractors, Mr. C. H. Wild, and Mr. M. Digby Wyatt were concerned; and Mr. Owen Jones produced most of the decorative details that Barry had not perfected, as well as the polychromy. The most important matter of detail structurally, due to Paxton's appearance on the scene, was the roof-construction. We have already adverted to the ridge-and-furrow arrangement, and to the modes of making the sash-bars (of which there were to be 205 miles) and of fixing (of which there were to be 205 miles) to be said the glass, but some few words remain to be said of the guttering. Paxton had a large amount of knowledge and acquired experience as to modes of treating these features of a building. The analogy between the work of nature, and the analogy of architecture, already shown by a comparison of the supporting members of the roof with those of the roof of this building, and ever to be noted of the art decorative as of the art structural, was never better shown than by the comparison of the arrangement on plan, of the gutters, with the disposition of the major and minor, and the confluent channels, of the surface of the leaf. The smaller channels running lengthwise with the building, were the “Paxton-gutters.” The bays, or spaces between the columns, being 24 ft., the water had to run 12 ft. each way to the transverse-gutters. The “Paxton-gutter” comprised at once a water-channel, and support to the spans of the ridge-and-furrow roofing. It was formed out of a solid piece of timber, by a machine similar in principle to that for the sash-bars. It was dished out at the top for the water-flow, and grooved at the two sides in channels for the condensed moisture from the glass. The gutter, or bearer, was trussed by tension-rods, a camber being given by serows at the ends, which could be adjusted to great nicety.

There were several claimants to priority of this invention, as well as of the ridge-and-furrow system. Information of some importance was communicated to the *Builder* in 1851, and will be found in our number for March 1st of that year.\* The author of the communication plainly said that Mr. Paxton was not the inventor of the said methods of roofing and construction. He stated that Mr. W. Strutt, of Derby, in conjunction with Mr. C. Sylvester, engineer, had, forty years previously, executed a ridge-and-furrow roof with the triple gutter,—the gutter however being iron,—and that Mr. John Sylvester had designed and executed seven years before 1851, a system wherein the same system was adopted, with the gutter in wood, formed out of the solid; and further, that going four or five miles along the Edgeware-road, there was to be seen a ridge-and-furrow roof over a greenhouse that had been erected twenty-five or thirty years previously. Afterwards, another statement appeared in the *Builder*, but similarly pointing to use of the system before Paxton's time.

The contrivance for keeping the building cool, other than the ventilation by louvres, consisted of an external covering of canvas. This method has been proved by experience at the Palais de l'Industrie, as well as that in 1851, to be open to objections, some of which indeed are obvious.

One of the most important of Paxton's unquestionable suggestions in matters of detail, was that derived from his trellised wooden pathways in greenhouses, of placing the boards of the flooring half an inch apart, so that the dust might fall through in sweeping. There is no doubt that this arrangement was greatly conducive, not only to the comfort of visitors, but to the continued effect, and freedom from injury, of articles exhibited. Whilst the ventilation was being considered, a bouse at Chatsworth was fitted experimentally with a contrivance similar to the Indian *gunkah*; and the result led to the contemplated adoption of a like system in the Exhibition building. When determining his design at the Society of Arts, Mr. Paxton showed that he had in view a perma-

nent winter-garden, with rides and carriage-drives in it.

The tender of Messrs. Fox & Henderson was accepted verbally on the 26th of July, 1850; and possession of the site was given on the 30th; but the first column was not raised till the 26th of September.

During the progress of the building, the value of mechanical appliances,—whether invented, suggested, or generally contemplated, by Paxton,—was apparent; in fact, in no case of a building has the importance of machinery to the realization of the object, (and the importance, too, of the same machinery, in the view of the employment and interests of workpeople,) been better shown. Our profession, however, was now at a discount. The members of the Society of Arts were told by an eminent professor, that architects made no calculations. Mr. Fergusson argued in this journal, that Paxton's success was due to the fact that he was not an architect, and had been practically carrying out an aggregation of his experience under the guidance of common sense. It would be easy to contend that *routine*, which architects were accused of, happened just then to have served Paxton. But Mr. Fergusson's assertion that we had got a building of which everybody approved, was shown to be erroneous by the fact of the discussion at the Institution of Civil Engineers, as well as by the proceedings at the Society of Arts; and the alterations that had to be made in Paxton's work, would simply have blasted the reputation of any member of our profession. The journals, however, were loud in praise of the great architect, as he was considered to be; and even men like Lord Brougham joined in the exaggerated laudation. One of the journals, after speaking of “the appropriateness, the elegance, the vastness, and the beauty of the design,” and “its simple but most admirable novelty,” acknowledged “Mr. Paxton's high claims to the grateful appreciation of his contemporaries, and to that enduring place in the national annals which is the best reward of all true greatness in any and every department of public usefulness.” Generally, writers in the papers mistook mere size for beauty, and the charm of perspective for something that had come of art-design.

The jury of Class VII, “Civil Engineering, Architecture, and Building Contrivances,” in their report, recommended the award of the council-medal “to Mr. Joseph Paxton, who originated the design” of the building, “and to Messrs. Fox, Henderson, & Co., who most ably carried it into execution.” Messrs. Paxton and Fox were knighted, as also was Mr. Cubitt, to whom the details of construction generally had been submitted. “As regards Mr. Paxton's claim,” the jury said,—“erroneously though, if the facts be strictly looked at,—that “amidst the competition of the whole of Europe, he proposed that mode and form of construction of building which appeared on first sight, and which has since proved to be, the best adapted in every respect for the purpose for which it was intended.” They discovered in the design the “peculiar merit of fitness” for the object, in its having no startling novelty. They recognised that designs nearly resembling it as to form of outline, and materials, had been sent in the competition; but said that in the combination and application, and in various details, it was “entirely distinct in character from all that had been proposed, and appeared at once to have the one single merit of being exactly that which was required for the purposes in view.” Our readers are in a position to judge to what extent these assertions are to be assented to. The building, far from being completed by the 1st of January, 1851, was not finished until long after the arrangement of the goods had commenced. The leakage was considerable, even after the building had been opened. Yet its retention as a permanent structure had been contemplated by Mr. Paxton. Upon the close of the Exhibition, an attempt was accordingly made to have the building retained in its site in Hyde Park. This, however, fell through. The question had scarcely been decided, when there appeared the scheme of the Crystal Palace Company, for the building at Sydenham. The original prospectus, dated 17th May, 1852, contains the name of Sir Joseph Paxton, as “Director of Winter Garden, Park, and Conservatory,” that of Mr. M. Digby Wyatt as “Director of Works,” and that of Mr. Owen Jones as “Director of Decorations.”—Messrs. Fox, Henderson, & Co. being “Contractors for the re-erection of the Building.” It seems, however, that Paxton had the direction of every-

\* Vol. ix., p. 131.

thing connected with the building as well as the grounds, the services of Messrs. Wyatt and Jones being generally confined to the collection of the works of art, and their arrangement in the finer courts designed by them.—Mr. Jones, however, having the management of the decorative painting of the building. The first column was raised in August, 1852. The report presented, and the chairman's speech, on the 17th March, 1853, repeatedly mention Sir Joseph Paxton, in connexion with plans and designs; and a printed paper issued in the following August, names Messrs. Jones and Wyatt as "Directors of Decorations," and Mr. Charles Heard Wild as "Engineer." Sir Joseph had now associated with him Mr. Stokes, to whom are due the architectural features of the external terraces and fountains, and the Sheffield Court. We believe also that Mr. Stokes assisted in the preparation of the original drawings of the building.

It is plain however that Paxton occupied a more important professional architectural position than he had filled in relation to the building of 1851. But those who would claim for him the entire status, at this time, of an architect, must be prepared to defend much of the work that there is reason to consider defective in the Sydenham building. The bulk of this particular construction is that of the building of 1851, and was the result of the employment of its columns and girders; but the defects so comprised must be considered as so many instances of original failure; since, as we have seen, even the building as designed for Hyde Park was contemplated as to be permanent. We have given attention to certain views on the particular system of column-and-girder construction, which are assumed to have gained importance from the destruction of one of the wings at Sydenham; and we may here add that many parts of the building are in gradual process of reconstruction, as by the substitution of iron supports for wood, or in order that the whole may have better chance of permanence. The brickwork supporting the iron columns, on the east side, where the slope commences, if we remember rightly, had no great strength; but what is most important for the question of the ability of whomsoever is to be regarded as architect, is the fact that the two water-towers, after considerable progress had been made with them, had to be taken down, that they might be erected on wider areas of base. As regards effect of outline in themselves, and the grouping with the main building, they were not very successful at first; and they are less so as they are. In an architect's work, there is no substitute for thought; and the danger from dispensing with it is so serious, that whoever even has had the luck once to achieve success that way, should be duly mentioned when the result is the reverse, or that which generally is probable. It is not a settled question whether the architect shares responsibility for the failure of a peculiar contrivance of scaffold, brought into use by contractors, under novel conditions of the execution of a design; otherwise, in the zeal after crediting Sir Joseph Paxton with the performance of the duties of an architect, he might have ascribed to him some of the discredit of the accident during the construction of the roof of the central transept, when there was sacrifice of life, and when no sufficient cause of the accident could be stated by the contractors. With the particular contrivance then, he had, however, as we believe, no connexion.

We have already alluded to claim made on Paxton's behalf, to the credit of the particular construction of the arched roof. If this be allowed, there should be attached to it that of the arrangement of the projecting pairs of columns, which support the principals, and add much to the internal effect.

It remains only to mention of the Crystal Palace, that the ceremonial of the inauguration took place on the 10th of June, 1854; and that the general conception of the scheme, the direction by Sir Joseph Paxton as to the building and its contents; and his designs for, and superintendence of, the unprecedented and most elaborate hydraulic works; as also his artistic skill in the arrangement of the grounds, are now monuments of him that require no addition here of panegyric.

Contemporaneously with the achievement of the Crystal Palace, Sir Joseph Paxton became absorbed in a successful career, both of general public usefulness, and, now unquestionably, of the practice of an architect. He was elected a member of Parliament, for Coventry, in December, 1854; and in this capacity, his experience in connexion with works of construction, bas-

hed of great advantage. During the Crimean war, he secured the establishment of the Army Works Corps, of "navies," and he also designed huts, of somewhat novel form, to which reference will be again made. He was a most useful man in committees; and it may be considered owing to his exertions that the Thames Embankment is now in progress, and that the Low-level Sewer is not being constructed along the Strand; which latter route, the engineer had been compelled to take into consideration, seeing the apparently interminable delay as to the originally designed route by the river-side. About the time of his active connexion with the Crystal Palace, Sir Joseph Paxton projected and designed a very important glass-roofed London thoroughfare, which is to be found illustrated in a Parliamentary paper on Metropolitan Communications. The first suggestion of a covered way of the kind, was however made by Mr. Gye, even before 1851. Somewhat later there was a design by Paxton, for a permanent exhibition building, of iron-and-glass construction, for a spot in the environs of Paris. It was first intended to be erected on the elevated ground near St. Cloud. The principal front was to have three circular projections, or attached rotundas, surmounted by domes. Mr. Owen Jones had made a design previously.

But of actual works to which Paxton's name must be attached as architect, there were several. Indeed, they might be said to have commenced before the period of his connexion with the building of 1851. The village of Edensor, near Chatsworth, was rebuilt from his designs, and is considered a great improvement in point of taste upon what had been done before. The farm-buildings at Chatsworth also were his. After 1851, he designed and carried into execution the house at Mentmore, in Buckinghamshire, for Baron Mayer A. de Rothschild, M.P.; illustrations of which have been given by us,—also the Dairy and Cottage, and the labourers' cottages at the same place. He was the architect of the mansion at Ferrières, in France (thirty miles from Paris, on the Strasburg line), which was erected, by Mr. Myers, for Baron James de Rothschild, and of the lodge and entrance. He also made extensive alterations and additions to Lismore Castle, in Ireland, for the Duke of Devonshire, a building which we have illustrated; and he had laid out the grounds of Bnton Cloes, near Bakewell, the seat of Mr. John Alcauld, the house being designed in some measure under his directions.

Besides these works, he had the planning and superintendence of some important public parks and gardens. A park at Liverpool was, we believe, completed some five or six years before 1851; and about the latter period he had in progress the park at Birkenhead. He laid out parks at Inall, Glasgow, and Dundee,—a pavilion at the latter place being designed by his son-in-law,—and the Coventry Cemetery—the chapels and lodges of which also were designed by Mr. Stokes. A design bearing his name, for the laying out of Shepperton Park, near Hampton, in building-plot, is now to be seen at the railway-stations. His last work was a design, just completed, for a park at Dunfermline, in Scotland.

In 1862, Sir Joseph Paxton exhibited a form of hot-house, of very ingenious but simple and economic construction. It was suggested by the Crimean huts, which consisted of two simple slopes, from caves at the ground, to a ridge, and spanning a space composed of two flat slopes which were cut in the ground. For the hot-house, nothing additional is required, unless dwarf-piers in the ground, some distance apart, on which to lay the eaves-guttering, which rests immediately on saddles. The sashes are hinged together at the ridge; and there are no rafters: thus the whole framing and glass can be easily moved; and it can be modified in arrangement in various ways. A lean-to, of course, can be fixed on the same principle. The span can be lessened or increased; or an addition of a fresh length of framing can be quickly made. Air is given by means of narrow sashes, hinged to spaces extending from eaves to ridge. These conservatories appear to be getting into extensive use.

Sir Joseph Paxton was a Fellow of the Horticultural Society, having been elected in 1826, a Fellow of the Linnean Society, 1833, and a Member of the Society of Arts, 1850. He was created a Knight of St. Vladimir by the Emperor of Russia, in 1814; and he became a Captain of the 11th Derbyshire Rifle Volunteers in 1860. He was a Magistrate of the county of

Derby, a Director of the Midland Railway, and connected with many other undertakings. His funeral, at Edensor, on Thursday the 16th, was attended by the Duke of Devonshire, the Lord Richard, George, and Frederick Cavendish, Mr. Jackson, M.P., and Messrs. Brassey, Wythes, Owen Jones, Mark Lemon, Evans, Scott Russell, Grove, and Bowley.

Though we have thought fit to endeavour to disabuse the public of the exaggerated notion of his greatness, and of his claims to rank as inventor of a form of architecture which he had rather the good fortune to apply to a single new purpose, we regard Sir Joseph Paxton as one for whose real abilities and services, and even works, the appreciation of architects is rightly due. His personal qualities had so much relation with what he was able to accomplish, that we should add that to his discrimination of character, his ability to retain friends and successful people about him, his sharpness of understanding means, even structural, conducive to ends, his industry, and that probity which procured him the friendship of the late Duke of Devonshire, in addition to his unquestionable achievements of a certain kind, his success may be attributed.

#### PORTRAIT MINIATURES IN SOUTH KENSINGTON MUSEUM.\*

NEARLY "blind yet bold," we have, with a dogged determination of purpose—fatigued rather than satisfied—made ourselves critically "up" to the test of examination in the special exhibition of portrait-miniatures, borrowed for public instruction by the "Science and Art Department of the Committee of Council on Education." The importance of the collection is very great, viewed in any of three lights in which it may be advantageously studied,—with a view to history, with a view to biography, or with a view to art. Of Holbeins proper, or "ascribed to," or believed in by their owners, we have twenty examples. We shall give them numerically:—

618. Mr. Hollingworth Magniac's Katherine of Aragon, first wife of Henry VIII., on vellum. From Strawberry Hill, Walpole calls it (Works ii., 477) "an admirable original by Holbein," and so Mr. Redgrave might have told us.

652. Henry VIII., from Strawberry Hill, 'now Mr. Hollingworth Magniac's.

673. Sir Stephen Poyntz, of Iron Acton, in profile, lent by Mr. R. S. Holtord, M.P.

1,011. The Countess of Kildare. Lent by Lord Boston: very curious.

1,039. The Earl of Kildare: ditto.

1,391. Queen Jane Seymour, Queen of Henry VIII., and mother of Edward VI. (very fine), lent by the Rev. Dr. Wellesley, of Oxford, whose knowledge and taste in Medieval art is indisputable. It is in crayons, tinted, and as fine as the best of the Windsor (badly engraved) Holbeins of the same character.

1554. Thomas Howard, third Duke of Norfolk, father of the poet Earl of Surrey; lent by Mr. Philip Henry Howard. This we remember to have seen before, and our doubts that it is by Holbein are confirmed by a further experience of six years.

1590. Katherine of Aragon, Queen of Henry VIII., on vellum. Lent by the Duke of Buccleuch.

1603. Thomas Lord Seymour of Sudley (on vellum), the Lord High Admiral of England, who married the widow of King Henry VIII. Lent by the Duke of Buccleuch.

1645. Queen Jane Seymour. Lent by Mr. Sackville Bale, whose well-chosen collection, purchased by himself,—not inherited,—merits to be carefully studied. End wall, division four, contains fourteen most valuable miniatures, the property of this gentleman.

1651. Queen Mary, daughter of Henry VIII., from the collection of the poet Rogers. Lent by Mr. Bale.

1810. Queen Anne of Cleves, fourth wife of Henry VIII., signed H. H. Oil on panel. Lent by that thoroughly well-informed Scottish antiquary, Mr. David Laing. This picture made us sigh to renew our acquaintance with the Meyrick (Goodrich Court) miniature of Anne of Cleves, the finest miniature by Holbein, or by any one else,—some connoisseurs hesitatingly assert. Colonel Meyrick kindly sent it to the Manchester Art Treasures Exhibition of 1857. Thanks to Colonels De Bathe and Meyrick, of the Scots Fusilier Guards, and to

\* See p. 403, ante.

Mr. John C. Deane, the *sole* father of that triumphant exhibition,—a great success, with a money balance on the right side.

When Mr. Redgrave revises his catalogue for a new and (we trust) cheaper edition, he will possibly think it well to insert, or refer, to a letter (printed by Sir Henry Ellis, 1st series, ii., 122), written by Nicholas Wotton to Henry VIII., and dated Duren, 11th August, 1539.—“Your Grace’s servant, Hanze Alheim, hath taken th’ effigies of my Lady Anne and the Lady Emelye, and hath expressed theyr images very lvelye.” Wotton and Berde were the two persons deputed to negotiate Henry’s marriage with Anne of Cleves. The passage just quoted we have copied most carefully into our own annotated Walpole.

2,082. Henry VIII. Oil. Lent by Earl Spencer.  
2,093. Portrait of a Gentleman, in a furred dress. Lent by the Earl of Shaftesbury.

2,627. Portrait of a Lady, “*Ano. Ætatis sue 23.*” Her coat of arms is affixed to the case. Card. Lent by Mr. J. Heywood Hawkins. Here we renew our cry for Herald’s College and Mr. J. Gough Nichols.

2,655. Hans Holbein, the painter. Oil. Lent by Lord Spencer.

2,661. “King Edward VI., in a black dress and jewelled cap, soon after his father’s death. Set in a case, enamelled on gold. 1547.” So runs the catalogue, p. 243; but at p. 293 of the same catalogue we are told, and truly, that Holbein died in 1513, four years anterior to his having painted this spurious Holbein. The portrait is lent by Mr. Henry F. Holt.

2,946. “Charles V., emperor of Germany, wearing the badge of the Order of the Golden Fleece, when a youth, about 1520.” A very old Parr of a youth, Messrs. Whittingham & Wilkins, printers.

2,947. Queen Anne Boleyn.  
2,948. King Henry VIII.

Both lent by Mr. William Mosely. Now, of these twenty half genuine, half doubtful, Holbeins, Dr. Wellesley and Mr. Sackville Bale possess the *very finest*.

Of Nicholas Hilliard, horn at Exeter in 1547, four years after Holbein’s death, and the second great name in point of time (if not of skill) in miniature art, or lying in little, the Kensington Exhibition supplies *twenty-nine* examples:—

103. “Portrait of a Gentleman in a ruff and white dress; ascribed to N. Hilliard.” Oval, and, as we remarked on the spot, “genuine.” Lent by Lord Cremorne.

308. Queen Elizabeth. Enamelled fram of the period. Lent by Mr. Samuel Addington, and a “gem” we pencilled in our catalogue when we stood admiringly before it. Blue background.

309. “Mrs. Holland, Maid of Honour to Queen Elizabeth,” signed and dated, “*Ano. Dni. 1593. Ætatis sue 26.*” Blue ground.

360. “Lord Keeper Coventry (died 1640), ascribed to Nicholas Hilliard.” This miniature, lent by Mr. Wm. H. Pole Carew, of Antony, in Cornwall, will not stand the test of dates. Hilliard, to whom it is given, died in 1619, and Coventry was not lord keeper in Hilliard’s lifetime. The Latin inscription on the portrait seems genuine.

632. Nicholas Hilliard, the miniature painter, by himself, 1547-1619; signed and dated, “N. H., 1550.” To this we say, very early ripe, Master Hilliard; here is a miniature by Hilliard, limned by a precocious hoy of only three years old. Lent by Mr. Hollingworth Magniac, as is—

651. Lady Arabella Stuart (very fine), from Lord Wilmington’s collection, and from the Strawberry Hill collection.

805. Queen Elizabeth, in a very richly jewelled dress and lace ruff; from the Strawberry Hill collection. Lent by Mr. John Jones.

\* Covetable.

1,009. Lady Arabella Stuart. Oval; *very fine*; blue background. Lent by Mr. William Maskell.

1,175. Nicholas Hilliard, miniature painter, died 1619; a copy by G. F. Harding, of the Pemburst miniature engraved in Walpole’s Works; but more satisfactorily in Dallaway’s Walpole.

1,488. Elizabeth Spencer, Lady Hunsdon, wife of George, second Lord Hunsdon. Oval, in flange gold frame; *very fine*. Lent by Lord Fitzhardinge.

1,578. Anne of Denmark, Queen of James I. Lent by Lord Wharnclyffe. Card. Oval, genuine, and good.

1,586. Lady Shirley; represented with her hair falling.

1,602. The Protector Somerset, dated 1560. In 1560 Hilliard was only thirteen. Somerset

was headed in 1552. “Facts are stubborn things.” “Pass this by,” as auctioneers are at times obliged to say, “and bring on the next lot, No. 1,642.”

1,642. Portrait of a young gentleman in a black dress and lace collar, his hair hanging loosely down on his left shoulder. Inscribed, “*Ano. Dni. 1594. Ætatis sue 20.*” Oval, very fine; without even a motto, and therefore, unhappily, without any clue to identification.

1,646. Lord Hunsdon, cousin to Queen Elizabeth, who made him her Master of the Horse. Inscribed “*Ano. Dni. 1605.*”

\* \* \* Hallo! Committee of Council on Education, Mr. Sackville Bale (to whom this miniature belongs), and Mr. Samuel Redgrave: look at the 36 ft. high tomb of Queen Elizabeth’s cousin Cary, Lord Hunsdon, in Westminster Abbey (chapel of St. John the Baptist), and there, as elsewhere, you will learn that Queen Elizabeth’s cousin, Lord Hunsdon, died in 1606, nine years before the date on the miniature. Who that has ever seen, will readily forget the Sherborne Castle picture of Queen Elizabeth’s procession to Hunsdon House?

1,652. Mary Stuart, Queen of Scots. Inscribed “*Ano. Dni. 1579. M.R.*” When Mr. Albert Way has passed his judgment on this miniature of Fotheringay Mary, we will give our own. 1,715. “Sidney’s sister, Pembroke’s mother.” Lent by the Rev. William Vernon Harcourt.

We should like to know the genealogy of this Hilliard.

1,814. Queen Elizabeth. Lent by the Earl of Derby. Oval and very fine; but seen to ill advantage in its modern and tasteless setting.

1,817. Sir Francis Drake. Inscribed “*Ætatis sue 42, Ano. Dni. 1581.*” Lent by the Earl of Derby, and very fine. Same remark about the setting.

2,002. Lady Montagu, mother of Anne, wife of Dudley, fourth Lord North. Lent by Colonel North, M.P. Fine.

2,012. Dorothy, Lady North, mother of Dudley, third Lord North. Lent by Colonel North, M.P. Exquisite.

2,068. Portrait of a child in a richly-quilted dress, with the inscription “*Anno Dni. 1578, ætatis 5.*” Lent by the Earl of Shaftesbury.

2,070. Portrait of a gentleman in a richly-decorated gorget, with the inscription “*Anno Dni. 1578, ætatis 32.*” “This,” Mr. Redgrave says, “is evidently the portrait of the father of the child No. 2,068.” Lent by the Earl of Shaftesbury.

2,346. Mary Stuart, with her son James VI. of Scotland, with a view of Edinburgh in the background.—and

2,347. Henry VIII., with his son Edward VI. Both ascribed to Hilliard, and both lent by Miss Wilson.

2,565. Queen Elizabeth. *Ano. Dni. 1564. Ætatis sue 25.* Lent by Lady Sophia Des Vaux. On this we remark; painted when Hilliard was 17. We must give a Lord Burleigh shake of the head against this being a genuine Hilliard of England’s Elizabeth.

2,629. Mary Stuart, Queen of Scots. Lent by Mrs. Naylor Leyland. The catalogue gives a descent of this miniature from one of the maids of honour to Queen Mary down to the present time. Our belief is, that Hilliard never saw the beauteous Stuart, and that Mrs. Naylor Leyland’s miniature is not a Nicholas Hilliard.

2,945. Portrait of a gentleman, inscribed, “*Ano. Dni. 1628. Ætatis sue 41.*” This small oval catalogue ascribes to Hilliard. It is beautiful, with a blue background in Hilliard’s manner, and with much of his marvellous delicacy of finish. Lent by Mr. William Mosely.

The pedigree of Hilliard, given by Dallaway, from the archives of Herald’s College, presents and records “Laurence Hilliard,” living in 1634, as the only son of Nicholas Hilliard and his wife Alice, daughter of John Brandon, Chamberlain of London. For this Laurence Hilliard we had a search the other day in the Prerogative Will Office of Canterbury (off Doctors’ Commons, in London). We were well repaid for our trouble.

Laurence Hilliard, of St. Bride’s, Fleet-street, in London, made his will 21st February, 1640. Two bequests particularly struck our attention.

The first was to his son Brandon Hilliard he bequeaths the Earl of Leicester’s picture, in a jet box, drawn in his cloak, with a cap and feather.

To his son Thomas Hilliard, he bequeaths his grandfather’s picture, in an ivory box, with a crystal over it.

To his daughter Laurence he bequeaths the excellent limned portrait of Mr. Hearne, “which I value at 20l.”

He particularly mentions “a full-length of Queen Elizabeth in a jet box” his “own portrait when young,” his lands in St. John of Jerusalem (Clerkenwell, of course), and his “pen of unicorn’s horn” (some Scottish antiquary can doubtless tell us what such a fabulous treasure was like)—the pen with which he worked on axes of hearts and tens of diamonds.

So little is known of Nicholas Hilliard (the best connected account is in Mr. Wornum’s edition of Walpole) that some new matter about so great a name in English art will, we are willing to think, find a founding asylum in the columns of the *Builder*.

In the accounts of the Treasurer of the Chamber to King James I., Mr. Peter Cunningham discovered the following entries:—

“To Nicholas Hyllyard his Ma<sup>ty</sup> Lymner upon the Councell warrant dated at the Courte at Hampton Courte 28 December 1603 for his paynes and travell heing appointed by direction to make certayne pictures of his Ma<sup>ty</sup> w<sup>ch</sup> were by his highnes gyven unto the Duke of Denmarks Embassador.—xli<sup>is</sup> s<sup>ix</sup>”

“To Nicholas Hilliarde upon the Lorde Chamberleynes warrant dated 31 January 1614 [15] for a picture of the Prince [afterwards Charles I.] in lymner drawn to the waste with a riche chrystall thereon and delivred to Mr. Murray his highnes Tutor.—viiij<sup>li</sup> s<sup>ix</sup>”

Among the Augmentation Records is a lease to Hilliard, for twenty-one years, of the Crown manor of Poyle, in Stanwell (Middlesex), “in consideration of his paines in engraving the Great Seal of England.”

At Nutwell Court, near Exeter (Exeter was Hilliard’s birthplace), is a miniature of Queen Elizabeth dated 1575, and two jewels exquisitely set in gold, presented by Queen Elizabeth to Sir Francis Drake. Did Hilliard, who was a goldsmith, ever work as a goldsmith?

The following extract from the accounts of the Treasurer of the Chambers to King James I., is here printed or referred to for the first time.

“To Laurence Hilliard his Ma<sup>ty</sup> Lymner upon the Councells Warr<sup>t</sup>. dated xvij<sup>th</sup> Apr 1624 for five pictures by him drawn as appareth by a Bill of particulars.—xliij<sup>li</sup> s<sup>ix</sup>”

That is at 8l. a piece, so that his charges were the same as his father’s.

In an Establishment Book of 1641, we were pleased to find preserved in the Lord Chamberlain’s office, the king’s “Limners” are described as Laurence Hilliard and Peter Oliver.

The name of Laurence Hilliard, as a *painter*, is not to be found in any edition of Walpole. Here we must pause for a week.

THE HALF-TIME SYSTEM OF EDUCATION.

WORKING MEN’S CLUB MEETINGS.

At the fifth of these meetings, held on the 13th inst., Lord Brougham took the chair, and Lord Lyttelton, in introducing the subject of the evening, which was “The Extension of the Half-time System of Education to Classes of the Population to which it does not now apply,” dwelt upon the real identity of interests which exists between masters and men, and which had been denied at a previous meeting. Were it otherwise, these meetings, which were intended to unite the different classes, would be useless. After paying a compliment to the veteran chairman, as having been the hardest “working man” in England, Lord Lyttelton proceeded to point out how the education which such men as Lord Brougham, who worked with their brain, received, enabled them to get through a vast amount of work, and contended that if those who worked with their hands were also better educated, it would be an immense advantage to them in every way. Now by the half-time system, which compelled every parent who chose to send his child to work, also to send him or her half the day to school, a very useful compromise had been effected between the demands of labour and education. He must, however, chiefly confine his remarks that evening to the question of the desirability of applying that system to the manufactories of Birmingham and Staffordshire. The inhabitants of Birmingham possessed, as they were, of many excellences, were not, however, remarkable, perhaps, for humility, and he believed they had something to learn respect-

\* Accounts of the Treasurer of the Chamber to King James I.—Cunningham’s “*Revels at Court*,” 8vo. 1842, pp. xxiv. and xlv.

† MS. Accounts of the Treasurer of the Chamber.

ing the frightful ignorance of many of the youthful operative population, which was most dangerous and disgraceful to those who allowed its existence. The existing state of things had been the subject of a Parliamentary commission, which had published the results of its investigation in a "Blue Book," from which Lord Lytton then made several startling and interesting quotations. Among the cases adduced, was that of a boy eleven years old, who had never heard of either Scotland or America, and thought the Queen was the Prince of Wales. The hours and nature of the work of these children and young persons precluded all opportunity of learning. He gave an instance of a little girl engaged in a brickyard, near Birmingham, from six a.m. to eight p.m., only having fifteen minutes for breakfast, and thirty minutes for dinner, no time for tea, and during one day she would have to catch and throw to her neighbour 15 tons of bricks. Yet this poor child did not murmur, but said she was quite willing to work hard, and that she was looking forward to a time of rest when she should be an angel in heaven. The half-time system of education, as carried out in the manufacturing towns of Lancashire and Yorkshire, had resulted in the increased education, and consequent improved life and conduct, of their inhabitants, as had been manifested during the late cotton famine, and in many other ways. His lordship concluded by urging that it would be for the best interests of all other districts similarly circumstanced to follow their example, and to seek for an extension of the half-time system of education for themselves. Lord Brongham said that it was a great satisfaction to him to preside at one of these meetings, and then proceeded to observe that by means of the half-time system of education a great saving of time, labour, and of the faculties of both body and mind had been effected; inasmuch as five hours of education when the mind was fresh, or five hours of work when the body was fresh, were equal to ten hours of either education or work, if during the latter hours the body and mind were exhausted.

#### THE ELEVATION OF MANUAL LABOUR.

In the course of Mr. Chadwick's recent lectures on the Condition of the Wage Classes, he said:—In want of trustworthy educated men among the wage classes fitted to fill the many responsible situations which the management of machinery requires, it would be desirable that some of the salaried classes should overcome the prejudice against manual labour, and take those occupations which ought to be elevated in the social scale. Such positions, for instance, as those of a locomotive engineer, or the engineer of a steamship, on the proper discharge of whose duties many lives and a large amount of property depend, ought to rank so high that an ensign in the army, a clerk, or a poor curate should not feel himself degraded by taking the appointment. One of the effects of machinery and of the division of labour had been to render apprenticeships unnecessary. When a carpenter was required to do all kinds of work in wood, even to the construction of a circular staircase, there might have been some reason for a long apprenticeship; but now that his work is confined to two or three things, and so much is made by machinery, there was no longer any necessity for that. He animadverted also on the beneficial effects of excessive labour in childhood and in manhood, which, in addition to overcrowding, had, he said, been the means of shortening the duration of life among the working classes nearly twenty years. The sanitary regulations that have been adopted to improve drainage, to establish dwellings for the poor, and to prevent overcrowding, had already produced an alleviating effect, and diminished the amount of disease one-third; and further improvements are being carried out which would add to the health and longevity of the wage classes in large towns. The effect of improved processes in agriculture will, in Mr. Chadwick's opinion, be even greater than it has been in manufactures. Comparing the general condition of the English wage classes with those of other nations, Mr. Chadwick said that their superiority might to some extent be attributed to race, Anglo-Saxons being able to do more work than most other races. He considered that two Englishmen could do the work of three Frenchmen; and to that concentration of force in the physical condition of the people he thought might be traced the cause of the power of this country. A difference in the physical and mental powers

is also to be observed in the inhabitants of different parts of England; those in the north being generally superior, both physically and intellectually, to the natives of the southern counties.

#### THE WASHING-DAY IN TENEMENTED HOUSES.

"Thump, thump, scold, scold,  
Thump, thump, away;  
There's little pleasure in the house,  
Upon a washing-day."

MANY a poor man, with an aching heart and dissatisfied mind, has with reason hummed the well-known song, of which we give the chorus, in most homes of the working classes. When this needful sanitary operation is attended to once a week, it is a time of discomfort and unpleasantness; but in most of the tenemented dwellings, especially in the metropolis, there is a washing on almost every day of the week, and in more ways than so far as the mere inconvenience is concerned,—the women are put to shifts in consequence of the present ill arrangements. We will very briefly jot down a few of these, as they have been given to us by a respectable woman who has been exposed to much painful experience.

Quarrels arise amongst the numerous inhabitants of a house respecting the day on which they can have the use of the copper, and about the lines and drying apparatus in the space which is often far too small and very inconvenient. It is by no means an uncommon, though a bad practice, in order to save fuel, time, and so on, for one woman to leave the hot dirty water in which her clothes have been washed for the use of another family; the mischief of this in cases where skin and other disorders are prevalent is evident. It is not unusual for the clothes in which the sick have lain, or in which persons have died, to be kept waiting for the washing-day in the rooms in which families live, or in the wash-house, which is accessible to every person (old and young) from the various apartments.

There is also a frequent scarcity of water, owing to the causes to which we have so often before had reason to refer. There is, however, one point to which we must direct especial attention, viz., the practice, which is far too common, of the person who rents the house and sublets the chief part, taking in large washings from two, three, and even more families. Sometimes others in a house imitate the example which is set: this causes the water-supply to be soon exhausted, even if care has been taken to provide hints of sufficient size.

Notwithstanding the various appliances which modern chemists have placed at hand for the use of washers of family clothes to save time, and, to a considerable extent, prevent the wear and tear to which many articles are subjected by some women, the old fashion is still persisted in, and they rub and scrub away, chattering, or what is worse, fighting, while the neglected children are roaring in some part of the premises, or exposed to the unprotected fires of the rooms, or fanned upon the street, where the danger of contamination, or of being run over by some of the numerous carriages, and other risks, await them.

With one kind of middle and another, the washing of a family, where there are four or five children, usually occupies the chief part of a day, when all is properly provided, without taking into account the drying, ironing, and mangling. At one of the public baths and washhouses, the same number of articles could be thoroughly washed and dried in two hours. The cost of hot-water steam drying-apparatus would amount to 3*l.*, and so on at the rate of 1*½* *l.* per hour. Here a woman, shut up in the box which she has chosen, can proceed with her work without interruption; but so much have persons been accustomed to the old method, that we fear that the isolation which most people would consider an advantage, is one of the objections made to the public washhouses. But it is unfortunately the case, that many have no opportunity of testing the advantages of these establishments. In the great parish of Islington there is nothing of this kind. From various quarters we hear of the pecuniary success of baths and washhouses, if placed in well-selected situations, properly but economically arranged in the first instance, and left to stand with their own good and frugal management, without being saddled with the large expenses which were incurred, in a variety of ways, by some so-

cieties that have been formed. We have always believed, and are still of the same opinion, that baths and washhouses, if rightly managed, would pay a satisfactory amount of expenses; but it seems to be the duty of the parish authorities to set up those establishments; and we would strongly recommend the matter to the parochial authorities of Islington. Let them gather with great care all the particulars of the washhouses which are at present in existence in the metropolitan districts and elsewhere,—let them fairly take the charges of construction, the working expenses, and the amount of income,—the latter will show an increase as the advantages become known; and, independently of the benefit arising to families by removing the washing from their homes, it will be seen that there will be eventually the advantage of money profit.

In the above brief notes we have said nothing about the annoyance of the smoke, the unpleasant effect of the steam rising into apartments when the washhouse is connected with the lower part of the premises, and the tumbling down of the plaster-work owing to the bad description of material which has been used.

#### SANITARY MATTERS.

THE *Gazette* announces the appointment of Messrs. R. Rawlinson, J. T. Harrison, and J. T. Way to be her Majesty's Commissioners,—

"For the purpose of inquiring how far the present use of rivers or running waters in England for the purpose of carrying off the sewage of towns and populous places, and the refuse arising from industrial processes and manufactures, can be prevented without risk to the public health or serious injury to such processes and manufactures, and how far such sewage and refuse can be utilised or got rid of otherwise than by discharge into rivers or running waters, or rendered harmless before reaching them; and also for the purpose of inquiring into the effect on the drainage of lands and inhabited places, of obstructions to the natural flow of rivers or streams caused by mills, weirs, locks, and other navigation works, and into the best means of remedying any evils thence arising."

Fever is raging in parts of Bristol. One of the scenes is thus described:—"In a wretched-looking court in Old Bread-street, named Butter-alley, on the bare floor of a room 11 ft. long by 8 ft. wide, lay seven human beings stricken with typhus fever. They comprised a mother and six children, the family of a labourer, who had only left the fever hospital, and was unable to work. A few bits of clothing had been placed by the mother underneath her children, who endeavoured to cover themselves with the rest of their clothes and a portion of their mother's underclothes, while the poor woman herself had only one of her skirts to partially cover her. There was not a single article of furniture in the room."

A report of a paper, by Dr. Clonston, on an outbreak of dysentery in the Cumberland and Westmoreland Asylum (of which he is medical superintendent), caused by the effluvia from a field irrigated by sewage, has been given in the *Medical Times*. The facts are thus summed up:—"The majority of the patients attacked were inmates of the wards on the ground-floor of the asylum, showing that the sewage effluvia is most concentrated near the ground. Little or no wind and a high barometrical pressure would seem to be the most favourable conditions for the injurious effects of the poison to manifest themselves. It would seem to be unsafe to apply sewage in any form to land with a stiff clay subsoil within 350 yards of human habitations. Diarrhoea in its ordinary form may also be caused by sewage exhalations. There are strong reasons for believing that the sewage effluvia which caused dysentery and diarrhoea in some persons may have caused typhoid fever in others. The sewage poison had a period of incubation in most cases before the dysentery appeared: the length of this period was probably from three to five days. The dysentery was of a very fatal character."

It is a remarkable circumstance that since a sanitary corps was organized at New Orleans, where yellow fever has hitherto been apparently indigenous to the locality, and therefore certain to make its appearance at the accustomed season, the summers of 1863 and 1864, and part of 1865, have passed without its reappearance. The sanitary corps on its appointment effectually dealt with the open sewers, the filthy streets, the undrained marshes, and the slimy mud deposits, so prevalent at New Orleans; and the consequent result seems to have been the extinction of the perennial pestilence which has so long made it notorious for its unhealthiness.

NO WATER ON SUNDAY.

THE medical officer of health of the parish of Marylebone, speaking of the centre of Lisson-grove, where a very poor and densely crowded population reside, says,—“The houses for the most part are exceedingly small and badly constructed, whilst provisions for a proper water supply have obviously been but little thought of or cared for. Generally speaking, a family occupies but one room, and it is not unusual to find a house, with only six rooms, inhabited by thirty or thirty-five persons. The cistern, if there be one, is ridiculously small, and generally placed in the worst spot that could be selected, viz., over a filthy water-closet; or if the water receptacle chanced to be a wooden hut, it is not unusually rotten and worn-out, without a cover, and in close proximity to the dust-bin. At no period of the week can the inhabitants be said to have a sufficient water-supply; but on Saturdays, for a long time past, they have been altogether without this necessary element of health and cleanliness; and, to use their own words, ‘have been running about in all directions begging for water to cook their Sunday’s dinner.’ I represented these facts to the secretary of the West Middlesex Water Company, who kindly gave to the subject his immediate attention, and I have very great satisfaction in stating that my request for an additional service, late on Saturday evening, has been most promptly and liberally complied with, for which these poor people express themselves exceedingly grateful.” In Marylebone, at any rate, therefore, a step towards the supply of a want we have for years pointed out has been taken. Dr. Whitmore rightly adds,—“By the 67th section of the Act (25th & 26th Vic. cap. 102) vestries and district boards have the power to compel a supply of water to every house, not exceeding thirty gallons per day for each person; and in the interest of those who are compelled to live in these crowded habitations, and with whom an ample water-supply becomes an absolute sanitary requirement, the law should be practically and strictly carried into effect.”

THE ALBERT CLOCK-TOWER FOR BELFAST.

SEVENTY-SIX designs were sent in competition, from which a sub-committee selected four, and recommended them to the general committee, in the following order:—  
1st. “Veritas,” Mr. Barre.  
2nd. “Palman,” &c., Messrs. Lanyon, Lynn, & Lanyon.  
3rd. Highly commended, — “Bloody Hand,” Mr. Linklater.  
4th. Commended,—“If so—well,” Mr. Barre.  
They did not open the letters accompanying the designs, though we have placed the names against the notices. The general committee, after discussion, placed No. 2 first.  
The following is a description of the selected design:—

“The main features of the design consist of a pedestal, shaft and clock stage, square on plan, surmounted by an octagonal belfry, with spiral termination.  
The pedestal is about 21 ft. square (not including the projections at angles), and 23 ft. in height; divided into three minor stages; the plinth being about 5 ft. high, while a moulded string-course divides the remaining portion about equally. Drinking-fountains are placed on three sides of the pedestal, the fourth being occupied by the door giving access to the interior of the building. At the angles of the base pedestals are placed to receive figures. These, however, it is stated, are not essential to the design, and may be added hereafter. Immediately over the recess for drinking fountains, on the side facing High-street, is placed a canopied niche and corbelled pedestal, which may be made complete by the addition of a figure of the late Prince, so as to be more particularly identify the structure with its especial purpose as a memorial. In the meantime suitable inscriptions may serve this purpose.  
The shaft is of very plain and inexpensive character—a treatment which, by contrast, very much enhances the richness of effect in the upper portion of the design, while the vertical lines formed by the pilasters lead the eye upwards to the clock face. The mean horizontal section of shaft is about 18 ft. square, the height about 70 ft. Each side is divided by angle and central pilasters, of slight projection, into two recessed bays, which are worked out into the full square at top by small corbelled arches. The recessed portions between pilasters are pierced at intervals by small lancet openings, which admit light to the interior.  
A dwarf stage, about 6 ft. in height, formed by an open arcade on each of the four sides, intervenes between the shaft and clock. At the angles of this stage are placed slightly-detached shafts, supported on angle corbels. The capitals of shafts carry pedestals at angles of clock stage. The clock stage shows on each side a square of 18 ft., the angles being played to a slight extent, to accommodate the figures and niches at angles. The clock-face is formed by a perforated stone shield about 11 ft. in dia-

meter, containing an outer ring of twelve quatrefoil openings to receive the numerals, the centre being a large cusped opening, the cusps corresponding in number with the outer perforations. The angle niches and figures have been introduced for the purpose of giving greater width of outline to the structure at this level, so as to arrest the eye as much as possible at the most important point of the building. The centre of the clock stage is about 108 ft. above the street level. This stage is finished at the top by an open-work parapet, stopped at each end by a canopied pinnacle. From this level rises the belfry, octagonal on plan, having coupled pointed arches on each side; the gabled hood-mouldings, over which, embracing perforated parapet, which latter is stopped at each angle of the octagon by a small pinnacle. The top of this parapet is about 12 ft. above that of the clock stage. The belfry is covered by a spiral roof enriched by pinnacled dormers, and surmounted by a small single-bell cot with projecting gallery of iron, which, with its pointed spire and ornamental iron vane, terminates the structure, the whole reaching to a height of 180 ft.”

PARIS.

FOR some days past considerable attention has been directed to the submarine infernal machine invented by Vice-Admiral De Chabannes, and tried lately at Toulon. The subject was brought before the Chamber of Deputies by M. de Kervéguen, who stated that an iron-plated ship of war, costing years of labour and immense sums of money to complete, could in a few minutes be annihilated by one of these torpedoes, so *four-dragons* were the results of the experiments. The commissary of Government, M. Dupuy de Lome replied, that although these engines were not new and had been in use for many years, it was impossible to deny the importance of all machinery of war of that class, yet that activity in the construction of iron-coated vessels should not in consequence be diminished.

The celebrated tenor, Duprez, is to re-appear on the stage at the Paris Opera-house, in September next, in an opera of his own composition, entitled, “Samson.” He is to have it all to himself, the direction of the *mise en scène*, the choice of the artists, and the conducting of the rehearsals.

The municipal administration of Paris has purchased the property on which the source of the River Seine is situated, with a view of erecting an appropriate and durable monument, which is being designed in the form of an ornamental grotto. It was the Parisian *navetes*, a powerful corporation of river merchants of the Seine who laid the foundation of the municipal body of Paris. The source of the river is not at Saint-Seine, as is commonly supposed, but near Chauceaux, a small village in the Côte d’Or, situated on the high road from Paris to Dijon. Turning to the right into the interior of the country, after about an hour’s walk, a charming valley is reached, between two mountains forming a portion of the Côte d’Or, in which a stream rises, and, descending rapidly, unites with other rivulets. This is the Seine, which, after a race of 497 miles, all through French soil, throws itself into the sea. In 1763, at the source of the Seine, was discovered a small bronze galley, now preserved in the Dijon museum. The president Rulley, an archaeologist, fancied he recognised in this relic an *ex-voto* anciently placed in a small temple elevated in honour of the Seine. Search was instituted, and excavations, as we some time ago mentioned, proved his conjectures to be a certainty, by the discovery of statues, shafts of columns, and a great number of Roman medals. The name Seine, or as it is anciently written *Senā, Sepvano*, is said to have been derived from the Celtic *Sin-an*, or *Sogh-an* (gentle river, peaceful water).

The drivers of the Paris *voitures de place*, or hackney coaches, struck for higher and more regular wages on the 10th instant, to the great inconvenience of the population. As the Compagnie Impériale des Voitures de Place is a monopoly private enterprises cannot interfere and offer accommodation. The number of coaches circulating through the town has, however, been on the increase these few days past. Among the considerations upon which *Messieurs les cochers* base their demand, they set forth in the first place the amounts retained from their daily wages.—Cleaning the horse, 25 cents; washing the coach during the night, 25 c.; accident fund for those occasioned by the drivers, 10 c.; relay during the day, 15 c.; unharnessing the horses on re-entering, 15 c.; damage, and wear and tear, 20 c.; garçons at the cab ranks, 10 c.; daily stoppage for clothes, fines, &c., 50 c.; total, 1 fr. 50 c. Among the ten articles specified in the circular issued by the drivers,

the principal seems to be that demanding a fixed clear salary, and no deductions, of 6 francs per day of fourteen hours, and 2 francs additional for every night passed at balls, soirées, or under other orders.

BRITISH ARCHEOLOGICAL ASSOCIATION.

At the meeting, June 14th, Mr. J. R. Planché, Rouge Croix, in the chair, Lord Boston exhibited miniatures of Charles I., and James, Duke of Mounmouth, formerly in the possession of Cardinal York; and Mr. Geo. Vere Irving produced rubbings of the chair of Cardinal Beaton, which has recently passed into the hands of Mr. Sim, a member of the Association. Mr. J. T. Irvine sent a coloured drawing of the Roman pavement found at Bath in 1864; also sketches of further architectural remains from the Church of Bradford-on-Avon, consisting of portions of Saxon crosses, richly sculptured with interlaced strap-work and bases, and capitals of Norman columns; also a sepulchral slab of the fourteenth century, and a sketch of the north aisle of the church, with thirteenth-century work.  
Mr. Cuming read some notes on “Ancient Bone Spear-heads,” with illustrations from his own collection and those of Mr. Gunston and the Rev. Mr. Simpson.

Various other exhibitions having been made, an elaborate paper, by Mr. F. J. Baigent, of Winchester, was read, detailing the various wall-paintings found during the restorations of the Hospital of St. Cross. Upwards of thirty beautiful drawings illustrated this communication, and will be published by the Association. This occupied the remainder of the evening, when the chairman adjourned the meeting to November next, reminding the members of the congress to be held at Durham in August.

PHOTOGRAPHY IN PRINTING INK.

MR. JOHN PONNEY, the well-known photographer, of Dorchester, was specially invited by Professor Dawson to give a series of experiments in his newly-patented process of printing photographs, direct from the negative, in printer’s ink, before a select party of eminent professors, at King’s College, London. Among those present were Professor Dawson; Dr. Miller, F.C.S.; Dr. Wallich; and Messrs. G. Hadow, F.C.S.; Benjamin Ferrey; G. Coles; G. R. W. Thomas; J. Sandford; &c. The whole manipulation of the process was successfully carried out by Mr. Ponney, showing the ease with which the pictures produced from the ink could be transferred either to paper or any other substance. The rationale of the process appears to be that the light hardens the ink on the surface of the paper, just in proportion as it passes through the negative, the part not acted upon by the rays remaining soluble, and being easily removed by washing with turpentine. The company present expressed themselves highly satisfied with the results, and a vote of thanks was accorded to Mr. Ponney. He also exhibited specimens of photography in ceramic colours for transfer to biscuit wares, which were much admired. The fact of Mr. Ponney having been awarded the silver medal and 400 francs from the Photographic Society of France, and the silver medal of the Photographic Society of Scotland, is a sufficient testimony in favour of a process which we have before this occasionally brought under the notice of our readers, and which appears to be one of much value, as advancing the permanency of architectural representation.

MALVERN COLLEGE.

IN accordance with the intimation that accompanied the view and account lately given in our columns of Malvern Proprietary College, built from the designs of Mr. Hansom,\* we publish in this number an enlarged view of the entrance-tower, and plans of the two principal floors of the building. The College, it will be remembered, is to accommodate 600 boys. The architect, in laying down his plans, appears to have taken as a *modus 5 ft.*, and to have confined himself to various multiples of that throughout.

MALVERN PROPRIETARY COLLEGE.—MR. C. F. HANSON, ARCHITECT.

## WAR WITH FRANCE.

In the improvement of our cities,—in the advancement of the social conditions of the people,—in the extension of our manufacturing and other industries,—the spread of artistic knowledge and good taste amongst the multitude, and even in the plans for the better rearing of animals for the purposes of sport or the food of mankind, we are well pleased to keep in a state of warfare with our neighbours the French, and to be led by the defeats which we suffer to make renewed exertions in ways where our failure—for instance, in the matter of horse-breeding, at the recent Derby race—should cause us to consider the reasons which have led to our defeat and the loss of laurels in a department in which we have so long felt sure of victory. Our long success has rendered us careless; and while in England we have in the racing-stable been, to a considerable extent, resting from our exertions, in France, a pupil of our own, as it were, in this respect, no well-directed labour nor the most lavish expense has been spared.

As regards art and taste, our news from France is of a more satisfactory description. In the French Chamber, on the 20th of May, in a debate on the subject, M. Michel Chevalier advocated increased exertions in France. This gentleman remarked that he had been in London three years since as a member of the jury for the International Exhibition. The names of his colleagues on that occasion were MM. le Baron Gros, Merimée, and Dumas, who were present in the Chamber. The fact which particularly struck the French jury was the considerable progress made by foreigners in the art of design, in connexion with industry: "it inspired us with admiration for the efforts made by foreigners; but it likewise inspired us with a fear that we might be outdone. We were impressed and frightened by the marked progress which the English had notably made in good taste." The speaker remarked that up to a recent time, although the English had some celebrated artists, they had not been remarkable for taste. Good taste was especially wanting in their industry. The great portion of designs used in the printed cotton manufactory at Manchester and Liverpool came from designers established in Paris. M. Chevalier said that the English had understood that during this industrial competition with the different foreign nations it was necessary to make great efforts; and they had made them: a museum had been established at South Kensington for the purpose of educating teachers, who were afterwards sent throughout the manufacturing towns of the country propagating good taste. A real revolution had been effected, and the jury were so much surprised at the progress which had been made, that when their report had to be made up, M. Merimée treated this point especially. This, remarked M. Chevalier, is "one of the most curious and best written pages of the six volumes which comprise the general report of the French jury." The following is a quotation from this paper:—"The school at South Kensington has been open for ten years. The corresponding provincial schools (and others which might have been added, to which masters have been sent) numbered ninety; the number of students trained throughout the United Kingdom was 91,886." M. Merimée said that these numbers were for 1862, and must have now greatly increased. M. Michel Chevalier continued,— "With respect to the influence exercised in so short a period by this great institution, we admit freely the assistance rendered to us by our colleagues in the English jury. In answer to our question as to the cause to which the progress so remarkable that year in their manufactures was attributed, they replied, 'The new resources opened to industry by the schools at South Kensington.' I conclude by quoting that 'the study of drawing and of mathematics is the foundation of the instruction which should be given to our students.'"

When we look around and notice the marked improvement which,—during the last five or six years especially,—has been made in many branches of our ornamental industry, and hear such favourable accounts from the French jurists, offered with so much candour, and in such a friendly manner, we cannot sufficiently express the surprise which we feel at the niggardly way in which the supplies for the promotion of art and advancement of the national taste are granted by the House of Commons. Year after year, millions are voted, with scarcely a grumble, for the pur-

poses of that warfare which causes such a vast destruction of life, and which is generally attended with very unsatisfactory results; but, if money be needed for purposes in connexion with the advancement of art, on which the actual welfare of the country as materially depends, the amounts are looked at with suspicion, and given in an ungracious and sometimes in even an offensive manner. It would be well if we could get the chief body of our legislators to understand and to act upon the fact, that notwithstanding the immense natural resources of Great Britain, and the energy of the people, if we do not keep a-head in matters of artistic taste and skill, the actual money loss which will fall on the whole community cannot be rightly or sufficiently estimated. The evidence of this liberally-minded French jury, we hope, will be without use in certain quarters.

## WAGES AND STRIKES.

London.—A numerous meeting of delegates from the operative carpenters and joiners of London, was lately held at Cambridge Hall, Newman-street, Oxford-street, to consider the propriety of adopting a memorial to the master builders of the metropolis, requesting an advance on the present rate of wages, 33s. per week, or 7d. per hour. About 100 delegates were present, representing the various carpenters' societies and the principal shops and jobs in the trade. A memorial, embodying the reasons for asking the advance was submitted, discussed, and adopted, and ordered to be presented to the masters forthwith. The house painters have also requested an advance of wages to 7d. an hour.

Sheffield.—In February last, the operative carpenters and joiners of Sheffield gave notice to their employers that, at the expiration of four months from that date, they should require an advance in their wages of 3s. per week in the summer, and 1s. in the winter; and, in addition to this, some alteration in the hours of labour was required. The employers, after some delay, expressed their willingness to meet a deputation from the operatives to discuss the matters; and, accordingly, on the 1st of June, deputations from both parties met, and a long discussion ensued. An adjournment for a week was agreed upon, and it was decided that the employers should be prepared at the adjourned meeting with a proposal to submit to the operatives. Unfortunately, this adjourned meeting was not held, for the operatives, as we are informed, required the masters' proposal to be submitted to them before their deputation could be allowed to again meet the employers. This the latter refused to accede to. The operatives met, to determine what steps should be taken: the attendance was very large, and after a long discussion it was unanimously resolved,— "That at all shops where the advance asked is not acceded to, the men cease work after to-morrow, as no terms have been come to with the employers."

Forfar.—A deputation, who were appointed by the operative masons to meet with the masters on the question of wages, have done so. The masters have agreed to give the small advance required. The masons' wages will now be 5d. per hour.

The strikes of the English operatives, as remarked by a contemporary, are already beginning to hear their bitter fruit. On the very day that a French horse won the Derby, a French locomotive was on its way to England. Even so, in our very strongest branch of industry we have been beaten by the foreigner. The tender of Messrs. Schneider, of Creusot, France, for the supply of locomotives to the Great Eastern Railway, has been accepted, to the astonishment and alarm of many of our engineering firms. It speaks volumes respecting the rapid advance of our Gallic neighbours, and affords a hint which our working men will do well not to despise. The success of the French manufacturers is indirectly due to the great number of strikes which have taken place from time to time in this country, and of which the French artisans, ever watchful, have eagerly availed themselves. A letter in the *Times* states that the French can supply rails of better quality than those supplied by the makers in South Wales; that the French locomotives are better than ours; that French sleepers compete with those from the Baltic; and that a Northamptonshire railway is laid with Belgian rails.

## WAGES MOVEMENT IN THE LONDON BUILDING TRADES.

SIR,—No doubt the majority of your readers were as much surprised as myself on learning that the building trade, after its short respite from excitement, was again to be agitated. I read a short notice in the *Beehive* of the 10th instant, and here and there one of the workmen had heard something of the rumour in the firm I am working at; but as I could not get any precise information, I waited for the next issue of the *Beehive* to learn the result of the meeting at Cambridge Hall, Newman-street. In the mean time, I sounded my mates as to what they thought of it, and not one of them was in favour of the agitation: some opposed it most determinedly, and others said, such a proposition required a careful consideration. One or two said it was bad policy, as the trade was in a better state as to pay and time than most other trades, and for some time, at least, they ought to be satisfied. I read the account of the proceedings at Cambridge Hall, and I find that tale, that the delegates have made up their minds for an advance. No secondary considerations as to the propriety of the movement are to be thought of. Immediate action, and no surrender. "The present flourishing state of the trade, the high price of provisions and house-rent, justify our present action." I believe this movement to be in all respects opposed to the interests of the men, and as ill-timed and as much to be deplored as the Midland masters' "discharge-note." In opposition to that note, quotations were freely given from Smith's "Wealth of Nations." As we have not heard anything as yet about what Adam Smith states on workmen's combination, it will be well to give an extract from the same chapter as was used against the masters:—

"Workmen sometimes, without provocation of any kind, combine to raise the price of their labour. Their usual pretences are sometimes the high price of provisions, sometimes the great profit which their masters make by their work. In order to bring the point to a speedy decision, they have recourse to the loudest clamour, and are sometimes to the most shocking violence and outrage. The workmen, accordingly, seldom derive any advantage from these combinations, partly from the superior steadiness of the masters, partly from the necessity which the greater part of the workmen are under of subsisting for the sake of present subsistence."

The above extract is applicable to the present movement. The reasons put forth by the delegates are similar to it: trade is brisk, provisions high, masters' profits large; but if such pleas are good, and the masters grant the advance, it will at once change the usual course of the trade. The present rule is, that let work be plentiful or scarce, winter or summer, wages always remain the same, and this fact every workman and master in the trade recognises; but if the rule be broken by the operative, the employer will be justified in reducing the wages twopence per hour in winter, and at any other time when trade is dull, and every honest workman will applaud the master for doing it. It is something wonderful that all the shops said to be represented were unanimous for the advance, whilst I, unfortunately, I suppose, have not come across one man that justifies it, or is at all anxious about the matter, and other workmen I have spoken to, outside the trade, say that the operative builders are going on too fast, and are preparing a rod for their own backs.

There is no doubt but that the primary movers in this affair are those whose interest and business it is to keep up agitation and promote strikes, as strike time is their harvest. They then thrive and fatten on the follies of their fellow men; and, of course, if all others are satisfied, the game is to create dissatisfaction. It is an old saying, when rogues fall out, honest men hear of things which are for their benefit; and I think something is to be learned from the recent cases and recriminations of Odgers, Potter, Applegarth, Cremer, and others. The question which now ought to be uppermost in the minds of independent and intelligent workmen,—Shall the great bulk of the metropolitan building operatives be any longer dictated to by the few who live by strikes, and are always on the look-out for the weekly levies of their dupes? I should think many would recollect the doing out the 1s. or 2s. 6d. a week in the lock-out strike,—how they were snubbed by the great men in that affair, who used to sit swelling in chairs, smoking cigars, and sipping brandy-and-water, whilst the worse than pauper recipients of the miserable pittance had broken up their homes, and starved their wives and children at the hiding of those who took care that their bread should

be buttered on both sides. I was for two years or more in difficulties through that affair, and others have recently stated to me they have not yet recovered the losses resulting from that suicidal movement. There is a difference in the statement of the number of workmen said to be represented at the Newman-street meeting. One paper states 2,000, another 3,000; but there is no doubt both statements are exaggerated. If the shops who sent delegates are unanimous, it must be evident that many of the men are doubly represented through the societies' delegates. But suppose 2,500 carpenters agree to agitate for an advance of wages when they have not one just plea for doing it, are the 20,000 outside to stand looking on until their silence involves them in the strike which is sure to ensue? I think it is the duty of those who disapprove of the affair to at once protest against it; and, if that is not sufficient, to oppose it outright by a direct organized opposition; and let the workmen in other trades and the general public know that the great majority of building operatives has neither part nor lot in the professional strike agitators' movement. The painters and masons, it seems, are also making a stir. I heard it publicly stated a short time ago by one who knows, that the painters' societies do not number 2,000 members out of 14,000; and yet the few pretend to speak in the name of the whole.

AN OPERATIVE.

\*\*\* The writer, who adds a long list of reasons against the threatened agitation, for which we are not able to find space, forwards his name and address.

CONSUMPTION OF SMOKE.

In your last impression "W.H." writes respecting the smoke nuisance. He must not compare a cooking apparatus to a boiler or any other description of furnace. Passing the smoke over a red-hot fire is the most effective way for consuming smoke. Let your correspondent feed a furnace, with a clear fire at the bridge and fire just over the dead plate, and then let a portion of cold air over the fire; he will not see a particle of smoke out of the chimney-shaft one minute after the furnace is once hot. I have applied this plan to boilers, brewers' coppers, &c., and it has given the greatest satisfaction, not by consuming the smoke alone, but saving a vast amount of fuel.

W. MAY, JUN.

THE ARCHITECTURAL ASSOCIATION AND THE INSTITUTE LECTURES.

SIR,—In your notice of the last meeting of the Architectural Association, I am reported to have made use of rather strong language in reference to the Institute. I must beg to state, that if the remarks I then made had been fully reported, a very different impression would be given than that which now appears in reading the report. In reply to the question as to why more members did not attend the lectures given by the Institute, I stated, that "I knew from some of our members, that they had come a considerable distance for the express purpose of hearing the lectures, and on two or three occasions found either that there was an Institute meeting, or that there were not sufficient present to warrant the delivery of the lecture, and were obliged to return home, having wasted their evening. Under these circumstances men could hardly be expected to come, to (I might almost say) be made fools of."

I do not know how it could have been gathered from my remarks that I believed the lectures would have been better attended if the Institute had held out greater inducements to the Association. The only inducements they could offer would have been to make the lectures of a more practical character, which would have been of equal advantage to non-members attending them.

I trust your sense of fairness will allow my publication of this letter, as on my own part and on that of the Association of whom I have the honour of being an officer, I should deeply regret it being felt that I had acted in any way ungentlemanly, and especially to a body of gentlemen whose age and position demand my respect.

J. DOUGLASS MATHEWS.

\*\*\* We do not find much material difference between our reporter's statement and that now forwarded.

MANCHESTER SOCIETY OF ARCHITECTS.

A NUMBER of the leading architects of Manchester have formed themselves into a society, to be called the "Manchester Society of Architects," having for its object the promotion of good feeling between members of the profession, and the establishment and maintenance of a recognised code of professional charges and practice, &c. At the first general meeting, held on the 20th inst., the following gentlemen were elected to serve on the council for the ensuing year:—Mr. Isaac Holden, president; Mr. A. Waterhouse, vice-president; Mr. W. Mangnall, Mr. W. R. Corson, Mr. J. Charlesworth, Mr. E. Salomons, Mr. J. Stevens; Mr. J. Murgatroyd, honorary secretary.

As there is already an Architectural Association in Manchester, we wait to hear something more of the differences in their constitution that render two bodies necessary.

PAYMENT FOR "QUANTITIES."

SIR,—You will greatly oblige if you can refer me to any settled case that will apply to the following, viz.:—I was the architect engaged in a certain work, and supplied quantities. The builder refuses to pay me for the quantities, on the ground that there was no mention on the face of them that they had to be paid for; the fact being that I had omitted to write at the foot, "so much per cent. for quantities." I have been in the habit of making this omission when I intended to charge 1½ per cent., taking it for granted that, when no amount was named, that was understood.

The case has been tried once, and the verdict given against me; and I am on the eve of trying it again.

The same builder has frequently had quantities from me with the same omission, and always paid for them. Your own opinion, in the absence of a case, will be valued.

ARCHITECT.

\*\*\* There is no settled case, so far as we know, that will apply. An opinion would be worthless without further inquiry, for which we have no time. If the builder did not include charge for quantities in the amount of his tender, it would probably be said that the proprietor, from whose representative they came, should pay for taking them out.

COMPETITIONS.

THE directors of the Sheffield and Rotherham Banking Company having determined to erect a new bank in Church-street, Sheffield, adjoining the Cutlers' Hall, invited Messrs. Flockton & Abbott, with Mr. Weightman, resident architects, to furnish designs for the proposed new building, and at their meeting last week accepted the designs of Messrs. Flockton & Abbott, and gave orders to those gentlemen to proceed at once with the work.

MIDDLESBOROUGH EXCHANGE COMPETITION.

SIR,—For the last five weeks I have been expecting to see something in the *Builder* referring to the Middlesborough Exchange competition. Surely every competitor is not in the same position with regard to it as myself, or before this we should have heard more complaints than that which emanated from "A Poor Draughtsman." What I complain of is that, although nearly six months have elapsed since the designs were sent in, and although I have written three letters of inquiry with regard to them, I have not had my plans returned, and have not received any answer to my letters.

I have heard that, although the instructions contained no statement of the committee's prejudices against the Gothic style of architecture, yet all designs in that style were excluded from the competition. My design was certainly in the Gothic style, but I am unconscious of having given any reason for such neglect in any other way, and I should be thankful, sir, if you or any of your correspondents could inform me whether the rest of the designs have been returned.

A COMPETITOR.

HINTS IN CONNEXION WITH LOCAL INDUSTRIAL EXHIBITIONS.

SIR,—In your last impression, under the above heading, you make reference to the drawings which contained the imitation Bank of England notes, &c. As the producer of one of these drawings, now exhibited at the West London Exhibition (No. 511 in catalogue), I trust that in justice to myself and fellow-workmen, you will kindly insert this letter.

In the course of your remarks you stated that

the execution of these drawings seems to be one of much greater difficulty than it is, and that by means of tracing or transfer paper, &c., a neat and steady-handed person, without artistic ability, might readily produce that which many persons would consider wonderful.

I do not doubt this; but allow me to state that my drawing, or Chinese imitation (as you call it) was not executed by any such means. It was intended as a drawing-study as well as a picture, and was for the most part free-hand, my only aid being drawing instruments.

I have not, as stated, received a prize for this work, as no adjudication has yet been made.

J. J. PICKWORTH.

TO MAKE STONE IMPERVIOUS.

IN reply to "W.B.'s" inquiry "How to make stone impervious," dissolve ½ of an oz. of bees-wax in a quart of raw linseed oil over a very gentle fire, taking care not to heat the mixture more than just sufficiently to melt the wax. Apply the mixture while warm to the surface of the stone with a painter's brush, during long-continued dry weather and hot summer days, the intention being that the stone should be dried and warmed as much as possible by the sun previously to the mixture being applied to it. The greater quantity the stone can be made to absorb the more successful will be the result. The surface should be well cleaned, and all soot, dirt, or other loose matter should be removed with a moderately hard brush and hellsows before the oil and wax are applied. Any discolouration occasioned by the above treatment will almost entirely disappear in the course of a few months.

P. G. SMITH.

WE may repeat a prescription which has been given more than once in our pages:—Take three-quarters of a pound of best mottled soap, and dissolve the same in one gallon of boiling water; spread this hot solution steadily with a large flat brush over the outer surface of the wall, taking care that it does not *lather*. This must be allowed to dry for twenty-four hours, when a solution formed of a quarter of a pound of alum, dissolved in two gallons of water, is to be applied in a similar manner over the coating of soap. The soap and alum mutually decompose each other, and form an insoluble varnish which the rain is unable to penetrate. It should be done in dry settled weather.

The effectiveness of this process has been testified to.

THE CROSBY SEWERAGE.

AS additional information to that published in the *Builder* last week respecting the Crosby sewerage, will you kindly state that the result of the inquiry before Mr. Morgan, the Government inspector, was to restrain the Board from fouling the shore, forcing them to adopt an inland route (which we may say is intended to be parallel with the one proposed in our scheme), as also to reduce the cost of the work to the amount of our estimate.

As the Board was forced to go inland, much against their wishes, they naturally, with their supporters, preferred their surveyor carrying out a plan of their own. Hence arise the modifications adopted. The plan has yet to receive Government sanction.

READE & GOODSON.

METROPOLITAN BOARD OF WORKS.

AT a special meeting last week, the clerk read a letter from Mr. Anstie, of the Foreign Office, stating that Earl Russell had to renew his complaints of the stench arising from the Thames Embankment works. The letter was referred to the engineer, with instructions to take steps to abate the nuisance, and report thereon to the Board. The Board then further considered a letter from the Board of Trade as to the material used for filling in behind the Thames Embankment wall, &c. The clerk read a letter that he had written to the Board of Trade, stating that the Metropolitan Board "are of opinion that the immediate hacking of the embankment wall should be formed of material wholly obtained from the land, and the remainder of the filling in supplied from the land and from the river, in such proportion as, in the judgment of their engineer, may be best adapted to form a solid embankment, and to complete the work within

the time specified in the contract." In reply, a letter from the Board of Trade recalled the fact that two engineers, mutually appointed by the two Boards, had given it as their decided opinion that the materials dredged by the conservators from the Thames are excellent materials for the embankment. Ultimately a resolution was moved:—"That so long as the material raised from the river opposite the embankment works continues to be, in the opinion of the engineer, suitable for the purpose of the embankment, the engineer be instructed to allow no other material to come into the embankment works, except for the backing of the embankment wall, the cross dams, the material required for piddling, and other necessary purposes." This resolution was carried by a majority of 11 to 3. It was then resolved that a deputation should wait upon the Right Hon. Milner Gibson upon the subject.

#### CASES UNDER THE BUILDING ACT.

At the Clerkenwell Police Court, Mr. Albert W. Bryett, builder, of 116, St. James-road, Holloway, was summoned by Mr. John Turner, district surveyor of the eastern division of Islington, for not having carried up the chimneys of two houses he is erecting on the north side of the Grove-road, Holloway, 3 ft. above the highest part of the roof adjoining thereto as required by the statute. Mr. Bryett, jun., attended, and stated that the chimneys were in course of alteration. Mr. Turner said he found them being altered as he came to the court; but that Mr. Bryett had had notice on two occasions to alter them, and to which he had paid no attention. There were four other houses besides those for which he had taken out the summonses.

Mr. Barker fined Mr. Bryett 20s. and costs of summonses in each case, and awarded Mr. Turner 21s. expenses in each case.

Messrs. Glenn, builders, of Liverpool-road, were also summoned by the same district surveyor for not having given notice, as required, before commencement of works. Those gentlemen not having attended, the hearing was adjourned to the 23rd instant.

#### RAILWAY MATTERS.

It is singular that a fearful railway smash, such as that on the Great Western the other day, is often followed by others almost similar in character, and arising from an almost precisely similar cause. The slaughter in the Clayton Tunnel, some four years ago, arising from neglect in working the signals, was followed, in nine days after, by the collision on the North London system, at Kentish Town, through which fourteen people were killed. Here, again, the non-boasting of the danger-signal was the cause. We have just had two terrific railway accidents, and both are attributed to the state of the rails. At the inquest on the bodies of the sufferers by the accident at Rednal, the jury found a verdict of accidental death, but they appended to it a series of censures.—First, on the Great Western Company, for not providing better rolling stock and taking greater care of the way; next, upon the engine-drivers, for neglecting signals and driving at too great speed; and, lastly, on the platelayers, for neglect in the manner in which they did their work.

The repairs of lines are necessarily always going on, and should be under eyes attentive to their hearing on the safety of the traffic, and not left to workmen with other business in their heads, and perhaps with brains as fatigued as their hands. The most important signalling is entrusted to these workmen or their gang-leader, and performed in the most slovenly, not to say careless, way,—a flag stuck at the distance the circumstances require according to their notions, necessarily very imperfect, of what is requisite for the safety of the traffic. The London and North-Western Railway Company, we are glad to learn, contemplate appointing a responsible officer over the plate-layers.

If a break could be invented strong enough to stop a train instantaneously, the disasters such a sudden stoppage would occasion would be quite equal to those which might be caused by collision. In an able paper on the subject, in *Cosmos*, M. Flammarion calculates that if a common train, going at the rate of 40 kilometres per hour, or 12 yards per second, were stopped instantaneously, the passengers would experience a concussion equal to that of a body falling from a height of 19 ft.; they would be hurled against the sides of the carriage with a force

equal to that they would be exposed to in falling from a window on the second floor of a house. If the train were moving at the rate of 50 kilometres per hour, they might as well fall from a height of three pair of stairs; and an express train would, in point of fact, make them fall from a fourth story. Instantaneous breaks are, therefore, not to be thought of, and, fortunately, have not been invented, the impetus of a train, even at half-speed, being much too great for any mechanical means of instant stoppage. A break, though instantaneous in stopping wheels, will still leave the train to go forward a little as a projectile, so that there is no fear of any break ever to be invented, perhaps, being too instantaneous in imminent danger. M. Achard, a civil engineer, according to *Galvani*, has invented an electric break, which simply consists in keeping the break or shoes which lie opposite the wheels away from them by means of an electric current, as soon as the latter is interrupted, the break falls upon the wheels, and the speed of the train is slackened in consequence. All the engine-driver has to do is to put his hand on a small interrupter, having much the appearance of a door-handle, and this takes him less time than giving the alarm by means of the whistle. Two small Daniell's elements are employed to produce the current—they are kept in a wooden box, and the shaking of the train when in motion contributes to maintain their activity. This system has been tried on the Paris and Strasburg Railway, it is said, with success.

The traffic receipts of railways in the United Kingdom amounted, for the week ending the 3rd of June, on 11,916 miles, to 706,217l., and for the corresponding week of last year, on 11,605 miles, to 632,172l., showing an increase of 341 miles, and of 74,046l.

#### PROVINCIAL NEWS.

**Worthing.**—The foundation-stone of new water-works, baths, and assembly-rooms, was laid last week, at West Worthing, in Sussex.

**Walsall (Staffordshire).**—At a special meeting of the council, the common seal of the borough has been affixed to a contract with Mr. C. Burket, of Wolverhampton, for the erection of the new town-hall and other works, for the sum of 5,083l., being an increase of 350l. upon the sum mentioned in his tender, on account of an error in calculation, proved to be so to the satisfaction of the town-hall committee, and being an allowance of such tender of 50l., in consideration of the dressings above the plinth being executed in Attleborough stone instead of Holford stone.

**Penarth (Cardiff).**—The Penarth Dock, near Cardiff, has been opened.

**Liverpool.**—The town council have resolved to expend 810l. in alterations necessary to make the robing and dining rooms at St. George's Hall more convenient for the use of the members of the bar.

**Maldon.**—Mr. Bentall's chimney, an elevated shaft at Heybridge, which is visible for miles round the country, has been finished. The chimney is 116 ft. high, contains 75,000 bricks, and has been built for the purpose of working a new nut-making factory, which will be extensive. The shaft was plumbed, and it was found the central deviation did not amount to half an inch.

**Gorton (Manchester).**—The chief stone of new offices for the Gorton Local Board of health has been laid. Messrs. Whyatt & Redford, of Manchester and Heywood, architects, prepared the designs. The building is to be erected upon a plot of ground at the corner of Hyde-road and Kirkmanshulme-lane. The main material to be employed is common bricks, set in old English bond, with dressings of Grinshill stone. The principal exterior decoration is the filling in to the spandrels of the upper windows in different coloured tiles; the arches being formed with ornamental brickwork, parti-coloured. A "Ringhiera," or balcony, is introduced to the board-room, from which constituents can be addressed at election times, and broad steps have also been placed at the entrance for a like purpose. In the centre of the building is placed an octagonal clock-tower. The offices will be situated on the ground-story; and a hall will contain stone steps leading to the board-room on the first floor. This room will be 32 ft. by 18 ft., having an open-timbered roof, and adjoining it will be a waiting-room. The structure is an adaptation of the style in which, during the thirteenth century, were built the "Brioletti," or town-halls of the Lombardic cities, as Monza, Como, &c. Mr. T. Clay, of Audenshaw, has

undertaken the contract for the sum of 1,443l., exclusive of fittings. The probable cost of the building, when completed, will be about 2,000l.

**Endcliffe (Sheffield).**—We are asked to add to our notice of Mr. John Brown's mansion, at Endcliffe, Sheffield, that in addition to the sliding iron shutters described, nineteen or twenty of Messrs. Clark & Co.'s patent self-collating shutters, in one sheet of steel, were fitted to windows.

**Harrogate.**—The new Post-office buildings have been opened for business, though scarcely completed. They are situated in one of the most frequented of the roads diverging from and within about 170 yards of the railway station, and occupy a position exactly central in the district. The new building has been erected by the Victoria Park Company, and forms a very prominent feature on the angle of James-street and Princes-street, presenting at the angle a portico-entrance to the post-office, money-order office, savings bank, and postmaster's residence. It forms part of a pile of new buildings, having a facade towards James-street of about 300 ft. in length, and towards Princes-street of 100 ft. The style is Italian, treated so as to show to advantage the building stone of the locality, which, being capable of being quarried in large and massive blocks, offers unusual facilities for producing effects of light and shade. Red bricks have also been introduced. The principal room of the Post-office,—size about 30 ft. by 20 ft.,—is lighted towards James-street by three semi-circular-headed windows, divided by stone columns with carved capitals. The adjacent new buildings are of similar design. The arched windows of the Post-office are repeated the whole length of James-street and Princes-street; the James-street consisting of a series of shops with dwelling-houses attached to the whole mass of buildings terminating with a projecting stone cornice and parapet continued along both streets. The architect of the Victoria Park Company is Mr. J. Hirst, a Yorkshireman, now resident at Bristol; and Mr. R. Ellis, the contractor.

**North Shields.**—The foundation stone of an Oddfellows' hall has been laid here. The edifice is to be built on the north side of Saville-street West. The material will be brick. There will be several shops on the ground-floor, and a large hall and other rooms above. Mr. T. Forrest is the architect.

#### CHURCH-BUILDING NEWS.

**Great Saling (Essex).**—The church of Great Saling has been re-opened after restoration. The roof has been constructed of new open timbers, in place of lath and plaster. The walls and windows have been restored, the tower cleaned, and the stone-work repointed: there is also a new chancel window, below which is a stone recess; and the pavements throughout are all new encaustic: the benches in the chancel and over the nave are of deal, stained and varnished. A spire was to surmount the tower, but for the present has been abandoned. The works have cost upwards of 1,000l., raised partly by rate. The church now contains 360 sittings, partly free. The architect was Mr. R. J. Withers, and the building works have been done by Messrs. Parmenter & Son, of Braintree.

**Cuckfield (Sussex).**—The new church of St. Wilfrid, at Hayward's Heath, has been consecrated. Mr. W. Serpison, of Cuckfield Park, gave the site; and the Misses Dealtry headed the subscription list with 1,000l. (the late Miss Ann Dealtry also bequeathed 500l.). The building stands upon high ground, in the middle of Sussex. The architect was Mr. Bodley; and the builder, Mr. J. Fahian, of Brighton.

**Northampton.**—St. Katharine's Church, which has for some time past been undergoing several improvements and renovations, has been re-opened for divine service. The principal portion of the work has been confined to the interior. A stained-glass window in the chancel, as an inscription beneath states, "was erected by subscriptions, collected principally in small sums, by twelve ladies of the congregation." The window was made by Mr. Wallis, of Newcastle, and the subjects are, our Saviour in the centre, with the four evangelists on the sides. In the lower compartment are figures of John the Baptist, Peter, Paul, James, and Jude, and the upper compartment is filled with figures of angels. Over the window are the words, "Glorious God in the highest, and on the earth peace." The heads of the side windows it is intended to fill in with ornamental glass, but this work is

not yet completed. The whole of the ceiling has been stencilled. The chancel ceiling has been painted in blue and gold, and the two figures on each side of the chancel arch have been gratuitously gilt by Mr. H. J. Atkins. The whole of the ornamental work in the ceiling and over the windows, we understand, has been done at the expense of the incumbent, the Rev. R. C. King. A portion of the walls has been coloured grey, and between the line of colour and paint there is a running stencilled border. The whole of the seats on the ground-floor have been taken down, and new seats, lower, with sloping backs, and tracery heads in the panels, have been substituted. The contractors for the woodwork were Messrs. Clark & Heap; for the painting work, Mr. Buswell; and for the colouring, Mr. Banks; and the whole of the work has been carried out under the superintendence of Mr. Ingman, of Northampton.

**Eydon (Northants).**—The church of Eydon has been re-opened. The work of restoration commenced about eleven months ago, and has been carried out by Mr. Watson, of Napton, under the superintendence of Mr. R. C. Hussey. The high inconvenient pews have all been removed, and their places supplied by low open seats. The tower arch, which was also blocked up by a gallery, has been thrown open, and the belfry roof levelled. Two new windows have been placed under the north aisle, a vestry has been erected at the east end of it, and a new roof has been placed on the chancel. The south aisle and porch are new. The pulpit and lectern are both new. The windows in the chancel and on the west end of the tower, are all to be filled with stained glass.

**Cold Ash (Thatcham, Berks).**—The new church here has been consecrated. The edifice is situated on a high hill. Mr. C. N. Beazley, of London, furnished the design. The tender of Mr. Hollis, of Windsor, to erect the building for 1,750*l.*, was accepted. The building, which is dedicated to St. Mark, is in the Early English style, and composed of grey and red brick and stone, and red tiles with ridge crests. It has a double bell-turret, with two hells by Meers, under which is a south porch, with stone cross at top. There is a large west tracery window, with smaller ones in the north and south sides. The chancel terminates in an apse with three windows. There is a vestry on the north side. The internal arrangements are as follows:—The roof is an open-timbered one, with the exception of the chancel, which is boarded. The walls are unplastered and bare, and the church is so arranged as to admit of future enlargement. The floor is of Minton's pavement,—of a richer design in the chancel. The seats are of polished pitch pine and deal, and will accommodate 224 persons. The seats for the choir in the chancel have carved poppy-heads. The pulpit is of stone, with alabaster incised in different coloured cements. The baptismal font is of Bath stone, with carved oak cover, surmounted by a wrought-iron cross. The church is heated by Perritt's warm air apparatus. The ironwork to doors, &c., has been made from the design of the architect, by Mr. Leaver, of Maidenhead. The glazing was by Mr. Reynolds, of Thatcham.

**Oxford.**—The Radcliffe Infirmary Chapel, dedicated to St. Luke, which has been erected at the sole cost of Mr. Thomas Combe, and presented by him to the Radcliffe Infirmary, has been consecrated by the Bishop of Oxford. It is understood that the cost of the chapel was about 1,000*l.* The old Norman church of Fritwell, having undergone a complete restoration, principally at the expense of the Rev. Samuel Yorke, of Fyner, has been re-opened.

**Radbury (Worcestershire).**—The parish church, after the restoration of the chancel, which has been carried out at the joint expense of the rector, the Rev. J. Haviland, and Mr. J. Cartwright, of Craycombe House, has been re-opened. The walls of the chancel have been cleansed and made good; the roof renewed so far as necessary; an Early English piscina, having two scroll-headed arches divided by a shaft, and a trefoil opening above, has been restored; and w. sedilia and credence-table provided. The rood is of alabaster, having in the centre a creek cross, inlaid with glass mosaic and half-gilt glass at the extremity of each limb of the cross, as also in the centre. The rood is the work of Mr. Bolton, of Worcester. Minton's encaustic tiles, in blue, white, green, and brown, have been laid on the chancel floor. The east window, which has been rebuilt, has five lights—very a copy from the old one—and for head a very a quatrefoil in centre and trefoil on each

side. It has been filled with stained glass by Mr. J. Cartwright, of Craycombe House, at a cost of 250*l.*, the artist being Mr. Preedy, who was also the architect employed for the chancel and the new schools. The central subject in the east window is the risen Saviour, with the Roman soldiers and the women coming to the sepulchre; this occupies three lights. The other two contain the marriage in Cana and Christ appearing to his disciples at the sea of Galilee after his resurrection. Above is the coming of the Holy Ghost at Pentecost, and in trefoils are angels playing musical instruments. On the south side of the chancel is a small window to the memory of the late Rev. F. Gauntlett. It contains the figures of Christ, as "Behold the Lamb of God," "Come unto me," "The Good Samaritan," and St. John holding the cross, with the label, "Repent ye." A vestry, on the north side of the chancel, has been added. Mr. Espley, of Evesham, was the contractor for the restoration of the roof, and also furnished the stalls in the chancel; and Mr. Hearn, of Worcester, as sub-contractor, executed the masonry. Externally, the soil has been lowered round the east end of the church, and footpaths made, in which work Mr. R. Preedy, the churchwarden, has rendered assistance. The churchyard being too small for the requirements of the parish, and being inconveniently crowded, a large strip of ground on the north side, containing 1,282 square yards, has been added thereto, being the gift of the rector, and a new boundary-wall has been erected.

**Rochford (Worcestershire).**—The parish church of Rochford, near Tonbury, is about to be re-opened, after having undergone a process of restoration, enlargement, and refitting. It was a remarkably small Norman structure, and in order to afford additional accommodation, an extension of the nave westward has been made. The nave roof has been repaired, and the timbers exposed to view internally. The chancel roof has been hoarded underneath the timbers. Several new windows have been inserted, and the new east window filled with stained glass, the work of Messrs. Morris, Marshall, & Co. There is also a small Norman window, by Messrs. Heaton, Butler, & Bayne. The fittings internally are generally of deal, stained and varnished. There is a new memorial font, with sculptured panel. The pulpit is enriched by some carving by the hand of the rector. A new open-timbered porch of oak has been erected against the south doorway, and at the west end is a new timber bell-turret for two bells, surmounted by a shingled spirelet. The church now accommodates 156 persons. Mr. Henry Curzon was the architect employed.

**Horsepoole (Gloucestershire).**—Horsepoole chapel-of-ease has been consecrated. The site is about 50 yards beyond the residence of Mr. S. Bowly, and the ground for the chapel and burial-ground was given by the lord of the manor, Mr. T. M. Croomie. The chapel, though in the parish of Painewick, is on the borders of five parishes. Mr. Danke, of London, formerly of Gloucester, was the architect; and the builders were Messrs. King & Godwin, of Gloucester. The style is Early Decorated, before the development of window tracery. The edifice consists of chancel, nave, and north aisle, and bell-tower and porch on the south side. It is large enough to accommodate 200 persons, and all the seats are free. The architect has reduced the usual height of the roofs and of the spire, in consequence of the exposed position of the building. There is a three-light window at the east end, with three quatrefoils, and a two-light window at the west end, with trefoil. The font, which in design accords with the building, is the gift of the Rev. F. T. J. Bayly. The seats are of stained deal. The rafters supporting the roof are interlaced and stained, and the panels being coloured a deep blue. A ribbon of pale colour is carried around the arches. The chancel is fitted with seats for choristers. The pulpit is of stone. The inscriptions in the chancel and porch are in illuminated characters, and have been executed by Mr. Hyett, of Gloucester, under the direction of Mr. J. D. P. Nihlett.

**Barvisland (Herefordshire).**—The parish church has almost been entirely re-built, except the chancel. The architect was Mr. H. Curzon, of London, and the builders were Messrs. Pearson & Son, of Ross. Three iron ties had been placed right across the nave to hold the walls together, for in some parts of both the south and north walls they had bulged out to the perpendicular about 18 inches. The walls have been partially rebuilt, and a new roof put on with a higher pitch, which follows in the line of the existing chancel

roof. The same treatment has also been adopted with regard to the porch. The only new window is that on the right of the porch, which, to match the one on its left, is of the wall-flower pattern. The chancel is yet unfinished. The roof has been made secure, but the interior work will come under another contract. The stone used has been obtained from Lucton. The windows have all been re-glazed, and the floor laid with Godwin's encaustic tiles. New arches have been put in at each end of the nave, the Bath stone with which they are faced contrasting with the dark native stone from the neighbouring quarries of Lucton. The tower has been made good up to the floor of the heltry. The original contract for the restoration of the nave, porch, and lower part of the tower was 1,600*l.*; and the contract for the chancel, 150*l.*

**Penarth (South Wales).**—The old church at Penarth has long been felt to be too small and unsightly for the rising town; and now, at the cost of the Baroness Windsor, a new church is about to be erected on the site of the old building; or rather the new one will encircle the old one, which will not be raised until it is absolutely necessary to do so for the purpose of completing the new structure. A design has been furnished by Mr. W. Butterfield, of London. The church will be built in the Gothic style, and will have a tower, nave, aisle, transept, and chancel. It will accommodate 700 persons. The cost will be about 7,000*l.* The foundation stone has been laid.

**Bellingham (Northumberland).**—The parish church of Bellingham, after being closed for nine months for restorative purposes, has been re-opened. On cleaning the decayed plastering from the walls, there appeared in each corner of the nave a semicircular respond pillar, with cap and base of Early English date, against which the present side walls have been built up; and the chancel arch, and north and east walls of the chancel, are probably of the same date. Tradition says that this church was burnt by the Scots, and the evidence from the building tends to confirm the belief. The wall above the chancel arch appears to have been subjected to the action of fire, and the construction of the present nave and transept, which is, it is believed, unique, indicates that in re-building the church, it has been desired to prevent the recurrence of a similar catastrophe. The chancel and sacristium have been floored with tiles, the latter being ornamental in character, and provided from a private source. The old nave and transept seats have had to be refixed, but it is hoped that some day funds may be available for suitably reseating the church. The walls have all been repointed outwardly, and provision made for removing the rain-fall from the building. The windows have all been re-glazed. Mr. Johnson, of the firm of Anstin & Johnson, was the architect employed to superintend the works, which have been carried out by Messrs. Weldon, Mr. Martinson, and others.

**Sacriston.**—The foundation-stone of the new church of St. Peter, Sacriston, has been laid in that village. The church, which will be of the Pointed Gothic style of architecture, will be erected from designs by Mr. T. C. Eddy, of Durham, and, when finished, will consist of a nave, a chancel, aisle, porch, and vestry,—the nave and chancel being sufficient for present requirements. The stone of which it will be built will be taken from quarries in the vicinity, and will be given by the Dean and Chapter of Durham. The windows in each side will be stained, and the west end, which faces Sacriston and Edmondsey, will be furnished with a bell-turret, with a Catherine window. Surmounting these windows are others. The total accommodation afforded by the church will be for 454 persons. The builder is Mr. J. Johnston, of Durham. The edifice will cost about 1,700*l.*

#### DISSENTING CHURCH-BUILDING NEWS.

**Bow.**—The New Union Church, Grove-road, Bow, the foundation-stone of which was lately laid by Mr. Benjamin Scott, F.R.S. (Chamberlain of the City of London), is built upon a plot of land at the junction of the Grove and Esmond Roads, Bow, and consists of nave, aisles, whole length of nave, chancel and chancel-aisles for singers' chamber, organ, and vestry. There is an attached tower, standing out from the church, at the corner of the roads, surmounted by an octagonal slated spire, the whole height being about 110 ft. The total length of the church, internally, will be 84 ft., and the width 56 ft.

6 in. The width of nave is 24 ft., and the chancel 20 ft., and the height from floor to ridge 50 ft. The nave will be separated from the aisles by arcades of four arches each. The chancel will have a similar arcade of two arches on each side. The interior of the church will be faced with white Suffolk bricks, and red and black bricks in bands and devices. The arches will be of ornamental and coloured bricks. The exterior will be of malm bricks, with red and black bands, &c., and Hollington stone dressings. The aisle-walls will be pierced with three-light windows with traceried heads, and the chancel-aisles with two-light windows. The chancel and west windows will be of four lights each, with an extra double and two single light windows to Esmond-road front. The tower, of four stages, contains the principal entrance. The baptistery will be in the chancel. The roofs will be open-timbered and boarded. The seats are to be open, and the whole of the woodwork stained and varnished. The cost of the church, with schools, &c., adjoining, will be upwards of 6,000l. The architect is Mr. W. Wigginton, of London, and the builder Mr. T. Ennor, also of London.

**Southend.**—The chief stone of a new Congregational chapel has been laid at Southend. The new building will be erected on a suitable plot of ground presented for the purpose by the Cliff Town Building Association, and the total cost is estimated at 2,532l., the greater part of which has already been raised. Mr. Dixon, of Kentish Town, is the architect; and Mr. Mann, of London, the builder.

**Folkestone.**—The foundation-stone of a new Wesleyan chapel has been laid here. The site selected is on the brow of the ascent on the turnpike road leading from Dover, at the junction of East-place with Rendezvous-street and Grace-hill. The new building will be in the Early English style, with a spire. The ground-floor will be occupied by school-rooms, and the body of the chapel, measuring about 50 ft. by 60 ft., will be furnished with pews. Galleries will be suspended on three sides, and accommodation will be provided for 900 persons. The walls will be of Kentish ragstone, having the windows, doors, &c. faced with Bath stone; the steeple, also, if erected (a point at present in abeyance), will be entirely of the latter material. The cost of the new edifice itself, independent of the site, will be 3,500l.; including the purchase of the land it will amount to 4,000l. Mr. J. Gardner is the architect.

**Luton.**—The foundation stone of a new Congregational church has been laid here. The proposed building will be situated in King-street, and it is to be in the Gothic style, with a spire. When completed, the chapel will accommodate 1,200 persons; and a school-room beneath the building is to be arranged so as to hold 1,200 children. The architect is Mr. John Tarring, of London; and the builders are Messrs. Smart, of Luton. The cost of the church, including the price of ground, is 6,000l.

**Oundle.**—A newly-erected Independent chapel has been formally opened. The chapel is in the Early Decorated style, the walls being of cnt stone, with Bath stone facings. The roof is covered with slate, and there are two entrance porches. The main timbers of the roof are visible, and, with the rest of the wood-work, stained and varnished. There is an end gallery facing the pulpit, and two side galleries are contemplated. A school-room and vestry are erected at the back. The area is 35 ft. by 63 ft., and will at present accommodate 500 persons. The entire cost was 1,620l. Mr. Poulton, of Reading, was the architect.

**Ipswich.**—The chief stone of the new Congregational chapel has been laid in Crown-street, High-street. The contract for the building is 2,040l. The site cost 750l.; but old materials yielded 250l.

**Cherrytree (Ecclesall).**—A new Wesleyan Chapel has been commenced at Cherrytree. The site selected is at the junction of Oakdale-road with Brincliffe-road, a short distance beyond Ecclesall Union Workhouse, and in a line with the building which the New Connexion has erected in the same road. Messrs. Wilson & Crosland are the architects, and they have prepared plans for a chapel with schools beneath it. The chapel will be in the Decorated style. There will be accommodation for nearly 500 persons, and the schools will form the basement. The cost of the building will be about 1,800l.

**Liverpool.**—The foundation stone of a new Congregational chapel has been laid in Church-street, Waterloo. The architect is Mr. C. O.

Ellison, of Liverpool, whose design was selected out of three or four sent in for competition by local architects; and the builder is Mr. J. Westmoreland, of Islington, in this town. The interior dimensions of the chapel will be:—Length, 67 ft.; breadth, 48 ft.; and height, 40 ft. The height from the ground to the top of the spire will be 90 ft.; and to the apex of the roof, 60 ft. Behind the chapel will be vestries and lecture-rooms of considerable size, with entrances from the side street, and communication with the chapel. Provision is also made for tea boilers, heating-apparatus rooms, and other conveniences. The cost of the building will be 4,000l. The building will accommodate about 800 people.—The foundation stone of a United Presbyterian church has been laid in Prince's-road. The church, which is to consist of a nave, transepts, and a lofty campanile, is to be built almost entirely of brick, stone being used very sparingly. The walls are to be of red patent brick, enriched by ornamented bands of black brick, and light-coloured stone. The arches of the windows and doors are to be worked in moulded red and black brick, and the jambs are to be finished in square brick. The tracery of the windows, columns, and tympani of the doors is to be of stone. There will be a tower 135 ft. high. Behind the church will be a lecture-hall, to seat 350 persons, vestries, &c. The architects are Messrs. W. & G. Audley; and the builders are Messrs. Haigh & Co.—The large church which has been erected by the United Presbyterian body, at the junction of the Breck-road and Queen's-road, Everton, has been formally opened for public worship. The edifice is a prominent feature amidst the numerous and still increasing buildings around it. The style is Perpendicular. The building is cruciform, having a nave about 74 ft. by 66 ft., with transept 15 ft. by 19 ft. The edifice is nearly square, the main frontages being in Breck-road and Queen's-road. The tower, at the corner of Breck and Queen's roads, is octagonal, with a square base of 21 ft. in extent, and rises to an elevation of 70 ft. It is surmounted by crocketed finials at each octagonal angle, and at the east, west, and north sides of the tower it is intended to place a clock.

From the summit of the tower a spire ascends to an additional height of 63 ft.; the entire elevation from the tower basement to the pinnacle of the spire being 133 ft. The spire tapers rapidly. It was the architect's desire to have carried it to an additional height of from 25 ft. to 30 ft. The area of the tower is large enough for a complete peal of bells. The interior of the edifice is plain. The windows on the north, south, and west sides of the edifice are uniform. They are of the large triplet character, all being filled in with stained glass, as well as four smaller windows on the east side. Including the gallery at the west side, the edifice will accommodate about 850 persons. In this respect, uniform with the pulpit, or rather platform, at the east side, by 2½ yards in depth. The architect of the church was Mr. W. H. Weightman. Mr. Hugh Yates, of Everton, was the contractor for the general work; Messrs. Edmondson, of Manchester, supplied the stained glass windows; Mr. C. W. S. Waters, the gas-fittings; Mr. R. Paterson and Messrs. Robertson & Mason, the upholstery. There is a bell in the turret, the gift of Mr. H. Wilson; and a clock in the interior, given by Mr. J. Millar. The estimated cost of the building is about 5,000l.—The foundation-stone of a new Welsh Calvinistic Chapel, intended to supersede the present one in Bedford-street, has been laid in Prince's-road, near Prince's Park. Mr. David Roberts, who laid the stone, presented 1,000l. while others have given in a like liberal spirit. Of the 15,000l. which it is calculated will be required to carry out the plans of the architects in their integrity, about 8,000l. have already been subscribed.

**Lock Bank (Derbyshire).**—The foundation stone of a new Congregational chapel has been laid here. The new building is estimated to cost, exclusive of a proposed tower, 2,100l., towards which about half the money has been paid or promised. The intended edifice is from a design prepared by Mr. Hull, of Northampton, architect; and the contractor is Mr. Francis, of Cromford. The chapel will accommodate 440 persons on the ground floor, and 100 in the gallery, with provision for additional galleries when required. The site has been contributed by Mr. Stevens, one of the deacons.

## Books Received.

*Transactions of the Royal Institute of Scotland.*

THE work just now issued under this head for the session 1863-4, is a thin folio of "Illustrations of Scottish Buildings." The buildings are Elgin Cathedral and Roslin Chapel. The first is set forth as measured and drawn by John Ogilvie, revised and drawn in lithography by E. F. C. Clarke; the second as drawn in lithography by E. F. C. Clarke. The work will, doubtless, be acceptable to the members; and if it had been issued by the gentlemen who made the drawings, would have met with no depreciatory comment on our part. Whether or not, however, it is such an illustration of Scottish buildings as the architects of Scotland as a body should be content to send forth in their names, is a question to which we do not feel ourselves in a position to reply in the affirmative.

## Miscellaneous.

**INSTITUTE OF PAINTERS IN WATER COLOURS.**—The Prince of Wales and the Princesses Helena and Louise visited the Institute of Painters in Water Colours this (Thursday) morning.

**THE NATIONAL GALLERY ENLARGEMENT.**—The House of Commons have voted 20,000l. out of a maximum sum of 100,000l. for the purchase of the site for the enlargement of the Gallery.

**ROYAL ITALIAN OPERA.**—*Linda di Chamouni*, revived for Mlle. A. Patti, was received with great favour by a good house on Monday evening. Both as actress and singer Patti was admirable. Mlle. Scalone made a good impression as the faithful Savoyard boy. *Eva Diavolo* is underlined for Saturday next.

**THE HANDEL FESTIVAL.**—We would briefly say, out of our desire to assist in rendering the approaching Festival at the Crystal Palace a great success for the Company as we feel persuaded the Company have ensured it being for the music-loving public, that on (this) Friday, the 23rd, the full Rehearsal will take place, commencing at one o'clock, and will include the most important parts of the works that are to be given completely during the following week, commencing on Monday with *Messiah*.

**THE REMOVAL OF TEMPLE-BAR.**—A correspondent, "G. E.," writes:—Having read that Temple-bar will be taken down for the purpose of widening the approaches to the contemplated improvements in the Strand; and thinking it pity that the old landmark should be either demolished or lost sight of, I take the liberty of suggesting the propriety of placing it in one of the parks. Perhaps the entrance to the ornamental enclosure opposite the Horse Guards would be a good a place as any, as it would harmonize very well with the building in front of it, and show with good effect from the entrance in Parliament street.

**WATER SUPPLY.**—At Bolton there is already scarcity of water. The *Bolton Chronicle* draw attention to the urgent necessity of economising the use of it as far as possible, alike for domestic and manufacturing purposes. At the same meeting it was stated that at present there are in the time last year. The quantity of water in the lodges is 139,000,000 gallons, or only two months supply; and, with dry weather such as the present, the supply must further diminish.—The engineers of the Sheffield Water Company a resuming work at the Agden embankment, which was partially completed before the Bradford inundation. Immediately after the bursting of the Dale Dyke, the directors of the company stopped the works at Agden. The directors obtain the advice and services of Mr. Hawksley, a engineer, instead of Mr. J. T. Leather. Mr. Hawksley immediately requested that Mr. Gunson would continue to act as the resident engineer. It is expected that the Agden dam will be completed in about two years. Mr. Strines dam will shortly be commenced. It is said that the embankment at Bradford is to be repaired so as to admit of the storage of a comparatively small quantity of water for the supply of the mills in the valley below; and that a large reservoir will be constructed at a point high up the stream.

TELEGRAPHIC.—A new submarine cable has just been laid between Sicily and Algeria. Italy will thus be directly connected with Africa by two telegraphic lines, establishing immediate communication with Tunis and Algeria. These lines pass over the island of Favogua.

FATAL COLLIERY EXPLOSION.—Twenty-seven men have been killed by another of these frequent explosions. The occurrence took place at Beddell's pit, Tredegar. There were two hundred men in the pit at the time, who escaped from the after-damp by retreating to the bottom of the pit.

THE DUBLIN EXHIBITION BUILDING.—We understand that some discussion has prevailed in Dublin with reference to the use to which the exhibition building should be put after the close of the Exhibition. The suggestion which has been most favoured is, that the greater portion of the building should be devoted to the purposes of a winter garden, while that portion now used as the machinery department should be converted into a gymnasium. The building belongs to a Company.

THE LIVERPOOL CONSULTING SURVEYORSHIP.—At the last meeting of the town council, a letter was read from Mr. Weightman, intimating his intention to retire from the office of consulting surveyor on the 1st of October next, and expressing grateful feelings towards the members of the council for the consideration and kindness which he had ever received. A general desire was expressed that, if it was consistent with Mr. Weightman's health and future arrangements, they should still retain some portion of his services. The letter was referred to the finance committee.

THE NEW COURTS OF JUSTICE.—A sum of 200,000l. has been voted by the Commons for the purchase of the site. For the year ending 1st March, 1866, the sum of 200,000l. will be required on this account. The House of Lords have agreed not to insist on their amendments to the Building Bill. They have also agreed to the alteration, by the Commons, of Lord Redesdale's amendment of the Site Bill, that the action should not be begun until the site was obtained and the plan approved of by Parliament. The delays have caused a proprietor of seventeen of the freehold houses to complain, by petition to Parliament, that she has lost all the rents and profits of these properties for the last ten years.

NORTHAMPTONSHIRE ARCHITECTURAL SOCIETY.—The annual spring meeting of this society was held at Brackley. The meeting was not so large as it generally has been for the last few years. In the course of the excursion several churches, which well repaid the visit, were examined and described. Sir Henry Dryden, bart., paid several preliminary visits to them, and made himself thoroughly conversant with all their details and peculiarities. All the churches were described by Sir Henry. The meeting opened at a museum, which was held in the town-hall. The great majority of the contents of the museum were contributed by Sir Henry and his sons, and by Mr. Samuel Sharp, of Dallington. In the course of the meeting, papers were read, by Mr. Sharp on Forgeries (of flints, money, &c.); and A Plea for Drapery (in churches), by the Rev. G. A. Poole.

SCIENCE AND ART DEPARTMENT.—The Committee of Council on Education have just published their twelfth report of the Science and Art Department. Under the present system of instruction in science schools and classes inaugurated by a minute of June, 1859, there have been six national examinations for certificates as science teachers, and four general examinations of students. The following statistics show the results:—

1859.	1860.	1861.	1862.	1863.	1864.
Candidates...57	89	103	125	109	115
Obtained certificates...43	75	97	112	95	98

Students there are now 91 classes, containing 66 students. The number examined last year was 2,070, and the number of prizes awarded, 18. The largest number of candidates are in chemistry; 851 having been examined in inorganic, and 142 in organic chemistry. The subjects embraced are very numerous—geometry, mechanical drawing, acoustics, electricity, geology, mineralogy, animal physiology, botany, nautical navigation, naval architecture, &c. Altogether there are now 114 classes and 5,064 students in them.

ACCIDENTS.—At the Calls, Leeds, a portion of the western gable fell outwards at the top of the seven-story warehouse of Mr. J. T. Pearson, agricultural chemist and corn merchant. The occurrence arose from a fracture of the roof-beam, caused by a defect in the timber. There were from 8,000 to 10,000 quarters of wheat stored in the warehouse, but in the top story only 520 quarters of grain were deposited, while on each of the other floors there were 1,500 quarters.

NEW BATTERSEA BRIDGE.—The Albert Bridge Company having obtained power to construct a bridge over the Thames to connect Chelsea with Battersea, the several points being Cheyne-walk on one side and Prince Albert-road on the other, are inviting applications for 9,000 shares of 10l. each, representing a capital of 90,000l. for that purpose. They have power also to borrow 30,000l. The bridge, of which we have given illustrations, is to be partly on the suspension principle, and a responsible contractor has undertaken to complete it ready for traffic in eighteen months for 82,000l., taking part payment in paid-up shares. Arrangements have also been made for the purchase of Battersea Bridge for a rent-charge of 3,000l. per annum, the tolls on which, in 1862, were 6,153l. A clear income of 9 per cent. is anticipated.

THE ELM-TREE.

The Elm-tree grew  
In the distance blue,  
For the hammer, and nail, and plane;  
For the dust of those  
Who need repose,  
Whom the arrow of death hath slain.  
  
The Bell was cast  
To chime the last  
Farewell hymn that can be shown  
To the friends we grieve,  
Whom Heaven receive,  
And the angels make their own.  
  
For God's deep care  
Is every where,  
And His love is ever thorough,  
When the Elm-tree grows  
In the wild hedge-rows  
To be sawn for us to-morrow.

A. II.

PROJECTED RAILWAY THROUGH THE THAMES TUNNEL.—A prospectus has been issued of a new metropolitan railway, to complete the system recommended by the Parliamentary Committee of 1864. It is to be called the East London Railway, with a capital of 1,400,000l., in shares of 100l. Its entire length will be about 8 miles, and it will run from junctions with the North Kent, Brighton, and South-Western lines in the New-cross district, south of London, to the Great Eastern Railway at Fenchurch-street (passing through the Thames Tunnel), and thence to a station at Liverpool-street, near the Bank, where it will connect with the Metropolitan district line. The work is undertaken by Messrs. Brassey, Lucas, & Wythes, and the cost per mile, it is stated, will be less than that of any other metropolitan railway. A return of 14 per cent. is anticipated.

STONEHENGE.—At a recent meeting of the Ethnological Society, the paper read was "On Stonehenge," by Professor Nielson. His views were, that Stonehenge was a temple of early fire-worshippers, and of pre-Druidical origin, and belonging to the "Bronze Period" of the northern archaeologists. The remains of Stonehenge, he remarked, are placed, not on the summit, but on the declivity of a hill surrounded by numerous barrows, from which bronze articles have been exhumed with others of flint, but never any of iron. He considers that fire-worshippers preceded Druids in Britain and Gaul, and gives what he considers as numerous proofs of the the declivity of a hill surrounded by numerous barrows, from which bronze articles have been exhumed with others of flint, but never any of iron. He considers that fire-worshippers preceded Druids in Britain and Gaul, and gives what he considers as numerous proofs of the building of such stone open temples by colonies of Phœnicians. Circles of large stones exactly identical in description with those called Celtic or Druidical, he continued, are found in countries where neither Celts nor Druids ever existed; but how does he know that? and who knows at what time the ancient religion of this country may be truly said to have been pre-Druidical or pre-Celtic in its principles? From various considerations the author of the paper thinks there may be sufficient reason to regard the remains of Stonehenge as Phœnician, and connected with the rites of Baal, like their congeners at Tyre and in the valley of Bethel.

POWDER.—The *Western Morning News* states that Mr. Gale, electrician, of Plymouth, has discovered a process by which powder can be rendered non-explosive, and its combustible properties restored when required. The cost is very small, and has the advantage of being readily applied. In five minutes a barrel of powder can be made non-explosive, and in another five minutes it can be restored to its original condition. If a shell burst in a store filled with the prepared powder, it would not fire!

IMPROVED TRAVELLING CRANE.—Mr. T. B. Burnett, of Mount Vernon, New York, has invented an improved travelling crane. The gearing by which the weights are raised is similar to that on ordinary cranes, and the hoisting chain is led up over a boom, which is jointed at the bottom, so that it can be raised or lowered. The rigging is composed of heavy iron bars, and there is a counterbalance box behind the crane. When the crane has been loaded, and is ready to be transferred from the point where it is at work, the labourers apply themselves to handles which act on gearing below the platform on the front axle. By means of a small pinion meshing into this gear, they are enabled to remove any weight that can be raised by the crane to any point on the truck.

AMALGAMATED SOCIETY OF ENGINEERS.—The fourteenth annual report of this society, for the year ending December, 1864, has just appeared. It is a voluminous compilation. The expenditure during the year was from all sources 51,518l. 12s. 6d.; and, at the close of 1864, the accumulated fund amounted to 86,947l. 15s. In 1863 the amount paid to members out of work was 32,653l. 6s. 10½d.; but in 1864 the sum under the same head was only 16,425l. 9s. 6½d., which, added to 13,612l. 4s. 7½d. sick benefit, 3,902l. 6s. 7d. superannuations, 3,924l. 0s. 11½d. funerals, and 1,100l. benefit in cases of accident, shows members to have received under the various heads 38,964l. 0s. 8½d. during twelve months. The accumulated fund of the society now averages 3l. 0s. 6d. per member.

THE ENLARGEMENTS AT KEISS.—A notion seems to be entertained that the human beings of what is called the stone period, were specimens of Nature's mere apprentice hand, and that their organization had not then reached the comparatively high order of development since attained. A discovery recently made at Keiss, in the north of Scotland, will help to explode this opinion; and, strange to say, the evidence is that of a woman, heretofore so rare of the stone period, that it is a wonder sticklers for matter-of-fact evidence have not doubted whether women especially then existed! The cranium of this witness "shows that in the amount of space for the brain, it not only considerably exceeds in its capacity that of the skulls of women of modern savage races, but is on a par with, or even somewhat in excess of, the average cranial capacity of the women of our own island at the present day." The ridges on the bones for the attachment of muscles "possess no great prominence: hence it may be concluded that the woman was not required to lead a life compelling any great amount of muscular exertion." The thigh bones were elegantly formed. The stature was probably not more than 5 ft. 4 in.

THE FOUNDATION OF THE MANSION HOUSE, LONDON.—At the last meeting of the Court of Common Council, a report was brought up by Mr. H. Haines, relative to the state of the foundations of the Mansion House, and for authority to expend 5000l. in part restoration of the same. The ground having been opened in George-street to examine the state of a sewer that ran from east and west of the Mansion House, they endeavoured to ascertain, if possible, the cause of the settlement that had taken place at that part, and they found it was built on a wooden foundation which showed very strong symptoms of decay, and which was, in several places where the ground had been opened, completely rotten. The city architect had been communicated with, and had made an examination, and was of opinion that steps should be taken at once to make secure the foundation in those places, which he estimated at a cost of about 5000l. Mr. Haines explained to the Court that it might not be the only sum which would be wanted, as perhaps, when a further examination took place, it might be found that the whole of the foundation was in the same state, and it would in that case become necessary to pin the walls up all round. The report was agreed to.

**GAS IN THE CITY.**—The several petitions against the present quality and price of gas having been referred to a special committee, the committee, in reply, recommend that an effort should be made to obtain some alteration of the Gas Act of 1860; but, as this solution of the matter seems unsatisfactory, a motion has been put before the Court of Common Council to return the report to the committee, with instructions to obtain power for the Corporation either to contract for the supply of gas or to manufacture the gas, as is done by the corporations of Manchester and other towns.

**GREAT RISE IN THE VALUE OF PROPERTY IN LONDON-ROAD, LIVERPOOL.**—Two blocks of buildings in the locality have been sold at the rooms of the Law Association in Cook-street. The premises are on the north side of London-road, between Norton-street and Stafford-street, and a little below the monument. They consist of eight tenements, six being shops, and two public-houses. The property is leasehold under the Corporation of Liverpool, for an unexpired term of fifty-four years, and was sold under an order from the Court of Chancery. The property has been valued by Messrs. Cushman & Griffiths at 8,540*l.*, the rentals averaging about 80*l.* per annum for each tenement. The total amount for which the property was sold was 16,430*l.*

**THE MORNING DRIVES OF CHILDREN.**—Often when the sun has been shining brightly on the hills of Highgate and Hampstead, and in other parts of the metropolitan suburbs, and the air there has been dry and healthy, in some districts the mists have been lying thick, and the humid atmosphere has rendered the vicinity of the parks, and several of young children or persons of delicate and sickly constitution. Nevertheless, we have hundreds of times noticed in the fashionable drives and walks about the Serpentine, St. James's Park, &c., young children of the higher classes, who should be in the care of those who are better advised, exposed to a most damp and unwholesome atmosphere.

**THE EXCAVATIONS AT KEYNSHAM ABBEY.**—A correspondent of a Bristol paper writes as follows in reference to the excavations at Keynsham Abbey:—"It is with regret that upon my visit this day to the above interesting remains of the Middle Ages I found that a large portion of the earliest tile pavement had been taken away, evidently by visitors. All our antiquarians must regret this act, as the portion removed was, I believe, the only Norman tiles remaining on the site. I trust all persons will refrain from removing even the smallest portion of the relics, as the proprietor of the land, who is clearing the soil and rubbish, is endeavouring to retain as much of the remains as possible *in situ*; and I feel sure he would much regret being compelled to close the site to the public, or to carry out his determination to prosecute any person that may be discovered taking away any portion of the antiquities."

**PNEUMATIC RAILWAY UNDER THE THAMES.**—The recent experiment at the Crystal Palace has led to the idea of carrying out a short line to connect the Waterloo Station of the London and South-Western Railway with Whitehall, passing in a troughed iron bridge, or surface tunnel, under the Thames. Three piers will be built below the bed of the river, by means of iron caissons. When these piers have been brought up to within a few feet of the bed of the river, the upper portions of the caissons will be taken off, and the bed of the river between the line of piers dredged down to the level of the upper course of the masonry of the piers, and in the trough thus formed the iron tube will be made. The tube will be lowered in four separate sections. When down, these will be kept securely in their place by cramps, and will be covered with a thick bed of concrete. The internal diameter of the tube will be 12 ft. The portion of the line between Whitehall and up to the river front of the Thames Embankment will be built in brickwork; and on the Surrey side the line will also be continued in brickwork under College-street and Vine-street, close to the Waterloo Station of the South-Western Railway, with which it will communicate by a flight of steps from the York-road side of the station. The steepest gradient throughout will not be more than 1 in 30, which is nearly one-half more favourable than the ascent of Holborn-hill, or that of the experimental line at the Crystal Palace.

**THORNLEY CHURCH.**—The parishioners of Thornley have resolved to place a stained glass window in Thornley Church, in memory of the late H. J. Spearman, who represented the city of Durham from 1847 until the general election in 1852.

**STAMFORD.**—The (R.C.) church of "Our Ladye and St. Augustine," although used for worship for some months past, was not solemnly opened until lately. The building, which is in the geometrical style, occupies a site in Broad-street. The nave has a wide span, and terminates in an apsidal recess, within which stands the altar. An apse to the right of the altar is appropriated as the Lady Chapel, and in this has just been placed a statue of the Madonna. On the left of the nave there is an aisle, the altar for which has not yet been obtained. The church will accommodate about 400 people. A residence for the priest adjoins the church. The architect was Mr. Goldie, of London.

**THE COAL TAR COLOURS.**—At the Royal Institution, lately, Mr. F. Field delivered a lecture on "Magenta and its derivative Colours obtained from Coal Tar," in course of which he stated that one of the recent discoveries of these colours was that of Hoffin's violet, a mass of which was placed on the lecture-table; and this material, though derived from a mere refuse product, is five or six times the value of its weight in silver, the mass on the table being estimated to be worth 700*l.* A great many experiments were exhibited, showing the production of various colours from the same agent, in which many substances were dyed. Mr. Field mentioned as an instance of the great intensity of the colour of magenta, that when the *Great Eastern* was disabled and lying in the trough of the sea, a considerable alarm was entertained on account of the blood-colour of the water extending far a great distance round the ship. It was afterwards discovered that this effect was produced by the breaking of a vessel containing a quantity of concentrated magenta. Much has been hitherto discovered respecting the nature of coal-tar dyes, a good deal yet remains to be found out, among which may be included the discovery of the means of imparting some of the dyes to woollen material as easily as to silk.

**DRY SOIL CLOSETS.**—A Galashiels correspondent, Mr. James Kerr, says he has since last year been using with satisfaction a simple apparatus, by which the deposits are at once deodorized by coal ashes or earth, and thus thrown out into a shoot or iron bin for removal by the dustman's cart or for garden use. The mechanical action of this "earth closet," he says, is very simple, the whole process being effected by opening and closing the lid, to which is affixed the lever cranks. He wishes to call the attention of landed proprietors, architects, builders, and others to the use of such earth closets in many situations where it would be preferable to a water-closet, viz., where there is a deficient water supply or want of proper drainage, and the immediate deodorizing of offensive matter ought to be effected at once, instead of running it into festering cess-pools or ill-constructed drains. By the admixture of ashes or earth with the night soil, also, the ammonia and other fertilizing properties are at once absorbed and retained for the field or garden. Mr. Kerr is not the originator of dry soil closets, but his plan may be an improvement on others. The Royal Scottish Society of Arts are said to have recommended it to the consideration of their prize committee for the simplicity of its mechanical action.

**TENDERS**

For building ten almshouses, with reading-room and small museum, at Ramsgate, for Sir Moses Montefiore, bart. Mr. H. D. Davis, architect:—	
Newman & Mann	26,340 0 0
Mayers	8,363 0 0
Myers & Sons	4,261 0 0
Sull & Richardson	5,969 0 0
Newly	5,920 0 0
Sawyer	5,110 0 0
Mathews	5,173 15 0
Edgar (accepted)	5,100 0 0
For forming an extension of the sea-wall and terrace, at Aberystwith. Mr. H. D. Davis, surveyor to the corporation:—	
Moore	23,997 0 0
Jones (accepted)	1,999 0 0
For alterations and additions to 7, Castle-street, City. Mr. Herbert Ford, architect:—	
Hostell	738 0 0
Rawlins	537 0 0
Palmer & Son	537 0 0

For painting, &c., at Christ Church, Rochester:—	
West & Morse	2,282 10 0
West & Nicholls	231 15 0
Kent	199 10 0
Smith	193 4 0
Baird & Co.	192 0 0
Day	192 0 0
Dunn	181 0 0
Peole	180 0 0
Richardson	179 19 0
Boyer	175 0 0
Nightingale	161 0 0
Minty	159 0 0
Richardson	155 0 0
Norris & Son	155 0 0
Johnson	136 0 0
Thorp	122 5 0
Dovsing (accepted)	118 0 0
Mahoney	118 0 0

For pianoforte warehouse, for the London Pianoforte Company (limited). Mr. Septimus Hoskins, architect:—	
Manley & Rogers	2,467 0 0
Mann	2,158 0 0
Lambie	2,139 0 0
Walton	2,040 0 0

For finishing a pair of villas, at Wood-green, for Mr. Vardie. Mr. P. W. Reed, architect:—	
Lambie	4,933 0 0
Sale	589 0 0
Jones	550 0 0
Green	525 0 0

For dwelling-house, in Bath-street, Sheffield, for Mr. J. Wragge. Messrs. Flockton & Abbott, architects:—	
Bradley	4,660 0 0
Robertson	655 0 0
Harrison (accepted)	600 0 0

For alterations and additions, at the Cutlers' Hall, Sheffield. Messrs. Flockton & Abbott, architects:—	
Neill	45,546 0 0
Messrs. Craven	8,535 0 0
Bradley	5,715 0 0
Wade (accepted)	5,715 0 0

For re-building and restoring Saville House, Leicester square. Messrs. Nelson & Lucas, architects:—	
Mansfield	13,110 0 0
Myers	12,718 0 0
Mason	11,485 0 0
Carter	11,467 0 0
Jackson	11,460 0 0
Simpson	11,450 0 0
Howard	11,111 0 0
Meley	10,355 0 0
Barlow & Rigby	9,930 0 0

For the erection of two houses, in Drummond-road, Bermondsey, for Mr. Daniel Martin:—	
West & Morse (accepted)	2,538 0 0
Steburny	825 0 0
Clark	611 10 0
King	610 0 0
* Too late.	

For sanitary alterations and repairs to the Ancle Barton, Long-leas, Bermondsey, for Mr. Chapman:—	
Carter	2,113 0 0
Roffey	119 10 0
Kippes	109 0 0
West & Morse (accepted)	108 10 0

For new sewers in Rouse-road, for the Bermondsey Vestry. Mr. Elkington, surveyor:—	
Carter	6,720 0 0
Kent	657 0 0
Parker	695 0 0

For alterations and additions to warehouse, No. Castle-street, City, E.C., for Messrs. Knight, Wells, Braithwaite & Co., architects:—	
Palmer & Son (accepted)	5,537 0 0

For Congregational Chapel, Sevenoaks. Mr. Tarriest, architect:—			
General Estimate.	Spiral.	Total.	
Newman & Mann	2,941	315	3,257
D. & J. Grover	2,914	211	3,125
Kilby	2,820	170	2,990
Simpson	2,765	200	2,965
Hoodley	2,713	220	2,933
Potter	2,250	160	2,410

For additions and alterations, at the Jews' Orphan Asylum, Goodman's-fields. Mr. N. S. Joseph, architect:—	
Kilby	22,593 0 0
King & Sons	3,590 0 0
Corder	2,281 0 0
Cohen (accepted)	1,900 0 0

For alterations to Congregation chapel, Hanwell. J. Scott, architect:—	
Tyrell	2,240 0 0
Hanson	97 0 0
Glendon	232 0 0
Batley	221 0 0

For alterations and additions to Mr. W. Tucker's messes, at Braekley, Northamptonshire. Mr. J. U. architect:—	
Munday	630 0 0
Robinson	320 0 0
Hackett (accepted)	488 0 0

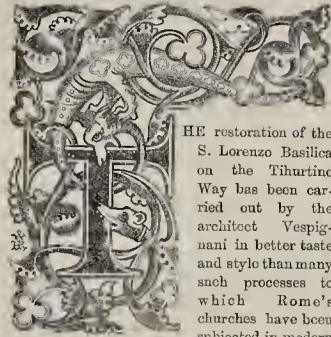

For rebuilding Rosebank, Fulham, for Col. McCM. C.B., &c. &c. Mr. John T. Wimperia, architect. (Cities supplied:—	
Foxley	43,539 0 0
Abbott & Sons	3,445 0 0
Nicholson	3,345 0 0

Hill & Sons	2,774 0 0

# The Builder.

VOL. XXIII.—No. 1169.

Restoration of Churches in Rome.

THE restoration of the S. Lorenzo Basilica on the Tiburtine Way has been carried out by the architect Vespignani in better taste and style than many such processes to which Rome's churches have been subjected in modern

times, though not, indeed, without some prejudice to olden details of interest. Absolutely Vandalic was one proceeding, that sacrificed a lateral porch with columns and mosaic decoration,—one of those beautiful monuments of the thirteenth century by the well-known Cosimati family (whose works are among the finest examples of the Medieval Gothic in Rome), this construction having been unscrupulously destroyed in order to form a sacristy in place of the lateral entrance it had so well adorned. We cannot commend the filling of the narrow-arched windows along the southern aisle, nor the opening of another row, much wider, though of similar form, along the lower part of the same walls; nor can we see without some regret the complete repainting of the curious series of frescoes carried, in two files, along the walls of the atrium, attributed to the Romano-Greek school of the thirteenth century, and illustrating the life and martyrdom of SS. Stephen and Laurence, besides other strangely romantic legends, as the contest between Demons and Angels for the soul of the Emperor Henry II.; the phantom High Mass, seen in this church at midnight by a pious sacristan of the Benedictine community, once occupying its cloisters; and the story (in several acts) of the transfer of St. Laurence's body from Constantinople to Rome in the year 557.

The history of S. Lorenzo is singular and complicated. It appears that two churches, both beautiful and famous in ancient times, existed on this site anterior to the conspicuous buildings of Honorius III., who added the present nave and aisles, with the portico and colonnade supporting a mosaic-inlaid architrave under a heavy pent-roof. One of these churches existed in the fifth century, when it was enriched by some donations from Pope Hilary. Another is spoken of as ancient in the eighth century; for we read in Anastasius that Hadrian I. constructed the major basilica to which it was annexed,—the writer in the sequel explaining what he here means by *constructed*—merely the renewal of the roofing, which had been quite ruinous. The church ascribed to Pelagius, and in which the body of St. Laurence was laid, is shown by notices in ancient writers to have been a building of earlier date, renewed and amplified by that pope in the seventh century; afterwards styled *speciosior-nova*, on account of the splendour with which Pelagius invested it. That "major" basilica which was newly roofed by Hadrian, and dedicated to the Blessed Virgin, was the edifice to which per-

tained the great triumphal arch (now adorned with the mosaics of the seventh century), which, from having terminated the nave of the original church, became the boundary between that compartment and the presbyterium, when the whole primitive structure was converted into the choir of the much larger basilica, brought to its present development under Honorius III., about A.D. 1216. This ancient portion (two churches, in fact) is on two levels,—the lower like a crypt, with its altar before the tomb of the martyrs Stephen and Laurence; the upper, an elevated choir, paved with rich marbles, with double colonnade of antique shafts, divided by a richly-chiselled architrave, and reached by several steps from the nave of Honorius's building. In the course of time (what period is uncertain), the crypt became in the greater part filled with soil; and the tomb-chapel consequently accessible but on one side,—that where stands its altar; the magnificent antique colonnade of fluted white marble, with Corinthian capitals, some beautifully adorned with military trophies amidst the acanthus leaves,—the spoils, no doubt, from some edifice of classic antiquity,—being still preserved, like a connecting link between the upper and lower churches. Those shafts rising high around the actual choir, their basements, at much lower level, are looked down upon from the parapet-walls enclosing that sanctuary. It is the restoration of this primitive crypt to its original state, and the dismembering of the sepulchral chapel under the high altar of Pelagius's church, so as to leave it accessible on every side, that constitute the most meritorious part of the project recently carried out by the architect of Pius IX. Before entering, we notice the bronze statue of St. Laurence leaning on the instrument of his martyrdom, that now stands on a column of red granite, with lofty pedestal and basement of marble; the statue about life-size, and therefore too small for effect at its high situation. The novelty that most strikes the eye on this church's front is the clothing of the whole upper façade, above the portico-roof, with frescoes in imitation of mosaic on a gold ground (to be ultimately executed in that more enduring art) by Capenari, a young artist, the pupil of Podesti, representing the colossal figures of the Emperor Constantine, and the Popes Honorius III., Pius IX., Sixtus III., and Hadrian I., the first two holding small models of this basilica. The figure of the present pontiff is at once a recognizable and speaking likeness; above, along a heavily-projecting frieze, half-lengths of the Saviour (who is blessing with uplifted hand), Saints Stephen and Laurence, and four other saints, male and female,—the general composition good; but in the very vivid tints of the painting thus placed on trial, rather too jarringly contrasted with the venerable and sombre aspect that distinguishes the whole exterior. The same artist is now engaged on another series of colossal figures, in fresco, over the triumphal arch, on the side towards the nave, only two of several saints yet appearing in the group begun. Another work still in progress is the colouring of the hitherto bare rafters that support the triangular roof, in a rich diaper-work, blue, red, and yellow. The round-arched windows of the choir are tinted (and, we believe, all the rest are to be so eventually) with a commonplace geometric pattern, in red, yellow, and orange, whose effect one can by no means command,—glass-painting, in fact, being an art never carried to perfection, and to this day most rare in Rome. A very rich decoration, in diaper-colouring, of a lateral chapel, for the Holy Sacrament, would be more pleasing if the chapel itself were not utterly alien in style, and apparently cut off from the more ancient constructions. Descending into the crypt below that choir, the most finely characteristic portion of the whole interior, we may enter and walk

round the isolated chapel, where the two martyrs repose in an enormous sarcophagus of Phrygian veined marble, surrounded by grating; around this extending a graceful colonnade of gray marble, forming three aisles, under a low ceiling, divided into bays at the eastern side, between the altar and end walls; single files of half columns, set against pilasters, extending laterally to that tomb-chapel, the interior of which we can look into through several narrow arched windows, with gilt grating. There is a solemn simplicity, well adhered to by the restoration, in the character of this semi-subterranean compartment, and the dim light accords with its quiet but stately architecture. Beyond it the extremity of the tribune is supported from below by a transverse nave, with a small altar at each end, and three antique arched niches, in two of which are frescoes (unknown till brought to light in these works), covering the end wall and part of the sides, a series of curiously archaic character, conjectured by Di Rossi to be of the tenth century, and certainly of a period when art was well nigh at its total eclipse. In one niche we see a Madonna veiled in attitude of prayer, with outspread arms, between two saints; two other saints, male and female, on the lateral walls. Another Madonna all covered with jewelry, and the child on her lap; a saint, male and female, on each side of her, and four others, male and female, on each lateral wall, the latter figure of the Virgin, with distinct characteristics of the declining Byzantine school, the former still more rude in style and devoid of expression; in this last instance alone the subject being distinguished by letters of a name, MPOI. On the walls of the aisle, which is quite cut off from the rest of the church, are set four ancient epigraphs, on marble slabs, discovered in fragments during the recent works, and now restored so as to be read with easy intelligence, the most curious referring to the pontificate and relatives of that far from respectable Pope, John XII., with date 963. A finely venerable cloister, interesting for the character of its architecture, and dating from the eleventh century, has been left untouched in the restoring works, and happily preserving to this day all its severe and olden dignity. Capuchins have been placed here, after the long desertion of the convent, by Pius IX., and among the renewed celebrations at S. Lorenzo, we shall remember that we last attended here in the golden light of evening; multitudes of tapers burnt on the high altar, and in large chandeliers, pendant between the antique columns round the choir; no paltry decorations or draperies interfered with the details of architecture. A plain deep-toned chant of the "Liturgy of all Saints" was accompanied by subdued strains from an organ, during the exposition of the Host; and the whole service seemed in harmony with the character of the fine old edifice.

Since the discoveries made in the last winter by Mr. J. H. Parker, in the subterranean well known to exist, but long left unexplored, below S. Pudenziana, on the Viminal Hill, now interest has attached to that venerable church, said to be the most ancient in Rome, and occupying the site of the house of the Christian senator Pndens, who entertained St. Peter as his guest, A.D. 44, and to whose sainted daughter it is dedicated. Within this house were baths (*balnea*, not *thermae*), which, it seems, continued in use till later ages, known as the "Baths of Wonatus," from the name of one of that senator's sons; and we read in Baronius that considerable ruins of that building were erect in the sixteenth century; in the "Sacra Stazoni Romane," by Piazza, an archeologic as well as devotional work, that those remains were still conspicuous about the end of the century following. It is believed the house, or (as tradition states) the baths, were first consecrated for worship by Pope Pius I., about A.D. 145, on the prayer of

Praxedes, another daughter of Pudens, who survived till that date; that at this earliest stage of the local conditions two churches occupied this site, known as Titulus Pudens and Titulus Pastoris, the latter dedicated to Pastor, a brother of the same Pope Pius.

These oratories (as they might be called in respect to size) were subsequently thrown together into a single sanctuary, as the church was rebuilt first by Adrian I. in the eighth century, afterwards by Gregory VII. in the eleventh, and by Innocent II. in the next; and, last of all, were effected the most judicious restorations (or rather alterations) in a style announcing almost the worst period of Italian art by the titular Cardinal Gaetani, in 1597. In its present state, little of the ancient architecture remains except twelve columns of *bigio marhle*, barbarously built up into heavy square pilasters along the nave, and two others flanking the portal; besides some quite plain mosaic pavement in one chapel and one aisle. But we recognise an early Christian period in the low reliefs on the lintel of the doorway, and representing the busts of SS. Pudentiana and Praxedes, and of two others, probably SS. Pudens and Pastor; the divine Lamb, supporting a cross, in the centre, and a graceful foliate ornament along the interstices. In the square campanile of brickwork (date probably about 1130, the period of the buildings of Innocent II.) we have one of the finest specimens of its description in Rome, with three stories of triple arcades divided by marble shafts, several bands of terracotta cornice moulding, and, on the upper part, inlaid disks and crosses in coloured stone. Reduced as the actual church is, by tasteless modern works, to a level with the many other uninteresting sacred structures of the sixteenth century in Rome, we may still trace the original plan dividing it into two sanctuaries; the larger corresponding to the present chancel, and perhaps also to the nave; the latter represented by a lateral chapel and narrow aisle, once the *titulus Pudens*, in which a council was held under Pope Symmachus (498—514), and whose pavement is still a field of primitive mosaic, laid simply in cubes of white and gray marble, intermixed with porphyry and serpentine, placed in irregular pieces. In the same chapel is kept the most revered relic of this church, said to be a part of the wooden altar on which St. Peter here celebrated the Eucharist; also a tablet recording the memories of the spot, as more fully given in another very curious inscription in the nave, repeated in Latin and Italian.\* One artistic treasure, of high value and antiquity, is still fortunately left in its place,—the mosaic of the apse, referred by Italian writers to the year 884, by Germans (*v. Beschreibung Roms*), supposed to be that ordered by Adrian I. in the eighth century;—at all events, a work of such merit that Poussin esteemed it the first among ancient Christian mosaics; and we see that Di Rossi, in his lately published "*Roma Cristiana*," agrees as to such claims. In conception and treatment this work is truly Classic. Seated on a rich throne, with gilding and red cushions, is the central figure of the Saviour, in vestments of gold tissue, extending one hand, and in the other holding a book that displays the words, "*Consecrator Ecclesie Pudentiane*;" laterally the two sainted daughters of Pudens standing with leafy crowns in their hands; and below the half-length figures of SS. Peter and Paul, with eight other persons, all males, of different ages and in amply-flowing costumes, antique Roman in fashion; beyond this group, a portico with arcades, divided by pilasters, and a pent roof, over which, in the distance, are seen several stately buildings with arched windows, arcades, and pilasters; one of these edifices in form a great rotunda; another near

\* "In this church, more ancient than any other in Rome, formerly the house of Pudens, a senator, father of SS. Novatus, Timotheus, and the virgin sainte Pudentiana and Praxedes, was the first residence of the holy Apostles Peter and Paul. Here those who became Christians used to assemble to attend mass and receive the holy communion; here are buried the bodies of 3,000 martyrs, and an immense quantity of martyrs' blood is collected. Those who visit this church every day obtain an indulgence of 3,000 years, with remission of the third part of their sins." Cardinal Wiseman, good authority as to a church from which he took his title in the Sacred College, assumes (*Fabola*, ch. x.) that S. Pudenziana was the principal place of Christian worship in Rome from the apostolic age; and that Pius I. only added another oratory, but did not first consecrate for religious use the house of that senator, who is the identical Pudens mentioned by St. Paul in his second Epistle to Timothy, and said to have suffered a martyr's death under Nero. His two daughters are represented, in the reliefs over the portal, with large vases in their hands, allusive to their care in collecting the blood of such witnesses to faith.

it, an oblong structure, with gable front; the former we may suppose a baptistery, the latter a basilica, probably faithful transcripts of the architecture of the time, as are perhaps all the other buildings in this interesting representation. The absence of the nimbus (all the heads introduced in the sacred group, except the Saviour's, might confirm the conjecture hazarded by some writers who ascribe this mosaic to a date so early as the fourth century; since it is certain that till the latter years of that, or beginning of the next century, such a symbol of sanctity did not obtain its place in Christian art. Above the Saviour's figure rises a lofty cross, studded with precious stones; higher, as if hovering in air, are the four winged emblems of the Evangelists, one of which has been entirely, and another almost entirely, sacrificed, with incredible vandalism, to some heavy modern detail in the framework overreaching the whole. It is certain that restorers have had much to do with this mosaic as now presented to us; the character of the Saviour's head has a severe solemnity; those of the apostles (who have no symbols) are nobly venerable; and the whole composition reminds us of the style distinguishing classic reliefs. Leaving the church, we observe (in a court on one side) the masonry of a primitive period,—perhaps that of the second century of our era, recognisable in a lateral wall of Roman brickwork, like that of the best ancient period, pierced by high arched windows (now built up), and supported by several constructive arches; elsewhere the additions of the fourth century, indicated in the square stone blocks set at intervals into the brickwork, a method practised under Constantine. Near one angle of these walls, we may enter through a gap rudely broken open, to descend into the subterranean, now in total darkness, and in great part filled up with soil, over different levels of which we must pursue an uneasy path; first, through a long interior under a stucco-covered vault, probably the nave of the primitive church; thence into some vaulted chambers with walls and roof alike stuccoed, in some parts painted in plain red bands that follow the lines of archways; elsewhere adorned in more decorative style with architectural subjects, reminding us of the Pompeian.

In one chamber is a fireplace with aperture filled by a wall, over which is a similar coating of stucco; and in another place we see a pavement in black and white mosaic, without any design, laid bare to but slight extent by the removal of the encumbering soil. It seems probable that these latter interiors belong to the baths, contiguous to which, but not so as to necessitate the sacrifice of their buildings, was formed that church within the senator's mansion. And these interiors, long left to oblivion, we know were once profaned for evil purposes; as it is on record how, in the time of Raffaele, they were ordered to be filled up with soil, as recently found, because become a haunt of brigands; Mr. Parker, who well explained the conditions and went over the story of this church at a meeting of the English Archeologic Society, has applied for permission to have the whole of its subterranean cleared out at his own expense, but we are sorry to say, without success hitherto; and we see, in the destinies of this interesting edifice (the supposed primitive cathedral of the Papal metropolis), a striking example of the negligence, amidst much costly and ostentatious church restoration, to be charged against Rome's authorities in respect to the less conspicuous, however venerable, monuments of Christian antiquity.

The Minister of Public Works has issued a Report, addressed to the Pope, on the exports from these States for the Dublin Exhibition, this document containing a full catalogue of objects sent, in whose columns appear,—100 sculptures (statues, busts, reliefs); 41 pictures on canvass; 182 engravings from the Camarcel *Catlografia*; 10 coloured plates from the chromolithographic establishment in Rome; 25 medals struck under different pontiffs since the reign of Pius VII.; a large number of cameos on shells and *petra dura*; objects in wrought marble, ivory, and wood; photographs, machinery; and among natural history classifications, 110 specimens of the mineralogy of these provinces. Cardinal Antonelli exhibits a precious cameo, by Lanzi, of St. George on Horseback; Cardinal Altieri, a geologic map of the mountains of Tofis, executed by Pouzi, professor of geology at the Roman University. The ministers flatter themselves that the hall in the Dublin buildings

appropriated to the produce of these States, will deserve the name of "Pearl of the Exhibition." All the objects were embarked at Civita Vecchia, at the expense and risk of the Irish deputation, in the steamer sent by the directors at their own cost; and the nomination of Lord Talbot de Malahide as Pontific Commissary for the Exhibition has proved generally acceptable. We need not further enter into a report the subject-matter of which now pertains to the sphere of British, rather than Roman, intelligence.

A set of antique Christian glasses, adorned with sacred representations, figures of apostles, symbols, &c. in gold enamel, has been purchased here for the English Government, through the agency of a gentleman authorized first to offer 160*l.*, finally 220*l.*, for the whole, consisting of thirteen specimens, some in a fragmentary state. They found their way to Rome from Sicily, after the dispersion of the Recanepo Museum; and are, we believe, the only such collection extant, except one of greater value in the Vatican Library.

#### NEW AND IMPROVED SCIENTIFIC INSTRUMENTS AND APPLIANCES.

The armoury of science is enriched with new weapons only at long intervals. But so much application, so many experiments, and such a high degree of skill and scientific learning are required for the perfecting of every step in the invention of instruments, that we cannot be surprised that they are of rare occurrence. The improvers of new ones, ought to be accounted as the greatest benefactors of science; yet this is scarcely the case. The inventor gives the most indicative name he can coin to express the nature and object of his invention, and his own is scarcely heard. The Daguerreotypic apparatus was an exception to this rule; but to what extent is the photograph, telegraph, or stereoscope associated in the mind of the general public, with their inventors? With this slight indication of our sense of the recognition due to the men who, in the closet or the laboratory, quietly pursue ideas and carry on experiments, the result of which is to put into the hands of man instruments that set free facts that have hitherto been hidden, or disclose powers of which we were bereft in ignorance, or adapt forces that have hitherto been wasted, we proceed to the mention of some recent inventions and a few improvements. Some of these may yet require subtraction of cumbersome details, or elaboration, or, perhaps, additions of exquisite simplicity before they can be put to remunerative use.—Just as the magnesian light would seem to require some happy suggestion which, being adopted, would render it steady and continuous; for it often happens that men stand on the very brink of success for years before they, by some master-stroke, attain it. Thus, by the simple adjustment of a diagonal sun-glass to an equatorial by Mr. Cook, Professor Phillips has been able to see certain bodies on the sun, which may be either mountains or clouds: some equally simple and happy addition to that contrivance may so assist the vision that we shall learn as much, and perhaps more, of that glorious orb than we know of the moon.

The balloon ascents of Mr. Glaisher would be of very different value if there were no such things as scientific instruments. It is, principally, the delicacy and perfection of the instrument he takes with him into the "firmament on high" that make his observations so exceedingly desirable. This intrepid servant has expressed his approval of a new anemometer by Mr. C. Cator. The instrument hitherto used for ascertaining the pressure and velocity of wind was made by Mr. Osler. In Mr. Cator's anemometer the pressure of the wind is measured by two curved levers of equal length acting against each other, their motion being in a vertical plane. Mr. Osler had used a spring—a light spring for a light air, and a strong spring for a gale. The pressure-plate, or surface upon which the wind acts, shows the greatest departure from previous forms. This is the base of a cone, the axis of which is horizontal and attached to a bar, by which it is moved backwards and forwards on friction-rollers. This much of the instrument must be out of doors; but a chain attached to the horizontal bar passes down a tube, and is connected with the rest of it within any building fixed upon. At one end of the upper of the two curved levers mentioned there is a fixed weight, and to the opposite end of the under one

is attached the end of the connecting-chain. When there is a calm, the point of contact is at the fixed weight. When the wind blows against the pressure-plate outside, it causes the chain to lift on these levers, and then the point of contact moves to the other end; and as the pressure subsides, the levers readjust themselves. Attached to the under one is a string which draws a pencil to and fro along a cylinder in the direction of its length, which cylinder revolving on its axis by means of clockwork once in twenty-four hours, is covered with paper, on which the pencil-marks are made. The ground of Mr. Gaisner's approval of this instrument is the preference of curved levers over springs, as well as its inexpensive simplicity.

M. Soleil, a French observer, who, if there is anything in a name, should be an apt scholar in the department he has chosen for investigation, has invented an instrument to illustrate the invisibility of light, which he calls a tenoscope. It is a tube blackened on the inside, having one end open and the other closed, with a wide opening in the course of its length, by which a strong light is admitted crossways through it. On applying the eye to the open end of the tube, this stream of light is perfectly invisible; but the raising of a small ivory ball into the course of its rays, by means of a trigger, reveals its existence by reflecting a portion of its light. After realising the fact of the invisibility of light by the optical demonstration thus afforded, we contemplate with a new interest the heavenly bodies set in the firmament "to give light upon the earth, and to rule over the day and over the night." M. Soleil has also invented a new micrometer, which the Abbé Moigno exhibited to the members of the Association for the Advancement of Science at their Congress at Newcastle-upon-Tyne. It consists of two Ramsden's eye-pieces,—one fixed near the object to be measured; the other moveable, to suit the vision of the observer, with a ruled glass micrometer-plate placed between them. The Abbé explained that the magnifying power of the eye-piece being ascertained by a comparison of the object as seen directly with the same object seen through the micrometer, it became, by certain adjustments, applicable to the telescope, microscope, and even to goniometry.

Mr. W. Symons has effected some improvements in marine and mountain barometers, and in maximum thermometers, with indices, which appear to be of value. Marine barometers, as before constructed, were liable to fracture from sudden concussions, such as the firing of a large gun. This is one of the disabilities Mr. Symons has removed by substituting an elastic support for the tube for its usual rigid fixture into the cistern. Mr. Symons has distributed a considerable number of his thermometers in which he has substituted a composition, the basis of which is clay, for the graphite generally used, which, owing to occasional impurities, sometimes corrodes the mercury and soils the tube, and has been rewarded for his numerous experiments by hearing of no failure. Two French savans have also turned their attention to variations of these instruments. The Abbé Jeannon has devised a free-air barometer and thermometer of peculiar sensitiveness; and M. Naudet has constructed a metallic, or "holosteric," barometer.

The telegraph, like our railroad system, is looked upon by many as at a comparatively low stage of development to that it may eventually attain. Hence both theorists and practical men have turned their attention to this invention with much earnestness. The difficulty of transmitting messages across seas no longer existing, we can scarcely believe that there ever was one. We look forward to amplifications or simplifications that will enable the telegraph to print its messages, and even to speak it. Morse's instrument requires four wires for each letter, and the dial seven; but Mr. D. E. Hughes has produced a telegraph that requires but one electric wire. It has twenty-eight keys, like those of a piano, each of which corresponds to a letter, or number, or stop. When one of these keys is depressed it brings a detent in contact with a pin corresponding to that letter on the circumference of a revolving type-wheel, stops it, and at the same time sends an electric wave to the distant station where an electro-magnet detaches a similar detent, and, after stopping the same letter, a revolving cane presses a slip of paper against the type and takes off an impression. The keys may be touched, one after the other, with this result, nearly as quickly as one would touch those of a piano, and would render four words per minute a length of 2,800

miles, or six words in the same time a distance of 2,000 miles, or ten words per minute 1,000 miles, or twenty-four words per minute a length of 500 miles. Bonelli's telegraph consists of two tables of cast iron placed inversely to each other at the corresponding station, each provided with a miniature railway, over which run two wagons, one containing the type-set message, the other the paper, and two combs formed by the extremities of the wires of the line, one of which touches the type at one station while the other passes over the prepared paper at the other. A spring catch to each of the wagons sets them free to move by the closing of an electrical current. Mr. W. Cook, who furnished particulars of this instrument to the Association for the Advancement of Science, asserted that a well-considered system of counter-currents had completely annihilated the inconveniences which, from the time of Bain to the present moment, had existed in electro-chemical telegraphy, and that no difficulty could be experienced in working it either on long or short distances. Mr. W. Ladd proposes to convey from station to station a musical note or sound which, divided into various lengths and combinations, would form a sound alphabet similar to the signals written by Morse's telegraph. This instrument consists of two pieces of apparatus, the one for transmitting the signal having a small mouth-piece. We may best describe them in his own words:—"On the right-hand side there is a finger-key, forming part of the circuit, and an electro-magnet, with a vibrating armature and binding-screw to connect with one of the line wires. Within a case, under a glass cover, is an elastic membrane, in the centre of which is fixed a platinum plate in connexion with the finger-key. A light piece of angular metal, resting on three pins, is so placed that the pin at the angle rests on the centre of the membrane, the other two resting in cups on its edge, so as to allow of free motion on the points. In the body of the receiver box is suspended a soft iron core, surrounded by a coil of silk-covered wire, one end of which is in connexion with the finger-key and the other with the binding-screw. The method of producing sound in the receiving instrument depends upon the fact that, at the moment of magnetizing or demagnetizing a piece of iron, there is an alteration in the arrangement of the particles, which gives rise to a slight ticking noise. Having connected the transmitter, by means of an insulated wire, with the receiver, and the binding screws having been brought in connexion with a battery of three or four elements, if the finger-key on the transmitter be pressed, the person at the receiving station hears the ticking noise." When a sound is made into the mouth-piece, the membrane vibrates and breaks contact between the pin and plate in its centre, causing the iron coil in the receiving instrument to be magnetized and demagnetized according to the number of vibrations with a musical sound. The production of exact fac-similes of pictures, or music, or writing, is another phase of this wondrous power. M. Cassell has elaborated Mr. Bakewell's principle by the contrivance of two cylinders moving at the two stations synchronously by mechanical means of his own invention. For the purpose of transmitting short-hand accounts of speeches at public meetings, or other news, this would appear to be likely to be useful.

Professor Chevallier has devised a little instrument for ascertaining the height of a cloud. This consists of two horizontal jointed rulers, graduated from the centre of the joint, the unit of gradation being the length of an upright sliding-piece, movable upon either of the rulers. To take the height of a cloud, one branch of the rulers is directed towards the shadow of a cloud, the horizontal distance of which shadow from the place of observation can be ascertained; and the other, with the vertical sliding-piece, is directed towards a vertical line drawn through the point of the cloud which casts the shadow. When the inner edge of the sliding-piece is made to touch the inner edge of the other horizontal ruler, an exact miniature representation of the known horizontal distance of the shadow from the observer is given on the ruler and sliding-piece, as well as the height of the cloud above the horizontal plane on which the shadow falls. Clouds, by-the-by, have been recently found to exercise a peculiar influence upon photographs of scenery. Views taken beneath the clouds do not reproduce distant details, such as the foliage and stones on hill-sides. The magnifying-glass applied to them reveals only a bare and hazy surface, or indistinctness. Those taken above

the clouds, on mountain tops, give the minutest details at the distance of miles. The photographs taken by Professor C. Piazzi Smyth, in Teneriffe, exhibit this fact markedly. Those taken at high elevations depict every little hush upon a hill-side four miles and a half distant from the camera.

Within the last few days, Mr. Alexander S. Herschel described, in the course of one of his lectures, delivered at the Royal Institution of Great Britain, upon meteorology and storm-warnings, a new marine fog-signal. This is proposed by its originator, Mr. H. T. Humphreys, to be placed on dangerous shoals and rocks out at sea, or upon headlands in great channels of communication subject to fogs. It consists of a large wrought-iron tank and a tall tower, furnished with such contrivances within that the action of the tide will cause it ever and anon to utter a loud shriek, such as is produced by the steam-whistle. These recurring screams, or warnings, made by the waves themselves, would acquaint mariners of their proximity to danger, both in fogs and in the dark. Mr. Herschel remarked, and we agree with him, that it was impossible to over-estimate the importance of such a contrivance to the maritime interests of the world. If we were only to count up the fine ships and brave crews that have gone down to the bottom of the deep on one spot—say the Goodwin Sands—for the want of a fog-signal, we should beat our breasts in horror of the apathy or penny that withheld it, were it ever so costly. Mr. Humphreys estimates that his Tide-shriek, or Clamor *Æstus*, would not exceed the sum of 8,000l. or 9,000l. in such a situation as that mentioned; and this does not appear to be extravagant, considering that it is self-acting, sounding all day and all night, week after week, year after year, requiring only the occasional removal of such seaweed as would find its way through gratings provided for its detention, or that became detached from its growth in the interior, to keep it in working order as long as it would hold together. It is proposed to form the whole edifice of plates, angle irons and rivets, upon a foundation made of screw piles, or otherwise according to the nature of the site, the whole being stayed and strutted from within by lattice girders, diaphragms, gusset plates, &c., to such an extent as would render it impregnable to the severest storms. The contents proposed are the apparatus to produce the noise, called the hammer-whistle, and gear to raise a body of water to a tank formed by the sides of the tower, by means of which, in times of slack water or when the tide gives out no power, the whistling would still go on uninterrupted. Thus the tower is intended to serve a further purpose than merely to raise the whistle above the waves, or the densest strata of fog. Two reflectors duly shaped for the purpose into paraboloids of revolution would concentrate the sound, and reflect it to the circumference of a circle, the radius of which would be its greatest audible distance. Two turbines, provided with valves to regulate their action, would admit the tidal waters at the base of the tower, and drive pumps of lifting power proportional to the amount of available effect to be got out of them. These pumps, working alternately according as the outward or inward flow turbine was in motion, would fill the tank by means of ascending pipes. Thus the tidal waters in entering and leaving apertures in the base of the large tank, give out a certain quantity of power, which is taken up by these two turbines; and this power is applied to drive two pumps, which keep the smaller tank in the tower continually in the process of being filled. The power resident in this tank is abstracted to sound the whistle by the following means:—A pipe leads from the tank to another, but slightly smaller turbine, which is kept revolving in one direction. The shaft or axle of this turbine drives a pinion, which works into the teeth of a large wheel, and so drives a cam in continual revolution round its axis, which slowly raises and suddenly drops a heavy hammer block on to the piston of a small air chamber which is in communication, by means of a pipe, with a large steam whistle placed at the top of the tower. The hammer block thus allowed to fall on the piston of the whistle chamber strikes it with considerable accumulated force, and by the sudden compression of the contained air causes it to rush through the whistle in a strong and violent blast, which will make it shriek in a very marked and peculiar manner, strikingly distinguishable from and over or above other sounds heard at sea. We are glad to find attention has

been turned to this subject, as we so recently called attention to the inefficiency and scarcity of fog signals. The perils incurred by the approach and presence of fogs—dreary, damp, and dread visitors—are surely capable of diminution.

Such are a few of the results of recent study of the possibility of extending our knowledge, and improving our appliances in certain directions. Astronomy, perhaps, more than any other department of science, is most dependent upon, as well as indebted to, modern improvements in instruments; but the beautiful contrivances now in use at Kew and elsewhere, by which the heavens are photographed and surveyed, the heavenly bodies catalogued, and space explored till this globe, with what we consider its interminable forests, inaccessible mountains, untraversed tracts, and un navigable oceans, yet closed to man, is dwarfed to a speck, require separate mention.

#### A DEATH MARCH IN INDIA.

If new instances were needed to show the want of sanitary knowledge, or, at any rate, of the use of this knowledge, amongst the officers of our army, the recent fatal march of a detachment of artillery from Mhow for Mahabaleshwar would be sufficient. It affords a fearful example of the want of knowledge of the laws of health which is shown by those who, in chief command, have charge of the lives and health of large numbers of their fellow men. As our readers may have seen, after three marches from Mhow, the ill-fated detachment arrived at Bulwara on the 15th of May, in good health (they left the first-named place on the 13th of May). At Bulwara the cholera broke out, and, day after day, cases became so numerous, that the detachment was sent back to Ilusora, a village 3 miles from Mhow. Here the authorities had made every needful arrangement. Fresh tents were pitched, and all necessaries were supplied; and then the mortality (so say the reports) ceased,—another instance of the certainty of the possibility of stopping this pestilence by means which can be easily obtained by those who are willing to use them.

At present the number of the detachment which was attacked by this deadly enemy is not exactly known; but it is said that the force did not count more than 120, and that, during this march, which occupied only seven or eight days, 21 men, 1 woman, and four children died,—in all, 26 deaths, or nearly a quarter of the detachment.

All past experience and well-directed inquiry show that the cholera, by the wise use of medicine and by the choice of good resting-places for troops, can be as surely kept in check as a well-trained horse can be by the skilled hand and the bridle, or the well-lined ship by the properly-hung rudder.

In connexion with this fatal march, we cannot but think of its increased terrors if 2,000 or 3,000 men and the camp attendants had been moved, instead of 120. In an army of 3,000 we should have had, perhaps, 700 deaths. In the notices of the Crimea, and, indeed, in all the accounts we have of modern warfare which have been written since the truths of sanitary science have become better understood, we see that the number of those who have been actually killed in the raging of the battles is but trifling in comparison with the deaths which occur from the want of clothing, food, medical treatment, the ill-chosen position of camps, and the abominable lodgings which are provided for both the healthy and the sick.

It is now several years since the black shadow of the coming of the war with Russia urged us to give notes of military preparation, after a long period of comparative peace. We went to Aldershot at the first formation of the camp there, chiefly for the purpose of gathering some notes for this journal, and the scene of confusion which met the eye would have struck any one except those who were harassed by military ideas as most extraordinary. The operations which were going on would have seemed to any one possessed of common sense, ridiculous, and worse than useless. We had here in this locality no enemy to contend with except that natural one which would strike at the health, and even the lives, of those splendid regiments of picked men; and yet, although the distance from London by rail, and a short way by other conveyances, might have been managed in less than a couple of hours from the

Horse Guards, it would seem that no sufficient person had been sent, before the men were marched to this isolated locality, to look even for water. The sight of the staff, at the head of which there was a famous general who is now no more, looking for water, would have made a subject which our contemporary *Punch* might have treated in his most effectively serious vein. It was laughable, but it had also its tragic side, as was soon after shown, in those terrible losses and privations which took place in the front of Sebastopol. Scarcely a tithe of the soldiers whom we saw cast with so little judicious care on this wild moorland are, we fear, now living. At the head-quarters, there was no little difficulty in obtaining information, and facilities for making inquiries, or even a due amount of civility from officers who, in the usual course of the life to which they had been accustomed, would have felt it a pleasure to have aided those who were engaged in seeking for the truth in connexion with matters in which the public are deeply interested. On this first visit, we left the camp with feelings of thankfulness for the long peace, and praying that, if this might be judged as an example, these islands might long be spared from the effect of military discipline. As years have passed along, the ideas and fears which we expressed at its formation have unfortunately been realized, and we fear that the mischief of this camp is not yet at an end.

For the sake of our soldiers—for the sake of the country—we hope that the rising class of officers will, in many respects, be different from the generation which is passing away, and that they will not forget that the *Times* reporter stirred up the nation to the sad state of the Crimean army; that the firm of Sir M. Peto made the railway from Balaklava, made the railway which took food and the munitions of war to Sebastopol; and then, that the medical staff of the Sanitary Commission, and the nurses under Miss Nightingale's charge, were the means of giving us victory in the Crimea; for without these aids the untiring skill of the officers and the endurance and bravery of the men would not have been sufficient to have prevented the Russians from driving both French and English into the sea.

Surely the loss of lives which has recently occurred in India will form a subject for the most careful inquiry. It is said, that before the troops moved from Mhow, it was telegraphed to head-quarters that the route had been attacked by cholera. *Is this really a fact?* Also, that no medical staff or medicine was forwarded. If this were the case, the persons who died were sent carelessly into death's mouth. Who is to blame for this? Surely, lest greater evil should happen, we should in this case undo the red tape and let it be known who is really responsible for these deaths.

#### THE OLD TOWN OF EDINBURGH.

BEFORE concluding our notice of the Old Town of Edinburgh, let us say a word or two on the few ecclesiastical buildings of the old time which it yet retains. They are easily enumerated: the Royal Chapel of Holyrood; Magdalen Chapel, in the Cowgate; the *Collegium Sacerdotum*, in the College Wynd, to which we have already alluded; the collegiate Church of St. Giles; Queen Margaret's Chapel, on the Castle rock; and the beautiful Church of the Holy Trinity, whose stones now lie at the side of the Regent-road. They are the more valuable, that of all the churches erected since the Reformation, as was truly said by the late Dr. Mems, an eminent judge of such matters, there is scarcely one which is not a positive deformity.\*

As St. Margaret's is undoubtedly the oldest building in Edinburgh, and probably the smallest, as well as the most ancient, chapel in Scotland: it merits priority of notice. It was dedicated to Margaret, the pious consort of Malcolm III, who died within the Castle, "which she had dignified by her residence and edified by her death," which took place in November, 1093. It is a small oblong building, on the south side of the High Battery, about 30 ft. in length, the walls being of equal height, and showing nothing of the division observed in the plan of the interior. Till very recently, this unique chapel was used as an ordnance lumber-room; to serve which purpose, the arch between the chancel and the spire had been bricked up. It has, however, of late years been restored, the blocked doorway

opened, and the windows filled with stained glass.

In the north wall, close to the western extremity, in accordance with a common arrangement in small Norman chapels,\* there is a plain square-headed doorway. There is another very similar to this in the west wall, with a small semicircular window over it. There is another window of the same description in the south wall, while the rest are square-headed, and were originally extremely narrow.

The chapel consists of a chancel measuring 16 ft. 4 in. by 10 ft. 4 in., and of a semicircular apse 10 ft. 4 in. long by 9 ft. 7 in. wide.

The semicircular arch, which separates the chancel from the apse, is of beautifully-wrought Norman work, and consists of two zigzag or chevron-moulded orders, with a trigonal hood, finished on the intermediate face with a string of lozenge-shaped ornaments, the pattern of which is changed as it approaches the springs of the arch. Within the apse the arch presents but one order, and has no hood. Two pillars, most probably cylindrical, have originally supported the arch; but have long since disappeared. The capitals, however, still remain, and two of the bases. The former are escalloped, and are surmounted by heavy abaci, which are returned on both sides of the arch.

The roof of the chancel is modern. The apse has an alviced ceiling, devoid of ornamentation. The east window of the latter is a plain square-headed trefoil.

Undoubtedly one of the most interesting of the antiquities of Edinburgh is the little chapel whose antique battlemented tower and spire arrest the attention of the passer along George the Fourth's Bridge, and which was erected "to the praise and honour of Almighty God, and of his mother—the blessed Virgin Mary, and of Mary Magdalen, and of the hail celestial court." The chapel, along with a hospital for the support of seven poor men, was left by the will of Janet Rynd, the widow of an opulent citizen, Michael Macghean, in trust to the Corporation of Hammermen. The charter is dated 1505, which gives us an approximation to the date of the building. The steeple, however, is of more recent times, for one of the tablets on the walls of the chapel records that "John Spens, burgess of Edinburgh, bestowed a hundred lods of Westland lime for building the steeple of this chapel, anno 1621," and the bell bears these two inscriptions round it in Roman letters: "God Biss The Hammermen of Magdalene Chapel," and "Soli Dei Gloria. Michael Burgerhius Me Feci, Anno 1632."

Little can be seen of the exterior of the chapel beyond the north doorway, and the square tower and steeple which surmount it. The windows on either side of and above the doorway are restorations,—if, indeed, the work is admissible here,—in a style quite incongruous with the rest of the building. The tower is square, and divided into four stages by string-courses. Each side of the third and fourth stages has a square window, with good moldings; and in the fifth there are pointed-arched windows filled with louvre boarding, and partially concealed by quaint-looking convex clock-faces. The upper part of the tower has a battlemented parapet resting on small but neat corbels, from which project curious cannon-shaped gurgoyles. From within the parapet rises a graceful octagonal spire, finished with a weathercock. The angles of the octagon are ribbed, while a centre rib divides each of the eight faces.

In an ornamental stone tablet over the door are sculptured the crown and hammer, the armorial bearings of the incorporation of hammermen, with the date 1553. On the pediment above it is the date 1643, and at the sides are two quaintly-sculptured figures, the one with a hammer, and the other with a chisel.

The interior contains some fragments of the original painted glass, which by some fortunate chance escaped the iconoclastic destruction of the year 1553. Among these are a figure of St. Bartholomew, and the royal arms of Scotland, encircled in a wreath of thistles, those of the Queen Regent Mary of Guise, within a laurel-wreath, and those of the foundress and her husband. With the exception of the Bartholomew, they retain all the brilliancy of colour which distinguished the work of the old glass painters. There is a number of mural tablets on the north and east walls, and at the east end is a sculptured slab, with an inscription round its border.

\* The chapel in the castle of Cransgillar, situated a mile and a half to the south of Edinburgh, may be cited as an instance.

\* "Edinburgh Literary Journal," vol. i. p. 25.

in old Gothic letters, which records the death of the foundress. Her armorial bearings, and those of her husband, impaled on one shield, occupy the centre of the slab. It is extremely probable that this is the top of an altar tomb, being level with a wooden platform, which has been erected in modern times.

This chapel is interesting from the fact that John Craig, a converted Dominican monk, who made his escape from the dungeons of the Inquisition at Rome, and was afterwards the colleague and successor of John Knox, and who refused to publish the ban of marriage between Queen Mary and Bothwell, preached in it for a considerable time in Latin, having, from his long absence from his native country, forgotten the use of his language.

The body of the Marquis of Argyll lay in this chapel for some days in 1661, while his head was affixed to one of the gables of the Tolbooth, until it was removed to the family sepulchre at Kilmun.

The chapel is situated on the south side of the Cowgate, and is now used as a place of worship by a congregation of Dissenters.

Come we now to the Collegiate Church of St. Giles:—

" Hoar relic of the past, whose ancient spire  
Climbs heavenward amid the crowded mart;  
Keeping as 'twere within the city's heart  
Gleams, where reverend thoughts may yet retire;  
And dreaming fancies, from the world's spurs,  
Wander among old tales, of which thou art  
Sole relic. Is it vain that we inquire  
Somewhat of scenes where thou hast borne a part?  
Mine own St. Giles' old fashions have gone by,  
And superstitions,—even of the heart:—  
Thyself hast changed some wrinkles for a smart  
Gleam of modern fashion. To my eye,  
The old one had bemused thee, yet the more  
Cling to it what remains, the soul of yore."

In these beautiful lines, the poet not naturally mourns sadly on the changes effected on this building, more particularly in the year 1829. The entire structure west of the central tower was then in a manner rebuilt; the most of the windows were restored in a mixture of bad Flamboyant and worse Third-Pointed; while the interior was impaired,—nay, all but ruined,—by the erection of unsightly galleries and pewing. The great eastern window is fortunately an exception to the bad taste displayed in these repairs, the tracery being an exact *fac-simile* of the original. The interior of the choir remains on the whole in a very perfect state of preservation; and the graceful open lantern, which forms so conspicuous an object to persons approaching the city, remains as it was rebuilt in 1648 on the model of the original tower. The greater number of the numerous altars and chapels, which pious people had founded within the church through successive ages, was destroyed by the blind zeal of the Reformers.

The main portion of St. Giles's was doubtless erected towards the close of David I.'s reign, or in that of his successor, Robert II. In 1466 James III. erected it by charter (it had been merely a parish church before) into a collegiate church for a provost, a curate, sixteen prebendaries, a sacrist, a bedel, a minister of the choir, and four choristers. About the same time, the choir was lengthened by the addition of the two eastmost arches, and had a clerestory added to it.

The church is cruciform in plan, with a tower at the intersection of the transepts by the choir and nave.

The choir is 88 ft. long by 26 ft. 7 in. wide, with north and south aisles, each about 20 ft. wide. The architecture is very pure Middle Pointed. The four piers on either side at the west end are plain octagons, with capitals consisting of one or two sharp-edged mouldings, surmounted by square-edged abaci. The two eastmost arches, those last erected, are wider and loftier than the others; the pillars, one of which is a respond, being formed of a cluster of eight large-pointed half-rounds, divided by triangular flutings. The capitals are ornamented with mouldings, many of which are cut out in an ogee curvature, and are decorated with cherubs' heads and blazoned shields, which project and hang down from the cardinal faces of the abaci. The north-east, or King's Pillar, as it is styled, bears on its east and west sides the royal arms of Scotland; on the north side, the arms of Mary of Gueldres impaled with the royal arms; and on the south those of France. On the pillar opposite are the city's arms, those of "the Good Bishop Kennedy," of Nicolson, and of Preston of Craigmillar. The pier arches are obtusely pointed, the two farthest east being loftier and set wider apart than the others. The bases of

these piers are fully spread, 3 ft. in height, and richly ornamented with foliated sculpture. The mouldings, among which the ogee prevails, follow the arrangement of the shafts of the column. The bases of the plain piers are concealed by the modern flooring.

The roof of the choir is beautifully groined, the ribs being tied at the intersections by a rich variety of bosses, some of which are very large. On the centre boss, at the division of the two eastmost compartments, is a large shield, with the monogram of Our Lord, I.H.S., and on that next it, round a carved centre, is the abbreviation: "Ave Gra. Pla. Dus. Tecu" (*Ave Maria, gratia plena, Dominus tecum*, the same legend as that which we have mentioned in the Collegium Sacerdotum in the College Wynd). The suspended vaulting-shafts have floriated capitals and corbel or bracket terminations, and their semicylindrical rolls are handed together by a string-course, which runs along the clerestory beneath the windows.

The aisles have vaulted roofs, carrying plain chamfered transverse and diagonal ribs, with shields and foliage-knots at the intersections.

An additional aisle, of three arches, to the south of the choir, has a finely-groined roof. It is known as the Preston aisle, having been erected in 1454 by the city of Edinburgh, in gratitude to William Prestonne, of Gortoune, for having presented the city with the arm-bone of its patron saint,—St. Giles. The charter sets forth, "yat forasmekle as William of Prestoun, the fadir, quham God assollie, made dilligent labour & grete menis, be a he and mighty Prince, the King of France, & mouy yur Lordis of France, for gettyng of the arme bone of Saint Gele,—the quhilk bone he freely left to our anoyr Kirk of Saint Gele of Edinburgh, withouthyn any condition makyn,—we, considring yo grete labouris and costis yat he made for the gettyng yrof, we p<sup>nt</sup> as said is, yat within six or seven zere, in all the possible & gudly haste we may, yat we sal big ane ile, furth fra our Lady Ho, quhare ye said William lyeis in the said ile, to be begunyin within a zere; in the quhilk ile yare sal be made a brase for his crest in bosit work; and above the brase a plate of brase, with a writ, specifand the bringing of yur relik be him in Scotland, with his arms; & his armis to be put, in hewn marble, yur three parts of the ile."\*

The privilege was further granted to Preston's lineal descendants of carrying St. Giles's arm-bone in all public processions. This relic, as well as a wooden image of the saint, were held in high veneration, until the reformed faith began to take root. In 1553, Sir David Lindsay, of the Mount, whose satirical exposure of the vices of the clergy had no small share in the overthrow of the Roman Catholic religion in Scotland,† published his "Monarchie," in which he thus refers to the bearing of the image of St. Giles in public procession:—

" Of Edinburgh, the greit idolatrie,  
And manifest abominatioun,  
On their feist day, all creature may see:  
They beir ane said stok image through the tonn,  
With tabrone, trumpet, schalme, and clarion;  
Quhilk he bene veit many ane year bygone,  
With priests, and frairis, into processioun,  
Siclyke, as Bell was borne throuch Babylone.  
Fy on you, feirist! that nis for to preiche,  
And dois assist to sik idolatrie:  
Quhy do ye veit the ignorant pepill teiche,  
How ane feild image carrit of ane tre,  
As it was haly, said nocht honourit be;  
Nor borne on burges backis, up and down:  
Bot, ye schaw planelic your hypocrisie,  
Quhen ye pas forment in processioun.  
Fy on you, fosteraris of idolatrie!  
That till ane said stok, dois sik reverence,  
In presens of the pepill publicklye;  
Feir ye nocht God, to commit sik offence?  
I counsell you do yit your diligence,  
To pas suppress this greit abusioun:  
Do ye nocht sa, I dreid your reconpence,  
Sal be nocht ellis, bot elene confusioun."

The "recompence" was not long of following. In 1558 the image was carried off from the church by the mob, who first drowned it in the North Loch as an adulterer (!) or encourager of idolatry, and then burned it as a heretic.‡ This occurred a few days before the 1st of September, the anniversary of St. Giles, on which day the image was wont to be borne through the town by the clergy in procession. A substitute, however, was obtained for "the auld St. Gele," the priests horrowing a small statue of the saint from the Grey Friars. This they secured with

\* "Archæologia Scotica," vol. i., p. 375.  
† In fact, Sir David was more the reformer of Scotland than John Knox, for he had prepared the ground, and John only sowed the seed.—*Pinkerton*.  
‡ Calderwood's History, vol. i., p. 341.

iron clamps to the feretoric shrine, in which it was borne aloft. On the 1<sup>st</sup> of the day, accordingly, this image was borne with great pomp through the streets of Edinburgh, a large assemblage of the clergy and the Queen Regent taking part in it. No sooner had the Queen left it, to go to dinner, than, as John Knox says, "some of them drew near to the idol, as willing to help to bear him up, and getting the feretoric upon their shoulders, begaune to shudder, thinking thereby the idol should have fallen. But that chance was prevented by yron nails. Then began one to cry, 'Down with the Idol! down with it!' So, without delay, it was pulled down. The patrons of the priests made some brags at the first; but when the priests and friars saw the feeltleness of their god, they fled faster than they did at Pinkey Cleugh. One of the professors, taking Saint Giles by the heels, and dadding his head to the canseway, left Dagon without head or hands, exclaiming, 'Fy on thee, young Saint Giles, thy father would not have been so used!' The friars fleeing, down go the crosses, off go the surplices, round caps and cornets with the crowns. The Grey Friars gaped, the Black Friars blew, the priests panted and fled, and bappy was he that got first to the house, for such a sudden fray never came among the generation of antichrist within this realm before."

The arm-bone of St. Giles was probably lost in this riot. At any rate, it is not heard of again.

There is one other incident connected with St. Giles and the establishment of the Presbyterian forms of worship, for which we must find a place. Charles I., who was bent upon the establishment of episcopacy in Scotland, created Edinburgh into a diocese, and appointed St. Giles's as its cathedral. On Sunday, the 23rd July, 1637, the dean, clothed in a surplice, ascended the reading-desk and opened the service-book. Immediately confusion and uproar ensued. The dean being quite non-plussed, his bishop called to him from the gallery to proceed to the collect of the day. The dean was about to do so, when an old green wife, Jenny Geddes by name, seizing the cutty-stool upon which she sat, and which is still preserved in the Antiquarian Society's Museum, hurled it at his head, exclaiming, "Colic! De'il colic the wame o' thee! Out, thou falso thief, dar'st thou say massat my lug?"\* The tumult became general, and the magistrats had great difficulty in clearing the church. The bishop was mobbed on the street, and narrowly escaped with his life, being rescued by the Earl of Wemyss, who sent a party of servants to his aid.

Among the so-called improvements of 1829 was the demolition of the Regent Murray's tomb, which stood on the west side of the south transept, which is generally styled the old church. Fortunately, it has been re-erected within the last few years. "The good Regent's" remains were, after his assassination at Linlithgow, deposited in this tomb on the 14th of February, 1570, when "Jobne Knox, minister, made ane lamentable sermond touching the said murther," and drew tears from the eyes of all present. A brass plate on the front of the tomb has the figures of Justice and Faith engraved on it, and the following inscription, which is from the pen of the accomplished historian, Buchanan:—

" Jacobo Slovarto, Moravie Comit. Scotia Prætori;  
Viro, ætatis sue, longæ optimo: ab inimicis,  
Omnis memorie deterritis, ex insidiis extincto,  
Cæo patri communi, patria meritis possit."

To the left of this inscription is the motto, "*Pietas, sine vniuersæ, loquet*," and on the right side, "*Jus exaratum est*;" while above are sculptured his armorial bearings.

This part of the church was long an open lounge for idlers, as also a place appointed for the payment of bills. Dining with Duke Humphrey has become proverbially synonymous with not dining at all; and a similar jest was at one time in vogue about the Regent Murray. Thus Robert Sempiell says, in the poem already alluded to,—

" Then I knew na way how to feul (struggle);  
My guts rumbled like a Hurtle-Barrow;  
I din'd with snots and noble men,  
E'en sweet Saint Giles and Earl of Murray."

To the east of this tomb is the sepulchre of the great Marquis of Montrose, whose scattered and mangled remains were re-interred there "very honourably and sumptuously" on the 7th of January, 1661.

\* Knox's History, p. 95.  
† Carlyle's "Cromwell," vol. i., p. 137.

The rich groining and vaulting of the south aisle of the nave, together with its light and beautiful shafts, merit notice.

The beautiful open lantern, which surmounts the square central tower, has been much and deservedly admired. It resembles somewhat the lanterns of St. Nicholas, at Newcastle; King's College, at Aberdeen; the Tron at Glasgow; and Chambord, in France,—all of which, however, it is generally admitted to surpass in grace and beauty. These had merely been formed by two crossed arches springing from the corbels of the tower; but in St. Giles's thro spring from within the gurgoyled and open quatrefoiled parapet eight beautifully crocketed flying buttresses, converging towards one another, and supporting an octagonal pannelled piece of masonry, from which, amid a cluster of small pinnacles rising tier over tier, rises a small and graceful octagonal spire, terminating in a cone and weathercock. The parapet, which besides being pierced by quatrefoils, has cusps on the upper edge, rests upon corbels, from which project cannon-shaped gurgoyles. Speaking of St. Giles's and the old Parliament House and Close, one has said,—

"A scene of grave yet busy life  
Within the ancient city's very heart,  
Teeming with old historic memories, rife  
With a departed glory stood apart.  
High o'er it rose St. Giles's ancient tower  
Of curious fretwork, whence the shadow falls,—  
As the pale moonbeams thro' its arches pour,—  
Tracing a shadowy crown upon the walls."

We find allusion made to this crown in a ballad descriptive of Gavin Douglas's visit to St. Giles's altar immediately after the disastrous battle of Flodden Field, quoting a verse or two of which we shall take leave of this old collegiate church.

"— Douglas sought nigh the noon o' night  
The altar o' gude Sanct Giles,  
By the hal' quire, whar the glimmerand light  
O' the Virgins' lamp gae the darkness sight  
To fill the eerie aiesles.

Belye, as the boom o' the mid-mirk hour  
Rang out wi' clang an' mane;  
Clang after clang, frae Sanct Giles's tower,  
Whar the fretted ribs like a bontree tower  
Mak a royal crown o' stane.

Or the sound was tint—fore mortal ee  
Ne'er saw sic sight, I trow;  
Shimmering wi' light lik canny,  
Filler an' ribbed arch an' fretted key,  
Wi' a wild unearldy low."\*

#### MR. FERGUSSON ON THE HOLY SEPULCHRE.

In your issue of the 3rd ult., a short notice appeared of Mr. Fergusson's new volume on the Holy Sepulchre and Temple of Jerusalem.

In the preface of this work, Mr. Fergusson complains of the treatment which it has received, and intimates that it is his desire that his theory should be carefully investigated, and that any arguments which can be adduced against it should be brought forward, in order that what is good in it may be established, and what is erroneous may be laid aside.

Most of your readers are probably aware that there exists at Jerusalem at the present day a church which is traditionally held to occupy the site, and to inclose the relics, of that sepulchre in which our Lord was laid, and which is also generally believed to be built on the same spot on which stood the basilica which Constantine erected in Jerusalem on the discovery of the Cross and tomb by the Empress Helena, his mother.

This, however, is not the opinion of Mr. Fergusson, for there is also at the present day, on the opposite side of the city, a large level space or inclosure, measuring about 900 ft. from east to west, and 1,500 ft. from north to south, in the centre of which, on a slightly-cleaved platform, is an octangular building with a magnificent dome, generally supposed to have been erected by the Caliph Omar in the seventy-second year of the Hejira, and which has received, from the extraordinary excavated stone or rock in the middle of the drum, the name of the "Khalat Es Socrab," or Dome of the Rock. Now this mosque, placed in the centre of an inclosure which is traditionally supposed to have been occupied in the time of our Lord by the magnificent temple of Herod, Mr. Fergusson supposes to be the very building which Constantine erected over the site of the Holy Sepulchre.

The opinion of so eminent an architect must, of course, be of great weight in treating of such a subject; but the theory is in itself so

extraordinary and unexpected, that I would ask your permission to make a few remarks concerning it.

The first argument which Mr. Fergusson brings forward to prove the identity of this Mosque of Omar and the church of Constantine, is the date of the style of the former. He gives us the latest buildings previously to the time of Constantine, and shows us what style prevailed at that date. The arch had begun to supersede the horizontal entablature, and the arched and flat styles were struggling together. In the one instance which he gives, the palace of Diocletian at Spalatro, built towards the close of the third or at the commencement of the fourth century, the entablature remains above the pillars, but the architrave is rounded into arches supporting a horizontal cornice, while in another part of the building the whole entablature rises into an arch over the principal gate. The pillars found in this building are of the Corinthian order, and are mounted on "stools" or square blocks of stone.

Mr. Fergusson next gives an example of what style had become in the early part of the sixth century, and shows how an arch which in its ornamentation and moulding approaches nearer to the work of more modern times, had superseded the entablature, and was supported by a pillar no longer classic, but crowned with a bulging capital, contrasting greatly with the hollowed form of the Corinthian, which is covered with rich mouldings of conventional foliage. Between these two epochs Mr. Fergusson informs us that no example of style is to be found; but he infers a gradual change from the horizontal to the arched style, which must have been going on between the fourth and sixth centuries.

Mr. Fergusson next turns his attention to the style of the Mosque of Omar and to that of the Golden Gateway, a closed portal on the eastern side of the great inclosure.

In the first of these buildings he finds a style which he supposes to be transitional between the two before mentioned. Pillars, of Corinthian order, but of apparently late date, standing on "stools" like those of the time of Diocletian, support a horizontal entablature, of which the architrave, owing to the wide intercolumniation of the pillars, is only represented by square blocks of stone over each column, upon which stands a wooden cornice, the frieze being omitted. From this entablature, or, rather, from this cornice, spring regular semicircular arches, highly ornamented with Saracenic arabesques; and this structure of a horizontal cornice supporting an arch, Mr. Fergusson considers to be a natural transition from the first arching of the entablature to the formation of a regular arch.

On the exterior side of the Golden Gateway, which is the next building that he mentions, a style of architecture is found which would appear to be of the time of Diocletian, namely, an architrave bent into the form of two regular arches, supporting a horizontal cornice; and this circumstance would seem to indicate the date of the Golden Gate as not later than the commencement of the fourth century, or about the same date as the Mosque of Omar. On the interior side of the gate-chamber Mr. Fergusson finds an order which he considers may be attributed to the same date. The closed entrance has on either side a pilaster, which supports a horizontal entablature, surmounted by an arch which is in the form of the arc of a circle, and on the opposite side of the chamber is a similar entablature and arch, while above the two rise flat domes with pendentives. The pillars in this building are of the Corinthian order, and the entablature is not structural, but merely ornamental, of which style of building no examples are found later than the fourth century, though they abound before that date; and hence, and from the similarity of structure between the Golden Gate and the Mosque of Omar, Mr. Fergusson concludes that both buildings may be attributed to the commencement of the fourth century, the date of the Emperor Constantine.

He next compares these buildings to the various octangular edifices erected by that monarch in Europe, about the time that he built the Basilica of Jerusalem, and describes them as bearing a great resemblance to one another.

Thus Mr. Fergusson concludes that the Mosque of Omar and the Golden Gate are works of Constantine. The answer to this argument does not appear to be very difficult, for, first, there is some doubt concerning the contemporary date of the two buildings; and, secondly, there is some doubt whether either can be attributed to the time of Constantine.

1. If the order of the Golden Gate be compared with that of the Mosque of Omar, it will soon be evident how different they are. In the Dome of the Rock a pillar, which Dr. Richardson considers not to be truly classic, standing on one block of stone and supporting another, has for its capital one covered with deeply-indented leaves, from which the volutes rise with a graceful curve. In the Golden Gateway a pilaster which, far from standing on any stool, appears to have no base of any kind, is crowned with a capital of clumsily-worked leaves, unserted and ungraceful, shorn of volutes, and with no architrave block above it. In the first building a screen (or entablature, as Mr. Fergusson calls it), made of wood, runs from pillar to pillar, unsupported by the wall, and is covered with mouldings, which, especially in the case of the graceful arabesque running along the centre, approach nearer to the Saracenic than to any classic style. In the Golden Gateway, a whole entablature, of which the modillions, dentils, and other mouldings are all classic, is built against the wall, and supports an unornamented arch in the form of the arc of a circle; while the arches of the Dome of the Rock are semicircular, or, according to Dr. Richardson, slightly pointed. Mr. Fergusson himself admits that, judging from style alone, the two would not be supposed to be of the same date, and gives as an answer that the temples which were built in Rome a century after the Flavian amphitheatre would, judging from style alone, be thought to be even earlier; but in the present argument, style alone is being considered, and if it differs, the conclusions drawn from it cannot be certain.

2. The second question which arises is, whether or no the style of the Mosque of Omar is really transitional; for although nothing could be more natural than that when the arch replaced the horizontal beam, a style more in accordance with circular work should replace the architrave, frieze, and cornice; yet that this should be affected by a transition from an arched architrave to a horizontal entablature supporting an arch, and thence to a regular arch, is, to say the least, not natural.

3. Mr. Fergusson himself points out the difference between the architecture of the Mosque el Aksah, of the seventh century, on the southern side of the inclosure, and that of the time of Constantine; yet in this building, and in the fourth building he mentions, namely, the Dome of the Chain, close to the Mosque of Omar, of which it is said to have been the pattern, we find other instances of the peculiar structure alluded to before, namely, a wooden beam or cornice over the pillars, supporting arches.

It may also be doubted whether or no this beam in the Mosque of Omar is entitled to the name of an entablature, for it is not natural that a stone architrave should support a wooden cornice belonging to the same entablature; and, again, it is doubtful whether the blocks above the pillars do really represent the remains of the architrave, for in the Saracenic architecture of Spain, even later than the seventh century, we find such blocks over apparently Corinthian pillars supporting arches only, and without cornice of any kind.

Again, it must be remarked, that this screen does not support the more important part of the building, for the dome, the drum, and the part without the screen, are of Saracenic architecture, such as is found in Egypt and Syria, as also are the pointed arches round the sacred stone and the graceful arabesques which cover the interior of the whole dome.

4. The fourth remark touches on the real style of the time of Constantine. There exists at Bethleem, at the present day, a basilica, built, according to tradition, by that emperor, and mentioned by Eusebius and other writers as having been executed by his orders and completed during his reign. This has been proved in an apparently satisfactory manner by M. Vogüé, who has also shown that this building escaped the general wreck in which so many of the Christian churches perished. Surely to this building we should turn for an example of the style of the time of Constantine, especially considering that Eusebius states it to have been similar to the basilica of Jerusalem; but here we find a style which, though somewhat similar to that of the buildings of Constantine in Europe, is unlike that of the Golden Gate and the Mosque of Omar.

Again, although Mr. Fergusson affirms that no traces of the basilica are found in the present church, yet Mr. Vogüé has discovered there several remains which, from their style, he

\* To be continued.

tributes to the time of Constantine, and from them he has made a restoration of the church and basilica fitting with the conformation of the ground and with the description of Eusebius, and forming a single edifice similar to that of Bethlehem. M. Vogné has also proved that only one building existed in the time of Constantine, and that afterwards it was replaced by the four churches described by Aurelianus.

5. Finally, if the buildings of Constantine in Europe are compared with the Mosque of Omar, they will be found to differ from it materially; for instance, in the tomb of the emperor himself, instead of pillar, cornice, and arch, we find a row of pillars supporting a light frieze and cornice surmounted by a second order of pillars, the only resemblance being in the octagonal form of the building. This structure is nearer to that of the basilica of Bethelcham than to the Mosque of Omar.

Such is the answer to Mr. Fergusson's first proof of the identity of the Mosque of Omar and the holy sepulchre of Our Lord.

C. R. C.

DECORATIONS FOR DINNER TABLES.

ROYAL HORTICULTURAL SOCIETY.

It will be remembered that Sir Wentworth Dilke, some time ago, offered three prizes for the best floral decorations for dinner-tables, or rather for the dinner-tables best decorated florally. Beautiful arrangement was the object sought, valuable fruit or flowers or china not being required. On Saturday last, the competition took place, and the judges made the following award,—

First prize, 10l. 10s., Messrs. W. P. & C. Phillips, 155, New Bond-street.

Second prize, 7l. 7s., Mrs. Dalton, the Haven, Ealing.

Third prize, 3l. 3s., Mr. A. D. Chapman, 22, Norfolk-street, Park-lane.

Commended: Mrs. Naylor, 7, Princes-street, Cavendish-square.

The following prizes offered by the proprietors of the *Gardener's Chronicle*, for flowers grown in a lady, were awarded as follows, viz. —

One Lady Doneraile, 9, Grosvenor-place, for a fine foliage plant, 10l.

Miss A. M. Williams, Sutton House, Highgate, for an orchid, 10l.

Spite of gallantry, the judges being ladies, we must dissent from their decision. The only table of the three rewarded that exhibited any originality and a right knowledge of how a dinner-table should be decorated, was Mrs. Dalton's, and to this the first prize was certainly due. The flowers, in small receptacles, quite flat, formed patterns on the table, and there was nothing whatever to interrupt the view. The colours of the flowers might have been better harmonised, but the thing was done on the right principle. The table to which the third prize was given (displaying some very well chosen flowers) had a heap of greenery in the centre that would render general conversation impossible. The same objection, in rather a less degree, applies to the first prize-table. We take the credit of having led in some quarters to a reform of our dinner-table in this respect, and have the more regret, therefore, that the judges did not keep it strictly in view. The only result of the present competition will be to advertise the wares of an already well-known and esteemed firm.

CONSUMPTION OF SMOKE IN FRANCE.

By a ministerial decree published in January last, in France, it is enacted that "All furnaces of boilers, of whatsoever class they be, are to consume their own smoke. Six months' delay is accorded to manufacturers to whom no notice was given at the time of authorisation to execute these last dispositions." Consequently, all attention has been directed to smoke-consuming apparatus, especially those of Beaumais, Palazot, and Thierry; but none of these have yet offered a practical solution to the problem. Meanwhile, M. Alfred de Pindray, civil engineer at Novion-Porcien (Ardennes), has invented a system of furnace which has been for several months successfully at work in the large factories at Sedan and the neighbourhood. The firms of Chéry, de Labrosse Frères, E. de Montagnac de Fils, Berteche, Baudoux, Chéouon et C<sup>ie</sup>, Collette,

Villette, J. B. Vilain, &c., all first-class manufacturers, have borne testimony to the practical working of this invention, and to the economy of about 20 per cent. upon the old system of fire-grate. The absence of smoke is almost complete: we say, almost, because when fresh coal is put on there is a burst of smoke, lasting, however, only for 30 seconds. Mr. C. A. Castagne, spinner, at Wé, near Carignan, and consul of America in France, has certified to a saving of 35 per cent. by the use of this furnace. It is constructed, as usual of refractory bricks: the sides are carried up vertically from the bottom of the ash-pit. Where there are two or more cylindrical boilers attached, the sides of the furnace are in line with the centres of the two outside boilers, and carried up as far as 4 in. below the bottom of the boilers. From this point the masonry contours the boilers as far as the junction with the main boiler, preserving a distance of 2½ in. between the bricks and the boilers. If there be only one boiler, the sides of the furnace are carried up, so that if produced they would pass 3 in. within the width of the boiler at each side, and are turned off at 4 in. from the bottom of the boiler to contour it, as in the first case, leaving always the space of 2½ in. all round. The combustible is placed at a distance from the boilers, in order to avoid the sudden bursts of heat to which they are liable when iron is placed too near the hurrying fuel. The ash-pit is rounded at the bottom, at the back of the grate, where it forms a quadrant to facilitate the passage of draught through the bars. M. de Pindray narrows in his furnaces for the following reasons:—He only requires 38½ square in. of fire-grate per horse power; he utilises the radiation by approaching the sides of the furnace to those of the boilers; he augments in length what he diminishes in width; in given extra length to the grate, he utilises all the heat by giving time to the gases in front of the fire to dilate and become heated, so as to be inflamed when they arrive at the end of the grate, where they become in the highest degree incandescent and strike vertically against the boilers.

The grate-bars are inclined towards the back as follows: for a grate 16 in. long, 4½ in. fall; for 15 in. long, 6 in. inclination; for lengths of from 3 ft. to 8 ft. 6 in., 8 in. fall; and above those lengths, 10 in. The bars extend, in all cases, throughout the whole length of the fire-grate, and are of one single piece; their depth at the middle will be, for a grate whose length of bar is from 16 in. to 20 in., 8½ in.; from 21½ in. to 3 ft. 3 in., 1 ft.; and from 4 ft. 11 in. to the greatest length, 14 in. The width of the bars varies, according to the required rapidity of combustion and the draught, and the space between the bars depends upon the quality and nature of the fuel supplied. For feeding this furnace, when the door is opened, a damper must be shut to within half an inch of closing it; and before putting on fresh coal, care must be taken to cover every part of the grate with a pretty uniform thickness of burning coals, otherwise the fire will go out. As soon as the fuel is supplied the doors should be closed, and five minutes afterwards the damper opened one-half its width; after the lapse of another five minutes it may be opened to its usual working extent. The licence for the use of this patent is 4l. per horse-power. One payment only.

THE HANDEL FESTIVAL, CRYSTAL PALACE.

The festival, so far as it has proceeded, has proved most successful, and has given delight to thousands. As our publication will be in the hands of many readers in time for a word of advice to be of avail, we say go, this Friday, June 30th, and hear "Israel in Egypt" with its mighty choruses, and in which Mdle. Patti, Madame Lemmens-Sherrington, Mr. Santley, and Mr. Sims Reeves, besides others, will sing. The sight alone of the vast orchestra filled with its thousands of executors, other thousands expectant in front, is a thing not to be forgotten. It may be true, in fact it is so, that the refinements of a solo singer can be better appreciated and enjoyed in an ordinary concert-room, such as Exeter Hall, than in the Crystal Palace, though few who heard Mdle. Patti, on Wednesday, sing "Let the bright Seraphim," Mr. Sims Reeves, "Sound an Alarm," or Mr. Santley, "O Rudder than the Cherry!" will recollect hearing them with greater delight; but in respect of the concerted music, nothing like it has ever been done elsewhere, and no such effects can be

heard on any other occasions. Speaking still of the Selection performed on Wednesday, the first chorus (from "Saul") "How excellent Thy Name, O Lord," the closing chorus from the same oratorio, "Envy! eldest-born of Hell!" and the "Coronation Anthem," could not be listened to without the deepest emotion, and will long vibrate in the memory of many who listened. The previous pains taken to insure such a result must have been enormous, and for these, thanks are due to Mr. Costa and those who assisted in that direction; while for the arrangements which enabled such masses of people easily and pleasantly to come and go, and find their seats without difficulty, Mr. Bowley and Mr. George Grove, working unseen, deserve applause. The "Book" is well annotated by Mr. W. H. Husk, the Honorary Librarian of the Sacred Harmonic Society.

PARIS NEWS.

Mons. E. JANICOT, architect, has submitted to the Imperial Commission of the Universal Exhibition (1867) of Paris, a projected plan of a construction to serve as a permanent circular building, also as a covered field for military evolutions. He proposes a system of wrought-iron ties, solidly attached to a permanent circular wall, and fastened at the circumference of the building to a circular walling, so as to bind it together like an arch. By this means he proposes to unite to the stability of rigid bridges the indefinite span of suspension bridges, and to shelter under one roof the exhibition of 1867, 20 hectares (about 50 acres), half the extent of the Champ de Mars, without any obstacle or any other support but the central tower and the circular walling.

This tower is to be entirely of open work, and will consist of several stories, with exterior balconies, from which visitors can embrace a *coup d'œil* of the whole area. The walling of the circumference is proposed to be double, the space between the walls being, on the ground-floor, laid out in offices, staircases, &c., and on the upper story, in a circular gallery, 25 metres wide, for objects requiring special lighting, such as painting and sculpture. There are to be four principal entrances and eight secondary doors. M. A. Oudry, engineer-in-chief of the Ponts et Chaussées, who constructed the iron bridge at Brest, has intimated his readiness to apply to this building, conjointly with M. Janicot, his system of rigid suspension with steel, as applied with success in his non-oscillating suspension bridges.

The assembly-hall of the municipal council of Paris at the Hôtel de Ville is to be decorated with four vast works by M. Yvon, the celebrated French military painter, representing memorable episodes in the history of the city. In chronological order the subjects will be,—The entry in state of Clovis, clad in Roman purple, into the capital; Philip Augustus, at the moment of leaving for the Holy Land, placing his children under the protection of the municipal body of Paris; François I., laying the first stone of the Hôtel de Ville; and the Emperor Napoleon III. signing the decree annexing the suburban communes to Paris.

As the present mains for the distribution of water through Paris have been inefficient, in consequence of the increased supply, larger conduits are being laid down in the Boulevard de Sebastopol, and other great thoroughfares of the capital, and the exchange will be continued until all the principal routes are provided with pipes of the increased calibre. These are placed in the *égouts* in two manners; those of the larger diameter are laid upon cast-iron pillars or supports, while the smaller tubes are supported on brackets let into the side walls of the sewers, with collars to retain the pipes in place.

Radiating from the centre of the Place de l'Etoile, at the upper end of the Champs Elysées, there are four grand avenues intersecting in the form of a cross, and eight secondary ones. The principal thoroughfares are the Avenues des Champs Elysées, Du Roi de Rome, De la Grande Armée, in line with that of the Champs Elysées, and the Avenue de Wagram, a continuation of that of the Roi de Rome. Between the first and second there are the Avenues Josephine and Jena, reaching through Chaillot to the river, at the Quai de Billy; between the second and third, the Avenues d'Eylau and De l'Impératrice communicating with the Portes de la Mactée and Daphnine of the Bois de Boulogne; and between the first and fourth, the Avenues de la Reine Hortonsa and Fridland. All the above

\* See the *Builder*, vol. xxiii., p. 104.

have been pierced through and laid out. It only remains to complete the group, to open out the Avenues d'Esling and Du Prince Jerome, between the Avenues de la Grande Armée and De Wagram, for which the demolitions are to be commenced at once. The Avenue d'Esling starting from the Arc de Triomphe, will cross the Avenue des Termes (or Boulevard Eugénie), at the Place Ferdinand, and join in with the Rue de Villers at its junction with the Boulevard Pereire, which lines the circular railway. The Avenue du Prince Jerome will start from the same point, and intersecting the Avenue des Termes at the corner of the Rue des Acacias, will abut at the intersection of the Route de Concolles with the Boulevard Pereire.

On the 19th ult. the justice of the peace was formally installed in the new Mairie of the seventh arrondissement, in the splendid mansion known as the Hôtel de Forbin-Janson, in the Rue de Grenelle St. Germain. This building, situated between a spacious court and a garden, has been successively occupied by several branches of the public service, and is well adapted for its new employment.

On the same day, the Association of Dramatic Artists of Paris held its general annual meeting, in the theatre of the Imperial Conservatory of Music, under the presidency of Baron Taylor. In course of the report read by M. Omer, it was stated that the society includes 2,641 members, and that the sums in hand amounted to 2,317,955 francs (92,718*l.*), the interest of which is, in the state funds, 58,500 francs yearly (2,340*l.*). There are twelve orphans provided for by the association. Besides the liberal contributions of all artists of every grade, one of the most important sources of revenue for the Actors' Association is the Bal de l'Opéra-Comique, under the patronage of the emperor and empress. Most of the actresses did not appear at the ball, but had, nevertheless, purchased or transferred tickets for various amounts, varying from 1,000 francs to 20 francs. The emperor paid 9,000 francs for his *loge*, and Prince Murat and the Duchesse de Marmier, after having contributed also handsome sums, abandoned their seats for the benefit of the treasury.

At the iron works of Holmberg & Co., at Lund, a new invention has been applied, by which tubes of iron can be cast by centrifugal force. The machine is of very simple construction: it is composed of a cylinder, which can be opened and closed, and into which molten metal is poured. A rapid rotary motion being imparted to the cylinder, the liquid mass is pressed against the sides, and the result is the formation of a perfectly uniform and straight tube. The first trials of this machine, invented by a young workman named Auguste Larson, have been completely successful.

#### RIGA FIR IN FRANCE.

THE introduction of the growth of Riga fir in France has lately occupied the attention of timber cultivators in that country. Some short time ago the French consul at Riga consigned a large quantity of these seeds to Paris for the benefit of societies of acclimatization who might wish to make an experiment of the growth of the tree. Of all forest trees those of a resinous nature are the least difficult in the choice of a soil; they are therefore eminently suitable for stocking barren hills and chalky wastes on which nothing else will grow. Most of the trees of this sort in France are cultivated for their resinous produce, and furnish timber of an indifferent quality, whereas the Riga fir yields timber of a quality at any rate equal to either that of Memel, Dantzic, or Sweden, and can be always depended upon whenever durability and strength are requisite.\*

Several doubts have been raised as to its probable success in France; but theoretically, considering that height in elevation above the sea compensates for the loss of a northern latitude, and that the flora of the high mountains of France and Savoy are identical with those of the Swedish and Siberian plains, a zone of land can easily be procured of an altitude of 120 metres above the sea corresponding to the wooded plains of Lidmaniana and Courtland. Besides this argument, direct experiment has been tried in the Department of the Eure, as far back as 1810, by the sowing of some seeds of Riga fir

in the Harcourt domain. These sprang up in due time, and are now tolerably good specimens, having averaged, in 1860, 82 ft. in height and 4 ft. 3 in. in girth.

The ground suited for Riga fir is, firstly, that of a siliceous nature (sandy, argillaceous sands, slates, granites, &c.); secondly, calcareous soil, especially that containing sand or argil. The Société d'Acclimatation, in assigning the post of importance to Riga fir, has not neglected other resinous trees of various qualities, such as the Corsican and Calabrian pines, delighting in a siliceous soil; the black Austrian pine, partial to calcareous regions and the towering *milze* or larch.

M. Bequerel presented, on the 15th ult., to the Academy of Sciences, a memoir on the influence of forests on climate, in which he discusses the statistics of forest clearing in France, and the resulting influence on water-courses and springs. He urges the immediate replanting of the hills as of the first necessity, in order to preserve the ground; stating that Great Britain, which has only 2 per cent. of wooded surface, and Spain, with only 3 per cent., are obliged to draw upon foreign markets for timber necessary for industrial purposes, while France has 16.7 per cent. of wood and forest. He warns the inhabitants of France to take steps at once, lest they be reduced to the same straits as England or Spain. The replanting of mountain lands and sandy plains, or even a portion of them, with resinous trees, is truly a sage measure; but it is, after all, an inadequate compensation for the loss of oak forests by clearing. The acclimating of the Riga fir, if successful, will no doubt go far towards remedying the evil done.

#### MASONIC MUSINGS.

##### THE GENIUS OF THE GREEK.

AGAIN to hallow'd haunts return'd,  
Bright with names we all adore,  
Where those hero souls that burn'd  
Sanctified the soil of yore.  
By the classic streams and meadows,  
By each sunny shore and creek,  
Draped with never-ending shadows,  
Rich in genius of the Greek.

Pure unselfish love of labour,  
Warm impulses, noble aims,  
Back, when shepherd's crook and tabor  
Hung on branches by the streams;  
Where the olive and scapulus  
Grew to grace that art antique,  
In the fabled far Atlantis,  
Rich in genius of the Greek.

Oh, ye bright inspiring fountains,  
Springs of primal art and taste,  
Rainbow, arch'd upon the mountains,  
Scintillating pure and chaste.  
Anatrophied, in rain scatter'd,  
By lone pool, and heben'd peak,  
Old mighty marble shrines shatter'd,  
Rich in genius of the Greek.

From out of ruins grand and solemn,  
Streak'd with glaze of reptile slime,  
Above each frieze and fluted column,  
Clogg'd with damp decay of time,  
Swelling forth from porch and portal  
Immortal scenes break,  
Redeem'd of life immortal,  
Rich in genius of the Greek.

Lead of old heroic spirit,  
Rise thine halo-wreathed head;  
Names like thine for aye inherit  
Glory from their mighty dead;  
Heirs of art still unexampled,  
Athens from your torpor speak.  
Lo! he comes, the Goth who trampled,  
Rich in spoil robb'd from the Greek.

Lamp of pristine Architecture,  
Beacon in all distant time,  
In your radiant retirement,  
Souls again will soar sublime.  
Virgin art and beauty vernal,  
Pointing heavenward ye bespeak  
Triumphs matches and eternal  
Crown'd in genius of the Greek.  
CLINTON HOEX.

#### THE BELFAST ALBERT MEMORIAL COMPETITION.

THE general committee, instead of acting on the resolution to which they had come, as mentioned in our last, resolved at a meeting, on Monday last, to refer the four selected designs to the president and council of the Institute of British Architects, or any one deputed by them—the decision to be binding on the committee. It was suggested that each of the competing architects should be requested to send a statement through the committee to the arbitrators. But the competitors were to hold no direct communication with those gentlemen.

#### THE O'CONNELL MONUMENT COMPETITION.

THE committee, after rejecting the whole of the designs first submitted to them, are seeking to induce artists to waste more time and send in other designs with equally vague expectations. One of the competitors on being so applied to in declining to submit a fresh design, wrote thus—

"It is evident that, in the first instance, the committee did not know what they required; but, when their request was complied with by about sixty architects, they gleaned from the designs and reports what they really wished to have as regards style, size, height, and material; whereas they should, in the first instance, have availed themselves of professional assistance, to enable them properly to state their views; and, having failed to do so, it would have been but fair and honourable to have awarded the three prizes to those designs coming nearest to the views and requirements of the committee (in the first instance), however they might have failed in their instructions and positive ideas.

Having done this, they should have asked the three successful competitors to compete against themselves, to the more explicit and realized ideas of the committee gained by the first competition, and awarded the execution of the work to one of the successful three."

#### THE SALISBURY GRAMMAR-SCHOOL COMPETITION.

AFTER publicly inviting and receiving a number of designs from architects in competition, the town council have coolly returned them to the competitors, with the information that for a certain reason the scheme has been abandoned. By the offer of a prize they induce a number of horses to run, and, when the race is over, announce that they intend to give no prize. A correspondent says, with reason,—“Under the circumstances, I think the competitors are all entitled to some amount by way of remuneration for being thus misled.”

It would not be amiss for the competitors to place the circumstances carefully before a lawyer, and learn what redress, if any, is obtainable. If the town council act as is described, they will to all intents and purposes commit a robbery, whatever their legal position may be.

#### LECTURES TO THE VOLUNTARY EXAMINATION STUDENTS.

WE are requested by some members of the Institute, who see the mistake made by their governing body, to state that the next lecture of the series will be given at 9, Conduit-street, by Professor Kerr, on Monday evening next, the 3rd of July, at eight o'clock, on the subject of “Constructive Science.” Mr. Bell, Professor Hayter Lewis, and other gentlemen will follow, weekly, to complete the course. It is understood that these lectures are open free to young men of the profession generally. Up to this time, if we may judge from statements publicly made, these lectures, in consequence of the unfortunate hole-and-corner policy pursued, have not been so satisfactory as they might have been either to the lecturers or the lectured. Publicity is needed to obtain an audience, and induce regularity in arrangements.

#### THE SALISBURY HOTEL, FLEET STREET.

THE hotel erected in quiet Salisbury-square, Fleet-street, with a view mainly to the accommodation of the agricultural interest, especially the Farmers' Club, has been opened, and seems likely to be amongst the most successful of the fine edifices of the sort which all at once have sprung up about us. It contains nearly 100 bed-rooms, besides private sitting-rooms, private dining-rooms, and ladies' coffee-room, on the upper floors. On the ground floor are hotel coffee-room, 50 ft. long by 25 ft. wide; three rooms for the purposes of the Farmers' Club, the largest being nearly 40 ft. long by 20 ft. wide; a smoking-room; besides the ordinary managers' room, bar, service, &c. There is also, on this floor, a large dining-room or hall for public dinners, meetings, &c., 70 ft. long by 30 ft. wide, and above 20 ft. high: this can be used either for the hotel purposes, or let separately. The basement contains capacious kitchens and offices, the fish, meat, and other larders being lined entirely with white tiles, giving a very clean appearance. The cellars also are large, and apparently prepared for a very large consumption. Beneath this basement there is a sub-basement, containing cellars in connexion with

\* “The Engineers' and Architects' Pocket-Book” (Lockwood), p. 128, says that Memel is best for size, Riga for quality, Dantzic for strength, and Swedish for toughness.

a tap and offices, which are intended to be let off. The architect is Mr. John Giles; the builders, as well as furnishers, are Messrs. Trollope & Sons, of Parliament-street.

ARCHITECTURE AND THE PARIS EXHIBITION COMMISSION.

Some discontent is felt, and not unnaturally, in respect of the position of architecture and the Royal Commissioners recently appointed to take charge of English interests and honour in the forthcoming International Exhibition to be held in Paris. When the commission was issued, Professor Donaldson was President of the Institute of Architects, and Mr. Majesty's advisers saw that in placing on the commission "The President of the Institute," they were providing Architecture with a fitting professional representative. Immediately afterwards, however, the Institute thought fit to elect to the office an esteemed and accomplished gentleman, well informed as to architecture, but not an architect. Painting is represented in the commission by painters, but at the present time architecture is not represented by an architect. In the eyes of our neighbours, this would seem ridiculous; they would not recognise the authority of an amateur; and some movement should at once be made, either by a memorial from the Institute, or, failing that, from some other body, to add to the Commission a properly-qualified architect of right standing. The President of the Institute would of course remain, his name being in the commission (and we are glad to have it there), but it will be a slur upon the profession, and there will be a weakness in the commission, if the addition we ask for be not made.

FIRES AND DISTRICT SURVEYORS.

On Tuesday, at a meeting of the City Commissioners of Sewers, the circumstance of two bodies having lain for five days in the ruins of the Pontlevers Arms Tavern, Leadenhall-market, which was destroyed by fire on the morning of Thursday week, was brought under special consideration. The General Purposes Committee of the commission had been directed to inquire into the circumstances attending the fire, especially as to whose duty it was to report it to the district surveyor or other authorities, and whether any neglect or unnecessary delay had occurred in taking the requisite measures in the case. Yesterday the committee reported that they had carefully investigated the circumstances, and had been attended by Mr. J. Young, the district surveyor, and Mr. Lightfoot, his clerk. Having considered statements, and examined the facts, the committee reported that it was certainly not the duty of the district surveyor in such cases to employ men to dig for the remains of persons supposed to have been buried in the ruins of a fire; but that the ruins in such cases were the property of the owner, or of the assurance company, if assured, who, if there were salvage to claim, would undoubtedly prevent any one but their own servants from so interfering. They were of opinion that the fireman, who, being on the spot, had the earliest knowledge of dangers arising from the condition of ruins, should in all such cases immediately communicate with the district surveyor, that the proper steps might be taken to secure them.

THE ARCHITECTURAL ASSOCIATION.

The usual meeting of members was held on Friday evening (the 28rd ult.), at the House in Conduit-street. The chair was occupied by Mr. J. H. Christian, the president of the Association. Mr. Montagu Davenport, of Lower Belgrave-place, Pimlico, was elected a member of the Association. Mr. J. D. Mathews, honorary secretary, reported that since the last meeting several members of the Association had paid a visit to Montagu House, Whitehall, built under the direction of Mr. Burn, for the Duke of Buccleuch, and were much gratified on the occasion. A vote of thanks to Mr. Burn and to Mr. Collings, for their courtesy in the matter, was accorded. Mr. Dmphy brought under notice a letter from Mr. Mathews, which had appeared in the *Builder*, taking exception to the accuracy of the

report of some observations made by him at the last meeting. According to the version in the *Builder*, Mr. Mathews was made to state, that when the Institute announced a lecture to be delivered on a certain day, and no lecture was delivered, it was "very like making fools of them" (the members of the Association). Mr. Mathews contended, that what he did say was, that "under these circumstances men could hardly be expected to come to (?), I might almost say, to be made fools of." This ungrammatical distinction without a substantial difference was pointed out and commented upon.

The Chairman said, he was glad to hear that the visit to Montagu House had been numerously attended, as such visits of inspection to buildings in progress were well calculated to give architectural students a practical knowledge of work. He hoped, too, that the voluntary examination class would direct its attention especially to this subject, so that as many students as possible might go up for examination next year. While upon this topic, he wished to state that the members of the Association who were deputed to meet the sub-committee of the Institute on the subject of the examinations, and especially in reference to the points set forth in the memorial of the Association, had been received in a frank and courteous manner. Every one of the items in the memorial was considered, and five of them were answered without doubt, while others were so thoroughly discussed that he was persuaded the Association had not only no fair ground of complaint against the Institute, but that it had many good friends on the sub-committee. Everything that was urged upon the part of the Association was listened to in a straightforward and conciliatory spirit, and nearly every requirement of the Association was acquiesced in without demur. On the whole, he might say, that the interview was most satisfactory, and the deputation could not arrive at any other conclusion than that every member of the sub-committee of the Institute was a friend of the Association. Under these circumstances he had taken upon himself to thank the Institute on behalf of the Association for the manner in which it had acted in the matter.

Mr. L. W. Ridge observed that, under these circumstances, the least the Association could do would be to show a disposition to meet the Institute by sending up as many candidates as possible for examination next year. He hoped that everything that could be reasonably done in this way would be done.

Mr. C. H. F. Lewes called attention to the necessity of getting up a practical knowledge of work, as it was owing to a deficiency in this respect that many failed on examination. This might perhaps be accounted for by the circumstance that in many offices the learning was more of a theoretical than a practical character.

The Chairman apprehended that this was too often the fault of the students themselves, who ought to avail themselves of every opportunity to inspect whatever buildings might be in progress in their offices in order to obtain that practical information which could not be acquired except upon the spot. He hoped the Association would now bestir itself so as to send up as many candidates as possible next year for examination, for otherwise the Institute might well say, "What is the use of our making concessions if you, on your side, do not avail yourselves of them." Moreover, if gentlemen did not go up, all prospect would be lost of inducing the Institute to make any further concessions that might be desirable.

Mr. Lemon suggested that if students would confine themselves to an attentive inspection of one building from its commencement to its completion, and study each detail of work as it arose, much practical knowledge might be obtained.

The Chairman said he quite agreed in the practical utility of the observation made by Mr. Lemon. He could see nothing derogatory in a student of architecture becoming temporarily a "clerk of the works." There was nothing in it to be ashamed of, and they might depend upon it the solid information to be acquired was well worth two years' application in that character.

Mr. Plumbe advocated the desirability of attending the voluntary examination class, and added that he himself was indebted to it for much valuable information which he might not otherwise have acquired. He quite agreed with the Chairman and other speakers as to the advisability of gentlemen going up for examination next year, and suggested that as the minimum number to insure examination was five, it might

not be well for five members of the Association to communicate with each other in order to go up together.

The Chairman next called attention to Mr. Tite's prize for the best design for a railway-station suitable to a small town. As he was himself obliged to travel a good deal by rail, he could speak feelingly on this subject, as his experience led him to know that there were a great many railway-stations very defective in their construction, and very unlike what they ought to be.

Mr. J. D. Mathews called attention to the announcement that the drawings for the prize were to be sent in by the 30th of September, and the essays by the 31st of August next.

Some formal business having been disposed of, including the election of the class of design (of which Mr. E. J. Tarver was chosen president),

Mr. Ridge moved a cordial vote of thanks to Mr. J. H. Christian, the president of the Association, on his retirement from office.

Mr. Christian in acknowledging the compliment, stated that his desire had been similar to that which he was sure had animated his predecessor in office, namely, to advance to the best of his ability the interests of the Association. He believed that they were now in an excellent position to make progress, and he hoped they would continue to prosper.

The following gentlemen were then elected office-bearers of the Association for the session 1865-66:—

- President—Robert W. Edis.
- Vice-President—B. O. Harris.
- Committee—J. H. Christian, E. Ferrey, H. L. Florence, F. Judge, J. Lemon, C. H. F. Lewes, Lucy W. Ridge, T. Roger Smith, E. J. Tarver, and J. Welber.
- Honorary Treasurer—J. Douglas Mathews.
- Honorary Solicitor—Francis Truitt.
- Auditors—G. B. New and C. B. Arding.
- Curators and Librarians—F. Judge and L. C. Riddett.
- Honorary Secretaries—J. Douglas Mathews and Rowland Plumbe.

Mr. E. J. Tarver subsequently read a paper upon organ building and cases, and after a short discussion the session of 1864-65 was brought to a close.

SURVEYOR TO THE CORDWAINERS' COMPANY.

The candidates were—Messrs. Cobbett, Clarke, Emerson, Knightley, Matthews, and Harry Oliver. The election took place on the 28th ult., when the voting was mainly for Mr. Clarke and Mr. Oliver. The votes being taken ultimately as between these two, Mr. Clarke was elected.

LEEDS SCHOOL OF MEDICINE.

The contemplated removal of the Leeds General Infirmary to a new site has induced the Council of the Leeds School of Medicine to erect a building near to the new hospital, planned to meet, as far as possible, the requirements of modern medical teaching. The building, plans of which we publish to-day, has been erected from the designs of Mr. George Corson, architect, of Leeds.

The new building comprises a lecture-room; museums of human and comparative anatomy, pathology, and materia medica; laboratories for the use of students and lecturers, furnished with all necessary apparatus for the study of the elements of chemistry, as well as of the more elaborate processes of chemical analysis (a collection of specimens illustrative of mineral and organic chemistry); a library and reading-room; and a complete suite of rooms for the prosecution of practical anatomy.

In the arrangement of the plan the great object aimed at has been to place all the working departments on one level, and to group them round the theatre. Each department will thus have easy access to the platform of that room, but will remain separate and complete in itself.

With this object the theatre is placed in the centre, and occupies both the principal and the upper floor, so that the space necessary for raised semicircular seating may be obtained. At the upper part it communicates with the first-floor by doors, for the admittance of students to the benches. Below, the platform, which is on the level of the principal floor, communicates on one side with the anatomical department, and on the other with the chemical.

The platform is lighted by a horizontal roof light, and is the only part of the room brightly illuminated—an arrangement by which it is hoped that diagrams, specimens, &c., will be exhibited in the best possible manner.

CARVED REREDOS, SHIREOAKS CHURCH.—MESSRS. HINE & EVANS, ARCHITECTS; MR. T. EARP, SCULPTOR.

The anatomical department will consist of three rooms,—a receiving-room; a lecturer's private dissecting-room; a students' dissecting-room, 40 ft. by 20 ft. In the latter great care has been taken to secure good drainage. An open ventilator runs the whole length of the roof.

The north side of the roof is constructed of glass from end to end, and there are two windows in the north wall. A macerating-room, lavatories, &c., are attached to this department.

Adjoining this department is the museum of anatomy, physiology, and pathology, 40 ft. square. This museum is lighted from the roof, and by two windows in the east wall. The windows are so placed as not to interfere with the specimen cases on the floor, and the room is of such a height as to admit of a gallery and second series of cases above.

The chemical department consists of a students' laboratory 25 ft. square, lighted on three sides and from the roof, a private laboratory for the use of the lecturer, and a room for chemical apparatus.

The library floor of the building is appropriated to resident curator's rooms and library.

The library, 40 ft. by 20 ft., is a handsome room with an open timber roof, lighted by three double windows in front and dormers at hack.

#### CARVED REREDOS IN SHIREOAKS CHURCH.

OUR engraving represents the reredos which forms part of a memorial, in Shireoaks Church, of the late Duke of Newcastle, comprising credence table, sedilia, and panelling round the apse of the new church lately erected. The reredos itself is executed in alabaster, inlaid with Italian marbles and Derbyshire spar. The sedilia, credence-table, and panelling being also of the same materials.

The reredos is divided into three compartments, surmounted by canopies supported on slender pillars, richly capped. The centre division contains, in *basso relievo*, the Crucifixion of Our Saviour; and the other two show Saints and Martyrs in Adoration. In the niches dividing the subjects are the figures of the four evangelists; and below, in quatrefoils, are their emblems. On the pedestals above these are represented angels, in attitudes of praise and adoration. The spandrels in the canopies are in Derbyshire spar and Italian marble, whilst the canopies of the figures are inlaid with mosaic-work. This reredos is nearly completed, and much of it is on its way to its destination. It was designed by Messrs. Hine & Evans, architects; and executed by Mr. T. Earp, sculptor.

**THE REPAIR OF ST. NICHOLAS'S STEEPLE, NEWCASTLE-UPON-TYNE.**

OUR readers will have some recollection of the dispute between the Newcastle corporation and the vestry of St. Nicholas's as to the repair of the steeple; and that there was, as we remarked, some risk of the steeple falling in the midst of the dispute. We are glad to notice, however, that there is now a prospect of the repairs being carried out at all events, although the dispute seems to be as far from being settled as ever. The corporation having offered to head a subscription-list with 500*l.* if the vestry would also subscribe, a vestry meeting has been held, and it has been unanimously resolved,—“That the churchwardens be authorised to subscribe a sum not exceeding 200*l.* out of any funds that may come into their hands, except charitable funds, and the rents of property vested in them and the overseers, in aid of a subscription to be set on foot for the preservation and thorough repair of the tower and steeple of the church of St. Nicholas; provided the corporation of Newcastle will head the subscription list with 500*l.*”

A committee has been appointed, composed of the Vicar of Newcastle, churchwardens, and overseers, with “such members of the corporation as may be by them nominated.”

**HOLY TRINITY CHURCH, WORCESTER.**

THE Church of Holy Trinity, Shrub-hill, Worcester, has been consecrated. The edifice has been built from a design by Mr. W. J. Hopkins, of Worcester, and will accommodate 850 persons, all but 200 free. Mr. Nelson, of Dudley, was the builder. A new quarry, near Hadley, was opened expressly for the stone of which the new church is built: it is a grey and red sandstone mixed. Bath stone is used for the tracery of the windows. The building consists of apsidal chancel, north and south transepts with eastern chapels to each, nave and south aisle; principal entrance at west end, with three other doorways, one at west of south aisle, another west of north transept, and the third at the north-east angle of the chapel in the same transept.

The building stands on an elevation by the side of the new road leading from Lowesmoor to the railway station. It has a steep-pitched roof, with pyramidal bell-cot at the intersection of the roofs. The cot is mounted on ornamental wrought-iron, supporting a shingle roof. Buttresses, with gabled offsets, are fixed between the apse windows, and bands of various coloured stone run beneath the windows.

In the interior, over the nave, are the remnants of the roof of the Guesien Hall, unfortunately destroyed some two or three years ago. Having been curtailed 4 ft. in width, the construction has been much altered and the lateral thrust lessened. The old timbers contrast with the lighter colour of the new hoarding rafters. The principals of the nave rest on dwarf wood shafts, supported by carved stone corbels—heads of apostles and prophets—the gift of Mr. Bolton, of Worcester. Bands of ornamental coloured stone run round the interior beneath the windows and below the wall plate. The south aisle is separated from the nave by three pointed arches, resting on circular columns with stilted square bases. The arches and piers have alternate courses of red and grey stone. There is no clerestory, for the arches reach nearly to the wall plate. In the north wall of the nave are four Decorated windows, two of which are copies of some in the late Guesien Hall, and the others are original designs by the architect. These windows are some 14 ft. above the ground. Also, in the west wall, is a Pointed rose window at a great height from the floor. This window is an original design by the architect. The rose, or wheel, has radiating mullions terminating in cinquefoils, and in the centre is a triple tau, as an emblem of the Trinity. A double doorway underneath this west window forms the principal entrance. The length of the nave is 98 ft. 6 in.; height of nave, 54 ft. to ridge of roof; breadth of nave, 30 ft. 6 in.; ditto, aisle, 16 ft. 6 in. The length of the chancel is 43 ft.; ditto width, 23 ft. 6 in. Across the transepts, 75 ft. 6 in. Total internal length, 140 ft. 4 in. The style is Decorated. The roofs are of one height, except the wooden vaulted crossing between the transepts, which is slightly lower, having diagonal groining of the same material. The chancel roof is of open timber work, shaped to suit the apsidal end, de-

corated in polychrome. There are five three-light decorated windows round the apse, and in the east wall is a canopied recess, containing a carving by Bolton, the subject being the “Last Supper.” The north transept has two two-light Decorated windows. In the south transept there is a five-light window with Geometric tracery. All the carvings in the chancel were given by the rector, who also presented the corona and one-half the painting of the roof, the other half being done gratuitously by Mr. Wells, the decorator.

The seats are open, of varnished deal. The pulpit stands at the north-west angle of the chancel by the north transept. It was the gift of Messrs. Wood & Son, and was carved by Mr. Bolton, from a design by the architect. The cost of the new building, site, &c., will be something under 7,000*l.*; and 2,000*l.* are wanted for the tower and spire.

**IMMANUEL CHURCH, STREATHAM COMMON.**

THE old church, erected about ten years since, consisted of a nave and aisle (deeply galleried), a small communion recess, and an octagonal bell-turret. Little now remains of this structure: a new south aisle, with a spacious chancel, a massive tower, an arcaded baptistery at the end of the nave, a north porch and stair-turret, and a lofty canopied drinking-fountain have been added. The thin metal columns and arches internally have given place to an ornamental stone arcade on each side of the nave, the shafts being of red Mansfield stone, with foliated caps. The chancel, built wholly at the expense of Mr. William Leaf, is paved with handsome encaustic tiles, and seated with richly-carved oak stalls. On the north side stands the organ-chamber, containing a large and powerful organ, built by Hill. The pulpit stands at the south side of the chancel arch, and is hexagonal, of Caen stone, supported by marble pillars, and having carved medallions of different design to each of its sides; the lectern and reading-desk being opposite. The baptistery is at the end of the nave, and is lined throughout with red brick, Scriptural texts, formed with glazed tiles, being handed round it at intervals. The font is the gift of Mr. Horsman Coles. Advantage has been taken of the irregular shape of the ground to make this portion architecturally effective, both externally and internally, and the somewhat novel feature of a drinking-fountain (forming part of the principal façade of the church) has been adopted. The tower contains four bells, by Warner (part of a future peal of eight bells), and has a lofty stair-turret at its south-east angle. The large chancel window is about to be filled with painted glass. The two baptistery windows are by Messrs. Lavers & Barraud. The cost of the entire alterations and additions exceed 6,000*l.*, independent of gifts to the church. The architect is Mr. Ferrey, F.S.A.; and Messrs. Dove, Brothers, are the contractors. The brasswork is by Hart & Son, and the carving is executed by Mr. Williamson and Mr. Robinson.

The church was consecrated and re-opened by the Bishop of Winchester, on Saturday, the 17th ult.

**ON THE ECONOMY OF WATER-SUPPLY AND UTILIZATION OF RAIN-FALL.**

THE continued rains of the spring of 1860 and the drought of 1864 should lead us to inquire whether the conservation of rain-water has received due consideration. An excess of moisture demands attention to drainage; a deficiency requires irrigation. As the necessity for observing these almost reciprocal conditions is variable, and not unfrequently local, it is as imperative to conserve and diffuse the water-supply and rain-fall with discrimination as it is to store the surplus sequence in grain, fodder, or animal food.

Man is the steward of Nature: he must not allow her profusion to run to waste, and then repine at her occasional parsimony, from which he should learn frugality. In fact, prodigality in nature is prophetic of, and provident for, deficiency—the seven years of plenty provided for the seven years of famine in Egypt during Joseph's government.

As population increases, the demand for pure water becomes more emergent, while a greater volume of water is rendered impure through the admixture of an increased amount of excre-

tions. Even if our rivers and water-courses are redeemed from the condition of open sewers and direct receptacles for excrement and filth of all kinds, they cannot be much improved by the filtration of fluid from pastures irrigated and saturated with the sewage of towns, the solid portion of which would naturally subside on the surface of the soil.

For wholesome water, then, we shall have to refer to the clouds, to mountain tarns, to high-land lakes; and there is little doubt but that aqueducts deriving their supply from such sources would prove the most economical mode of distributing water in their progress from a greater to a less altitude, the gravitation of that fluid on a declining gradient being its own conveyance. The adoption of such sources would also insure purity of quality, as no permeation of impure fluids, which does occur to wells, could affect water derived from an altitude.

By a system of interception and collection admitting of diffusion at pleasure, the desiderata of irrigation and drainage may be attained. The natural proclivity of water may be arrested by transverse cuttings. Alternately opposed curvilinear canals will diffuse water throughout a large area, and also aid pneumatic navigation, or vessels propelled by sails. Witness meandering rivers, and the advantages of a “reach” in aiding sailing-vessels to “tack,” or “make a board.”

If every house-roof was a rain-tank, the contents would contribute something towards the water-demand. Waste-pipes could be fitted to allow the excess from the loftier houses to find its way to the lower ones; and the excess would, after performing some salutatory office, perhaps, reach the sewers. This roof-cistern system would also be auxiliary in case of fire.

Farm-buildings should be so constructed as to save the largest possible quantity of rain-water by means of roof-cisterns or gutters, and troughs for the reception of the surplus from waste-pipes or eaves. There would then be little necessity for man or beast resorting to the liquid drainage concentrated in the “pond,” situated, necessarily, at the lowest part of the farm.

**THE NATIONAL GALLERY AND ROYAL ACADEMY.**

I VENTURED to propose, some few months back, and to submit to the members of the Royal Academy, a plan for a new National Gallery, in which, and connected with it, I ventured to suggest that the Royal Academy should have provided for them rooms for their annual exhibition of pictures, and space for their schools and library. This plan has been thought so well of by individual members of the Academy, that I cannot help asking you for permission to urge it somewhat more publicly now that it has been determined finally by the House of Commons that the Gallery of National Pictures shall not be moved from its present site, and, as a necessary consequence (*at the time*), that the Academy should find a home elsewhere. To me it seems a subject of the first importance and interest, and may help either to further or retard the progress of art in no slight degree; and—which makes me feel especial interest in it—it involves the acceptance or rejection of the principle as to whether or not a museum or gallery of pictures shall be regarded as a school and consequent inspiration to those who study in it, or merely a record or storehouse of the works of those who have passed away and left specimens of their art-power for us merely to look at,—*i.e.*, a hook, as it were, of the history of fine art and painting. I will be as short as I possibly can.

First, then, I will—if, for the sake of clearness, you will permit it—indicate in a few lines what I have ventured to propose to the council of the Royal Academy, and to the Chief Commissioner of Public Works, for combining the two great institutions, the Gallery and Academy. I propose to leave the present gallery as it now is, without any alteration whatever, to do its duty as a receptacle for the whole collection of national oil paintings;—the workhouse and schools of Archbishop Tension, immediately behind it, to serve, with as little done to them as possible, as space for water-colours, engravings, photographs, &c.;—the two buildings, *viz.*, the chapel and baths, as further space for sculpture and architectural details; a temporary communication being made in each case between these now separate buildings. The Royal Academy would then occupy temporarily the harrack buildings (for a more inconvenient place for

soldiers and military work cannot be conceived), for the purpose of its annual exhibition, and to be also united to the buildings just named, so that during the Academy Exhibition a clear communication through all these galleries may exist, thus to give the public opportunity for seeing with comfort the real state of modern painting as a progressive art action consequent on the study of the older art. The power of doing this, and the attractiveness of the larger space, would, I feel no doubt, double the number of visitors to the Academy Exhibition. All this would be done at simply the cost of the existing buildings, the existing rooms of them being no more inconvenient than were the old rooms of Somerset House or Montagu House. Thus the Royal Academy would form, as I think it ought, a part of the idea of a national gallery of the fine arts. The first new building for the Royal Academy I suggested should be a circular domed hall, to be built in the centre of the present Barrack-yard; and the first section of the future National Gallery built on the site of the houses immediately adjoining the present gallery, the future gallery forming a square;—a somewhat, I fear, startling and peculiarly alarming notion; but—and it shows what fine art is worth in the public estimation—it may be borne in mind, as a contrast, that no sooner did the public convenience ask for a way from the Underground Railway to the other side of the river, than no less a sum than *four millions* were found to accomplish the work, while Mr. Cowper is now asking timidly but for twenty *thousand* for a room or two more for pictures that cannot now be seen for the want of space to put them in. Both are alarming, but may fairly claim the merit of indicating as an art thermometer the force and pressure of fine art on the public mind! Artists have but little to boast of in these days.

I must ask pardon for so much explanation, but I could not say what I want without. It is the need there is, as I conceive, for a greater liberty of art action than now anywhere exists, and a change from the present fine-art monopoly, art protection, as it may well be called, to a free-trade action and policy in art. This seems to me the one urgent question of the time, for it is, indeed, to do for art and labour or work what has already been accomplished so magnificently for trade and commerce. Mr. Cobden, to whom society owes so deep a debt, said but a few days—*my, hours—before his death*, that what was now needed to be done, was to agitate for a free trade in labour; and I took the liberty of explaining to him, as far as I could, what *art labour* meant and is, and to ask him to consider a subject so entirely new and hitherto unthought of. The political economists seem to have passed it completely by; and yet it really is not until fine art, in some form or other, has touched and moulded the rough and unformed materials that human labour, as an *expression of the powers of the hand and mind*, can be said to have an existence as a final pleasurable result. I ask your attention to this great principle. It requires a little thought, and is worth a little trouble to come at; but is worth having when got; for the labour of the ancient Greek was, as I urged on Mr. Cobden, a *fine mental fine-art result always*, whether in a building or a water-plot, and bore the impress of his time and race, while our labour now does neither the one nor the other. The Greek wrote his name on every thing he made: we merely scribble unmeaning marks, or try—always to fail—to copy, by a process of manufacture, the writing of other men as far off as dead. Art has, if we will consider it in these modern days, not yet *begun*, if this idea has any truth or value. How necessary, therefore, it would seem to be to urge the reform of the only institution in England which ever affords specimens and proofs of the genuine art handwriting of its members; and how can the public be asked, through the House of Commons, to do more for their own benefit than by affording it space to work in. Two things are requisite,—*fairness*, on the part of the Academy, and *interest*, on the part of the public.

The Royal Academy is now the narrowest and most *protective* body remaining in this materially great country; but its vocation, as I think, is before all others; but it can only carry out that vocation worthily by exchanging its protective for a free policy, and by making itself worthy of public help. I think it should form a part of, and be, in itself, a national institution, and should lead and guide to the creation of a finer and nobler order of labour. It needs, further, only that the public be interested; for monopolies such as the Academy now is,—and it is one of the

worst that ever existed, even in Lord Bacon's day,—can only be broken down by public opinion and public discussion.

I have ventured to trouble you with these few thoughts, in the hope that some little interest may be excited on the subject of them before the Royal Academy is finally transported to the wretched site to which its own narrowness only has condemned it, or can yet condemn it.

C. BRUCE ALLEN.

#### METROPOLITAN BELLS AND BELFRIES.

APPEAL FOR A NEW PEAL FOR ST. BARTHOLOMEW'S.

The steeple-keeper of St. Martin's-in-the-Fields, Mr. George Morris, whose sensible and interesting enough though not very literary production, as to metropolitan belfries and bells, we put into shape for the *Builder*, in June, 1864, now writes to thank us for doing so, and to state farther that, having been ringing-steeple-keeper also of St. Bartholomew's, the Great, Smithfield, for the last ten years, he has long wished for an alteration in the bells, as the present five bells are very old, and have lost their tone; so he laid the matter before the rector, and Messrs. Jackson & Poole, churchwardens, who have all approved of his proposals, "as the promoter of a new peal of bells," and Mr. Jackson has agreed to become treasurer, and Mr. Morris himself (No. 5, Long's-court, Leicester-square) will be a collector of subscriptions, which Mr. Jackson (No. 22, Bartholomew's-dose, W.C.) will also receive, for the new peal, which will be in memory of Prince Alherl. Mr. Morris evidently expects us to add that, "with our friend's great undertaken, we wish him every success, with God speed;" and that we do, although this is not quite the way in which we would have said so.

Mr. Morris expresses his gratification to observe, from the *Builder*, that so many new churches have of late been supplied with new peals of bells, but he very naturally says,—*"As so much is being done to our new churches, I think our old ancient London church bells ought not to be forgotten which our fourfathers built,"* and, as to the state of the metropolitan belfries, he adds:—"My last publication came before the Lord Bishop of London; and, in a letter to me, his lordship's chaplain, of August 2nd, 1864, says:—"Sir, the Lord Bishop of London has made some inquiries as to the matter brought before him in your letter of 8th ult., and hopes that any neglect in keeping the steeples and bells in good order which may exist will be remedied. I am, Sir, yours faithfully,—W. H. FREEMANTLE, Chaplain."

#### UNFAIR DEALING WITH ESTIMATES IN SHEFFIELD.

The town-council of Sheffield have sanctioned proceedings of their Watch Committee, with respect to the estimates for their new police offices and prison-cells, which one of their own members characterized as "very wrong," and another admitted to be inconsistent with "professional etiquette;" and which we consider to be unfair dealing, not only towards the building tenderers, but towards the rate-payers themselves, whose pecuniary interest the council professed to consult.

An advertisement appeared in the Sheffield newspapers and in the *Builder*, inviting tenders for the new police offices, &c., and the following tenders were accordingly sent to the watch committee:—

Byron .....	£8,690 0 0
General .....	8,675 0 0
Wade .....	8,670 0 0
Craven, Brothers .....	8,489 0 0
Neill .....	6,840 0 0

The Watch Committee accepted the tender of Mr. Neill, it being the lowest; but, after the amounts of the tenders had been advertised, Mr. Neill asserted that he had made an error, and sent in a second tender 727l. higher than his first one. The committee at once saw the impropriety and unfairness to the other contractors of such a proceeding, and unanimously resolved to accept the next lowest tender, which was the only fair course they could take. Mr. Neill, however, subsequently had an interview with the committee, who thereupon accepted his second tender, although Mr. Neill said that, rather than lose the contract, he would complete it in a workmanlike and satisfactory manner for his *original tender*. The council have since adopted the procedure of their committee.

The local master builders have publicly complained of this departure from all tradesmanlike custom, so that the council to re-consider the question, so that an example so pernicious to trade should not have the highest official authority of the town. As they remark, "The custom of the trade is to let every tender stand on its own merits; and, if any contractor is not prepared to accept the work on his tender as sent in, it is considered withdrawn, and the next tender accepted. It is not the first time (they continue) that a contractor has found out a mistake when it has transpired that his tender was considerably lower than that of his competitors. Such a circumstance occurred in Sheffield a few years ago, in connexion with the Brightside Bierlow Cemetery, and the error was found out, as in this case, when the estimates had been published in the *Builder*, and not before. The Burial Board, however, at once set aside the amended tender, and the next lowest tender was accepted." Other cases of a similar kind occurring at Sheffield are quoted, so that the trade practice is as well known there as everywhere else.

A correspondent of a local paper asks, "Who in the first instance accepted Mr. Neill's tender? By what authority was it declined? and, how came it to pass that Messrs. Craven were communicated with? by whose sanction and orders did they commence the work? and, after commencing and continuing upwards of a week, how were they stopped?"

#### SOCIETY FOR IMPROVING THE CONDITION OF THE LABOURING CLASSES.

The twenty-first annual meeting of this society was held on Tuesday, at Willis's Rooms, King-street, St. James's; the Earl of Shaftesbury presiding. The object of the society is to improve the dwellings of the labouring classes. In carrying out this, the report states that the society have renovated old houses and erected new buildings. The first scene of their operations was Pentonville, where they have set up model dwellings for the accommodation of 23 families and 30 single women. In Charles-street, Drury-lane, they have three lodging-houses, affording superior accommodation, at low rents, to 82 men. In George-street, Bloomsbury, they have a model lodging-house capable of accommodating 104 men. In Hatton-garden they have also a building for single men. In Streatham-street, Bloomsbury, they have erected a building to accommodate 54 families. In Port-pool-lane they have a building for 20 families and 128 single women. To this building a wash-house is attached, and during the year, up to last December, there have been 20,766 washings. Several houses have been renovated by the society in Wild-court, Drury-lane, and 11 houses have been renovated in Clark's-buildings, Broad-street, St. Giles's. In Tyndal's-buildings, also, several houses have been repaired and put into tenable condition. With regard to the funds, the sum received in the year ending the 31st of December, 1864, from all sources, for the general purposes of the society, was 6,399l. 17s. 9½d., which, with the balance in hand at that time (being 294l. 10s. 4d.), made a total amount to be accounted for of 6,694l. 8s. 1½d. Against this was to be charged for current expenses of all the lodging-houses, including repairs, painting, &c., 3,431l. 8s. 2d.; loans repaid and other claims and interest, 2,298l. 10s. 2d.; rent of offices, salaries, managers' commission, printing, plans, and other incidentals, 677l. 9s. 9d., making a total of outgoings of 6,407l. 8s. 1d., and leaving a balance of 257l. 0s. 0½d. The real property, &c., of the society (valued at cost) is estimated at 44,561l. 9s. 1½d., and the general liabilities are set at 21,789l. 6s. 5d., leaving assets amounting to 22,772l. 3s. 6d.

Various addresses having been made,—Lord Shaftesbury, in returning thanks for a complimentary vote, said it should never be forgotten that the society was merely a model society, and not one intended to do good on an extensive scale, but rather to show what was possible to be done provided sufficient capital were embarked in the work. In some cases they had built houses, in others they had only renovated old ones; but in every instance their experiment had been successful. It had proved that the people, on being transferred from bad to better dwellings, were improved in morals; and it also established a fact which some persons had questioned, that the people were themselves desirous of living in better dwellings. But

experience had also proved that these better sorts of dwellings could not be built to realize a profit of more than 5 per cent., and as individual builders expected to make at least 10 per cent. on their outlay, it was obvious that no such houses as were contemplated by the society could be built for the use of the working classes, except by a body possessing a large amount of capital. As to bringing the present houses under public inspection, he had made the attempt twice in Parliament, but had hitherto failed; still, it was an object to be constantly kept in mind.

THE OPERATIVE PAINTERS OF LONDON.

The operative House painters have asked the masters, as we mentioned last week, for an advance of wages to 7d. an hour, on the following grounds:—1. The high price of animal food; 2. The present increased house-rent; 3. Believing that our labour is as remunerative as other branches of the building trade.

In forwarding to us a copy of their memorial the secretary says,—

"We have been for years in the receipt of less wages than other branches of the building trade, the wages of painters being only 6s. per day, and our employment far more precarious, whilst the pernicious character is well known, seriously affecting in many cases the health of ourselves and families; whilst, in point of intelligence, honesty, and respectability, we are, as a body, second to none. Allow me, sir, to inform you we are asking quite independent of any other branch of the building trade; also that there is not one man upon the committee, or acting with us, who has ever before been concerned, directly or indirectly, in getting up memorials, strikes, or any other agitation likely to destroy the good feeling that should exist between employers and the employed."

A skilled painter should be able to command as much as a skilled bricklayer; but, if every man who can take a pound brush and slobber over a wall or iron railing is to be regarded as a painter entitled to ask for the regulation wages, masters will, of course, refuse to make the advance required, because the supply of such labour is unlimited, and much overpasses the demand.

THE FEMALE SCHOOL OF ART.

The prizes to the successful pupils of this school have been distributed in the theatre of the Geological Museum, Jermyn-street, by the Right Hon. H. Bruce, M.P., the Vice-president of the Committee of Council on Education. The school has now been established some time, and has been conducted with considerable success. The present number of pupils is 117, as against 80 only at this time last year. At the last competition for local medals at South Kensington the school sent 105 drawings and paintings for the competition, and to the large proportion of twenty-five of them medals were awarded, and three obtained the reward of honourable mention. Of the successful drawings eleven were selected for the national competition, and three of the students were so far successful as to obtain the national medallions. At the Government inspection, on 27th March, when the annual examination for the second grade took place, forty-nine students presented themselves for examination on the four subjects of freehand, geometry, perspective, and model drawing, when twenty-one obtained cards for having passed, and to sixteen prizes were awarded for having, in addition, obtained the mark "excellent" for their papers. The bazaar, in June of last year, at which the Princess of Wales presided, produced 2,412l., a portion of which had been appropriated to the completion of the final purchase of the premises. The principal class-room of the building, now completed, is 47 ft. long by 27 ft. wide, and the building affords ample space for the reception of 200 pupils. Her majesty has promised 10l. a year towards the establishment of a Queen's scholarship.

THE WORKMEN'S CLUB AND INSTITUTE UNION.

That the objects and plans advocated by this excellent society can be practically worked out with most beneficial results, is now, it seems, amply proved in Croydon, Leeds, Canterbury, Winchester, Newcastle, Hull, York, Rotherham, Bolton, Derby, Brighton, Faringdon, Manchester, Preston, Bristol, Devizes, Shore-ditch, Chelsea, Camden Town, Holloway, Southwark, Westminster, Nottingham, and other places, making a total of about 165 clubs, twenty-eight of which are in the metropolitan districts, and above 100 of which have been formed under the auspices of

this union in the course of little more than two years. The applications at the office for advice and information, personally and by letter, average about sixty weekly; and the secretary has attended, by request, upwards of 250 meetings in different parts of the country. Several clubs are now being formed in various localities by the impulse, and under the guidance, of the union. But, if the council are to continue their labours, they must receive largely increased support. They complain of the low condition of their finances. The work has been performed principally by the help of donations: the whole annual income of the union is only about 350l., and the total cost of all its operations during two years and a quarter, including salaries, printing, travelling, public meetings, &c., has only been about 1,700l. Yet, with this small amount, in the course of twenty-seven months, it has been mainly instrumental in gathering above 25,000 working men into these clubs, and away from the ruinous public-houses. Sir George Grey has authorised the enrolment of working men's clubs and institutes under the Friendly Societies' Act. An annual subscription of 1l., or a donation of 10l., constitutes the contributor a member of the union.

PRIZES FOR ART-WORKMANSHIP.

ACTING on the invitation of the Society of Arts, the Worshipful Company of Plasterers, London, offer (subject to the general conditions of the Society of Arts), a prize of 10l. for the best floriated bracket or truss in the Italian Renaissance style—dimensions, 14 in. on the beam, 12 in. on the wall, and 8 in. on the face—to be designed and modelled by the competitor, or the designer and modeller may co-operate in the production, when 5l. will be awarded to each.

Five pounds will be given for the next best model, or 2l. 10s. each to designer and modeller. Artisans' apprentices and students may compete for these prizes, but not master tradesmen, Masters in Schools of Art, or those training for Masters in the Central School of the Department of Art.

ANCIENT MORTARS.

The composition of ancient mortars has been examined by Dr. Wallace, and the results given in the *Chemical News*. The first specimen was from the Great Pyramid, and presented the appearance of a mixture of plaster, of a slight pinkish colour, with gypsum. It did not appear to contain any sand, the place of which was taken by coarsely-ground gypsum. Large quantities of this material and of alabaster are stated, by Professor Smyth, to be found in the vicinity. Analysis showed this mortar to contain 82 per cent. of hydrated sulphate of lime, and 9½ per cent. of carbonate of lime, besides smaller quantities of other bodies. A very ancient mortar, supposed to be the most ancient in existence, was obtained from the ruins of a temple near Larnaca, in Cyprus. The temple is now wholly below the ground, still the mortar was exceedingly hard and firm, and appeared to have been made of a mixture of burnt lime, sharp sand, and gravel. This mortar contained chiefly 26¼ per cent. of lime, 20·2 of carbonic acid, 16·2 of silica, and nearly 29 per cent. of small stones, the lime being almost completely carbonated. Ancient Greek mortars showed somewhat the same composition. Ancient Roman mortars differed, however, being evidently prepared by mixing with burnt lime, not sand, but puzzolana, or what is commonly, although improperly, called volcanic ash. From his analyses, Dr. Wallace deduces the following conclusions:—That in the course of time the lime in plasters and mortars becomes completely carbonated; that where the mortar is freely exposed to the weather, a certain proportion of alkaline or earthy silica is formed, which probably confers hardness, as those mortars are the hardest which have been long below ground. It is known that those walls are strongest which are built during the rainy season, as then a small proportion of silicate of lime is formed, but not only makes the mortar itself harder, but causes it to unite more firmly with the stone. The mortar which is probably the most ancient is by far the hardest, appearing like concrete. Its excellence seems to indicate that a large-grained sand is best for building purposes; and that even small gravel may, in certain cases, be used with advantage.

TO MAKE STONE IMPERVIOUS.

At page 437, a correspondent wants to know what will make stone impervious to rain. Having had some forty years' experience in these matters, as to stone, stucco, and cement, I write to say, for his information, that there is nothing better than paint and sand to keep out wet. Give the parts required to be done two good coats of the best white-lead paint, mixed with raw linseed oil (only). After that is dry put on a very thick coat of the colour required to match stone: when the paint is wet dredge it with fine white sand until the surface is thickly covered over. H. H.

RAVAGES OF PLAGUE IN THE LEVANT.

NOTWITHSTANDING the sad loss of life in Great Britain which might be prevented, we should feel thankful for being preserved from those terrible outbursts of pestilence which once scourged this land, and which in the East still pass like destructive whirlwinds over the country. The accounts of the Russian epidemic are not yet very clear or definite; but news of more certainly fatal results come recently from Medina and Mecca, where the raging of pestilence seems to be terrific. In Mecca the number of deaths has been frightful, and at both places the scourge seems to have taken the form of a combination of fever and cholera, these, in fact, as we are persuaded, being the hot and cold fits of that tremendous ague called the plague. On the eve of the Conrhan-Beiram and, says the *Levant Herald*, on the first and second days of the feast, the scourge carried off 40,000 victims amongst the pilgrims. The plague has to some extent lessened, but the deaths are still enormous, so that it is likely that the disease has partly declined rather from the want of materials for it to act upon than from the diminution of its violence. Still multitudes continue to perish. The inhabitants have fled, and the streets, on June 7th, were still filled with corpses.

We hope that the angel of death which has passed over this region may have spared some one who has knowledge of sanitary matters and may tell us of the over-crowding, the filthy conditions, and unwholesome food, which, no doubt, brought about this terrible calamity.

To us in Britain, a somewhat more seriously alarming circumstance is the news which has just been announced in *Galignani's Messenger*, that virulent cholera has broken out, and is rapidly on the increase, in Alexandria. The daily deaths in the week rose from 3 to 61. The present summer with ourselves has hitherto been rather a close one: we have had but one rattling thunder-storm over London. The cholera seasons in this country, we have noted, always followed close and oppressive summers. Let us hope to have soon a good thunder-storm or two to clear the air and sweeten the ground.

STATISTICS OF LIFE.

DR. W. FARE, of the General Register-office, has completed his supplementary volume on the mortality of England in the ten years 1851-60, the census of 1851 and of 1861 furnishing the means of comparing the population with the deaths. Some years ago Dr. Granville collected statistics of the history of 400 mothers, married women who applied to the Westminster General Dispensary; and he found that though 272 of them had had only live children, the other 128 had in the previous ten years borne 556 live children and 305 dead embryos, the latter most frequently in their earlier months, just as the mortality in the first year of breathing life increases rapidly as we proceed backwards from the twelfth to the third, second, and first month. In the 26 years 1838-63 there were registered in England the deaths of no less than 2,374,379 infants born alive but not living for a single year! At this present time 100,000 infants of less than a year old die every year in England. Passing on to the higher ages, we find the rate of mortality declining with every year of life up to 12 or 13, when it is at its lowest. Between 10 and 15 years of age less than five boys in a thousand die in the year. Twenty years later in life the mortality is doubled, and it goes on increasing to the close. At all ages the variation in the rate in different districts is shown to be very striking. The mortality of men in

towns demands a careful investigation. At 45-55 the mortality of London men is not far from double that of men in the healthy districts of the country. It is much higher at every age than the mortality of women in London. Ill-ventilated workshops have something to do with this, and so has indulgence in spirits and other stimulants. The workmen in all large towns suffer as much as the workmen of London, and often more. For instance, at the age of 25-35, and again at the age 35-45, and again at the age 45-55, the workmen of Liverpool, Manchester, Bristol, and Newcastle-upon-Tyne die at a still greater rate than the men of London. In the ten years 1851-60 the deaths in thirty large town-districts of England, with an aggregate mean population of 2,541,630, comprising seven London districts and the principal provincial town districts, averaged 71,191 a year, while the deaths at the rate in healthy country districts would have been only 38,459,—an annual loss of above 32,000 lives in much less than a seventh of the population. If the mortality of all England be arranged in five great groups, the following result appears.—Where the mortality was 14, 15, or 16 per 1,000 persons living, the population was only 86 to the square mile; where the mortality was 17, 18, or 19, the population was 172 to the square mile; where 20, 21, or 22, 255; where 23, 24, or 25, 1,128; and where 26 and upwards, 3,399. Yet there can now be no doubt that more proximity of dwellings does not necessarily involve a high rate of mortality. If an adequate water-supply and sufficient arrangements for ventilation, drainage, and cleansing be secured, the evils which make dense districts so fatal, will, to a certainty, be mitigated. It is remarkable that some of the dense districts of cities are already comparatively salubrious.

#### GAS IN THE CITY OF LONDON.

The Lord Mayor, at the request of nearly 1,000 City gas consumers, many of them of eminent firms, has convened a public meeting, in the Council Chamber, Guildhall, on Monday, the 3rd of July, at one for two o'clock, to take steps to secure a reduction in the price of gas from 4s. 6d. to 2s. 9d. per 1,000 cubic feet, and to consider the propriety of petitioning Parliament for the repeal of the Metropolitan Gas Act, 1860, which deprived the public of the benefits of competition.

The gas movement in the metropolis is also being well supported by the Sewers Commission and the Court of Aldermen; at a recent meeting of the latter of whom, Mr. Haines (chairman of the General Purposes Committee) brought up the report on the several petitions relating to the supply of gas to the City. The Committee generally expressed their opinion in favour of the recommendation and resolution come to by the Court of Sewers, and of the course which the Commissioners recommend should be taken under the circumstances; and Mr. Haines moved the Court "To agree with the Committee in their report."

Mr. E. Dresser Rogers then moved the following amendment, of which he had given notice:—

"That the report be referred back to the said Committee with instructions to confer with the Law, Parliamentary, and City Courts Committee to consider as to the best method of proceeding, at the earliest possible period, with an application to Parliament for an Act to empower the Corporation either to purchase the existing mains, plant, and works in, or supplying, the City of London; and to contract for the supply of gas into those mains, or to erect works, and enter into the manufacture and distribution of gas to the consumers, as is now so successfully carried on by the Corporation of Manchester and other towns."

Mr. Rogers said he did not intend to insinuate that the Commissioners of Sewers, as well as their officers, had not done their duty in this matter, but his object was to obtain for the citizens what they had a right to demand—namely, a better and cheaper supply of that most necessary article of consumption, gas. There was no necessity to prove the high price or the bad quality of the gas.

Mr. Rudkin, after complimenting the mover of the amendment on his able address, seconded the amendment, which was unanimously carried amidst loud cheers.

Thus at length the Londoners seem to be in earnest in their determination to cast off the incubus which has hitherto paralyzed all their endeavours to carry out a thorough gas reform in the metropolis; to which reform they were first and for-long urged by the *Builder*, who often adduced the example of Manchester for their consideration and adoption.

#### CASES UNDER METROPOLITAN BUILDING ACT.

**Roof Coverings.**—At Marlborough-street, Mr. John Dabbs, builder, of Hackney-wick, was summoned before Mr. Mansfield by Mr. Jennings, district surveyor of South Marylebone, for omitting to cover the roof, flat, gutters, and lantern-light of a building situated in Black Horse-yard, Rathbone-place, with slates, tiles, metal, or other incombustible material, and to render fire-proof the flues, and to carry up the chimney in brick or stone work to the height provided by the Building Act.

Mr. Hooper appeared for the defendant. Mr. Jennings said he surveyed the work in Black Horse-yard during its progress, and he found that the roof was being covered with what he had no doubt was asphalt. The Scyssel Asphalt Company admitted that more than 10 per cent. of the composition was tar. He had tried if asphalt would burn, and he found that it was combustible. He could not say at what temperature the asphalt with which the roof was covered would melt.

Mr. Mansfield remarked that it was not the question of melting, but of igniting, that was to be decided.

The surveyor said the roof of this building was composed of wooden joists, and then filled in with concrete, which was afterwards covered with asphalt. Other buildings with asphalt on the roofs had been allowed by him; but in most of them they were first covered with tiles, and the asphalt only added to keep out the wet. In the present case he thought there was absolute risk; the roof had wooden and not iron rafters, and was, therefore, not incombustible.

Mr. Dabbs stated that he had been extensively engaged in building. When zinc or lead was used, the roof was combustible. In the present instance concrete and Portland cement were used, and above them asphalt with sand and silicate. There was originally only 10 per cent. of combustible matter in the asphalt, but, by the addition of sand and silicate, the per-centage was considerably reduced. Lead would melt at a lower temperature than the asphalt used for roofing.

Mr. Mansfield would not pretend to say whether asphalt roofs were combustible or not; and, from the evidence, the fact remained in a very uncertain state. Nothing had been shown before him to prove that asphalt roofs were combustible. If materials less combustible than those named in the Act were put upon a roof, he could not bring himself to say that the roof was so constructed as to be an infringement of the Act. He should refuse to make an order on that point, as the matter was so uncertain; but, with respect to the other two points, he should make an order against the defendant, with a specified amount of costs.

#### COMPENSATION CASES.

##### THE HOLBORN VALLEY.

At the Sheriffs' Court, Red Lion-square, the first case for compensation for property in Middlesex required for Holborn-valley Improvements, *Darke*, Committee of Henry Bryan, a lunatic, and Manran, trustees of W. B. Blackwell, *v.* The Corporation of London" was heard last week, before Mr. Under-Sheriff Burchell, and a special jury, where a claim was made for nearly 25,000l. for thirteen houses in Ely-place, required for the formation of the new street from the corner of Hatton-garden to the Farringdon station, in a slanting direction.

The case was opened by Mr. Bovill.—Ely-place belonged to the two parties before the court, each taking a moiety. It was once a fashionable lounge, and noted for its strawberry beds; it was then considered "out of town," and resorted to by the grandees of the City. Subsequently it became the residence of the Bishop of Ely. Latterly solicitors resided there, and it became extra-parochial. Solicitors were giving way to wholesale silversmiths and watch manufacturers, and now a portion was required for the City improvements.

Several witnesses were called to substantiate claim to nearly 25,000l.

Mr. Fuller, surveyor, put 3,000l. for the depreciation of the houses left after the others were removed.

Mr. Hawkins ridiculed the idea that the improvements could depreciate the property left, but, on the contrary, they would increase the value. All property in the City and contiguous

thereto had increased in value, and Ely-place and the neighbourhood would be greatly improved when the contemplated alterations were carried out.

The case occupied several hours, and eventually the parties agreed to a verdict for 18,000l., each party taking 9,000l.

**Bartrum & Co. v. The Corporation of London.**—*The Holborn Viaduct.*—This was a compensation claim of nearly 49,000l., made by Messrs. Bartrum, Harvey, & Co. woolen warehousemen on Holborn-hill, for their premises and the loss on their trade. The claim was 7,000l. for the leasehold premises, and 42,000l. on account of their business. The premises were required for the Holborn Valley Improvements.

The case, which occupied the Court until a late hour, disclosed some remarkable features. In 1832, Messrs. Bartrum and Harvey were assistants to Mr. Bardwell, who carried on the business; and in 1837 they became partners. The business had since greatly increased. In 1845 the takings were 53,322l., and last year they had reached 138,492l. The stock was worth 30,000l. New premises had been taken in Gresham-street, at a cost of 18,000l.; a premium of 15,000l. was paid for the premises. Several witnesses were called in support of the claim, which was placed before the jury at 39,864l.

Mr. Lloyd claimed a liberal compensation for the loss of Messrs. Bartrum & Harvey. The party would gain by the contemplated improvements, and there should be no loss sustained.

Mr. Hawkins addressed the jury to "cut down" the compensation. He called no witnesses on the part of the City.

The Recorder placed the case before the jury, and said the evidence showed that the claimants had made a profit of more than 9,500l. a year.

The jury retired, and, after consulting one hour, assessed the compensation at 28,000l.

**The Crown Assurance Company.**—A claim was made in the case of *The Crown Assurance Company v. The London, Chatham, and Dover Railway*, for premises in New Bridge-street. New premises were being built in Fleet-street, near St. Dunstan's church. After a long investigation, a verdict of 10,500l. was agreed upon.

#### PROVINCIAL NEWS.

**Leicester.**—Among the many private and public edifices lately built in this improving town, and various others now in contemplation, is a new warehouse and factory now being erected for Messrs. N. Corah & Sons. The building, which is of Classic design, will be four stories high, on a Derbyshire stone basement, the face of the walls being of small red bricks, with stone architraves round the windows, quoins to the angles, and a cantilever stone cornice, the whole surmounted by a colossal figure of "Commerce" in Box Bath stone. The factory and engine-houses will, in architectural character, correspond. The engine chimney, 16 ft. square at the base, will be hunched from a rectangle to an octagon; and, when carried up to a height of 124 ft., will finish with an ornamental stone cap of about 20 tons in weight. The engine bed, which is to be of red Mansfield stone, will contain upwards of 3,000 cubic ft. The whole of the buildings, including recreation-grounds for the work-people, will occupy a space of four acres. Mr. W. Jackson, of Leicester, is the architect; Mr. W. F. Mowbray, formerly of Salt Aire, near Bradford, is the engineer; Mr. H. T. Porter is the stonemason and bricklayer for the factory and engine-houses; and Messrs. Osborne, Brothers, are the stonemasons and bricklayers for the warehouse. The present warehouse of the Messrs. Corah, in Granby-street, it is understood, has been purchased by the Government for the purpose of converting it into a post-office, the present post-office being far too small and inconvenient for the rapidly-increasing trade and population of the town.

#### CHURCH-BUILDING NEWS.

**Bournemouth.**—The first stone of a chapel at the side of the Sanatorium has been laid by Mr. C. W. Facks, M.P. Mr. Street, of London, is the architect of the building, which, in its style, will much resemble St. Peter's church, Bournemouth; and Mr. J. W. K. Nethercott is the builder. The chapel will be 52 ft. in length, by 17 ft. 6 in. in width (12 ft. being taken up for the altar), and it will be capable of seating 100 persons. The flooring will be of oak, and along the centre aisle will be laid encaustic tiles. The pews will be of modern construction each seat being capable of holding four persons, and the windows will be seven in number. There will be a bell turret. The bell, altar, gasfittings, and encaustic tiles, are not included in the estimate of 1,000l. The slate for the roof will be worked in pattern, and the building will be erected with the Swanage stone, except the corners, which will be of Bath

stone. It is intended to heat the building by means of hot-water, and to erect a covered passage of glass connecting it with the Sanatorium. In consequence of the limited space of ground at disposal, the chapel will necessarily be built north and south, instead of east and west, as usual.

**Rochester.**—The cemetery for the united parishes of St. Margaret and St. Peter, together with its chapels, tower, board-room, &c., have been completed, and consecrated. The buildings consist of two large chapels, one for Episcopalians and the other for Nonconformists. These are connected by a couple of light arcades, which give access to the chapels, whilst in the centre stands a tower surmounted by a spire, the whole rising to a height of about 100 ft. The design of the group of buildings is in the Early English style, by Mr. Bulmer, architect. The whole is constructed of Kentish rag, with freestone dressings. The contractor for the erection of the tower, chapels, &c., was Mr. S. Jennings, and the amount of the contract, 3,770l. The cemetery occupies a space of six acres of ground, the land having been purchased of the bridge-wardens for the sum of 1,080l.

**Ogbourne St. George.**—The restoration of the parish church of Ogbourne St. George having been effected, the re-opening for public worship has taken place. The edifice has been restored and beautified, at a cost of 1,900l., by Messrs. Marquis & Munro, of Bristol, under the superintendance of Mr. W. E. Baverstock, architect, Mr. Wyatt. Of this sum 1,100l. have been raised by rate and voluntary contributions, leaving a debt of about 200l.

**Anst (Gloucestershire).**—The Rev. J. H. Way, vicar of Henbury, of which parish Anst is a chapelry, publishes in the *Guardian* an appeal on behalf of the proposed restoration of the ancient church of Anst. The sum of 1,200l. is required to effect the restoration in a manner becoming the honoured memory of Wycliffe. Of this amount 1,000l. have been raised.

**Wells.**—A new bell has been hoisted to the roof of the central tower of the cathedral. A petition has been signed and presented to the dean and chapter of Wells, praying that the bell may be hung in the centre of the tower, instead of in the corner, where the old one was surrounded by masonry so as to encompas the sound. The bell, we understand, weighs 18 cwt., and the tone is E flat.

**Eyam (Derbyshire).**—It is rather strangely proposed to restore the parish church of Eyam, "as a memorial of the removal of the plague from that village in 1666." The restoration is also to commemorate, after the lapse of precisely 200 years, the virtues and labours of the Rev. Mr. Mompesson, the then rector of the parish. Have there been none worth commemorating since then? The inference is not very complimentary.

**Oldham (Lancashire).**—The foundation-stone of a new school-church at Oldham has been laid. The building will stand as directly east and west as the irregular nature of the ground will allow, and will consist of a nave 53 ft. by 35 ft., and a chancel 9 ft. by 15 ft., semi-octagonal in form, which will be used for school purposes during the week and for divine service on Sundays. The whole of the seating, &c., will be moveable. In the basement will be a room 26 ft. by 25 ft., which will be used as vestry, class-room, ten-room, and for general purposes. Adjoining this is the heating-chamber, 9 ft. 9 in. by 8 ft., and boiler-room, 15 ft. 6 in. by 8 ft. The height of the basement will be about 9 ft. The porch floor stands 8 ft. above the Middleton-road, and is approached by steps and an asphalted slope running along the north wall of the building, and inclosed by iron palisading. The style is Early Gothic. The walls will be built of Plat's red bricks, and the arches, hands, and patterns will be of black bricks. The walls internally will be faced with picked bricks, and whitewashed; patterns in bricks slightly projecting will be left red. The chancel arch will be formed of monied bricks. The church will accommodate about 300 persons. The total height from the floor of the basement to the top of the ornamental bell-turret, which saddles the main roof at the west end, will be about 60 ft. The slates of the roof will be of two colours, green and blue, laid in broad bands. The cost of the building will be about 1,000l. Mr. W. Dawes, of Manchester, is the architect; and Mr. Wrigley, of Oldham, is the contractor.

**Swinton (Yorkshire).**—A school-church is being built in the Old-lane, Swinton. The foundation-stone has been laid. The building is designed

to seat a congregation of nearly 300. It is being built of brick in two colours, and covered with a steep-pitched slated roof. At the eastern end a quasi-chancel is screened off, rising by four steps to the altar, above which in the east wall is a three-light tracery window. Over the arched principal, which marks off internally the chancel from the nave, there will rise from the roof an open belfry for two bells covered with a four-sided spirelet. The contract has been taken at 514l. by Mr. J. Grundy, of Pendleton, who works under the direction of the architect, Mr. J. M. Taylor, of Manchester.

**Carlisle.**—St. Stephen's Church, erected at the sole cost of Miss Burdett Coutts, has been opened and consecrated. According to the designs at first submitted, the cost of the building would have been some 4,000l.; but additions and improvements have suggested themselves, and under the hands of the donor the work has increased in cost. Embellishments have been made, a peal of bells has been added, and the total cost will not be less than 6,000l. The foundation-stone was laid in March, last year, by Miss Coutts, as noted by us at the time. Red sandstone is the principal material used, the stones being rock-faced and laid in thin courses; while the quoins and traceries are of white Prudham stone. The general style is Geometric.

The entire length of the building is 110 ft., and its breadth, including the two wings, is 62 ft. The height from the ground to the ridge is 48 ft.; the height to the top of the wings being 24 ft.; and above these runs a clerestory. A chief feature is the square tower at the James-street end, from the top of which an octagonal spire rises, terminating in a gilt cross. At each corner of the square tower there is a buttress, that at one corner containing the staircase to the belfry. The tower is finished by a cornice 2 ft. deep, from which the spire is broached in a distance of a few feet, and then gradually tapered, its apex being 130 ft. from the ground. There are two two-light windows on each side of the tower, and a single-light window filled with tracery on four sides of the spire, projecting from the spire about 2 ft. at the top, coped with white, and finished in a finial. On the east side of the tower there is a door into the bell-ringers' room. All the windows in the church are ornamented with label moldings in white Prudham stone, ending some in carved heads, and others in foliage. Additional effect is obtained by introducing, above these white stone carved arches, a relieving arch of alternate red and white. All the carving has been done by Mr. Edwin Stirling, of Liverpool, from drawings furnished by the architect. Mr. Scott, of Newcastle-upon-Tyne, was the sole contractor, but sublet the joiner's work to Messrs. Lowry, of Newcastle-upon-Tyne; the painter's and glazier's work to Mr. Gibson, also of Newcastle; the plumber's work to Mrs. Thompson, of Carlisle; and the plasterer's work to Messrs. Johnston, Brothers, of Carlisle. The clerk of the works was Mr. Beckett, of Liverpool. Mr. James Nelson, jun., of Carlisle, was the architect.

**Cockermouth (Cumberland).**—Christ Church, Cockermouth, has been consecrated by the Bishop of Carlisle. The church has been erected mainly by the means, and entirely through the exertions of the Rev. Herbert Puxley, now incumbent of All Saints', Cockermouth, and some circumstances connected with the undertaking give it more than local interest. During the five years that he held the appointment of curate to the late Rev. E. Fawcett, of All Saints', Mr. Puxley laboured among the parishioners in a manner which met with their approbation; and, feeling convinced a necessity existed for a new church for the working classes, he set about collecting subscriptions among his friends for the erection of one. He met with much success, the interest the reverend gentleman had manifested in the schools and the charities in his district having made him very popular, and the building of Christ Church was commenced. There was a general understanding amongst the parishioners and many of the principal subscribers that Mr. Puxley was to be the first incumbent. Eventually, however, a stranger in the district, the Rev. W. Williams, was appointed to the incumbency. The ratepayers and inhabitants held an "indignation meeting," and it was resolved that a testimonial should be presented to Mr. Puxley, who, instead of ceasing to take an interest in the work, however, completed the church, at a cost of 900l. out of his own resources. Meanwhile, the incumbency of All Saints' fell vacant by the death of Mr. Fawcett, and to that Mr. Puxley was appointed by Lord

Lonsdale. The edifice is built from plans executed by Mr. Bruce, of Whitehaven, architect, the contractors being Messrs. Hepworth & Cape. The style is a mixture of the Gothic and Early English, and the construction is of white freestone from Tallentire quarries. The interior is simply arranged, the galleries, sittings, pulpit, and reading-desk being stained pine, which are relieved by blue and gold pillars supporting the gallery. The church is constructed to seat 900, two-thirds free.

#### DISSENTING CHURCH-BUILDING NEWS.

**Castleford (Yorkshire).**—The foundation stone of a new chapel for the Primitive Methodists in the rising town of Castleford has been laid. The building will stand upon a plot of land in the centre of the town, and, when completed, will afford accommodation for about 550 persons, at a cost of about 1,000l., inclusive of school and class-rooms attached. It will be erected from the designs of Mr. H. Fippard, of York, architect, under whose direction the work will be executed.

**Middlesbro'**—The new Presbyterian Church has been opened. The church, which is in the Early English style of architecture, and has cost 1,700l., is the design of Mr. W. H. Blesley, of Middlesbro'. It is 53 ft. by 42 ft., and will accommodate 700 persons. Behind it there is a school-room, play-ground, and a master's house.

**Ryhope (Sunderland).**—The new Wesleyan Chapel at Ryhope has been opened. It is situated near the Colliery Schools, and was built by Mr. Myers, from a design by Mr. J. Tillman, the site and a quantity of stone, lime, and other materials being supplied by the owners of the colliery. The building is fitted out with open benches, and will seat about 200 people; while a small vestry is attached for ministerial use, the whole having a gravelled front and white brick dressings. The entire cost incurred is about 340l.

**Sunningdale.**—The memorial stone of a new Congregational church has been laid at Sunningdale, by Mr. J. R. Mills, M.P. The design is Early Decorated. The turret at the angle is 56 ft. from the ground to the top of the finial. The building will be 25 ft. 6 in. wide, and 74 ft. 10 in. long, internally, exclusive of two transepts, each 15 ft. 10 in. by 6 ft. 8 in., and an apse at the end, 13 ft. by 6 ft. 6 in. The materials of construction are brick, with Bath stone dressings. The accommodation is for about 240 persons on the ground-floor. The ceiling of the church will be below the roof line, and will be divided into panels. All the internal woodwork and fittings will be stained and varnished. The contract is being carried out by Mr. Oades, of Egham, at the sum of 1,161l. Mr. W. F. Poulton, of Reading, is the architect. The total cost will probably be about 1,200l., towards which 800l. have already been promised.

**Derby.**—The Baptist Chapel, St. Mary's Gate, Derby, has been re-opened, after having been repaired, cleaned, and ventilated. The ventilation has been fixed by Mr. Watson, of Halifax. The heating apparatus has been planned and fixed by Mr. William Abell, of Derby. The woodwork alterations have been executed by Mr. Dusautoy; the gas-fittings reacquored and fixed by Mr. Longdon; and the painting and decoration by Mr. Basford, all of Derby. The ceiling has been divided into panels; the flats being white with a French grey border and an ornamental line of vermilion. The rafters are coloured buff, with a mauve ornament on each side. At each angle are gold bosses.

**Birmingham.**—The new Wesleyan Chapel, which has for some time past been in course of erection at Aston Villa, Lozells, has been opened for Divine service. The new chapel, which has been erected from designs by Mr. J. G. Bland, of Birmingham, will cost 4,000l., of which about 3,000l. have been raised. It is of the Gothic style of architecture, after the order common in France about the thirteenth century, modified to suit the materials used, viz., red and blue brick, finished with Bath stone dressings. The building consists of a nave of five bays, and north and south aisles. At the eastern end of the interior is a chancel, of shallow depth, opening into the nave, with a lofty arch of brickwork and incised stone. At the north angle of the chancel is the vestry, with a chamber over it opening into the north gallery. The galleries extend the whole length and breadth of the aisles, and are supported with iron columns with floriated capitals. The roof is high and open,

and contains provision for ventilation. The pews, which are without doors, are constructed of deal, stained and varnished, and afford sitting accommodation for 1,100 persons. The western end of the chapel is lighted by two windows of two lights and cusped arch, over which is a St. Katherine's window. All of these are filled in with stained glass, the workmanship of Messrs. Heaton, Butler, & Bayne. All the other windows are glazed with toned glass in pattern. The western end, facing George-street, is the only part completely exposed to view, and shows a gable rising to a height of 70 ft. To the north of the gable stand the tower and spire, rising 130 ft. high, and dividing the new chapel from the old, which is in future to be used as a school-room in connexion with the new chapel. The works have been carried out by Mr. Partridge, builder. The heating apparatus has been executed by Mr. Taylor, the staining by Mr. Naughtin, and the carving by Mr. Allen.

**Dudley.**—The Methodist New Connexion Chapel, after being some months closed for extension and alteration, has been re-opened. By the alterations the chapel is extended 24 ft. in length, and two side wings are added, the chapel thus being considerably widened, and a separate entrance to the galleries obtained, together with additional lobby room. The chapel is now 80 ft. long and 46 ft. wide. The windows are fitted with modern casements, and Mr. Millward has, at his own expense, fitted each of the thirty with a double row of stained glass. By night the chapel is lighted from the roof by a starlight pendant of 132 jets, manufactured by Messrs. Winfield & Co., of Birmingham; and under the galleries are nine smaller pendants, corresponding with the larger ones. The organ has been enlarged and improved by Messrs. Holmshaw & Sons, of Birmingham. The architect employed was Mr. E. Marsh; the builder, Mr. Millward; and the decorator, Mr. Wyther.

**Swindon.**—A new Independent chapel is to be erected at the top of Victoria-street, Swindon. The foundations are being prepared. The chapel will be in the Lombardic style, with a square tower at the south corner. It will be built of Swindon stone, with Bath stone dressings. At the entrance there will be Pennant stone columns, with carved free stone caps. The roof will be covered with patent tiles, made to a special pattern. There will be no gallery inside. The seats will be open. The edifice will be constructed to accommodate 500 persons, and will cost about 2,000l. Mr. John Phillips is the contractor for the erection of the building, Mr. Pontin, of Warmminster, carrying out the masons' work. Mr. Stent, of Warmminster, who prepared the plans, will superintend the works. This, with the Corn Exchange, which is progressing, will cause a considerable number of men to be employed in the town.

#### STAINED GLASS.

**St. Margaret's Church, Lynn.**—In the east end of the chancel of this church, remarks the *Norfolk Chronicle*, is a window of doubtful antiquity and peculiar form, its principal feature being a large circular opening with what may be called inverted open spandrels beneath, forming altogether a round-headed arch, though at first sight the idea is suggested of a hoop standing on a flat base. The hoop itself is filled in with a poor kind of perpendicular tracery, devoid of taste, and suggestive of the "Churchwarden's Gothic" period of architecture. The poverty of this window has now been somewhat mitigated by the insertion of painted glass, by Messrs. Ward & Hughes, of London. The new window is the gift of Capt. S. G. Cresswell, R.N., and is a memorial of his late father, Mr. Francis Cresswell. Each of the numerous lights contains a figure, the three central ones being those of the Saviour, the Virgin Mary, and St. Margaret; and the others attendant angels.

**St. John's Church, Eton.**—The erection of a new east window in St. John's Church, Eton, has now been completed. The general treatment adopted by the artist is founded on that of fourteenth century work. There are eight main subjects in the window, each inclosed within a flowing stem, fruit, and foliage of "the vine," after the example of the ancient "Jesse" windows, the foliage being all relieved upon a groundwork of grisaille glass, introduced for the purpose of giving breadth of effect to the whole as a composition. At the base of the window the groups have reference exclusively to our Lord's Passion. They consist of the pro-

cession to Calvary, with Christ bearing the cross, the weeping women following; the Crucifixion; the descent from the cross; and the dead body of our Lord borne to the sepulchre. Above these lower groups, and on a greatly increased scale of size of figures, are three subjects, in harmony with each other, of our Saviour's appearance after His resurrection, each subject occupying the greater portion of two lights. First, our Lord's appearance to St. Mary Magdalene ("Touch me not," &c.) Second, the appearance of the Holy Women returning from the sepulchre. The third and next prominent group, occupying the centre lights, is the Saviour's appearance to St. John (to whom the church is dedicated), St. Peter, and the other disciples at the Sea of Tiberias. The whole of the figures in these three subjects are nearly the size of life. The tracery in the upper portion of the window consists of a series of openings, and they have been made available for the treatment of one subject, that is, "The Resurrection of the Dead, blessed in the Lord." In the top opening, our Redeemer is represented glorified in heaven, inclosed in an aureole of light, with outstretched arms; all the other openings containing figures of "The Just made perfect," ascending and borne by angels. The entire window is the design and work of the Messrs. O'Connor, of London. The insertion of the stained glass was done by Mr. Harrison, the surveyor to Eton College. The window, which has been erected by general subscription, at a cost of nearly 500l., is intended as a memorial of the many benefactors of the parish of Eton, and particularly his Royal Highness the late Prince Consort, who laid the foundation-stone of the church, and who contributed in so many ways to the welfare of the poor of Eton. The inscription, not yet inserted, will run thus:—"The pious memory of his Royal Highness the Prince Consort, the founder of this church, and of the Benefactors of this Parish."

**Gloucester Cathedral.**—The window memorial of Dr. Jenner in this cathedral has now been completed by the artists, Messrs. Clayton & Bell. The window, remarks the local *Chronicle*, consists of five lights, in each of which are represented three of the miracles of healing performed by our Lord, the centre and chief representation being that of the Raising of Lazarus. The five lower subjects, from left to right, are, Healing the Blind, Healing the Woman with the Issue of Blood, Healing the Deaf, Healing the Man Sick of the Palsy, and the Impotent Man at the Pool of Bethesda. In the second tier, the objects are, the Raising of Jairus's Daughter, of the Son of the Widow of Nain, and of Lazarus, Healing the Centurion's Servant, and Cure of the Deaf. In the upper row are, Healing the Lunatic in the Tombs, the Leper, the Dumb, and the Lame. In the tracery lights are angels hearing crowns, and scrolls with "Alleluia." The memorial of the late Mr. J. Elliott will also be forthwith erected. The window selected is the westernmost of the south aisle. The whole of the windows at the west end of the cathedral will then have been filled with painted glass. The windows in the south and west walks of the cloisters, which have been for many years bricked and plastered up, are to be opened. Three of the windows in the south walk have been filled with church glass. A gentleman of the city has proposed to fill two of these windows yearly until all are restored.

**Blockley Church (Worcestershire).**—In Blockley Church, near Moreton-in-Marsh, a five-light stained glass memorial east window has been completed. The glass has been designed and executed by Mr. Holland, of Warwick. It contains, in medallions, the Nativity, Baptism, Crucifixion, Resurrection, and Ascension of our Lord; the Charge to Peter and Conversion of St. Paul being introduced in the outside openings, Peter and Paul being the patron saints. The background is of the vine and passion-flower pattern. There are also small medallion heads of the twelve apostles, emblems, &c. &c. The tracery contains Gothic ornament, emblems, I.H.S., &c. The window was erected by Sir Charles Rushout, bart., and his children, as a memorial of the Hon. Mrs. Grieve.

**Coston Church, near Birmingham.**—A stained-glass memorial window has been placed in this church by Mr. J. S. Steck, as a memorial of his two children. It contains three openings filled with the one subject of Christ Blessing Little Children, under a floriated canopy, in which are introduced the Lamb and Pelican, angels in tracery, bearing scrolls, &c. The work was executed by Mr. Holland, of Warwick.

#### SCHOOL-BUILDING NEWS.

**Southminster (Chelmsford).**—The Southminster New National Schools have been opened. These schools have recently been erected at a cost of 1,500l., the greater part of which has already been raised by subscriptions in the parish, assisted by the Corporation of the Charterhouse. The new building has been erected from designs by Mr. G. E. Pritchett, the builder being Mr. Stanmer, of Southminster, and the bricklayer Mr. Cook, of the same place. The building is of the late period of English architecture, with open roof, the main room being 65 ft. by 20 ft., with a class-room of similar width, forming, as it were, a continuation of the school, with a raised platform for class purposes. There are two separate lobbies, with distinct yards, in the rear, with a dwelling-house for the master.

**Finchingfield.**—The new school and lecture room in connexion with the Independent chapel, at Finchingfield, have been opened. The building is on the east side of the chapel, and is of red brick, in the mixed Gothic and Byzantine style, with black facings and stone dressings. The area of the main room is 45 ft. by 25 ft., the height being 13 ft. to the plate, and 14 ft. more to the ridge, having an open trussed roof stained as oak, with perforated quatrefoil ventilators; the windows, quarry glass, of Hartley's patent. The entrance from the front is by a Gothic porch, paved with Minton's encaustic tiles. The south end of the ridge of the roof is terminated by a finial. There is at the north end of the building a class-room, 18 ft. by 12 ft., and a small cloak-room.

**Elmswell (Suffolk).**—The first stone of new national schools has been laid here. They will be built of red brick, and will contain a school-room, 45 ft. 6 in. by 17 ft.; a class-room, 16 ft. by 12 ft.; and various other offices. The roof will be open, high-pitched, and stained and varnished. The plans and specifications were furnished by Mr. A. Andrews, of Bury, builder, who has engaged to build the school. Sir George Seymour, bart., gave the land for the site, and the total cost will be about 500l., the larger portion of which will be raised by subscription.

**Fladbury.**—The old school, it seems, was greatly deficient in accommodation, dilapidated, and otherwise inconvenient, in consequence of which a subscription was set on foot; but as the estimated cost was nearly 900l., the whole amount has not yet been raised, although the school has been built and opened. The architect was Mr. F. Freedy, of London, and formerly of Worcester; builder, Mr. Griffiths, of Ellesfield; and the site is near the church. The school, which has a residence for the master and mistress attached to it, consists of one large apartment, 51 ft. 6 in. by 19 ft., and will accommodate 112 children. The building is of brick, with tiled roof, steeply pitched, open wood-work internally, and small bell turret. At the north end is a window of five lights, with stone mullions, and a quatrefoil opening above; and in the west side wall are two similar but smaller windows, with a fire-place under each, the two fires meeting in the wall between the windows. The facings and masonry of the windows are of freestone, and in the walls externally are bands of blue brick along the centre and at the base. A porch, with open roof, completes the building. There is a large inclosed play-ground.

**Wincle.**—The foundation stone of a new school and school-house, in connexion with Wincle church, has been laid, according to the *Macclesfield Courier*. The new school will be built on the site of the old one, on ground adjoining the churchyard, given for the purpose by Mrs. T. R. Dainty. Mr. Sugden, of Leek, is the architect, and the building contract has been let to Mr. J. Naden, of Leek, who will use for the work stone obtained in the neighbourhood from Bennett's Hill Quarry.

**Liverpool.**—The foundation-stone of the Fairfield National Schools has been laid on a site of land presented by Mr. T. S. Gladstone, on the Old Swan-road. The buildings, when completed, will comprise boys', girls', and infants' masters, with class-rooms, and a residence for the master; and they will afford accommodation for about 500 scholars. The plain Early English style of architecture has been followed in the designs, which were prepared by Mr. T. J. Kilpin, architect.

**Sheffield.**—The foundation stone of the schools which the Wesleyans are about to erect in Ellesmere-road has been laid. The site is on the right of Ellesmere-road, which has been laid out

below the old Grimesthorpe-road. The district contains a large and rapidly-increasing population. The schools will be a part of a larger scheme, which includes a chapel; and the total cost would be about 6,000*l.*, of which one-third will be devoted to the erection of the schools. The character of the architecture is Gothic, and the building will be two-storied, with school-rooms for children of both sexes, and a number of class-rooms. The designs have been prepared by Messrs. Wilson & Crossland, architects.

**Kenton (Newcastle-upon-Tyne).**—A new Free Methodist Chapel has been opened at Kenton. The chapel has been erected from designs furnished by Mr. George Smith, of Newcastle, and under whose superintendence it has been carried out. The style of the building is Gothic, and it has been designed to hold 200 persons, all on the ground floor, with vestry and other conveniences behind. The pews are open, with ornamental bench ends. The whole of the internal fittings are stained and varnished. The cost of the building (exclusive of the site) will be about 3,000*l.* Mr. E. Brewis, Low Friar-street, Newcastle, was the principal contractor, Messrs. Bellwood & Son, Russell, Montgomery, Dawber, and Richardson being the sub-contractors for the mason work, plumbing, plastering, slating, and painting respectively. The stained glass spandrels in the two lancet windows in the west end of the chapel were presented to the trustees by Mr. G. Cooper, Clayton-street, Newcastle.

RECENT PATENTS CONNECTED WITH BUILDING.\*

**PREVENTING DAME, INSECTS, AND VERMIN, FROM ENTERING DWELLING-HOUSES, &c.**—*F. Reichinger.* Dated 22nd August, 1864.—In erecting a house or building according to this invention, a sheet of glass, either plate or other glass of any suitable size, is fixed by cement or mortar against the interior of the walls, running the entire length of the building; in fact, every apartment has a glass wall, which can be ornamented or papered as may be required. In the case of a house already built, the glass is bent and inserted at the top of the room, meeting the glass which is inserted from the room above, and overlapping each other. By this means there is no possible entry or escapement either into an apartment or from the apartment.

**KILNS FOR BURNING QUARRIES, TILES, BRICKS, &c.**—*T. Bennett.* Dated 29th September, 1864.—For the purposes of this invention the exterior of a kiln is built of a similar form to that heretofore very commonly used of an oblong rectangular form. Fire-places are constructed on either side in such manner as to be below the bottom of the kiln. Each fire-place is arched or covered over, openings being, however, left for the heat and products of combustion to rise up through the roof of each of the fire-places into narrow spaces between pairs of walls, by which the interior of the kiln is divided into separate longitudinal compartments. It is, however, preferred that a kiln should be thus divided longitudinally into five compartments, but this number may be varied. The fronts of the fire-places are capable of being closed, and have each a door at the upper part. The interior of the kiln is lined with a wall leaving a narrow space between the interior of the outer wall and the lining wall, and into this space the products of combustion of each of the fire-places pass by means of an opening through the arch or cover of each of the fire-places. At the inner ends of the fire-places there is a hollow longitudinal space which is divided longitudinally, and there are openings into this space at the inner end of each fire-place, so that the heat may get freely under this part of the bottom of the kiln, and consequently, below the bottom of the central compartment, by which the lower part of such central compartment is heated. Near the upper parts of the pairs of walls, and between them, there are horizontal tiles across the open space, and a little below these there are inclined bricks, or tiles fixed across the narrow spaces, by which the products of combustion may fairly rise up, while dust will be prevented descending between the spaces on either side of each fire-place, but will, by the inclined tiles or bricks, be caused to descend to the openings into the fire-places. The quarries, tiles, or other articles, are piled within the longitudinal chambers, and when they are all they are covered over with tiles and then with sand, in such manner as to prevent

the flame, dust, and smoke entering the chambers. Over this covering, and over the pairs of walls and spaces between them, bricks or other articles are piled, which, from their nature, do not require to be burned in closed chambers. By thus arranging the fire-places at right angles to the pairs of walls which divide the kiln longitudinally, and by forming the ends of fire-places with openings into the spaces under the central part of the bottom of the kiln, the heat and products of combustion rising from the several fire-places become very uniformly diffused, and all the chambers are very equally heated.

**CAISSONS.**—*G. Furness and L. G. Moore.* Dated 31st August, 1864.—For the purposes of this invention it is preferred to employ caissons of an elliptical horizontal section, but other forms may be resorted to when carrying out the invention. Each caisson is constructed as heretofore of a series of short lengths or rings, which are connected horizontally by flanges and screw-bolts and nuts as heretofore; but in addition to the horizontal joints, each short length or ring is formed of two halves or parts, which, by upright flanges, are fastened by screw-bolts and nuts, so that while a caisson consists of a series of short lengths or rings connected horizontally together, as heretofore, the two parts or halves of each short length or ring are connected vertically, so that when a series of caissons have been sunk to a given depth, and parts of the foundation have been formed therein to the height where the caissons are to form permanent parts of the work, the inner halves or parts of the caissons which are above the permanent structure may be removed, while the outer halves or parts are allowed to remain in order to present an arched coffer-dam to prevent the water from getting to the interior while the work is being carried up, more or less resting on the foundation, or parts of the foundation, formed by and in the lower and permanent parts of the caisson.

**CONSTRUCTION OF CHIMNEYS AND FLUES FOR HOUSES, &c.**—*W. H. Kelso.* Dated 14th October, 1864.—The patentee claims, first, the construction of chimney breasts in houses and other buildings with a single flue for one series of fire-places throughout the several floors, as described. Secondly, the adaptation and application to a chimney or flue of a register capable of being adjusted, in the manner described, by means of a rack or by other suitable means, for the purpose of putting the fire-place on each floor into communication with the common flue, as required; and also, for regulating the draught from the fire-place into the flue. And, lastly, the adaptation and application of a movable scot-door to the bottom of the chimney, as described.

Books Received.

The *British Workman* for July 1st has a powerful portrait of Abraham Lincoln, and a memoir of that very able and true-hearted man; besides an excellent engraving of a rural scene, after Birket Foster; and all for a penny!—"Sketches of the Sanitary and Social Condition of Greenock," by Walter Gunn, Missionary, Greenock; Black. Mr. Gunn is a missionary of the right sort: he is not only a religious and moral missionary, but a sanitary and social one. He not only recommends tracts and Bibles, but mops and lime-white pails and brushes; and his teachings not only tend to the promotion of religion and morality, but of sanitary truths, such as the evils of overcrowding and close apartments, and the healthfulness of fresh air and cleanliness. And a fine field he has at Greenock, one of the nastiest and most unhealthy towns in Scotland, where fever has of late been probably far more prevalent and deadly than anywhere else in the north. Mr. Gunn's pamphlet is a sensible production, useful to those he visits, and to others, as a sanitary and social tract, and interesting to all concerned in such subjects.—"The Railway's Construction Facilities Act, 1864," with Notes and Abstract of Nineteen general Statutes incorporated therewith; and the Act for giving additional powers to existing Railway Companies, By C. Wordsworth, Q.C., and Counsel to the Institution of Civil Engineers." Mr. Wordsworth's reliability in editing a volume like this is too well known to need any certificate from us. The Railway's Facilities Act, 1864, is a very important statute, which virtually takes the place of a special Act of Parliament, where all parties concerned consent to the requisite procedure in carrying out new railway works, and obtain a licence or certificate from the Board of Trade.

Miscellaneous.

**THE STATUE OF THE LATE SIR CHARLES BARRY.**—The statue of Sir Charles Barry, in the Inner Hall of the New Palace of Westminster, will be uncovered on (this) Saturday, July 1, at twelve o'clock noon.

**INAUGURATION OF THE ALBERT MEMORIAL, ABINGDON.**—The memorial of the late Prince Consort, designed by Mr. Gibbs, of Oxford, and erected on an elevated situation in the recreation-ground, henceforth to be known as the Albert Park, Abingdon, has been inaugurated by the Earl of Abingdon. We have already given a description of this memorial, with an engraved view of it, in the *Builder*.

**MONUMENTAL.**—A marble statue, by Noble, of the late Mr. J. F. Foster, chairman of the Salford Hundred Sessions, has been presented to the magistrates of the Manchester division of the Salford Hundred, by Mr. J. F. Bateman, civil engineer, and placed in the hall of the Assize Courts. The statue represents the learned gentleman in his wig and robes, and is placed at the east end of the hall.—The monument at Logierait, to the late Duke of Athole, is to take the form of a Celtic cross, and with the pediment, will reach to a height of 59 ft.

**BELGRAVE MANSIONS.**—A limited company is being formed for the erection of "maisons meublées" at Grosvenor-gardens, Grosvenor-place. Messrs. Trollope & Sons having become the lessees from the Marquis of Westminster of a large portion of the land comprised in the "Pimlico Improvements," the opportunity has been taken for the erection of an establishment of this kind, without the enormous cost involved in clearing ground for the purpose. The site lies between the bottom of Grosvenor-place and Victoria Station. It will be in future known as Grosvenor-gardens. The elevation of the proposed buildings, as well as of all the adjoining buildings, has been designed by Mr. T. Cundy, jun., the architect of the Marquis of Westminster, who has also laid out the garden inclosures in front of the houses. The ground-floor and basement of the building, as in Paris, will be let off in shops, and a portion of the ground-floor will be let for a restaurant, the proprietor being bound to supply the residents in the apartments. The upper part of the building will be the "maisons meublées," and will comprise about 200 rooms. These will be so arranged that any number may be let off as a separate "apartment," and as there will be several entrances direct from the street, a tenant taking any considerable number of rooms might have the sole use of one of such entrances, thereby securing entire privacy. Messrs. Trollope have entered into a contract with the company, for a sum not exceeding 105,000*l.*, to deliver up the building furnished complete on 25th March, 1867.

**THE METROPOLITAN FREE DRINKING-FOUNTAINS ASSOCIATION.**—The annual meeting of this body has been held in Willis's Rooms, but was very thinly attended. Mr. Samuel Garney, M.P., occupied the chair. The report stated that several drinking-fountains and troughs for dogs had been erected by the society since last report, but the great value of space in the metropolis had rendered them unable to provide larger troughs for cattle except in a few places. Between thirty and forty fountains had been given by private individuals. In addition to eighteen new fountains and one cattle-trough erected by the Association, and the seven private fountains given during the past fifteen months, arrangements were made for three other fountains. The cost of one to be placed near the Houses of Parliament would be defrayed by Mr. Charles Buxton, M.P.; and amongst the donors' names were those of Earl Russell, the late Cardinal Wiseman, and the Rev. Newman Hall. The amount guaranteed was far less than was required to carry on the work; and unless increased aid were given, there was danger of the benefits of the Association being stopped. Six years ago there were no fountains in London. The Society had since erected ninety-one. Many of those given by private individuals, and which were under parochial control, had fallen out of repair, and unfortunately the discredit of the circumstance was erroneously given to the society, whose desire it was to have these fountains within their management. The income required was, however, 1,000*l.* a year, and all the annual subscriptions did not at present amount to half that sum.

# The Builder.

VOL. XXIII.—No. 1170.

Dwellings, and the Union Chargeability.

It is sometimes difficult to say in the case of a particular measure of reform that is an instalment only, whether it should, with a view to progress, be accepted or rejected. We felt in this position during the discussion in both Houses of Parliament, of the Union Chargeability Bill, which, before our number appears, will have become law. Meant to aid in the correction of the inequality that exists between the demand for places of residence of the least expensive sort, and the supply of them, as well as in the amelioration in other ways of the condition of the humbler classes of the people, it is a measure the objects of which must necessarily interest us deeply. The difficulty we have referred to arises from experience of the delays, sometimes approaching a life-time, that separate the entire accomplishment of a work of social improvement in which legislation is required, from the period of general agreement as to the necessity of some measure; and which delays often appear to be caused by the confirmation given by an Act of Parliament to an original falling short in the grasp of the whole question. Of the whole desired reform in the system of chargeability of the poor, the Bill now passed is, we consider, but a very slight instalment. But the discussion of it has been the means of registering pledges of further reform, and of showing what are the points which yet require attention.

The object of the measure has been succinctly stated as to give the labourer a wider range, and a freer scope for making the most of his industry. Thus, that unfortunate state of things alluded to above, and a constant subject of comment and illustration in the *Builder*, by which the labourer is either domiciled worse than the cattle, or is compelled to waste his strength in daily walks of eight or twelve miles, it is hoped will be ameliorated. It is hoped that amongst the circumstances which involve the difficulty that the labourer has in procuring a dwelling not directly hurtful to him, or a dwelling of any kind, will not in future be found the particular deficiency that has resulted from the discouragement given by many landowners, to the building of cottages, under the apprehension of increased charge upon the rates.

During the discussions upon the Bill, it was contended that allegations respecting an actual destruction of cottages had no foundation, at least as regards the last few years; or that where cottages had been destroyed, they had been replaced by others. These last giving better accommodation than the equal number of cottages destroyed, it was argued, somewhat incautiously, that all that was necessary had been done. But, besides the provision for a greater number of persons, one of the improve-

ments needed has been that of the allotment of a greater number of rooms to each family. New cottages ought to be larger than the old, although to provide for the same number of persons. It would require much space to explain the discrepancy between certain statements, and some of those of the report of Dr. Hunter which was so often referred to in the debates; but it is not necessary to do so. It may, however, be mentioned in this place, that the figures of number of houses and increase of population were taken from the census returns. The report had not been intended to be quoted by Mr. Villiers in evidence of the condition of affairs which it was hoped to remedy. As to that condition, abundant other testimony was and had been adduced. It would, indeed, be quite sufficient to rest the case for some legislation, on the restricted statement that house-accommodation does not keep pace with the population, and upon evidence that where houses are not demolished, they are often allowed to fall down and are not rebuilt.

There are however parishes in which no new houses are allowed to be built; and there are certainly others in which houses have been pulled down. Surely, a more stupid and harsh system could not exist. If the object have been a pecuniary gain by driving paupers out of a parish, it is difficult to see how in the majority of instances, that has been attained, and therefore what exact improvement the change in the law has to effect in the direction referred to. The state of the law of settlement, even after the passing of the Union Chargeability Bill, remains unaltered. It is only promised, by Mr. Villiers, to be taken in hand shortly. The law is one with which no one except a parish-officer seems to profess acquaintance; indeed, we have heard the remark that no one but the late Mr. Baines knew much about it. It is worse than obscure: it is framed as though intended for cruel deception. This will appear in the sequel. Let us first explain further what the new Act aims at effecting.

The Union Chargeability Act is based on the principle that the area of rating for the poor, should coincide with the area of management. The union is taken as the unit of administration, instead of the parish. It is said that the Act will put an end to removal from parish to parish in the same union, and that the poor will be removable only from union to union.

The popular belief is that a settlement is obtained by residence of a certain number of years in a parish. On the other hand, the law is such that a person may reside any number of years in a parish, and not obtain a settlement in it. Yet Mr. Villiers is reported to have said on one occasion:—"The great source of settlement and charge in parishes, is the residence of the poor. The poor obtain a settlement by residence, and their families derive their settlement from them. Therefore, the great object, in order to keep down the poor, is to prevent them from residing in parishes." Now, mere residence did not, and does not yet, give a settlement. The residence must be connected with something else,—property, or renting, or what it is not within our speciality to be able to explain. Moreover, the children of a person who has resided for a number of years in a parish, without having obtained a settlement in it, may be removed, on becoming chargeable, to the place where their grandfather was bound apprentice, or to one where their great-grandfather was hired and served for a year. But though mere residence will not confer a settlement, it seems understood to confer what is called irremovability, if continued for the requisite time. This was not long ago five years; but in 1861, the period was reduced to three years; and it is now to be one year. The residence is said to confer the irremovability in fact, and always; but with our knowledge of a case to which we shall refer, we

do not see how this can be. However, it appears that whilst comparatively few paupers have gained a settlement, an important number have the irremovability. The maintenance of these last, without the Act just passed, has been chargeable on the common fund of the unions.

Thus, it has been pointed out by the *Pall Mall Gazette*, it is difficult to see that a landlord has been under any inducement to pull down cottages with the object so frequently referred to, or "how the introduction of union-chargeability will affect the matter." An employer would have gained nothing by the pulling down, unless he could have driven his labourers, not only out of the parish, but out of the union, for their residence. This might be possible indeed in many cases, as near the border of a union, where the labourers might be driven into a town in a different union. The writer in the *Gazette* reasonably enough asks why, since the poor will be chargeable to the unions, and will be practically speaking removable only from union to union, the principle of union-settlements should not at once be recognised. He would have added to Mr. Villiers's Bill a clause to this effect,—"Every person who is irremovable by reason of having resided three years in any union shall be settled in the parish from which he is irremovable,"—and says that thus nearly all the misery of the law of settlement would be swept away; since,—"It would realize the popular and perfectly just notion that there ought to be a substantial connexion between the pauper and his place of settlement, and it would enable a poor man to go out of the bounds of the union from which he is irremovable for some temporary purpose without thereby falling under the tender mercies of the law of settlement." It is desirable that the man should be unfettered in his efforts to get the best price for his labour; but the labourer feels he is not free, so long as he is unable to move where he pleases without danger of losing his right to relief.

In the Yorkshire manufacturing districts there is a deficiency of cottages; but it is said to arise from the circumstance that the demand has increased more quickly than it has been possible to build. Such a case as that of some agricultural districts, where there is increasing population, but decreasing house-accommodation, is not met with. Of these last, some of the worst cases are produced by the system of the parishes where there are large landed proprietors resident. Pattern-villages are built; but the cottages in them are restricted in number; so that the surplus of population goes to increase the crowding in villages four or five miles away, where there are no restrictions. Now the aim of the Yorkshire manufacturer is to supply his mills with labour; and his mode of effecting this is by having cottages in the vicinity of his mills. As cottage-building does not pay of itself, the landowner must be induced to look at the question in the same light as the other employer of labour. At present there is by no means an excess of labour in many districts; and some farmers have found an advantage in conveying their labourers, the four or five miles from their place of residence, on donkeys.

It is not surprising, therefore, that the employers, as distinct from landowners, and as represented by the Farmers' Club in the Blackfriars-road, were unanimously in favour of union-rating, and of the abolition of the law of parochial settlement. According to one statement from an attorney at Swindon, quoted by Mr. Villiers, the law has operated unfavourably upon the farmer, by diminishing the supply of labour; has led to the crowding of labourers into particular parishes to the exonerating of other parishes; and has worked against the employment of free labour and the best labour. The Rev. Mr. Huxtable has shown what are the

consequences when the wages of superior men are diminished, as in parishes where a certain amount of work has had to be distributed alike among all the labourers. He says, speaking of what we may now hope is a past state of things, "If a few did a much greater quantity of work, and thereby earned higher wages, there would be so much less employment for the rest, so that there is really no encouragement for the superior labourer in the parish, nor can he carry his skill to another market; where there is no fit residence for him, and no provision in sickness and old age under the present system." The Rev. Sir A. Henniker, incumbent of Thornham, Suffolk, also as quoted by Mr. Villiers, stated that he knew of places in which, having noticed the diminution of cottages, he was informed that "the village was supposed to look prettier with fewer cottages," and that "the labouring class of men came from the adjoining parish." The Hon. and Rev. Mr. Talbot, Chairman of Quarter Sessions in Staffordshire, has "frequently observed that when a man who lived near his work came to be about 50 or 60, he was still fresh and active, while a man who had to walk daily two miles to and from his employment was worn out by the time he attained that age. . . . He always found that the men who lived near their work preserved their strength for many years longer than those who resided two or three miles from it." In the debate on the late Mr. Baines's Bill, it had been said by Mr. Ker Seymour, that in consequence of the law, "for one man who left his settlement and was returned to it a pauper, 100 were prevented from leaving home in search of work." Some of the most important evidence adduced by Mr. Villiers was drawn from prize essays of the Royal Agricultural Society. It spoke of the practice of "clearing off cottages" as to be found in Somerset, of a system of depopulation as systematically carried on in some districts in Northamptonshire, of more cottages as wanted in numerous counties, of evils in health and morals from overcrowding, and of the useless wear and tear by long distances required to be traversed. Again and again is there some such observation, as that it "is the unfortunate policy of the settlement law to offer inducements to the demolishing cottages where they are urgently required, and to the congregating them where they are not."

We must leave to others explanation of the discrepancy which there would seem to be between "irremovability," or that which has been acquired by simple residence of three years, and the fact that a person can be removed from the neighbourhood of his friends, hundreds of miles away, to a parish with which he has had no relation except from having been born in it. But we happen to have the best reason to be acquainted with a case exceeding in the cruelty of it, any that we could have supposed possible under English law, and which shows that besides the cruelty, there is positive stupidity in the existing system.

Some three years ago, a youth, who held at the time a subordinate position with a certain architect, became insane. He was then resident, with his mother and younger brother, the latter an idiot, at a place where he had resided within a month or two of three years, in the suburbs of London, on the Surrey side of the Thames,—having previously resided for more than five years in one parish in the north of London, and before that in different quarters of the metropolis. His mother whom he had helped to support and console, when the malady broke out, having no other course, sought the authorities of the Lambeth workhouse, and having answered all questions truthfully (some might say too much so), was allowed to bring her son, who was shortly afterwards transferred to the County Asylum, where his mother was able from time to time to visit him. It is now necessary to state that the youth was born in Cornwall. The brother was born in Oxford. The mother's birthplace was in Devonshire; but she had resided in London for twenty years or more. The father's birthplace had been somewhere else. The youth remained at the Surrey Asylum for some months; but one day, the mother received a letter from the stewards' clerk of that institution, informing her that three days later her son would be removed to the Cornwall County Asylum at Bodmin. Her assent was not asked. At the time named, which happened to be over the period of three years from the date of taking up the residence in the parish in Surrey, her son actually was taken away, both in spite of her protest, and

in spite of the Commissioners in Lunacy, who were addressed without an hour's delay, and who immediately took up the matter. Were it not obvious that the influence of the affections would go to assist in a cure, or otherwise in alleviating the condition of the patient, and also that watchfulness on the part of relatives may be necessary to prevent ill-treatment even in county asylums, we could readily give evidence on those points from the reports themselves of the Commissioners. It seems that the original accident of birth in a place where the mother was living during only some weeks, led to a claim, many years afterwards, by the Surrey parish or union, against the Cornish one, and to the removal, which was the act of the latter. The mother has now not seen her son for three years; she has had no letter from him for that time, and has only learned that he is suffering from an old disease, which may have had something to do with the mental disorder, and as to which the information that she could give would be important. She has no means of earning a living in Cornwall, and has no hope of getting there to see her son, unless by the charity of friends, and for a very short visit. Now, how can such a state of things as this which we have described, be reconciled with "irremovability," or with Christian charity? Can it be reconciled with public policy and economy even? The youth's brother, if no other member of the family, may need treatment: thus, the remaining son would be deported to Oxford. Can anything in this country be more stupid and uneconomical, leaving the cruelty out of the question?

For all that the Union Chargeability Bill has become an Act, we believe that the case which we have described might be reproduced this very year. All we learn of the probability that the state of affairs will be eventually other wise, is that Mr. Villiers is "favourable" to "the abolition of removal," that he "does not deny that it would be an immense advantage to get rid of this system of removal," and that he would be "glad to see the system of settlement abolished."—the present measure being proposed "as an instalment," and as this alone can we accept it.

#### THE ROMAN CATACOMBS.\*

The first impression, on descending into catacombs, when the light of day is suddenly lost, and the eye follows the dim perspective of corridors lined with tier above tier of funeral niches, partially shown by the glare of torch-light, is one that chills and repels. Imagination calls up what Reason rejects, and sports, as if fascinated, with ideas of danger—mysterious, undefinable—corrected, indeed, by the higher associations and reminiscences that naturally take possession of the mind in any degree acquainted with that past so replete with noble examples from the story of those who here—

" . . . in the hidden chambers of the dead,  
Our guiding lamp with fire immortal fed."

We may, perhaps, descend into these abysses from some lonely spot in the Campagna, whence the Vatican cupola is distinctly visible; and certainly nothing could be more glorious, from the point of view of Roman Catholicism, than the confronting of such a monument to triumphant religion with the dark and rudely-adorned subterranean once serving as sanctuaries of the primitive church of this centre, subsequently raised into such proud ecclesiastical supremacy! Another thought, that may spring from this range of antiquarian study, and invest its objects with still deeper interest, is that of a promise for something higher than either Catholicism or Protestantism, in the Christianity of the future.

In their primitive mode of interment, the early Christians may be said to have taken, as their model, the sepulchre of the Redeemer,—a cavern, with entrance closed by a stone, in which usually but one body lay; and in the especially honoured tombs of martyrs, or other illustrious dead, the form called *arcosolium*, like an excavated sarcophagus, with arched niche above, supplied the norma for the later-adopted altar of solid stone (instead of the plain wooden table in earliest use), with relics inserted in a cavity under the *mensa*; the practice of consecrating the Eucharist over such martyr-tombs having passed into the universal discipline of the Latin church, through a decree of Pope Felix (269—275),

ordering that henceforth all masses should be celebrated over such burial-places of the holy dead.

"Altare quietem debita  
Prestat beatis ossibus."

as Prudentius testifies to this ancient usage. From the same poet ("Hymn on St. Hippolytus") we learn that these subterranean were not originally, as we now find them, in total darkness, but lighted, however dimly, by those shafts (*lumina*) still seen in many parts piercing the soil above our heads, though no longer in every instance serving for that purpose. The circumstances under which catacombs have been rediscovered within modern times, at the several points where we now descend into them, form a sufficiently singular detail in the story of their vicissitudes; and it is remarkable that the period of the greatest religious conflict among Christian nations, was that which witnessed the revival of this long-forgotten testimony, conveyed in such striking monumental language, to the faith and practice of the primitive Church. Energetically as these hypogea were explored in the sixteenth and seventeenth centuries, little had been accomplished, in comparison with the results attained within years quite recent, by any of those earlier undertakings; and much of the fruit long since secured was lost through Vandalic spoliation or inexcusable neglect. It was on the 10th of December, 1538, that the first exploration was commenced by Bosio, in company with Pompeo Ugono and others; and subsequently, between that year and 1600, were explored by the former all the subterranean into which he could find access along the Appian, Salarian, Flaminian, Ostian, Latin, and Portuense Ways. In the library of the Oratorian fathers at Rome may be seen four large folio volumes of his, entirely written by Bosio, and comprising the vast material for the work he did not live to produce. Another example of industry, in its results frustrated by fatal accident, was the compilation intended to comprise all the arborescent, epigraphs, and other details found in catacombs, on which Marangoni and Boldetti had been occupied for seventeen years, when the whole fell a prey to the flames in 1720; the few fragments saved being, however, turned to account by the former, whose energies proved dauntless even after that shock, and brought out as an appendix to his "Acta S. Victorini," Rome, 1740.

Bosio, in the course of his long labours, discovered only one group of sepulchres historically noted (in 1619); another such was found by Boldetti in 1720; and in 1845, Father Marchi had the merit of like discovery in regard to the tombs of the martyrs Protus and Hyacinthus. The catacombs called after the Christian matron Lucina, entered between the extramural basilicas of St. Paul and St. Sebastian, were discovered by the accidental sinking of the soil in 1688; and the opening of those of St. Terentianus, on the Latin Way, in the year previous, was alike due to mere accident. In 1849, the Cavalier di Rossi began his task of directing works in two catacombs, for the costs of which a monthly subvention was assigned by the pope. Soon afterwards Pius IX. appointed an "apostolic visitation," for ascertaining the condition of all the Roman catacombs; and a more practically important step that soon followed was the creation of a "committee of sacred antiquities," with charge and superintendence over all works and objects within that sphere, under whose direction the first excavations in catacombs were commenced in November, 1851; by this arrangement being superseded the appointment made by decree of Pope Clement XII., in 1672, for intrusting the care of all these hypogea to the cardinal-vicar, under the authority of whom, and that of the papal sacristan (a prelate), all excavations used to proceed, immediately directed by *custodi* as official deputies. Even whilst that earlier organization continued in force with respect to such undertakings, the loss and destruction of monuments from catacombs reflects most unfavourably.

Marangoni (after long experiences as assistant *custode* with Boldetti) tells us that thousands of epigraphs were taken from these cemeteries to the church of S. Maria in Trastevere; seven cartfuls to S. Giovanni de' Fiorentini; two cartfuls to another S. Giovanni, of this city; yet, at the present day, only about a score of epigraphs are seen in the portico of the former, not one in either of the two latter churches above named. Mazzolari ("Vie Sacre," Rome, 1779), describes what he had himself seen, the deliberate destruction of a corridor and *cubiculum* (sepulchral

\* See p. 385, ante.

chapel) in the catacombs of St. Lawrence, almost immediately after the reopening of that section in the long inaccessible cemetery on the Tiburtine Way.

The works carried on in such subterranean near Rome within recent years have led to most interesting results. First of all may be classed, for importance, the discovery of the vast hypogee identified as that which took its name from St. Callistus (pope, A.D. 218), though of origin still earlier; not founded, but enlarged, by that bishop; and in which all the popes were interred during the third century, the first mention of this as a Christian cemetery, whose possession was legally guaranteed to the church, occurring under the reign of Septimius Severus. About two miles beyond the Appian Gateway stands, on an elevated ground, an old brick edifice with apex and vaulted roof, long used as a gardener's store-house, now identified as the chapel raised for his own sepulchre by Pope St. Damasus. Near this were directed, in 1841, the researches that led to the opening of those long-unexplored catacombs at a short distance from the basilica of St. Sebastian, below which are entered other subterranean long erroneously supposed to be the real Callixian cemetery. Some years previously had been found, near to this spot, a broken marble slab with the letters of an inscription—NELIUS MARTYR, and the discovery of the tomb of St. Cornelius (pope, A.D. 251), soon rewarded the labours here undertaken; the missing fragment, with the letters COR . . . EP(iscopos), being found within a *cubiculum* dimly lighted from above, where we see both the empty grave and the image of Pope Cornelius, represented in *juxta-position* with St. Cyprian of Carthage, near the figures of two other saints: one distinguished by the written name "Sixtus," another martyred pope; the two first thus associated, not because here interred together, but because commemorated by the Church on the same day, having both suffered on the 10th of September, and in life-time held frequent correspondence. These four figures have the nimbus round the head: all show the same characteristics of style, individually marked in the features, draperies well treated, and a period not later than the sixth or seventh century can be assigned to these, as to other paintings in the same subterranean—that of St. Cecilia (in the chapel where she was interred), a large head of the Saviour near her full-length figure, and her contemporary Pope Urban.

At a glance we may go through the entire range of Scriptural subjects, from the Old and New Testaments, admitted in the art of the primitive Church. That circle is narrower in the paintings than in the sculptures, and obviously determined by traditions of religious propriety, from which the imaginative faculty was slow to emancipate itself. In considering the selection to which this art was so rigorously confined, we are struck by two predominant features,—the avoidance of all subjects invested with most awful sacredness, as the crucifixion, the resurrection, the ascension, the institution of the Eucharist, and the pervading mysticism which ever led to prefer such themes, in miracle, type, or historic incident, as suggest more than they represent; for, in fact, the more frequently-recurring subjects seen in catacombs and among the reliefs of Christian sarcophagi, always imply a truth or principle addressed to the moral sense of the believer, lying far too deep for the apprehension of the uninitiate. In sculptures this is more strikingly carried out, as indeed these (for the most part) later products exhibit the higher technical skill attained in those earlier ages. Nothing could be more judicious than the selecting and arranging of contents in the Christian museum at the Lateran Palace, founded by Pius IX. Yet in the valuable series of sculptured sarcophagi there, we miss the finest specimen, that of Junius Bassus, prefect of Rome, who died a neophyte, A.D. 359, and was buried at St. Peter's, where his beautifully-chiselled tomb was rediscovered, after ages of oblivion, in the works for the building of the new basilica, but still to be left near its original place, within a corridor of the crypt below the high altar.

In freedom of design, in conception as well as execution, these reliefs surpass all others of the same epoch: five groups are ranged along an upper, and five along a lower file, divided by pilasters, the lower under canopies alternately circular and pointed; the subjects historic, except the principal one, that of the Saviour: here a beautiful youth seated between two apostles, with His feet upon the earth, personified as an old man just emerging from the ground

and holding over his head a canopy of draperies. The Sacrifice of Abraham; the sufferings of Job; the Fall of Adam and Eve; Daniel in the Lions' Den; Christ entering Jerusalem seated on an Ass; again seen before Pilate, who is washing his hands; the Denial of St. Peter, and the Arrest of that apostle, are the representations ranged around; but more curious still are the groups of sheep, minutely represented on the flat space between the arches of the lower file, serving to attest both the simplicity and earnestness of the minds to which such art-treatment could be addressed: for we see these animals performing a series of acts from both the Old and New Testaments, thus being naively admitted to personify Moses, John the Baptist, and the Redeemer himself. A sheep strikes water from the rock; a sheep performs the miracle of multiplying loaves; a sheep gives baptism to another of its kind; a sheep touches a mummy-like figure with a wand to represent the raising of Lazarus. In the Lateran Museum, the most interesting and complete series of reliefs is a large sarcophagus brought from St. Paul's, on the Ostian Way, where it was probably placed at the time of the rebuilding of that basilica, late in the fourth century. The groups here seen form a valuable record of religious ideas, and of the interpretation of Scripture; but we are shocked to find the traditional reverence of earlier days so soon departed from in the admission, among the now larger art-range, of such a subject as the Supreme Being manifest alike in the Father, Son, and Holy Spirit, under the aspect of humanity, with identity of type, stern, strongly marked, and indicating middle age, in each of the co-equal Three! First, we see the creation of Eve out of Adam's side, by God the Son, in presence of the Father and Spirit; the former seated, and in the act of blessing the new-born woman; the latter standing behind the Father's throne; next are seen the Son awarding to Adam and Eve the symbols of labour, which was a part of their punishment,—a wheat-ear to the man, a lamb (for spinning wool) to the woman; and it is remarkable that in this instance the Son appears under quite a different aspect, more youthful and beautiful than when associated with the Father—thus to announce the mystery of His Incarnation. Successively follow the miracles operated by our Lord upon water, bread and wine, the Adoration of the Magi (the Virgin of a somewhat severe matronly type) with the Holy Spirit (again of human aspect), standing beside the chair of the Mother and Child; the restoring of Sight to the Blind; the Raising of Lazarus; St. Peter denying Christ; St. Peter between two Jews (his arrest, as probably intended); Moses striking the Rock; the Story of Jonas; Christ entering Jerusalem; Daniel between the Lions; and this last an instance of very original treatment, for, besides the figures essential to the story, appears the Holy Spirit, in the same form as previously; and Habakkuk carried by the hair of his head, bringing the bread he was desired by an angel to supply for the prophet's sustenance (another admitted type of the Eucharist), as narrated in the supplement to the Book of Daniel, rejected as apocryphal by Protestants. As to the selection from the miracles of our Lord (constantly repeated in other as in this series of reliefs), the mystic meanings, it is urged, are intended; thus they say, that the healing of the paralytic implies absolution from sin; the giving of sight to the blind, illumination through faith; the multiplication of loaves and fishes, as well as the change of water into wine, the Eucharist. Moses striking water from the rock is said to imply baptism; the raising of Lazarus the general resurrection; the adoration of the wise men, the calling of the Gentiles to Christ; the trials of Job, his affliction who was the "man of sorrows;" the story of Jonas, the resurrection of Christ; Elias carried up to Heaven, the ascension of Him whose last sufferings and triumphs upon earth are reverently shown, but under veils of symbolism. On two other sarcophagi in the same museum is seen the Labarum, guarded by soldiers, and with birds on the arms of the cross supporting the holy monogram. On another are very curious details of architecture, in two backgrounds, where we recognise a Christian basilica and baptistery, of circular form, no doubt, correct representations of the sacred buildings of Rome in the fourth or fifth century. Another of the finest examples of these funereal sculptures is in an almost dark chapel (no longer used for worship) off that of "La Pietà," at St. Peter's—the tomb of an illustrious wedded pair, Prohus

Anicinus, praetorian prefect, who died A.D. 395 and of his wife Proba, whose virtues are commemorated, with those of her husband, in a long poetic tribute, still extant. On the sarcophagus front is the Saviour, youthful and beardless, holding the book of the Gospels, and standing on a rock from which issue the four rivers of Paradise (a type of the Evangelists); beside Him stand SS. Peter and Paul; and behind, divided by twisted colonnettes, the other apostles, most of them in that attitude, with one uplifted hand, understood to express assent or reverential attention. Elsewhere in this city's churches, at St. Peter's and St. Maria Maggiore, are to be seen ancient Christian sarcophagi converted into altars, adorned by observable sculptures; and another collection of sacred antiquities in Rome, besides those of the Vatican and Lateran, containing numerous paintings from catacombs, is the *Custodia* of Relics, in the Apollinaro Seminary, made public but one day in the year, shortly before Easter.

Besides those above named, there is another remarkable range of subjects serving to illustrate doctrine or religious usages; and the judgment of competent critics, who assign to certain catacomb paintings antiquity so high as the first or second century (see Northcote, "The Roman Catacombs," ch. iv.; Gournerie, "Rome Chrétienne;" Agincourt, "History of Art?") may enhance the interest of our studies in this walk. A figure kneeling before another, who seems to give absolution (Catacombs of Hermes) is supposed to record the story of some person *lapsus* during the period of persecution, or other notorious sinner publicly reconciled to the church before death. The Five Wise Virgins (Catacombs of St. Agnes) are represented with torches instead of lamps, conformably to Roman practice, but each carrying also a little vessel for oil. Also, in the same catacombs, we see the Virgin with the Child, not (strictly speaking) on her lap, but rather standing in front of her, whilst her arms are extended in attitude of prayer, the holy monogram on each side serving to determine the date of this perhaps earliest example of the perpetually-repeated "Madonna and Child" in art, as not prior to the end of the fourth or beginning of the fifth century, no certain example of such symbolic letters being found before the period of Constantine.\* A group of the Saviour in the midst of the Twelve Apostles (Catacomb of SS. Nereus and Achilles),—two only, SS. Peter and Paul, those nearest to Him, being seated, whilst the others stand—seems evidence to the idea of superiority alike shared by those co-founders of the Church in Rome. A banquet at which persons of different age and sex are assembled, waited upon by two allegoric personages, Peace and Love (*Irene* and *Agape*), whose names are written near (Catacomb of SS. Peter and Marcellinus), is a scene supposed to represent the joys of Paradise, as do the recumbent figures in rich vestments, holding goblets, on Etruscan tombs. A dignified person (perhaps hislop) seated on a chair with another (a deacon?), who gives a veil to a female; in the middle a taller female who stands in prayer; and opposite, another seated with a naked infant in her arms (Catacomb of St. Priscilla), is a group interpreted by Bossio as the ceremony of consecrating as a nun the daughter of St. Priscilla, by Pope Pius I., assisted by St. Pastor, before the mother herself, beside that holier presence the seated Madonna with the Divine Child. The *Agape*, frequently seen both in painting and among the reliefs of sarcophagi, is represented as a banquet at a crescent-formed table, the viands usually consisting of a lamb, or fish and bread, with wine. A group representing two persons, male and female, the latter with arms extended in prayer, beside a tripod-table on which are laid a fish and some loaves marked with the cross (Catacomb of St. Callistus), is a strikingly-expressive illustration of the Eucharistic doctrine, with not only the proper substance of that sacrament in one kind, but also the mystic emblem of our Lord's person—the Divine Presence—associated with it; another sacramental subject, in the same catacomb, where we see a man pouring water over the head of a boy while both stand in a river, conveying proof that infant, or at least pedo-baptism, was the practice of the ancient Church. It is, indeed, in the aggregate, a grand and affecting ideal of primitive Christianity that this monumental series,

\* Such, at least, is the general conclusion; though Bottari asserts this monogram to have been seen on the sculptures of two martyrs who suffered under Hadrian and Antoninus; and by himself found, in mosaic and on terracotta, in examples he assumes to be of the earlier periods,

painted, sculptured, and chiselled, presents to us—a moral picture of purity and peace, devotional earnestness without fanaticism,—mystic ordinances undegraded by superstition, the truly godlike manifest in the supreme sacrifice of the heart, the mind, and life. In the varied and mystic illustration of sacraments, in the selection from the evangelic history of such miracles as convey lessons of Divine goodness and love, or confirm belief in immortal life, it may be said that one subject dominates throughout the entire range, like a star throwing its hallowed light over the religious sphere, the person and office of the Redeemer, towards whom all hope and faith ever tend, from whom proceed all power, all strengthening and consoling virtue.

The idea of a headship over other apostles, vested in St. Peter, appears occasionally with most decided expression, though indeed tempered by other proofs of an admission to spiritual equality for those co-founders, Saints Peter and Paul. In the sculptures on sarcophagi (which in far the greater number may be referred to the fourth and fifth centuries) this idea of St. Peter's supremacy becomes more manifest, as natural at periods when the Roman bishopric was rapidly advancing in power and grandeur. Moses and the apostle constantly appear in the juxtaposition, the one striking the rock, the other standing between two Jews; the aspect of both absolutely identical; and the wand, symbolic of authority, is as often held by the apostle as by the lawgiver. In an enamel on glass this becomes an absolute interchange of offices,—St. Peter (designated by name) is striking water from the rock in place of Moses. In regard to that vast range of monuments, the epigraphy of the catacombs, we must turn for the best of guides and authorities to De Rossi's "Inscriptiones Christiane Urbis Romae," an immense compilation, intended to comprise nearly 11,000 epigraphs, all collected by the writer during twenty-one years of assiduous research, and all to be eventually classified, under the same gentleman's direction, in the Christian Museum of the Lateran.

The first volume supplies fac-simile plates of 1,374 inscriptions, ranging in date from the earliest known to A.D. 375; the proposed limit to this series being the sixth century, here considered the final term of the Roman imperial period, and also that which the series of subterranean epitaphs ceases.

Di Rossi expresses the conviction that numerous decorative and art details, hitherto ascribed to the third century, are really much older, among proofs of which high antiquity, approaching even the Apostolic age, this writer points out the classic style manifest in various frescoes and decorations on stucco; also the constructed (not merely excavated) crypts, the chambers and corridors without sepulchral *loculi*, but provided instead with ample niches for sarcophagi; the numerous epitaphs wanting the usual Christian formulas, and with nomenclature quite classic—all particulars found in certain pygogees. Till the latter years of the third century no spoliation had impaired any of these cemeteries, no intolerant edict had driven the faithful from their limits; but during the Diocletian persecution all places of Christian assemblage were burnt down or devastated, all ecclesiastical books given to the flames, the Roman see being left vacant for six (if not seven) years and six months. That tempest was finally stilled by the relenting policy of Maxentius, A.D. 306; but the restitution of what the Church had lost did not ensue before 311.

The legalized possession of these cemeteries (as naturally followed) that of their churches likewise, by the Christians under Pagan government, is one historic point clearly established, and, we believe, for the first time, by the arguments and proofs in Di Rossi's "Roma Christiana." Valerian, it is true, decreed that the followers of our religion could not even enter the cemeteries formed for their use; but Callienus restored such sites by law to the bishops, implying the recognition of the aggregate claim. During the third century, at latest, that possession was generally and legally guaranteed. The Christians of Antioch applied to Anrelian, in order to compel a bishop deposed in council, the heretical Paul of Samosata, to evacuate "the house of the Church," and in the sequel the decree of a Catholic synod was enforced against that offender by a Pagan magistrate. It is an ingenious suggestion of De Rossi, that originally perhaps, it was under colour of associations for mutual aid and charitable interment that the

Christians obtained the first conceded tolerance gradually extending to their places of worship, as well as of sepulture.

The chronology of primitive Christian art, cannot, of course, be brought within bounds of distinct definition, and has been subject to various conjectures. Its earliest forms were purely symbolic: sacred emblems, the Lamb, the dove, the ship, the lyre, worn on rings or bracelets, or embroidered on vestments (of Clement of Alexandria, second century); if any human figures were represented, no other save the Good Shepherd, mentioned by Tertullian (early in the third century) as sometimes seen, probably enamelled, on chalices, statues, and all attempts at portraiture, were prohibited till after the time of Constantine; and Mahillon concludes that ten centuries had passed before the church ever allowed images to take their place on the altar. From evidences of style, it is inferred that several paintings in the *catacombs* may be so ancient as these second century (?); that a much larger number, besides certain of the reliefs on sarcophagi, may be referred to the last years of the following; and Agincourt sees marks of superior skill in such subjects (among these reliefs) as the crossing of the Red Sea; Elias ascending to Heaven, and leaving his mantle to Elisha; the Samaritan woman; the bestowal of the keys on St. Peter, leading him to ascribe their execution to the artists of the first two centuries.

The beauty of the social picture presented by those ages of faith could indeed be little appreciated, were we only to regard ritual and æsthetic aspects apart from practical realities and the claims of duty. Charities under the Early Church were wisely regulated as well as most generously liberal: one-third of the aggregate ecclesiastical revenues went to the relief of the poor; another to the bishops and clergy; another to public worship and sacred edifices. Before the end of the fourth century, existed hospitals for the poor and aged, founding asylums, and *xenodochia* for travellers, all supported by the several churches, and mostly founded by bishops who were their local superiors. The Christian stranger was always at home among his fellow worshippers, and maintained gratuitously, if he brought letters of recommendation (*epistola formule*) from the bishop of his diocese. In the observance of fast-days, it was enjoined that the costs for ordinary meals should be saved for the relief of widows, orphans, or others in want (so the "Pastor" of Hermas). The religious instruction of children was from an early period provided for on system. Proof how early was condemned by the Church, and, to the extent of her means, put down, that great social evil of Paganism, slavery, is supplied with striking force in the ancient Christian epigraphs. Among the entire number, about 11,000, belonging to the first six centuries, scarcely six inscriptions (and, as Mr. Northcote shows, two or three among these doubtful) contain any allusion, in their brief and simple language, to this fundamental division of ancient Roman society; whilst *alumni* (adopted foundlings) are named in a greater number of these Christian inscriptions than in the entire range of those from Pagan monuments,—a further proof of the prevailing beneficence, the new-born domestic virtues, to which so many outcast children owed their maintenance, and even life, as members of the Christian community.

In the nineteenth year of Diocletian, date of the persecuting edict, one clause in which enforced the destruction of all Christian churches, the new worship is said to have been celebrated in forty such sacred buildings within this city.

The officiating clergy were (till the end of this primitive period) attired in the classic white vestments common to Roman citizens, but distinguished by the long hair and beard of philosophers; and not till the Constantinian period did the bishops begin to wear purple; not till the ninth century was that costume entirely white (sometimes, indeed, slightly adorned in purple or gold) laid aside by the priesthood generally.

Di Rossi concludes that both pictures and sculptures had begun to appear, though not in very common use, among the ornaments of sacred buildings, at least so early as prior to the last persecution; that it was in consequence of the outrage inflicted on such sacred art-objects under Diocletian that the Council of Elvira, A.D. 303, passed the variously interpreted decree: "*Ne quod colitur et adoratur in parietibus depingatur.*"

The actual number of catacombs has been

very differently reported. Aringhi, followed by many other writers, first raised it so high as sixty; but without proofs adduced from any personal experiences. Di Rossi now sets the question at rest by supplying a list in which are reckoned forty-two; not more than twenty-six being of vast extent, and five being cemeteries whose origin was subsequent to the peace secured for the church under Constantine,—all within a circle not more than three miles distant from the walls of Servius Tullius; though, indeed, other such hypogæes are known to have been formed beyond that radius. The name *ad catacumbas* was originally given to only one, that of St. Sebastian, on the Appian Way; and *catacumba* was the primitive title proper to a small oratory behind the extra-mural basilica of that saint, where is still extant a crypt chapel, built about the middle of the fourth century, for consecration of the spot on which (according to legend) the bodies of Saints Peter and Paul reposed for a time after the attempt, made shortly after their deaths, to remove those revered relics from the original places of sepulture to the East; a sacrifice thwarted (as the legend narrates) by a violent thunder-storm, which detained the emissaries from the East till certain Roman Christians arrived, who rescued the bodies, and here gave them interment. To the same spot, it is said, the body of St. Peter was a second time transported, in the fear of profanation, when a new circus, to extend on the Vatican hill above the site of the Christian cemetery, had been projected by Heliogabalus. About half below the level of the ground, behind St. Sebastiano, stands this ancient chapel, circular in form, and very inferior in masonry, with a plain altar in its centre, above the deposit in which the apostles' bodies are said to have lain\* for a year and seven months, according to some writers; for not less than forty years, as one chronicler states. Round the walls are, at regular intervals, several *arcosolia*, apparently made to receive sarcophagi, once adorned with painted stucco in the style of a very early period, but now barbarously covered with whitewash. Another oratory, at higher level, is entered near this, in form and construction similar, where are still seen, though but dimly, on the low- vaulted ceiling, some frescoes, evidently of a Mediaeval period, described by Nibby as Greek works; the Saviour in the act of blessing; Saints Peter and Paul, and other figures; the Divine Master, also represented in a large head, of solemn expression, within a nimbus; a Crucifixion, not without merit as to design, however rude in execution.

#### PORTRAIT MINIATURES IN SOUTH KENSINGTON MUSEUM.†

ISAAC OLIVER, PETER OLIVER, ETC.

Of Isaac Oliver, a very great historical name (1555-1617) in the fascinating art of portrait-miniature in England, the South Kensington Museum exhibits on loan forty-two examples, the greatest number ever seen together in one exhibition.

Of Peter Oliver (1594-1648), "the eldest son of Isaac, and worthy of being compared with his father,"‡ the same collection contains twenty-two examples.

A like opportunity for studying so many works of two such masters "in little" will not recur in our time, and should not, therefore, be overlooked.

Forty-two Examples of Isaac Oliver.

Catalogue No. 298. William Herbert, third Earl of Pembroke (the supposed "Mr. W. H.," of Shakespeare's Sonnets). Signed and dated, 1. O. 1610. vellum. Lent by Mr. Anderson. What Mr. Anderson? This is a good miniature, Isaac Oliver, in the Blackfriars of London, lived at Baynard's Castle, on the left bank of the Thames, within arrow-shot of Lord Pembroke.

Lady Ayres, wishing to have a copy of the famous Lord Herbert of Cherbury's picture, to wear in her bosom, went "to Mr. Isaac, the

\* This sepulchre, now concealed from view, is described by Mr. Northcote as a square aperture, between 5 ft. and 7 ft. in length, breadth, and depth; lined in the lower part with marble, and divided into two equal compartments by a marble partition. The crypt chapel is supposed to have been begun by Pope Sixtus and finished by Pope Damasus, a great restorer of cemeteries and martyrs' tombs.

† See p. 444, ante.

‡ Walpole.

painter, in Blackfriars, and desired him to draw it in little, after his manner." \*

305. Dr. John Donne, Dean of St. Paul's (1573-1631). Signed and dated "I. O. 1610." Vellum. Lent by Mr. Samuel Addington.

482-486. Five miniatures, lent by the Hon. William Ashley, representing (1) Queen Elizabeth, (2) Lady Arabella Stuart, (3) John Earl of Harrington, (4) Sir Nicholas Throgmorton, and (5) Erasmus. The Erasmus is of course, a copy. The Earl of Harrington is Prince Henry's earl (of the Hampton Court and Wroxton pictures), and is very fine.

631. Elizabeth, Queen of Bohemia, daughter of James I., and mother of Prince Rupert and Prince Maurice.

"By beauty first, then choice a queen."  
Sir Henry Wotton.

Signed "I. O." Card. Lent by Mr. Hollingworth Magniac.

633. Gaspar de Coligni, Admiral of France. Lent by the same well-informed collector.

702. Mary, Queen of Scots. A copy of the miniature, by Isaac Oliver, in the royal collection, formerly the property of Dr. Mead. Engraved by Honbraken, in Birch's "Illustrations Heads."

748. James I. Inscribed Ano. Dni. 1608. Ætatis aue 42. On card. Lent by R. S. Holford, M.P. Oval and genuine.

868. Sir Philip Sidney. Lent by Mr. John Jones. The portraits of this great man bear little resemblance to each other. The unengraved Harleian miniature (now at Welbeck), is very characteristic. There is a good photograph of it by Caldesi.

871. Henry, Prince of Wales, eldest son of James I. Lent by Mr. John Jones. Among Prince Henry's expenses is a payment of thirty-three pounds to "Mr. Isaack for three pictures." Compare the reference to Isaac Oliver, in the Blackfriars, in Lord Herbert of Cherbury's entertaining autobiography.

1,145. Sir Philip Sidney. Very like the Harleian miniature we have just referred to. On card. Lent by Mr. J. Heywood Hawkins.

1,340. Study for a portrait of a Man wrapped in a Cloak, chiefly executed in sepia. Lent by the Earl of Gosford.

1,364. Lady Rawlings. Vellum. Lent by same.

1,367. Sketch of a Lady. In bistre. From the collection of Sir Joshua Reynolds. Lent by same.

1,476. Portrait, called Queen Elizabeth, but most probably that of Anne of Denmark, Queen of James I. Lent by Lord Fitzharding. Oval; very fine.

1,483. Portrait of a Gentleman. Dated Ano. Dni. 1619. Clever, but then remember, Mr. Samuel Redgrave, that Isaac Oliver died in 1617.

1,579. Lady Hnsdon. Painted on a playing-card of the suit of hearts. Signed "I. O." Lent by Lord Wharfedale. Oval; good.

1,580. Lady Arabella Stuart. Card. Lent by the same nobleman. Query, if properly named.

1,619. Sir John Clench. Signed and dated "I. O. 1583." Lent by the Duke of Buccleuch.

1,632. Lady Shirley. Vellum. Lent by the same nobleman. Oval; fine.

1,640. Shakspeare's Earl of Southampton. Signed and dated "I. O. 1616." Lent by Mr. Sackville Bala.

1,648. Portrait named Dr. Donne. Signed and dated "I. O. 1623." Lent by the same gentleman.

1,653. Richard Sackville, third Earl of Dorset. A large full-length miniature on thick card, 9½ in. by 6½ in. This is the husband of "Anne Pembroke, Dorset and Montgomery." The miniature fine, and signed in full "Isaac Olliners, fecit, 1616." Very unusual, and more than possible out of Isaac's inscribing. From Jeremiah Harman's collection. Blue background; ebony frame. Lent by Mr. Sackville Bala.

1,811. Frances Howard, Countess of Essex and Somerset. Circle; very fine in old black frame. Lent by the Earl of Derby.

1,812. Elizabeth, Queen of Bohemia (daughter of James I.), when young, in an open lace ruff, over which her light Auburn hair falls upon her shoulders and down to her waist. Oval; very fine. Probably in her bridal dress. Lent by the Earl of Derby.

1,818. Queen Elizabeth's Robert Devereux,

\* See Lord Herbert of Cherbury's "Autobiography," first printed by Horace Walpole. The Earl of Powis should have been asked for the loss of the large Isaac Oliver of Lord Herbert of Cherbury, in armour, reclining in an enchanted forest, his horse and squire in the background. The engraving of it is well known.

Earl of Essex; unfinished miniature. Card, and good. Lent by the Earl of Derby.

2,091. Portrait of a Gentleman, "ascribed to" Isaac Oliver. Lent by the Earl of Shaftesbury.

2,095. Portrait of a Lady, with a black lace collar and richly-coloured dress. Lent by the same nobleman.

2,096. Portrait of a Gentleman, wearing the ribbon and badge of the Order of the Garter. Lent by the same nobleman.

2,169. Lady Arabella Stuart. Signed "I. O." From the Strawberry Hill collection. Lent by Mr. George Digby Wingfield Digby.

2,174. Lady Venetia Stanley, afterwards wife of Sir Keneil Digby, immortalised by Ben Jonson and Vandyck. From the Strawberry Hill collection. Lent by the same gentleman, with other of the Digby miniatures that Walpole prized so highly.

2,178. Lady Lucy Percy, mother to Lady Venetia Digby. From the Strawberry Hill collection. Card. Isaac Oliver's name has been dropped by the editor, who, when he inserts it in a new edition of his labours, will probably add the following quotation from Walpole:—

"But the first (at least, the best preserved) of all his [Isaac Oliver's] works is in my possession: it is the head of Lady Lucy Percy, mother of Venetia, Lady Digby. She is in black, with a large hat of the same colour, and a very large ruff; the whole painted on a blue ground."—Horace Walpole's "Anecdotes of Painters," ed. Wornum, p. 173.

2,543. Catherine Cary, Countess of Nottingham, daughter of Queen Elizabeth's cousin, Cary, Lord Hunsdon. Lent by Mr. I. F. Wadmorc.

2,559. Anne of Denmark, Queen of James I. Small and exquisite. Lent by Lady Sophia des Veaux.

2,560. James I. of England. Lent by the same lady.

2,564. Lady Arabella Stuart, with a jewelled anchor as an ear-ring. Lent by the same lady.

2,709. Thomas, second Lord Arundel, of Wardour. Lent by Lord Arundel, of Wardour. Genuine, and very fine.

Of the prices paid to early miniature painters in England, our ordinary and extraordinary sources of intelligence (Walpole and his Editors) afford no kind of information. In a previous notice of this exhibition, we gave some hitherto unpublished prices from authentic sources touching Nicholas Hilliard; we have now, through the courtesy of one well read in English history (Mr. Everett Green), the pleasure of making known what Isaac Oliver, "of the parish of St. Anne, within the precinct of the Blackfriars, London, gentleman," (for thus he describes himself in his will), received for his labours. In the Privy Council Register of King James I. is the following hitherto unpublished entry:—  
"1616, April 21.

A warrant to the Lo[rd] Stanhope to pay unto Isaac Oliver the summe of FORTY POUNDS for three pictures made by him and delivered to the Prince his Highnes, as appeared by a bill of the particulars signed by Mr. Thomas Murray."

Or something very little above thirteen pounds apiece of money of the reign of James I., or forty pounds apiece at least of the money of her Majesty Queen Victoria.

The payment just quoted was one of the last, if not the very last, Crown payment made to imitabile Isaac Oliver. On the 4th of June of the next year he made his will, and on the 30th of October of the same year his will was proved "by the oath of Elizabeth, the relict of the deceased."

Peter Oliver, the eldest son of Isaac, was the able son of a very able father, and by some has been thought superior to his father. This exhibition supplies a fair opportunity of comparison; and on the whole, to our thinking, Peter, in many points, is not fully up to his father's excellence, in "the art of limning in water-colours differing somewhat from oil-colours."†

Twenty-two Examples of Peter Oliver.

1,034. King Edward VI. Lent by the Duke of Devonshire. This, of course, is a make-up in little. Something after a picture of King Edward in Lord Yarborough's collection.

1,123. "Lord Winbleton"—so catalogue (lent by Mr. William Meyrick). On card, signed "P. O." Collectors should not rely too much on "initials."

1,147. Henry Frederick Earl of Arundel (died 1632). Lent by Mr. Heywood Hawkins,—a Judge from whom it is seldom safe to differ.

\* Wills from Doctors' Commons, printed for the Camden Society in 1863, p. 88.  
† Sanderson's Graphical, fol. 1658, p. 52.

1,594. Lord Chancellor Bacon. Lent by the Duke of Buccleuch. Very doubtful.

1,687. Shakspeare's Earl of Southampton, of whom the catalogue tells us that "the earl wrote to Lord Ellesmere, then Chancellor, commending Shakspeare as deserving favour, and as his special friend." . . . Which Lord Chancellor Ellesmere, my "Lord President of the Committee of Council on Education," never did, as far as proof producible lies in living beings.

1,722. The Queen of James I. Lent by Mr. John Stewart, once the property of the Princess Charlotte of Wales.

1,724. Charles I., when young.

1,731. James VI. of Scotland and I. of England. Lent by Mr. John Stewart. Query.

1,834. Peter Oliver (himself). Small square black frame. Bought by our Homerite Earl of Derby at Strawberry Hill. Genuine and therefore valuable.

2,067. Portrait of a Gentleman in a ruff and black quilted dress, signed and dated "1619, P. O." Card. Lent by the Earl of Shaftesbury.

2,071. Ditto, much in the same manner. Surely the Earl of Shaftesbury can identify the likenesses or "characteristics" of some of his own "unfeathered ancestors." We quote Dryden in a mood of compliment.

2,088. Portrait of a lady, signed "P. O." Card. Lent by Lord Shaftesbury.

From Lots or Nos. 2,166 to 2,178, we come to Mr. George Digby Wingfield Digby's "loan," and in miniature and English biographical art it is a Rothschild Stock Exchange loan. Everards, Kenelmis, and Venetias rise before us. Digbys and Stanleys look at us and we at them. This little "lot" was one of Horace Walpole's "pets" at Strawberry Hill. Mark and linger over,—

"Pray come not near,  
For Dame Venetia Stanley lodgeth here." \*

Consult John Aubrey and Sir Nicholas Harris Nicolas, cultivated visitor to South Kensington, and you will additionally appreciate these—not too well seen—miniatures.

Here, at 2,178,—with an anonymous painter of "Lady Lucy Percy, mother to Lady Venetia Digby," from the Strawberry Hill collection—insert "Isaac Oliver," artist, and consult our only text-book (unhappily) on such points, "Walpole," by Wornum, p. 179.

No. 2,209 is lent by one of the Bramstons, of Essex (men who called Lord Chancellor Clarendon friend). Take the catalogue's description of this Master Peter Oliver:—

"2,209. Portrait of a Young Man in a black dress and falling lace ruff. Signed and dated 'P. O. 1619.' Card. Mounted in a pendent gold case, enriched with dark-blue translucent enamel, of the same period as the miniature."

\*\* Could not this miniature be shown to greater advantage?

2,563. Here is Henry Stuart, Prince of Wales, who (had he lived) would never have fallen into the follies of his younger brother and successor King Charles I. This is lent by Lady Sophia Des Veaux, who deserves to possess what she so well appreciates. Careful viewer, look at No. 2,568, called a Peter Oliver—but not so,—but fine. Ask Mr. Henry Shaw; ask Mr. Farrer.

Lastly, No. 2,972, a Willoughby D'Essex, a Suffolk Brandon (lent by Mr. Emilius Clayton).

A few words more. The getting together of this "Student's Home" Portrait Exhibition of known names and hitherto imperfectly-known faces in English history, is one of the very best works that the Committee of Council on Education has attempted, and fairly accomplished; though to our thinking, were these miniatures arranged chronologically, the careful student would leave the exhibition better informed than he has to leave it now.

HEAT, VENTILATION, AND ORGANS.—A writer in the Musical Standard, draws attention to the effect produced on organs in churches, by unwise arrangements, for heating and lighting. The subject deserves more consideration than it has had.

\* "About 1676 or 5, as I was walking through Newgate-street, I saw Dame Venetia's bust, standing at a stall at the Golden Cross, a brasser's shop. I presently remembered it, but the fire had got off the gilding; but taking notice of it to one that was with me, I could never see it afterwards exposed to the street. They melted it down. How these curiosities would be quite forgot, did not such idle fellows as I am put them downe." John Aubrey (Lives, ii. 333).

## ON MOSAICS AND THEIR ADAPTABILITY.

At a meeting of the Leeds Philosophical Society not long since, Dr. Salviati, of whose works in mosaic in this country we have several times had occasion to speak, read a paper on Mosaics, and the superior Advantages and general Use of Enamel Mosaics. From this we take some passages:—

Doubtless mosaic was first used in the formation of pavement, and was made, in part, or wholly, of marbles and precious stones. Mosaic made of these materials was known either as *lithostratum*, or *opus tessellatum, vermiculatum, Alexandrinum*, or *opus tessellatum*, according as it was formed of large or small pieces, and of its representing figures or otherwise.

*Lithostratum* mosaic was made of tablets of marble, sometimes interspersed with precious stones, on which no figure at all was shown. Ciampini, in his work "Vetera Monumenta," affirms that the first example of such mosaic floors was in Persia. Against this opinion we have the statement of Abbot Hasselin, in his observations upon ancient mosaics, where he asserts that they had their origin in Egypt. M. Laborde states that the practice of embellishing pavements with rich and precious stones was followed in the Eastern countries before it made its appearance in Greece.

It would seem that the earliest *tessellatum* mosaic (formed of smaller pieces of marble) was made in Greece, and some authorities assert that its inventor was Sosus, of Pergamus, who executed that charming mosaic now in the museum of the Vatican, at Rome, of which Pliny wrote, "*celeberrimus fuit in hoc genere Sosus umbra capitis infusca.*" The historians assert, however, that the mosaic pavement of the temple of Olympia was executed at least two centuries before the time of Sosus of Pergamus; and much praise is due to Parnesus, who decorated with mosaic the temples of Jupiter at Olympia, and of Minerva at Elis.

The ancients well knew the advantage of colour, and the prominence that should be given to it in architectural decoration, and therefore, having used marbles of different colours, and painted substances, without being able to obtain the effect they desired, they became aware of the necessity of discovering some other material for the purpose of mosaic, in order to obtain those varieties of tints and shades which natural substances were unable to provide them with. Thence arose the use of coloured glass, first transparent, then opaque—that is enamel—as the fittest material by which to obtain the desired advantages, and also for its power of resistance to atmospheric injuries. Pliny calls this a new invention of his time, "*vitro novitium et hoc inventum.*" (Lib. xxxvi. cap. 28.)

The next step in improvement was with the view of producing more striking and brilliant effects, and for this purpose the ancients thought of incorporating the precious metals; but, as this would be beyond measure expensive, a simple means of obtaining similar results was invented, and thus gold and silver enamels were introduced into mosaic works. These enamels are, in truth, made of the precious metals, but in such thin sheets that their use is comparatively inexpensive. The process is a difficult one, for to produce true gold and silver enamels, great knowledge and experience are necessary.

As few persons have a clear and distinct knowledge of the difference between coloured and gold and silver enamels, it may be well in this place to say a few words upon the subject.

Coloured enamels are made of a vitreous paste (paste being the generic term by which any glass works are familiarly known). The enamels are formed of the same siliceous and other materials of which common glass is composed, but to these materials are added other mineral substances, which, when properly prepared and fused together, impart to the paste its density and extreme hardness, and also its colour. By such means the requisite degree of opaqueness, purity, and solidity of the enamels is obtained, as also the beauty, softness, and great variety of their colours; and all these are partly dependent upon the quantity and quality of the mineral elements in union with those of common glass, and are partly dependent upon the degree and continuance of heat to which the whole composition is subjected in the process of fusion.

If the manufacture of the coloured enamels be imperfect, many inconveniences result, both as regards the appearance and durability of the mosaic work. If the paste be not well and care-

fully elaborated, or if it be improperly or insufficiently fused, if the mineral elements of the colours be not exactly proportioned, so that either the paste is transparent or some other defect ensues;—then it is utterly impossible for the enamels to render the effect of the painting, as the colouring is uncertain, weak, and almost lost through the transparency of the materials.

In this state of imperfect manufacture the mosaic is liable to be injured by damp, smoke, and all atmospheric changes; but if, on the other hand, the coloured enamels are well produced, then they can be made to give precisely the same effect as the painting. In many respects, a thoroughly successful mosaic work has advantages superior to a painting, on account of the greater brilliancy and transparency of its colours, as well as for the ease with which such a work can be washed or cleaned. Enamels are much more permanent than any other substance that has ever been used in the composition of mosaic, whether stone, marble, or clay, on account of their less porous and less dilatable body.\*

Gold and silver enamels are the result of a very different operation. On a ground of thick glass or enamel, according as it is desired to render the gold enamel transparent or opaque, or to impart to it a warm or variegated colour, there is laid a leaf of gold or silver which is attached principally by the action of fire; then a film of the purest glass is spread over it, and this may either be perfectly colourless or of any tint that may be required. When well manufactured, these three layers, after being fused, become perfectly united with each other, and form a homogeneous body.

If the operation above described be perfectly successful, the metal will be for ever protected against all possibility of injury, either by atmospheric action, dust, gas, smoke, or insects, and in such a manner as not to lose aught of its brilliancy or splendour, even after many centuries of exposure. When this most delicate film of glass possesses the requisite thinness, fineness, and purity, and when the whole surface of the sheet exhibits no inequality of thickness, the metal appears in all its native beauty, and the glass with which it is covered is scarcely discernible.

Whence the reverse of this occurs, that is to say, when the metal remains as it were entombed between the upper and lower strata of glass, and does not present an even surface, then the eye becomes arrested by the glitter of the glass rather than the brilliancy of the metal, and the mosaic work has the utterly wrong appearance of being varnished over.

These explanations will show that the manufacture of enamels for mosaic is attended with very considerable difficulties and inconveniences; and that to obtain ease and certainty in their production, according to the purpose they are designed to serve in imparting to mosaic-work an effective and pictorial appearance, coupled with the utmost durability, not only is a knowledge of general principles in their manufacture necessary, but also long experience and continual and laborious experiments.

In speaking of coloured enamels, it should be remembered how very difficult it is to produce in an exceedingly hard and vitreous material so many beautiful and delicate shades of colour, as are required to impart to a mosaic work the identical effect which the painter obtains simply by the use of oil or water colours. How great, also, is the difference between the production by an inexperienced manufacturer of the various colours on the basis of general principles, and the production according to circumstances of precisely the exact tints or shades of colour which in a special case may be required at a very short notice! And, also, how little faith can we have in the durability of the enamels if their production be not very carefully, skillfully, and conscientiously watched and attended to!

With regard to gold and silver enamels, it must be remembered that the whole process has to undergo the action of fire, and that it is extremely difficult to protect the tender delicate gold-leaf from becoming disturbed, or torn, or crumpled, and to guard against the introduction between the glass and the metal of minute bubbles of air, the effect of which would be,

\* Those who may desire to obtain an exact idea of how far mosaic renders the effect of the painting, will be able to do so, by visiting the South Kensington Museum, see the figure of Niccolò Pisano in mosaic on gold ground, which I lately delivered. It is placed on one of the walls of the New Court, and on the opposite wall is the original cartoon, painted by that accomplished artist Mr. F. Leighton.

sooner or later, to separate the delicate film of glass from the metal; nor, finally, is it an easy matter to render the surface of the enamel tablets so smooth and even as is essentially requisite, with an entire absence of waving lines and sinuosities of any kind.

I trust I shall not be accused of being misled by a love for my native country, if I assert that Venice has, from the Middle Ages until last century, when her political and commercial decay happened, held the first place in the art of making mosaics, both as regards the manufacture of the material elements and the production of the finished works.

In order to make themselves thoroughly acquainted with the art, the Venetians sought the aid of Greek artists, and in the earliest age we find them enlisting the aid of Theopane of Constantinople, who came to Venice and opened a school, where mosaic designing and manufacture were taught; and I quite agree with our Muratori, who writes, "*Summa fuit Græcis in Musivis conficiendis peritia;*" but it is also true that the skill, patience, and love of the art increased so rapidly among the Venetians that they were soon able to improve upon the works of their teachers, and to accomplish within the boundaries of their own limited State a greater quantity, and, perhaps, more perfect mosaic works, than those possessed by any other nation; and they were even able to supply foreign people with enamel, as is the case now with Rome in regard to the primary colours. They also were able to send abroad their artists and mosaicists to execute many important works, and these, doubtless, became founders of schools in those lands to which they emigrated.

All writers on the subject, however, whether Venetian or otherwise, speak of the pre-eminence of my own city in the art of mosaic, and I will not record a sentence of Lanzi, in his "*Storia Pittorica della Toscana*," where, after having related the useless attempts of the Florentines to decorate worthily the chapel of St. Zenobi, he says, "It seems, indeed, that the glory of making mosaics has been reserved to Venice."\*

It is impossible to set it down as mere chance that Venice succeeded in reaching so high a degree of perfection in the mosaic art; for more probable is it that it was a privilege afforded to her by peculiar and natural circumstances, arising out of her material and artistic position, her natural inclination, her skill, and her possession of the greatest examples for study and imitation. It is well known that in any art or artistic manufacture, the best elements of origin, development, improvement, and perfection, are firstly, instinctive feeling of the people; secondly, proper material means; thirdly, good schools of instruction; and fourthly, good examples to be placed continually before the eye and mind of the pupil and artist, so that his instinct and knowledge of detail may be constantly growing and improving.

Now, as regards the instinct, it is an undeniable fact that, as every race and people, like individuals, have some peculiar natural, artistic, or industrial basis, in addition to those general inclinations common to all humanity, we have ample evidence that the Venetians possess that instinct which is the primary element of the mosaic art, namely, a true appreciation of colour, and its proper adaptation.†

As regards material elements, some countries have the privilege of producing one kind of material better and cheaper than others. This frequently depends less upon skill and often-repeated experiments than upon physical causes, lying either in the soil or the atmosphere.‡ It

\* Andrea Tafi arrived in Venice A.D. 1141. He came from Florence for the purpose of studying the art of mosaic. In the fifteenth century Angelo Berovico, of Murano, became so famed for the production of enamels and stained glass, that Avellino, in his work "*De Architectura*" (translated into Latin by King Matthias Corvinus), tells us he was sent to Ferrara, Milan, Florence, Naples, and Constantinople, to introduce his productions and to teach the nature of his inventions and improvements. About the middle of the seventeenth century it was the same Venice, granted to Cosimo II., Grand Duke of Tuscany, as a most special favour, permission for the renowned Venetian mosaic artists Jacopo and Alvise Luini to visit and decorate Florence.

† This was, perhaps, the reason why the mighty Venetian school of painting, headed by Titian, Tintoretto, Cagliari, &c., has remained unrivalled for the strength and beauty of its colouring.

‡ It is well known, for example, that one country can produce the best colours in silk stuffs; and so far is this a privilege to it that other countries have in vain attempted to obtain the same result, even by using precisely similar material elements of the colouring, and by employing the same workmen. Nobody would certainly dare to assert that in China and Japan the art of painting is on the same level as in Europe; but nobody can deny the extraordinary vivacity, brilliancy, and peculiarity of the Chinese and Japanese colouring.

would seem that, in regard to enamels, this advantage was given to Venice (that is, to its neighbouring island, Murano), for no other country has succeeded in producing in glass so great variety, brilliancy, and peculiar fineness of colour. It may so happen that this arises from atmospheric causes or from some other unknown reason; but to prove the truth of the statement, it is necessary only to mention the ancient Venetian glasses, which in our time are esteemed most precious and deserving to enrich the finest collections of works of art. So also I may name the yet living manufacture of beads, those little fragments of endless variegated coloured glass, which are sold all over the world, and give to Venice a monopoly in spite of all competition by foreign manufacturers. The same reason, perhaps mostly physical, which enables the Venetian manufacturers to produce the best and most variegated colours in their yet unrivalled heads, are those which form the most efficient elements in the production of the best enamels; those most fitted to the requirements of the mosaicist.\*

As regards the school of instruction. From the commencement of the practice of mosaic in Venice, down to the time of its decay, there were schools where every artist could be taught until he was capable of becoming himself a master. We know of schools of the twelfth and thirteenth centuries under Greek masters, and of many where Venetian teachers were famous for the magnificent works now extant. Among these masters I may mention the Zuccati, Bozza, and Bianchini.

There never have been wanting in Venice the very best examples to be studied by the pupil and the artist. Firstly, the city possessed the masterpieces of the Greek artists on the walls of their glorious cathedral; there and in other buildings were placed, in the course of about five centuries, the splendid mosaic works produced by the Venetian artists themselves, and these works have always been open to the view of the whole population, so that the artists of Venice have ever had the means of being taught by, and of becoming acquainted with, every kind, style, and manner of mosaics.

Even for Venice the age of glory and prosperity was not to be perpetual. By-and-by the Queen of the Adriatic declined, and the sunset of her political and industrial decay was also the time of the decadence of the mosaic art. At last the republic died, and the art which had taken such deep root there fell into lethargy.

But it was not dead, nor even was it forgotten. The elements of its existence and of its prosperity were not so much dependent on political changes as they were bound up with the nature and spirit of the people; so that they were capable of being awakened and directed towards a noble and successful purpose, until it aroused among civilized nations a warm and powerful agency in aid of art and true religion.

THE MARCH OF PESTILENCE.

ATTEMPTS have been made in certain quarters to deny the fact, but there can be little doubt that pestilence, which is said to present several varieties of form, is progressing through parts of Asia and Europe on a scale of great magnitude.

In some places the scourge presents the distinctive features of that terrible Asiatic cholera which has on comparatively recent occasions startled England; in others, the raging disorder is said to be a species of spotted typhus fever, or an intermittent fever; but all agree that pestilence, rising in the usual centres and moving by the customary ways, is destroying multitudes of lives, and, especially at its first onset, setting at defiance all the known appliances of medical science.

Thoughtful persons can see terrible warnings a long way off.

Time after time the grim visitor has called at

the same spots with remarkable regularity; and in Central Asia and other parts, he always finds everything prepared for his reception; for no other monarch could there be a more plentiful and tasteful banquet prepared than that which is sure to be ready to welcome King Cholera throughout the burning clime of India and other deadly regions, where the unwholesome conditions of nature are aggravated by the ignorance and neglect of man. The ravages often spare not a sufficient number of persons living to bury the dead; but in far too many instances it is usual for those who are able to fly from the devoted localities, leaving thousands of bodies putrefying under a tropical sun. Then, after a time, people who have been spared return to their accustomed homes, where all is tainted and poisoned, and the former conditions are rendered more dangerous by the neglected remains which the disease has left. The rivers have become more polluted; on the shores the remnants of decomposing human and other matters are laid, and throw off dangerous exhalations; the water sources have become poisoned; and the inhabitants, notwithstanding the fatal cautions they have received, have continued in exactly the same ways as formerly, seeming, in fact, to look upon it as a wickedness or an unrighteous dealing with the fictions of the great Creator to put forth a hand for the purpose of effecting any change which might, which, in fact, would,—be the means of preserving much life, and rendering less serious the visitations of the pestilence. It is really distressing to read the accounts which come to us of the sanitary condition (and the usual results) of cities like Calcutta, Bombay, and of other places which are now entirely under British rule; let us hope, however, that a short time only will be allowed to pass before steps are taken in a sanitary direction. From the most ancient times tradition and such substantial history as we have show that, in the Eastern regions, all plagues and pestilence have been generated, and so passed step by step to other longitudes and latitudes.

We know that in England the visitation of cholera can as surely be prevented by the introduction of proper drainage, ventilation, cleanliness, attention to the general laws of health, and the timely application of preventive medicine, as we can regulate the working of a steam-engine, or stop the machinery of a watch. See, for instance, when the last outbreak of cholera took place at Newcastle-on-Tyne, when over the whole town deaths and sickness were rife, especially where sanitary care had not been taken. In the barracks, situated about half a mile to the north of the town, where there were many hundreds of men and their families, and where sanitary care had been taken, there was not a single death, or even a case of actual cholera, notwithstanding there were such premonitory symptoms as clearly showed that the distemper was in the air. Besides, in parts of the town approximate to the barracks, the cholera was especially fatal. Moreover, at North Shields, where on a former visit the disorder had been especially fatal; on the last occasion referred to, when Newcastle suffered so much, North Shields entirely escaped. We believe that not a single fatal case occurred. The North Shields people had taken timely warning and set their place in order, when they saw the threatening indications from abroad. We have before spoken of this, but it is needful for the present purpose to refer again especially to this point.

If in this little island of England we can show by actual demonstration that we can hold in check, and even prevent cholera, fever, and other complaints of this class, does it seem unreasonable to hope that the very centre and hot-bed of the pestilence may be in time so purified that it may be extirpated altogether? Till then it will, we trust, ere long pass over our land and leave it at least untouched. To a certain extent this has been already achieved.

Without inducing fear and panic, we ask for renewed care in these islands of Great Britain and Ireland. Let our readers take a nap of the world in hand, and note how a deadly pestilence has passed across parts of Asia to the east shore of the Red Sea, and to Alexandria; let them look in another direction, and mark how a deadly sickness has passed through parts of Russia to St. Petersburg and Prussia. Let us consider the particulars of former attacks of epidemic sickness, and see how close in these days of rapid transit a plague is to our shores, and it must be evident that it will be a wise course to set our places in order.

THE STATUE OF THE LATE SIR CHARLES BARRY, R.A.

THOUGH more than five years have elapsed since the remains of the architect of the New Palace at Westminster were deposited in the neighbouring Ahhey Church, and though measures were taken by his friends very soon after the event to commemorate his talent and professional services in the building with which his name and reputation are most intimately associated in the public mind, unforseen causes of delay prevented, from time to time, the full consummation of their wishes till the noon of Saturday, the 1st inst., when (as we warned our readers in our last number) the portrait-statue in marble, which the well-known skill of Mr. Foley, R.A., has produced, was uncovered in the presence of many friends, personal and professional, whom a brief notice had called together in the Inner Hall of the building to witness the short but interesting ceremony.

The occasion, however, was not allowed to pass without some appropriate and impressive observation on the character and genius of Sir Charles Barry by his friends of very many years' standing—Sir Charles Eastlake, P.R.A., Sir Edward Cust, K.C.M., Mr. Tito, M.P., and Professor Donaldson—which were acknowledged in a most feeling manner by Mr. Charles Barry, who expressed the sense of the honour done to the memory of his late father entertained by Lady Barry and the family.

Mr. Foley has been most successful in producing both a truthful likeness and a work of art worthy of his own high reputation, and of a position, along with other notabilities of our land, in the Palace of the Legislature.

Some further improvements in the decoration of the wall space, forming the background, in addition to those already made, are contemplated, the whole of which, with the cost of the statue, pedestal, &c., will have been defrayed entirely from private sources; the public obtaining as a free gift a most valuable addition to the number of statues already in the edifice.

The subscription-list of the memorial contains the name of almost every architect of repute in the kingdom, besides those of many of the nobility, gentry, and private friends of Sir Charles Barry.

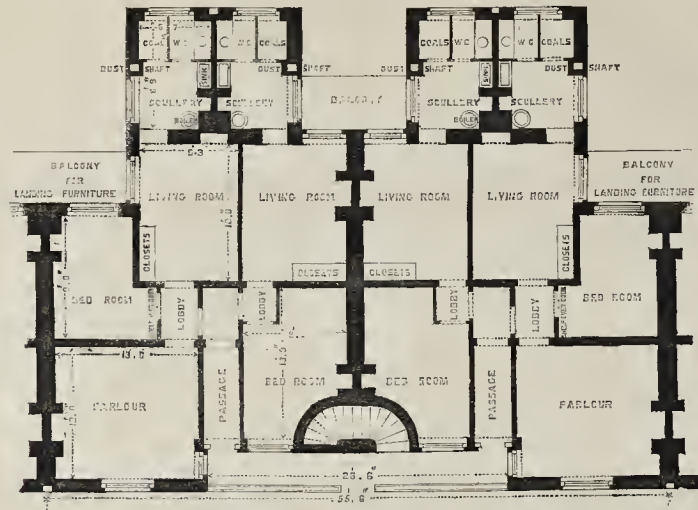

Of the five trustees of the fund—the Right Hon. W. Cowper, the Hon. Sir E. Cust, Sir Charles Eastlake, P.R.A., W. Tito, esq., M.P., and C. R. Cockerell, esq., R.A.—the last-named has not survived to witness the termination of the work; while of the other members of the working committee—Messrs. T. L. Donaldson, J. Gibson, G. Godwin, A. J. B. Bessford Hope, P.R.I.B.A., H. A. Hunt, Owen Jones, Hayler Lewis, Charles Lucas, J. R. McClean, P.I.C.E., D. Roberts, R.A., J. L. Wolfe, T. H. Wyatt, and the honorary secretaries, Mr. Digby Wyatt and Charles C. Nelson,—Mr. David Roberts has also recently been taken from among us.

SKILLED LABOUR.

AT the annual general meeting of the Society of Arts, held on the 28th ult., Mr. T. H. Hardley said, that early in the session he called the attention of the Society to the subject of the scarcity of skilled labour in this country. The importance of that question was becoming more and more apparent from the great inconvenience which manufacturers were put to, and he thought it was a matter which should be discussed by the Society, and with that view he had sent a communication to the Society for the consideration of the Council. It was evident that if some means were taken to a greater extent than had yet been done to train the youth of this country to skilled occupations, our manufacturers would be obliged to depend mainly upon foreigners. It was the case that in his own branch of business—the working of marble—he was obliged to depend a good deal upon foreign workmen, from the great scarcity of native skilled labour. At the same time there were great numbers of youths now confined in prisons and reformatories, who, if turned out from thence as skilled workmen, would be of great service to the state, instead of being a constant burden upon it. He was not aware of any society which was so well adapted to take up this question as the Society of Arts, being one cognate to its objects in the encouragement of arts and manufactures. The present state of the law with regard to apprentices was such as to discourage masters from taking them, and thus the great source of supply of skilled

\* In all branches of glass manufacture, where perfect production is more the result of careful and skilful manipulation than of the peculiarity of the material elements, the moral and industrial decay of the people brings with it the decadence and ultimate loss of the industry; as, for instance, the manufacture of looking-glasses, monied crystals, lamps, &c., for which the island of Murano was formerly so famous, has now been surpassed by foreign manufacturers, and mostly by the English, Germans, French, and Belgians; but where the production is mainly dependent upon the physical nature of its material elements, and upon the peculiar possibility and ease of using them to obtain the best result by means of colour, there Murano has ever kept its privilege; for this is a God's gift, and no competitor, although even more skilful or more civilized, can venture to touch it.

CORPORATION BUILDINGS, FARRINGDON ROAD, LONDON.—Plan of Apartments.

labour was, to a considerable extent, cut off. There were no other means of continuing that supply except by training the youth of the country, so as to replace the skilled workmen who died off. Another effect of the present state of things was, that business suffered and wages were increased to an enormous extent. He always desired to see the workman well paid; but he had no doubt that if things went on in their present course wages would soon rise to 10s. per day. He begged to press this subject upon the attention of the Council. The training of workmen was carried to the greatest extent on the Continent. In Denmark, Sweden, and Prussia, it was made compulsory that youths of a certain age should be apprenticed to some branch of skilled labour; and those countries were now manufacturing very largely, avowedly for the supply of the English market. He was himself taking a large number of apprentices, notwithstanding the trouble this involved, and he had established a "home" for them, where as many were housed as the place would accommodate. He had also encouraged, as far as possible, the system of out-door apprenticeship, and he felt confident, if it were properly carried out on a larger scale, it would add greatly to the wealth of the nation in the supply of skilled labour applicable to the various branches of manufacture.

Mr. Henry Cole, C.B., said he believed he might say, on behalf of himself and his colleagues in the Council, that they would be happy to place an evening at Mr. Hartley's disposal next session for the reading of a paper on this subject if he would be good enough to prepare one, and he had no doubt the matter would then be fully discussed by the Society. The question of skilled labour was an important one, but for his own part he had no dread of workmen getting 10s. a day.

#### PRIZES OFFERED BY THE PLASTERERS' COMPANY.

In addition to the sums offered through the Society of Arts by the Plasterers' Company for designing and modelling, as mentioned in our last, the Court of that company has offered a further sum of 10l. for a design, through the South Kensington Art-Schools. We hope their liberality will elicit a good response. The same total sum, 25l., will be devoted by the company, we believe, every year to the advancement of the art-trade they represent.

#### CORPORATION BUILDINGS, FARRINGDON ROAD.

In our present number is given a representation of these buildings, which have recently been erected by the Corporation of London.

The necessity of providing accommodation for the large number of the poorer classes displaced by street improvements and other great public works in the City, has for some time past occupied the attention of the Corporation; but it was not until 1862 that any positive steps were taken to erect improved dwellings. At the close of that year Mr. S. H. (now Mr. Alderman) Waterlow drew the attention of the Common Council to the subject; and, in an earnest address, induced the Court again to refer the question to the Improvement Committee, under the able presidency of Mr. Deputy Fry. A report recommending the erection of improved dwellings was subsequently presented to the Court, and the result has been a good one. The Corporation realized its obligations, and has discharged them. A piece of freehold land, having an extended frontage in the Farringdon-road, was at once appropriated to this purpose, and the substantial pile of buildings shown in our engraving has been erected upon it at a further cost of 37,000l.

These buildings are now almost entirely occupied, and contain accommodation for 168 families, each in a separate and distinct tenement; also twelve large roomy shops, with good basements, and let for ordinary commercial purposes. The buildings are similar in design to those erected in 1863, by Mr. Alderman Waterlow, in Finchbury, with the exception of the shops on the ground-floor, and that the elevation in Farringdon-road is in harmony with the probable erections in the same line of frontage,—a manifest advantage as divesting the buildings of any exclusive character. The rents of the tenements range from 4s. 6d. to 7s. 6d. per week. For the lowest price the tenant obtains a sleeping-room, a living-room, fitted with kitchen-range, oven, and boiler, and a scullery, with copper, sink, water-closet, coal-place, and dust-shoot; while the higher price gives the tenant two sleeping-rooms, kitchen, and the other conveniences, on the first and second floors. The other floors are rather less in price. The general plan of the building may be described as a parallelogram of 56 ft. by 43 ft., divided into four sections by a party-wall in the centre and two passages in the middle of each wing.

The two centre sections are set back about 3 ft. from the line of frontage for the purpose of

giving space for a balcony of that width on each of the upper floors. Each section comprises one suite of rooms, to which access is obtained from the passage leading (on all the upper floors) direct from the balcony. The balconies are reached by a fireproof staircase, having a semi-elliptical form, the entrances to which are shown on the elevation by the two doorways in the centre of the building. This staircase is continued, and gives access, to the roof. The larger lettings, consisting of three rooms and a washhouse, occupy the end section of the building. Leading out of the living-room is the washhouse or scullery, which contains, in every case, what may be called the accessories of the dwelling,—water-cistern, sink, a small fire-place, washing copper, dust-shoot, water-closet, &c. It is expected that the fire-place in the washhouse will conduce greatly to the comfort of the living room in the summer time.

The centre sections, comprising the smaller lettings, consist of two rooms and a washhouse. The washhouse and living-room are exactly similar to those in the larger letting. The bedroom can be conveniently converted into a parlour by arranging a set of curtains across the recess at the back of the room, and thus dividing the part where the bed would be placed from the rest of the apartment.

Close to the ceilings of all the rooms a ventilator is placed, which communicates with air shafts running through the centres of the chimney-stacks. The air is thus constantly rarified, and a system of natural ventilation is produced. Besides this it will be seen that by setting open the windows a current of external air can be at once passed through every room. The dust shaft carries the dust to covered receptacles at the base of the building, and each shoot is provided with an iron cover so as to prevent the return of dust and effluvia. The dust shafts are also continued to the top of the building, and act as ventilators to the dust-hins. The greater part of the rooms, especially the living-rooms, have scarcely any external walls, so that they will be always warm and dry. All the rooms are plastered and papered, and the washhouses are plastered and coloured. Every tenant has his apartment completely to himself, and nothing is used in common except the roof as a drying and recreation ground. These buildings contrast favourably, we need scarcely point out, with the aspect of the low dirty hotels in this district. They were built from the designs, and under the superintendance, of the City Architect, Mr. Horace Jones.

CORPORATION BUILDINGS, FARRINGTON ROAD, LONDON.—Mr. HORACE JONES, ARCHITECT.

MUSEUMS AND ART TRAINING FOR  
THE PEOPLE.

This was the subject of the address made by Mr. A. H. Layard, M.P., at the last social meeting, in Exeter Hall, of the Working Men's Club Union, the Duke of Devonshire being in the chair.

Mr. Layard said.—The British Museum, wonderful and admirable a collection as it was, had outgrown its plan, and was now too much a mere unarranged collection of curiosities. He would only have two classes of objects in that museum.—1. Those which would form an historically classified art department; 2. Those which would make an historically classified archaeological department; and whatever could not be arranged under these heads might be removed to other parts of the metropolis, and form the basis or nucleus of a museum or exhibition illustrating the development of some other art and science. In such a collection of art as that contained in the British Museum, historical arrangement was of the greatest importance, both in giving to the articles their just value and to the student a correct impression. Thus a thing of art, standing alone, might be of very little value; but when in its proper place among a classified series, illustrating the historical development of art, it would be seen to be of the greatest value and use. Egyptian art, *per se*, was not of much value, but as a very early link in the chain it was indispensable. In the British Museum there was not room for carrying out this classification, and at present nearly all was a *jumble*. Too much had been crammed into it; for instance, there was a Natural History Department, indicating the history of the earth, and this required a separate building. Every nation should have a museum illustrating the present state of art as applied to, and expressed in, social, domestic, and practical life, and especially in manufactures; and he was prepared to say that no other nation possessed a collection equal to that in the South Kensington Museum; moreover, he was quite certain that this museum and the Exhibitions of 1851 and 1862 had caused a vast improvement in British manufactures, and so promoted the best interests of the nation. During the Exhibition of 1862, France had sent forty-two representatives of different branches of manufacture to examine and report upon the various corresponding branches exhibited therein, and they all had declared that England had vastly improved in all, but especially in the manufacturing of glass, porcelain, china, &c., and was likely to heat themselves out of the market. Mr. Layard did not agree with all the arrangements of the Kensington Museum, but he thought that the richness of its collection and the value of its results could not be too highly praised. As to the question of opening the British Museum, the National Gallery, and the South Kensington Museum at night to the working classes, he should say they should be opened if it could be done with safety. But the late Mr. Braidwood, and other very reliable authorities, had reported on the lighting of these places, and had shown that there was great danger of injuring the collections by the gas, or of destruction by fire. And it should be remembered these collections, if once destroyed, could never be restored. This nation was bound to preserve these treasures for the use of all nations and ages. He thought that if the idea of having local museums was carried out, the Ethnological Department might be taken from the British Museum and made the nucleus of a museum in the East-end of London, and might receive frequent additions from masters of ships returning from distant countries. And the Indian Museum, now at the back of Whitehall, might be removed south, and form an Oriental Museum for South London. Mr. Layard then observed that he thought the Industrial Exhibitions which had been or were being held were highly calculated to be of great use. 1st. They gave pleasant employment to the leisure hours of the working man, and kept him at home to employ them, and so tended to keep him from bad associations. 2nd. They showed him what he could and could not do. 3rd. They secured an intermingling of the working and the upper classes, not in the way of false patronage, but in a way honourable alike to both parties. He thought that these local exhibitions should be held every year, as a preparation for great exhibitions, held every ten years. From them the Government should purchase the best things in every department, to be kept as

an embodiment of the art and science of that year, and as a means of improvement for the future. Art training might be obtained in two ways:—1st, by attending schools of art; 2nd, by visiting museums. Only the latter, at present, was to be secured by the working classes. If the means of cultivating art were more accessible to them, it would be more sought after by the people, just as it had been with music. There had been great improvement, however, in their art-culture, as might be seen in the improved ornamentation of the homes of both the middle and the working classes, and much more remained to be done. Perhaps it was of greater importance to cultivate artistic tastes among the middle classes than even among the working classes, inasmuch as they possessed the means of purchasing what their tastes led them to seek, and what the working man produced. Besides, culture was sure to descend. He would, before concluding his remarks, just put the following questions to the meeting for discussion:—1. Should the British Museum be opened at nights and on Sundays? 2. Should the Natural History Department of the British Museum be taken away from the Art and Archaeological Departments? 3. Should local industrial exhibitions be annual or not? 4. Should the South Kensington Museum remain where it is and what it is, viz., a museum of art as applied to manufactures?

At the close, an interesting discussion took place, in which Mr. Hart, R.A., the Dean of Chichester, several working men, and a lady visitor, took part.

## LAW LIFE ASSURANCE SOCIETY.

When the directors of a society can say, as the directors of the "Law Life" said at their last general meeting, that the invested assets exceed five millions and a quarter sterling, that the annual income is half a million sterling, and that at the six divisions of profit which have been made, bonuses amounting in the aggregate to 4,164,177, have been added to the several policies, they need nothing more to be advanced in its favour. The progress of the society has been singularly steady. According to the chairman, the society commenced in 1823, and then there was paid up a capital of 100,000*l*. In 1833 we find that this 100,000*l*. had grown to three-quarters of a million; in 1840 to a million and three-quarters; in 1847 (the examination of the accounts and the declaration of bonuses being then and until 1854 septennial) it had grown from a million and three-quarters to 3,200,000*l*.; in 1851 it was four millions and a third; in 1859, 4,800,000*l*.; and now, in 1864, it is five millions and a half; so that, not only has the success been large, but gradual and progressive; and, therefore, it gives the greatest promise that is capable of being given in any great commercial enterprise, that the future will reflect the past. The profits realized by the society during the past five years amount to 518,000*l*. The chairman said, he spoke the universal views of his colleagues when he attributed a great part of the success of this office, and the very satisfactory success laid before them, to the constant and undeviating exertions which are made by Mr. W. S. Downes, the actuary, and the very able mind and large experience which he was able to bring to the performance of his duties. This was echoed by proprietors present.

## LIMITED LIABILITY.

The transitions of many kinds, especially the changes of the manner in which various trades are managed, and the enormous increase of manufacturing establishments, with the known profits which are derived from many of them, are amongst the most remarkable signs of the present times, and will afford curious matter in the historic pages of this and other countries. Within the last quarter of a century, the peculiar genius of individuals and their aptness for business, have originated and carried to vast dimensions establishments for the execution of ship building, cotton works, printing and publishing businesses, engineering, and other concerns, which are so numerous that it would require a considerable amount of space to mention even some of those which have risen to much consequence.

In many cases, works commenced by individuals have risen to a degree of eminence and extent which the projectors never dreamt of,

but although the prospects were of the most satisfactory description, and the ultimate success and future large profit appeared certain, there arose difficulty in raising the money which was required for the purposes of extension, or allowing firms to avail themselves of suitable markets both for the purchase and sale of commodities, for the employment of labour on a scale sufficient to meet regular demands, and for other purposes. In times when money became of high price and panics set in, accommodation could not be had, and ruin fell on many houses, which the law of limited liability would have been the means of placing in permanent prosperity.

For long before the passing of the Limited Liability Act, the principle had been carried out privately to an extent far greater than was generally understood; and throughout England there were hundreds of firms which had a widely-spread reputation, and were supposed to be entirely in the possession of the one or two persons who were reputed to be the sole proprietors, and who might be supposed to be in the receipt of enormous incomes. There were, however, parties behind the scenes, who having in times of emergency advanced sums at a large and ruinous amount of interest, became in fact the secret proprietors, and reduced the original heads of the firm to the position of mere managers, who were often very inadequately paid. To remedy this evil, to enable those who had expended their time, intelligence, and capital, to hold fairly intact the property which they had created, and also provide the means of needful expansion, the law of limited liability was wisely made; and, looking at the results, they have been generally most satisfactory, and the system will eventually effect important changes in the industry of the country. By the new law, the possessor of 50*l*., 100*l*., or 1,000*l*., may invest it in schemes which promise success, and no doubt the principle will lead to the extension of co-operative principles amongst workmen.

In a recent account of the money market, we noticed that John Brown & Co. (Limited) of Sheffield, published their net yearly profit at 76,136*l*., equal to 21 per cent. on the subscribed capital. In these enormous profits the public generally, to a considerable extent, participate; first of all by providing capital, without which, on a large scale, no business can be remuneratively worked. Many other establishments might be mentioned, such as the Elswick Works, founded by Sir William Armstrong; Charles Cammell & Co. (Limited), Sheffield; the Fairbairn Engineering Company; Mr. Mar's establishment at Blackwall; Bolckow & Wall; and a hundred other industrial establishments throughout the country.

THE PAYMENT OF BUILDING  
ARTISANS IN LONDON.

For some weeks past, as our readers know, an agitation has been kept up by the masons, carpenters, joiners, and others connected with the building trades in the metropolis, in some cases attended by partial strikes.

On Friday, the 30th ult., a meeting of many of the principal builders was held at the Freemasons' Tavern, and a resolution was carried to the effect that, on and after the 1st of January next, the wages of the skilled artificers engaged in the building trades, now generally paid at the rate of 7*d*. per boy, shall be increased to 7*d*. per hour.

A meeting has since been held by the men, whereat, after a long discussion, the following resolution was ultimately adopted unanimously:

"That the men in each shop shall, on Monday next, the 10th inst., wait upon their respective employers, and inform them that nothing less than three farthings per hour advance could be accepted; such advance to commence on the first week in August next; and that a definite reply should be requested from each employer on or before Saturday, the 15th inst., as to whether he was prepared to give such advance at the time stated. That the meeting stand adjourned for a fortnight, to receive the replies from the employers before taking any further action."

A correspondent writes as follows:—"Will you be good enough to state in your widely-circulated paper, for the benefit of those who wish to act justly without yielding to every demand, whether it is the acknowledged custom to pay mechanics time and a half after eight o'clock at night and one o'clock on Saturdays? Also, whether, under the hour system, *one hour's* notice and time to grind tools is not all that

joiners can rightly claim? I am not aware of any organisation of builders whose decision on these points has ever been accepted."

We have appealed to two large contractors, who say they pay their men "time and a half" and refreshments after nine o'clock at night until six o'clock next morning; but if the men work on Saturday afternoons, and the usual pay only. They invariably give two and a half hours' notice for grinding tools.

COMPETITIONS.

*The Holy Trinity Church, Kilburn.*—In reply to the invitation from the committee to a selected number of architects, some nine or ten gentlemen submitted designs for the above church. The cost was to be about 6,000l., and the church to seat 1,200 persons. After examination of the relative designs, the committee has given the execution of the work to Mr. W. Smith, of Kilburn; the first premium to Mr. F. Todd, of Norland-square; and the second premium to Mr. Tyne, of Gray's-inn.

*Fullers' Almshouses at Tottenham.*—The design selected is that of Mr. Casar A. Long, of London.

COMPETITIONS IN MONTREAL.

SIR,—In your issue of the 13th of May, which I have just received, I see the notice of a new church now in course of erection in this city, by Mr. C. P. Thomas. Thereby hangs a little tale, which I propose to give you, in order that you readers on the other side of the Atlantic may see that we are endeavouring to follow in the steps of the profession at home, and to place competition on a better footing than it has been for some years past, a subject which I am glad to see from time to time you have strongly advocated, in the excellent remarks that have appeared in your paper.

In the spring of last year a limited number of six architects were invited to compete for the above church, receiving from the building committee written instructions of a very plain and positive character, which were "strictly" to be adhered to. One of these instructions was to the effect that the cost of the whole building was *no* account to exceed the sum of 8,000l., and the competitors were more than once informed by members of the committee, that should any selected plan be found to exceed that amount, it would be at once thrown aside, and the next in merit taken. Five of the designs sent in adhered closely to the instructions, and were capable of being carried out for the stipulated amount; but Mr. Thomas's was not in conformity with the instructions either as regards cost, number of drawings required, or as containing all the requisitions laid down by the committee. Nevertheless, on account of the highly decorative appearance of the design, his was chosen; the committee, however, stating at the time, that should the tenders for its execution exceed 8,000l. it would be rejected. Tenders were taken, and not only 8,000l., but 10,000l. were exceeded. Still, "*Côte que Côte*," Mr. Thomas's plan "was so pretty," they must have it; one of the committee going so far as to say he would double his subscription (a large one) if the selected design were accepted! What was done, then? Mr. Thomas receives instructions to cut down this and that; to substitute wood and iron for stone, and make any alteration he could, until the cost was reduced to something near the original mark. This has been done, and the altered plan is now being carried out for 8,300l., independently of heating,—an item which cannot, for so large a building, cost less than from 400l. to 500l. additional. More than one of the other plans sent in were accompanied by a *builder's tender*, engaging to do the whole of the work, including heating, for the sum specified.

I need say nothing to your readers by way of explaining the injustice of such proceedings, thus virtually destroying competition; but I may add that two of the competitors have refused the bonus offered by the committee to the authors of the unsuccessful designs, and a suit is now pending in the courts on the subject.

Whether the action be gained by the architects or not, it will at least have the effect of showing the public that if competitions are not to be fairly and honestly conducted, architects will not be found to run the risk of so much loss of time and labour as has in this instance been sustained, amongst others, by

A SUBSCRIBER AND CONSTANT READER.  
Montreal, June 13th.

ARCHITECTURE AND ENGINEERING, UNIVERSITY COLLEGE.

THE following is a list of the prize men, and of those commended, in the two classes:—

Architecture, Professor Donaldson, Ph.D.—*First Arts, First Year's Course*.—Prize—T. Battersbury, of London. Certificate.—E. M. Whitaker, of London. *First Arts, Second Year's Course*.—Prize—Ralph Selden Wornum, of London. Construction—*First Year's Course*.—Prize—(equal) Frederick Topha, of London; E. M. Whitaker, of London. Certificate.—2, Lewis Solomon, of London; 3, R. C. Joy, of London; 4, George Stanley Rees, of London; 5, J. T. Hanson, of London. Construction—*Second Year's Course*.—Prize—Henry Thwaites, of Hampstead. Certificate.—2, Robert F. Whellock, of Pretham; 3, Ralph Selden Wornum, of London. Civil Engineering, Professor Polo, F.R.S.—*First Prize and First Certificate*.—Henry Thwaites, of Hampstead. Certificate.—2, George F. Risco, of London; 3, equal, Lewis Solomon, of London; R. C. Joy, of London; W. P. Morrison, of London.

THE BELFAST ALBERT MEMORIAL COMPETITION.

THE following letter has been addressed to the Institute of Architects by a competitor:—

I have seen in the *Belfast News Letter* newspaper of the 27th ult. a report of the proceedings of the Belfast Albert Memorial General Committee, from which I learn that the selection of the designs for premiums for the drawings lately submitted in competition, is now depending for decision upon the President and Council of the Royal Institute of British Architects. As one of the competitors, I beg leave to lay before the President and Council of the Institute some account of the proceedings of the Belfast Committee, believing that, in the absence of knowledge, as to the previous proceedings, it is impossible for the President and Council to arrive at a just decision. I shall have to point out that the Belfast Committee has placed itself in a most equivocal position, and that one of their body, Mr. Lanyon, who is also a competing architect, occupies a position as unfair to his brother architects as can possibly be conceived; and I am obliged to mention the name of Mr. Barre, another competitor, who, I believe, like Mr. Lanyon, is an architect of Belfast. In the criticisms which I have to make, I wish it, however, to be distinctly understood, that I attribute no intentional unfair, or dishonourable favoritism, partiality, or connivance to any member of the Committee, or to either Mr. Lanyon or Mr. Barre. It is the misfortune of the Committee, from ignorance of the inherent difficulties of the mode of proceeding they selected, to have placed themselves and these gentlemen in a position of odium from which now they evidently look to the Institute to rescue them.

In accordance with the invitation of the Belfast Committee, seventy-six designs for their Albert Memorial were submitted to them on the 1st of June. A sub-committee was then appointed, of whose terms and proceedings I give a history in the newspaper to which I have referred. Upon the assembling of the sub-committee, a discussion arose as to their authority, some believing that the choice of the designs rested "absolutely" with them, others contending that their power was only recommendatory. They finally resolved that they had the power of selection, and by ballot selected two designs marked "Veritas" and "Palman," assigning to "Veritas" the first premium, and to "Palman" the second. The discussion as to the authority of the sub-committee appears to have occurred at the meeting at which this selection was made, and the whole meeting occupied, Mr. Macnaughton says, four hours. I submit that no proper examination, such as Mr. Macnaughton claims to have made, of the seventy-six designs, can have been made in the time. Mr. Lanyon's drawings occupy four sheets,—probably an average of the whole, which would, therefore, give 304 sheets of drawings; there were eight gentlemen conducting the examination, which gives 2,432 examinations, or equal to one person examining between ten and eleven sheets in a minute. The impossibility of doing this is obvious. But, when we discover that Mr. Lanyon's design was the one that was the authors of the designs selected, it is equally obvious that many reasons would occur for fixing the attention of the sub-committee on their designs.

After the decision of the sub-committee, a general committee was held, and before them were laid the two selected designs. They did not regard the decision of the sub-committee, but proceeded to discuss the merits of the drawings; and Mr. Lanyon being a member of this committee, was present. Mr. Macnaughton spoke to him frequently, but is quite certain that Mr. Lanyon in no way influenced their acts. He acknowledges that Mr. Lanyon had been most useful and influential previously, and that to him the committee was indebted for arranging and drawing up the terms of the competition. The committee-meeting now in question, in Mr. Lanyon's presence, changed the decision of the sub-committee, and placed "Palman," Mr. Lanyon's design, first; and "Veritas," Mr. Barre's, second. Seeing this result, I imagine that no one present at the meeting will believe that Mr. Lanyon's reputation and well-earned influence in Belfast, together with his presence, did not so far settle the question.

The settlement, however, aroused a storm "out of doors." The general committee assembled again on the 20th of June, when the previous proceedings were publicly narrated; and, after a long discussion, it was resolved to seek the decision of the President and Council of the Royal Institute of British Architects. From the report in the press, it is not easy to discover exactly the point referred to the Institute; whether they are to have before them four, six, or seventy-six designs. I contend that no proper decision can be had upon either four or six selected elsewhere.

I wish to urge upon the Institute, that Mr. Lanyon, having become a member of the committee, is totally ineligible, either in himself or his firm, as a competitor; and that, therefore, his design must be withdrawn. I think, in the next place, that the remaining seventy-five designs must then be adjudicated by the Institute.

I inclose the printed terms of the competition, forwarded to me by the secretary of the Belfast committee. It will be observed that by the terms of the design of Mr. Lanyon from the competitors now, by no means prevents his employment by the committee, as they are not obliged

to do more than give the premiums to the successful competitor. However inexpedient this course may seem to competitors, they cannot complain of what was from the first in the terms. I, for one, should not be displeased at seeing Mr. Lanyon, after all, engaged as architect to the memorial. It would have been a sensible course for the Belfast people to have employed at first, and without competition, so capable a man as Mr. Lanyon, who has had from the first the confidence of the committee, and in whose favour so powerful a bias has been felt; but having once chosen him as their confidential committee-man, it is quite unjustifiable that they should admit him as a competitor. Whether or not the Institute ought to decide when their decision may not be final, is for the consideration of the council. GONNOR M. HILLS.

CONGRESS OF THE BRITISH ARCHÆOLOGICAL ASSOCIATION.

THE programme for the meeting to be held at Durham August 21st to 26th inclusive, runs thus:—Monday, August 21st—Reception at the Castle Durham; Inaugural Address; Antiquities of Durham; Public Dinner at the Castle; Rev. G. Ormsby at the Castle. Tuesday—Lmley Castle; Chester to Street; Lancaster; St. Cuthbert's College, Ushaw. Wednesday—Durham Cathedral and Monastic Buildings; Finchale Abbey; Solway and Papers in the Castle, Durham. Thursday—Barnard Castle; Staindrop Church; Raby Castle; Soirée and Papers in the Castle, Durham. Friday—Newcastle-on-Tyne.—Museum of Antiquities; Tyne-mouth Priory; Soirée in the Castle, Durham; and Saturday—Brancepeth Castle; Bishop Auckland; Darlington; and concluding Soirée in the New Town Hall, Durham. Numerous papers are already promised.

ENGINEERS' CHARGES.

SCIENTIFIC EVIDENCE.

*Symons v. Foxwell*, in the Court of Queen's Bench.—This was an action to recover remuneration for services rendered as a skilled or scientific witness in a cause. It was an action by Captain Symons, who of late years has practised as a civil engineer, as the surviving partner in the late firm of Richard Roberts & Co., to recover the sum of 124l. 15s. 6d., the amount of their charges as consulting engineers, for services rendered to the now defendant in a suit by him in the Court of Chancery against Mr. Bostock, in which Mr. Foxwell sought to establish the validity of certain patents for sewing-machines. The particulars claimed that sum. The defendant paid into court 50l. and denied any further liability. The particulars were as follow:—

Jan. 18, 1864.—To receiving instructions in the case, and reading of specifications and other documents relating thereto .....	£ s. d.
Jan. 20, 1864.—To travelling expenses from Wals to attend as witness .....	15 15 0
Jan. 20, 1864.—To charge for time and consulting with Mr. Lodge on arrival .....	2 15 6
Jan. 21, 1864.—To consultation with Mr. Lodge in the above case, and attending in court .....	10 10 0
Jan. 22, 1864.—To attendance in court .....	10 10 0
Jan. 25, 1864.—To ditto .....	10 10 0
Jan. 27, 1864.—To ditto .....	10 10 0
Jan. 28, 1864.—To ditto .....	10 10 0
Feb. 6, 1864.—To letter from Mr. Wickens, enclosing copy of Lord Chancellor's opinion in the above case, and reading same .....	10 10 0
Feb. 12, 1864.—To attending consultation at Mr. Wickens's office .....	10 10 0
Feb. 13, 1864.—Attendance in court .....	10 10 0
Feb. 13, 1864.—Hotel bill .....	8 15 0
Remaining in town in apartments from Jan. 25 to Feb. 28 .....	13 10 0
	4124 15 6

It appeared that professional men, especially civil engineers, are often engaged in causes not only to consult and advise, but also to give evidence as skilled or scientific witnesses on matters rather of experience and opinion than on mere matters of fact. In such cases it appeared that they usually receive a fee for perusing the papers and making themselves generally masters of the case, and also at the rate of ten guineas a day for consultation and attendance in court. At all events, this appeared to be the rate of remuneration for gentlemen of eminence and experience in the profession, who would not be sufficiently remunerated by the ordinary allowance of three guineas a day as between party and party on taxation of costs.

Mr. Paul Hodge, Mr. Scott Russell, Mr. Fothergill, and Mr. Braithwaite, all eminent engineers, were called as witnesses in support of the claim. The first-named gentlemen were asked by counsel whether he had not been customarily "employed as a professional witness."

The Lord Chief Justice observed,—"I don't like to bear that phrase, "employed as a witness." The Counsel said he meant being employed to advise and consult as an engineer. The duty of a scientific witness, he added, is not confined to giving evidence.

The Lord Chief Justice, I wish it were. It would be well if there were a distinction between advising and assisting in a case, and giving evidence in it. Perhaps it was the mixing of the two characters,—of the character of adviser, and of witness,—which tends to make what is called "scientific evidence" so much open to animadversion. The gentleman who is consulted is intended to be, and afterwards becomes, a witness in the case, and all his professional interest and personal bias are enlisted on the side of the party by whom he is called or "employed."

Mr. Scott Russell, in giving his evidence, said that the value of a man's opinion, of course, would depend upon his skill and experience, and that the time of a man of first-rate eminence and experience was worth a great deal, so that the rate of charge mentioned was quite reasonable and usual. He added that he quite concurred in what his lordship had said on the subject, and went on to say emphatically, I take it really as a kindness to my profession that his lordship should have spoken in reprobation of men who are in the habit of selling their opinions and calling it evidence. But there are men calling themselves civil engineers who in fact abuse the profession, and bring discredit upon it. I quite concur in what your lordship said as to the desirability of separating advice from evidence, and I wish that we were paid only for our professional advice and assistance, and not for our attendance as witnesses to give evidence."

The Lord Chief Justice observed that it was not reasonable that a professional man should be paid for his loss of time, whether occasioned by attendance as a witness or otherwise; and of course this remuneration for loss of time should be in proportion to the value of the professional man's time. It would not abate the bill he alluded to merely to charge nothing for attendance as a witness, as the amount would probably be thrown on the charge for advice and assistance.

The case for the defence in assistance was, that the charges were excessive; that 5*l.* a day was enough for attendance in court or at consultation; that Mr. Roberts was ill, and hardly able to attend to the case; and that in point of fact, and as it turned out, he was not actually examined, and his evidence was worthless; and that, for these and other reasons, the sum of 60*l.* paid into court was amply sufficient.

The Lord Chief Justice intimated his opinion that the plaintiff was not entitled to recover the charges in respect of his coming up from Wales, as his place of business was in London.

At the close of the case, the Lord Chief Justice, in summing up the case to the jury, said, in the absence of any evidence of special or express contract, the question would be, what was the ordinary rate of remuneration in such cases, a liability or contract for payment being admitted, and the dispute being only as to amount. It was entirely a question for the jury whether the charges were reasonable. Upon the general question as to the payment of remuneration for attendances in court as witnesses a man, no doubt, ought not to be allowed to make a profit by a traffic in testimony; but, on the other hand, he was fairly entitled to remuneration for loss of time while waiting in court, and as to this the proper standard was, what he would probably make on an average in the ordinary exercise of his profession; and, if usage had established a certain rate or standard of remuneration, at so much a day, then it might be reasonable to have regard to it. The question was, on the whole, what charges were fair and reasonable—whether as to the items or heads of charge, or the amount of each charge—as to which the jury must form a judgment.

The jury, after a little consultation, went out of court to consider their verdict; and, after an absence of about an hour, they returned with a verdict for the plaintiff for the sum of 18*l.* 6*s.* beyond the sum paid into court, making altogether the sum of 68*l.* 6*s.*

#### HOW TO MAKE STONE IMPERVIOUS ?

I HAVE seen in your journal a letter under the above title, containing a request that some one would indicate a process by which stone would be rendered impervious to rain.

In reply thereto, I would beg to recommend Ransome's process, by which a solution of silicate of soda is injected into the pores of the stone, and, by means of a second solution of chloride of calcium, an insoluble silicate of lime is formed. I have tried this process upon Caen stone and brickwork in exposed situations with satisfactory results.

G. R. BURNELL.

#### RAILWAY COMPENSATION CASE.

At the Sheriff's Court, Red Lion-square, on June 27th, the case of Hickman and Others v. The North London Railway Company came on for hearing.

This was a compensation claim in respect of an interest in two freehold houses in the Holloway-road, belonging to a Miss Hickman, and which were let as shops. The claim was about 3,000*l.*, and the property, like all other metropolitan property, had gone up in value.

In this case evidence was given on both sides as to the value of the property in question, amounting to about 3,000*l.* for the share claimed. On the part of the company Mr. Pownall and other surveyors were called, and their valuation was 1,449*l.*

Mr. Under-Sheriff Burchell placed the case before the jury, and they assessed the compensation to Miss Hickman at 1,750*l.*

A correspondent wishes to know if Mr. Under-Sheriff Burchell has anything to do with the firm of Messrs. Burchell, of Westminster, largely engaged as solicitors for railway companies? Some other correspondent will perhaps enable us to reply.

#### DRINKING FOUNTAINS.

A GREAT deal has been done by the public press to support this important movement, by the liberal insertion of leading articles and correspondence, but by none more usefully than your interesting journal. At the commencement of every summer public attention is drawn to the subject, particularly by the Free Drinking-Fountain Association, which throws blame rather unfairly upon parish officers for the miserable condition in which some are kept. The complaint is somewhat qualified, and I venture to believe the parish of Kensington may be one of the few exceptions alluded to, inasmuch as those in operation are well attended to, affording drink to man and animal, during the summer months, and, being carefully covered up in the winter, are not subject to abuse in that season.

It should be known and understood that the Association claims a right over those it erects, and that the water supply should be filtered through charcoal, which the Kensington vestry thought needless, and therefore erected them without aid from that institution. It may be true they possess no pretension to beauty or elegance, but they are by no means unsightly, and possess the simple element of perfect utility, with white earthenware drinking-cups that even the most fastidious person would consider unexceptionable (too frequently broken and misused, I must admit), but a very important element for public convenience; and the waste water for cattle passes through pipes into the road channels, which are slightly raised in places to form small pools accessible to them, without interfering with bipeds who use the fountain, whereas the small troughs under the fountains are not so accessible to dogs and other animals.

The metropolitan parishes may be blameable for not subscribing to the funds of the Association, but the latter is alone to blame for the condition of their fountains, which in the winter months have no covering or protection, and are therefore subject to the greatest abuse from disorderly people and mischievous children.

I admit there is a lamentable apathy in many of the middle classes in respect to the necessity of these fountains, and consequently great difficulty in finding sites for their erection. In 1859 the vestry of Kensington kindly voted for the erection of six, besides those given by private individuals. Two were prepared, but only one of these was erected, owing to this difficulty, which has never since been surmounted: it therefore remains on hand as well as four others, sanctioned but not made, which would doubtless be erected under any outward pressure or stronger feeling of necessity. It is very tiresome and disheartening to hear of the abuse of these useful gifts afforded to the service of humanity, but the vast number who properly appreciate them should not be neglected because the few misuse them: and as one of the public I sincerely thank you for your liberal advocacy on all occasions.

KENSINGTONIAN.

#### READING ALOUD.

RECENT gatherings of children and teachers at the Crystal Palace and elsewhere have shown to what extent the power of vocal melody has been acquired in the national schools; and thousands have been entranced by the multitudes of youthful voices which joined in the execution of those simple yet beautiful melodies which, both as regards the music and the poetry, may be classed amongst the original and pleasing features of the present age. Notwithstanding it is painful to hear the style of reading which is generally acquired; and while we duly appreciate the value of music as an accomplishment, reading must, as a branch of useful education, be of far greater consequence. But it is not in connexion with the national schools alone that this fault has to be noticed, for in educational establishments of much higher pretensions, and in expensive schools, we have heard with pain the sing-song manner in which the rudiments are drawn; and when the scholars begin to read verses of Scripture, the sounding of the whole in one key is indescribably unpleasant. No attention is paid to the emphasis of particular words; and speeches are spoken in a manner very different from that aimed at in the advice which Shakespeare puts into the mouth of Hamlet for the benefit of the players.

The effect of this kind of early teaching is evident in the general style of reading aloud prac-

tised when the scholars have arrived at manhood and womanhood. Amongst young females this failing is most distinctly to be observed; and there are many who can play admirably on the piano-forte, who cannot decently read a sentence from the newspaper, or from our household classics. In a chief measure this failing is to be attributed, as we have hinted, to the want of school-culture; but another important cause is the want of practice in reading at home after school; and we have often met with those who could read rapidly to themselves, who blundered and mispronounced words if made to read them aloud.

#### LINOLEUM.

THE substance so euphoniously named consists of the linseed oil of commerce, rendered solid by a process patented by a manufacturing company in Cannon-street, City. By this process the linseed oil is made to assume similar properties to those of india-rubber and gutta-percha, or becomes, in fact, what we long since suggested, that it might be made a sort of artificial india-rubber. It is said to be soft, flexible, and elastic, and adapted to many valuable purposes. In the manufacture of floor-cloth the linoleum is first reduced to the consistency of dough, and then intimately mixed with ground or powdered cork by machinery; and, being extremely adhesive, it combines so thoroughly as to form a substance almost like leather. By the joint action of heat and great pressure this material is rolled on to stout canvass, which is afterwards waterproofed, and the surface of the linoleum is then printed with appropriate designs. At the time when we suggested the formation of artificial india-rubber, a dealer in leather, it may be recollected, sent us a specimen of a material made from shreds of leather as the result of his rumination over our suggestion. The cementive matter, however, was merely bituminous; but with oxidized lused oil waste leather might be used up to great advantage.

#### WINDOW GARDENING.

MORE and more is the pretty practice of decking with growing flowers the windows of the industrious and poorer classes coming into use, and in many a bye street and lane in the metropolis the care of the inhabitants produces a pleasant appearance such as has not been seen since the now urban and widely-surrounded part formed a suburban precinct. In a neighbourhood persons who perhaps come from the country see the example of flower-growing, which, like an epidemic, spreads with rapidity, notwithstanding the difficulties that are in the way, and which are mostly caused by the opposition of those who have not yet been smitten with the love of flower-growing. In tenemented houses the extent of unpleasant feeling which exists amongst neighbours is a matter causing surprise to strangers; but it is unfortunately a fact, that to manage a tenemented dwelling in peace is a difficult matter, and requires a skilful diplomacy to achieve. It is true that there are so many great matters of complaint that it leaves ground for persons addicted to fault-finding to make mischief. But to the especial subject of flower-growing. Many an angry quarrel is caused by the dripping of water from the window-sills on to the parts below. In London, where there is so much smoke to contend with, water is especially needed to keep the sooty particles from the leaves, and in going this the water falls from the upper windows and dirties those below, and still further descends to the premises of the "lady" who lives in the kitchen; who is an unpleasant person, perhaps, who does not like the trouble of flowers herself, and does not see why she should be annoyed by the water from the person above, so that quarrels long and lasting are the consequence. To say the truth, the water dripping in this way is not pleasant, but by a simple plan this may be remedied.

CLOSE OF THE MASONS' STRIKE AT BRADFORD. The masons' labourers who were out on strike at Bradford, have returned to work, the employers having yielded what they sought,—an advance of one shilling per week; making their wages 20*s.* per week.

FROM SCOTLAND.

**Edinburgh.**—The city council have agreed to a report of their Plans and Works Committee, recommending various minor improvements on the Calton-hill. They have also agreed to a report from the Streets and Buildings Committee, recommending the council to consent to the erection of a portico in the re-erection of the Theatre Royal.—A new branch of the Sinclair Cooking Depot has been opened at Greenside-place, Leith Walk. The new branch is below Lady Glenorchy's Free Church, and is divided into three halls—store-room, pantry, and kitchen. The main hall, which is very suitably furnished, is about 100 ft. long by 18 ft. wide, and supplied with twenty-two tables, at which 250 people can dine at once. The second hall is 90 ft. long by 27 ft. broad, and the third 42 ft. long by 18 ft. broad. It is calculated that in the first hall a thousand persons will be served daily.

**Dunbarton.**—The foundation-stone of a new town-hall and burgh academy has been laid with Masonic honours, and amidst great demonstrations of rejoicing. The erection of a hall and a new burgh academy had been long talked of, and much needed. The town council took the matter in hand last summer, and the necessary funds (nearly 7,000*l.*) were soon subscribed.—Mr. Peter Denny, shipbuilder, and Provost McAusland, each contributing the sum of 1,500*l.*; and Mr. White, of Overton, 1,000*l.* Operations, according to plans prepared by Messrs. Melvin & Lieper, of Glasgow, were commenced in the end of last autumn, and the mason-work is now in an advanced state, a portion of the building being roofed in.

**Dumfries.**—Designs for a new church, amounting to thirty-two in number, having been submitted to competition, the joint committees of the town-council and congregation have almost unanimously selected the design furnished by Mr. Starforth, architect, Edinburgh. The site occupied by the present church is the one on which it is proposed to erect the new edifice, and this site is surrounded on three sides by buildings, and limited in area. The plan shows that the nave of the church is about 65 ft. long and 30 ft. wide, the transepts being similar in breadth, and the aisles about 15 ft. in width. The aisles and transepts have galleries, which, with the area of the church, will accommodate about 1,300 persons. In order to gain space for the large school-room, vestry, and other requirements demanded by the committees, these departments are placed beneath the north end of the nave and transepts. The school-room contains an area of about 1,000 square feet. The pillars of the church, between the nave and aisles, are of cast-iron, clustered. The roof is open. The roof timbers, together with the seating and gallery fronts, will be of pine timber, stained and varnished. The principal front of the church is towards Church-place. The form is somewhat octagonal, having the tower in the centre, on each side of which is a circular staircase communicating with the galleries, and flanked by gables and pinnacles. The principal entrance to the church is by two large coupled doors in the tower, from which access is gained to the area of the church and the gallery stairs right and left. The tower is about 20 ft. square at the base, and, with the spire, will rise to about 60 ft. The windows below the galleries, and especially those to the principal front, are filled with tracery. The triple windows in the gables flanking the central tower are deeply recessed. The design is Early Decorated.

**Langholm.**—Premises in Market-square, for many years occupied as the King's Arms Inn, together with a house adjoining, having in whole the frontage of 67 ft., and extending backwards a distance of 150 ft., will be pulled down, and on the site thus obtained it is proposed to erect buildings which will embrace a temperance hotel, a working men's reading-room, a large bill-room for the volunteers, and a hall to be used for meetings and other public purposes. The plans have been prepared by Messrs. Haberton, Spedding, & Brock, of London, and are in course of being estimated. The cost of the whole undertaking will probably exceed 3,000*l.* Among other works now going forward in Langholm, is the erection of a new police-station, for which the plan was prepared by Mr. Fraser, architect, Dumfries.

**Morebattle.**—The foundation-stone of a new P. P. church at Morebattle has been laid. The edifice is to be erected from plans by Mr. Skelington, architect, Edinburgh, and will cost 3,000*l.*, the most of which, 950*l.*, has already

been raised by the congregation; Messrs. Scott, farmers in the district, having given 600*l.*

**Forres.**—The Forres Water Company have just completed a reservoir. The town has hitherto had its main supply from a spring about four miles from Forres, on the farm of Fornaley, Rafford, which is led by pipes into a large covered cistern 300 ft. above the High-street. In order to have command of a reserve in case of excessive drought, the company have had an embankment made at the lower end of "Glenbeg," about half a mile further up than the tank. The new reservoir accumulates water from several springs west of the farm of Clauy, and when full will contain about five millions of gallons.

FROM IRELAND.

**Enniskillen.**—The foundation-stone of a Wesleyan chapel has been laid by the Earl of Enniskillen. The chapel, which is in the Corinthian order of architecture, will be capable of accommodating about 600 people, in addition to a school-room under ground. The cost, including site, will be about 3,200*l.*, of which 2,600*l.* have already been subscribed. The architect is Mr. W. J. Barre, of Belfast; and the contractor, Mr. Wm. Campbell, of Enniskillen.

**Bray, near Dublin.**—A stained glass window is now completed, intended to be fixed in Bray Church, near Dublin, by Mr. Holland, of Warwick, containing four subjects, in medallions, of the Nativity, Adoration of the Magi, Presentation in the Temple, and Flight into Egypt, with angel in tracery. This window is the gift of the Countess of Meath.

**Garrane.**—The foundation stone of Trinity Church, Garrane, which will be situated just at the mouth of the Ballinacurra river, has been laid by the Bishop of Cork, Cloyne, and Ross. The plan was furnished by Mr. William Atkins, of Cork, architect, in the style of architecture prevailing in the early part of the fourteenth century. The church will consist of a nave 50 ft. by 22 ft., with tower and spire 75 ft. high, grouping with a semi-octagonal chancel, lighted by two-light windows, with large cinquefoil circles in the heads. The materials used in the walls will be red-coloured stone, with limestone dressings and bands. The interior of the church will be lined with bricks of different colours, varied with stone and tiles; and an arcade with marble shafts will be carried round the chancel, having carved stone-caps and bases. The roof will be open. Accommodation will be afforded in the church for about 150 people. The site was granted by Mr. R. W. G. Adams, Jamesbrook, and the erection of the church is in the hands of Mr. Devlin, the builder of the Cork Model Schools.

PROVINCIAL NEWS.

**Oswestry.**—The "Savin column," or shaft, in Oswestry, 150 ft. high, and which, with its abutments,—the Cambrian workshops,—will cost upwards of 100,000*l.*, has been completed, according to the *Shrewsbury Chronicle*. It will give future employment to some 400 or 500 skilled artisans, at an expenditure of 500*l.* a week, or 26,000*l.* a year. The Cambrian Railway Workshops, as the premises will be called, are 482 ft. long and 244 ft. wide, comprising large and lofty workshops, engine-fitting shops, carriage and wagon shops, engine-house, boiler-house, and a shaft 150 ft. high. A flag has been hoisted from the summit of the shaft, announcing that the "rearing" of these extensive works has been accomplished. Mr. Humphrey Roberts was the builder; Mr. Wilson, the engineer; and Mr. R. B. Jones, the architect. No serious accident has taken place during the construction.

CHURCH-BUILDING NEWS.

**Leicester.**—A font and carved cover have been placed in St. George's Church, as a memorial of the late Rev. Robert Burnaby, who for thirty-seven years was incumbent of this church. The necessary funds were raised by subscription. The font and cover are Perpendicular in style, and designed to harmonise with the church. The font is of Caen stone, octagon in plan, and carved; the eight sides being panelled and the sprandrels filled with foliage. The oak cover is 3 ft. high, and of spiral form, with numerous arches, buttresses, and pinnacles. The cover is suspended from the roof by a weight and chain,

and can thus be easily raised or lowered. The whole of the work has been carried out by Mr. John Firm, from the design and under the superintendence of Messrs. Goddard & Son, architects.

**Wendy (Cambridgeshire).**—The chief stone of a new church has been laid here. The old church (dedicated to All Saints) having been erected upon a defective foundation, gave way, and showed signs of falling; and at last it became so unsafe that the archidiaconal architect, Mr. R. R. Rowe, was requested to prepare plans for a new church, and Messrs. Bullock, of Cambridge, have contracted for its erection. It will consist of a nave, chancel, and vestry. The nave is to be covered with the oak roof now upon All Saints' old church, Cambridge, which has been secured for the purpose.

**St. Alban's.**—In March last, Mr. G. G. Scott, architect, made a survey of St. Michael's Church, and reported that it was in a most deplorable condition. He considered that a thorough and careful restoration of the whole church was necessary; and in consequence of this report strenuous efforts were made to obtain subscriptions, and the work of restoration has been commenced in earnest. The tower has not yet been touched, because there are not at present funds sufficient for that purpose. The contract has been taken by Mr. Young, builder, of this town, for the re-seating of the church, and the restoration of the nave, chancel, south chapel, and north aisle, at a cost of 1,500*l.* The process of demolition which precedes that of restoration has been gone through, and the old church now looks almost in ruins.

**Croydon.**—Steps have been taken to erect another place of worship in the parish of St. John. Sufficient was raised in a short time to justify the promoters in commencing the new edifice. The church, which stands on a piece of ground in the Addiscombe-road, will cost in round numbers 5,000*l.* Of this sum already 4,700*l.* have been promised. The work of preparing plans was entrusted to Mr. Arthur W. Blomfield, architect. The church is somewhat peculiar in plan, owing to the shape of ground on which it is to be built. The site, as originally contemplated, is unusually short from east to west; and although 15 ft. have now been added, this was not done until after the work was actually commenced, and when it was too late to modify the plans. The details partake of the Early French character. Mr. G. Pearson is superintending as clerk of the works. Messrs. Dove, Brothers, are the builders; and Mr. W. Greenfield, general foreman. The work is so far advanced that the foundation-stone has been laid. The length of the building internally is 97 ft., and one width 47 ft. It consists of a nave, a north and south aisle, with a transept, vestry, chancel, &c., and will seat about 600 persons. It is contemplated at some future period to extend the church westward and southward, ground having been purchased for the purpose. The wall at the south side is built somewhat temporarily, in order that any alteration may be effected with as little trouble as possible. It is calculated that by extending the church in the direction proposed, viz., 15 ft. at the west end, and about 10 ft. at the south side, additional accommodation will be provided for about 400 persons.

**Wythop (Cumberland).**—The foundation stone of a new church at Wythop, in the Lake district, has been laid by the Bishop of Carlisle. The church which this new edifice is intended to supersede is a decayed barn-like structure, with which there are some curious customs associated. It was built in 1673. Not many years ago nettles grew luxuriantly beneath the seats in the pews and along the middle of the passage. For some hundreds of years the inhabitants of the chapelry were in the habit of dividing it into four quarters, from each of which a representative was elected yearly; the functions of the four being set forth in a document dated 1623. They had to elect a parish minister or reader, who was generally the schoolmaster, a layman being eligible. They had to collect "devotion money" supervise the repairs of the fabric, and look after the parish school. The stipend of the minister was 10*l.* per Sunday, and was supplemented by "whitlegate," that is to say, the reader was boarded and lodged by the inhabitants of the four quarters in turn. The church furniture is of a most primitive kind. A narrow board on a moveable bracket constitutes the communion table, and the vessels employed in the celebration of the Lord's Supper are a cheese-plate and a pewter pot. There is no font provided for baptisms, nor is there any vestry-room attached to the building. This old church is to remain

as a curiosity. For the new one, a subscription of 700l. has been raised. The site, at the foot of the mountain, has been presented by Sir H. R. Vane, bart. Mr. Bruce, of Whitehaven, is the architect, and the builders are Messrs. Grave & Moor. The style is Early English; the nave roof having curved traces, crossed at the apices, and supported on stone corbels. The nave will be 40 ft. long by 21 ft. wide, and the chancel 194 ft. long by 16 ft. wide. The building is intended to seat 120 persons, all free.

#### STAINED GLASS.

*Romsey Abbey Church.*—This building has received another enrichment (though of modest pretensions) in a coloured memorial window to the late Mrs. Berthon, the wife of the vicar. The window is inserted over what is known as "the nun's doorway," which now serves the purpose of a window, but is about to be restored to its original use. The artist of the stained glass was Mr. A. Gibbs. The figure in the centre represents Faith. Another head is said to be in process of painting to replace the existing one which is in the antique type. Considerable restorations are in progress in the outside stonework of this part of the building.

*St. Helen's Church, Lancashire.*—This church, after considerable alterations and improvements, has been re-opened. Some time since the organ had been moved from a loft above the altar to the side, and now the entire east end has been filled by a new window by Messrs. Pilkington, the gift of Mr. R. Fildes, of St. Helen's. The subjects, all medallions, comprise, in the right light, six incidents, manifesting the glory of the Son of God in the Son of Man. The six on the left illustrate the words, "He showed Himself alive after His passion." The centre light has three subjects,—the Burial; and above, the Appearances of Angels to the Women at the Sepulchre; the middle and main subject is the Ascension. A suitable inscription accompanies the subjects.

*Kendal Parish Church.*—A memorial window to Mr. John Yeates (first mayor of the reformed corporation of Kendal) and Margareta his wife, with new masonry, has just been added to this church. Mr. Warrington, of London, was the artist. The new window is inserted in the south wall of the church (being the most westerly but one on that side) and consists of three main compartments, surrounded with tracery in six divisions, containing an Angelic host in the act of adoration, the apex of the window being occupied by a small ruby cross on a shield of argent. The window, besides the two principal subjects, contains numerous shields of arms belonging to the families of Yeates and Brettagh (from whom Mrs. Yeates was descended) and their several connexions. In the left hand compartment is depicted the Angel appearing to Cornelius, while in that on the right hand, the subject is the Centurion beseeching Christ to "come and heal" his servant.—Matt. viii. 5—13. Mr. William Atkinson, of this town, prepared the masonry.

#### G.A.S.

The Townyn people have resolved to construct gasworks, without delay. At a meeting held in the town-hall, it was proposed and carried, that Mr. W. E. Crake, C.E., of London, be the engineer of the works during the progress of erection; and that tenders for building, laying the mains, &c., be solicited, as soon as the plans and specifications are prepared. The company has been started by some of the neighbouring gentry and a few inhabitants of Townyn.—Mr. Malam, the proprietor of the gasworks at Lynn, has determined to reduce the price of gas to private consumers to 4s. per 1,000 cubic feet, by allowing 1s. per 1,000 discount from the price charged if paid within a month.—A very unusual case has occurred at Whitehaven, which tends to define the lowest limits of price under favourable circumstances. The Whitehaven gas company, who had been selling their gas at 2s. 6d. per 1,000 cubic feet, have felt obliged to raise the price again. Considering, however, that 2s. 9d. is a price which has been proved at Plymouth to be capable of yielding the highest allowable profit, we think the Whitehaven directors are probably erring now on the other hand in raising their price to 3s. 4d. to all consumers of less than 75,000 ft., and 3s. to all above that quantity. The two companies have combined to charge the same prices. Had there only been

one company, perhaps even 2s. 6d. might have been found sufficient.—The Hinckley gas-light and coke company's directors have reduced their price from 5s. 10d. to 5s.—The Wolverhampton gas company have commenced additions and improvements at their works. In addition to an enlargement of the retort-house and other improvements within the Stafford-road works, a new 21-inch main is being laid along the turnpike road.—A company for lighting Madrid with gas has been formed by some Franco-Spanish capitalists, through the medium of the Spanish Credit Mobilier. The company begins its operations on excellent conditions, as, from the opening throughout of the Northern of Spain Railway, the price of coal has experienced a notable fall at Madrid. The working of coal mines in Castile, which belong to the Mobilier Espagnol, is being developed, and presents good results.—The public meeting of ratepayers and gas consumers convened by the Lord Mayor of London, has been held, and resolutions unanimously passed to the effect that the supply of gas ought to be placed in the hands of local authorities, so that, after lighting the public lamps, the private consumer might get gas at cost price; and that the Gas Act of 1860 ought to be repealed. The meeting also urged the necessity of steps being taken towards that end, and approved of the measures adopted by the Corporation with the view of applying to Parliament for powers to make gas for the citizens.

#### Books Received.

*Practical Specifications of Works executed in Architecture, Civil and Mechanical Engineering, &c.* By JOHN BLENKARN, C.E. and Architect. E. & F. N. Spott, Bucklersbury. 1865.

In this volume Mr. Blenkarn gives the specifications for works executed mainly, as it would seem, under his own direction, including road-making, drains, cottages, villa residences, wells, and bridges. The author says in his preface:—

"If the writer had consulted his own pleasure and convenience, either he would not have written at all, or on a subject more congenial to his taste; but, from long and constant practice, he has witnessed so much ignorance and inaptitude on the part of young men in these particulars studying for the profession, and, indeed, after their studies should have been concluded, and fitted them for useful assistants, that, with the advice of his publishers, he has selected in the form now presented a series of specifications, forms of contract agreements, bills of quantities, schedules of prices, and reports, all bearing on practical subjects, and of works executed, not intended to apply to very extensive undertakings or to works of any special character, but to such as are likely to come within the scope of general practice particularly of the young architect and surveyor; and in choosing this path the writer is not aware that he has trespassed on pre-occupied ground, either as to the expense of the book or the questions treated of in it. An attempt has been made to introduce a variety of subjects, and as these are discussed under the divisions given in the index, a more detailed account seemed scarcely necessary in a work of such limited extent."

The drawings are added for some of the works, and the cost of execution; serving to make the book complete so far as it goes. The cost, by the way, of some of the buildings—as, for example, the two-story villa residences at East Coves, one 1,035l. and the other 1,115l.—seems to us large. One of the specifications provides that the clerk of the works is to be appointed and paid by the contractor—an unusual and not good arrangement. Nor have we any particular fancy for the stipulation that the contractor is to pay the architect three guineas for a copy of the specification.

Mr. Blenkarn's book will be found useful by those who do not possess, and object to the larger expenditure required to obtain, Professor Donaldson's more complete work on the same subject.

#### VARIORUM.

"ON Radiation: The 'Rede' Lecture at Cambridge, May, 1865. By John Tyndall, F.R.S." London: Longman & Co. Some of the results of recent inquiries in the interesting domain of radiation are here recorded by Professor Tyndall. To his theoretical views we need not here revert. The lecture is much less a theoretical than a practical one. Nevertheless the author rightly upholds the importance of a free culture and exercise of the imagination in the study of experimental science. "Throughout the greater part of this discourse," he remarks, "we have been sustained by this faculty. We have been picturing atoms, and molecules, and vibrations, and waves, which eye has never seen nor ear heard, and which can only be discerned by the

exercise of imagination. This, in fact, is the faculty which enables us to transcend the boundaries of sense, and connect the phenomena of our visible world with those of an invisible one. Without imagination we never could have risen to the conceptions which have occupied us hitherto-day.

"We are led irresistibly to inquire what is light? and what is heat? and such questions lead us at once out of the region of sense into that of imagination."—"The Amateur's Manual of Photography," edited by Richard Kingham. London: Thomas Kingham, Strand. Although the publisher's name here is suspicious as to motives for publication, this, so far as we have seen, appears to be a manual of general utility to amateur photographers, and does not smother offensively of "the shop," as no few do.—"Inconsistencies of the English Census of 1861, with the Registrar General's Reports; and Deficiencies in the Local Registry of Births." By W. L. Sargant. This is a reprint of a paper read before the Statistical Society in January last, and published in the Society's Journal. We have already drawn attention to the subject of this paper. It is an important one, and calls for careful inquiry. Mr. Sargant believes that the population is far more numerous than it appears by the census to be. One hurried counting, in a single day, he regards as quite insufficient to secure anything like accuracy. The deficiency is considered to be far greater in some districts than in others, and inquiry might be in the first place restricted to the most suspected districts as a test. Livor pool and Hall are ranked as the worst in respect to the registration of births, with London, Chelsea, Plymouth, and Portsmouth following in order of demerit.—"The Sewage Committee of 1864, and its Report as to the Purification of River Water from Town Sewage." By Thomas Spencer, F.C.S., &c. E. Stanford, Charing Cross. Anything written by the discoverer of electrolyte merits respectful consideration. Mr. Spencer's chief purpose in this pamphlet is to recall the public attention to the merit of his method of purifying foul water by means of the magnetic oxide of iron. We have more than once spoken of this method as a promising one. Mr. Spencer's explanation of its *modus operandi* is that it ozonizes, or polarizes, oxygen, which then oxidizes the carbonaceous foulness of the water. Ozone may now be said to be ascertained to be Nature's great scavenger. Whatever be the precise nature of the change which oxygen undergoes when it becomes ozone, it at all events acquires a powerful activity which induces it to act vigorously on decaying organic substances, converting them into carbonic acid gas, which gentle acid is what gives water its value as a pleasant drink. Oxygen is ozonized naturally in various ways, as by lightning in thunder-storms; and indeed, ozone has been regarded simply as oxygen excited by electricity into an active state. There are also influences at work in the strata of the earth which are believed to ozonize oxygen and so to purify water containing it while filtering through the strata. Doubtless the well-known deodorizing and disinfecting power of earth itself over sewage is attributable to the same cause; and above all other earths Mr. Spencer maintains that protoxide, or magnetic oxide, of iron, which is widely diffused, to be the best for such a purpose. There is something exceedingly feasible in this idea, and it may involve a discovery of vastly greater public importance than even the electrolyte.—"The Popular Review of the July sustains the interest of this excellent periodical. The leading paper is one by Mr. Glaisher, on "Balloon Ascents, and their Scientific Importance."—"A Dictionary of Science, Literature, and Art." Edited by W. T. Brande, D.C.L., &c., the Rev. G. W. Cox, M.A., and others. London: Longman & Sons. Part I. Mr. Brande is a high chemical authority, and his dictionary contains evidence of the value his helping hand in it. The list of contributors too, is a powerful one, containing such names as Frankland, Owen, Lindley, Ansted, &c. The work, however, is intermixed with matter of inferior value.—"Theodolites, Levels, Drawing Instruments, &c." Archmt & Sons. Midsummer, 1865. Our purpose in placing this catalogue among "Books received" is not to criticise the merits of the manufacturer, but merely for behoof of those, especially country readers, who may wish to look over some such catalogues. Messrs. Archmt's have the advantage of being illustrated by numerous engravings of the instruments referred to.

The Life Boat; or, (quarterly threepenny) Journal of the National Life Boat Institution, vol. v., No. 57, for July quarter, contains a very good paper on "Our Lights and Lighthouses," with illustrative diagrams.

Miscellaneous.

THE LATE MR. MANNS, C.E.—Died, on Thursday, June 29th, aged 52 years, at his residence, Popper's Hill, St. Helen's, Mr. John M. Manns, C.E., Surveyor to the St. Helen's Improvement Commissioners, which office he held for many years previously to his death. He was formerly Surveyor to the Ormskirk local Board of Health. He has left a widow and eight children quite unprovided for.

LEEDS BOROUGH SURVEYORSHIP.—Mr. Alfred Fowler, for some time past borough surveyor of Rochdale, was, at a special meeting of the town council, appointed borough surveyor of Leeds, at a salary of 300*l.* per annum. Before he obtained his appointment at Rochdale, Mr. Fowler was for several years in the office of the late borough surveyor at Leeds. His local knowledge and experience were greatly in his favour in the consideration of his claims; and though forty-eight candidates applied for the appointment, it was unanimously conferred upon him by the council.

THE PARIS EXHIBITION.—Our correspondent writes,—Nothing has been yet decided as to whether the plan or the site of the new exhibition building, though it is very likely that the Champ de Mars will be the spot, and that M. Horeau's plan will be adopted. The spirited office of the united companies of Parent, Shacken, Caillet, Bail, & Co., to erect a temporary structure for 12,000*l.*, or a permanent one for 560,000*l.*, includes every contingency that can arise from an undertaking which is meant to surpass predecessors.

THE FIRE AT MARLBOROUGH HOUSE.—The dangerous fire at Marlborough House, of which every one must have heard, and at which the Prince of Wales displayed an energy and spirit beyond all praise, appears to have been the result of extreme negligence on the part of those who altered the interior of the building some few years since. Ventilating shafts run perpendicularly from the bottom of the building to the top; and within these, in several of the passages, gas-lights, for the purpose of increasing the draught of foul air. Each gas-light is easily reached by means of a small glass door, through which a little light shines. This would have been all very well, and ventilation would have been safely attained, had the builder cased the interior of the shaft with sheet-iron; but wood was used; and, as the brackets for the lights were made to swing in all directions, instead of being rigidly fixed, so that the flame of gas could be in the centre of the shaft, it follows that nothing more was needed than that some careless servant, after obtaining a light, should bring the burner round against the woodwork, in order to bring about a catastrophe such as the building has narrowly escaped from on the present occasion.

WEST LONDON INDUSTRIAL EXHIBITION.—A meeting of the exhibitors has been held, for the purpose of aiding the committee in promoting its success. The exhibitors feel deeply that the poorer classes in general have withheld their support, and expressed a determination, so far as is in their power, to prevent the promoters from suffering pecuniary loss; donations were appointed from among them to wait upon the principal employers of labour at the west of London, and for this work lady exhibitors also volunteered. It is also informed the following have already responded by taking tickets for distribution among their employes.—Mr. Peter Graham, 500; Mr. Thos. Lucas, 500; Messrs. Benham & Son, 200; Mr. W. H. Smith, 200; Mr. W. S. Burton, 100; Mr. J. Crace, 100; Mr. H. Heal, 100; Messrs. Lambert & Butler, 100. The committee may feel surprised at their want of success, but we certainly do not; the high price charged and the general want of management are quite sufficient to account for it. The *Builder* has been amongst the foremost for years in promoting industrial exhibitions of all kinds; and when we say that we even an intimation of the opening of this West London Exhibition has yet reached this annual, the sort of management that has preceded will be at once seen.

VALUE OF METROPOLITAN PROPERTY.—In a recent debate in the House of Commons the value of property in the metropolis was put at 900,000,000*l.*

SHARES.—The first annual meeting of the shareholders of the Valencia Slate Sink Company (Limited), was held at the offices, 40, Upper Belgrave-place, Piccadilly, on Thursday, June 28th, when a dividend of 5*s.* 3*d.* per share, being at the rate of 10 per cent. per annum, was declared.

BEDS ARCHITECTURAL SOCIETY.—The annual public meeting of this society has been held at Bedford. The High Sheriff opened the proceedings, and papers were read, by Mr. C. L. Higgins, "On Local Museums;" by Mr. James Wyatt, "On Ancient Bedford;" and by Mr. S. Sharp, "On Antique Counterfeits and Counterfeit Antiques." A valuable collection of curiosities was exhibited at the meeting.

STOCKPORT.—A new bridge has just been completed across the River Mersey; built at the expense of Mr. Cephas Howard, of Stockport, for the purpose of connecting and opening up his building estate. The bridge is in one arch of 70 ft. span, in brickwork set in cement; the parapets are of stone. The cost has been 2,000*l.* Messrs. Thackrah & Pierce, of Stockport, have been the contractors; and Mr. Bricley, of Blackburn, the engineer.

ST. PETER'S ENGLISH CHURCH, CHANTILLY.—The ceremony of laying the first stone of the English Protestant Church of St. Peter's at Chantilly has just taken place in the presence of nearly the whole English congregation and a large number of the French inhabitants. The church is expected to be opened for Divine service early in 1866. The English residents have subscribed liberally, and the proprietors of the domain, in addition to the site—2,000 square metres in a central part of the town, which is in itself a liberal donation—have given 3,000*fr.*; but a further sum of 5,000*fr.* is still required, and will be raised by voluntary contributions.

SKIDMORE'S ART MANUFACTURES AND CONSTRUCTIVE IRON.—A limited company is being formed for purchasing and developing the business carried on by Messrs. Skidmore & Co., of Coventry, their contracts requiring more capital than they can command. These contracts, including the canopy and spire of the National Memorial in Hyde Park, to the memory of the late Prince Consort, are said to amount to about 25,000*l.*, and good and remunerative works, to the extent of more than 200,000*l.*, have been offered and declined, it is said, for want of the necessary capital for their completion, but part of these may yet be secured. A contract has been entered into for the purchase of the works and business for 30,456*l.* The directors have secured for seven years the services of Mr. Skidmore, as managing director, with the option, on his part, of renewing his engagement; and they have also arranged for his chief assistants and skilled workmen to remain with this company. Messrs. Skidmore take 10,000*l.* in shares. The capital of the company is to be 100,000*l.*, in 10,000 shares of 10*l.* each.

THE DALBEATIE AND KIRKCONNELL GRANITE. The selection of this granite for the Thames Embankment has led to the announcement that a limited company is being formed, to be called "The Dalbeattie and Kirkconnell Granite Company," with the view of working the quarries on a sufficiently extended scale. The Company's capital will be 120,000*l.*, in 12,000 shares of 10*l.* each (with power to increase); deposit 1*l.* per share on application and 2*l.* on allotment. Sir John Dalrymple Hay, Bart., M.P., F.R.S., is chairman of the directors. The Dalbeattie quarries, of which six are opened and in full work, with all the necessary plant and machinery, are situated on the estate of Munches, in the numerous large undertakings in the execution of which the stone has been already used, the following are mentioned: the Liverpool Docks; Graving Docks, Birkenhead, harbour at Trinidad; Maryport Docks; Newport Docks; Swansea Docks; Silloth Docks; Workington Docks; Bank of England Branch, Liverpool; new municipal offices, Liverpool; Brown's-buildings, Liverpool. The interest of the Company in the present leases of these quarries will expire in 1896. A preliminary contract has been entered into for the purchase of the leases, railways, and plant, together with the existing contracts, for 25,000*l.* The project certainly promises well.

NOTTINGHAM SCHOOL OF ART.—An extensive exhibition of paintings, sculpture, textile fabrics, lace of all countries, ancient and modern pottery and glass, works in metal, architectural drawings, and a selection of art treasures from the Royal Museum of South Kensington, has been opened with a *conversazione*, at the new School of Art in Waverley-street, which attracted a numerous and fashionable company of visitors. The commodious rooms in the new building are now occupied as a spacious museum, with galleries for paintings and sculpture, and affording such facilities for the advantageous exhibition of their contents as have never before been realised in Nottingham. Mr. Birkin delivered an address on "The Nature and Advantages of Art Education."

KIT'S COTTY HOUSE.—A correspondent of the *Maidstone Journal* suggests that the stones of which Kit's Cotty House is composed, with others of a similar nature lying about in that vicinity, were floated to their present site by icebergs, probably from a great distance, and while the land was under water. No such stone exists *in situ* within the county. Whether geologists have had their attention turned to Kit's Cotty House in particular we do not recollect, but the suggestion that such stones, or holdiers, as are scattered about throughout the country, and have frequently been made use of in old times, as in the formation of dolmens, rocking-stones, &c., were so scattered about by icebergs, is one quite well known to and accepted by geologists as the only possible explanation of their evident transportation from one district to another, and even from one country to another, and often with hilly land intervening between their present site and the original quarry or stratum whence they were obviously derived.

THE ATLANTIC TELEGRAPH.—In anticipation of the opening of the cable to the public, the Atlantic Telegraph Company have issued a provisional, and rather premature, tariff, together with the traffic arrangements. They confidently expect, however, that the cable connecting Europe with America will be open for public business before the end of the present month. The following are the principal charges.—From any telegraph station in Great Britain or Ireland to any telegraph station in America—20 words or less, including address, date, and signature, not exceeding in all 100 letters, 20*s.*; for every additional word not exceeding five letters, 20*s.* per word. From any telegraph station in Europe to any telegraph station in America—20 words or less, including address, date, and signature, not exceeding in all 100 letters, 21*s.*; for every additional word not exceeding five letters, 21*s.* per word. From any telegraph station in Africa, Asia, and India, to any telegraph station in America—20 words, including address, date, and signature, 25*s.*; for every additional word not exceeding five letters, 25*s.* per word.

MONUMENTAL.—A report on the progress of the Manchester Albert memorial, now being erected in Albert-square, has been published. The total sum received and promised up to the present time amounts to 3,711*l.*, of which 1,569*l.* have been already expended. Mr. T. Worthington, the architect, says,—"The foundations, which were commenced in the summer of 1863, were completed up to the level of the street during the autumn of the same year. This part of the work became more costly than had been anticipated, in consequence of the ground being intersected to a depth of upwards of 17 ft. with old drains, which rendered it necessary to excavate to the rock, on which the structure has been built. The contract now in course of execution by Messrs. Paterson & Sons, amounts to 2,630*l.* The memorial will still be in a very unfinished and incomplete state when the present contract has been fully carried into execution, and the expense of the decorative part of the work which has to follow, cannot be estimated at a less sum than from 2,500*l.* to 3,000*l.*, whilst double that amount might be advantageously spent in more fully developing the ornamental details of the design. Rough blocks of stone are built in preparatory to carving, and many of the moldings are unworked, the stone being left projecting in the rough for foliage and carved decoration. A meeting is to be held to initiate measures to secure the early completion of the work.—Signor Reggiti, an Italian poet, has written a letter to the foreign minister of the kingdom of Greece, suggesting that a monument should be erected in Athens to Homer! *Punch's* projected monument to Adam may well come next.

**THE TOTTENHAM, EDMONTON, AND ENFIELD INDUSTRIAL EXHIBITION.**—This exhibition was opened on Saturday, the 24th of June, at the Drill Hall, Park-lane, Tottenham.

**DRINKING-FOUNTAIN MOVEMENT.**—Two granite drinking-fountains have just been erected at Crews station, one on each platform, presented to the company by Mr. C. P. Melly, of Liverpool. They have been fixed under the superintendence of Mr. Lee, of Chester, engineer, and are supplied with an abundance of pure water from the company's new works at Madeley.

**PREVENTING OXYDATION OF IRON AND STEEL.**—According to the patent of Mr. J. B. Chamheyron, of Paris, it is proposed to prevent the oxydation of iron and steel by the forced incorporation of volatile metals having little affinity for oxygen. Tinning, zincing, and leading only give incomplete results, and Mr. Chamheyron has discovered that it was only by incorporating into the iron itself, and to a certain depth, a metal or an alloy little affected by the action of oxygen, and considered practically inoxydizable, that iron and steel can be protected from oxydation in sea and other acidulated waters.

**OPEN SPACES IN THE METROPOLIS.**—The second report of the select committee of the House of Commons has been issued. Among other recommendations, the committee propose that no enclosure shall take place under the provisions of the Enclosure Act within the metropolitan area,—that a Board be appointed to act as trustees for the preservation of commons and open spaces within the metropolitan area,—that they be authorised specially to inquire into, and report on, the rights and circumstances affecting any particular common or open space which in their judgment may require special legislation in the public interest;—that they be empowered to authorise drainage works, to sanction applications to Parliament, &c. The committee consider that the action of the police, so far as the public safety is concerned, should extend to all open spaces in the metropolitan area.

**SOCIAL SCIENCE ASSOCIATION.**—At the meeting to be held in Sheffield from the 4th to the 11th of October next, the special questions arranged for discussion in the departments of Health and Economy and Trade, are as follow:—**Health.**—1. In what way can the unnecessary exposure of workmen to dangers of life or health be best avoided, especially in collieries, mines, and manufactures? 2. What are the best means of preventing the spread of contagious diseases? 3. To what extent can the contamination of air in towns be diminished, and by what means? **Economy and Trade.**—1. What are the best means of establishing a system of authoritative arbitration between employers and employed in cases of strikes and outcrops? 2. Can the principles of co-operation be profitably applied to production; and, if so, under what conditions? 3. Is it desirable to consolidate the existing railways of the United Kingdom into one system under Government control? To the department of Education a section of art has been added for the consideration of the following and other questions:—What improvements can be made in the schools, museums, and exhibitions of art, with a view to the development of the public taste and the prosperity of our manufactures?

**STRENGTH OF MATERIALS.**—It is a remarkable fact that one of the most abundant materials in nature—iron—is the strongest of all known substances. Made into best steel, a rod one-fourth of an inch in diameter will sustain 9,000 lb. before breaking; soft steel, 7,000 lb.; iron wire, 6,000 lb.; bar-iron, 4,000 lb.; inferior bar-iron, 2,000 lb.; cast-iron, 1,000 lb. to 3,000 lb.; copper wire, 3,000 lb.; silver, 2,000 lb.; gold, 2,500 lb.; tin, 300 lb.; cast zinc, 160 lb.; sheet zinc, 1,000 lb.; cast lead, 55 lb.; milled lead, 200 lb. Of wood, box and locust, the same size, will hold 1,200 lb.; the toughest ash, 1,000 lb.; elm, 800 lb.; heech, cedar, white oak, pitch pine, 600 lb.; chestnut and soft maple, 650 lb.; poplar, 400 lb. Wood which will bear a very heavy weight for a minute or two will break with two-thirds the force acting a long time. A rod of iron is about ten times as strong as a hempen cord. A rope an inch in diameter will bear about 2½ tons, but in practice it is not safe to subject it to a strain of more than about 1 ton. Half an inch in diameter, the strength will be one quarter as much; a quarter of an inch, one-sixteenth as much; and so on.—*American Artisan.*

**GREAT LANDSLIP AT VAUXHALL.**—During the past week, that part of the thoroughfare between Vauxhall and Nine Elms has been opened, as has frequently been the case in this neighbourhood of late, for the purpose of laying down new gas or water mains. The cutting has been carried to a depth of, in some places, 20 ft., the sides being supported by the usual timber supports. On Friday in last week, the rain compelled the men to suspend operations, and just after they had left the works, a loud noise of cracking timbers was heard, and the whole of the cutting, from the goods yard of the London and South-Western railway to the Nine Elms-lane, instantly fell in, snapping all the pipes in two which intersected the pit, like so much earthenware, and reducing the timber to fragments. The ground for a considerable distance was left full of large fissures, and another slip was feared before the labourers could resume their work. The pavement on the Nine Elms side of the road was all torn up in a very singular manner, and barricades were placed round the works to prevent persons getting near.

**SIR CHRISTOPHER WREN'S MALLET.**—At a late general meeting of the London and Middlesex Archeological Society, says a correspondent of "Notes and Queries," the original mallet, with which it is said King Charles II. laid the first stone of St. Paul's, was exhibited. By the kindness of Mr. C. J. Shoppee, the honorary secretary, I have been furnished with a copy of the inscription; which is on a silver plate, let into the head. It is as follows, and I believe will be interesting to many readers:—

"By Order of the M. W. of the Grand Master, His Royal Highness the Duke of Sussex, &c., &c., and W. Master of the Lodge of Antiquity, and with the Concurrence of the Brethren of the Lodge, this plate has been engraved and affixed to this MALLET. A. L. 5831, A.D. 1827.

To commemorate that this, being the same Mallet with which His Majesty, King Charles the Second, levelled the foundation Stone of St. PAUL'S CATHEDRAL, A. L. 5677, A.D. 1673, Was presented to the Old Lodge of St. Paul's, now the Lodge of Antiquity, acting by immemorial Constitution. By BROTHER, SIR CHRISTOPHER WREN, R.W.D.G.M., Worshipful Master of the Lodge, and Architect of that Edifice."

**OPENING OF THE LANGTON-WOLD TUMULUS.**—The great burial-mound on Langton-Wold, which has for a long period formed the most prominent object of the only oolitic ridge in the East Riding, has been opened for scientific purposes by the Rev. W. Greenwell, M.A., of Durham. The deductions resulting from his examinations are that the tumulus contained the bodies of two distinct tribes of Britons; that it marked a transition of the tribes; and that it was used in the north for numerous Anglo-Saxon deposits. In all, British and Saxon, there must have been considerably over a dozen interments; and it is a singular fact that the Saxon pottery was found exclusively on the north and east sides. This is the first tumulus opened by Mr. Greenwell, which contained unburnt British bodies, and it is inferred, that the period represented from the primary long-head male burial to the Saxon interments was at least 2,000 years. The absence of flints is remarkable, especially as flint implements abound on the wold adjoining.

**A NEW ATMOSPHERIC RAILWAY.**—A new railway, worked by stationary steam-engines, has of late been exhibiting at No. 338, Albany-road, near Camberwell-gate. This railway is the invention of a Mr. Halliwell, and is worked, somewhat like the old atmospheric line at Croydon, by forced or exhausted air in a tube which is placed between the rails, and runs along the whole length of the line, by which the use of the locomotive engine is superseded. The patentees, Messrs. Halliwell and Allison, claim for the invention that lighter rails and sleepers can be used, one half of the coal saved, and the tear and wear on the rails made not half so great. The tube, which is of cast-iron, is 18 in. in diameter, more or less. On this tube is a sliding valve of iron, which is so tight, it is said, that it will stand as much pressure as any other part of the tube. By the old atmospheric railway, a lifting-valve of leather was used, which could not be made tight, and was the main cause of its failure. A stationary engine will be placed at intervals of five miles, more or less, with self-acting valves, so that through trains may be run any distance without stopping. With regard to the speed of the train, that, it appears, may be carried as high as fifty, or even a hundred miles an hour.

**GIANTIC LARCH.**—An immense larch, containing no less than 193 cubic feet, has recently been cut near Llanidloes. It is the largest of the kind on record in this part of the country.

**IMPROVED DWELLINGS AND WORKSHOPS FOR ARTISANS.**—The Lords of the Treasury have signified their readiness to apply to Parliament for powers to assist, by advances from the funds at the disposal of the Public Works Loan Commissioners, the projects already in course of being carried out, providing improved industrial dwellings. The condition of the loans will be that the bodies to whom they are granted will limit the profits of their undertakings to 5 per cent. —At the Marylebone Vestry a discussion arose recently on a motion by Dr. Richardson to invite all the other metropolitan vestries to elect two members each, with their medical officer of health, to consider the desirability of taking steps for the erection of public workshops in the various parishes, for the accommodation of artisans who at present worked in their own small and crowded houses and rooms, and as to the propriety of obtaining an Act for the establishment of such workshops, similar to the "Baths and Wash-houses Act." It was thought, however, that the proposal might be an excellent one brought forward as a public institution, or started by a limited liability company, but one quite beyond their province as a parochial Board, and a motion as to it was negatived by a large majority.

**TENDERS**

For repairs, &c., to houses at East Greenwich, for Mr. Coles Child. Mr. Thos. Dinwiddie, architect:—	
Lucas	£595 0 0
Canham	580 0 0
Jarrett	565 0 0
Wahel	561 0 0
Gibbs	520 0 0
Adams (accepted)	510 0 0

For additions to residence, stabling, and offices, St. Neots, Hunts. Mr. Robert Hutchinson, architect:—	
Smith	£1,090 0 0
Osborne	1,030 0 0
Balmer	939 0 0
Jackson	795 0 0
Williams	800 0 0

For the erection of farm buildings at Easton, Hunts. Mr. Robert Hutchinson, architect:—	
Williams	£968 10 0
Balmer	786 13 0
Cennell	743 0 0
Richardson	735 0 0
Bridge & Whiteman	659 0 0

For the erection of stables, carriage-house, and offices, at Abbots Rippon, Hunts. Mr. Robert Hutchinson, architect:—	
Balmer & Rowe	£368 10 0
Allpress	325 0 0
Male	318 0 0
Bridge & Whiteman	309 0 0

For house at Rossway, near Great Berkhamsstead, for Mr. C. G. Hadden. Messrs. Hine & Evans, architects Quantities supplied:—	
Young	£4,365 0 0
Young (accepted)	3,900 0 3

For boys' national school, Putney. Mr. S. J. Laforest architect. Quantities supplied:—	
Tarrant	£1,291 0 0
Ramsay	1,167 0 0
Tenny	1,092 0 0
Sims & Martin	1,057 0 0
Bisch	850 0 0

For six cottages, Deptford. Messrs. Chadwick, Brothers, architects. Quantities not supplied:—	
Rudkin	£1,298 0 0
Gorett	1,180 0 0
Day	1,091 0 0
Ramsay	1,000 0 0
Hunt	990 0 0
Bunyan	913 0 0

For alterations, &c., No. 232, Tottenham-court-road for Mr. A. Cottrell. Mr. C. Bradley, architect. Quantities not supplied:—	
Dalry	£622 0 0
Simpson	550 0 0
Ramsay (accepted)	522 0 0

For the erection of an engine-house, boiler-house, coalsheds, and boundary-walls, at Croydon Waterworks, for the Croydon Local Board of Health, in accordance with plans prepared by Mr. Baldwin Latham, C.E.:—	
Jarrett	£9,150 0 0
Sims & Marten	7,760 0 0
Chapp	6,862 0 0
Bennett (accepted)	6,330 0 0

For national schools and teachers' residences, Walsingham. Mr. W. H. Britton, architect:—	
Hill & Keddel	£2,980 0 0
Emnor	2,909 0 0
Axford & Co.	2,849 0 0
Perry	2,735 0 0
Killyb	2,738 0 0
Turner	2,755 0 0
Heed	2,575 0 0
Heard	2,610 0 0

# The Builder.

VOL. XXIII.—No. 1171.

Portraits of Oliver Cromwell.  
The Miniature Exhibition.\*

FOURTH instalment of what was to us a pleasant and instructive pursuit of knowledge under double-glass difficulties in visiting, peeping at, and poring over the

Kensington collection of "Portrait-Miniatures," has brought us to the great name of SAMUEL COOPER (1609-1672), limner in ordinary to King Charles II., "the great limner in little," as Mr. Pepys calls him,† "the most famous limner in the world for a face" (for so Mrs. Mary Beale, the painter, describes him), of whom we have here forty-eight examples, the greatest number ever brought together, and yet, as we shall have occasion to show, the largest and finest female portrait miniature of the master is not among the number.

So little is in print about Cooper (the best account is in Walpole, brief as it is), that our readers will, we feel assured, be pleased to become better acquainted with our "Vandyck in little." Pepys knew him, and Mrs. Pepys sat to him; and what Pepys records so pleasantly about him in different entries in his Diary we have seen at the pains to bring together:—

"1661-2. Jan. 2.—By appointment to meet with Mr. Grant, who promised to bring me acquainted with Cooper, the great limner in little.

1668. March 30.—By coach to Common-garden Coffee-house, where, by appointment, I was to meet Harris; which I did, and also Mr. Cooper, the great painter, and Mr. Hales; and thence presently to Mr. Cooper's house, to see some of his work, which is all in little, but so excellent as, though I must confess, I do think the colouring of the flesh to be a little forced, yet the painting is so extraordinary, as I do never expect to see the like again. Here I did see Mrs. Stewart's picture, as when a young maid, and now just done before her having the small-pox; and it would make a man weep to see what she was then, and what she was like to be, by people's discourse, now. Here I saw my lord general's picture [Monk's], and my Lord Arlington, and Ashly's, and several others; but among the rest, one Swinfea, that was secretary to My Lord Manchester, the lord chamberlain, with Cooling, done so admirably as I never saw anything; but the misery was, this fellow died in debt, and never paid Cooper for his picture; but it being seized on by his creditors, among his other goods, after his death, Cooper himself says that he did buy it, and give 25*l.* out of his purse for it, for what he was to have had but 30*l.* Being infinitely satisfied with this sight, and resolving that my wife shall be drawn by him when she comes out of the country.

1668. July 2.—Calling on Cooper to know when my wife shall come and sit for her picture.

6th.—To Mr. Cooper's, and there met my wife and W. Hower and Deb.; and there my wife

first sat for her picture: but he is a most admirable workman, and good company.

8th.—With my wife to Cooper's, and there saw her sit; and he do extraordinary things indeed.

10th.—To Cooper's, and there find my wife and W. Hower and Deb., sitting and painting; and here he do work finely, though I fear it will not be so like as I expected: but now I understand his great skill in music, his playing and setting to the French lute most excellently; and he speaks French, and indeed is an excellent man.

13th.—To Cooper's, and spent the afternoon with them; and it will be an excellent picture.

19th (Lord's Day).—Come Mr. Cooper, Hales, Harris, Mr. Butler, that wrote "Hndibras," and Mr. Cooper's cosen Jacke; and by and by come Mr. Reeves and his wife, whom I never saw before: and there we dined: a good dinner, and company that pleased me mightily, being all eminent men in their way.

25th.—At noon, after dinner, to Cooper's, it being a very rainy day, and there saw my wife's picture go on, which will be very fine indeed.

1668. Aug. 10.—To Cooper's, where I spent all the afternoon with my wife and girl, seeing him make an end of her picture, which he did to my great content, though not so great as I confess I expected, being not satisfied in the greatness of the resemblance, nor in the blue garment: but it is most certainly a most rare piece of work, as to the painting. He hath 30*l.* for his work; and the crystal, and ease, and gold case, comes to 8*l.* 3*s.* 4*d.*, and which I sent him this night, that I might be out of his debt."

That is, 38*l.* 3*s.* 4*d.* in all. Where is Mrs. Pepys by Samuel Cooper, crystal, and ease, and gold case?

The most celebrated siter that sat to Samuel Cooper was Oliver Cromwell. The great Protector had little time to give to portrait-painters, bust-makers, and medallists. He sat to Cooper, to Lely (it is said), and to Simon for the obverse of his coins and medals.

Remembering that the much-vexed and canvassed question of three or five years since "Shall Cromwell have a statue?" is much like a peenage case—*dormant* rather than *extinct*—a collection of the known facts about the genuine portraits of the great Protector, their several pedigree possessors, and the artists they are by, may, we submit, well find a space in the columns of the *Builder*. As the statue must (when erected) necessarily be a portrait-statue (look at Falkland, Hyde, Selden, Hampden, already erected, all portraits, and in great good taste), *likeness* is indispensable.

When Derbyshire-born Chantrey received a commission from the senate at Washington for a monument to George Washington, and was asked what shape it should take, England's great bust-sculptor said (taking a pinch of snuff at the time from his tortoiseshell box), "A standing statue of the man, as he looked and moved in his noblest moments." Jonathan at once said, "Yes;" and one of the very finest portrait-statues in the world was "ordered" for America, in a few minutes would call a "business dealing" of a few minutes, and, better still, is in Washington, and equally admired by the discordant Lancaster and York factions, or "jars," of North and South.

Among the many portraits of Oliver P. (for so in the armed terror of his greatness he signed his name), the foremost place is due to a copy made in 1723, by the famous Bernard Lens, and not in the Kensington Collection. Its pedigree is equal to the requirements of justice, law, or turf. Its magnificence of head is equal to the demands of Spurzheim; its mental developments portray the history of the man, and fully satisfy the biographical demands of the three living men who know most about Oliver, and admire him most—Thomas Carlyle, John Forster, and John Bruce.

The copy to which we allude belongs to his Grace the Duke of Portland (the London and Nottinghamshire descendant of King William III.'s right hand), to whose family it came through the *Portland Vase* Duchess of Portland, the accomplished daughter and granddaughter of the famous collectors of the Harleian Library and the Harleian MSS. "Where" the *original*, by Cooper, from which Lens worked, is, has long continued, and seems likely to remain, as great a problem as the locality of the flesh-and-blood remains of Oliver himself has been and still continues to be. Lens copied an original by Cooper, finished everywhere but in the tapestry, or column, or curtain-filling-in of Cooper's assistant, and very masterly and delicate is Lens's work.

When the *great* (for so we must call it) Art Treasures Exhibition was on, in the year 1857,—there was no cotton famine in Manchester that year,—it was our good fortune to have repeated and then renewed conversation with two skilled scholars in art in England,—unhappily no more,—John Scott, of Colnaghi's, in Pall Mall East, and Frank Graves, of the "house" of Graves & Co., in Pall Mall West,—need we add, London? How much knowledge of art useful to collectors, connoisseurs, auctioneers, and all who love art, died with these two men, we will not here stop to tell. The Duke of Buccleuch's collection had been mainly formed and arranged by John Scott, with indisputable judgment and unlimited allowance of price. Frank Graves (John Scott's rival) held almost unlimited commissions from noblemen and gentlemen to buy what was good and undoubted. It fell to our luck to show the Oxford (Harleian) Portland miniatures to Frank Graves and John Scott. The Portland miniatures were then (1857) wholly unknown to both connoisseurs. We asked (good-naturedly) to be allowed to renew our acquaintance with some of the Buccleuch miniatures, and praising some and hesitating over others as original, "*Wellbeck*" was for the first time opened unto them! But not to digress or be disobedient to the requirements of our readers, we will confine the observations of our two deceased friends to one particular miniature portrait, the "*Cromwell*," which we reserved nearly to the last, as a *pièce de résistance*.

This was Lens's exquisite miniature of "Oliver P.," Oliver, of Marston Moor and Naseby, in England; Oliver, of the Death Warrant; Oliver, of Dunbar, in Scotland; Oliver, of Drogheda, in Ireland; Oliver, of "all time," Scott, of Colnaghi's, like Dryden's Alexander, looked,

"And sigh'd and look'd, sigh'd and look'd,  
Sigh'd and look'd, and sigh'd and sigh'd."

first at the writer—"we"—of this article and then at one another,—delighted, confounded. Returning the much-to-be-prized miniature to its case, "What," we asked, "would Scott, of Buccleuch, give for Scott-Portland's miniature of 'Oliver,' as he was?" "Priceless," replied John Scott; "Beyond all price," replied Frank Graves. We can recal their voices as we write. The inscription on the back of this exquisite historical portrait will now appear in print for the first time:—

"Done from the original of Cooper in the hands of Thomas Frankland, Esq. Bern. Lens, fecit. Nov. 19, 1723."

This Mr. Frankland became Sir Thomas Frankland, knight. The faithful Vertuo made two engravings from the *Frankland* Oliver, and left a MS. note in his Collections about Art in England, that Richard Cromwell gave it to his sister, the Lady Falconbridge; and that she, a little before her death, gave it to Sir Thomas Frankland. In 1826—when Dallaway wrote—the unfinished original was in the hands of Mr. Henry Cromwell Frankland, of Chichester, and "set in a snuff-box."\*

\* Walpole, in 1758, was asked 400*l.* for Cooper's unfinished miniature of Oliver Cromwell (Walpole's Letter to Mann, 9th Feb. 1758).

\* See p. 480, ante.  
† Diary, 2nd January, 1661-2.

When [1653?] Oliver sat to Lely (the future Sir Peter was then only "Mr. Lilly, of St. Paul's, Covent Garden, or, rather, Paul's, in Covent Garden"), he is said (so Captain Winde told Sheffield, Earl of Mulgrave and Duke of Buckinghamshire) to have requested, while sitting, "Mr. Lely, I desire you will use all your skill to paint my picture truly like me, and not flatter me at all, but remark all these roughnesses, pimples, warts, and everything as you see me, otherwise I will never pay you a farthing for it." The future court's painter of "The Beauties" (Windsor Beauties) of the court of King Charles II., bowed approval, and painted "the counter-fact presentation," of the Great Protector, as he sat many-minded before him.

This portrait of Oliver is so little known,—it is, or was, at Chicksands, in Bedfordshire, the seat of the Osbornes,—that it deserves to be sent to London for public exhibition, with a troop of Monk's Coldstream Guards to protect it there and back again.

At Sidney College, Cambridge, is a "limning in large" of Oliver, made, it is said, by Samuel Cooper, as a study for his miniature of the Protector. It was given to the college (Cromwell's own) one hundred years ago (1765) by Mr. Thomas Brand Hollis, a ripe scholar and ardent republican of the Algeron Sidney and *Oceana* Harrington mood. Application was made by letter, officially, to the head of the college (the accomplished brother of our great Shakspearian actor, Mr. Phelps), and the following was the master's reply:—

"Sidney College, Cambridge, April 26, 1837.

Sir,—I regret that I am not able to comply with your request. To do so would require the consent of a majority of the fellows of the college, in a regular college meeting, and I shall have no opportunity of laying the proposition before such a meeting earlier than the 12th or 13th of May.\* Moreover, I have very little hope that I should then obtain their consent, owing to the present state of this picture. It is painted in distemper on paper fastened to panel, and from some cause or other several cracks have appeared in the paper, and seem gradually to extend. We are at this very time taking measures for remedying the evil.—I am, Sir, your obedient servant,

"ROBT. PHELPS."

What has been done since 1857 (a period of eight long years) we have not learnt. Surely a photograph, full size (if possible) would meet with more than encouragement. A portrait of so great a man as Oliver, by so skillful an artist in and at heads as Samuel Cooper, deserves perpetuation beyond the Sidney College original. Let some skilled photographer think seriously of this.

We have lately mentioned the late Mr. Frank Graves, and must return to his name, and once more honourably. He kindly called our attention to a marble bust of the great Protector, which Mr. Farrer had secured, and was willing to sell "to one who could fully appreciate it, had a good house for it, would pay well for it, and would not part with it." The bust was Oliver all over, rather coarsely but vigorously carved, unlike the filing-finking art of bust sculpture in the present day. The sculptor, Frank assured us, and we believe him, was Edward Pierce. The bust "turned up" at No. 39, Portland-place, London, the house of Mr. John Fitzgerald, at a sale there in 1849. The massive head attracted the attention of Mr. Lanchere (now Lord Taunton), and was soon on its way to Stoke. A terra-cotta—perhaps the terra-cotta of this fine bust—is now in the National Portrait Gallery, Great George-street, Westminster.

It has been asked, and will again be asked, what has the South Kensington exhibition of portrait miniatures contributed to the preservation of the exact lineaments of the head and face of Oliver Cromwell? The portrait of the Protector, engraved for the great work of "Lodge's Portraits of Illustrious Personages," is from a picture by Robert Walker. Oliver is in armour; a page fastens a sash to his waist. The picture is in Earl Spencer's collection at Althorp. This, Lodge's catalogue tells us, is "the finest portrait of the Protector." There are several repetitions of it. Are the men who ought to know satisfied with the pedigree and portraiture of the Althorp picture? Do the whole fourteen so-called Cromwells in the Kensington collection, or indeed any of them, support the authenticity of the Althorp Cromwell? A general resemblance of features is at once observable throughout, as in all kinds of Napoleons and Wellingtons. Mr. Carlyle will of course give his adherence to No. 476, "Lent by Mr. John Berners," and engraved before his Cromwell. Lord Houghton will vote for No. 2,537, Oliver, by Cooper, in

profile, and cry with the catalogue, "This miniature was sold by the Lady Cornwallis to Sir Joshua Reynolds for one hundred guineas. He bequeathed it to Mr. Richard Burke, who left it to Frances Lady Crewe, from whom it descended to her granddaughter, the present Lady Houghton."

Lord Cremorne likes his Cromwell,—an enamel (121).

Mr. Henry Farrer, jun., fancies his Oliver,—large oval, on card, and fine frame, old (303).

Mr. Charles Polhill would not exchange (351) his very small oval of an enamel, after Cooper. "This was a present made to Bridget Cromwell on her marriage with General Ireton, in 1646, and was worn by her as a clasp to a huclet; the back is enamelled in light blue, and bears a crown, the sun and moon, and the letter P."

Earl De Grey and Ripon prefers (373) a so-called Cooper miniature of Oliver, "long the property of the Pallavicini family at Genoa, before it came into the possession of its present owner." He is looking to the left.

Mr. Edward Cheney is not dissatisfied with his Protector portrait (415).

Messrs. Hunt & Roskell would only be content to take "a large figure" for their, to our thinking, poor old copy.

Mr. John Berners, backed up by Mr. Carlyle, does not envy any one else his Cromwell. An oval in a small square black frame, touched up in the blue.

The Earl of Verulam has every reason to believe in his David Logan (534), pencil on paper, looking to left; after Cooper, we think Logan was an engraver of the time of Charles II., and exquisitely neat in his pencil portraits.

Mr. R. S. Halford, M.P., is not to be envied the possession of the (762) Oliver. "Poor" is our catalogue mark against it at the time.

The Duke of Devonshire exhibits (1,037), the profile drawing in pen and brown tinted, from which Houbraken engraved.

Lord Fitzbarding contributes a Cromwell, "on card," by "Cooper" (1,472).

Lord Boston sends (1,853), an Oliver, in profile and armour. "Oil." Ascribed to Samuel Cooper.

Mr. John Rolls has lent (1,873), "Oliver Cromwell. Ivory."

"Cromwell, our chief of men," looks alive, thanks to Thomas Simon, citizen and goldsmith, all "matchless fortitude,"\* on his medals and coins. The silver currency of the great Protector, the work of Thomas Simon, "chief graver of his Highness's mints, scales, and medals," of St. Clement Dances, London, citizen and goldsmith, "have not been equalled in vigour of conception, boldness of execution, and exquisite subtilty of detail, by any one who has wrought" in England—not by Thomas Rawlins, not by John, or Philip, or Joseph Roettier, not by Nicholas Broet, not by Peter Blondeau, not by John Croker, not by John Sigismund Tanner (who lives in a nick-name), not by Signor Pistrecci, not by Alfred Joseph Stohard, not by William Wyon or his able son, Leonard Wyon.

The lucky owner of a fine silver crown-piece of Cromwell, by Simon, may feel assured he possesses one of the finest portraits of the Protector—one that was received and passed current with Cromwell's contemporaries,—with Round Head and Cavalier,—with Episcopalian and Presbyterian,—with Roman Catholics, and even with Anything-Arians; a likeness known to King Charles II. and Prince Rupert, to Monk and to Blake, to Jeremy Taylor and to Baxter, to Milton and to May, to Sir Peter Lely and to Samuel Cooper himself.

#### M. VOGÜÉ'S RESTORATION OF THE BASILICA OF CONSTANTINE.

SOME light may perhaps be thrown on the true position of the Basilica of Constantine at Jerusalem, which is at present the subject of most interesting discussions, by a short abstract of M. Vogüé's arguments in favour of his elaborate and careful restoration of this building.

On the west side of Jerusalem, in a quarter of the city which appears to have been the earliest times to the present day the Christian quarter, there is a piece of uneven and hilly ground which is covered by a large church of comparatively modern date, the whole inclosure being surrounded by a special curve of the city wall. Starting from these fortifications to the

west of the church, the ground sinks gradually and then falls suddenly, forming a wide but shallow ravine, surrounded on the east and west by vertical walls of rock of about five metres in height. To the east of this the ground rises again rapidly, forming a kind of promontory overlooking the ravine, which has been held, at least since the time of the Crusaders, to be the true Hill of Calvary, or Golgotha. In the western face of this eminence is a small excavation traditionally called the tomb of Adam; while in the side of the hill to the west of the ravine are two somewhat similar excavations, also supposed to be tombs.

The first of these is evidently of Jewish origin, having the ante-chamber and chief chamber found in all the ancient sepulchres round the city, the latter being surrounded with loculi, or niches for the reception of the dead, placed at right angles to the walls of the chamber, two to the north, two to the south, and three to the west.

The second, which is situated to the north-east of the former, is either not a Jewish tomb, or, if it is, it must have been left unfinished, as M. Vogüé considers to be the case, having no loculi for the reception of the dead, but, on the contrary, only one niche or couch for the reception of the body, placed at the end of the principal chamber. It consists of two small apartments, the first being a kind of vestibule entered from the east, and the second a chamber of irregular shape, entered from the vestibule by a low door originally closed by one of those great stones which are frequently to be found at the entrance of ancient tombs. The first sepulchre is called "The Tomb of the Family of Joseph of Arimathea," and the second is supposed by all true believers to be the Holy Sepulchre of Christ.

At some distance from these excavations, near the promontory of Golgotha and down in the ravine, is a sunk chamber or cistern, shallow and dry, in which our Lord is said to have been placed during the preparation of the cross; and near it is another in which that cross was afterwards laid.

Such was the original form of the ground on which the basilica stood, and such was its appearance at the time of the erection of that building, after the Empress Helena had cleared away the mounds of earth with which Adrian had filled the ravine, and covered the Holy Sepulchre and the Hill of Golgotha.

The description of Constantine's basilica which is given in Eusebius is extremely minute, but it has been justly observed that nothing is more difficult than to restore even the simplest building from mere verbal reports which have not endeavored to make such a restoration.

The general idea of this building appears, however, to have been that of a semicircular court surrounding the sepulchre; to the east of this a basilica surrounded by pillars, and an atrium or entrance-hall to the east of the basilica.

That the basilica formed part of the same building as the semicircular church round the tomb, is evident from the text itself; and even if it were questionable, the passages cited by M. Vogüé from Saint Cyrel, the Bordeaux pilgrim, and Antoninus of Piacenza, especially that in which the last-mentioned speaks of the basilica as being built over the Holy Sepulchre and Mount Calvary, would leave no doubt on the matter.

The appearance of the sepulchre, after it had been adorned by Constantine, was extremely magnificent, marble, gold, silver, and precious stones being lavished upon it; while the whole hill was cut away on all sides, so as to leave the rock in which the tomb was excavated standing in the midst of a level court.

Rond this monument was the hemicycle or semicircular court, which was adorned with twelve pillars, according to the number of the twelve apostles; and this is the first portion of the building which M. Vogüé shows to be still existing in the present church.

The rotunda of the edifice now standing contains three small apses, one to the north, one to the south, and one to the west. Now if these three had been originally built for a circular church, their centres would have been on radii of the circle, and the distance between them would either have been equal, dividing the circle into three, or a fourth apse would have been added to the west; but, on the contrary, the circumference of those to the north and south is on the diameter of the rotunda, thus making the eastern walls of these apses flush with the

\* The Manchester Art Treasures Exhibition opened on the 1st of May.

\* Milton.

centre of the rotunda, making it evident that they were built for a semicircular edifice. Thus M. Vogüé identifies the hemicycle with the rotunda of the present church, and in this theory he is borne out by the remains of Roman masonry found on the west wall of the rotunda which surrounds the present traditional tomb, as the semicircle surrounded the tomb in the time of Constantine.

On the east side of this court was the basilica, and to the east of that the atrium; if, therefore, the limits of this entrance-hall could be fixed by the discovery of the position of the principal entrance, the extent of Constantine's edifice would be satisfactorily determined; and if the bounds of the basilica could be determined, it would be easy to restore the whole building, dividing it into church, atrium, and basilica.

Now, in the ancient street of St. Stephen, to the east of the Church of the Holy Sepulchre, Dr. Schultze has discovered the remains of an ancient gateway. These relics consist of a mass of masonry, resembling the corner of a wall, with a pilaster projecting from it, and of the remains of four pillars of grey Egyptian marble, having an intercolumniation of 2 metres, and a diameter of about 60 centimetres. These M. Vogüé considers, with great reason, to be the remains of the colonnade of the principal entrance of the atrium.

The width of the whole building is given by the diameter of the rotunda, and the length from east to west is confined between the principal door and the west wall of the rotunda; the only thing, therefore, required to perfect the plan was the discovery of the limits of the atrium and basilica.

Now, about half-way between the first remains and the sepulchre itself were found part of an ancient pier and arch, covered with rich mouldings. They appear to have formed the north-west angle of a quadrangular portico, a pilaster of beautiful work being attached to the south and east faces of the pier, and two others of much plainer appearance facing to the west and north, while four arches spring above, two being ornamented with rich mouldings, and spanning the space between this pier and the two next, on the west and north sides of the portico, and two others of less ornamental appearance connecting the pier with the wall. From its architectural style, M. Vogüé attributes this fragment to the time of Constantine, and from its position it would naturally form the north-west angle of the atrium, thus facilitating the restoration of that building, and determining the limits of the basilica; while from the span of the arches the distance between the piers may readily be found, and they can be all restored with some degree of certainty.

The description of the basilica itself is somewhat confused; but the general idea seems to be that of a five-aisled building, supporting a second order of pillars and a second story of galleries.

The proportions of this part of the edifice M. Vogüé has restored from the Basilica of Bethlehem, giving the same proportional width for the five walks, and the same intercolumniation for the pillars, of which the two inner rows were round, and the two outer were square pilasters.

Thus has M. Vogüé restored from a fragment of the chief entrance, from one pier of the atrium, and from the wall of the semicircle, the whole plan of the basilica of Constantine, in a manner which fits perfectly with the confirmation of the ground, with the description of Eusebius, and with all that we know of the architecture of the time of Constantine. The general plan of the building is similar to that of Bethlehem, of which every pillar in the five-aisled basilica still remains, together with the greater part of the atrium, and the semicircle at the end of the basilica, which contains three apses similar to those of the church of the Holy Sepulchre.

This resemblance seems to give further proof of the correctness of M. Vogüé's restoration, and from the similarity of some parts of the buildings, those parts which are totally destroyed in the basilica of Jerusalem may be safely inferred to have been similar to the corresponding structures in the basilica of Bethlehem, especially since the description of Eusebius would apply equally to either edifice; on the other hand the slight differences which are found will be but natural when we consider the different conformation of the ground, the superior magnificence of one building, and the different sites round which they were erected.

Thus, although the height of the basilica and all the measurements of an elevation, can only

be approximately ascertained, yet still enough remains of the building to perfect the plan which is of much greater importance.

On arriving at the basilica from the broad agora, or market square of the city, round the principal gate, the pilgrim entered through a noble colonnade into an atrium, which was filled by the multitude, and thence into the basilica, or covered walk corresponding to the cloisters of the ancient temple; thence he passed into the court of the Sepulchre, in the midst of which rose a marble monument, in the form of a small chapel, adorned with pillars and shewing with gold.

The size and proportions of the whole edifice were very great, and even approached to those of the temple of Herod; and we may well judge from the remains of fresco and arabesque, from the graceful forms and rich mouldings of the building of Bethlehem, what must have been the splendour of this still more beautiful structure, which was the first Christian church ever erected in Jerusalem.

The Empress Helena first visited Jerusalem in the year of our Lord 326, and the basilica was commenced in the same year, and was completed and dedicated nine years after. It stood in all its glory for nearly 280 years, until it was at last completely destroyed by the Persian monarch Chosroës II., who laid siege to Jerusalem, and took it in the year 614.

The wife of the conqueror was the sister of Maurice, emperor of Constantinople, and she still professed the Christian religion amongst the Pagan Persians: although powerless to save the noble edifices of Constantine, she yet obtained leave for the Christians under Modestus, the superior of the Convent of Theodosia, to rebuild the church; and accordingly, in the space of fifteen years, four small churches were erected on the same site, which were again replaced by the buildings of Constantine Monomachus, and these latter were rebuilt by the Crusaders in the form of a single church, the greater part of which is to be found but little modified in the present building.

Such is the history of the Church of the Holy Sepulchre from the time of Constantine down to the present day.

LUNATIC ASYLUMS.

WHETHER or not there has been during the last twenty or thirty years an advance in architecture, certainly the period has been marked by activity in the erection of buildings of several classes, calling for considerable skill in their planning, and special attention by architects to requirements as they are set forth by those whose duties enable them to judge of details to be attended to. It would be interesting to have from time to time, a tabular statement of the works in each of the classes referred to, including churches, with the amounts of cost, total for each building, and per head of the accommodation. The statistics however are not very easily procurable. But we have occasionally collected from the reports of the Commissioners in Lunacy information of the building-progress in one of the classes; and the Nineteenth Report, just issued, affords means of recording what is the present provision for the insane, and what has been done most recently. As we have said in former years, every architect who has occasion to plan an asylum should be perfectly acquainted with the Commissioners' Reports: though we must say that, wanting plans of the buildings which are spoken of, and some items interesting to us, they are not so directly serviceable as they should be.

The places for the treatment of the insane in England and Wales, exclusive of lunatic-wards in workhouses, are classed as County and Borough Asylums, Hospitals, Metropolitan Licensed Houses, Provincial Licensed Houses; and Naval, Military, and State Criminal Asylums. The total number of Lunatics on the 1st of January last, in these, was 29,425, as against the number in the previous year, 28,385, which did not include patients in Fort Pitt, and the State Criminal Asylum. Only 3,534 of the 29,425 were deemed curable. Of the same number, 23,764 were paupers. There were 22,284 of all the lunatics, in the county and borough asylums. The county asylums were, on the 1st of January last, as we count them in the list, 40 in number. One asylum, serves for the three counties, Bedfordshire, Hertfordshire, and Huntingdonshire; one for Cambridgeshire and the Isle of Ely; one for Cumberland and Westmoreland; one for the

counties of Denbigh, Anglesea, Caernarvon, Flint, and Merioneth; one for Leicester and Rutland; one for Monmouth, Hereford, Brecon, and Radnor; one for Oxford and Berks; and one for Shropshire and Montgomeryshire. There are three asylums for the county of Lancaster, two for Staffordshire, and two for Middlesex. There is one asylum for the North and East Ridings of Yorkshire, and one for the West Riding. Only a small number, five, of the boroughs, are yet provided with asylums; and, of these, Norwich has made only a provisional arrangement, so sanctioned by the Commissioners.

The return does not give the number of patients for which each asylum was planned, or the cost of the building. All such omissions should be rectified in subsequent reports, correction being made, each year, where there has been any enlargement. The average number of patients resident in each asylum during the year, however, is given; and where not exceeding the accommodation for which the building was planned, we believe it may be taken as approaching, with few exceptions, very nearly the intended capacity. The largest number of patients were those in the Colney Hatch Asylum, where there were 1,945. In the Hanwell Asylum there were 1,603. In the asylum for the West Riding of York, at Wakefield, there were 1,075 patients; in the Surrey Asylum, near Tooting, there were 913; and in one of the asylums for the county of Lancaster, that at Prestwich, there were 911. In each of these cases the number must be considered in excess of what is desirable, following the recommendations of the Commissioners. Actually, proper supervision and treatment by the superintendents and medical officers is impossible; and the staff of attendants is far below requirements. In all the asylums, classification of the patients would seem to be very inadequately provided for; and the Commissioners should revise their suggestions and instructions, so that any omission in the plans of the recently erected asylums may not be repeated. The classification observed hitherto has been made correspondent with the different forms or manifestations of the disorder; and little attention seems to have been paid to the fact of original difference in the habits and social state of those affected, and who have only become equally paupers by the affliction itself. To place one who has been always cleanly in his habits, and courteous in his demeanour, in the same ward with those who are just the reverse, and without enough supervision to prevent violence or threats on the part of the unruly, must be calculated to aggravate the malady. So little had the point that we refer to been considered, that at the Surrey Asylum, which has been characterized by many defects of management, it was not long ago the practice to bathe four or five patients in the same water. Few of our readers would be surprised to hear, in one case with which we were acquainted, that this dirty practice was felt as the worst part of the affliction from being deprived of liberty. The supply of water for some of the asylums is lamentably deficient. The Commissioners now require that not more than two patients be bathed in the same water.

The smallest number of patients in a county asylum, in 1864, was in the case of the building for the counties of Cumberland and Westmoreland, near Carlisle, where there were only 225 patients. About 500 is not an uncommon number. There was just that number in the asylum for Beds, Herts, and Hunts, at Arlesley, Baldock; there were 410 in the asylum at Sedgfield for the county of Durham; there were 600 in the asylum at Gloucester; but there are several asylums with less than 300 patients, as those of Bucks, at Stone, near Aylesbury, 286; and Cambridge and the Isle of Ely, at Fulbourn, 288; and several, besides that at Gloucester, with more than 500; as the Devon Asylum, at Exminster, 674; Kent, at Barming Heath, near Maidstone, 686; and Lancaster, at Lancaster Moor, 736, and Rainhill, 864. Of the five borough asylums, the largest is that of Birmingham, where there were 534 patients. There were 202 at Bristol, 116 at Hull, and only 28 at Haverfordwest.

Next to the class of buildings called asylums, comes that of the "hospitals." There are only two of them that receive pauper patients, namely the Northampton Lunatic General Hospital, and the York Lunatic Hospital. There are in all, only fifteen of the hospitals, including the Asylum for Idiots, Earlswood, near Reigate. The fifteen institutions are the Northampton

Hospital, with 418 patients of all kinds; the Earlewood Institution, with 370 idiots; Bethlehem Hospital, with 263 patients, an unusually large number of whom, or about 195, were lately deemed curable; the York Lunatic Hospital, 176 patients; St. Luke's Hospital, in Old-street, 163; the York Retreat, 124; the Charitable Institution for the Insane, Cotton Hill, near Stafford, 123; the Manchester Royal Lunatic Hospital, Cheadle, 95; Bethel Hospital, Norwich, 76; Lincoln Lunatic Hospital, 67; St. Thomas's Hospital, near Exeter, 58; and Warneford Lunatic Asylum, Headington Hill, near Oxford; Nottingham Lunatic Hospital; Liverpool Lunatic Hospital; and Barrowwood House, near Gloucester, with somewhat smaller numbers. Institutions of this class, in which patients might be received at a small charge, are much wanted. The remaining hospitals or asylums, not private, are the Royal Naval Hospital, Yarmouth, average number of patients in 1864, 156; Fort Pitt, Chatham, 29; and the State Criminal Asylum, Broadmoor, near Wokingham, 209. Haslar Hospital is not now in use. The Commissioners found in 1864, 7,207 insane, idiotic, and imbecile inmates of workhouses in the 320 places of this class which they visited; and it appears that in North Wales, half the insane papers are disposed of as single patients. Much has to be done before the wants of the insane can be considered to have been cared for as charity demands.

As regards the workhouses, some provision in them for insane persons, was in their last report but one, contemplated by the Commissioners. Recent Acts allow the visitors of any asylum to make arrangements for removal of a limited number of chronic lunatics from the asylum to a workhouse, with the approval of the Commissioners, and of the President of the Poor Law Board. The object was to meet the deficiency of accommodation in asylums, making room for recent and probably curable cases. Before giving their approval, the Commissioners insist that there shall be in the workhouses, separate wards, properly constructed, arranged, and furnished for the patients of the respective sexes; that the dormitories be distinct from the day-rooms; and that the former afford 500 cubical feet space per patient, and the latter 400 feet; also that single bed-rooms contain at least 600 ft. The general defects of workhouses, in the buildings and management, however are such, that it appears those removed to them will be, by no means benefited. The airing-courts especially are inadequate. So that, after having expressed the opinion in their Eighteenth Report, the Commissioners were obliged to add that every year's experience confirmed them in the opinion that where lunatics in workhouses required wards apart from the rest of the inmates, the result was disadvantageous. Amongst matters to which they had to object strongly, was the use of flagged or cement floors to day-rooms.

During the past two years, many of the county asylums have received additions; and some new buildings have been completed. Amongst the latter is the Dorset asylum, near Dorchester. The old building has been preserved, that pauper lunatics from other counties, and non-pauper lunatics generally, may be provided for in it. A new asylum for Glamorganshire, at Bridgend, was opened in November last. In accordance with the recently approved system of distribution, it has detached buildings for the accommodation of working and "convalescing" patients,—these buildings being in connexion respectively with the workshops and the laundry. They are described as well adapted for their purpose, or as being provided with excellent kitchens, sculleries, bath-rooms, and lavatories, all the in-door arrangements being as far as possible of a domestic kind; and each having ample space available for out-door recreation and exercise. The report says:—"The men's block is placed near the entrance, in proximity with the lodge and the chapel; and the diversified effect of these and other buildings, which, without intercepting the beauty of the view beyond, form a kind of honorary to the patients' airing-courts, is extremely pleasing." As regards the airing-courts, "than which there can be no provision more important for the successful treatment of the insane," those in the Glamorganshire Asylum are spoken of as promising "to be as nearly perfect as they can be made." Besides the men's court, more than an acre in extent, and besides a good garden with drying-ground at the laundry-block, there are two large and two smaller courts attached to the main building, laid out and

planted. None of them intercept the view of the country, a sunk wall and a light iron fence being used. Some "oddities of construction" are spoken of as in the main building; but it is observed that there is nothing incompatible with comfort. The dormitories will be ventilated partly by gas-burners, to be kept burning at night. Numerous closets, well constructed and fitted, and opening to the air; baths, three or four in one room, with dressing-room adjacent, and a ready supply of hot and cold water; a bath-room judiciously placed adjoining the dormitory in certain divisions; and the sick-rooms arranged to secure as much cheerfulness as possible, are specified as deserving much praise. All the offices are described as good, and the ventilation throughout the building as having been the subject of great care; and almost the only suggestions made, relate to easy access for the sick and infirm women to their airing-courts, if it be practicable, and to the papering the upper portion of the walls throughout the asylum, and the painting the lower portion in cheerful and pleasing colours. The building, as it was originally, had defects; these have been remedied, and some of the errors have been turned to advantage by the architect, Mr. Martin, who is mentioned as having been called in.

During the past year an idea was entertained of enlarging the asylum at Littlemore, of the counties of Oxford and Berks; but this has been given up; and a new asylum will be erected in Berkshire, whether for the united counties, or for Berkshire alone, is not settled. The Commissioners would prefer the latter arrangement. The building would be for 220 patients.

An additional asylum for the county of Stafford, at Burnwood, near Lichfield, was opened during the year. The site has a gradual slope to the south; and pleasing views are obtained from it. The estate consists of more than 9½ acres, and was purchased for 6,963*l.*; but only 18 acres, certainly, of this can be used till 1872. The Commissioners remark that the building has not been placed as indicated on the plans submitted to them. The women's wards were only about being commenced in April last. The men's wards, constructed to accommodate 240 patients, are considered as well arranged; but it is regretted that the lower bath-rooms have been floored with tiles, and that the mantel-pieces will not admit of shelves upon them. The workshops, washhouse, and laundry are described as too small for an asylum containing 500 patients; and the oven had already proved so. The necessity for making all these departments of ample size was urged by the Board originally. The arrangement of some of the passages with the corridor, and doors connected with it; the size and arrangement of the steward's store-rooms; the disposition of doors of communication, or absence of such doors, in the case of attendants' rooms and associated bed-rooms; and the want, in all the staircases, of hand-rails, are condemned; whilst the importance of porches to the doors of day-rooms opening directly into airing-courts; and the defective position of the "foul linen washhouse" and of the dead-house, are mentioned; but it is admitted that the defects admit of easy remedy; and generally the Commissioners have to report very favourably of the construction of the asylum, and disposition of its plan.

We do not find in the last report, any detailed description of the Prestwich Asylum, one of those of the county of Lancaster, to which additional accommodation for 280 patients of each sex has been provided, making the asylum now capable of receiving 1,000 patients; but in the previous report praise was given to what was then nearly completed; and the cost, including that of alterations in the old building, was stated as having amounted to "only 41*l.* per head."

In the way of enlargement of asylums, much, as we have said, has been done of late. In the Bucks Asylum, at Stone, near Aylesbury, new wards for fifty female patients were to be completed early this summer, at a cost of 2,850*l.* Wards are about being erected at the Cambridgeshire Asylum, Fulbourn, costing 1,200*l.* Two lock buildings, to contain each 105 patients, are to be added to the Cumberland and Westmorland Asylum, near Carlisle, which are estimated at 8,900*l.* The Recreation Hall at the Chester Asylum has been enlarged at a cost of 750*l.* For the Cornwall Asylum, Bodmin, a plan has been approved for a building to accommodate fifty-two private patients at a cost of 4,860*l.* At the Durham Asylum, Sedgfield, two additional cottages for attendants have been

built, with rooms between them for ten convalescent patients. At the Hants Asylum, Knole, near Farnham, a range of store-rooms has cost 1,000*l.* A new water-tower at the Kent Asylum, near Maidstone, is estimated to have cost 1,000*l.*; and, at the same place, the chapel has been enlarged at a cost of 600*l.*; and a new residence for the medical superintendent is to be built. In Middlesex a new detached Fever Infirmary has been erected at Colney Hatch, costing 1,539*l.* The visitors of the Joint Counties Asylum at Abergavenny, have been considering enlargement at a cost (including outfit and furniture) of 18,000*l.*, for 120 female, and 100 male patients. The asylum for Salop and Montgomery will be enlarged to provide for, we believe, 76 additional patients at a cost of 2,400*l.* A new day-room, dormitory and nurse's room have been constructed at the Warwick County Asylum, on the female side, at a cost of 420*l.*

Under the head of borough asylums, the chief new building that would call for notice, is the Asylum for the City of London, at Dartford. It is however not open; though the building has been given up some time by the contractor, and the medical superintendent has taken up his residence. The chief fittings had not been procured when the building was visited in October last; and the furniture had not been decided upon. But it was expected that the building would be opened this July. A site for an asylum for Newcastle-upon-Tyne has been purchased; and a new dormitory and day-room have been added to the Birmingham Asylum.

The State Criminal Asylum at Broadmoor, near Wokingham, was opened in 1863, but at first only to receive a portion of the inmates, the work having been found imperfect, and the materials of an inferior character. During the past year, a portion of the male division has been brought into use. The accommodation for 100 female patients is already found insufficient. Additional single rooms; double-panelled and heavily-harred doors; and small circular windows substituted for those of the former construction, have been introduced quite recently. Some of the detached blocks are not yet ready for reception of patients. The airing-courts are described as very defective.

At the Royal Naval Lunatic Hospital, Yarmouth, considerable improvement has been effected by the purchase of land between the building and the sea; and walls which confined the view have been lowered or removed. The provision for the insane from the navy has no counterpart in the provision for the insane of the army.

The Commissioners are directing their attention to the case of idiots. Besides the institution at Earlswood, and one at Essex Hall, Colchester, they refer to two asylums as recently founded, namely, the "Western Counties Idiot Asylum," at Starcross, near Exeter; and the "Northern Counties Asylum for Idiots" at Lancaster. The condition of idiots has been too much neglected. Much however has yet to be done for the more aggravated forms of insanity; and architects will do well to be informed of the progress of the question; many asylums are yet required; and improvements will be needed in those already built.

#### THE OLD TOWN OF EDINBURGH.\*

LIKE to the architect, the ecclesiologist, and the student of history, the beautiful and picturesque ruins of the Chapel Royal of Holyrood must ever prove an object of extreme interest. Founded by the sainted King David in the same year as the Abbey of Kelso, it has seen so many varied vicissitudes, has been so often the object of the spoiler's and incendiary's hostile wrath and blinded fanaticism, so often repaired and added to—the latter work being, in many instances, so ingeniously engrained on the older as to render it hardly possible to define the amount of change, that, as it now stands, the Chapel Royal is, in the language of Mr. Daniel Wilson, "a complete ecclesiastical enigma." The legend of the miracle to which it owes its foundation; the number of royal marriages which have been celebrated within its holy walls—the last being that of the unhappy Mary Stuart to the Hly-fivered hoy Darnley;—the coronation of Charles I. therein,—"the most glorious and magnificent coronation that was ever seen in this kingdom, and the first King

\* See p. 460, ante.

of Great Britain that ever was crowned in Scotland," says the contemporary Lord Lyon,—its connexion with the Most Ancient Order of the Thistle;—all invest it with an ndying interest. It has proved, too, the resting-place of many royal and distinguished persons. Prior to 1776, when it was sacrilegiously plundered, the Royal vault contained the bodies of David II, James II., James V., Queen Magdalene, and Darnley; and in 1848, what were supposed to be the remains of James II.'s widow, Mary of Gueldres, were removed thither from the Collegiate Church of the Holy Trinity. The aisles of the chapel are paved with mortary tomb-stones, beneath which are interred many haughty nobles and scarcely less haughty ecclesiastics. In truth—

"You never tread upon them, but you set Your foot upon some reverend history."

It is not our intention at present to trace the history of the chapel, deeply interesting as it is; but we cannot refrain from giving our readers an epitome of the alleged miraculous foundation of the abbey to which it was attached. In the story given by Abbot Bellenden, in his translation of Boece, printed in the *Liber Sancte Crucis*, we are told "how Kyng David past to the hunters on the Croce Day in harvest, how he was dung fra his hors be ane wyld hart, and how he fumd the abbay of Halyrudus be myracle of the Holy Croce." This "Kyng David" was the first of the name, and the monarch to whom Scotland is indebted for many of her finest ecclesiastical edifices. In the year 1128, the fourth of his reign, he was on a visit at the Castrum Puellarum, or Castle of the Maidens, as the fortress of Edinburgh was then termed. On Rood or Croce Day, on which the exaltation of the cross was celebrated with great solemnity, after divine service, some of his nobility requested the king to accompany them on a hunting party to the neighbouring forest of Drumsheugh, through which then roamed the wolf, the deer, the elk, and the wild white cattle. His confessor, Alwin, endeavoured, but in vain, to dissuade him from joining the hunting party, and the cavalcade, with the king at its head, proceeded to the Forest of Drumsheugh, which then covered the Queen's Park, and the ground to the south of the Old Town of Edinburgh. In the excitement of the chase he soon found himself separated from the others, and near the northern slope of Salisbury Crags, he was furiously attacked by a large and powerful stag, which in the graphic language of Abbot Bellenden, "dung him fra his hors." He received a severe wound in his thigh, and the infuriated stag was continuing its attack, when a crucifix, made of the cross on which our Saviour was crucified, and which he wore suspended to his neck, miraculously slipped into his hands. The now affrighted animal "fled away with great violence," vanishing into thin air or disappearing through the earth at the spot, "where now springs the rde well." When his attendants came up and learned his providential escape, they fell on their knees, and devoutly worshipped the Holy Cross. In the course of the following night the king had a vision from heaven, in which he was told to found an abbey for the Canons Regular of the Order of St. Augustine, near the spot of his miraculous preservation. His father confessor, Alwin, was consulted on the following morning, and strongly urged the king to obey what he said was clearly a divine command. Is the reader surprised to learn that this ghostly adviser was himself an Augustine canon? We fancy not. Priests in all ages have had a shrewd eye to business, and the advancement of their own order. The priestly advice prevailed, and the king immediately sent to France and Flanders, for "richt crafty masons," and the building of the abbey and chapel was commenced forthwith. They were dedicated to the honour of the Holy Cross, and of the Virgin Mary and all Saints; and the canons adopted as the arms of the abbey, a stag's head, with a crucifix betwixt the antlers.\*

The chapel was originally in the form of a process, consisting, as the *Liber Sancte Crucis* informs us, of a lady chapel, choir, transepts,

and nave. With the exception of some slight traces of the north transept nothing now remains to tell of its former glory except the great north-west tower and the ruined and roofless nave, where, we are told, "*Populus clero scmolus divina mysteria per clathros suspiciebat.*"

The holy rood itself was deposited with great solemnity in the chapel. This precious relic, of which, says Abbot Bellenden, "Na man can schan of quhat mater it is, metal or tree," remained in the chapel until King David Bruce took it with him on his ill-fated invasion of England in 1346, which terminated in his complete defeat and imprisonment. The holy rood was captured by the victorious English, and enshrined on the high altar of Durham Cathedral, partly, we suppose, as a sacred relic, partly as a warlike trophy. Of its subsequent history we are in ignorance.

The principal entrance to the chapel, reserved in former days for ecclesiastics, is by the great western doorway, which is in the very best style of late First-pointed architecture, and is in good preservation. The archivol, which is rich with flowered and dog-tooth mouldings, is lofty and deeply recessed, and is supported by clustered jambs with beautifully-carved capitals. The tympanum is supported by a square-cut oak beam, which, as Charles II.'s cypher is carved upon it, was probably inserted in the course of the repairs of the chapel by that monarch in 1633; and above this runs a row of angels' heads, in stone, very spiritedly carved. The tympanum is occupied by a blank arcade of highly-ornamented pillars and pointed arches.

Above the archway, but a little off the mesial line, are two very curious windows, with flat segmental arches, richly cusped, on a level with the wall, which have a good deal in common with the Perpendicular style. The lowest third of these two windows is occupied by an open arcade of circular arches, while within two slender shafts divide either window into three lights. The wall in which these windows are placed is a mixture of the Saxon and Norman styles; and in the central column between them there is a stone tablet with this inscription,—"*He shall build an house for my name, and I will establish the throne of his kingdom for ever. Basilicam hanc semi rutam, Carolus Rex Optimus restauravit Anno Domini MD. CXXIII.*" What a striking comment upon the first part of this inscription does not the history of this unhappy monarch and his descendants supply! On either side of the upper portion of the arch of the door is a semicircular arched niche, now empty.

On the north side, a wall, which is Norman in its character, connects the western doorway with a massive square tower. Originally a like tower stood at the south-west corner of the chapel, but it was either destroyed when the abbey was demolished by the Earl of Hereford, in 1543, or taken down to make room for the palace buildings, in 1674. The north-west tower, which is 53 ft. in height, but originally was much higher, belongs to the transition period, prior to the complete development of the First Pointed style. It is ornamented with ranges, one above another, of small columns and pointed arches. These ranges and the hold trigonal string-courses which separate them are continued along the face of the wall which intervenes between the tower and the archway. In the spandrels of the arches are medallions containing human heads, very boldly and artistically carved.

Let the reader now accompany us through the open archway into the interior of the chapel.

"The sacred tapers' lights are gone,  
Grey moss has clad the altar-stone,  
The holy image is overthrown,  
The bell has ceased to toll,  
The long-rib'd aisles are burst and sunk,  
The holy shrines to ruin sunk,  
Departed is the pious monk,  
God's blessing on his soul."

Yet ruined and roofless as it is, the Chapel Royal well merits our attention.

Looking east, the view is particularly striking and impressive. The colonnade of the north aisle has all but disappeared, but that of the south is in tolerable preservation. It consists

of seven piers, each composed of eight slender columns arranged around a thick central pillar. The capitals of the columns are all of different designs, and of great beauty, the human face figuring prominently in many of them. The central half-rounds facing the body of the nave are carried up the face of the triforium and clerestory. These massive piers are connected by pointed arches, immediately above which runs a bold string-course. The bases of the piers, which are high, very fully spread, and ornamented with a great variety of mouldings, are very beautiful. The triforium is composed of a series of pointed arches, twice the number of the range beneath, and each containing two smaller arches. It forms a gallery running the entire length of the chapel. There are also visible the remains of a third arcade or gallery, the clerestory, which was open to the interior, and contained windows externally. The whole of the central aisle is in the very best style of late First Pointed.

The capitals of the pillars on the wall of the south aisle are especially worthy of attention, presenting some very striking bas-reliefs. All the mouldings are cut with great boldness, fine deep shadows being formed by the hollows. The windows are lancet-shaped, and flanked by elegant cylindrical pillars. Beneath them runs a range of beautiful columns and pointed arches. The roof of this aisle is groined and adorned with carved bosses. Conspicuous in this part of the building by their repulsive ugliness, are the Royal vault and the burial-place of the earls of Roxburgh. Prior to 1776, the former contained the remains of James V., Queen Magdalene, whose head is described as being entire, and even beautiful, at that time, and of Darnley. These, however, were shortly afterwards stolen, though for what object does not appear very clearly.\* In 1818, when the beautiful Collegiate Church of the Holy Trinity was being taken down to make room for the North British Railway, the skeleton of a female was found in the Lady Chapel, supposed to be that of the fondress, Mary of Gueldres, the widowed Queen of James II. Upon that supposition, it was transferred to the Royal vault, where it still lies. In the course, however, of removing the Trinity Church, the skeleton of another female, inclosed in a lead coffin, was found in the eastern apse. This last-discovered skeleton many antiquarians (among others, Mr. Laing, the accomplished treasurer of the Society of Antiquaries of Scotland,) are, for several reasons, disposed to think is that of the Royal fondress. It was deposited outside of, but near the Royal vault.

A private passage from the south aisle communicates,—or rather did so before it was blocked up,—by a small door through a hanging of massive and now mouldering tapestry, with Queen Mary's chamber, through which Riccio's murderers passed to the little cabinet, "where he, the Lord Ruthven," we are quoting the words of his own confession, "found the Queen's Majesty sitting at her supper at the middle of a little table, the Lady Argyle sitting at one end, and David at the head of the table with his cap on his head; the King speaking with the Queen's Majesty, and his arm about her waste." (See.) Near the doorway of this passage there is a sepulchral stone, which is supposed to mark the spot where the unfortunate Italian was buried. It bears traces of a shield much defaced. It forms a portion of the flooring of the ancient abbey cloisters.

Both aisles are paved with incised or sculptured tombstones, many of them belonging to ecclesiastical dignitaries. The floriated or Calvary cross is engraved upon most of those, and they generally have the chalice and paten on each side. Monumental brasses there are none.

There is a cloister door-way in the west end of the south aisle, now closed up by the palace buildings, which presents undoubted remains of the original foundation of King David. The arch is semicircular, and is ornamented with characteristic zig-zagor chevron and dice-pattern mouldings. It is supported by two Norman columns. It is against this doorway that the royal vault is built.

\* The arms of the canons may be seen on the very interesting old market-cross, called St. John's Cross, which now rests against the wall of the Canonage Tolbooth, but which originally stood in the middle of the street. In those days it was mounted on an octagonal stone gallery, which has long since disappeared. From the middle of a circular stone, which forms the uppermost of a flight of three steps, rises an elegant hexagonal shaft, on the upper part of which is a battlemented capital, surmounted by a cross crosslet with a heraldic shield, bearing the Holy-wood arms. The staple of the joists (that curious instrument of ecclesiastical discipline) still remains; and there

was also a contrivance of some sort for fixing the legs. Old people, still living, Mr. James Drummond, F.S.A., tells us, recollect of a woman being put in the jongs here for stealing yarn, a hank or hamp of it being coiled round her neck during the pilory.

A somewhat similar legend is attached to the foundation of the exquisitely beautiful chapel of St. Hubert, in the grounds of the children of Ambrose, in Touraine. The saint, who had hitherto been a sceptic, was converted to Christianity by the miraculous appearance one day, when he was hunting, of a stag bearing a crucifix betwixt its tines. The arms of the two chapels are identical.

\* In Sir Walter Scott's "Border Antiquities," there is this passage regarding this despoliation,—"*They* (the populace) "*sold the lead of which the collars were made, and left the bodies an awfully spectacle and a degrading memorial of popular fury.*" The mansions of the mighty dead seem in all ages to have been liable to such despoliation. From curiosity, or to glean materials for history, the ancient sepulchres of the Egyptian kings were ransacked, and but one of the tombs of the Cæsars remains undescended. After the Restoration, Cromwell's bones were exhumed and hung upon a gibbet.

Of the piers of the north aisle, which were borne down by the falling in of the roof in 1768, only two broken shafts remain; but they are sufficient to prove that they belonged to the same style of architecture as those of the south. The north wall, which belongs to the transition period, is ornamented by blank ranges of interlacing semicircular arches. They are supported by columns, the shafts of which are extremely elegant, and the capitals beautifully sculptured.

Between the remains of the two piers of this aisle is a mortuary slab to the memory of the "Nobil and potent Lord James Douglas, Earl of Carlell and Thorthorwald, who married Dame Elizabeth Carlell, heir and heritrix thairof, who was slain in Edinburgh the xiiii day of July in the year of God 1608, in his 43 year."

The finest feature in the interior of the chapel is undoubtedly the window, which occupies the great centre arch of the transept, and is a restoration on a reduced scale of the great eastern window. It dates from Charles I.'s repair of the chapel in 1633. It has five light-looking mullions divided by a transom. The feathered geometrical tracery in the upper portion, which is in the form of quatrefoil openings, is extremely airy and elegant. The capitals of the arch are richly sculptured, and the spandrels contain some exquisitely carved heads. This window was blown down during a violent storm in 1795, but has been very judiciously restored. In front of it was placed the high altar. The side arches, by which the aisles of the nave communicated with the transept, are now occupied by two pointed windows, of two lights each. Beneath them is ranged some Gothic screen-work, which formerly disfigured the nave.

Before quitting the interior of the chapel, the visitor will do well to ascend to the rood-loft, access to which is obtained by a door a little to the north of the great west entrance, and from which a beautiful view is obtained of the whole building. The rood-loft was formerly occupied by the great organ.

Another door to the north of this gives admission to the square tower already noticed. The precise use of this tower is not known, but in all probability it was the belfry. It contains a monument, of considerable architectural attractions, to Robert Douglas, Lord Viscount Belhaven, who died in 1699. Upon a pedestal, 5 ft. high, and underneath a pediment supported by fluted columns, a full-length statue of the viscount lies in a recumbent position, the right arm resting on a cushion, the head raised, and the left hand grasping the pommel of a sword. He is arrayed in robes of state, and wears a viscount's coronet. In the open pediment there is a shield chequered with armorial bearings. The monument is of fine Parian marble.

Passing out of the nave by the north, or Abbot Crawford's door, we have an opportunity of examining the exterior of it, and of the north wall. This entrance, which was the one made use of by all persons other than ecclesiastics, and the seven richly ornamented buttresses, which support the now fast decaying wall, were reconstructions of Abbot Crawford, who succeeded to the abbey in 1457, and are favourable specimens of First Pointed architecture. The arch of the door, which springs from clustered jambs, is semicircular, and ornamented with richly flowered mouldings. It is surmounted by a crocketed triangular canopy, containing the abbot's arms, and terminating in a finial. The junction of the arch and the pediment forms an ogee curve. On either side of the door are two flat pillars, with highly decorated pinnacles, and at the upper portion of the arch are four beautifully canopied niches, two at either side, which it is almost superfluous to say are now empty. The buttresses, on some of which the abbot's arms are empanelled, are ornamented with canopied niches and pinnacles.

Passing round by the end of the Chapel Royal one approaches the south wall, which, like the others, presents a variety of styles of architecture. The east door of the cloister in this wall, the window immediately above it, and the pillars at the sides of the arches of the other windows are Norman in their character. The flying buttresses, which are especially worthy of attention, and those overarching the cloister, are crocketed and pinnacled, and in the late First Pointed style.

Before quitting these interesting ruins, one cannot help wishing for a space to admire the elaborately carved sun-dial, in the north garden of the palace, which is generally called Queen Mary's dial, as well as the magnificent cast-iron railing on the north-west and south-west of the palace. For elegance the latter is unsurpassed

by any similar construction in the kingdom, unless, indeed, it be by the celebrated railing in the Phoenix Park, Dublin. The dial is undoubtedly of much later date than Queen Mary's time. This is proved by the cypher of her grandson and those of his queen and the Prince of Wales occurring on its most prominent carvings.

And now, perhaps, our readers expect a description of Holyrood Palace; if so, they will be disappointed. The place, with all its associations, possesses but little architectural interest, and there is so much of quackery about its lions—the fabulous blood-stains of David Riccio, the Puritan trooper's corselet falsely assigned to Darnley, and the mythical portraits of the Scottish kings, many of whom were myths themselves, or, at any rate, lived and died long before the invention of oil-painting,—that we have no stomach to act as *diceros*. True the palace is so interwoven with the eventful life of the hapless Mary Stuart, that it must claim an undying interest. Let him who would look far back into those other years turn to the eloquent pages of Mr. Fronde's latest published volume; or, if he be too zealous a partisan of Queen Mary to digest all the severe things said by that gentleman, he may peruse Miss Strickland's or Sheriff Bell's more eulogistic accounts.

There is, however, one interesting architectural feature deserving notice, inasmuch as, though common enough in Scotland, it is nowhere to be met with in England. In the original north-west tower of the palace and its modern copy, the south-west one, a lofty conical turret rises at each of the four corners from behind the rampart. The mounting of these lofty cones was borrowed from France.

The palace, which was built in 1674, is a servile copy of the Chateau of Chantilly, the residence of the noble family of Condé.

There only remains to be mentioned the beautiful church of the Holy Trinity, which still stands at the foot of Leith Wynd. It was taken down then to give more room for the terminus of the North British Railway Company, the stones being all carefully numbered, with a view to their re-edification on another site. The city received a large sum in compensation, but the magistrates refused to rebuild it, and at length, after a tedious litigation in the Scotch courts, the House of Lords decided that they were not under any obligation to do so. And so, *miserabile dictu*, the stones get leave to lie uselessly on the side of the Calton Hill. What we have thus lost, or are, at least, likely to lose, may be gathered from a sentence or two from Mr. Rickman's "Gothic Architecture." "The interior," he says, at page 283, "is a very beautiful decorated composition, with the capitals of the piers enriched with foliage, not exceeded in any English cathedral. . . . This building is all of good decorated character, and is deserving of minute examination and study."

This church, which was collegiate, was founded in 1462, by the queen dowager, Mary of Gueldres, for a provost, eight prebendaries, and two singing boys, and was dedicated to "the praise and honour of the Holy Trinity, of the ever-blessed and glorious Virgin Mary, of St. Niman the Confessor, and of all saints and elect of God." The foundation charter affords us some curious peeps into the state of the morals and education of the fifteenth century. Thus it provides that "no prebendary shall be instituted unless he can read and sing plainly, count and discount, and that the boys may be found docile in the premisses." But the most extraordinary provision is the following:—"And if any of the said prebendaries shall keep a concubine or fire-maker, and shall not dismiss her, after being thrice admonished thereto by the provost, his prebend shall be adjudged vacant, and conferred on another."

The plan comprised a choir with aisles and a polygonal apse, south porch and north chantry chapel, and north and south transepts. There was an octagonal belfry-turret on the west of the north transept, and two similar turrets on the east walls of the transepts. Of the two latter, three sides of the octagon projected exteriorly, and five of the former. At the intersection there was a square tower, which had only been partially built and finished with crow-steps and a sloping roof. The length of the choir was 53 ft., and that of the transepts, from wall to wall, 25 ft. 3 in.

The architecture was of the best Middle Pointed style.

The windows were the least meritorious features. Those of the transepts were large but meagre, of four lights each, the upper portion

being filled in with unfoliated loop tracery. In each of the three sides of the apse was a tall narrow lancet window, the head of the middle one being more acutely pointed and loftier than the other two. In the west walls of the transepts there were two eight-foiled circular windows, the cusps of one of which were floriated.

At the angle of the apse, and of the transepts, were buttresses divided into stages by offsets. They were ornamented with niches having sculptured canopies, and terminated in long square-shaped pinnacles, with crocketed finials. Those of the aisles were of heavier construction, to enable them to sustain the thrust of the flying buttresses of the clerestory.

The whole roof was originally "thelkit with stone," and plain parapets were carried continuously round the building. From beneath the parapet projected quaint fanciful gurgoyles, principally representing apes in different attitudes. The octagonal turrets had high pyramidal stone cappings and finials, and contained newel staircases, those on the east wall of the transepts giving access to the parapet.

The principal entrance was by an open porch, with a groined roof, underneath which a beautiful round-headed doorway, composed of continuous filleted quarter-rolls, gave access to the south aisle of the choir. The porch was formed by a circular segmental arch placed between two good buttresses.

The interior of the choir and apse was extremely imposing. The piers were square, set diamond-wise, with half-round and semi-hexagonal mouldings and floriated capitals, with extremely grotesque figures introduced among the foliage. The arches were obtusely-pointed, of three orders, and with hoods on the choir side. The clerestory-windows were large, and filled with tracery. The cornice was ornamented with a modification of the ball-flower occurring at intervals in the hollow. Between the clerestory windows and the pier arches a string-course, which was striped with a broad fillet, banded together the vaulting-shafts, which supported the lofty and beautifully-groined and bossed roof. The vaulted shafts rested on corbels, most of which were carved into grotesque faces; one, however, representing the figure of an angel, with expanded wings, holding a scroll in both hands. Their capitals, which had semi-octagonal or half-circle abaci, were of beautifully-designed foliage, with heads or faces embossed among the stalks, which issued from their mouths. The central longitudinal and the groin ribs were richly moulded, the square fillet being of constant occurrence, and were ornamented with beautiful and highly-sculptured bosses.

On the north and south walls of the apse crosses patee were incised within a circle. These were probably dedication crosses. In the south of the apse were the priests' door, and to the west of it a canopied niche, probably either a baptismal or a piscina.

The aisles were vaulted, with transverse and diagonal ribs springing from the capitals of the piers on the one side, and from curiously-sculptured corbels on the other. One of the latter represented a winged figure with a most sinister countenance. In the east wall of the north aisle there was a piscina in a niche surmounted by an octagonal canopy. In the middle of this aisle a semicircular doorway with roll and chamfered mouldings, and a hood over it, gave access to a mortuary chapel, in the north wall of which there was a beautiful Gothic fireplace, and a square niche to the east of it, which had a floriated corbel and sculptured canopy, and contained a polygonal piscina.

Of the transepts little need be said. The label terminations of the windows were carved into grotesque figures. From the capitals of two of the piers projected shields, the one containing the monograms of our Lord and the blessed Virgin, flanked by the letters I. O., and on the other were represented three millets and a cock between the letters I. B. That a nave had been contemplated was evident from the trusses for tying it, and the weatherings of the roof being visible on the west wall. The church contained a great variety of armorial bearings, in one instance the supporters being angels.

PROPOSED SANITARY ASSOCIATION.—The formation of a Metropolitan Association for promoting Sanitary Laws, and assisting to spread sanitary knowledge, is contemplated. Several meetings to forward it have been held in the large room of the Society of Arts.

## NEW ST. THOMAS'S HOSPITAL.

THE governors of St. Thomas's Hospital have now under their consideration, and will probably determine on Tuesday, the designs prepared by Mr. Henry Currey, for the new hospital proposed to be erected on the south bank of the Thames, and which are set forth in twenty-two drawings, including one very large and very good perspective view, showing the aspect of the building, or rather pile of buildings, will present from the river, along which it will extend 1,200 feet. It comes close up to Westminster Bridge, on the right-hand side (when going towards Ashtley's), and shows towards the river seven separate blocks, four stories high above ground, connected by corridors and service-buildings, the pavilion principle being of course adopted. The pavilions are placed at a distance of 125 ft. from each other, the centre court being increased to 200 ft., which distance will admit of ample sunlight and air to every block. The wards are designed to be 28 ft. in width by 120 ft. in length, and 15 ft. in height, and will accommodate twenty-eight beds, giving a cubic capacity for each patient of 1,800 ft. The beds are placed at distances of 8 ft. from centre to centre, and the windows are arranged alternately with the beds, at a level to enable a patient to look out of them. The number of beds will be 588. The water-closets, lavatories, and bath-rooms attached to each ward, are projected from the main building, and are cut off from the ward by intercepting lobbies, with windows on both sides. The water-closets and lavatories have also windows on all four sides to provide for thorough ventilation, with a view to prevent the escape of any noxious effluvia into the ward. The arrangement here seems very satisfactory. The chapel is placed in the centre of the building, communicating with the corridor of one pair story, with convenient access for both sexes, and is designed to give 300 sittings. The museums, school buildings, lecture theatres, &c., are proposed to be placed at the southern end of the ground, as indicated on the plans, but the detailed arrangements of this department are not completely matured. The building is designed to have fire-proof floors throughout, formed with wrought and rolled iron joists, and concrete. The windows go up to the ceilings of the wards. The floors will be of oak, and the wall surfaces finished with Keene's or Parian cement. The terrace towards the river is proposed to be kept 4 ft. above the public footway. This, with the height of a parapet, 3 ft. 6 in., will prevent any overlooking by the public. The style adopted may be called, broadly, Italian.

Mr. Currey's approximate estimate, the walls being of brick with stone dressings, is 330,000. If the whole building be faced with stone, the cost would be about 30,000 more. The estimate includes a bed of concrete, 10 ft. thick, under the whole surface, and some idea is given of the size of the area covered, when it is mentioned, that for every additional yard in depth of concrete, the extra expenditure will be 4,000.

## LAMBTON CASTLE.\*

HAVING been requested to address you on the subject of Lambton Castle, I do so with great pleasure, not only on account of the interest which I naturally feel in the work itself, but because I sincerely desire to promote and encourage, in however trifling and humble a way, a practice which of late years has grown up, especially among men devoted, practically, either to art or to science, of meeting together for the friendly consideration and discussion of subjects in which they feel a common interest, without the restraint and inconvenience of a crowded lecture-room; but in the open air, or, at all events, amidst the scenes and objects to which their attention is invited. When the geologist, with his hammer in hand, and surrounded by men interested in his special science, addresses us amidst the very rocks which form the subject of his studies, how far more instructive as well as intelligible his lessons become! On the hill-top, or under the escarpment of some ridge of rocks, Nature herself lays bare the secrets of her handiwork, and explains the wonder of the creation with more clearness and force than the lecturer can hope to attain by any, even the most carefully-digested, treatise.

\* Address delivered by Professor Sydney Smith, at the June meeting of the Northern Union of Mechanics' Institutions, at Chester-le-Street.

It is the same with the archaeologist. The learned expositor in his study may exhaust his stores of knowledge, in terms the most accurately scientific, and in language the most unexceptionable, and yet produce on his audience an impression but faint and languid compared with the lively interest which excites them when, amidst the ruins of some time-honoured structure, the lecturer lays his hand upon the very pillars and arches which form the subject of his exposition.

These considerations lead me to hope that, on the present occasion, I may succeed in securing your attention whilst I expatiate for a short time upon the building before you. As a work of venerable age it has and can have indeed no attractions. It is graced by none of the charms of genuine antiquity, though it may well lay claim to that regard and that careful survey which your respect for its noble possessor, rather than any architectural merits, will secure for it. I am induced to say this, not from any affectation of modesty, but for fear you should suppose that, in entering into what may be a tedious description of the works at Lambton Castle, I am inviting, or awaiting, your approval of them. The sole reasons that induce me to enter upon this description are, firstly, that I have been courteously invited to do so; and, secondly, because I think it possible that a plain account of a large and important work of this nature, and of the particular views that have influenced the designers of it, may be of some service to you who are for the most part engaged in the same pursuits as myself.

Having detained you with these preliminary remarks, I will at once enter into the subject of my address.

Harraton Hall, now Lambton Castle, is situated about a mile below Chester-le-Street, upon the banks of the Wear, a river abounding in romantic scenery. It was anciently the seat of the D'Arcys, who conveyed it to the Hedworths, or Hedworths; and after the decease (in 1688) of the last male heir of that family, it became the property and seat of Mr. Ralph Lambton, through his wife, who inherited it on the death of Mr. John Hedworth. Some fifty or sixty years ago the grandfather of the present Earl caused to be built a residence on, or nearly on, this spot, and he could hardly have selected a more agreeable site; but, unfortunately, the architect was not aware of the singular nature of the spot so selected. Highly picturesque as it is, rising magnificently above the valley of the river on whose steep and richly-wooded banks the castle stands, it happened that the whole neighbourhood had at a remote time been undermined in search of coal. At the depth of about 69 fathoms below the surface of the hill, there were a series of beds of coal, reaching downwards to I know not what depth. These beds had been worked out, and had then been deserted and forgotten, so that the beautiful knolle, whilst it appeared to be as solid as any other portion of the great mountain range of coal measures, was in truth a most unsubstantial tract of perforated ground unable to bear the weight artificially imposed upon it. The castle showed early symptoms of the gradual subsidence of the earth on which it stood, and, by the time that the present earl came into possession of the estate, the building had become in some parts insecure. His lordship had, in fact, to choose one of two courses; either to take down the structure and abandon the site as a place of residence; or to restore to the hill that stability of which the miners had deprived it, and, when thus rendered solid and trustworthy, to re-erect thereon the castle.

The beauty of the surrounding scenery, as well as, perhaps, a not unnatural partiality for a site already selected by his predecessors as their residence, ultimately induced his lordship to adopt the latter course, notwithstanding the large expense that was inevitably occasioned by the adoption of it.

Accordingly, over the whole area occupied by the castle, the succession of empty coal seams were all diligently and substantially built up or "stowed" with solid masonry. The very core of the hill was restored, not by occasional props or piers, but by a series of solid, continuous, beds of masonry.

I need not tell you how difficult, tedious, and expensive this work necessarily was; nor need I dwell on the serious responsibility that must have been felt by all who in recommending this course had, as it were, guaranteed its success. The process occupied upwards of six years, and till this was completed little advance could be

made on the superstructure. This remarkable work, however, was undoubtedly successful, and is a great triumph of practical skill.

The offices and private suite of apartments were, for the most part, rebuilt at the beginning of the year 1862, when Mr. Dobson fell ill. His vigorous mind and powerful constitution, together with those temperate habits which had marked all his previous life, enabled him to struggle with paralysis for about three years; but throughout that interval of suffering he was utterly unable to attend to professional duties. Under these circumstances his lordship thought proper to honour me by placing in my hands the further conduct of the work. The completion, therefore, of the private suite of apartments and the whole of the reception-rooms has been carried on,\* and I am in the hope that early next year his lordship will have the enjoyment of the whole residence, but little disturbed by the operations of the builder.

I will now proceed to call your attention to such portions of the building as seem to me most likely to interest you as practical men.

With regard to the foundations, it will be readily understood that the very unfavourable nature of the subsoil rendered them a work of primary importance. The principal walls have had to be taken down, in most cases, to the depth of 15 ft. below the cellar floor, and under them has been placed a bed of concrete 10 ft. wide and 8 ft. deep. To the clerk of the works, Mr. Leighton, who has been on the spot for five years, I cannot but express my thanks for the special attention he has paid to this important point, as well as to the soundness and solidity of the masonry throughout.

There is no sham more discreditable than the mode of construction by which we have walls of formidable apparent thickness, but consisting in truth of two thin faces of worked stone, filled in between with loose rubble. Nor is this a dishonesty chargeable on modern contract work alone. It is a sham of ancient standing, met with not infrequently in buildings of various Mediaeval dates. A long list might be drawn up of the towers and spires that have prematurely perished or become rent in twain from this cause.

We are apt to look back upon our ancient worthies with awe and reverence as to men of a golden age; but "This distance lends enchantment to the view," and could we go back again to the time of the cowl and hauberk, we should probably find that human nature is not so much worse than it was of yore, and that amidst those freemasons of pious simplicity not a few rogues might have been found.

I must, however, hasten to take you rapidly over the principal parts of this mansion.

After entering the outer hall, which is so placed as to prevent the cold winds, which are here often very violent, from rushing into the interior and so chilling all the adjacent apartments, we are introduced into the great hall, which was always an essential part of the baron's residence in feudal times, and which I expect in the present case will be found of great and various utility: besides forming a handsome means of communication between all the principal parts of the house, it will afford room for recreation and exercise to both young and old in bad weather, and on state occasions will become a brilliant hall for receptions, banquets, or balls.

The floor will be laid with *parquet* panels of wainscot, and the walls will be similarly panelled, the upper part of them clothed with pictures, and perhaps armour and banners. The great end window will be glazed with richly-stained glass, which, together with the side windows, is now busily engaging the attention of Mr. Wailes. Before quitting the hall, I must not omit to invite your attention to the carved oak roof, which is a specimen of sound workmanship by the Burnups, of Newcastle, worthy to be compared in execution with any similar work of the fifteenth century.

These framed timber roofs are one of the special glories of Gothic architecture, contrasting favourably with the cobweb-like structures to which engineers are so prone, and of which it may be truly said that they are "a work to wonder at;" the wonder, however, being that they do not more frequently collapse, and resolve themselves into their simple elements, a heap of rods, bolts, and bars.

It may be of some interest to compare the

\* It may be well to note that some portions of the damaged building, being sound, were preserved, although the severe archaeological critic would condemn them.

dimensions of this hall with those of some similar halls of various dates. I subjoin a few examples:—

	Ft.	Ft.	Height to Ridge.
Westminster Hall, London.....	238	by 67½	80 ft.
Guildhall, London.....	153	by 50	52
Lincoln's Inn, London.....	120	by 45	50
Raby Castle, Durham.....	120	by 35	—
Christchurch, Oxford.....	115	by 49	50
Whitehall, London.....	110	by 55	55
Hampton Court Palace.....	106	by 49	54
Eltham Palace.....	101	by 36	54
Middle Temple, London.....	100	by 40	50
Mansion House, London.....	90	by 50	60
St. Stephen's Hall, Westminster.....	90	by 30	60
Lambton Castle, Durham.....	81	by 38	64

Proceeding onwards, we enter the principal staircase, which is 50 ft. by 24 ft., and 36 ft. high. Its walls will afford ample space for the exhibition of pictures and other objects of interest. From the deeply embowed window at the first landing there is a charming view of the wooded hills which surround the mansion and of the valley of the Wear, whose stream runs 120 ft. below.

Returning now to the hall, a central door towards the east leads into the dining-room, 59 ft. by 25 ft., and 22 ft. high. Although this room is in temporary use, its final decorations are postponed until a more convenient time: the ceiling will demand gilding and coloured treatment.

A door on the west side of the hall leads into the drawing-room, overlooking the terraces and garden. It is 68 ft. by 26 ft., exclusive of the bow, and 22½ ft. high. The walls will be richly clothed by the ample stores of works of art in his lordship's possession. The floor will be parquetry in various woods. The carved chimney-pieces, rising to a height of 18 ft., have been executed by Messrs. Mazaroz & Co., a firm in Paris eminent for artistic workmanship of this nature. It is a fact well worthy of your notice and emulation, that such is the energy of our French neighbours, these elaborate chimney-pieces, together with those, equally enriched, in the hall, and that in the state bedroom, comprising together a prodigious amount of carving, were modelled, carved out of the solid oak, framed and fitted together, packed up and delivered, from Paris, at the castle, within three months.

I do not know that it is worth while to detain you by any description of the other less conspicuous parts of the mansion. Mr. Leighton will, with readiness and intelligence, explain every detail that you may think worthy of inquiry, and there are 400 or 500 drawings open for your inspection. This structure I hope you will consider to lie upon the whole, a noble pile, not unworthy of the family which possesses it.

Join me, gentlemen, in wishing that it may for very many years be to them a happy and a comfortable home.

#### COUNTERFEIT ANTIQUITIES.

MR. SAMUEL SHARP has been reading some papers in Northampton on ancient and modern counterfeits of antiquities, and although we have been amongst the earliest to bring these deceptions before the public, part of his *résumé* of the more recent impositions will not be out of place or without value:—

In 1857, extensive excavations were going on at Shadwell, in the making of new docks; and during that and the following year, a respectable dealer in antiquities in London purchased a large number of remarkable objects, said to have been found in the course of these excavations, a smaller number having made their way into the hands of other parties. They were led, and exhibited all the corrosion and encrustation of age: in fact, every material mark of antiquity. The dealer called them "pilgrims' signs," a term first used by Mr. Roach Smith as applied to somewhat similar objects, which he considered to have been badges worn by pilgrims to indicate the shrines of saints which they had visited. This term, however, could only apply to a small proportion of these Shadwell objects, which consisted of figures of "monarchs, knights, archbishops, bishops, and priests, incense cups, reliquaries, vessels of all forms, and numerous plaques and large medallions with loops for suspension." They were of all sizes (some being 2 in. or 3 in. in diameter, and others from 2 ft. to 3 ft. in height), and in numbers sufficient to fill a large room. Mr. Roach Smith, in the course of the publication of his "Collectanea Antiqua," published several articles upon them, and held that they were genuine, notwithstanding some

difficulties and anachronisms which they presented. These he reconciled by concluding, from the lettering, that they were of the time of Queen Mary, had been imported from abroad, and were "copies of early examples." Some members of the British Archaeological Association, however, busied themselves to inquire about these strange objects. One of the secretaries examined 800 of them, and ascertained that their aggregate number was not less than 12,000. As a result, the learned Association concluded that they were forgeries; and, in the report of their proceedings, published in the *Athenæum*, *Literary Gazette*, and *Gentleman's Magazine*, "the public was put upon its guard against forged leaden images then being offered for sale." The dealer, aggrieved, brought an action against the *Athenæum*, and was defeated. The great number and variety of these objects seemed opposed to the conclusion as to their spurious origin—the ingenuity of many persons must have been taxed in their production—no single forger could have exhibited such facility of invention. Mr. Franks, Mr. Syer Cuming, Mr. Gunston, and Mr. Charles Reed, determined to solve the mystery, and at last laid bare the imposture. Mr. Reed obtained some of the plaster moulds in which the objects had been cast, and ascertained the process (the use of acids and compounds) by which they had been made "antique." Another gentleman cunningly entrapped the forgers into copying in lead, from a drawing he left with them, a figure seated on a lull; which, when made, as in the case of the other objects, was as broadly and as truthfully asserted to be antique. Mr. Evans has afforded me the pleasure of exhibiting this very figure here. Even this crucial test was not enough. Mr. Gunston made a sketch of the statuette of a bishop at Rochester, and, in a vein of racy humour, he placed upon the pedestal in the drawing the word "Fabricatus." He left this sketch with one of the workmen, with a request that he would inquire after such a figure, as if he supposed such a one had been found. In twelve hours, an ancient-looking leaden figure, true to the drawing, was produced, and lo! "FABRICATUS" was upon the pedestal!

These things are still being made, and some of them have penetrated even to Northampton. They are very incongruous in their design—helmet, armour, and costume of different ages being frequently combined; they have meaningless inscriptions, and dates varying from 1000 to 1200, in Arabic numerals! Besides the figure on a lull, Mr. Evans has lent me a knight, two medallions, two leaden bottles or *ampulle* (one with its ancient carb washed off), and an "apostle spoon" (also cleansed of its antiquity). The last is a curious model to have chosen, as being altogether inconsistent in date with the other objects. I exhibit for comparison a genuine apostle's spoon (so called from the figure on the handle).

The venue for the sale of these forgeries has now shifted to the works of the Thames Embankment, which has become quite a mart for counterfeit antiquities. The manufacture has advanced with time; and in addition to, and partly as a substitute for, articles in lead (probably by this time become a drug) articles of bronze have been introduced, marked with the same inconsistency as to period. Here are three bronze celt, nearly similar as to type, but varying in size, the largest of which, having been cleansed, offers a strange contrast to the others (to these I oppose a genuine one, found at Eye, near Peterborough, three years ago); also three Roman daggers (two of which, and one lead medallion, belong to Mr. Cosford, of Northampton, who purchased them of some of the Thames Embankment workmen). These daggers present two forms, one seems very familiar, copied, I suspect, from some old print. The handle is formed of a broad spiral band, terminating in a composite head, something between a ram and a deer; the hilt is of the form of the letter *f*, and on each side of the intersection is a lion's mask, under which, on one side, are the letters "MOML." Can we suppose that the designer knew anything about *Momus*,—that he was a wag, and that, in placing the name of the god in the genitive case on these figures, he was having a laugh by anticipation at their future purchasers? Perhaps it is a blunder for "Romi;" but then, this, too, would be a mistake. The second form I may describe as an elegant and original invention: the handle consists of a nude female figure (holding what may be supposed to be an apple), which may be intended to represent either Venus or Eve: the hilt has a kind of

crecent form. These daggers have been roughly cast, apparently in sand, and show blemishes and file-marks. A spear-head is a clever fabrication; but a lack of correctness in form betrays its character. A graphic headed head, on a massive bronze ring, is a novel form of antique. The ornament might be worn appropriately in a burlesque: its age is clearly at the choice of the purchaser.

The remaining forged antiquities which I have to notice consist of various forms wrought in jet, Cannel coal, stone of several kinds, and flint, and I will group these together, because a large proportion have a common parentage.

Some years ago, two individuals in Yorkshire acquired an infamous notoriety as clever rivals in the forgery of antiquities. The one was William Smith, alias "Skin and Grief;" alias "Snake Willy;" the other was Edward Simpson, of Whitby, alias "Flint Jack." These men manufactured stone hammer-heads, ancient British urns, flint implements of all kinds, jet seals and rings, and other objects, in great numbers; and not only were ordinary forms produced by them, but knives, saws, rings, and even fish-hooks, in flint, some of which were actually engraved as genuine in local archaeological publications.

These men travelled through the country, vending their peculiar merchandise. With both I have become into contact, and by both have I been victimised—but by the latter not lately! Some ten or twelve years ago, a shabbily-dressed man called upon me at Stamford; he was a tradesman, he said, "on the tramp," in search of employment: he had happened to be in Bull-street, in Oakham, on the previous day, where an old house had been pulled down, and in the rubbish of the foundation he had found this jet seal. It presents a venerable-looking male head in profile, in a kind of helmet, with falcon crest, and a mail curtain falling from the helmet to the shoulders. The bust is hidden by a shield, having a bordure bezantée, and bearing the words "Cap. Ser. Dei"—"the head of the servant of God. Surrounding the device, are the words, "Sigillum Gustavi de Aldburgh." He asked no great price for it; and I gladly bought it, esteeming myself fortunate. It was the first antiquity of the kind I had seen! I have seen many since! I never saw him again, but I learned afterwards that he was the William Smith of peculiar aliases. About the same time, I heard of a remarkable Roman signet ring in jet, which had been found by a labourer near Peterborough, and was on sale at a silversmith's, at Spalding. I bought it at an enhanced price. I thought it would assort well with my jet seal. It did! It was made by the same person! It is neatly ornamented, and bears a laureated head, and the curious word "Imperatorium." Some time afterwards, I was shown a jet seal of Julius Cæsar, said to have been found in Dourin Fen, Lincolnshire. I took a rough impression of it in gutta-percha. It bears the head of Cæsar, and the inscription, "SIG. IVL. CÆSAR. IMP." From the character of the lettering, and the whole look of the thing, I saw this was a forgery at once. It is not nearly so well executed as my seal and ring, but I have no doubt it was by the same hand. Before this last incident, a man shabbier even than the other, called upon me with a little assortment of six arrow-heads and a sling-stone, in flint. I bought them, and thought I was getting on. This was "Flint Jack." I added nothing in this way to my collection until 1862, but I had long since learned the character of my jets and flints. In 1862, a man brought to my house a rough seal in Cannel coal. I did not see him, but bought it as a forgery for 1s. 6d. I found afterwards that he had sold its counterpart at Northampton as genuine, and also some flint arrow-heads, which reminded me of my Stamford purchase. He soon called again upon me—with a stone axe-head this time—and I recognised him; upon which he was very candid as to his occupation, stating that he was the genuine "Flint Jack," and giving me a few aliases, which I need not repeat. I have seen him several times since, and have obtained from him much information and various specimens of his skill. He has shown me his mode of working both in flint and jet, having made some arrow-heads and commenced a seal in Cannel coal in my presence, selling me for a trifle the implement (a common table-knife sharpened to a point) with which he had been accustomed to work.

Objects of another class, and these the most ancient, considered archaeologically, have furnished subjects, and offered inducement for fraudulent imitation. The ancient remains and

works of man, found in Swiss lake-dwellings, Danish kjökkenmødding or "kitchen-heaps," caves in England, France, Germany, and Spain, and associated with extinct species of animals in gravel deposits in numerous localities both in this country and on the Continent, have excited so much interest and induced so much discussion amongst almost all classes of persons, both at home and abroad, that it was certain that in them would be opened a wide and profitable field for the exercise of the dishonest ingenuity of the results of which I have given so many examples; and accordingly forgeries of these remains from every source have been duly perpetrated. "Flint Jack" was not likely to be an exception, and I have four flint implements from the drift of his manufacture, and the simple tool (part of a hinge taken from a field gate) with which they, and (as he declared) eight hundred others, were made.

It may, perhaps, be thought that in the face of such universal forgery, it is unsafe to rely upon the genuineness of scarcely anything assuming to be ancient, and that it is folly to collect objects so liable to be counterfeited. But the risk, after all, is not so great as it appears, and chiefly attaches to the incautions tyro. It is surprising, in the present day of take-nothing-for-granted inquiry, how soon a counterfeit comes to be found out, and how soon the inexperienced collector, after being taken in a few times (more or less), learns to discriminate the real from the false. There is a danger to be avoided of falling into the error of rejecting as forgery the whole of any class of objects, because some, many, or even most, of the examples we have known have certainly been forged; the very fact of forgery would generally imply the existence of a genuine model. It behooves us to be cautious, but it is as great a mistake to reject rashly as to accept credulously.

PARIS.

The annual Exhibition of the Fine Arts of the present year, held in the Palace of the Clamps Elisées, comprised 3,554 numbers altogether of the several classes, of which 2,243 were of pictures, 601 of drawing, 327 of sculpture, 56 only of architecture, 272 of engravings, and 58 of lithographs. Of course, among so great a number there was a great mass of mediocrity, the leading artists abstaining from contribution excepting of works for public edifices. Of the works of the few exhibitors in the architectural department, there is little to mention, the designs for new churches being unusually bare of artistic merit. One very elaborate and pretentious drawing by M. Gros, proposed to cover the Hill of Montmartre with palaces, colonnades, fountains, cascades, &c. from the summit to the base.

About 300 ft. of the old gallery of the Louvre have been razed to the ground, nor is there any preparation to join it by a new erection to the heavy construction adjacent to the Pavillon de Flore, which latter, although rebuilt, is covered by an enormous scaffolding, with numerous enclosed parts where sculptors are busily at work.

In the salons of the old Louvre, the Campana Museum (now called the Museum of Napoleon III.) is placed. The pictures of the French School which were formerly hung there, have been transferred to the new gallery which runs laterally with the famous old gallery; and the Claudes, Poussins, Lesueurs, and others, are now congregated in this new locale. In the Salon Carré, the portrait of a man, painted by Antonella da Messina, is the only new addition. It was purchased at the Pontalba sale for 4,200l., the Count having purchased it several years before for 20l. in Venice.

The picture gallery of the Duke de Morny at his official residence in the Palace of the Corps Législatif, was constructed by the side of the ball-room, and entered by five large openings. The pictures were hung on one side principally, lighted from the roof by day, and at night by lamps similar to those in use in London for lighting shop-windows from the street. The walls were covered with dark maroon damask, and the whole of the woodwork, without exception, was dark oak.

The Grand Opéra is much advanced: the principal story is completed to the capital of the columns. The Northern Railway Station is far from completion, nearly one-half of the interior not being yet roofed over.

It appears that the site of the new Hôtel-Dieu has been at length definitely agreed upon.

This is the plot of ground occupied by the block of buildings in the island of the Cité bounded by the Rue de Constantine on the north, the Rue d'Arcole on the east, the Rue Saint-Christophe on the south, and the Rue de la Cité on the west. The inhabitants have received notice to quit on the 15th of October next.

The Saint-Denis canal has been laid dry for want of water, the limited supply derived from the Ourcq being reduced to nothing during the dry weather. In consequence all the shipping of the port of Paris has been obliged to take refuge in the Port St. Nicholas, opposite the Louvre, thus giving the quay a most animated appearance.

A plan is being studied at this moment for taking, by means of a powerful set of steam-pumps, a supply of water from the Marne sufficient not only for alimenting the Canal Saint-Denis, but for keeping the Canal St. Martin constantly full, and the *bornes-fontaines* of the capital well supplied.

The *Mondes* informs us that M. Emile Trélat has taken the initiative in founding a central school of architecture. The number of subscribing founders is already considerable. The studies are to be of three years' duration: the pupils, all externs, are to remain eight hours at the school, each day, from 8½ a.m. till 4½ p.m. The scholar-year will last for eight months, from the 10th of September to the 10th of August, and at the end of the studies the school will deliver a diploma certifying as to their architectural capabilities. National subjects and strangers will be admitted after they have been subjected to the examination indicated in a special programme. The temporary offices of the society are No. 9, Passage Saunier. Among the professors are MM. Jansen, physics; Dehérain, chemistry; Tresca, stability of construction; Baillon, botany, &c.

ST. LUKE'S CHURCH, CHORLTON-UPON-MEDLOCK, MANCHESTER.

ST. LUKE'S CHURCH is of the Early Decorated style, and comprises nave and north aisle, 70 ft. by 46 ft., and chancel 24 ft. by 20 ft. A small gallery is at the west end; the accommodation being 740, of which 323 are free. The tower, which is prominently placed at the north-east angle of the nave, is capped with a broach spire, surmounted with gilt coronal and vane, the total height being 148 ft. Adjoining the chancel are the vestry, organ-chamber, and choristers' vestry. The church is built with Yorkshire Pierpoint stone, with Longridge and Hollinton stone dressings. The approaches of the church are from the north and south, the former being the principal one; while the access to the gallery is obtained from the west end by a stone covered staircase, with a pinnacle at the angle, with carved gargoyles.

The arches between the aisle and nave are supported by double iron pillars (picketed out in colour), which add to the lightness of the church, and interfere as little as possible with the line of sight in any direction. The roof is of high pitch, with open framed principals, with carved spandrels, wind beams, tospars, &c., and covered with slating of different tints, with ornamental cresting to the ridge.

A dwarf wall of Caen stone, inlaid with marble, determines the boundary of the chancel, in which are the choir stalls. The altar is approached by five steps. The floor is paved with Mow's encaustic tiles.

All the seats and other internal fittings are of oak, the pulpit and reading-desk being enriched and inlaid with walnut and ebony. The font is of Caen stone, with marble shafts, of elaborate design, and is placed at the west end adjoining the entrance. The altar rail, of polished brass, with floriated standards, is by Skidmore & Co., of Coventry; also the gas-fittings, by the same firm. The heating and ventilation apparatus is by Haden & Co., of Trowbridge.

The east window of the chancel is by Wailes of Newcastle, in memory of the late wife of the patron; and all the other windows are enriched more or less by the introduction of stained glass from the works of Edmundson & Son, of Manchester, who have also supplied the brass tablets and other decorations. The organ was built by Imhof & Muckle, of London. The clock, which has three faces, was made by Joyce, of Whitechurch, and is provided with Denison's gravity escapement. There is one hell (G sharp), by Taylor, of Loughborough.

The masonry is by Ellis & Hinchcliffe, of

Manchester; and the woodwork and general supervision of all other trades were undertaken by the contractors for the whole building, Messrs. Bowden, Edwards, & Forster, Manchester, under the direction of the architect, Mr. John Lowe, of the same city.

The grave-yard is enclosed with a dwarf wall, of similar materials to the church, with iron rails at intervals, with an entrance gateway to the east elevation, of elaborate design. All the gates are of English oak. The whole of the cost has been defrayed by the patron, Robert Gardner, Esq.

THE LADIES' SANITARY ASSOCIATION.

THE public have reason to regret, as we very much do, that the last annual report of this most useful and important Association announces a great falling off in the funds during the past year, which must paralyze the labours of the active and efficient staff of the Association, at a time, too, when constant appeals for grants of sanitary tracts and for lectures are being made to the committee from the working men's clubs and the Bible women in all parts of England, as well as in the metropolis and, from the City missionaries and the clergy. The funds, instead of increasing as last year at the rate of 200l. per annum, have fallen short of even the income of 1860; and, to begin their present financial year with, there were only 12l. in hand, while it is a rule of the Association not to incur expenses which cannot be met by the funds available. The valuable sanitary work of these good ladies will thus be actually stopped in the very midst of their arduous and willing labours, and at a time when these labours had very much increased. Surely, notwithstanding the endeavours of the press, in which we have taken an earnest part, the public do not yet know of or appreciate the purposes and endeavours of the Ladies' Sanitary Association; and that this may no longer be the case (as far as our efforts may help it), we shall here re-state the objects for the promotion of which the Association was established, and which it has already done a great deal to realize.

"The promoters of this Association, convinced that one of the principal causes of a low physical condition is ignorance of the laws of health, have combined to extend and popularize sanitary knowledge.

- For this purpose—
- 1st. They write and distribute simple interesting tracts on sanitary and domestic subjects. The greater part of these are written specially for the poor.
  - 2nd. They establish loan libraries of popular books on subjects relating to health and social well-being.
  - 3rd. They arrange for the delivery of practical lectures on health, sanitary improvements, and domestic economy.
  - 4th. They form branch associations in various localities for carrying on practical sanitary work.
  - c. By distribution of the tracts among the poor of the district, and in schools, hospitals, and mothers' meetings.
  - b. By collecting money for sanitary improvements, such as opening windows, curing smoky chimneys, removing nuisances; giving soap, and lime for whitewashing; lending hooks, patterns of clothes, scrubbing-brushes, saucepans, and cooking recipes.
  - c. By requesting the medical officers of health, and other professional and well-educated gentlemen, to deliver popular free lectures.
  - d. By instituting mothers' meetings, and classes of adult girls, and giving them sanitary and domestic instruction.
  - e. By forming or aiding Penny Clothing Clubs, Coal Clubs, Baths and Wash-houses, Temperance Associations, Cooling Depôts, and Working-men's Clubs.
  - f. By establishing nurseries for motherless babies, which may serve as schools for mothers of all classes, schoolmistresses, and nurses."

Already no fewer than 760,000 of the many sanitary and domestic tracts referred to have been distributed. During the past year alone eighty-three lectures have been given. Throughout the country, including Scotland and Ireland, ten branches have already been formed. From the meetings of the Association on overwork, the London Dressmaking Establishment has arisen. Park parties of ragged school children were sent out last summer, conferring happy holidays on 29,000 children. The committee wish not only to continue all this work, but to increase it, by offering prizes for clean and tidy rooms, by encouraging flower shows, establishing nurseries for motherless babies, by employing sanitary missionaries, &c. But unless funds are speedily forthcoming, they will be unable not only to extend their operations, but even to sustain those already in hand. An annual subscription of 10s., or a donation of 10l., constitutes the subscriber a member of the Ladies' Sanitary Association, and there are no other resources for it to fall back upon. The funds are well administered, and the Association is in excellent hands. Lady

Burrell and Mrs. Osborne Stock are the honorary secretaries, and Miss Griffiths is the secretary. The office of the Association is No. 14, Princes-street, Cavendish-square, W. The Hon. Mrs. W. F. Cowper is the president; and on the committee are such names as Miss Burdett Coutts, the Countess of Airlie, Miss Isa Craig, Lady Stanley, and many other well-known persons. The president's name appears on every sub-committee,—finance, tract, lecture, park parties, gymnastics, and branch association. Branches have already been established at Brighton, Oxford, Reading, Bath, Leeds, Glasgow, Paisley, Aberdeen, and Dublin; and efforts are being made to extend such branches to Bristol, Cardiff, Greenock, Edinburgh, &c. The Association is affiliated with the National Association for the Promotion of Social Science, every member of which, we think, is in social duty bound to support so excellent an institution as the Ladies' Sanitary Association.

To give an idea of the nature of those domestic and familiar sanitary and social teachings which are promoted by the extensive tract distributions of the Association we may here give a few of the titles, although we have already done so on former occasions.—The Black Hole in our own Bedrooms—The Mischief of Bad Air—Washing the Children—The Cheap Doctor—The Massacre of the Innocents—A Model Wife—Measles—When were you Vaccinated?—The Use of pure Water—Never Despair—The Health of Mothers—How do People hasten Death?—Woman's Work in Sanitary Reform—Hyaline Dwellings, &c. &c. A condensation of useful precepts such as many of these tracts inculcate has been tastefully arranged, together with various other scraps of useful information, such as rates of postage, weights and measures, &c., round a chromo-lithograph of a humble home, which forms the chief ornamental feature of a very neat "Home Art" for 1865, which will no doubt, even yet, appear in thousands of humble dwellings in course of this year if an access of funds enable the sanitary lady visitors to distribute them farther while carrying on their various other useful labours, as it is our earnest hope they will shortly be enabled to do.

#### THE WORKING MEN'S EVENINGS AT EXETER HALL.

The series was closed on the 4th inst., with a paper by Mr. J. M. Ludlow, entitled "Can Arbitration be successfully used in Disputes between Employers and Workmen?" The Earl of Lichfield was in the chair. The writer remarked that his subject logically preceded the subject of strikes and co-operation, which had been discussed at the first two of these meetings. Co-operation was the end—arbitration one of the means of securing that end. The question of applying arbitration to the settlement of disputes between masters and men had been embodied in this nation's laws since 1800, and again in the reign of George IV. But these legal provisions have been very unsuccessful, and there is at present great need of dealing with the question afresh. Mr. Ludlow distinguished between mediation and arbitration, indicating that mediation would often be a step in securing sound and effective arbitration, but the latter must be endowed with a greater authority than could belong to the former. He thought that if the working conditions could be secured, it would be as easy to arbitrate between masters and workmen as between any two persons who might disagree; and these conditions, he said, were confidence on the part of the parties disagreeing in the members of the council of arbitration, who should be experienced in the subject in dispute, and be armed with authority to enforce their award. It would be impossible to secure arbitration which should never fail, but the great thing was to secure a system which should fail as seldom and with as few evils as possible. For councils of conciliation and arbitration he would select, by vote, equal numbers of experienced masters and workmen; and the qualifications for a vote, in both cases, should be twenty-one years of age, having worked five years in his trade, and having resided three years in the town in which the council met. The selection of a chairman was a difficult and very important arrangement, inasmuch as the numbers of masters and men being equal, it might often happen that with the chairman would rest the entire decision. The council of conciliation and arbitration should have power to enforce its advice or determinations; and that this might be done

thoroughly, it would be necessary to legalise trades' unions, that so their councils would legally represent their own members when before the court. Another very important question was whether these courts were to fix or simply declare a scale of wages, but into that he should not then enter. It seemed to him that the present means of fixing wages obliged both employer and employed to maintain their respective hostile organizations. He thought that the expense of these councils should be paid out of national or municipal funds. He would have, in connexion with the councils, the right of appeal, which would prevent constant re-hearings of cases. Mr. Ludlow said he had for seventeen years considered this subject under different phases, and had always advocated councils of arbitration as a great improvement upon the present state of things, as a safe and simple means of bringing the different classes and opposing interests into more friendly relationship. The results of this system would be most blessed in teaching men how to prevent and remove class warfare.

A brisk discussion ensued. The chairman, in reply to a vote of thanks, said,—Co-operation between employers and employed had been advocated as a means of preventing the mischief; but he feared it would be a long time before that system could possibly be brought into action; and, even if it were adopted, it seemed to him that disputes would arise as to the manner of dividing the profits. Nothing could be so useful as co-operation among the working men themselves, but not so between one man and one thousand. He thought that arbitration, at all events at present, was best calculated to remove the difficulties of strikes; but there would be difficulties even in that system, and one would be that of applying or carrying into effect the awards of the courts of arbitration. To effect this it would be useful to do what Mr. Ludlow had recommended, viz., to give trades' unions and societies a legal status, and thus enable them as corporations to use or be subjected to the law. In this way public opinion would be brought to bear upon these unions, and would make them feel what he feared they had not sufficiently felt, viz., their sense of responsibility. The funds of these societies were obtained for the support of men on strike or outlocked from other societies, which did not always know the merits of the case, and were not, indeed, asked to contribute on the merits of the case, but simply on the ground that there were so many brother workmen out of employment who must be supported. One great benefit which would be secured by courts of arbitration would be the bringing masters and men together to talk over any change which was proposed to be made, either in their relationships or wages, and would secure the points being thoroughly discussed before any action was taken. This arrangement alone, would, he believed, put an end to one-half of the distressing strikes and outlocks which were taking place. The appointment of a chairman for these councils of arbitration would, he admitted, be a difficult work, as had been said, but one which, with care, might be satisfactorily performed.

#### ARCHAEOLOGICAL INSTITUTE.

At the last meeting for the session of the members of the Archeological Institute of Great Britain and Ireland, the Marquis Camden took the chair. The first paper read was a joint communication from Professor Westwood and Mr. Way, respecting the removal and supposed demolition of an ancient cross, which was in the old church at Leeds. It was asserted that the architect, when pulling down or "restoring" the building, had removed the cross and built it into the wall of his own residence, near King's Cross, and that his horse having been required for a railway, the cross was demolished. Drawings of it were exhibited, which represented a highly decorated cross about 7 ft. high. A visitor, a gentleman from Leeds, gave a different account of the fate of the cross. He said he remembered it very well in its original position in the church, and he afterwards saw it at the architect's, who resided at Highbury, and not at King's Cross. It was not built into the wall, but stood by itself in the garden, and it is possible it may be there yet.

Two curious large gold ornaments, which had been discovered at Padstow, in Cornwall, in the spring of this year, had been sent for exhibition by the Prince of Wales, the patron of the Institute, and were described by Mr. Smirke. They

are crescent-shaped, and turned up at the ends, each one being about 6 inches long, and their value, as mere bullion, is estimated at 80l. They were found by some men working in a rock at a depth of 6 ft., and associated with them were some bronze ornaments and some "cells." They had evidently been placed where they were found for concealment. One or two similar gold ornaments of smaller size are in the collection of the British Museum.

A paper was read on the discovery of bronze implements and other relics of antiquity in Denmark. A long description was then given of a journey from Smyrna to Halicarnassus, and of some of the excavations there undertaken on behalf of the British Museum.

#### WEST LONDON SCHOOL OF ART.

At this school (which is in connexion with the Department of Science and Art) and is established at 204, Great Portland-street, W., with branch classes, the second annual distribution of medals and prizes took place on the 4th inst. Mr. Harvey Lewis, M.P., occupying the chair.

The statement put forward by the council showed, that during the year 1864 they had 519 students attending the school, of whom 48 were artists and designers, 54 were decorators, writers, and gliders, 46 were wood, stone, and ivory carvers, 9 modellers, 27 glass painters, 13 papier mâché, &c., workers, 20 goldsmiths and chasers, 19 engravers and die-sinkers, 20 metal workers, 35 cabinet makers, 30 upholsterers, 10 musical instrument makers, 32 carpenters and joiners, 27 machinists, 11 masons, 11 photographers, &c., 29 salesmen and clerks, 25 teachers, 21 at school, and 31 miscellaneous. In the ordinary studies of the pupils, 23 were awarded medals, and 6 honourable mention; and subsequently in the national competition the large proportion of 3 national medals and 2 honourable mentions were awarded. Six senior students had during the past year been admitted as students of the Royal Academy.

The chairman, in opening the proceedings, said it was very gratifying that notwithstanding the head master had for some time been ill, the school had progressed in so satisfactory a manner, and also that there were more prizes to be given than in any previous year.

The principal prize, the Queen's prize, was won by Mr. Horace Montford.

Mr. M. D. Wyatt and Mr. Peter Graham, the treasurer, addressed the meeting, and proposed a vote of thanks to the chairman, which was unanimously carried.

#### OFFICES OF THE CROWN LIFE ASSURANCE COMPANY, FLEET STREET, LONDON.

The offices of this highly-esteemed company occupy the whole of the ground floor, and consist of public office, secretary's room, board-room, medical officers' and waiting rooms; strong rooms and clerks' luncheon-rooms in the basement. It is proposed to let the upper floors in suites of offices, the first-floor having a separate entrance from Fleet-street. There are laboratories and a w.c. to each set of apartments. The building is constructed with fire-proof floors throughout.

The materials used in the facing are Portland stone in the piers and caps; Forest of Dean, red Mansfield, and blue Warwick, in other portions of the front; and over the arches, Sicilian marble. The carving is by Whelan, who is also engaged on the new buildings at Christ Church, Oxford, now nearly completed. The cost of the new Crown Office will be about 16,000l. The contractors are Messrs. Piper & Wheeler, of Bishopsgate-street. The architect is Mr. T. Newenham Deane. The result promises to be very satisfactory.

INDUSTRIAL EXHIBITION FOR THE CITY OF LONDON.—A crowded meeting has been held in the Sussex Hall, Leadenhall-street, in connexion with the proposed Working Classes Industrial Exhibition for the city of London. The Lord Mayor presided. It was resolved, "That a Working Classes Industrial Exhibition for the city of London is most desirable; and that this meeting pledges itself to adopt means for the furtherance of this object." A committee was appointed.

OFFICES OF THE CROWN LIFE ASSURANCE COMPANY, FLEET STREET, LONDON.  
MR. THOMAS NEWENHAM DEANE, ARCHITECT.

TOBACCO SMOKING.

It is not one of the pleasing signs of the times that this practice has become in use amongst boys who have scarcely passed beyond their school days; and so numerous are the instances in which small boys may be seen, without any seeming shame, smoking pipes in the open street, that it is often difficult to resist the inclination to administer a little reasonable correction. On some points the doctors differ, but on the unwholesomeness of the practice for boys who have not arrived at a proper bodily development using narcotic fumes, there is no dispute whatever.

In France, reliable statistics show that in proportion to the increase of the sum which is derived by the Government as a duty on tobacco, so has the extent of insanity and some other diseases which have their origin in the derangement and weakening of the nervous system increased. The French physicians say that to no other cause than the excessive use of tobacco is the vast increase of lunacy in France to be traced.

At home, we fear that a great deal of mischief is due to excessive smoking. The use of the tobacco-pipe before the bodily functions have been developed, stops and dwarfs the growth. It leads to idleness, and is in far too many instances a sort of connecting link with dishonesty and habits of drinking. In the artificial conditions in which young men live in the metropolis and in our great towns, in the midst of unsanitary arrangements and other disadvantages, the tobacco-pipe destroys more lives than is generally supposed; and it would be useful if in our hospitals, especially those devoted to the cure of consumption, a note were made of those who have at an early age been accustomed to the use of tobacco.

In these days we need to increase the intellectual and bodily strength of our youth: we therefore beg of the masters of schools, of the fathers, mothers, and others who have charge of boys, to have no hesitation about the matter, but to put out the pipes of the small boys at once.

THE AMALGAMATED ENGINEERS.

We recur to this subject, in order to note that the last report of this Incorporated Society of Engineers, which consists of engineers, machinists, millwrights, smiths, and pattern-makers, is full of information of an encouraging description, not only to the members of this society, but also to those who may be contemplating the formation of similar institutions, or to others who may be connected with societies of a kindred nature in various stages of their progress. The report is admirably drawn up, and in its clear and business-like arrangements might well serve as a model to the directors and managers of establishments which have far more lofty pretensions. This is the fourteenth yearly report; and in glancing back at the history of this society, it is instructive to note its various and severe struggles, and also the elasticity which has caused it to rebound from various adverse circumstances to increasing prosperity.

In carefully arranged tables, the financial position of the Amalgamated Engineers, and of the numerous branches connected with the parent body, is distinctly shown; and some of the features are curious; but upon the whole the facts are very encouraging. For instance, in the year 1860, the balance in favour of the society, upon the year's accounts, after paying all expenses, was 23,366*l.*; whilst, during 1861—the first year of the American cotton famine—it was only 13,194*l.* In 1862, the state of the funds was so bad that there was actually a deficiency, and the funds were reduced that year by 5,782*l.*; but mark the elasticity of the society: in 1863, the loss was only a little over 200*l.*; and in 1864, the cloud of adversity was rolling away, and the return to prosperity was shown by the increase of the fund during the year to 9,537*l.*; so that the money position of the society is better than it was before the great depression of the cotton trade first took place.

The amalgamated fund of the society now amounts to 31,086*l.* a member, and the arrears are equal to 5*l.* 8*s.* a member, this being 7*l.* a member more than in the year before. This amount of arrear is one of the few unpleasant features of the report, and it would be well if the members were to make an effort to get this blot removed before another year's report is pub-

lished. The secretary says, "I have shown, in tables appended to this statement, the principal sources of expenditure, the amount which has been required for various benefits, as well as the cost of management. It will be seen that the amount paid to members out of employment during the year was 16,425*l.* 9*s.* 6*d.*, or 11*s.* 4*d.* per member. The amount paid during the previous year was 32,653*l.* 6*s.* 10*d.* The vast improvement in trade during the past year is thus to be seen at a glance, and the improvement would seem to be somewhat permanent. Sick benefit during the year has been 13,612*l.* 4*s.* 7*d.*, or 9*s.* 5*d.* per member, being a slight decrease on the amount per member in the previous year, although the total expenditure was about 1,000*l.* more. The amount expended by these two principal benefits was 30,037*l.* 14*s.* 2*d.*; and there were three other important benefits, upon which the following sums had been paid, viz., superannuation benefit, 3,002*l.* 5*s.* 7*d.*; benefit in case of accident, 1,100*l.*; funeral benefits, 3,924*l.* 0*s.* 11*d.* The three benefits amount to 8,926*l.* 6*s.* 6*d.*"

In all ways the money expended amounted to nearly 40,000*l.* (38,964*l.* 0*s.* 8*d.*).

The whole year's expenditure amounted to 51,518*l.* 12*s.* 6*d.*, and the accumulated fund amounted to 86,917*l.* 15*s.*

The deaths during the year have been, in proportion to the number of members, about the same as last year: 282 members have died during the year, and 165 members' wives; and to this item we beg to direct special attention, first, to the large proportion of deaths of the men who work at these special trades, which are, for the most part, so well paid, that a want of a sufficient supply of the necessaries of life should not be one of the causes of this peculiarity of death-rate. Moreover, the secretary says, "Consumption has been the main cause of death, as will be seen by the table appended."

We have before referred to the enormous death-rate from consumption, or lung diseases, amongst the English workmen who are in the prime of years, and we have no doubt that its fatal effect is as dependent on the sanitary condition of houses and workshops as is that of the zymotic complaints to which so much attention has been very properly given. May we hint that advantage would result if those able and clear-headed men who have assisted in drawing up the report of the Amalgamated Engineers were to form a supplementary health committee, who would inquire into those matters? No doubt they would, if needful, be able to get useful information from the medical attendants of the branch societies, &c., and some valuable hints might be given in the yearly reports at but little additional cost to the society.

EIGHTEEN YEARS OF LITIGATION.

M'INTOSH V. THE GREAT WESTERN RAILWAY CO.

This cause, which has been several times mentioned in our columns, and has been litigated for upwards of eighteen years, came to a final hearing, in Vice-Chancellor Sir John Stuart's Court, on the 28th ult., when the Vice-Chancellor delivered his judgment on all the matters involved. The circumstances are shortly as follow:—The late Mr. David M'Intosh had a contract for a portion of the company's main line near London, and other contracts for portions between Bath and Bristol, including in the latter the execution of a large quantity of rubble masonry. Various questions arose between the contractor and the company as to their respective rights under the contracts, and the amounts due to the former. Among others, was one as to the quality of the masonry, it being contended by Mr. M'Intosh that the engineer, Mr. Brunel, had, by various orders directing particular modes of working the stone, so increased the value of the work as to make it ashlar, or equal to it. After many abortive attempts between 1840 and 1847 to bring the company to a settlement, Mr. M'Intosh in the latter year filed his bill claiming from the company payment of 248,000*l.*, the balance of his accounts, delivered some years before. The company defended the suit on every point, alleging want of jurisdiction in the court, setting up the Statute of Limitations as to some portions of the demand, and want of written orders and other similar defences, and made a counter claim of 340,000*l.* for penalties for delay in completion of the work. After nine answers had been put in by them, the cause came to a hearing in the year 1855, and after a

hearing extending over sixteen days, a decree was made for an inquiry whether anything was due to the plaintiff. This inquiry was accordingly taken before the chief clerk in chambers, where every item of the plaintiff's account of works was gone through before him, and the defendants' counter claims were also discussed. The whole of the latter were disallowed, and in February, 1863, the chief clerk made a certificate, finding a gross sum of 147,593*l.* due to the plaintiff, including interest at 4 per cent. from the opening of the line. The company objected to this certificate, that it did not give the particulars of the items allowed. And on appeal to the Lords Justices, their objection was sustained, and sent back for revision. The chief clerk accordingly, in February, 1864, made a new certificate, finding 118,271*l.* due, and setting out the detail. The company then objected to upwards of 900 items as improperly allowed; and the plaintiff also objected that a sufficient sum had not been found due to him. The defendants' objections were heard last year, occupying in all upwards of thirty days, when the Vice-Chancellor did not think it necessary to call on the plaintiff's counsel in answer, and the latter then declined to enter on their motion to increase the sum found due, expressing themselves willing to take that sum to end the matter. The cause then having been heard, on further consideration the Vice-Chancellor gave his judgment. After referring to the fact that each of the items objected to had been the subject of an elaborate investigation, and that the evidence was now before the Court for the fourth time, he said that the Court had a concurrent jurisdiction with the courts of law on such matters, and that the course of the Court was to consider each item having reference to the others and all the circumstances; that this had been done, and the chief clerk had stated the result of the inquiry at great length. The company had now objected to more than 900 items, the sum in dispute on one being 3*l.* and in another 9*l.*, and there being 53 disputed items under 1*l.* each, and 145 under 5*l.* each. No such proceeding would have been allowed at common law, and this was of necessity, from the nature of the questions, which were questions of compensation and estimate, on which no two men could agree; and the sum which the jury agree to fix, although not perhaps one which any two of them acting separately would have fixed, yet, being agreed to on a compromise of opinion, is to be accepted as conclusive. The same principle must be acted on in this court, and he could see no reason to alter the certificate. As an illustration, he referred to certain charges for gates, which the plaintiff's witnesses valued at 5*l.* each, while Mr. Brunel stated they were worth but 3*l.* 10*s.* Another item was for compensation for expense and delay caused by orders given by the company's engineer to preserve for a considerable period the site of a Roman villa discovered in the line of the works. This item had also undergone a long and laborious investigation before the chief clerk. Various modes of estimating the compensation might be suggested, but there was no safe ground for an alteration of the certificate unless manifest error were shown. As to the questions raised with regard to the amount of the 3 B Extension and 6 B Contract sums, and the penalties, he concurred with the chief clerk. The Attorney-General having intimated on the part of the plaintiff his intention not to proceed with his motion to increase the amount without prejudice to his right to appeal if the defendants did so, he proceeded to consider the questions of interest and costs. The decree left the question of interest open. In the case of the Duchess of Marlborough v. Strong, it was laid down that when the compensation was fixed at an increased rate on account of slow payment, no interest should be allowed, but that slow payment must be compensated either by interest or an increased allowance. In this case the time for payment was certain; and if the engineer's certificates had been for proper sums, the sum was certain too. As to the rate, he would have considered 5 per cent. a proper rate; but the chief clerk having fixed 4 per cent., as he could not say, on a question of estimate, it was wrong, he should on principle decline to alter the certificate. As to costs, the contracts contained Arbitration Clauses, but the defendants had, before litigation, during litigation, and up to the last day of the argument, refused to submit to arbitration; and they, nevertheless, objected to the jurisdiction of the court. The litigation was not occasioned by any failure of the plaintiff to

deliver accounts. It was no part of his contract to do so; on the contrary, a careful consideration of the terms and nature of the contracts, as to the engineer's certificates, and of the duties imposed on the defendants, led to a very unfavourable view of their conduct as the cause of this litigation. It was the duty of the engineer to make just certificates. It now appeared clearly enough that great injustice had been done to the plaintiff in these certificates. This was almost decisive on the question of costs. As to those parts of the case where any distinction should be made as to the costs. The demand for ashlar had been disallowed. This was a question of singular difficulty. It seemed certain that by insisting on having coarse rubble wrought and finished in a very perfect manner, although not so finished in point of style as to answer the technical description of ashlar, yet the labour might make it so expensive that payment at less than ashlar prices must be a very insufficient remuneration. As the plaintiff had withdrawn his motion to vary the certificate it was unnecessary to consider whether the conclusion came to by the chief clerk was perfectly correct. From an examination of the evidence he was satisfied that the exacting nature of the directions given by the engineer had occasioned the litigation on this point; that the terms of the contract on a point of difficult construction had exposed the plaintiff to a loss not contemplated; and that, looking at the vastly complicated circumstances of this unparalleled case, there was no such failure on the plaintiff's part as would warrant any distinction as to costs. As to the hardness of strata, there was no separate evidence, and no time occupied to warrant any distinction. On the whole, the result was that the defendants' motion to vary the certificate must be refused; there must be a decree for payment of the sum found due, with interest; the costs of the defendants' motion to be costs in the cause; and the defendants to pay the costs of the cause. For the reasons before mentioned, the plaintiff's motion to vary was refused, without costs.

The counsel engaged were:—For the plaintiff, the Attorney-General, Mr. Bazalgette, Q.C., Mr. F. C. J. Millar, instructed by Mr. Barnard. For the defendants, Mr. Bacon, Q.C., Mr. Malins, Q.C., and Mr. Stevens.

#### ANOTHER NOTE ON THE CUPBOARDS OF TENEMENTED HOUSES. EXTEMPORISING A FAMILY CLOSET.

The subject of cupboard accommodation is of far greater consequence to the working classes of the metropolis than is generally supposed by those who are not obliged to suffer from the want of it: we will therefore add somewhat to the particulars which have been already given. In the present changing state of the dwellings in which many thousands are obliged to live the matter is of even more than usual importance.

To keep tidiness in apartments which are occupied by families, without proper closets, is quite an impossibility. Notwithstanding, it will be found that many rooms which are let to families are without any provision in this way. In glancing at a number of houses we have jotted down particulars, and give examples which might be multiplied.

In two rooms on the first floor, occupied by a numerous family, there were two closets in the front room, the size of each, 23 in. high, 24 in. wide, and 15 in. deep. In the back room there were no cupboards at all. In houses let in this way a similar arrangement will be found throughout.

We find numerous instances of back rooms, let to families, in which there are no cupboards. In some cases tenants have bought second-hand closets, and fitted them up for the reception of plates, tea-cups, saucers, bread, and other necessaries; in other instances, carpenters living in such places have purchased materials and put up shelves, which, to a certain extent, are a means of preserving order. Some housewives have an opportunity of storing saucepans, frying-pans, washing-tubs, and other articles, in the wash-house; but here they are liable to be spoiled by the damp, or to be constantly used by other people living in the house. The keeping of coals and coke is a sore trouble: for this purpose, hair-covered trunks, boxes which have once contained clothes, &c., are often applied,—so are baskets or sacks; sometimes the half or

three-quarters of a hundredweight is shot underneath the bed or sofa-bedstead, where are also stored the pans and other cooking utensils.

In some houses closets are contrived underneath parts of the staircase, and for these a weekly rental of 3d. or 4d. each is readily obtained, and, under the circumstances, when a good padlock is placed upon the door, they prove cheap at the money. For an orderly woman to be without closet accommodation is a most troublesome and unpleasant matter. Fancy a tradesman, or any person engaged in business, to be provided with a suit of clothes without pockets, and we may form some estimate of the state of a good housewife who has a home with no closet accommodation.

The dwellers in the kitchen are generally tolerably well supplied in this respect, for there are dressers, shelves, &c., which have been put up by the owner of the premises, when they were occupied in a different way.

Slovenly women make their homes worse than they would be in consequence of the want of cupboards. Morning, noon, and evening, the crocks,—most of them broken in some way,—remain unwashed, standing on tables or chairs, sometimes on the mantel-piece, or even on the floor or the bed.

For Want of a Closet.

Women who wish to keep their rooms in decent order in the absence of sufficient cupboard accommodation, are put to many shifts and contrivances, and, in their desire to keep unreasonable matters from the view, adopt plans which cannot be approved of, however worthy the intention may be. Some of the contrivances which are resorted to would scarcely be credited; for instance, in an apartment of a clean and very decent appearance, in consequence of the want referred to, one of the old-fashioned press-bedsteads is in part, during the day, devoted to the purpose of a cupboard. At night, in consequence of the framework and tick being broken, it is necessary to place the mattress, and bed, on the floor for the children to sleep on. In the morning these articles are carefully replaced, as also are a number of plates, dishes, and other things which at bedtime had been taken out; so that during the day there are bread and other provisions, tea things, and matters which do not associate well with the sleeping things on which they are placed. We give a sketch of the result.

Hundreds of other instances of the inconvenience which arises from this household want might be mentioned, but they are all of a very similar kind: we will therefore only further mention that this subject is of far more consequence than is supposed by a large number of persons. No apartment should be let for the use of families which is not provided with cupboards: in many instances these might be fitted in rooms at a very small expense. At times, staircases might be made available for this purpose; and meat and bread safes be placed outside windows, especially those which have a northern aspect.

Many into whose hands these few lines will fall will recognize the truthfulness of the remarks; and to these we would say, when looking for a home for their families, "See after the cupboards." Formerly, a corner cupboard was considered a necessary article of furniture, which was removed by the owner from house to house: why should the working man be without his movable cupboard now? Landlords of tenemented property would generally find it to their advantage to attend to the matter of cupboards;

and one or two apartments properly provided in this way would be usually worth 3d. a week more than those without cupboards.

In all houses about to be built or adapted to the use of the working classes, cupboards should be made an especial consideration.

#### POLLUTION OF RIVERS.

The instructions given to the commissioners (Mr. R. Rawlinson, Mr. J. T. Harrison, and Mr. J. T. Way) appointed to inquire into the best means of remedying the pollution of rivers, are as follows:—

"Her Majesty having been pleased to appoint you to be commissioners for inquiry into the pollution of rivers, I am directed by Secretary Sir George Grey to send you the following instructions for your guidance in the proposed inquiry.

Although it may be taken as proved generally that there is a wide-spread and serious pollution of rivers, both from town sewage and the refuse of mines and manufactories, and that town sewage may be turned to profitable account as a manure, there is not sufficient evidence to show

that any measure absolutely prohibiting the discharge of such refuse into rivers, or absolutely compelling town authorities to carry it on the lands, might not be remedying one evil at the cost of an evil still more serious, in the shape of injury to health, and damage to manufactures. It is, therefore, suggested that your inquiry should include selected river basins, illustrating different classes of employment and population; that these river basins might be:—

1st. The Thames Valley,—both as an example of an agricultural river basin, with many navigation works, such as locks, and weirs, and mills affecting the flow of water, and many towns and some manufactories discharging their sewage and refuse into the stream from which is mainly derived the water supply of the metropolis.

2nd. The Mersey Valley,—including its feeders, particularly the Irwell, as an example of the river basin, most extensively polluted by all forms of manufacturing refuse, particularly that arising from the cotton manufacture and processes connected therewith.

3rd. The Aire and Calder Basin, as an additional example of the same class, particularly in connexion with the woollen and iron manufactories.

4th. The Severn Basin, for the same reason, but in particular connexion with the great seats of the iron trade.

5th. The Taff Valley, in connexion with mining and industry applied to metals.

6th. A river basin comprising a mining district in Cornwall.

Your special points of inquiry should, it is conceived, be, in the Thames Valley,—1. The condition of the river as affected by mills, weirs, and locks, and as affecting the drainage of towns and villages and adjacent lands. 2. The condition of the river, as affected both by the discharge of sewage from towns and villages, and the refuse of manufactories, paper-mills, &c., and the possibility of intercepting and rendering useful or innocuous these sources of pollution.

As to the other rivers mentioned, the same

object of the inquiry should be, bow far the use or abuse of the rivers is, under present circumstances, essential to the carrying on the industry of these districts? How far, by new arrangements, the refuse arising from industrial processes in these districts can be kept out of the streams, or rendered harmless before it reaches them, or utilized or got rid of otherwise than by discharge into running waters? In the course of these investigations you will make inquiry into the effect on health and comfort of the existing system of sewage of towns and populous places in the districts examined, and into the best mode of protecting individual and public interests in the purity of running water.

Secondary questions will, no doubt, arise contingent on these leading points, in which case you will include them, as far as it is necessary, within the scope of your inquiry."

ENGLISH CUSTOMS THROUGH FOREIGN GLASSES.

THE *Nazione* has the following remarks on one of our English customs:—

"Every London house is inhabited by one single family,\* and as the outer doors are always shut, the knocks at the door, counted from within, indicate the station in life of the person at the door: to give more or less knocks is an act of insolence or degradation. The milkman, sweep, hegg, the servants, knock with one single knock, as if to say, 'Allow me to come in.' Two knocks denote the postman, tax-gatherer, &c., and seem to say, 'It is my business to enter this house.' When three knocks are given, they indicate the master of the house or a friend of the family, and are given with an air of command, as if to say, 'Open.' Four knocks steadily given denote a person of consequence, some aristocrat, arrived in a carriage. These four knocks may be supposed to express, 'I intend to enter.' He who gives four knocks and, after a short pause, repeats them with a certain proud impetuosity, is decidedly either a milord or milady, an Indian nabob, a Russian prince, German baron, or Italian marquis. These seem to say, 'Open quickly—I wish to honour you with a visit.'"

MR. UNDER-SHERIFF BURCHELL AND RAILWAY COMPENSATION.

SIR,—In answer to your correspondent (page 488), Mr. Under-Sheriff Burchell is related to the firm of Messrs. Burchell, Westminster, Solicitors to the Metropolitan Railway; but he does not sit as assessor in cases where they are so concerned. J. R. B.  
North London Railway.

PREMIUMS AWARDED BY INSTITUTION OF CIVIL ENGINEERS.

THE Council of the Institution of Civil Engineers have awarded the following premiums:—

1. A Telford Medal, and a Telford Premium, in books, to J. W. Bazalgette, for his paper "On the Metropolitan System of Drainage, and the Interception of the Sewage from the River Thames."
2. A Telford Medal, and a Telford Premium, in books, to Colcott Kelly, for his paper "On Uniform Stress in Girder Work, illustrated by reference to two bridges recently built."
3. A Telford Medal, and a Telford Premium, in books, to E. Hele Clark, for his "Description of the Great Grimsby (Royal) Docks, with a Detailed Account of the Enclosed Land, Entrance Locks, Dock Walls, &c."
4. A Telford Medal, and a Telford Premium, in books, to Captain H. Whistley Tyler, R.E., for his paper "On the Fastening Railway for Passengers."
5. A Telford Premium, in books, to J. England, for his paper "On the 'Giffard's Injector.'"
6. A Telford Premium, in books, to T. Hawthorn, for his "Account of the Docks and Warehouses at Marselles."
7. A Telford Premium, in books, to E. Fletcher, for his paper "On the Maintenance of Railway Rolling Stock."
8. A Telford Premium, in books, to E. Johnston, for his paper on "The Chey-Air Bridge, Madras Railway."
9. A Telford Premium, in books, to Geoffrey Oates Mann, for his paper "On the Decay of Materials in Tropical Climates, and the Methods employed for Arresting and Preventing it."
10. A Telford Premium, in books, to W. J. Walker Heath, Assoc. Inst. C.E., for his paper "On the Decay of Materials in Tropical Climates, and the Methods employed for Arresting and Preventing it."
11. A Telford Premium, in books, to Joseph Taylor, for his paper on "The River Tees, and the Works upon it connected with the Navigation."
12. The Mackay Premium, in books, to H. Burdett Hederstedt, for his "Account of the Drainage of Paris."

\* Mistaken individual!—Ed.

COLOUR AND FORM.

'COUNT not antagonist to form  
The issue of the solar ray,  
Nor, prompt to theorize, deform  
Their iridescent grace away,  
And take from art's successful strife  
The evanescent buds of life.

In colour, robed by Nature's care,  
Creation's loveliest forms are seen;  
And sea, and sky, and terrene wear  
Blent harmonies of blue and green;  
And o'er obtrusive tints she lays  
A general monotone of haze.

Deep hidden in the soul of man  
The glorious tones of vision lie;  
And form and colour, one in plan,  
Raised Thebes' gigantic dynasty;  
Whose splendid beauty still commands,  
While Luxor lasts or Karnak stands.

This well the favour'd Grecians knew,  
And join'd the sister arts in one;  
Thus Pericles and Phidias drew  
The chaste and solemn Parthenon,  
And left us in their shrine to see  
How all things beautiful agree.

The natural homage of the mind,  
In sensuous youth or sated age,  
To neither race nor sphere confined,  
Seeks contrast sweet in every stage:  
Such contrast as the sun displays  
When morning breaks and night decays.

And shall we sever, e'en in thought,  
Such wondrous curves, such splendid tones,  
While yet those arts again are wrought  
By Gibson, Scott, and Owen Jones?  
No; let us hail in Britain's clime  
The Beautiful and the Sublime.

W. R. COOPER.

Working Men's College.

MR. FERGUSSON ON THE HOLY SEPULCHRE.

SIR,—Mr. Fergusson's work on the Holy Sepulchre is a reprint, with notes of two lectures on the subject, delivered by him at different times. The first of these lectures is principally devoted to the architectural argument; but in the second, he strives to prove his theory by evidence of an independent character.

It is certainly impossible that the sepulchre of Joseph of Arimathea, or, indeed, the site of the Crucifixion, should have been within the temple courts; and it is most improbable that the Basilica and other buildings of Constantine should have existed within that inclosure, if its limits were known in his time. Accordingly, Mr. Fergusson begins his second argument (that of Topography) by endeavouring to prove that the Mosque of Omar was always without the temple.

Leaving aside for the present the beautiful restoration of the tabernacle, and the descriptions of the temples of Solomon, Zerubbabel, and Ezekiel, with which Mr. Fergusson opens this part of his work, as having no immediate connexion with the point in view, the Temple of Herod first claims attention; and it will be unnecessary to prove that the Mosque of Omar was without the two former temples, if it can be proved that it was not within the boundary-wall of Herod's building; for the area of this last was much greater than that of Solomon's or Zerubbabel's temple.

That the temple did really cover some part of the great square commonly known as the Haram Inclosure, in which the Mosque of Omar now stands, Mr. Fergusson does not doubt; but that it occupied the whole area, as it is traditionally reported to have done, he does not believe; and the only question which he raises is, in what part of the inclosure to place it.

The length and breadth of the outer wall of Herod's temple, according to Josephus, was a furlong, or 400 cubits; but the length of the cubit has been differently determined, and there appear to have been two,—a longer one of 21 inches, and a lesser one of 18 inches, making the furlong to be either 600 ft. or 700 ft. Mr. Fergusson, however, considers that there cannot be much doubt which of the two was used in the measurement of the temple, and fixes the furlong, or stadium, as being 600 ft. The only question to be settled is, from which of the four corners of the Haram to measure this distance;

and on this subject, also, there is fortunately little difficulty. About 40 ft. from the south-west angle of the present wall are found the remains of an arch of enormous stones, which, there can be little doubt, must have belonged to the bridge which connected the royal palace of Herod with the king's cloister on the southern wall of the temple. From this corner, therefore, Mr. Fergusson measures a furlong north and east, inclosing a space which he considers to have been the largest ever covered by any of the three temples of Solomon, Zerubbabel, and Herod.

At the distance of a furlong from the south-west corner, and also on the western wall, are the remains of a second bridge, connecting the city and the temple; and between these two points the wall is built of those enormous stones which characterize the times of Solomon and Herod, and which also extend along the south wall of the Haram to the same distance of 600 ft., at which point the ground ceases to be solid, and the level platform is supported by a series of vaults, which Mr. Fergusson supposes to have been built at a much later date than the rest of the structures to the west of this point, and which he points out as being greatly inferior to the vaulted passage and hall of El Aksa within the temple inclosure. Thus, measuring from the ancient temple bridge, Mr. Fergusson places his temple in a part of the Haram where the remains of the megalithic masonry of Herod are found at the present day, and infers that the inclosure excluded the Golden Gate and the whole platform of the Mosque of Omar.

Mr. Fergusson has also another topographical argument, which he brings forward in his first lecture, namely, the position of the Mary Church of Justinian, which is described as being near the portico of Solomon.

Now Dr. Richardson has suggested in his travels that the site of this building may be marked by the present Mosque El Aksa, because under this edifice are found vaults similar to those described by Procopius as forming the sub-structures of Justinian's Church; and although, according to Mr. Fergusson, this is impossible, because there is abundant historical and architectural evidence to prove that the Mosque El Aksa is a Saracenic building of the seventh century, yet the description of the historian is so clear as to leave but little doubt concerning the position of the edifice in question; and the expression, "*Secus porticum Salomonis*," seems to place it, according to Mr. Fergusson, over the vaults already mentioned at the south-east corner of the Haram, which are called the stables or portico of Solomon. That Justinian's Church should have stood within the precincts of the "accursed temple," Mr. Fergusson considers impossible; but these vaults he has before shown to have been without the boundary-wall of Herod's building.

Now, if this Christian church was built here upon a level platform obtained by the erection of such enormous substructures, in a part of the city far from the Christian quarter and the numerous Christian edifices, in such close proximity to the "accursed temple," and altogether in so difficult and unexpected a situation, what could have been the reason of the erection there, unless that the Church of the Holy Sepulchre, the sacred Mount of Calvary, and the Basilica of Constantine were all situated in its immediate vicinity?

Thus, from the limits of the temple excluding the present mosque, and from the supposed position of Justinian's Church, Mr. Fergusson finds fresh proofs of the truth of a theory which he considers to have been already independently established. The answer to this second series of arguments is not more difficult than that to the first, and is, perhaps, more conclusive against Mr. Fergusson's theory.

1. The character of the masonry of the times of Solomon and Herod can be made out at the present time with a tolerable degree of certainty. The stones composing the exterior walls of the Haram are of two kinds, the first Cyclopean blocks of marble with rebated edges; the second, stones of even greater size, but plain and not rebated. The first is found below the second kind, and the great bridge of the royal cloister appears to have been built in the latter style of masonry. Hence it may safely be inferred that the rebated stones are those of the time of Solomon, and the plain stones the work of Herod. Now, in the vaults at the south-east corner of the Haram the piers are built of stones of the first order, the rebating being still plainly visible, although, owing to the damp and the trickling of the rain from the platform above,

most of the stones have become greatly disintegrated. The arches supported by these piers are of much later date, as in the case of the vaults of El Aksa. The colonnades formed by these arches run north and south, forming vaults, said by Mohametan tradition to have been erected by Soleyman, the son of Daoud.

These substructures are the eastern boundary of Mr. Fergusson's temple, but they are apparently of the same age as the vaults of El Aksa, which he allows to be ancient. His northern limit is the second bridge of Herodian masonry, leading to one of the four western gates; but, according to Mr. Fergusson's plan, half of it is within the temple enclosure, and the other half in that of the citadel of Antonia, to the north of the temple.

2. Mr. Fergusson informs us that the megalithic masonry extends between the boundaries which he gives for the temple; but he does not mention that the whole southern wall of the Haram to the eastern corner is composed of stones of similar character, and that the eastern wall to the north corner is also of the same masonry, especially near the northern end and on either side of the Golden Gate; that at the north-west angle of the present wall, the ancient corner, is also found; and that glimpses have been obtained of the same masonry all along the course of the western wall.

Again, Mr. Fergusson has placed the royal viaduct opposite the centre walk of the king's cloister, which would, indeed, be its position, if the greater cubit were used, but not if the lesser cubit were taken, which Mr. Fergusson considered to have been the case. Nor has Mr. Fergusson noticed that the length of this bridge, 350 ft., is an exact number of the larger, but not of the lesser cubit. He has also laid aside the words of the rabbis, who are more likely to be correct than Josephus, when they state the length of the temple-wall to have been 500 cubits, considering this expression to be a clumsy adaptation of the 500 *rees* of Ezekiel, which equals 3,000 cubits; yet the length of the present Haram wall is exactly 500 greater cubits, and all its foundations are of ancient masonry.

That Josephus should have understated the length of the temple wall in giving an approximate measurement (for in no case does he state the length in cubits) is not so impossible if we reflect that he probably never actually measured the distance, and that at the present day a difference of nearly 200 ft. has been made in actual measurement.

Again, if the distance of 500 great cubits be measured along the east wall of the Haram from the southern corner, which will bring us near to the Golden Gate, a change in the masonry will be found, and the stones, although still of the same antiquity, become somewhat larger and less polished. In this part, north of the temple, the tower and court of Antonia would be situated, the masonry of which would naturally be stronger and less ornamental.

This larger area given for the temple would include the Mosque of Omar within its limits.

3. It can be clearly proved from the words of Josephus that the inclosure of Antonia was nearly equal in size to that of the temple; and even if it were proved that the temple only occupied the smaller space of 600 ft., still the area of Antonia would include the Mosque of Omar and nearly half of Mr. Fergusson's Basilica; while, if the larger measurement be taken, the whole of the larger space would be occupied by the courts of Antonia. Now, it is quite as impossible that the sepulchre in the garden should have been within Antonia, as that it should have been in the temple; and quite as improbable that this spot should have been selected by Constantine as a likely one, as that any spot in the area of the court should have been chosen.

4. If it be the case that the church of Justinian was not within the temple, it is impossible that it should have been within the Haram, which was apparently all occupied by that building, and therefore all Christian associations with this part of the city are dissolved; while, before the expression "*Secus Porticum Solomonis*" can be made use of, it must be well understood what was meant by the "portico of Solomon" in the times of the writer.

5. Mr. Fergusson has appended to his topographical arguments a chapter on Local Indications; but among these must be noticed the indications given by the cavern of the Sacred Rock, which he supposes to be the Holy Sepulchre. It is certainly not a Jewish tomb; and, in fact, it is not a tomb at all, for there is no concub

loculus for the reception of the body, and in the centre is a well or drain, generally known by the name of the Well of Souls, whence has arisen the unsavoury hypothesis that the Sacred was originally a cesspool.

Such appears to be the answer to Mr. Fergusson's second train of argument, and only one more remains to be mentioned.

C. R. C.

#### MORE QUERIES ON STAINED GLASS.

1. Ought a stained-glass window to be composed of an innumerable quantity of little pieces of glass, of various and flaring colours, in order to produce the effect of a kaleidoscope? This is a very common thing in modern glass, but certainly not in old English, the best of all schools.

2. Is not this kaleidoscopic effect very vulgar?

3. Are not figures of rich subdued colours on a ground of silvery white quarry-glass the most beautiful and chaste in effect?

4. Which look best, single figures or subjects, in glass? Which are the most distinct? Can you keep confusion of colour out of subjects? If you treat subjects, must not figures be kept distinct?

5. Can bad colours ever be toned down by besmearing with black? Must not colours be originally quiet, good, subdued, richly cool?

W.

#### RAILWAY MATTERS.

The new railway route from London Bridge to Euston-square, by way of Waterloo and Kensington, which is intended to afford direct communication between the South Coast and the North of England and Scotland, has been opened. There will be ten trains each way daily (Sundays at present excepted), between Kensington and Waterloo, Blackfriars, and London Bridge stations direct, while there will be fourteen trains each way daily (on week days only) between Waterloo, Blackfriars, and London Bridge stations.

The Metropolitan District Railway, one of those sanctioned in the last session of Parliament with a view to connecting lines in London, has been begun at several points. Among these, that in Earl-street, Blackfriars, is 30 ft. below the London, Chatham, and Dover Railway; from thence it will pass beneath the new street to the Mansion House, and in a westerly direction along the new embankment of the Thames. The line, which will relieve the London and Brighton Railway Company's main line of the sole charge of traffic to and from the Crystal Palace, will soon be completed. It will use the terminus which is just opposite to the central transept of the palace.

The Act for the South Wales and Great Western Railway, which is to cross the Severn by a high-level bridge at Chepstow, has been passed. This line will facilitate the supply of coal to the metropolis, and therefore, in some partial degree, mitigate the effect of the recent rejection of the coal line of the Great Eastern Company, by which the interests of London and the Southern Counties were sacrificed in order to secure a monopoly to the North-Western and Great Northern Companies.

The traffic receipts of railways in the United Kingdom amounted, for the week ending the 24th of June, on 11,961 miles, to 707,980l.; and for the corresponding week of last year, on 11,605 miles, to 671,195l.; showing an increase of 356 miles, and of 36,785l.

#### FROM SCOTLAND.

Lockerbie.—The late Mr. Easton, of Chester, having devised certain funds towards the establishment in his native village of Lockerbie of a library and mechanics' institute, the foundation stone of the building has been laid with masonic honours. The new building will comprise lecture-hall or concert-room, reading-room, library, and keeper's house. The style of architecture may be termed Scottish Medieval. The front elevation presents to view the end of the hall, which is gabled, and contains two large and three smaller circular-headed windows; the front entrance-door is also arched and label-moulded. Over the doorway and at the side of the large gable of the hall a square turret is formed, in which the trustees contemplate placing a clock. The internal dimensions of the hall are as follows:—Length, 52 ft. 6 in.; width,

28 ft.; height from floor to ceiling, 29 ft. Accommodation is provided for about 400 sitters. The roof is open nearly to the ridge, the timbers of principals, &c., being shown, which will be stained and varnished. The total cost will be about 500l. The building is from plans by Mr. Alex. Fraser, Dumfries, architect; and the following are the contractors, viz., Messrs. John Edgar, mason, Dumfries; J. Thomson & Co., joiners, &c., Dumfries; J. & G. Corrie, plumbers, &c., Annan; E. Moffat, slater, Lockerbie; and Laidlaw, plasterers, Dalton.

Elgin.—The new court-house in Elgin has just been completed, at an expense of 4,110l., part of which has been given by Government, as has been the case with some other court-houses recently built in Scotland. The building has been erected to the east of the old court-house, and is close proximity to it. The style of architecture is Palladian. The court-house itself is 40 ft. long, 29 ft. broad, and 25 ft. high, and is lighted by eleven windows. The roof is panclled. The building is heated and ventilated on a principle applied by Mr. Farnell, engineer, Glasgow. The contractor for the building has been Mr. Stewart, Peterhead; the architects, the Messrs. Reid, Elgin; and the inspector, Mr. Mortimer. A new street is to be opened at the east end of the new court-house.

Lyntrick.—The foundation-stone of a new U. P. Church has been laid at Muggartburgh, on the estate of Lyntrick, Leochel-Cushnie. It is being built by the congregation presently worshipping at Baffle. The church is to be seated for about 350 persons, and will be a Gothic structure, built partly of dressed granite.

#### PROVINCIAL NEWS.

Windsor.—The foundation stone of St. Andrew's Convalescent Hospital, in connexion with the House of Mercy at Clower, has been laid. The site is nearly opposite to the House of Mercy, and the hospital is to accommodate 24 men, 18 women, and 15 children, together with the sisters in charge. The excellent objects of this charity are to provide careful nursing and medical attendance to invalids who are disqualified from admission to, or have been discharged from, ordinary hospitals; and, in cases of incurable disease, there is secured a quiet home during the remainder of life. The estimated sum required for all purposes is 12,000l., of which about 6,000l. have already been subscribed. The subscription list is headed by a donation of 100l. from her Majesty, who, besides, gives 20l. as an annual subscriber. One of the sisters of Mercy has also subscribed 2,000l.; and amongst the liberal subscribers are,—A Friend, 500l.; Hon. Mrs. Harris, 100l.; Hon. Miss O'Brien, 50l.; Lady Lonsa Greville and Lady Charlotte Greville, 40l., and an annual subscription of 55l.

Romsey.—The Town Hall and County Court Building Committee have received tenders for erecting the new town-hall and county court. Mr. Bedborough, of Southampton, the architect employed by the committee, attended. There were six contracts from builders, the respective amounts of which were as follow:—Mr. Dallimore, Fareham, 2,725l.; Messrs. Bull & Son, Southampton, 2,926l.; Mr. E. Prichard, Portsmouth, 3,122l.; Mr. Stevens, Southampton, 3,130l.; Mr. Till, Romsey, 3,350l.; Mr. G. Wheeler, Romsey, 3,450l. It was resolved that Mr. Dallimore's tender be accepted. The cost of the new building, as originally estimated, was 2,600l.; but since the framing of that estimate two or three alterations have been determined on, with a view to complete the accommodation of the building; hence an increase in the contract price. The building will be constructed in red brick with stone facings.

Worcester.—At a recent meeting of the City Council, the Markets Committee reported that they had advertised in each of the Worcester newspapers for tenders for re-constructing the roof of the market hall, in accordance with the plan and specifications of Mr. H. Bove, architect; that five tenders were sent in, and that the committee accepted the tender of Messrs. Hemming & Son to execute the work for 930l. The report was adopted.

Bradford.—The new eye and ear hospital has been opened. It has been erected from plans by Messrs. Lockwood & Mawson, at an estimated cost of 5,251l. odd. At the opening ceremonial Mr. J. Behrens, on the part of the building committee, said, "We had to consult the plans and descriptions of the newest general

infirmaries, and it was our aim to combine their best features with the peculiar wants of an institution devoted to the cure of diseases of the eye. For this purpose perfect ventilation was to be combined with a complete command of the light admitted. We hope that both purposes have been accomplished by allowing to each patient 1,500 cubic feet of breathing space, by having large sash-windows, open fire-places, by warming only the corridors by hot water, and by providing each window with close-fitting shutters, venetian and common blinds, so as to regulate the light according to the directions of the medical officers. This hospital possesses an advantage over every other similar institution, in an airy and convenient day-room, to be occupied by patients sufficiently recovered to be no longer confined to their beds and yet not allowed to go home. The washhouse under the building is completely separated from it by a brick arch, filled up with concrete, preventing every escape of steam or unpleasant smells into the part occupied by patients. A hoist connects the cellar with the kitchen, the scullery, and the upper story. The waiting, consulting, and ophthalmoscopic rooms, with the dispensary, are very conveniently situated."

**Pontefract.**—The foundation stone of a new town-hall at Knottingly has been laid. The hall, when completed, will also be used as a mechanics' institute.

CHURCH-BUILDING NEWS.

**Petistree (Suffolk).**—The church of this parish has been re-opened, having been closed for the purpose of re-paving, and the erection of a new pulpit, &c. The pews are of old English oak throughout, and are carved. The pulpit is an octagon, standing on a pedestal, carved, and the reading-desk is of open tabernacle work. The whole has been done at the sole expense of a lady resident.

**Edmondthorpe (Leicestershire).**—The parish church, dedicated to St. Michael, is about to undergo restoration. It has a lofty nave and spacious aisles; the south aisle containing several monuments to the memory of the family of Sir Alexander Smith. The works to be done comprise repairs to roofs, removal of old paving, to be replaced with oak benches, new pulpit and reading-desk, repairs to the handsome rood-screen, opening out the chancel arch, new windows in south aisle and in tower, re-banging the bells, new fence walls, gates, &c. It is expected that the necessary repairs and restoration of the chancel will follow. Mr. E. W. Johnson, of Melton Mowbray and Leicester, is the architect employed.

**Bassingbourn (Cambridgeshire).**—The church here has been restored and re-opened. It was found necessary to take down the whole of the nave and aisle, and these have been rebuilt upon the old foundations. The walls are faced externally with split flints from the neighbourhood, and have dressings of freestone. The ancient work has been copied where possible. Messrs. Nash, of Royston, were the architects, and Mr. Gibbons, of Buntingford, the contractor. The cost of the work is upwards of 1,700l.

**Easthampstead (Berks).**—The church in this parish being in a very dilapidated condition, the Rev. O. Gordon (the rector), the Marquis of Downshire, Sir W. C. Hayter, and other proprietors, decided upon rebuilding and enlarging the body of the church, and erecting a chancel. The work is now about to be commenced, under the direction of Mr. J. W. Huggall, of London, whose plans comprise a nave and a north aisle, with a transeptal chapel on the south, for the family of the Marquis of Downshire, and a chancel with south aisles, appropriated as an organ-chamber and vestry. The style adopted by the architect is Early Geometrical. The nave is 70 ft. by 27 ft.; the aisle, 11 ft. wide; the chancel, 36 ft. by 22 ft. The furniture in the nave, and the open timbered roofs, are to be of deal, varnished. The chancel fittings are to be of oak, and the floors will be paved with Maw's tiles. Accommodation will be provided for all classes in benches of one uniform character, and principally free.

**Kindbury (Berks).**—The Earl of Craven having conveyed to the Ecclesiastical Commissioners sites for a chapel of ease and parsonage at the Crossway, in the parish of Kindbury, a new edifice, to be called Christ Church, is in course of erection, and the corner-stone of the chancel-arch has been laid by the Bishop of Oxford. The sum required to complete the building is 2,500l.

The new building is distant about two miles from the parish church. The style selected is that of the Second Pointed period. The plan consists of a nave 66 ft. long by 25 ft. 6 in. wide; a chancel, 25 ft. long by 20 ft. wide, with a vestry and recess for an organ on the north side. The entrance to the church is under a tower at the south-west angle of the building, which breaks into the roof. The walls are to be built of brick, and the windows, weatherings, doorways, and copings are to be of Bath stone. The roof is to be covered with tiles of varied colour and pattern. The passages will be paved in tiles in patterns; the seats will be of deal, stained and varnished. The height of the nave will be nearly 50 ft., and the tower about 100 ft. to the top of the cross. The church is intended to hold 254 persons, and the sittings are nearly all free. It is intended to erect a school and house, as well as a small parsonage. The architect is Mr. T. Bury, of London. The stonework has been intrusted to Mr. Skates, of Newbury, and Mr. Cummer, of Kintbury, will execute the whole of the brickwork, tiling, paving, and plastering; and the carpentering work will be done by Mr. Cruse, of Kintbury.

**Headbourn Worthy (Wincchester).**—Headbourn Worthy church, portions of which it is supposed were built anterior to the Conquest, is undergoing a partial restoration, under the direction of Mr. Street, of London, architect. Mr. C. Fielder, of Wincchester, is the contractor. The floor of the church must be again raised: the one just removed was quite a foot above the original level, which would now, from the gradual accumulation of soil in the valley around, be quite under water.

**Arrow (Warwick).**—The Bishop of Worcester has consecrated the new north aisle and the memorial aisle of Arrow Church. The edifice, which previously comprised only a nave and chancel, has now been enlarged to accommodate about double the number, by the addition of a north aisle; a memorial aisle has also been erected, at the sole expense of the late Admiral Meynell. A stained window has been inserted in the eastern end to the memory of the late rector; the subjects represented being, the Good Shepherd, the Raising of Lazarus, Healing of the Cripple, and the Good Samaritan. There is also a smaller window of two compartments, representing the baptism and the temptation of the Saviour. This was the gift of Mr. T. Hubbard. A new school-house has also been built.

**Gloucester.**—At present immediate or early improvements are contemplated in three or four of the Gloucester churches. It would seem that the ancient parish church of St. Nicholas, a church possessing not a few features of antiquarian interest, but sadly disfigured by its multifarious pews, many of them in a state of rottenness and decay, much needs the like treatment. The dilapidated state of the roof and ceiling, and of the battlements of the tower, has at length rendered imperative immediate and extensive repairs. The dampness of the floor is to be remedied by raising it a foot, and repaving; and a re-contraction of the pews on a uniform plan, so as to give a large increase of free and comfortable accommodation, is contemplated. The walls of the church are still firm, and in the opinion of the architects who have the management of the work, the repairs and improvements now designed will make it good for another century. It will require at least 600l. to effect this work. The parishioners and congregation are combining with their minister to subscribe one-fourth of this sum; and some effective aid is counted on from ecclesiastical charities, but half the entire amount has to be sought for from other sources, and especially from the city and county.

**Newland (Gloucestershire).**—Some additions have recently been made to the church. Stained glass has been put in the west window. The subject is the Four Rivers in the Garden of Eden. On the chancel arch has been painted a representation of the Last Judgment. Over the centre of the arch is the figure of our Saviour standing in a circle, showing the wounds in his hands. On his right, and lower down the arch, are three circles, beneath which is the tree of life. The figure of the angel nearest our Lord is in the act of blowing a trumpet; while in the circle below is another angel holding a crown of glory in his hand; and in the third circle are four figures of saints carrying palm branches. On this side of the arch are birds of Paradise and flowers. To the left of our Saviour are three circles to correspond with those on his right. In the first is an angel blowing a trum-

pet; and in the next, another angel with a flaming sword in his hand, thrusting the condemned into the third circle, in the centre of which are flames of fire. Beneath this is the tree of knowledge of good and evil, round which the serpent is twined. The ribs of the arch are painted in colours relieved with gold.

**Frome.**—On the eve of St. John Baptist's day the completion of one of the chief portions of the work of restoration at the parish church was celebrated, viz., the tower and belfry. The whole of the tower has been strengthened and restored, and the bells have been re-hung and re-tuned by Mr. A. York, of Bristol. The chancel arch and nave roof will next be proceeded with, in conjunction with the west front.

**Llandudno.**—The chief stone of Trinity Church, Llandudno, has been laid. The design is by Mr. George Felton, architect for the Mostyn estate. The new church is to occupy a site near the railway station, will be built in the style prevalent in the thirteenth century, and accommodate, when the design is completed, 10,000 persons, the estimate being 7,000l. At present, as the funds are inadequate, the nave and aisles will alone be built, at a cost of 3,900l., the seat-room thus afforded being for 700 persons. The building will be of blue native limestone, set in cornices with freestone dressings, and have a tower and spire, and three entrances. It will be cruciform, and measure from east to west, 133 ft., inside measurement, the length of the transepts being 83 ft., and the width of nave and aisles, 58 ft. 6 in.; width of transepts, 27 ft.; of chancel with circular apse, 27 ft. 6 in.; and the greatest height, 52 ft. On the south side of the chancel, which will be lined with Bath stone, the spandrels between the windows having incised patterns, will be an organ. The building will be covered with an open roof, timbered, and stained and varnished. The interior will be lined with polychromatic brickwork and with stone dressings.

**Huddersfield.**—St. Bartholomew's church, Scammonden, Huddersfield, built to replace one erected in 1805, but in a very dilapidated state, has been consecrated by the Bishop of Ripon. It contains 380 sittings, and consists of nave, transepts, chancel, and tower, the latter being placed at the south-east corner, and serving as a vestry. The length from east to west is only 60 ft., being curtailed on account of graves and vaults at each end. The tower is surmounted by a broached spire, the height being 90 ft. from the ground to the iron cross and cock. There is a children's gallery, at the west end, entered by means of an outside staircase. The entrance to the church is by a south-west porch. The total cost, including value of old materials, has been 1,800l. The architect employed was Mr. E. W. Tarn, of London. The contract for the mason's work was taken by Messrs. Whitehead, of Massden; for carpenter's work, by Mr. Holroyd, of Stainland; for slating, by Messrs. Goodwin, of Huddersfield; and for plumbing and glazing, by Mr. Garton, of Huddersfield.

**Jarrow.**—Mr. Hudspeth's contract for rebuilding the nave of Jarrow church has been accepted by the Restoration Committee. A few hundred pounds are still wanting to complete the work. The committee, not wishing to run unnecessarily into debt, have let the contract without the fittings.

DISSENTING CHURCH-BUILDING NEWS.

**Stonstad Mountfitchet (Essex).**—The new Congregational Chapel has been opened for Divine service. The old chapel, which was pulled down in the latter end of last year, had been standing from about the year 1698, and was consequently in a very decayed and dilapidated state. The material of the new chapel is white brick, with stone dressings, and the style of architecture Italian or Lombardo-Venetian. The front entrance is approached by a circular-headed doorway to a porch paved with Minton tiles. On either side of this are projecting towers, surmounted exteriorly by finials, the doors through which form the entrance to the gallery, which is ascended by stone staircases. The protection in front of the gallery is of cast-iron, and open ornamental panels, the clock being in the centre; while the windows, which are circular-headed, are five on each side. The open hoarded roof is supported by queen-post trusses, stained and varnished, the exterior being slated. The area is filled with open deal benches of light-coloured oak, stained and varnished, constructed to hold 300, the present gallery about 200, and there is provision made for the erection of side galleries

when necessary, which will give 150 additional sittings. At the further end is a raised platform with circular front and open trellis work with mahogany rail, behind which is the movable and very low pulpit. The two vestries are divided by a movable partition.

**Faversham.**—The new Congregational chapel here has been opened. The new structure will accommodate about 500 persons. It is in the Gothic style. The pulpit is placed on a platform, and the seats are of the modern low-backed description. The chapel is situated in Mortimer-street, and has been built by Mr. Adams, of this town; the architect being Mr. W. F. Poulton, of Reading.

**Guernsey.**—The foundation stone of a new Wesleyan chapel was laid, on the 27th of June, at St. Martin's. The new edifice will face the road, and is to be constructed of red granite from Cobo, and in random masonry. The style will be Gothic; the coigne, millions, windows, tracery, and water-tables to be plastered with cement in imitation of Caen-stone dressing; the windows to be of rough plate quarried glass. The front of the building will have a large three-light window, with millions and tracery, and two smaller windows,—one on each side of the entrance porch. Four two-light windows on each side will admit as much light as is necessary for the congregation. The plan of the building will comprise two vestries or classrooms, at the rear, with other necessary accommodation for organ, &c. Without galleries there will be sufficient accommodation for 400 persons in the body of the edifice. The principal feature of the interior will be a Gothic arched ceiling, with a ventilator the entire length of the roof, and cornices at the spring. The whole of the woodwork will be stained in imitation of oak, and varnished. The cost of the whole is estimated at about 1,000*l*. The length of the building inside is 58 ft. by 37 ft. 6 in.; height from the floor to the top of the ceiling, 32 feet; entire height to the top of the roof, 40 ft. The erection has been undertaken by Mr. James Le Page.

**Harborne (Staffordshire).**—The new Baptist chapel here has been opened. It has been built upon the site of the old place of worship, and will accommodate some 300 people, as compared with 120 formerly. Provision has been made for enlargement, should it become necessary. Mr. A. B. Phipson was the architect of the building, which is in the Gothic style, cruciform in shape, with open-timbered and plastered between two towers, which rise at the two front corners of the chapel, and which form a prominent object in the building. All the seats are open; and the chapel is lighted by large windows. At the back are two rooms, which may be used as vestries or classrooms. The materials of the exterior are bricks, with Bath stone facings. Mr. W. Matthews was the builder; and the cost has been 2,000*l*. This includes the expense of a school-room, which is detached, and stands immediately behind the chapel. There will be accommodation for about 200 children.

**Over (Cheshire).**—The foundation-stone of a new Congregational church has been laid at Over. The new edifice is to accommodate some 500 persons, and the old one, which would contain no more than 300, is to be used as a school-room. The estimates for the building amount to 1,800*l*. The building is to be in a modified Gothic style, with a vestibule and columns in front, and an open-timbered roof. Its extreme length will be 70 ft. and its width 41 ft. From the ends of the vestibule staircases will lead to the galleries, which, however, it is intended to devote entirely to the organ and the choir. At the end opposite the entrance a platform will be erected, upon which the pulpit and communion-table will be placed, and the vestries will be, as usual, in the rear. The seats for the congregation will be made open, and will be constructed with a slight bend inwards, in orchestral fashion; at the same time the floor will descend some 18 in. from front to back, both these arrangements being adopted for the purpose of facilitating the circulation of sound. Above the pulpit a wheel window will be placed, which, together with the tracery of the east windows, will consist wholly of painted glass. The edifice is to be built chiefly of white pressed bricks, from the Farnley Iron Company's works, the facings for the windows, doors, &c. consisting of Rincorn stone, and the columns in the vestibule of Aberdeen granite. Mr. Douglas, of Chester, is the architect; and Mr. Dutton, of Over, the builder.

## SCHOOL-BUILDING NEWS.

**Bedford.**—St. Mary's Sunday-school has been opened. The site once formed part of the churchyard of St. Peter Dunstable. The school presents a gable end to the street containing a five-light window with a single independent light above. There is a smaller window of similar character at the opposite end, but none in the side walls on account of the adjacent buildings, some additional light being obtained by means of dormers. The material is red brick, which is shown internally without plaster, stone windows, &c., and open deal roof. The porch is attached on the west side. The plans were furnished by Mr. J. T. Wing, architect, and the contract has been carried out by Messrs. Winn & Foster, of Kempston.

**Hemel Hempstead (Herts).**—The memorial stone of new schools, in connexion with Marlowes Chapel, has been laid here. The building now in course of erection adjoins Marlowes Chapel. It is estimated that the cost of the new school-house, with all its fittings, will be 800*l*. The architect is Mr. James, and the builder, Mr. Seers, of Hemel Hempstead. The class-rooms, eight in number, will be on the ground-floor, and the large room above them will be 50 ft. by 30 ft. in size. The school-house will be simple in its architecture, though in accordance with the style of the chapel adjoining.

**Leigh.**—Leigh Sinton Church School is in progress. Mr. G. Warner, of the Link, is the builder. The building consists of what would be called, if it were to be used for a church service only, a nave and chancel: in the former the school-children will be taught, and in the latter—which will be shut off by a curtain—the service will be conducted. The entrance is on the west, by a porch. The materials in the building consist of bricks, with Cradley stone for window and door jambs and coigne. The roof is iron, and part of the floor laid. The windows in the school portion are Perpendicular in style, while those in the chancel, one on each side, are Early English lancets. The cost of the building is to be about 550*l*.

**Wolneggfield Heath.**—New schools, in connexion with the Wesleyan Chapel in this place, are about to be commenced. The contract has been let to Mr. Evans for 1,058*l*. 9s., including boundary walls and fittings. The architect is Mr. Bidlake, of Wolverhampton.

**Guernsey.**—The local *Comet* says that the foundation-stone of a new school-room, adjoining Morley Wesleyan Chapel, Guernsey, was laid on the 26th of June. This building will be of red granite from Cobo, constructed in random masonry, to correspond with contiguous buildings. The style is Early English Gothic, each gable being adorned with a decorated Caen stone finial. The roof will be an open one, and the exterior of the building strengthened with buttresses. It will contain sufficient accommodation for 200 children. For the purposes of ventilation the windows will be supplied with pivot sashes; but, in order to supply the requisite amount when the windows are closed in wet or stormy weather, a plan has been devised by which a constant current of air will be supplied along the skirting, and outlets also will be placed under the eaves, so that the desideratum of ventilation may be secured under all circumstances. By the erection of the new building, and the connexion of the former school-room with the chapel, ninety-three additional sittings will be obtained. The dimensions are as follows:—Length outside, 47 ft.; length inside, 44 ft.; inside span, 25 ft.; pitch of the roof, 52 degrees. The builder is Mr. Edward Hart; the architect is Mr. J. Crewe. The cost, it is expected, will not exceed 500*l*.

## RECENT PATENTS CONNECTED WITH BUILDING.\*

**MANUFACTURE OF BRICKS, TILES, &c.**—*S. S. Anderson.* Dated 24th October, 1864.—This invention consists in the construction, at the end of the pug-mill remote from that at which the raw material to be moulded is introduced, of a cylindrical chamber, the diameter of which is less than that of the pug-mill. Within this chamber, and mounted upon the revolving shaft of the pug-mill (which shaft passes into the chamber), the patentee places a double-threaded screw, large enough to fill the area of the chamber, allowance being made for the rotation of the screw within the chamber. This double-

threaded screw receives the clay or other plastic material from the pug-mill (where it has been tempered), and propels it in a straight and continuous stream through a die or dies fixed at the end of the chamber remote from the pug-mill.

**STOVES FOR HEATING PURPOSES.**—*A. Hippis.* Dated 14th October, 1864.—This stove is constructed of iron and brick in combination, and is fitted with metal doors. The grate or hearth is situated in the lower part, and is arched over or covered with a large fire-lump, having an opening in front or side through which the fuel is inserted above, and sometimes at both the sides and back of the fire space. The stove consists of a series of horizontal or vertical flues, which, being heated by the fire and smoke when ascending to the chimney, communicate their heat to the entire stove, which then in its turn radiates it throughout the apartment. The stove is closed by hermetical doors, which, when closed, exclude the draught and prevent all possible escape of any particle of hot air contained in the stove through the chimney. Below the fuel door is another one, also capable of being hermetically closed, through which a draught of air is conveyed below the flues, channels or passages in the brickwork of the stove, through which the external air enters, and, becoming heated in its passage, re-enters the room by one or more openings. This heated air may also, when desired, be conveyed from the stove, by flues or earthenware pipes, to any part of the house.

## Books Received.

## VARIORUM.

The new number of the *Quarterly* includes an article on "Sanitary Reform in the Metropolis," written by one who evidently feels the importance of the subject, and calculated to awaken attention to the matter in quarters where it has been heretofore disregarded. We shall hope to find it in future *Quarterlies* carried farther. The writer properly urges men of position and education to come forward and take their share in parish business. Again,—

"In order to give the medical officers of health in the metropolis that independent standing which is useful in effect, we would urge that they should not be liable either to be dismissed, or to have their salary reduced, without the consent of the Privy Council. This would be in accordance with the present position of the medical officers of unions, who can only be dismissed by the authority of the Poor-law Board, and who are certainly in no sense more important or more responsible functionaries. At present we hear strange tales of vestries threatening to cut down the salaries, to turn out the medical officer of health, if he be what they consider 'too busy.' If such things are true, there is an urgent call for improvement. But if such improvement is not to embrace one point only, but to be general and adequate, it can, as far as we see, be effected in but one of two ways,—either by developing and extending the jurisdiction of the Health Department of the Privy Council (at the risk of a centralization hardly in unison with English tastes), or by men of enlightened views and business habits putting their shoulder to the wheel, each in his own locality, in the administration of the sanitary laws of the metropolis. And why should not this be done?"

—"The Timber Importers', Timber Merchant's, and Budder's Standard Guide." By R. E. Grandy. London: Lockwood, 1865. The tables in the first part of this very useful volume are arranged with equivalent values for quantities in dollars, currency, and sterling, when referring to North American markets, and there are other distinctive features of mercantile arrangements recognised in the various North American and Baltic ports, referring to standard deductions, surplus measurements, and freights. The second part contains much valuable information for the builder and salesman;—lists of comparative values for joisting, flooring (plain, tongued, and grooved, or otherwise), with prices per leaf and square; lists for roofing, slating, lathing, stone-work, brickwork, painting, glazing, &c., with explanations and methods for finding number of squares, or other necessary quantities in building. The numerous short rules given are valuable, though some of them might have been a little more clearly rendered.—The last part but one of "Homes without Hands" (Longman & Co.) has been issued.—*Fraser's Magazine* for July (Longman also) contains a paper on the late operations on the Serpentine, in which an account of the engineering and other operations is given, with a running accompaniment of witty, sharp criticism, especially on the Office of Works. The writer remarks that "it would really seem as if everything connected with the recent attempts to improve this unfortunate water was fated to

\* Selected from the *Engineer's* Lists.

have about it a touch of absurdity; and he strongly condemns not only the "extravagant waste of money and the ridiculous disproportion or misapplication of means to ends," but also and most especially the irremediable "destruction of our fine old trees, another group of which has been fatally injured."

Miscellanea.

**CALAIS.**—At Calais, the famous old Fort Rouge has disappeared, only a few piles remaining; but it has been so often painted that its memory will remain in many pictures by Stanfield, Turner, and other of our eminent artists.

**A STRIKE.**—The whole of the carpenters and joiners employed in London and the neighbourhood by Messrs. Cubitt & Co., to the number of about 400, have struck for an advance of wages to the extent of 3d. an hour instead of 2d., as offered by the masters.

**OPENING OF THE RAMSDALE VALLEY BRIDGE, SCARBOROUGH.**—The greatest processional demonstration ever made in Scarborough was on the occasion of opening the Ramsdale Valley Bridge. The fallen girders of the iron lattice bridge across the Ouse at York were used in its construction. The contract for the work was taken by Mr. Ald. Cahry, of York, under the direction of Mr. E. Clarke, the engineer. The bridge is now completed, with the exception of a few minor details, and it has been opened as a public toll-bridge.

**ERECTION OF A POLICE STATION FOR THE S DIVISION.**—A new station for the S division of police is in course of erection, in Albany-street, Regent's Park, it having been found that, in consideration of the extensive space of ground the force has to perambulate on duty, there was not sufficient accommodation at the station which was its rendezvous. It will afford accommodation to about thirty single men, while stabling will be built for the horses of the patrol.

**ROYAL MASONIC INSTITUTION FOR BOYS.**—The new school for boys in connexion with this Institution was inaugurated on Saturday last. It is situated at Wood-green, Tottenham. It is intended to accommodate 150 boys—sons of deceased and distressed brethren—and when completed will have cost about 30,000l. Earl de Grey and Ripon, R.W. Deputy Grand Master, and Provincial Grand Master for West Yorkshire, presided. The Secretary (Mr. Binckes) announced that the result of the day's festivities, so far at least as could then be approximately ascertained, was the receipt of 6,500l. towards the 10,000l. which the committee had anticipated realising. The total amount would probably be 8,000l., when the promised donations came in.

**WEST LONDON WORKING CLASSES INDUSTRIAL EXHIBITION.**—With reference to a remark in the *Builder* of last week, the secretary writes,— "The agreement with Mr. Gye for the Floral Hall only being ratified a fortnight or so before our opening day caused great haste, and consequently some oversights in the arrangements. I can assure you it was the desire of the committee to pay proper attention to the press. I must add that the high prices charged for the first week was a compromise with Mr. Gye, who sought to keep them high throughout, and who, by the nature of the agreement, has a voice in the fixing of the prices. Mr. Peter Graham and Mr. Thos. Lucas being appointed arbitrators, in case of differences between the committee and Mr. Gye."

**THE METROPOLIS SEWAGE AND ESSEX RECLAMATION COMPANY** has been announced, with a capital of 2,100,000l. The prospectus is introduced to the public by the International Financial Society, and the object is to utilize the sewage of the northern area of the metropolis, the concession of which has been granted to Messrs. Napier & Hope, who have agreed to part with it to the company for 50,000l., "in fully paid-up shares of the company, and a small contingent-percentage of the net profits." A contract has been entered into with Mr. William Webster (who has constructed more than one-third of the Main Drainage Works of the metropolis, including the Crossness Outfall) for the construction of the works mentioned above, together with the necessary pumping-stations, for the sum of 1,853,418l.

**SASH-WINDOW.**—Unlike the window that opens and shuts on hinges, and with a horizontal movement, the sash-window works up and down like a *sluice*. Hence, I have always thought that sash-window meant sluice-window, *Sasse*, in old English, a *sluice*: so, in Dutch, *sas*. Sash-window = *sasse*-window. — *Notes and Queries*.

**THE TYNDALE MONUMENT.**—It may be remembered, that some time ago, after the monument to Tyndale, on the Nibley Knoll, had been in great part erected, the construction proved to be faulty, and part came down. Fresh efforts have been made, and the foundation-stone of the erection has been relaid.

**FÊTE FOR THE ROYAL DRAMATIC COLLEGE.**—In aid of the "poor player" let us mention and ask attention to the fact that this annual fête will be held at the Crystal Palace on (this) Saturday, the 15th, and Monday, the 17th. Richardson's Show, Womwell's Menagerie, Messrs. Toole and Paul Bedford, a Circus of all sorts of odd lectures and songs, will fill the day with fun and it, may be hoped, the coffers of the charity with *haser metal*.

**VALUE OF CAMBRIDGE PROPERTY.**—There can be no doubt, says the *Cambridge Chronicle*, as to the increasing value of freehold building ground and house property in Cambridge: only on Wednesday last Messrs. Wentworth & Son brought into the market, for sale by auction, about three acres of land, on the Mill-road, near Parker's Piece, which was planned and arranged in fifty-three lots, every one of which was sold at a large price, and they realised in all the sum of 3,245l. The chief portion was purchased for Cains College, who have land adjoining.

**THE NEW SEWAGE ACT.**—The Act to facilitate the more useful application of sewage in Great Britain and Ireland is issued. It recites that it is expedient to remove difficulties under which local boards and other bodies having the care of sewers labour, in disposing of the sewage in their districts so as not to be a nuisance, and to give facilities to such authorities to make arrangements for the application of sewage to land for agricultural purposes. There are various provisions in the Act. The sewer authorities are to prevent the pollution of streams, and to dispose of the sewage.

**COLOGNE EXHIBITION. — STEAM FIRE-ENGINE TRIALS.**—At the recent competitive trials of steam fire-engines at the Cologne International Exhibition there were exhibited four steam fire-engines, two being of English, one of American, and one of German manufacture. Messrs. Merryweather, of London, have carried off the first prize of 500 thalers, placed in the hands of the Exhibition committee by the Colonia Fire Insurance Company to be awarded to the makers of the best steam fire-engine, as well as a diploma certifying that they have received the first prize for the best steam fire-engine. Messrs. Merryweather's engine raised steam from cold water, and commenced working with 100 lb. pressure in 7 min. 25 sec. from the time of lighting the fire, weighed one ton less, and was of considerably less cost than either of the other two competing engines. The German engine was considered out of the contest, as its jet failed to reach the water-target efficiently.

**AMALGAMATED SOCIETY OF OPERATIVE CARPENTERS AND JOINERS. BRADFORD BRANCH.**—On the 4th inst. a meeting of operative carpenters and joiners of Bradford was held in the Teetotal Hall, Southgate, for the purpose of witnessing the handing over to one of their number, a member of the above society, of the sum of 100l., a benefit to which he had become entitled (though he had been only one year a member of the society), through having his hand cut off. Mr. C. D. Dewhirst, president of the branch, occupied the chair, and spoke strongly in favour of their society, as having increased their wages and shortened their hours of labour, and urged all present who were not members to join it. He then called on Mr. R. Applegarth, general secretary of the society, from London, who made some remarks on trade societies, their history, and purposes. He contended that the interests of masters and men were not in fact identical, nor ever could be so, but were opposed. Nevertheless, he said, no one felt more strongly than himself the necessity of a good understanding between employers and employed.

**A HIGHLAND LODGE FOR HER MAJESTY.**—A new lodge is in course of erection, for the convenience of her Majesty and attendants, in Glengelder. It is to be on a pretty extensive scale, and is to be built of granite.

**OAK CARVING.**—Several specimens of oak carving, for the reredos of Cliphsham Church, have just been completed, by Messrs. Richardson, of Stamford, according to the *Lincolnshire Chronicle*, which says,— "One piece, representing the Last Supper, is especially worthy of commendation, and we hope to see it in the forthcoming industrial exhibition at Nottingham. The carving has been done by a workman named Rippin, in the employ of Messrs. Richardson."

**THE HOTEL MOVEMENT.**—The Duke of Cornwall Hotel, according to the *Devonport Independent*, has been opened. There are more than two hundred rooms in the house, nearly all of them luxuriously fitted up. The dining-rooms are decorated, and there are smoking rooms, ladies' coffee saloon, &c.; and a fine view is obtainable from an observatory erected on a tower at the west end of the building.

**MASTERS AND SERVANTS.**—The select committee on masters and servants agreed to the following report:—"That, inasmuch as the state of the law of contracts between masters and servants is a subject of the highest importance, affecting as it does the relations of employers and employed throughout the kingdom, and any inquiry as to the operation of the law should be full, searching, and complete; and inasmuch as there is no probability of your committee being able to complete such inquiry in the present session, it is desirable that the evidence, so far as it has been already taken, should be reported to the House, accompanied by a recommendation that a committee should be appointed in the next session of Parliament to consider this subject."

**WIDENING THE POULTRY AND NEWGATE-STREET.**—At the last court of Common Council, Mr. Stewart moved that it be referred to the improvement committee to consider whether any steps could be taken, in reference to the present condition of the property on the north side of the Poultry, to widen and improve that important thoroughfare. Deputy De Jersey, the chairman of the Sewers Commission, said that they had found that it would take such an enormous amount of money to purchase the property, that they could not venture to tax the ratepayers to such an extent. The motion, however, was agreed to. Mr. De Jersey next brought forward a motion having reference to certain improvements that had been effected by the Commissioners of Sewers by setting back several of the houses in Newgate-street, and with a view to obtain a contribution from the corporation funds in aid of these improvements. This gave rise to a discussion, but in the result the motion of Mr. De Jersey was agreed to by a majority of 36 upon a division.

**COVERED YARDS.**—That cattle kept in covered yards enjoy better health than others kept where the cover is only partial, is established by abundant evidence. In support of this view, Mr. J. G. Marriage, of Ham Farm, Redhill, says,— "Our holdings are 130 ft. by 103 ft., and afford accommodation to 180 head of stock; and, to give you an idea of the health they enjoy, I may say that, for the last seven years, the farmer's bill has not averaged 20s. per year." By far the greater proportion of ordinary farm-yard manure consists of straw and water, the remainder being the excrements of the cattle. Under cover, about 20 lb. of straw per diem is found litter sufficient for one animal; in open yards, more than twice that quantity is required. It would be superfluous to dwell on the deteriorating influence exercised by rain-water falling on manure, or the great loss incurred by exposure to its washings. The curious in this matter will find ample information by referring to the researches of Way, Voelcker, and other modern writers on Chemistry. Mr. Chancellor says:—"The late Mr. James Beadell always stated, as the result of his lengthened experience (and he might be considered as one of the pioneers of the system), that one load of covered-yard manure was worth more than two loads of open-yard manure. Its tendency to get dried and heated has always been advanced as an argument against covered yards by those who have not tried them; but I never heard it used by any one who had. The truth is, it keeps infinitely moister than in open yards in a dry season."—*Bridgegate Mercury*.

**MONUMENT TO PEDRO IV. AT LISBON.**—Two French artists, M. David and M. Robert, have obtained the first prize in this competition; a native artist obtained the second; another French sculptor the third; and the fourth and fifth were awarded to Italians. The monument will consist of four parts,—a basement of granite, a pedestal, a column, and a statue. The column is decorated with four figures of fame, in bas-relief, on its lower portion, and these figures are connected together by garlands. The figure of Don Pedro IV., dressed in a general's uniform, is to be 10 ft. high, cast in bronze, and gilt by the electro-galvanic process. The entire monument will be nearly 140 ft. high.

**SCHOOLS OF ART.**—At Chippenham, a public meeting, convened by the mayor, has been held, at which Mr. Buckmaster, from the Science and Art Department of the South Kensington Museum, attended, and addressed the meeting in favour of establishing a school at Chippenham. The mayor said he was pleased to state that gentlemen whom he had called upon for subscriptions had liberally responded to his appeal. The meeting was not largely attended; but a number of artisans present expressed their opinion that a drawing-class should be formed without delay.—At Abingdon, also, the lecture given at the end of last season by Mr. Buckmaster appears likely to bring forth good results.—Mr. J. K. Leake, of Cokhill, near this town, who was present at that lecture, having taken action in the matter of the formation of a branch School of Art in the town. A preliminary meeting was called by that gentleman, and it was resolved unanimously—"That it is desirable to form a branch School of Art in Abingdon." A provisional committee was formed to make the necessary inquiries, and to report to another meeting.

**SALES OF PROPERTY.**—At Garraway's, by Messrs. Toplis & Harding.—One undivided moiety of and in the leasehold house with shop, being No. 57, Quadrant, Regent-street, let on lease at 250l. per annum, term 75½ years from 1818, and a reversionary term from 1894 of 23½ years—2,000l. Leasehold stables and premises, being No. 15, Swallow-street, Piccadilly, let on lease at 150l. per annum, term 99 years from 1818, ground-rent 16l. per annum—1,800l. At the Guildhall Coffee-house, by Messrs. Norton & Trist.—Freehold house, being No. 18, Bennett-street, Stamford-street, Blackfriars-road, let at 30l. per annum—500l. At Curraway's, by Mr. Peake.—Freehold house, situated in Queen-street, Southwark, let at 31l. 10s. per annum—500l. Freehold building land, comprising an area of 1,150 superficial feet, situated in Mint-street, Southwark—190l. By Messrs. Kemp.—The rectorial titho-rent charges, commuted at 550l. per annum, near Dartford, Kent, together with the parsonage house and the Manor or Court Lodge Farm, containing about 395 acres, and producing 691l. 10s. per annum—10,150l.

**NATIONAL ASSOCIATION FOR THE PROMOTION OF SOCIAL SCIENCE.**—The annual business meeting of the members of this Association was held on the 6th, at their office, Adam-street, Adelphi, Mr. Godwin in the chair. The report stated that in consequence of the dissolution of Parliament, the annual meeting was held this year at an earlier date than usual, but the council were enabled to wind up the financial and other business of the Association in a very satisfactory way. The meetings during the year had been generally well attended. The permanent income of the Association had increased this year by 134l., but there was a decrease in the total receipts. The balance-sheet showed a total receipt of 2,167l. 16s. 5d. After defraying all expenses, there remained a balance of 64l. 14s. 1d. In July, 1864, the balance in hand was 364l. 6s. 5d., which showed a falling off of something like 300l. The assets of the Association were estimated at 1,544l. 11s. 7d. The total liabilities amount to 424l. 0s. 6d., which left a surplus assets of 1,120l. 10s. 1d. The adoption of the report having been moved, Mr. G. W. Hastings, general secretary, explained that the falling off in the total receipts was not in any degree to be attributed to a want of prosperity, and stated that the Association was never in a more flourishing position. The chairman, in putting the motion, congratulated the society on the very interesting papers which were read at the evening meetings during the year. The report was unanimously adopted, after which the election of officers, standing committees, &c., was proceeded with. Lord Brougham was re-elected president.

**ABOLITION OF MORE TURNPIKE GATES AND BARS.**—By the Turnpike Continuance Act, just passed, every gate and bar in the south metropolitan area (except the Greenwich and Woolwich Lower-road Trust and the Dulwich College gate) will be levelled on the 1st of November next. The removal will extend into the three counties of Surrey, Kent, and Sussex. Provision is also made in the same Act for the removal of the archway gate in the Kentish Town Junction-road on the 4th of August next; and it also fixes the 1st of November, 1866, as the day for the expiry of the Greenwich and Woolwich Lower-road trust and the Middlesex and Essex trust, unless a private bill be obtained for a prolonged term. The total number of gates and bars which, including last year, will be removed on the 1st of November from the metropolis and neighbourhood will be 143, and the length of roads set free, 164.

For three pairs of villa residences, at Brixton. Messrs. Pain & Clark, architects. Quantities not supplied:—

Wardle & Baker	Each pair
Stone & Pearce	2,310 0 0
	1,900 0 0
	Three pairs.
Lamble (accepted)	4,767 0 0

For additions to the Organ factory of Messrs. Brycecon, Brothers, at Brook-street, Euston-road, for the adaptation of steam power. Messrs. Pain & Clark, architects. Quantities supplied:—

Manley & Rogers	£457 0 0
Lawrence, Baugh, & Co.	449 0 0
Wardle & Baker	437 0 0
Bowe	412 0 0
Lamble (accepted)	383 0 0

For new church at Ebernoe, near Petworth, Sussex, for Mr. Wm. Frisley. Messrs. E. Habershon, Spalding, & Brock, architects:—

Woodridge	£1,150 0 0
Simpson (accepted)	1,009 0 0

For St. Andrew's Mission Church and residence, North Bromley, Middlesex. Mr. John W. Morris, architect:—

Black & Son	£1,967 0 0
Sheffield	1,618 0 0
Heiser	1,610 0 0
Ennor	1,585 0 0
Hedges	1,549 0 0
Kilby	1,525 0 0

For three dwelling-houses, Devon-road, Bromley, Middlesex. Mr. John W. Morris, architect:—

Kilby	£725 0 0
Hopkins	705 0 0
Stevens	675 0 0
Heiser	630 0 0
Sheffield	607 0 0

For house and offices, Silver-hill, Hastings, for Mr. A. J. Wollaston. Messrs. Voysey, Jeffery, & Skiller, architects:—

Simons & Marten	£3,985 0 0
Hopkins	2,849 0 0
Page	2,825 8 0
Roddie	2,562 0 0
Broadbridge	2,781 4 3
Catt & Co.	2,737 0 0
Howell	2,587 0 0
Homan (after time)	2,568 0 0
Kenwood	2,493 0 0

For finishing tavern, and erecting and finishing two villas, Lancaster-road, for Mr. J. Davis. Mr. R. Stap, architect:—

	Tavern.	Villas.
Green (accepted)	£290 0 0	£1,690 0 0

For additions and alterations to house at Feitcham, Surrey, for Mr. William Sturt. Mr. F. J. Dibble, architect, Dorking:—

Spicer	£245 0 0
Batchelor	709 0 0

For dwelling-house at Mersham, Surrey, for Mr. J. P. Maynard. Mr. F. J. Dibble, architect:—

Francis (accepted)	£390 0 0
--------------------	----------

For lodge, cottage, walls, gate, &c., at Ashurst Headley, for Mr. R. A. Glass. Mr. F. J. Dibble, architect:—

Haynes	£1,003 0 0
Inkpen	808 0 0
Lynn & Dudley	760 0 0
Hamblin (accepted)	750 0 0

For the erection of the first portion of Messrs. Winstor & Newton's new artist's colour factories, in Spring-place, Kentish Town. Mr. F. Fred. Holoworth, architect:—

Gammon	£3,147 0 0
Fish	4,940 0 0
Lawrence	4,719 0 0
Manley & Rogers	4,487 0 0
F. Anson	4,203 0 0
Tracey & Son	4,185 0 0
Scribner & White (accepted)	4,125 0 0

For the erection of Percy Villa, Bromley, Kent, for Mr. W. Hewett. Mr. W. F. Potter, architect:—

Outwaite	£785 0 0
Tosser	700 0 0
Southall & Watson	685 0 0
Honour	630 0 0
Peerless (accepted)	600 0 0

For new bar fittings and alterations to the Prince of Wales Tavern, East-road, City-road, for Mr. Wallace Ritchie. Mr. W. F. Potter, architect:—

Sited	£379 0 0
Sahey & Son	350 0 0
Williams	349 10 0
Moore	335 10 0
Warne	309 0 0
Jenkins	319 0 0

For house and offices at Reigate, Surrey. Quantities by Mr. James G. Smith:—

Haward (accepted)	£3,740 0 0
-------------------	------------

For Fairfield House, Stoke Poges, for Mr. J. W. Hanson. Mr. J. L. Pearson, architect. Quantities supplied by Mr. T. M. Rickman:—

Shoppee & Son	£7,275 0 0
Macers	5,945 0 0
Gibson	5,863 0 0
Snowball	5,667 0 0
Sharpton & Co.	5,533 0 0
Fessenden & Son	5,394 0 0
Coles & Nelson	5,230 0 0
Nicholson	5,190 0 0

For new premises, Broad-street, Hereford, for Mr. Thomas Landon. Messrs. Elmslie, Franey, & Haddon, architects:—

Mason (accepted)	£3,575 0 0
------------------	------------

For premises, High-street, Hereford, for Mr. E. Smith. Messrs. Elmslie, Franey, & Haddon, architects:—

Welsh (accepted)	£721 0 0
------------------	----------

For restoration of church at Rowlestone, Herefordshire. Messrs. Elmslie, Franey, & Haddon, architects:—

King & Godwin (accepted)	£353 0 0
--------------------------	----------

For additions and alterations to Beauchamp Hotel, Great Malvern. Messrs. Elmslie, Franey, & Haddon, architects:—

Smart (accepted)	£1,035 0 0
------------------	------------

For additions to vicarage house, Dilwyn, Herefordshire, for the Rev. W. Heather, LL.D. Messrs. Elmslie, Franey, & Haddon, architects:—

Lewis & Day (accepted)	£380 0 0
------------------------	----------

For new parsonage, Lingen, Herefordshire. Messrs. Elmslie, Franey, & Haddon, architects:—

Ford (accepted)	£430 0 0
-----------------	----------

**CHURCH, TURRET, AND STABLE CLOCKS.**  
J. W. BENSON, having erected steam-power and improved machinery for clock-making, at the manufactory, Ludgate-hill, will be glad to furnish to clergymen, architects, and committees, Estimates and Specifications of every description of Horological Machine, especially cathedral and public clocks, chiming tunes on any number of bells. A descriptive pamphlet on Church Clocks post free for one stamp. Watch and Clock Maker by Warrant of Appointment to H.R.H. the Prince of Wales, and maker of the great clock for the Exhibition, 1862. 33 & 34, Ludgate-hill, E.C. Established 1749.

# The Builder.

VOL. XXIII.—No. 1172.

Out and About :  
The Grove, Watford.

Is there anything to see near Watford? writes a correspondent. "We want an outing, and love trees, old buildings, and pictures." Anything to see! Of course there is. In fact, with such likings, there are few places in England where "something to see" could not be found. The railway ride from London, to begin

with, is a pretty one, including a fine view of Harrow; passing which, though the churchyard is scarcely discoverable, the mind's eye may see Byron lounging, and recal his reference to the practice when he afterwards wrote,—

"Or when oppress'd with sad foreboding gloom,  
I sat reclined upon our favourite tomb,"

Pinner and Bushey, too, both give pretty landscapes. At Watford, the church has two or three points of interest, including some monuments by Nic. Stone. The places, however, where trees and pictures are to be seen are Moor Park, the residence of Lord Ebnry; Cassiobury, belonging to the Earl of Essex; and, above all, The Grove, the seat of the Earl of Clarendon—all within an easy drive. The house at Moor Park, in pseudo-classic style, was built by Giacomo Leoni, a Venetian architect, who settled in England, and built, among other things, a considerable addition to the Elizabethan pile, Lyme Hall, in Cheshire. He died in the middle of the eighteenth century. The chief feature of the house is the Hall, the whole height of the building, painted originally by Thornhill, with deceptive openings in the roof, and subjects from Ovid in the panels below. There are two or three interesting pictures, some fine models (in porcelain) of pagodas, and a capital sculptured marble chimney in the drawing-room, whereof the frieze of sculptured white marble figures, with a hack-ground of lapis-lazuli, is exceedingly well executed. The gardens and grounds are charming. The statement is, that they were first laid out by Lucy Waters, Monmouth's mother, and altered by "Capability" Brown, who may be called the first that practised landscape gardening in this country as an art. "The place has capabilities," said Brown usually, when first called in to look at it, and so he got his name. It was in 1773 that he died.

For even finer foliage and some extensive sweeps, get on to Cassiobury. The variety here is great, and some of the trees are mighty. A new poet has described such a scene as may be found here, and hit off very admirably the characteristics of the component features. Above,—

"Some ancient Pines, their limbs fantastic spread,  
And rich warm perfume in the sunshine shed;  
Each tufted branch was edged with lighter green,  
And redly bright their rough stems glow'd between.  
The toppling Larch their welcoming arms held out  
To myriads of their fellows; while, without  
Sufficient air to stir their pensile threads,  
The Silver Birch inclined their graceful heads.  
The smooth-barked Beech, trailing its branches down  
Like garlands; and the Mountain Ash, whose crown

Of shining fruit had ripen'd in the sun,  
Though summer's hottest days had setree begun.  
And, nearer still, the Oak threw plots of shade,  
While at their feet a fragrant couch was made  
Of graceful Fern, which shov'd in high relief,  
As the bright sunshine stream'd through many a leaf.  
The stately Lime at intervals was seen,  
A faultless cone of fresh and brilliant green,  
Rising majestic from the turf-spread ground,  
On which its lower branches rested round.  
The Wych-elm, with its ev'ry limb leaf-fringed;  
The Sycamore, already golden tinged;  
And o'er the sloping lawn, that downward led,  
Their gorgeous masses, noble Cedars spread."

Under one of the trees, when we were pacing the park, reclined a shepherd, a creature very different from the vision of the poets in that direction. Sad deceptions dogs are some of these poets! "I see you have your crook, shepherd," once said a gushing young lady, on Brighton Downs; "but why have you not your pipe?"—"Because I've got no haccy, marm," was the less poetic reply.

"While the ploughman, near at hand,  
Whistles o'er the furrow'd land,  
And the milk-maid singeth blithe—  
And the mower whets his scythe—  
And ev'ry shepherd tells his tale—  
Under the hawthorn in the dale.

Hard by a cottage chimney smokes,  
From betwixt two aged oaks,  
Where Corydon and Thyrsis met,  
Are at their ev'ry dinner sat,  
Of herbs, and other country messes;  
Which the neat-handed Phyllis dresses;  
And then, in haste, her how'r she leaves,  
With Thestylis to bind the sheaves."

So sings Milton, and sweetly fall the words in their true measure, like pleasant music on the ear, and most temptingly does the description lead the thoughts of the pent-up town dweller to delicious country scenes, while the landscape painter is urged by the description to seize his pencil and palette, and endeavour to give permanent form to those images which the great writer brings so vividly to the mind.

But painters and poets are prone to look only at the silver side of the cloud and the sunny aspect of the landscape; and it is feared that Milton, Thompson, and other of our descriptive poets would not feel delighted by too long interviews with the majority of the ploughmen, milk-maids, and shepherds of the present time, who labour in the rich rural districts of "Merrie England." It usually turns out, that the first sight of objects which are known only from poets' descriptions are disappointments. For instance, the actual raging of the sea—even on our rough northern coast—is, when seen in reality after a long course of reading, disappointing. In this, however, as it is with other natural phenomena, the reality impresses the mind to a greater extent the more it is studied. But our experience does not prove that this is the case generally with shepherds and shepherdesses. We well remember meeting, years ago, with a shepherdess in one of the English border counties, and certainly few female forms could be readily found which presented a more unlovely appearance: the rough guttural speech, the peculiar dialect, the common-place matter-of-fact ideas, the rude, unpicturesque, and not over clean costume, and the large, ungainly, and clumsily-shod feet, formed a most unpleasant contrast with the shepherdess of the poets. We have met with intelligent shepherds, who, like experienced seamen, have studied the phases of the weather and the peculiarities of the seasons; but, as a rule, in comparison with the advanced intelligence of the age, shepherds, milkmaids, and ploughmen are disappointing if we gauge them by the poets' descriptions.

From cottages backed by trees, overgrown with roses and creeping plants, come sickly, pale-faced children, and, with them, the neat-handed Phyllis, more attenuated, careworn, and sickly-looking than the rest: in the rich fields are groups of children labourers who are let to ill-mannered and ignorant men, who dispose of them in gangs at a fixed price per head; and, after the hours of labour are ended, herd the untaught boys and girls without care

together. While on the roads the "weary ploughman" and other labourers of the farm may be seen wending their way to dwellings which are not fit for human habitation in the undrained villages or in the hack-slums of the neighbouring towns.

It is inharmonious, amid all the beauty of the vegetation, the fields of waving corn, and luxuriant grass lands, to see the neglected and worn-out labourers, who, in days gone by, have whistled at the plough, bending beneath their hundo of fire-wood or some other harden; and to find pent up in the workhouses, such multitudes of worn-out men and women, who, from their slender earnings, have with difficulty reared a family: the family themselves unable to assist their parents. To save upon the slender means which have been afforded by their labour, under the circumstances, was an impossibility; so that, when no longer able to work, the union is the only resort; and, in old age, those who have been solemnly joined together, are separated by the harsh working of the poor-law system, before their earthly pilgrimage has been completed. Most exquisitely beautiful are our English landscapes, and well worthy of the poet's best praises; but how greatly would the delight of exploring be increased if the human workers could be made to take their right position and to harmonise with it, by means of improved dwellings, better education, and a remuneration for labour; instead of being, as they are now, a blot upon the fair face of nature.

We are forgetting however the advice of the poet, who says—

"Digressions are inexpressibly bad;"

and as we have not the purpose with which Swift asserts that Dryden's "prefaces" were written,—

"Alone for filling;  
To raise the volume's price a shilling,"—

we may as well continue our ramble.

The House at Cassiobury (the name takes us back to a very early period in the history of the tight little island—to the days of the *Cassii* and struggles with the Romans), is a modern Gothic pile of the time of the early revival of the Mediaeval styles amongst us, the beginning of the nineteenth century, and, viewed by our present lights, is a tame and tasteless affair,—now undergoing repair. It is interesting to trace the progress of this revival from the days when poet Gray, Warburton, Warton, and Essex wrote, and Walpole (from 1750 to 1776) built his Strawberry Hill; but now is not the moment to dilate upon it.

It was a charming and cheering day when we were at Cassiobury; an afternoon that would justify Longfellow in again singing,—

"O gift of God! O perfect day:  
Whereon shall no man work, but play;  
Whereon it is enough for me,  
Not to be doing, but to be!"

And certainly it was happiness enough for one to lie under the trees and watch the deer. The house contains some good pictures, but these can be seen only by arrangement.

At the Grove, on the contrary, if the family be away, there would seem to be no difficulty in entering,—at any rate, we found none, the obliging and well-tempered housekeeper appearing to take a pleasure in showing its treasures and giving good testimony of a good master. And treasures in both an historical and art point of view there are. This collection, as many of our readers will recollect, is part of that gathered by the Lord Chancellor Clarendon, and which has been made the ground for charges against him of bribery and corruption. The collection comprised an extraordinary assemblage of portraits of the different members of conspicuous families on the King's side in the Civil War, painted by Vandyck and others; and it was contended that, as people do not usually give away family portraits to a stranger, and more-

over, that as it was not usual for collectors to have portraits not belonging to their family, it might be taken for granted that they had been received as bribes or extorted by threats. Fortunately, Evelyn, in his Diary and in letters to Pepys, had left an account of the plan on which the Chancellor had determined on forming his gallery,—that it was intended to be made up of "our ancient wits, poets, philosophers, famous and learned Englishmen, the most illustrious of our nation, especially of his lordship's time and acquaintance, and of divers before it;" and he showed how he had aided in it himself by sending lists of names of those who ought to be included. This, it will be seen, materially assisted the friends of the Chancellor's character in disposing of that part of the evidence against him. The collection has been divided, many of the pictures being now in Bothwell Castle, in Scotland, while others are missing altogether; and certainly, concerning those now left at The Grove, no wonder need be expressed as to want of connexion, a good reason for being there being obvious in nearly every case, quite irrespective of the idea the Chancellor had in view when he made the original collection. Some thirteen years ago, Lady Theresa Lewis published three interesting volumes, entitled "Lives of the Friends and Contemporaries of Lord-Chancellor Clarendon," illustrative of portraits in this collection. It was a capital idea, and was worked out with ability and pains. The men, and women too, whose "counterfeit presentments" are here gathered together, moved during an eventful period of our history; while an account of their doings and sketches of their character have been handed down to us by Clarendon's own pen. "Through him we live again in their times; we view them, as it were, with the eyes of a contemporary, and acquire the personal interest in each portrait which personal intimacy would give."

The number of Vandycks is considerable, and some of them are rare specimens of his rare art:—

"His pieces so with their live objects strive,  
That both or pictures seem, or both alive.  
Nature, herself amazed, does doubting stand  
Which is her own, and which the painter's hand;  
And does attempt the like with less success,  
When her own work in twins she would express."

Vandyck was in England, it may be remembered, from 1620 to 1621, and then from 1632 till he died, in 1641. The small study of the equestrian picture of Charles I. now at Blenheim, Queen Henrietta Maria, the 10th Earl of Northumberland, Philip, the 4th Earl of Pembroke, Lord Falkland, and the Earl and Countess of Derby and Child, not to mention half a dozen others all by the same great hand, will strike the visitor. Honours's the Queen of Bohemia, Jansen's Lord Keeper Coventry, and Sir Peter Lely's picture of the Chancellor when he was 52, are sure to get attention. The last picture was painted seven years before Clarendon was impeached and banished. How many persons know that the Clarendon Press in Oxford was partly founded on the profits of the sale of copies of Lord Clarendon's "History of the Rebellion," the copyright of which was presented to the University by his sons?

There are two or three of Lely's best pictures at The Grove, very unlike some of the rubbish with which he is credited. Lely came to England and began to paint in the very year in which Vandyck died—1641. He himself died suddenly of apoplexy thirty-nine years after that, while painting the Duchess of Somerset. The pictures and drawings left by him were so numerous that their sale by auction is said to have occupied forty days, and to have produced 26,000*l.* In the churchwardens' accounts of St. Paul's, Covent Garden, the following entry appears:—"1680, Dec. 7th. Received for the ground for the corp of Sir Peter Lely, and use of the pall, 6*l.* 13*s.* 4*d.*" A monument was placed in the church, with a bust, by Grinling Gibbons, and an epitaph by Flatman; and was destroyed by fire in September of 1795. Lely had left 200*l.* "for funeral expences, and one hundred pounds more for a monument." He devised 50*l.*, by the way, towards the rebuilding of St. Paul's Cathedral.

Amongst his pictures at The Grove, though not one of the best, is a portrait of Anne Hyde, daughter of the Chancellor, Duchess of York, and mother of two queens, Mary and Anne. Of these queens there are here well-known portraits by Wissing and by Kneller. As to persons of another kind of eminence, there are portraits

of Fletcher the poet; Spelman the antiquary; Waller, a capital piece of Lely; Madame de Sévigné; and a few more. In the library, a remarkably comfortable and cosy room, filled with—

"Gold of the dead,—  
Which Time does still disperse, but not devour;—"

the present earl sits, surrounded by engravings of the statesmen and warriors he has known, mostly passed away.

Looking back over the fields of Life, as may be easily done moving through such a company as is found at The Grove, how rapidly do the labourers seem to disappear: how slight was the tenure, how short was the term of the longest life-holder! The years, pall-bearers of the ages, tramp on remorselessly, bearing all towards the grave! We may not stay, however, to moralize or muse. One glance, when in the hall, at a masterly rendering in tapestry of the grand fish-miracle cartoon, with its small boats often carped at, and then out into the clear air for a walk under the great trees that in the sunlight throw—

"Tangles of light and shade below."

We have probably said enough to indicate that there is something to be seen near Watford.

#### FRAUDS OF PAINTERS.

WHEN our profession was younger by some twenty years, the question was not uncommonly discussed whether the work in building was better executed on the system of general contracts, than by that wherein each branch was undertaken directly by a separate master,—that is to say, not only as a separate craft, but as a separate trade. If the "conscript fathers" of the profession,—alas! sadly diminished in number,—were now polled, we apprehend there would be some repining at the change that has been consummated. The actual system, however, has been found convenient alike by architects and the public; and there is so much advantage in knowing beforehand the lump-sum that a building will cost,—if not subject to changes of intention on the part of the proprietor, or to the consequences of want of foresight on that of the architect,—that it is not perhaps to be desired that the practice should revert to that which is become matter of history. The Government, at least, advised by one capable of forming an opinion,—we mean Mr. Hunt,—appear to have adopted the system supposed to be favourable to a reliance upon estimates.

Why the system of general contracts should be so peculiarly favorable for given work, or where there is an architect, does not immediately appear. It is to be assumed that under either system, the work is correctly specified, and that the supervision is equally well performed. However, it is not to be questioned that the manner of execution of work has not progressed to the extent that might have been accordant with progress of time; until the crafts themselves, or the available skill of workmen, are thought to be deteriorated. There is no other sufficient explanation of the discrepancies in estimates which we are constantly publishing, than that something in the manner of work is constantly eluding the greatest precision of specifications, together with what is practicable in the supervision of an architect. Were materials, that is the designated qualities, and labour, always the same, as they are assumed; and were only capital, and tact in watching the markets, in direction, and in the use of machinery, variable; we apprehend that the difference between the positions of those tendering for works to the same specification, would fail to account for such discrepancies as those found in a list of tenders where, with nine or ten parties tendering, the lowest amount will be half of the highest, and the others will be in regular gradation. The explanation must be, not chiefly that there is elasticity in the sum to be set against given materials and labour, but rather that there is considerable scope of selection and allotment of these latter.

Now we would invite the attention of architects and builders to the consideration of this state of things; which we could exemplify and elucidate from one particular trade, that of painters' work. We would seek an answer to the question whether it is possible to import greater precision into specifications, which may be read and attended to, or in what direction there is better chance than at present appears of getting work done according to the

just expectation of the person paying for it. It is useless to say that the difference of 50 per cent. represents a difference in the actual quality of work; the real point is whether the person for whom the work is to be done, understands that there is such difference in the conditions, and is content to accept, say, the inferior work.

If the conditions be not identical, the whole politico-economical theory of benefit from competition is inapplicable. More, if the conditions are presented and ostensibly taken as equal, any tender calculating upon profit by work inferior in quality to that which may be presumed to have been intended, is made at the expense of moral rectitude on the part of its author, however consistently with practice in trade. Not denying that cases occur in which those calling themselves architects may endeavour to cut down fair prices for work, we must say that the general disposition in the profession is to allow the reasonable profit; and at all events that those in the several trades will never stand in a right position till they cordially co-operate with architects in devising such a system as will allow tenders to be made on the same conditions, and only visit with condemnation those cases in which the expressed or implied understanding is not observed.

We have suggested that the fact of the discrepancy between tenders, might be explained by a want of precision in the wording of specifications. The reports of cases at law show the latitude that is countenanced in trade, as to the interpretation of the word "best" as applied to material or work. Ordinary parts of speech expressive of quality, would not seem to suffice for the description of articles; and, in some trades, a jargon of adjective piled upon the same adjective is brought into use, in a manner which both implies ignorance, and directly tends to confusion of one quality with another. But there is something more than this circumstance; which may indeed be met in part, by specifying prime-cost and name of manufacturer. The difficulty extends to the whole manner of executing work; and where the materials and the details of manipulation are very numerous, as they really are in painters' work, there appears to be no medium between what is little better than entire dependence upon the contractor, and a length and precision of description such as we imagine no architect has dared to attempt. Assuming that particular directions are given in place of the usual rather general clauses, the result is almost necessarily length; and the direct tendency of this is not simply that it may be left unread, but seems to be that it will produce an extravagantly high estimate. Certainly, in some of the trades, we have known a very simple matter, only shown by the most complete drawings, priced at a very high rate, and apparently through the fact that the drawings, which really went to ease the labour, and demonstrate the simplicity, were complete. On the other hand, every architect finds estimates sent to him on the basis of the bill of quantities, after scarcely a glance at the drawings and specification; which latter may contain things that mere items in the quantities would fail to give a sufficient idea of.

We believe that masters in the trades would find it their interest to help to terminate the state of things by which the conditions in a tender are practically not equal in the view of the competitors, and from which in many cases deception is practised. If the mode that they discern be by addition to, or modification in, the terms of specifications, they should not hesitate to point it out. Estimates for painters' work are precisely those in which the greatest discrepancy is observable; whilst, also, the proper work is most in contrast with the portion of specification relating to it. The whole space given to the heads glazing, painting, and paper-hanging, in the specification for almost any house of ordinary dimensions, does not generally amount to more than ten or twenty lines. If the work were properly gone into, the description might occupy two or three hundred lines.

It is not alone omission of things not specified that characterizes painters' work: there are gross frauds perpetrated, as by the substitution of one thing for another specified, to save materials and labour, and at great loss of durability. Mr. Iny, many years ago, in one of the later editions of his "Laws of Harmonious Colouring," particularly mentioned some of the practices, as one of the substitution of a coat of size for a coat of paint; and we happen to have at hand a pamphlet by M. Leclair, the house-painter, of Paris, which, though it is dated as far back as the year 1812, is so much to the point,

\* Quoted in "A Selection from the Wills of Eminent Persons," printed for the Camden Society, in 1863.

still, of the present article, that we shall make some use of it in what is to follow.\*

M. Leclaire's name is well known to our readers. It has been most recently mentioned in referring to his judicious and truly philanthropic efforts to raise the condition of men in his employ; and he shows in the pamphlet now before us,—as we may be said to have shown in our article on the "Prevention of Strikes,"—the connexion of the subject affecting workmen, with that which we have at present in hand. It is evident from M. Leclaire's pages, that precisely the same practices have prevailed in France as in England; and we fear that to this moment, the case is little altered as to either country.

So long as masters set the bad example, they must not be surprised if they have difficulty in procuring "a fair day's work" from the hands employed by them in deceiving others. It were much to be desired that men, who are generally well aware of what is required to make good work, would put their acquired knowledge into explanatory words. Thus, the precise required steps might be taken by sufficient clauses of specifications, and in the supervision of work, to check that which we have adverted to. As we have said, the practices are maintained in great part from the latitude allowed to parties who tender and take contracts. Honest men would welcome particularly and minuteness in description of work, feeling disembarrassed of all competition except that resting on the true basis, namely equality in conditions. The only losers would be those who deserve to lose.

One of the most frequent practices saving cost, at the expense, and to the injury, of the person for whom the work is done, has been already alluded to. A first coat of size is substituted for one of oil or paint; whereby a considerable immediate gain accrues to one party to the contract, and a corresponding future loss to the other. The gain and loss are greatest where the material painted upon is plaster. Occasionally a little turpentine is mixed with the size, just to give an odour, and to make believe that something workmanlike is being done. When the work is so closely supervised that the first coat of size cannot be given, the plaster may be moistened immediately before applying the coat of oil; thus the plaster having imbibed water, will not soak up much oil. On woodwork, a first coat of size is given; and it is represented to be necessary, as enabling the rubbing-down to be done more easily. But there are other modes of deception. The difference in the price of varnish being considerable, the least expensive kind is chosen, which will not bear the slightest cleansing. In distemper work, an excess of water, perhaps, is mixed with the colouring material; and when the result is insufficiency of tint, the contractor will explain that the plaster was wet; and there is an end of the matter. When the colour peels off, in consequence of the plaster-surface not having been well prepared, the circumstance is said to be a sign of solidity, and that the size has been employed too strongly.

M. Leclaire, in the form of a dialogue between two contractors, makes one of the parties observe, that even when there is a competent supervisor of the work, the contractor can always find means of protecting himself from consequences of having taken the work at too low a price. "The architect, as well as the proprietor, breakfasts, dines: sometimes they have regular hours for coming upon the works;" these are taken notice of, and use is made of the intervals: besides, a multitude of individuals know nothing about painters' work, either in the state of its progress, or after. Even by scraping with a penknife, with a view to ascertain the number of coats, nothing can be positively proved, unless the material scraped off be subjected to analysis. Spanish white is substituted for white of lead; but if the analyst should ask for one of the mixing-pots, opportunity might have been found to cover the inferior material with an upper stratum of the white of lead, which therefore he would probably take up for his analysis. The tricks employed in estimating, or to make up a profit after a low estimate has been submitted, are endless. As regards gilding, should an estimate be asked for, a clever tradesman in France will

never give any except for oil-gilding on plain surfaces, and without indication of the nature of the preparation. As to measurement, previous agreement upon the method of it will be avoided as much as possible: thus there will be latitude for making out the bill in the form that may be most to the contractor's advantage. For paper-hangers' work, there are various ways of turning the business to account; although a low price may have been set down for the paper itself. A border may be required; and as each roll of borders has four bands, it may be separated into two rolls; and the price of a roll of two bands will appear moderate. In works of repa-ration where canvass is found under paper, the tradesman, having said that new material would be necessary, may simply stretch the old canvass, charging it as new.

The workman lends himself to the deception practised on architect, or proprietor, sometimes under the idea that durability of work is not "good for trade" and for demand for his labour. But he forgets that the same act which gives the proprietor coats of size whilst paying for oil, subtracts from him, the workman, remuneration that he would have had for the work in oil in excess of that which he has for the work in size; since more labour is required using the former material than the latter. Moreover the workman injures others besides himself, of his class. The manufacture of size, for instance, demands a smaller amount of labour than that of oil.

According to one of the parties in M. Leclaire's supposed dialogue, when a detailed estimate is demanded of the master, his cue is not to set down all the work that will require to be executed. Thus he does not frighten the proprietor by the total cost. After the execution of the work, it is measured; the estimate is exceeded greatly; but the end will be the payment of the demand. When a schedule of prices is asked for, such items are put down as will not be wanted; the agreement will contain a clause that all unforeseen works shall be priced by analogy; but the base on which analogies may be established, is large in painters' work. If the client, in conversing with the contractor, should cite the name of another master-painter, the contractor, even without knowing the other, will say of him that he is the greatest thief ever seen. When there is no architect, and the proprietor himself is inspecting the work, his attention is to be constantly directed to the beauty of what is done; thus the idea will never occur to him, that so much care is taken only the better to entrap him. Should the proprietor unfortunately discover some piece of fraud, it may be put down to the workman, who can be threatened with dismissal: or the latter may be actually dismissed: for a consideration, he will consent to anything; and a hint is given to the new foreman not to allow himself to be caught.

Such is a representation of the tricks of trade, as in France. It would fit the state of things at home.

One of the conditions of improvement being more exactness in the specification of painters' work, and other work commonly falling to the share of the same master-tradesman, we look further to the pamphlet of M. Leclaire for suggestion. The pamphlet contains a specimen "Cahier des charges," or specification, for works of painting, gilding, paperhanging, and glazing. It has forty-four clauses, or "articles," treating of the manner of executing the painting on surfaces not previously painted, and on those which may have been so painted, of the cleansing of painters' work for the preservation, of painting in distemper, of the treatment of mouldings, of gilding in oil and in water, of the paperhanger's work, of the glazier's, and of the liability of the contractor, and the damages to which he will be subject in the event of non-performance of his agreement. The first article sets forth that no coat of paint may be laid without written order of the architect. The next following articles specify the colour to be adopted for the first coat (and sometimes that of the second also), according to what may be intended to be the finished colour; and for the remaining coats, they say that the colours are to be those which may be selected by the architect. Another article sets forth that as to certain portions of the work, as the backs of shutters, parts of back-stairs, kitchen-doors, and the like, not executed after previously described methods, the price of a third coat of paint shall not be demanded unless after production by the contractor, of the written authorization. We should mention that in no part of the specifica-

tion, do we find allusion to more than three coats. The next article directs that coating of size is never to be used, to receive painting in oil, whether for plaster or woodwork, under pain of consequences referred to afterwards; and that the contractor must conform to certain stated articles of those which relate to the painting of the work that has been previously painted.

Under the general head for this latter, the first article directs that when the tints are to be similar to the old, they shall be mixed somewhat lighter, that the contractor shall paint a surface as specimen, and that where there are two coats, the second is not to be paid for without the production of the architect's written order. The next article directs the use of tinted putty for stopping, after the last coat but one, and also mulcts the contractor in the price of one coat if he be unable to produce a note from the architect, or proprietor, attesting that the stopping has been done in conformity with the terms of the article. Then there is an article to distinguish the work requiring the greater amount of rubbing-down from the other work. In following articles it is stated that painting in two tones to the back of shutters, and insides of cupboards, without written order, will be disallowed; and there are rules for the measurement of Venetian blinds, and the estimation of the painting of various matters of ironmongery.

As to the cleansing of old work, the contractor is to direct attention to such work, if it be in a bad state, before commencing; and if the cleansing should be done in such manner as to compel repainting, he is to bear the charge thereof. Distemper-work is to be executed subject to the chief conditions given for the painting in oil; and when the work is finished and dry, it is when rubbed, even rather hard, with a piece of black cloth, not to soil the cloth any more than would work in oil; at least, this, it is said, should be the case unless there be humidity in the plaster. Five articles relate to oil-gilding, three to water-gilding, and six to paperhanger's work. They chiefly aim at the prevention of demand for extras. Under the head of glazing, one of the articles requires that specimens of the glass, marked with the signature of the contractor, shall be deposited with the architect, in order that the latter may have recourse to the manufacturer to ascertain if the material be really that originally approved of.

The articles defining the responsibility of the contractor, relate to the breakage of glass, damage caused by the workmen of other trades, and to various omissions.

The last division, relating to damages to which the contractor may be exposed, is in some respects the most important. Its first article states that the architect's supervision at every instant being impossible, the proprietor reserves, notwithstanding the previous clauses, the right, after the works are finished, to scrape parts of the painting, or gilding, in order to submit them to chemical analysis; when in case the white of lead should be found inferior to that of certain specified manufacturers, the contractor will be made to submit to a deduction of 25 per cent. in all work where such pigment has been introduced. Should the analysis disclose the use of size to replace oil, there will be a deduction of 50 per cent. upon the whole of the work where it might have been possible to use the size, reason alleged being the bad result sooner or later to attend the use of any such matter as size, especially on plaster. Deductions of 25 per cent. are provided for in the case of defects made apparent by the examination of other parts of the work, as in the material of the gilding.

The analyses here referred to may be made without much experience in practical chemistry, and at an expense ranging from 8s. to three times that sum. The methods adopted by M. Leclaire, are due to M. Bannel, professor of practical chemistry at the École de Médecine, and would enable the experimenter to recognise the presence of size, or paste, or to discover whether the white of lead were pure. In each case a portion of the paint must be scraped off, to be subjected to the experiment.

The object of the pamphlet that has been noticed above, was to show that competition without limits or conditions, produces ill effects; the entire means to ensure good work in house-painting, as in other branches of the building craft, are still left for the consideration of those who are competent to take up the subject.

\* "Dialogues sur la Concurrence sans Limites dans la Peinture et Bâtimens, ainsi que dans la Dorure, la Peinture, et la Vitreerie," 8vo. pp. iv. & 36. Paris, 1842. M. Leclaire has issued in the previous year, "Recueil de Notes sur les Abus introduits dans la Peinture et Bâtimens, ainsi que dans la Dorure, la Peinture et la Vitreerie," etc. (4to. Paris, 1841) and about the same time, "Des Améliorations qu'il serait possible d'apporter dans le Sort des Ouvriers Peintres en Bâtimens."

### THE SANITARY CONDITION OF NEW YORK.\*

The City of New York ought to be one of the most healthy cities in the world, for no other large city is favoured with greater natural advantages of locality and climate, and probably no city has a greater influx of a vigorous and healthy population, from the rural districts and from foreign countries. But a very high death-rate with proportionate sickness prevails. The total number of deaths during 1863, according to the city inspector's returns, was 25,196 out of a population of scarcely 900,000. This is equal to one death in every thirty-five of the inhabitants.

Hitherto there has been no proper organization for sanitary purposes established in New York; but the immense benefits already derived from sanitary improvements in this country have been appreciated by the more enlightened and energetic of the citizens; and a Citizens' Association has been formed, on voluntary principles, for the purpose of showing forth the need for sanitary reforms. This association has appointed a Council of Hygiene and Public Health, the executive committee of which, first of all, addressed a letter to twenty-four of the principal physicians of the city, for the purpose of obtaining from them the fullest and most reliable information relative to the public health. The medical men thus addressed not only responded with the utmost cordiality and public spirit, but afterwards, as voluntary sanitary inspectors, reported minutely on the sanitary condition of various districts into which the city was divided for the purposes of this sanitary inspection. These reports, together with reports of the executive committee and the council to the sanitary association of the citizens, have now been published, and they form a portly volume of 360 octavo pages, a copy of which the council, by their secretary, Dr. Harris, have just sent us.

"It should be borne in mind," says the council, in their Introductory Statement, "that this preliminary labour of the Council of Hygiene, and its corps of skilled and indefatigable sanitary inspectors, has been planned and performed voluntarily, and by gentlemen whose time and thoughts are burdened by their ordinary professional and official duties; and that none of the means or power of the municipal government could be used in prosecuting the great work of inquiry and recording, which has, under peculiar disadvantages, but with marked success, been prosecuted by them."

The Citizens' Association asks the attention of the people of the City and the State of New York to the facts set forth in this Sanitary Report, and it also asks that the needed works of sanitary improvement be immediately begun by competent minds and competent hands. The skilled labours and trustworthy advice of a voluntary council of hygiene have definitely determined when and how such works of improvement should be commenced; they have shown what is the nature, and what must be the preventive or curative of existing causes of needless sickness, mortality, and public peril from removable evils."

Such is the position of the sanitary question in New York. A new war, — a war against nature's powers of evil, — has been resolved upon just as the fearful and destructive civil war has ceased; and the citizens may be assured that they can save, if they choose, as many lives during the next few years in their city as they have lost of their citizens by war during the past few years.

The physicians, in their joint response to the address of the committee, while drawing attention to the "fearfully high death-rate" of the city, say:—

"By means of suitable sanitary regulations, and a faithful and competent administration of such laws, the rate of mortality in this city ought to be very greatly reduced. The experience of other great cities, and the teachings of sanitary science, warrant the opinion that the present rate of mortality may be reduced fully twenty per cent. Such a reduction would save from 7,000 to 8,000 lives in this city during the present year. But the saving of this vast number of precious lives is not the only, nor is it the greatest, benefit that would result to the health and welfare of the city by means of suitable sanitary government."

It is a medical and statistical fact that for every death in a large community there are at least twenty-eight cases of sickness. This would give, in the population of our city, upwards of two hundred thousand cases of preventable and needless sickness every year! This conclusion is fully warranted by the statistics of our public charities, and by medical observation, and it is based upon broad inquiries and generalization respecting sickness and mortality in Great Britain, as stated by Dr. Lyon Playfair, a distinguished authority in Hygiene.

It is a maxim in the medical profession that it is far easier to prevent disease than to cure it, and it certainly is far more economical to do so. And when we remember that the great excess of mortality and of sickness in our city occurs among the poorer classes of the population,

\* "Report of the Council of Hygiene and Public Health of the Citizens' Association of New York, upon the Sanitary Condition of the City." Published, with an Introductory Statement, by order of the Council of the Citizens' Association. New York: Appleton & Co., Broadway, 1865.

and that such excessive unhealthiness and mortality is a most prolific source of physical and social want, demoralization, and pauperism, the subject of needed sanitary reforms, in this crowded metropolis, assumes such important bearings and such a vast magnitude as to demand the most serious consideration of all persons who regard the welfare of their fellow-beings, or the best interests of the community."

The reports of the inspectors show that in certain portions of the city there exists an almost universal neglect of sanitary regulations; the streets, courts, and alleys generally filthy, the gutters obstructed, the house-drainage defective, and the sewerage faulty; while in the subdivided "tenant-houses" of such localities are found numerous cases of typhus, small-pox, and all varieties of pulmonary and infantile maladies, which are perpetuated and rendered fatal by overcrowding, domestic uncleanliness, and want of ventilation. In such localities, however, great the advantages of natural salubrity, and however well fed and well-to-do the resident population, sickness is always very prevalent, and diseases are very fatal. On the other hand, there are portions of the city in which the streets have been well paved and kept clean by private enterprise, or by the influence of the residents; where the dwellings are kept in a cleanly and not overcrowded condition; where the local drainage and general sewerage are good, and local nuisances of every kind are abated. Here a very different state of health prevails. Thus, while in the Fifth Ward, included in the third Sanitary Inspection District, the death-rate is one in twenty-eight of the resident population; in the Fifteenth Ward, which is included in the same district, the death-rate is only one in sixty. The Council of Hygiene, in their report, were speaking of the inevitable mortality of the total population of the city, point to the Fifteenth Ward, and say:—

"It is entirely practicable to bring the standard of health throughout the city up to the present standard in that ward. Good sanitary regulations will bring up the health-standard in some wards, the Twenty-first, or Murray Hill district, for example, to a point considerably higher than that of the Fifteenth. The entire city, with a death-rate of 1 in 80, which is the present rate of mortality in a central, crowded, but salubrious ward,—the total mortality of the city—would be at the rate of but 16,668 to the million, instead of ranging as it now does from 25,500 to 35,000 deaths to the million of the inhabitants. And if, for the present, the death-rate in the city were brought down to the standard which, by the agency of sanitary works, was speedily reached in London, and which New York enjoyed fifty years ago, under better sanitary regulations than are now enforced, namely, about a death to every 45 of the population, it still would be too high a rate of mortality, though it would be a saving of several thousand lives annually upon the present mortality."

Of course, the contrasts just referred to are observed no less in the relative amounts or rates of sickness than in the rates of mortality; and, in the study of causes which induce and perpetuate the diseases prevailing in the insalubrious quarters, the physicians find the full explanation of such wide differences in the sickness and death rates of particular localities.

The reports of the sanitary inspectors show that particular diseases are connected with special conditions of insalubrity. Typhus fever and consumption are found in the overcrowded tenant-houses, and in dark noisome quarters excluded from sunlight and fresh air. Cholera infantum, dysentery, diarrheal diseases, and various typhoid maladies are found to prevail in badly-drained and neglected streets and alleys, and in cellars, or in damp and filthy domiciles surrounded by nuisances and poisonous effluvia. In such localities it has also been observed that scrofulous, rheumatic, and eruptive diseases prevail, and that the average or constant sickness-rate in the families and houses so situated is very high, the proportionate number of persons sick, or the total days of sickness, being three, five, or even ten times the ratio of sickness in the localities where better sanitary care prevails. And physical and rational evidences combine with overwhelming proof to show that specific and removable physical conditions both produce and perpetuate such sickness.

Within a single "block" of streets from the elegant mansions of Stuyvesant Square, is a row of tenant-houses in which typhus has been constantly prevailing for more than a year past. From one of these houses, in which reside twenty families, the Sanitary Inspector reports that he has sent more than twenty patients to the fever hospital during the year 1864, and that at least eighty cases of the fever occurred in that house during the year. Again, in a group of crowded tenant-houses, near the corner of Mulberry and Canal streets, typhus has prevailed very fatally, and almost constantly during the past three years; and in the first two months of

the winter of 1865, twenty-three patients and five deaths from that fever were witnessed by the sanitary inspector in two of the smaller houses. In another quarter, upon a great thoroughfare, the infection of typhus has for a long time been so virulent and fatal, that in consequence of the panic it creates among the families which it enters, a perpetual succession of hasty removals both of families and fever patients has been kept up during the year, and by that means the seventy-four domiciles of that single rookery have sent on an incessant and widely-distributed current of the typhus poison to other and distant sections of the city.

In short, the sanitary investigations of these New York inspectors confirm, in reference to this city, the truth of the conclusions now familiar to the public of our own cities,—

"That filth, overcrowding, bad drainage, excessive humidity, imperfect supply of air and sunlight, neglect of excrementitious and decaying matter, and the putrid exhalations from sinks, sewers, gutters, and dirty streets, both produce and perpetuate disease; and that whatever sickness occurs in such localities is more virulent and destructive than the same or similar maladies when occurring in places where such conditions do not prevail."

The council recommend,—

"First.—That a system of faithful Medical and Sanitary Inspection should be maintained throughout the city, for the purpose of searching out and reporting to a central authority the existence and the sources of all the various and other pestiferous diseases; and that, in the absence of a competent board of health, such duties of inspection, &c., should be maintained by voluntary organization; and, in the further, that such sanitary inquiry should be accompanied by the needed personal advice, and such other influences as would tend most certainly to diminish the evils thus discovered and reported."

"Second.—That either by public authority, or a competent bureau of Hygiene, or by voluntary and private enterprise, there should be instituted such a system of general inquiry and advice concerning the spread of contagious and dangerous diseases, as will not only enable the people of the city of New York to protect themselves against dangers that now exist in their midst, but also more effectively guard against small-pox and fever from external sources, and at the same time intelligently provide adequate measures to prevent the spread of such infectious diseases from this city to other communities."

The evils and abuses of the tenant-house system are seen on every hand, and the council have adopted the *Builder's* mode of forcing this on the public eye by graphic illustrations of various "fever nests" of this description:—

"Not only do filth, overcrowding, lack of privacy and domesticity, lack of ventilation and lighting, and absence of supervision and of sanitary regulation, still characterise the greater number of them; but they are built to a greater height in stories; there are more rear tenant-houses erected back to back with other buildings, correspondingly situated on parallel streets; the courts and alleys are more greedily encroached upon and narrowed into unventilated, unlighted, damp, and well-like holes between the many-storied front and rear tenements; and more fever-breeding wynds and *culs-de-sac* are created as the demand for the humble homes of the labouring poor increases. Disease and death bear fearful sway among the inhabitants of this class of dwellings. "These evils," as the council remark, "must be remedied; and as far as possible they should be prevented by faithfully executed sanitary regulations." The subject of improved dwellings and model lodging-houses needs to be far more seriously considered in New York than it has yet been. The council recommend:—

"First.—That capitalists, architects, and builders should unite in devising and executing the construction of improved dwellings for the industrial classes in the city."

"Second.—That effective measures be immediately undertaken to procure the introduction of needed improvements in the ventilation, lighting, and cleanliness of the tenant-houses of the city."

"Third.—That citizens should put forth the requisite efforts to procure the enactment and execution of suitable sanitary laws for the better regulation of tenant-houses, and to enforce the necessary care and cleanliness of the same by the owners, leases, and occupants."

"Fourth.—That a Department of Social Statistics and Dwelling Improvements be maintained in connection with the plan of labours pursued by the Council of Hygiene and the Board of Engineers and Architects of the Citizens' Association of New York, for the purpose of acquiring and imparting needed information relating to the social statistics and improvements in dwellings which sanitary science and the public welfare require, and which will best conduce to the immediate development and execution of successful plans and examples of the dwelling improvements which are demanded for the physical and the social welfare of the industrial classes."

\* By the way, it is notable that while these reports are so frequently alluded to by English writers who have only followed the lead of the *Builder*, we find only one instance in which anything like justice is done us in this respect. The *Builder*, like the *Times*, appears to be regarded, in New York, as the only property which any one is entitled to make use of without much acknowledgment.

There are 173 slaughter-houses in the City, all of them too offensive to health and decency to be longer permitted in their present localities. These establishments are thrust into the midst of the most crowded districts, and a loathsome train of dependant nuisances is grouped in the same neighbourhoods.

Towards the full attainment of the prospective sanitary advantages which the Association of Citizens and their council have in view, one grand agent is already prepared in ample force;—that is, water. New York is blessed with a noble system of water supply, and which for years past has exerted a most direct and important influence in protecting the inhabitants from the general prevalence of typhoid infections and diarrheal diseases. Indeed, the Croton-water, in its universal distribution and abundant supply everywhere throughout the city, tempting to cleanliness of person and premises, preventing the use of water saturated with organic poisons from wells, and of worse poisons from stills, is to be regarded as the chief agency of sanitary protection which the city enjoys. Especially as regards preventable diseases, Croton-water is to-day the only well-administered agency of sanitary protection yet provided. But, alone, this agency is insufficient to guard against the incursions of disease; and, when house drainage and sewer cleaning are neglected, and when, in crowded courts and in obstructed gutters and cesspools, the filthy ooze and fever-breeding exhalations are kept up by means of waste water and putrefying organic matters, even the rich blessing of abundant water-supply becomes in particular instances a source of disease. Nevertheless, the value of the benefits outweigh the aggregate of evils from neglect, even in such instances.

THE UNDERGROUND WORKS AT LAMBTON CASTLE.

HAVING been solicited to furnish a paper relative to the underground work recently done under my supervision, to prevent the further subsiding of Lambton Castle, I beg to make the following observations. They will serve to supplement the paper contributed by Professor Smirke.\*

Soon after the castle, which is the property of the Right Hon. the Earl of Durham, was discovered to be sustaining damage by the subsidence of its foundations, I was, in October, 1854, requested by Mr. Henry Morton, his lordship's principal agent, to endeavour, without loss of time, to ascertain whether the workings in the main coal seam, which are at 199 ft. below the floor of the Castle, were the cause. On the 24th of that month, I, with others, descended to this seam by means of the Old Engine pit-shaft, near to the river Wear, and east of the park; and, after freeing the workings from the accumulated silt, a work requiring some little time, found no evidence that the cause of the shrinking of the building existed in the workings of this seam; for, although the roof in some places had fallen to the extent of 10 ft. or more, the pillars of coal, and also the strata immediately above, remained perfectly firm and unshaken: this seam itself being 6 ft. in thickness, and in places 10 ft. of the roof having fallen, the height of several of the pillars, wholly new in part, were of course found to be 16 ft., which gave them the appearance of not being of such strength as to withstand any general movement of the under or overlying strata without becoming crushed and causing a corresponding subsidence of the surface.

Mr. Morton, with his usual prudence, caution, and forethought, consulted two of the oldest and most eminent mining engineers of the district; and, acting upon their suggestions, the workings under and around the castle, to the extent, in this seam, of an area of upwards of 4½ acres, hereinafter alluded to, were carefully and compactly stowed or filled up with the fallen debris brought from the adjacent workings. This stowing was completed on the 14th of February, 1857. Whilst the above work was being prosecuted, communication, by means of a staple, was made with the seam below, in the workings of which similar results to those already mentioned, excepting only that fewer stones had fallen from the roof, were discovered. These workings were also stowed in a similar manner to those of the seam above named, being begun on the 10th of

December, 1855, and finished on the 13th of September, 1856.

Failing to discover in either of these seams the cause of the damage to the castle, it was sought for in the seams above and below them: the upper seams previously, however, were not known to have been worked. I may now state that below the castle floor,—

Pt. In.		Pt. In.	
At a depth of 30 0	is a coal seam of 2 0 in thickness.	2 0	"
" 60 3	" " " " " "	2 4	"
" 100 4	" " " " " "	4 1	"
" 136 0	" " " " " "	6 0	"
" 199 0	" " " " " "	4 0	"
" 259 0	" " " " " "	4 0	"
" 415 0	" " " " " "	4 0	"

all of which seams have been worked in the whole mine, or, in other words, worked so as pillars only are left, which pillars in some of the seams stand over and exceed the whole area occupied by the castle, excepting the top seam, that at 30 ft. depth, which being only drifted into a few feet, is standing unworked; the second, third, and fourth of these seams, which are called the second, three-quarter, and five-quarter (the first, that at 30 ft., being called the top seam), are those in which the pillars of coal have been left of insufficient strength to support the weight of the superincumbent strata and castle, and were therefore, from their weakness, the cause of the damage.

Finding the pillars of coal much crushed in these seams, more particularly those in the second and third, in order to secure the foundations at all satisfactorily, it was found necessary not to stow the workings as those of the fifth or main coal, and the sixth or Maundlin seam; but instead, to remove all the crushed coal and other disturbed material, and to fill the space with solid brickwork, which, in the second seam, was begun in February, 1856, and left off in October, 1858; the third, or three-quarter seam, was begun in January, 1857, and left off in December, 1858; and in the fourth, or five-quarter seam, the solid brickwork, in like manner, was begun in November, 1858, and left off in August, 1860.

The main coal and Maundlin seam workings, below these, as already stated, being stowed or packed with fallen debris, there remains to be mentioned as having been worked under the castle, or as having reference to it in anywise, only one more seam, which, as mentioned above, is the seventh, or Hutton seam, and the workings in it, under and about the castle, for the most part are not what are generally called *wide*, but *narrow*, workings, the widest being about three yards, and consequently they present but little if any risk of damage to the surface, or castle, so long as the working of coal is not permitted to approach within a proper distance of, and such as will not diminish the lateral support necessary to prevent undue pressure upon the pillars of coal left immediately under and around the castle. This observation, with respect to the lateral support, in my opinion, applies equally to the main coal, Maundlin, and other seams, notwithstanding that the workings in them may be hilt or stowed: such precautions being self-evident will, no doubt, at all times have the proper attention of his lordship's agents.

When the brickwork in the workings of the three seams as already stated, viz., the second, three-quarter, and five-quarter seams, arrived at that state of completion to warrant the prudent removal of the masons engaged at the work, and consequently of their being prudently employed at the restoration of the castle, the underground work was discontinued, and the restoration was commenced,—the underground work being intended to be afterwards resumed and completed, which at this time (June, 1865) is about being proceeded with, with a view to its being finished; and now, after a lapse of nearly five years, it is far from unpleasant to me to be enabled to record that I understand not the least appearance of shrinking has presented itself in any portion of the building. In conclusion, I may state that there have been built,—

	Bricks.
In the top seam, over an area of 45,000 square feet, surrounding 100 small sound pieces of pillar coal	1,856,500
In the third or three-quarter seam, over an area of about 199,000 square feet, surrounding about 120 pillars and portions of pillars of sound coal	5,042,980
In the fourth or fifth quarter seam, over an area of about 55,000 square feet, surrounding about 140 pillars and portions of pillars of sound coal	2,875,520
Together	9,775,000
Which with 6,000 used in the main coal seam, and say 211,710 yet required for second, third, and fourth seams together, make the gross number, say	10,000,000

Before leaving the subject with reference to the brickwork, I would observe that, in certain places in the second, third, and fourth seams, it was required to be carried to a considerable height to reach firm material, such as was considered of sufficient solidity, and in several instances, in the latter seam, the height exceeded 30 ft.

The quantity of stowing in the workings of the seams next below those last mentioned, may be stated as being,—

	Cubic Yds.
In the fifth or main coal, over an area of about 4½ acres, or 185,000 square feet, including 122 pillars of sound coal, assuming 12 ft. as the average thickness	40,000
In the sixth or Maundlin seam, over an area of about 3 acres, or 130,000 square feet, including 104 pillars of sound coal, and assuming 6½ ft. as the average thickness	13,000
Making the total number in these two seams...	53,000

The seventh, being the lowest or Hutton Seam, as already observed, is not built up or stowed, but is considered to be left in a condition strong enough, so far as relates to it, to render any apprehension as to damage on the surface unnecessary, so long as proper precaution is taken to keep the working of coal sufficiently distant from the castle, and which, as already remarked, will doubtless from time to time have the attention of his lordship's agents.

Not only in the removal of the fallen debris, and in the substitution for it by stowing and masonwork, but from the accumulation of noxious gases in the whole of the workings, some of which workings, those of the upper seams, are believed to have been made about 200 years ago, considerable danger, as may readily be imagined, had to be encountered; and I, as having had the entire direction of the work, have much comfort and satisfaction in the fact that in an undertaking of such magnitude no accident of a nature at all serious, nor such, indeed, as to cause any of the workpeople to be absent from their work, occurred, excepting only in a single instance, where one man, from a slight bruise, was prevented coming for a few days.

I think it due to the memory of the late Mr. John Cawthorne, who was for many years master-mason at the Lambton Collieries, to state that the manner in which he executed the underground masonwork was to me highly satisfactory; and with respect to the dangers and critical work connected with the removal of the much fallen strata, and the freeing of the workings from inflammable and other gases, credit is, I consider, due to Anthony Winslip, for the steady and attentive way in which he carried out the directions he, from time to time, had given him.

R. HECKELS.

CHICHESTER CATHEDRAL.

A CORRESPONDENT, signing "F. S. A.," writes:—"It is well known that the Gothic central lantern is the counterpart of the Byzantine dome, as the detached bell-tower is of the Lombardic campanile: both of these fine features occur at Chichester. During the destruction of the bell towers, in many instances the lantern was converted into a belfry story, and shut out from view by a vault, to the destruction of the original effect. A long continuous vault or ceiling, unrelieved by the occurrence of the lantern, is always a sensible diminution of grandeur in a building. It is said to be the intention of the Executive Committee to restore the vault in the newly-rebuilt lantern at Chichester, simply from a somewhat superstitious desire to make a *fac-simile* in this respect of the tower which fell. It is a scheme to be deprecated, and, if possible, prevented. The walls, it is true, are now wholly unornamented, but they offer a grand opportunity for the exhibition of the finest mural enrichment and of frescoes on a noble scale, which would form a fitting base to the windows if filled with stained glass; whilst a coved vault of different stones above would form a donelike termination to the interior. We all admire, to the highest degree of delight, the superb octagon of Ely and the open lantern of other cathedrals, showering down a flood of radiance upon the crossing. Is it possible, then, that with this rare opportunity for creating a matchless effect, the eminent architect engaged at Chichester will not embrace it? The alternative is a regulation vault inside, and a system of detestable louver-boards, with their rigid lines choking up the windows, without any object to serve. I do hope, sir, that you will

\* See p. 469, ante.

now exercise your influence whilst there is time, to withstand a resolution which will, if carried out, be a source of endless regret hereafter."

The suggestion appears to us well to deserve the serious consideration of those who are engaged in the rebuilding. Visiting the five-aisled cathedral recently, we were glad to find the work advancing. The tower is up, and the spire commenced. The work appears to be, generally, soundly done. Iron bars, we may note, tie the four arches of the tower together at the springing. The carved ornaments in the upper part of the tower, by the way, would be the better for a little extra force, scarcely showing at the height at which they are placed.

What has become of the portraits and other painted decorations of the south transept? It is to be hoped they were not destroyed in the fall of the tower. The curious sculptured groups in relief affixed to the south wall of the aisle at the east end of the building should not be overlooked by the visitor. They would seem to belong to the eleventh century, though the verger (an obliging one he is) has been persuaded to make them two or three hundred years older.

The tower, once Cissa's camp (*Cissa's Ceaster*), will always afford a pleasant day to the tourist. The fifteenth-century bell-tower, the only one in England attached to a cathedral, the market cross (going rapidly to ruin, apparently), and St. Mary's Hospital, are the most important features.

At Bosham Church, a few miles off, where Canute's daughter was buried, where Christianity was first taught on the Sussex coast, and whence Harold started when he visited Normandy, some works are going on and have made evident the very early date of much of the building. In that division of the Bayeux tapestry which is inscribed, "Harold and his Knights riding towards Bosham," the church is indicated, though not properly represented.

#### A SUGGESTION FOR HOMES OF THE INDUSTRIOUS CLASSES.

In all directions we hear complaints, especially in Clerkenwell parish, of the demolition of the houses of the industrious and poorer classes, and that so little has been done for the purpose of relieving the evil which is complained of, notwithstanding opportunities which, if allowed to pass by, will not be again readily found. For several years an immense area, from which a great multitude of people have been removed, has been left lying waste. The line of street which has been marked out, with the arches formed, and the roadway made, and reaches from Farringdon-street to the bottom of Coppice-row, has been left without use, except the part which is occupied by the railway and station: the rental lost in this way would amount to a considerable sum. Although the houses and shops are not yet formed, the wayfarer will notice the great increase of the traffic which comes this way, and soon the basement of these premises will, in the shape of shops for various kinds of business, turn in a goodly sum; and it is well worthy of consideration, if the under part of the buildings be devoted to the purposes of trade, whether the superstructure should not be let in flats, like parts of Edinburgh, for the use of families. For a large number of persons who have families and whose employment causes them to be engaged in the City, this site is most convenient: its close position to the Underground Railway, which will ere long be a means of transit to the chief points of the metropolis and the suburbs, will in other ways be of advantage in rendering this a useful place of residence. Let us therefore hope that the opportunity which is here afforded may not be allowed to slip away: at any rate, let us have an estimate of what the shops here would be likely to bring; and of the rental of sets of apartments arranged in flats after the Scotch fashion,—the houses being raised say to the height of five stories above the shops. We have no doubt but that apartments of the kind indicated would, in this situation, let as readily as those in Stratton-street and some of the other so-called model lodging-houses. The cost of building houses of this kind could be readily estimated, and the ground-rent and working expenses exactly known: we could then see the chance which there would be of making an undertaking of this kind pay a fair amount of interest. There are at the present time heavy calls on the London corporation, in consequence of the Holborn viaduct and other works; but

there is a duty resting with the corporation of this great city, to set an example in providing dwellings for the use of those who have been ejected from their homes, in consequence of the needful changes of this time of transition; but if the provision of dwellings on the plan which we have hinted hold out a fair promise of paying, shops and all together included, a return of 5 per cent., any amount of money which might be needed for a purpose of this kind could be obtained, in consequence of the new order in council which has been made, in connexion with sums which the Government has at its disposal for the purpose of assisting schemes of this description. The opportunity to which we have referred may, if allowed to pass by, not be again readily met with. Farringdon Market, the street facing the Fleet Prison, the property in Smithfield, are well worth the most careful consideration of those whose duty it is to attend to the provision of houses which are so much needed.

It may be said that by the erection of houses, and dividing them in flats, the amount of rental which will be required to make them pay will confine them to the best paid classes of mechanics,—to clerks and others engaged in various ways of business;—but the fact is, that by providing house-room for any particular class, we make way for those who are, to a certain extent, below them.

#### NEW BLACKFRIARS BRIDGE.

On Thursday, at the moment of our going to press, the foundation stone of the new Bridge at Blackfriars was laid by the Lord Mayor with considerable ceremony. The stone bears a Latin inscription, of which the following is the, not very precise, official translation:—

The former Bridge over the River Thames having fallen into decay,  
The Court of Common Council  
of the City of London  
ordered the Construction of a New Bridge  
on the same site,  
of which the Right Honourable Warren Stormes Hales,  
Lord Mayor,  
laid the first stone, on the Twentieth Day of July,  
in the year of our Lord, One Thousand Eight Hundred  
and Sixty-five.

We trust under better auspices:  
for the former Bridge was built  
during a period of general war;  
the construction of the present has been undertaken  
in a time of profound peace,  
in the Twenty-ninth year of the reign  
of QUEEN VICTORIA,  
at a moment when the former restrictions of commerce  
have been removed,  
and, by the adoption of Free Trade,  
those separate interests which divided nations  
have been happily bridged over.  
May the Almighty,  
of His infinite goodness,  
grant to the emen a happy completion.  
JOSEPH CUBITT, Engineer.

The original says, *Josephus Cubitt Construxit*, which, to future ages, should the bridge last, will not convey the same idea as the English version given: in fact, it is not the right expression.\*

We must in justice add, though we now give no constructive particulars, that Mr. Henry Carr is joint engineer with Mr. Cubitt; but the committee to whom the work is entrusted refuse, in accordance with an existing rule, to recognise more than one name.

Mr. R. W. Mylne writes as to the old bridge:—In February, 1760, the decision was finally made by the City authorities, approving, out of fifty designs, the one sent in by my grandfather, Mr. Robert Mylne; and, four months later, the first pile was driven for the south middle pier. No works whatever were carried out on the north bank of the river until May, 1764, when the excavations for the north abutment were commenced; but those on the south bank were begun much earlier.

The laying of an inauguration stone on the City side of the river by Sir Thomas Chitty, in 1760, before the expiration of his mayoralty, was considered so desirable that, although no permanent works had been commenced, it was decided to have a great public ceremony, and for that object a special excavation was made in front of the old wharf wall adjoining the mouth of the River Fleet, to the west of the ancient causeway, or public ferry landing-place, at the foot of Water-lane.

Four large Portland blocks were fixed on a platform, over which a stone 6 ft. by 3 ft. was

\* A view of the proposed Bridge, and some descriptive particulars, will be found in our Vol. XX. (1862), p. 732.

placed, having a cavity 47 in. by 30 in. for medals and other objects, besides a plate of tin bearing an inscription.

This inauguration stone was laid on the last day of October, 1760, and was securely fixed with fourteen iron cramps, dove-tailed, and leaded, and, subsequently, two additional blocks were fixed to prevent the possibility of its being disturbed, the total cost being 185*l*.

In the following year the pile-driving at the south middle pier had so far advanced as to permit a caisson to be floated and set, and masonry founded within.

The first stone at the south-east angle of this pier was laid on the 23<sup>d</sup> of June, 1761, by Sir Robert Ladbroke, chairman of the Bridge Committee, under which was placed a slab of Devonshire marble, with an inscription, and immediately above, another slab of similar marble, with inscription, was laid by desire of Sir Francis Gosling.

The whole of these inscriptions, besides medals, &c., were discovered in this pier in 1834, when the repairs were carried out, renewing the cutwaters with granite, in lieu of Portland; and on the 14th of January, 1835, they were again relaid, on the occasion of an official ceremony by the Bridge Committee, at which I was present.

#### THE PROPOSED EXHIBITION OF NATIONAL PORTRAITS.

A MEETING has been held in South Kensington Museum for the purpose of organising the projected National Portrait Exhibition. Amongst those present were Earl Granville, the Earl of Derby, the Duke of Buccleuch, the Marquis of Lansdowne, the Earl of Clarendon, Lord Houghton, Lord Tannton, and Viscount Sydney.

On the motion of Earl Granville, Lord President, the chair was taken by the Earl of Derby, who said that it was not intended that the present meeting should come to any resolution, but that it should act as a committee of advice, and give information as to any details which it might be thought advisable to take into consideration. The object in view was to form a collection of portraits—beginning probably about the middle of the fifteenth century and coming down to a very recent period,—which should exhibit in chronological series the great contemporary characters of the successive eras—the statesmen, warriors, men of letters, and artists of each age—whose portraits could be collected together from private sources. It would also be useful and interesting as illustrating the progress and condition of British art at various periods. There were in private houses a vast number of such portraits now entirely unknown, but which would be brought to light by the exhibition, and afford valuable materials for history. It was proposed that the exhibition should take place in one of the arcades—that which had served for the refreshment rooms—of the Exhibition of 1862. There they would have space for about 800 portraits. It was proposed that the exhibition should be opened in April, 1866, continuing open for several months, and it would depend upon the number of contributions whether there should be a second or even a third exhibition in the following years. He had received a letter from General Grey, intimating that her Majesty entirely approved of the project, and that it should receive her warmest support.

Earl Granville, Mr. Scharf, Mr. Redgrave, Mr. Cole, the Earl of Clarendon, the Marquis of Lansdowne, the Duke of Buccleuch, and other gentlemen, addressed the meeting, and it appeared to be of opinion that a very numerous and valuable collection would be obtained for exhibition.

#### COST OF CHORLTON HOSPITAL.

With reference to the cost of this hospital, of which we recently gave illustrations, we learn that the general contract for the five pavilions, with the corridor, very little exceeds 15,000*l*, or, in round numbers, 3,000*l*, a pavilion, with portion of corridor. This does not include fittings or administration, but the cost presents a great contrast to that of the large foreign hospitals, or to our own military hospitals, at Netley and Woolwich. The architect observes,—"I need not say that all attempt at architectural effect has been carefully avoided, but the work is substantial and good, and the main sanitary objects will be attained."

M. MICHEL CHEVALIER AND ENGLISH ART.

Sir,—If it be difficult sometimes to come to a correct judgment on a subject by reason of its distance, it is equally hard at times to do so by reason of our closeness to it. We are unable to see the definite outline of an object very far off, and equally unable to take in the same outline from the fact of standing so near to it that we can see but a part of it, thus missing as much of the truth of things by nearness and intimate knowledge as by remoteness and ignorance.

The truth of this will be evident to any one who has ever tried to estimate the value of the common and every-day art about him, by watching the growth of new buildings close to him,—by noticing the perpetual change of fashion, and the ever-changing art of the time, as seen, and to be seen only, in the contents of the shop windows. We are so near them that they seem all unchangeable. What a vast help, therefore, it is, and must be, when some one of sufficient capacity and knowledge looks at all these things for us from a distance, and who then tells us in plain and pointed language how these same things, that seem so and so to us that are near, appear to him at a favourable distance and entirely unprejudiced. We must, therefore, as I think, all feel much obliged to M. Michel Chevalier, the great French economist, for looking, in a kindly way, at English art as it was and is, and comparing it with his own French art. I do not know what others may have thought of his remarks in the French Chambers, and which have now gone the round of the newspapers; but I think, with all possible respect, that they are as erroneous and void of foundation as anything ever yet uttered on art matters; and it is to dispute their correctness—no one having, as far as I have seen, yet done so—that I plead for space for a few lines on so very important a matter. I must ask again for a little attention to facts, and of those with short memories for form and pattern, to go once or twice up and down any one of our principal shop streets and look into the "windows" for evidence. Bond-street is always enough for me.

M. Chevalier tells us that it is now three whole years since he was in London; but that then (1862), both himself and his colleagues were struck at the progress made by us English "in the art of design in connexion with industry," and it inspired them with "admiration and fear,"—admiration at our English capabilities, and fear lest his own countrymen might be outdone. Let me observe here, in passing, so as to avoid mistakes, that he is speaking of the evidences of art-strength as seen in the 1862 Exhibition; but that it is necessary to bear perpetually in mind that there was nothing more in the building—nor, indeed, in these ever in any of our exhibitions—than is to be seen every day out of them, they having been nothing more than pickings from the principal shop windows. The "exhibition" is, therefore, still open to those who will fairly look at it. What was it, then, that so struck the accomplished mind of this Frenchman?—the progress in art-manufacture made during the eleven years from 1851, the year of the first Exhibition, to 1862, the year of the second Exhibition. I must beg simply and laboriously to ask him—where? What evidence is there of such advance, and where may specimens be seen showing in themselves, in any kind of material, visible and tangible signs even of it? What was it that M. Chevalier was especially or generally looking at? Was it the building! outside or inside, or the decoration of it? Was it in stone, or wood, or metal, furniture or "fabrics," printed cottons or carpets, or paper-drawings or architectural drawings? What, I must ask, was it? and more, where are all the specimens now? If this wonderful progress was so clear then, it must now be still clearer. If these wonders had an existence, they must be still in being, and visible somewhere or other. They were visible, and all may yet see them, viz., in our shop windows—those true and unmistakable thermometers of the arts of nations. I ask therefore again, what proof is there at this moment, in the contents of these shop windows, of advance in the arts of design and execution made from '51 to this hour? Can M. Chevalier point to one single specimen? I say he cannot; and even more, that no such little group of art-objects could be got together as a series of "material art-results and impressions of the mind" of an artist in material as was to be seen in that little court of Gothic work of Pugin's. We may therefore ask yet again, what style of art is it that has been or is progressing? M. Chevalier is

in Paris, we in London, and he can see without prejudice what is, perhaps, here viewed with patriotic partiality. Looking at tangible results to be daily seen everywhere, I deny the truth of all this this Frenchman has told his countrymen and us.

I know the interest you have always taken in these common though little heeded art matters, but I can only ask you for space to notice in detail one or two actual specimens of art-manufacture now to be seen, without cost, in the great London Exhibition of this year,—the shop windows. I refer to the most costly.

Mr. Ruskin has asked somewhere,—“What is vulgarity?” and has attempted, with the help of worthy Shakespeares, to define it in words. Material may help both him and us, and certainly my present argument. Vulgarity is insincerity, says Mr. Ruskin. I ask, is it vulgarity, or insincerity, or the progress of the art of design, or manufacture, which can induce a fine lady to dress herself up in a white "fabric," covered all over with huge black, dead black, round spots, or balls, the size of pennypieces, 3½ inches apart! Is this French or English? because M. Chevalier says, that before 1851, all woven fabric patterns were designed by French artists, but that since then this special work has been done by the pupils of our Art Department. Again, is it design, or what is it, which can see progress or art in ornamenting an article of dress, with the representation of a "hand at whist," some eight or ten playing-cards ranged in a semicircle in rows? Is it "insincerity," which covers a blue fabric all over with gilt rings, some 4 in. across? Who will claim the merit of dotting a surface with small feathers, as picked from a fowl, with dice in twos and threes, with exploding bombshells, postage-stamps, an English invention at least; rifles, percussion-caps, stripes half the width of the stuff itself and hosts of others, which it would take pages to catalogue? Are all these things French or English, "designs or accidents"? Are they the results of knowledge or ignorance? Surely it is for M. Chevalier, and such as he, to find in these performances either "art" or "progress." They are things to be ashamed of, whether French or English, and are to be accounted for, in part it is to be feared, by the fact of so enlightened and advanced a man as M. Chevalier allowing himself to talk of things of which he either knows nothing, or perhaps did not take the trouble to look at a second time. But all this is, as I have said, new to the political economists, and they with him have yet to look with a serious interest at what they have hitherto regarded as childish toy-work. The brightest page of their book has yet to be written.

I had thought to have left off here, merely contenting myself with calling attention to the inaccuracies of the French writer, in consideration of his eminent position and the effect his words are likely to have if unquestioned; but he has said much more. Before '51, says he, everything in "good taste" was French: we English, "though having some celebrated artists, have not been very remarkable for taste." After '51 came the Schools of Design, and to them exclusively, he informs us, is to be attributed his so-called and thought improvement in our art manufactures. I have indicated a few of the "improvements," and might have gone on and cited the like improvements in other art trades as little to be proud of as "fabrics"; but whether all these things are improvements or no, I must, from personal knowledge, deny that the Art Department is to be held responsible for them, either by way of credit or blame. It has had nothing whatever to do with the matter. All these fabrics may be covered with noble "patterns," but they are not of the Department; or they may be foolish abortions, but they are not of the Department, as he has been led to suppose. The action of that institution has been, as far as art, or even art manufacture, is concerned, simply nil. Movement, but not progress, has been, for reasons which might be given, the motto of the Department; for the very self-same system of work and model drawings in use now thirty years back—all one vast mass of error and falsity—is in use at this very hour. Stagnation the Department may be accused of, but not the "dulness" before the '51 Exhibition, nor the "progress" after it. M. Chevalier should first look at facts.

One more remark you must kindly allow me. In a number of the same journal, that of the Society of Arts, in which this valuable series of

opinions of an illustrious man first appeared, there is a long and detailed account of a "National Conservatoire of Music and Elocution," with a list of regulations, course of studies, salaries and duties of officers, etc., the whole complicated apparatus being for the simple purpose of teaching people to sing, or play on some instrument. The French are beginning to find out "how not to do it." The whole work of the institution as a school seems to rest with the inferior and assistant professors; and on looking at the scale of salaries it will be seen that these working teachers are paid, or to be paid, some five-and-twenty per cent. less than the "servants" of the establishment. The amount of knowledge required of these professors, low as they are, is something appalling; but however accomplished or able, it will be but to find out that to be able to play on, and to teach to others to play on, even the most difficult instrument is of less "value" than the being trusted with the duty of dusting it. Haa M. Chevalier looked at this institution as a political economist? I mention it for the sole reason of asking whether or no there is not something radically wrong in the present idea of art action and teaching. If it be all right, how can such things be? or how can such able men as M. Chevalier or M. Cormébe be brought to talk as they have done?

C. BRUCE ALLEN.

NOTES ON FUNERAL OBSERVANCES AND MEMORIALS OF THE DEAD.

FROM the most remote periods, so far as history goes back, to pay honour and respect to the remains of eminent personages, or those of departed friends, is shown to have been an inherent feeling of human nature; and in connexion with the remains of the most celebrated of the ancient people, the tombs and other receptacles of the dead are, for the most part, remarkable for the permanent nature of their construction, and for the artistic skill and extent of their ornamentation.

The discoveries which have been made in recent years show with what great care the Egyptians, many ages ago, preserved the bodies of their dead; and in their anxiety to show their regard to their race, they also embalmed and preserved with care animals of various kinds which were held in favour during lifetime by their departed relatives.

In the sacred writings there are various accounts of anxiety shown in the selection of final resting-places by the ancient men whose lives are therein recorded; for instance, we have particulars of the purchase of the cave of Machpelah and the ground in which it was situated, by Abraham, for the burial of Sarah his wife. As time passed on this became a more and more honoured spot, by the burial in it of the patriarch and others of his race. As a last request, Jacob desired, in a most impressive manner, to be taken from Egypt to the land of Canaan, in which this cave was. On the death of his father, Joseph, in compliance with this request, caused his servants, the physicians, to embalm the body of Jacob, "and forty days were fulfilled for him; for so are fulfilled the days of those who were embalmed: and the Egyptians mourned for him three score and ten days." (Gen. 1. 3.) After this observance, Joseph begged of Pharaoh that he might be allowed to go to the land of Canaan to bury his father, as he had sworn to him to do. Pharaoh gave permission, and Joseph went up to bury his father, and with him went up all the servants of Pharaoh, the elders of his house, and all the elders of the land of Egypt.

"And all the house of Joseph, and his brethren, and his father's house: only their little ones, and their flocks and their herds, they left in the land of Goshen. And there went up with him both chariots and horsemen: and it was a very great company." (Gen. 1. 8, 9.)

Joseph, on his death, caused his brethren to swear that his body should be buried with his father's, in the cave of Machpelah; but he was embalmed and chested or cophined in the land of Egypt.

Without especially referring to books which illustrate the various conditions, so far as the ornamentation of tombs and sepulchres are concerned, an observant wanderer in the antiquarian galleries of the British Museum will find much that is instructive and interesting in viewing the gatherings which have been made from so many places of former fame. Passing over multitudes of objects, he will notice some of rare

valve, which have been deposited in tombs and other repositories of the dead. Of varied date are these relics, but notwithstanding, in all there is shown the same desire to snatch from oblivion the name and repute of those who have been closely allied to the entombers by the ties of love, relationship, or other bonds. Amongst these is the devotion which is shown by various peoples to great warriors, or national benefactors,—in various centuries, in different parts of the world,—in a period ranging from three to four thousand years back to the present day. From the days of those Pharaohs, to preserve whose memory huge pyramids were reared, to those of the present era, when goodly monuments of different kinds have been completed, or are in progress, to show our love and admiration for the late lamented Prince Albert, cultivated nations have been moved by the same spirit to preserve, as many vainly hope for ever, the memory of those who have done worthy things in their generations, and who have been so much admired by, and so familiar to, their contemporaries. But vain are the attempts of man to achieve immortality, or to contend against the ravages of time. The Pyramids still stand in Egypt, but if they were built to record the worth or the renown of famous rulers we know but little or nothing of them, their peculiarities or exploits.

In our walk through the ancient remains in the British Museum, we note that, considering the enormous time which has elapsed, the Egyptians have been very successful in preserving the remains of their dead: in the mummy forms, the skin and the bones have been wonderfully kept from decay; and in their colossal and other statues there have, no doubt, been preserved the truthful representation of mighty men who, in the time of the greatness of the land of the Pharaohs, were chief movers in the management of the State; and so perfect is the preservation of their surfaces, although so many thousand years have passed away, has been scarcely dimmed or in any way injured.

Closely in connexion with the dead Assyrians, Greeks, Romans, &c., were strewn in profusion hand and other rings, personal ornaments of many kinds, richly-wrought armor, and choice articles of domestic use. Although the Romans burnt their dead to ashes, the choice vases in which this valued dust was placed still remain as things of hearty use to the art-student and delightful to all persons of taste. The Roman tombs were, in many instances, of chaste and simple design; and the inscriptions show a kindly feeling, a love of home, and a respect for family ties. The hosts and statues of the soldiers, statesmen, orators, and others of note amongst this people, are so evidently faithful and life-like, and so well preserved, that they will for a long time remain as valued memorials.

In Great Britain, since the first dawn of modern civilization, the methods of burial have been varied, and in the British Museum we find many relics which have been gleaned from rude earthen tombs of ancient British date; others from cairns and barrows, and relics from places of sepulture where the introduction of Christianity caused a marked difference to be made in the funeral ceremonials. A large volume would not afford sufficient space to contain all that might be usefully said on this subject. As time passed on, the funerals of royal personages, ecclesiastics, and persons of high rank became stately pageants; and the tombs placed over the graves, until awhile after the Reformation, increased in the style and extent of their elaborate execution, and the expensive nature of their design. The tomb of Henry VII. may be taken as an example.

In the pages of English history we have long and careful accounts of those funeral feasts, which often crippled for long the means of noble families; and of the example of the great having been followed by those of lower position. The funeral of a relative often brought a family to ruin. In the Print-room and in the King's Library, at the British Museum, there will be found representations of some state funerals; amongst them those of Queen Elizabeth and General Monk. Anything more unsightly than the costume used on those occasions it would not be easy to imagine. Very gradually, except on very special and more and more rare occasions in England, the rough feasting, the excessive drinking, the lying-in-state, and other marks of what was considered to be a proper respect for the departed, were in a great measure dis-

used. In the Highlands, and in other portions of Scotland and Ireland, the quantity of meat and drink consumed was extraordinary and disgusting. Even still we find in the local newspapers accounts of the lingering of this bad custom. During the lifetime of the present generation there have been but few state funerals. Many of the particulars in connexion with that of the late Duke of Wellington will not be readily forgotten by those who had the opportunity of noticing them. In connexion with Royalty, we are not likely to have any more lying-in-state, hurrying by torchlight, or other ceremonials which were once common.

The funerals of our people of talent and repute, nevertheless, have lost none of their impressiveness, as has lately been shown by the great gathering of friends, in their ordinary costume, who crowded round the graves of Jerrold, Thackeray, John Leech, and others who have departed from amongst us. There have, however, been two remarkable funerals, in which, to a certain extent, the ceremonials of the past have been revived. One of these was the funeral of Cardinal Wiseman; the other that of the Duke of Northumberland. But, in the metropolis, and in the large towns, the mutes in their sable robes, the silk and crape-covered staves which denote their office, the feathers carried before the hearse, those which nodded on the horses' heads and on the carriage which conveyed the remains of the dead, the costume of the mourners, &c., &c., have fallen greatly into disuse. Few will regret this. But there are certain funeral observances common in some rural districts which would be sorely missed by those who like picturesque ceremonials, and evidence of kindly feeling amongst those of low degree. Amongst these is the practice of hanging garlands of flowers and ever ribbons on the tombs and, in the churches, over the seats which have been generally occupied by those who have died. These garlands, often withered and far too great in their number, are glanced at with the eye of affection, and do not seem out of place amongst the richly-carved tombs, the knightly banners, the monumental brasses, and other objects connected with the memory of those of rank.

In the churchyards we would regret the disuse of those plain wooden monuments, on which are painted some pious texts, together with the names, and times of birth and death, of the departed.

#### NEWS FROM GERMANY.

**Prussia.**—In Berlin the erection of a new National Museum has been determined on, and will probably be begun this autumn. The site is fixed in the rear of what has hitherto been known as the "New" Museum, fronting the Royal Palace; and the costs are estimated at one million thalers, or about 150,000. It is to be finished in six years.—Von Kaulbach, the well-known animal and fresco painter, will have finished the frescoes in the great staircase of the present "New" Museum this autumn, after a labour of twenty years. The great staircase will then be free of all scaffolding for the first time, and some kind of ceremony is expected on the occasion.—The Institute of Architects of Berlin has opened a subscription for a handsome tomb to be erected over the grave of the architect Von Stüler, who died in the spring.—The question of the new Houses of Parliament has now been so far decided that the two Houses are to be separate. A site for the Lower House has been obtained where the Royal Porcelain Works now are. These will be removed beyond the city, and plans for the new chambers are now being prepared.—A new and handsome Exchange, in Gothic style, is in course of erection at Breslau. The capital is furnished by a company, and the plans are by a M. Lüdecke, a local architect.—In Cologne the works at the Dom are steadily progressing. The Rhinish and Cologne-Minden Railway Companies have forwarded 10,000 thalers towards the North Tower fund. A new church, St. Maritius, has been lately consecrated. The style is German Gothic, somewhat resembling the church of Notre Dame, at Treves. The dimensions are,—length of nave, 164 ft.; transepts, 110 ft.; height of vaulted nave, 70 ft.; of side aisles, 35 ft. The funds for the tower have still to be collected,—*tout comme chez nous*. It will be 230 ft. high.—At Falkenberg, near Aix-la-Chapelle, an interesting tessellated pavement has been discovered, at a depth of 4 ft. under the soil: 3 ft. deeper, three handsome vases,

a medallion with the portrait of an emperor, and six large jars with ashes were found. All these objects are of the time of immediate descendants of Charlemagne.

**Austria.**—The church of the German order of Knights Templar, at Vienna, has been restored, and a new altar-screen, sculptured by Peter Kahlunger, inserted.—Six architects have competed for the new Houses of Representatives.—Professor Schmidt (Gothic); Hansen, two designs (Classic and Italian Renaissance); Ferstl, Zettel, and Uchl (French Renaissance); and Essenwein (late Romanesque). We have not yet heard whose design has been chosen.—Eleven huge blocks of Carrara marble have arrived for the figures on the new opera-house, on the Kärntner Ring. The largest of these is 9 ft. by 6 ft. by 6 ft., and is destined for a group of "Dannhina and Vindobona," the latter being the tutelary deity of Vienna. This block weighs 500 cwt. The opera-house itself is now nearly up to the height of the cornice, but will scarcely be roofed in this winter.

**Bavaria.**—A new polytechnic school is being erected at Munich, for which the Government has demanded a vote of 1,000,000 florins (84,000*l.*). The chief front is 480 ft. long, and faces the Pinacothek. It is two-storied above the ground-floor, and is flanked by two receding wings 125 ft. long each, which again return at the back for a length of 105 ft. It is in the usual Bavarian style, but in keeping with the surrounding buildings.—A mausoleum is in course of erection, for the remains of the late King Maximilian, at the church of the Theatines (Theato was the see of Bishop Caraffa, one of the founders of the order). The designs were prepared during the king's lifetime, and are now being executed under the supervision of Mr. Riedel, architect.—King Ludwig, who, since his abdication, nearly twenty years ago, has made the erection of monuments to men of worth or fame his especial and very praiseworthy hobby, has discovered two more men of Bavaria, who are as yet unrepresented in this manner; these are F. von Gärtner and Leo von Klenze, both architects. The sculptors Brugger and Professor Widmann are commissioned to produce sketches by September next.—Widmann has just completed a very beautiful recumbent figure of the Grand Duchess Matilda, to be placed over her tomb at Darmstadt.—The two towers at the Cathedral of Ratisbon are now being completed. Judging from the sums received by the committee for this purpose, the completion may be looked to in 1870.—The cathedral church of Passau is now completely restored, after a work of eight years. The expenses were entirely defrayed by the inhabitants, who, at liberally responded to the call of the bishop, Heinrich von Hofstätter. The church, originally of the eleventh century Romanesque style, had been terribly disfigured internally with rocco plastering, but all this has now been removed.

#### ITALY.

The foundations of a Temple of Jupiter have been discovered in the garden of the Caffarelli Palace, at Rome, but we have no particulars, as yet, further than that space about 70 ft. square was laid open in taking down some outhouses, when enormous blocks, like those of the Tabularium, were found, proving the former existence of a very large public building on this spot. Similar remains were also found lately at Torriglia, near Genoa. At Ostia, the two Visconti are pursuing their researches with success. Three well-preserved frescoes were discovered, and carefully copied by them. One of these is particularly interesting; representing a ship, with figures on board: over the heads of each are scrolls, with the names of their respective offices. The frescoes are transferred to canvas by a peculiar process, which is said to be very successful in reproducing works of this kind.

**THE MEMORIAL CHURCH AT CONSTANTINOPLE.** The ceremony of laying the corner-stone of the church to be erected at Constantinople, in memory of the British troops who died there during the Crimean war, was performed on the 4th instant by the Rev. W. H. Ewald, in presence of a numerous attendance of British, foreign, and native spectators. The works are being vigorously pushed on, and will, it is hoped, be completed early in the coming year. Mr. Street is the architect.

FRANCE.

THE Treaty of Commerce entered into by France with Prussia and the Zollverein, the free and Hanso towns of Lübeck, Bremen, and Hamburg, the United Kingdoms of Norway, Sweden, and Switzerland, came into vigor on the 1st inst., but it was inaugurated by a dreadful event, the destruction by fire of the little manufacturing town of Laroche, in Belgium.

Upwards of a hundred houses—and, consequently, a hundred factories—for every house in the village was a factory of more or less importance—are now in ruins. Raw material, merchandise of all sorts, looms, machinery, and tools, were all destroyed. For some months past commercial exchanges of goods had been suspended between France and the Zollverein, both countries waiting for the favourably amended tariffs of 1st July; consequently all the warehouses near the frontiers were completely filled with goods. Laroche, which supplied with woollen stuffs the neighbouring provinces of France, Belgium, and Prussia, was thus stored with merchandise, and the fire, having abundant aliment, spread with great rapidity through the village in one general conflagration.

An order has just been given to an engineering firm in the Department of the Haut Rhin for twenty-four locomotive engines, and from two to three hundred carriages for the German railways.

PARIS.

A PORTION of the double bridge by which the Auteuil Viaduct of the circular railway traverses the Seine, at the Pointe du Jour, was opened for the traffic of vehicles on the 1st inst. The structure is to consist of two series of arches, one over the other, the upper one carrying the railway, and the lower one serving for general circulation. The latter is composed of five semi-elliptical arches, of 99 ft. 1 in. span each, and two land arches, one at each end, of 65 ft. 7½ in. span. Above this stands the viaduct, the level of rails being 67 ft. 3 in. over the water: it commences at the Auteuil station, and terminates on the left bank of the river, about a kilometre from the bridge, and throughout its whole length there is a double arcade for foot passengers. At the base of the viaduct, on the lower bridge, a roadway on each side, 28 ft. wide, bordered by a footpath, 6 ft. 6 in. wide, has been constructed for vehicles, the bridge being 116 ft. 10 in. wide between parapets, and 36 ft. 5 in. high over the water. One of these passages is the portion opened a few days ago: it places Auteuil in direct communication with the Ronte de Sèvres and the military road of the fortifications.

The *Moniteur* states, that the Imperial Commission, after having examined most carefully the numerous projects which have been submitted to it for the Paris Exhibition, has, according to the report presented in the name of its Committee of Plans and Constructions, by M. Dumas, definitely adopted the preliminary project prepared by the commissary-general, as answering completely to the different requirements of the Universal Exposition of 1867. The execution of this plan has been confided to M. Krantz, engineer in chief of bridges and roadways.

For some time past the Hôpital Saint Louis has been under repair, by the care of the Assistance Publique, or general committee of the Paris hospitals. This building was founded in the year 1607, during the plague which then raged in Paris, and placed, outside the town-limits of that period, between the Portes du Temple and Saint Martin. It was created, not as is often supposed, from the designs of Claude Châtilon, but according to the plans of Claude Villefaux. A document preserved in the bureau of the Hôtel Dieu gives the text of the deliberation, dated the 27th of November, 1607: "The Company to deliver a mandate to Claude Villefaux, juré du roi des-œuvres de maçonnerie à Paris, for the sum of 255 livres 3 sols, as the reimbursement of what he has paid to those who have assisted him in making the design and model in elevation of the hospital."

The establishment was put under the patronage of Saint Louis, because that king died of the plague.

A complete bathing service has been for many years added to this hospital, with all the improvements and requirements of modern hydro-therapy. Lately the chapel has been restored, and new arches, flooring, woodwork, windows, and a hypocaust have been added. In the sick

wards, the sales St. Augustin, St. Marthe, and St. Jean have also been renewed, and the gas-stoves for warming replaced by others upon a less objectionable calorific principle. Apropos of gas, we may mention that there is preserved in the Conservatoire des Arts et Métiers in Paris, a model of the apparatus for lighting with coal-gas, said to have been constructed by the engineer Lebon for the St. Louis Hospital. Lebon's patent is dated September 28, 1799; and a certificate of addition more particularly relating to the general lighting by gas bears the date of August 25, 1801.

The Assistance Publique is not connected with the corporation of Paris. It is a great institution which has its own administrators; a chief director named by the Emperor; and as directors, MM. Troplong, Dupin, Le Pelletier d'Aulnay, and Davillier, president of the Tribunal of Commerce of Paris. This public body had formerly held in different quarters of Paris vast lands, which had become its property by legacies or pious donations, and for many years had permitted the town of Paris to establish thereon its markets, which had thus become a source of joint revenue for the two parties. Finding, however, this state of co-partnership inconvenient and the accounts difficult to regulate, the Assistance Publique, about twenty years ago, sold all these lands to the town for the sum of 493,221 l., payable in 1874. The site of the new Hôtel Dieu and the plan of construction having been decided upon by the above committee, they set about building it at once, and the town has agreed to pay the debt of 493,221 l. now, instead of in 1874.

The estimate and accounts of treaty between the two bodies are as follow:—Expropriation, materials, &c., 856,000 l.; the Assistance Publique contributing from its own resources the debt due by the town of Paris, 493,221 l.; the value of the lands ceded to the town in the neighbourhood of Notre Dame, &c., 192,000 l.; the proceeds of the sale of the houses and lands of St. Perreine and ancient hospices des Ménages and Incurables, &c., 100,000 l.; total, 785,221 l. The town of Paris consents to pay 70,779 l., the sum by which the expense of construction, installation, &c., of the hospital, exceeds the amount furnished by the Committee of Assistance, as above stated, independently of the other expenses of street and highway works, exclusively at the municipal charge.

In the ancient Hôtel-Dieu there were 826 beds, and the area was 11,000 square metres (133 square metres per bed); whereas the new building will contain 716 beds, standing on 22,000 square metres (30·7 square metres per bed), and thus disposed:—15 wards, containing from 26 to 30 beds; 19 ditto, of 6 to 10 beds; 3 ditto, from 6 to 12 beds; and 41 rooms, with 1 or 2 beds; total, 84 separate apartments, averaging from 8 to 9 beds, containing a greater cubic quantity of air than has hitherto been possessed by any similar establishment. These 716 beds will cost 556,000 l., or at the rate of 1,195 l. per bed.

The following is a statement of the comparative mortality in the Paris hospitals:—Lariboisière (Embarcadere du Nord), 1 in 8·01 patients; Hôtel-Dieu (Cité), 8·35; Beaujon (Faubourg St. Honoré), 8·39; Pitié (Jardin des Plantes), 8·75; Necker (Vaugirard), 8·91; Charité (Faubourg St. Germain), 9·43; Saint Antoine (Faubourg St. Antoine), 9·13; Cochin (Faubourg St. Jacques), the smallest hospital in Paris, 9·96.

This difference in mortality does not seem to be owing to the nature of the surrounding population, nor to the considerable number of consumptive patients, but seems to be the effect of overcrowding. The Lariboisière, in which the mortality is greatest, was constructed for 400 beds, whereas it now contains 600.

A new Asylum has been lately founded behind the new Church of Saint Augustine, for children, orphans, and infirm persons. The building for the children has been completed, and contains room for 400 pupils, and dormitories for 350 beds, large court-yards, &c. The expense of lodging, board, lighting, warming, washing, clothes, linen, bedding, instruction, musical lessons, vocal and instrumental, the hire of pianos and organs, only amounts to 1 franc per day for each pupil. This institution, having for its object the preparation of children either as teachers in small seminaries in Paris, for the examinations of teachers held in the Hôtel de Ville, or for the office of chorist or organist, was opened on the 1st inst. under the direction of the Sisters of Charity founded by St. Vincent de Paul.

PROPOSED NEW INFIRMARY, SWANSEA.

A NEW infirmary for Swansea has long been under discussion, the present building, which was erected some forty years ago, near the sea-shore, having been found quite inadequate to the wants of a large and rapidly increasing community. The infirmary Committee have recently purchased a site of about 2½ acres on the outskirts of the town, and in the best quarter, and about 36 ft. above the level of the sea. The site commands a south-west aspect, and receives the soft prevailing winds direct from the Bristol Channel.

The new building provides for 100 in-patients, of whom sixty-eight are men, and for a large number of out-patients. In connexion with this latter department, will be a bath establishment, the object of the Institution (which is supported by voluntary contributions) "being to afford warm and cold sea-water bathing, and medical and surgical relief to the sick poor from every part of the Kingdom."

The building may be considered as divided into four distinct parts, viz.—the out-patients' department, the men's wards, the women's wards, and the administrative offices, communication being effected by a corridor on the ground-floor, and by an open terrace over, affording access to the wards on the upper floor direct from the matron's department.

The ward arrangements, which are the same for men and women, consist of a large and small ward under the same supervision. In the case of the men's wards the surgical cases, which are very numerous in consequence of the extensive works throughout the district, will probably be treated in the large wards, the small wards being appropriated to medical cases. The cubic space per bed is 1,600 ft.; the floor space per bed, 100 ft.; the wards being 16 ft. high. The wards will be warmed by open stoves, placed near the wall, so as not to interfere with the symmetrical arrangement of beds and windows. The ventilation of the wards and W. C.'s, &c., will be effected by inlets for fresh air, placed near the ceiling, and by outlets at the ends of the wards, the shafts being carried up separately into the towers, and terminated by louvers. The wards will have sash windows, 5 ft. wide, opening from 9 in. below the ceiling line to within 2 ft. 9 in. of the floor, the sashes being hung in two widths on account of excessive size and weight. They will have, externally, the appearance of French casements.

The ward walls and ceilings will probably be finished in Parian cement, but as the committee are now raising subscriptions for the new work, the employment of any but the ordinary materials will depend much upon the amount of support given to this praiseworthy undertaking.

There is a basement to the building devoted to administration, containing the kitchen and necessary stores. The upper story is appropriated entirely to dormitories for the nursing staff.

The building will be constructed of coursed rubble limestone, from the immediate locality, with dressings of Bath stone. The roofs will be of slate. The design, of which we give a view, and plans of the two principal stories, was selected in competition.

The architect of the work, which will shortly be commenced, is Mr. Alexander Graham, of Carlou-chambers, Regent-street.

PROPOSED SWANSEA INFIRMARY.

PROPOSED SWANSEA INFIRMARY.—MR. ALEXANDER GRANT, ARCHITECT.

THE BELFAST ALBERT MEMORIAL COMPETITION.

Sir,—Had Mr. Gordon M. Hills taken a less partial glance at the *Belfast Newsletter* of the 27th ult., he might have learned some facts connected with this matter which, if placed before your readers, would go far to rebut the charges which he has thought proper to make, and be quite sufficient to show that Mr. Lanyon had no intention whatever of occupying "a position as unfair to his brother architects as can possibly be conceived."

In the first place, I may mention that Mr. Lanyon did not "become" a member of the committee in the sense Mr. Hills would seem to imply. His name happened to be placed on the committee when the memorial was first talked of, immediately after the Prince's death; and, being one of the chief promoters of the movement, it has remained there since. Secondly, Mr. Lanyon,—individually,—not being engaged in the authorship or preparation of the design "*Palnam*," and therefore not so personally interested, and being innocent of any desire to exercise undue influence, the peculiarity of his position, under the circumstances, did not strike him. Thirdly, Mr. Lanyon took nothing to do with the proceedings of the committee regarding the competition, beyond advising as to the "instructions" to be issued to architects; and his presence at the meeting of the general committee (on which simple fact so much misrepresentation has been based) was owing solely to his having, like the other members, received a circular to attend, for the purpose of inspecting the selected designs. This he did, believing the selection to have been finally made, and without knowing that "*Palnam*" was one of the four; but on finding, after the reading of the report of the sub-committee, that the general committee, owing to the report not being unanimous, intended to rediscuss the relative merits of the selected designs, he left the room, without having attempted, in the remotest manner, to influence a single individual, and did not return until a final decision had been come to. Therefore Mr. Hills's suggestion that Mr. Lanyon's "influence in Belfast, together with his presence" went far to settle the question, is quite unwarranted. Fourthly, Mr. Lanyon, when he did return and found that the design he was interested in had been placed first, proposed to the committee that the *six* best of the designs should be submitted to the further adjudication of the president of the R.I.B.A.

These are the simple facts of the case. I happened to be out of town during the proceedings of the committee; and finding on my return (Mr. Lanyon having in the meantime left for London) that the final selection was found fault with; I proposed, in a letter to one of the local papers, as well as to members of the committee individually, that they should request the Institute to nominate some one of their members to visit Belfast, to examine and report on the whole of the designs. The committee again met, to consider the question of further adjudication; and, notwithstanding the suggestions before them, determined on submitting only the four designs to the examination of the Institute.

I admit that it must appear strange to competitors at a distance that the four designs selected as the best should have emanated from local architects; I say the four, as the author of that placed third (Mr. Linklater, of Manchester) had been a pupil, and in our office, until a short time previous to the competition. On this point, however, I can assure Mr. Hills, that if the committee have been guilty of an error in judgment, he has no ground for censure so far as we are concerned. The selection committee placed "*Palnam*" second under the impression, I understand, that they were selecting an English design, so little did they know of the authorship.

I am sorry to occupy your space on a matter about which more has been written and said than the whole thing is worth; but such statements as contained in Mr. Hills's letter (although they have been fully refuted here) should not, I think, be allowed to go before the profession without question.

In conclusion, I shall merely remark, in reference to a point which Mr. Hills urges on the Institute, that although the position of a member of a committee, if at the same time he is a competitor, may appear equivocal, it is quite possible, practically, that no improper influence should follow, when such a member does not take part in the deliberations, for instance. And when the whole of the designs submitted in a

competition are referred to such a tribunal as the Institute, every member of the committee might be a competitor for that matter, as their position, in any respect, could have no influence on a professional judgment.

W. HENRY LYNN (Lanyon, Lynn, & Lanyon).

DID THE ANCIENT EGYPTIANS KNOW THE NILE SOURCES?

By the interesting discovery of Mr. Baker, public attention is again drawn to the Nile and its source. We may congratulate ourselves that the enterprise and courage of Englishmen have secured for Great Britain the honour of this discovery. I am satisfied that the Nile source was well known to the ancient Egyptians; for, when at Thebes, I saw a picture which had just been discovered, and which was as fresh as if but newly executed, which represented a procession of negro captives, amongst whom were two of the enormously fat women described by Captain Speke. The other figures in the procession resembled those given in Captain Speke's illustrations so completely, that when I first saw these I was at once struck with the resemblance.

I was not allowed to sketch the picture then newly discovered: an Arab guardian had been placed beside it, with orders to prevent all sketching. This being the case, I hope that careful drawings have been made by order of the Egyptian Government, and that nothing has happened to this interesting representation. Unluckily it was not within a rock excavation, but was external. To the best of my recollection this interesting picture was near the tombs of Shekh Abd el Koornel. At all events, if still preserved from the devastating bands of native or other ruffians, it is near those interesting tombs where the architect may have his mind set at rest as to the antiquity and origin of the arch: by comparing what he may observe there with what remains at Memphis, he can have little doubt as to what first suggested the arch, or as to its gradual perfection, step by step.

When I first saw the picture to which I have alluded, I thought that the two enormously fat women, so carefully tended, were curiosities destined as gifts to Pharaoh: they realized the expression, "as broad as they were long," and exceeded all representations which I had ever seen of fatness.

It appears to me, judging from this picture, that the great lake, now the Victoria Nyanza, and the country around it, were perfectly known to the ancient inhabitants of Egypt. It would be very desirable to obtain drawings of the ancient work of art which I saw. I should have made sketches, but felt that I had no right to do so without permission.

CHARLES H. WILSON.

METROPOLITAN BOARD OF WORKS.

At the usual meeting last week the Chairman intimated that eight tenders had been received for the Southern Embankment works, and that out of the tenders was from Mr. Samuel Bidley. Mr. Newton moved that the tender in question be not received by the Board.

The motion was lost by 8 votes to 13.

The Chairman then proceeded with the reading of the tenders, as follows:—Mr. Ridley, 279,000l.; Mr. W. Webster, 309,000l.; Mr. G. Furness, 311,000l.; Mr. G. Smce, representing J. Earle & Son, 327,361l.; Mr. W. Dethick, 335,000l.; Mr. T. Pearson, 340,000l.; Messrs. T. Brassey & Company, 355,000l.; Mr. Ritson, 386,000l. Tenders had also been received for covering and improving the open Stamford Brook sewer. The tenders were:—Messrs. J. and S. Williams, 24,600l.; Mr. J. Nibley, 24,900l.; Mr. E. Thirst, 25,089l.; Mr. W. H. Rowen, 25,170l.; Mr. W. Dethick, 26,200l.; Mr. T. Pearson, 26,300l. For reconstructing the White Post-lane branch, tenders were received from Mr. T. Wainwright, 3,210l.; Messrs. Hale & Kettle, 3,987l.; Mr. W. H. Howe, 4,207l.; Mr. W. Dethick, 4,550l.; Mr. T. Pearson, 4,638l.

The Board then resolved themselves into committee for consideration of the several tenders. On the re-admission of the public a report was read recommending that the tenders for the Southern Embankment works be referred to the Thames Embankment Committee; and that the tender of Messrs. J. and S. Williams for covering and improving the Stamford Brook sewer, and that of Mr. T. Wainwright for reconstructing the White Post-lane branch, be accepted. The report was approved by the Board.

SQUARING THE CIRCLE.

WE find the following in the *Ottawa Citizen*:—\*

"VARIORUM.

To the Editor of the *Ottawa Citizen*.

Dear Sir,—An article appears in the *London Builder*, of June 3rd, with the above heading, which states that a Mr. Smith has published a work demonstrating that twenty-five diameters of every circle is exactly equal to eight circumferences. Now, if Mr. Smith be correct, he must be prepared to prove that the chord of an arc of his circle is greater than the arc itself, which is an impossibility.

If the radius or chord of sixty degrees be unity, we easily find the chords of 30°, 15°, 7½°, 3°, by the 6th book of Euclid. Hence the chord of 3° 45' = .0654380. And if we divide Mr. Smith's circumference 6.25 by 96, we get the length of the arc 3° 45' = .0651040; so that it appears the chord is 3340 parts longer than the arc, which proves Mr. Smith's quadrature a failure, and that his circumference is too short. The old standard for the circumference, calculated by Van Culen and others, should be increased, rather than diminished, as it is one hundred and ninety-ninth part of the whole circumference by Mr. Smith.

For the past twelve months I have been daily employed at the quadrature of the circle; and, from many calculations, I found that when the diameter of a circle ... = 432900080569 miles, the circumference ... = 135995712854 miles.

Now, although this circumference is short for the diameter, if you add to it a hair's breadth it will be too long. I believe this to be the nearest ratio of the diameter to the circumference in the whole numbers yet discovered.

WILLIAM MURRAY.

Ottawa, C. W. June 21st, 1865.

The *Builder* will please notice the above.\*

A HOSPITAL FOR MORIBUND PATIENTS.

In the course of inquiries respecting the conditions of the sick poor of the metropolis, we have, in hundreds of instances, noticed the difficulties that there are in dealing with cases in which hospital treatment stops in consequence of cures being said to have been effected. Sometimes patients are discharged in such a weakly condition, that when they return to their ill-ventilated and unwholesome homes, and the improper and insufficient food, which have in so many instances been the actual cause of disease, something worse than a relapse takes place. We have often mentioned these circumstances, and will just now confine our remarks to one point, viz., the discharge of patients from the hospitals when they are on the verge of death. The effect of this is often most serious and distressing. As an instance we will mention one case. A man, who was twelve months since the very picture of health, a mason, came from a country district, to reside, with his family, and to work in London. He took a tenement dwelling in Islington, and with his wife and four children, kept, as is usually the case, possession of the kitchen. The change of air from the country to this underground room, poisoned to an extra extent by the drains passing through the apartment from the cesspool at the back, soon produced an unfavorable change on the man's appearance, and all the marks of consumption became clearly conspicuous. After trying other means of cure in vain, he became a patient in the Brompton hospital. From the first it would seem that there was scarcely a chance of any permanent relief being afforded; and towards the end his wife was sent for, and the man was with difficulty taken home in a cab, and, after much suffering, evidently aggravated by the journey, the sufferer died in about a week from the time of his discharge from the hospital. In this instance, besides the family of the dead man, the other parts of the house were thronged with children; and altogether, the change was a sad one from the quiet regularity of the hospital, from the light, the properly-arranged beds, the trained nurses, the good and proper food and nourishment, and the rightly administered medicine, which, in the hands of the skillful medical attendants, can be made, in nine cases out of

\* In the same paper we find the opening of "Her Majesty's Theatre" announced, "with a highly talented company, under the management of John Townsend, late member of the British House of Commons!"

ten, so much to relieve the last pangs of suffering humanity. No wonder that a week's residence in the kitchen home, with its usual look of discomfort, its polluted air, the incessant worry of children in the house and in the street, and other annoyances, sufficed to end the poor man's life.

In this case, the decomposition of the body ensued with great rapidity; and although the coffin was speedily screwed down and the funeral took place within a week, the effect of keeping the body in the back kitchen of a house in which so many were living was revolting and dangerous. When the time for burial came, too, a most painful occurrence took place. So narrow were the stairs leading from the kitchens to the street door, that the coffin could not be got out by that way; and after much jolting, and eventually by putting the dead man on his feet in a most unusual manner, the body was forced into the front kitchen, and in the same position was raised by the area and carried head first into the hearse. In reality, it is no matter in what position the dead be taken to the last resting-place, but there is something harrowing in such procedure to the feelings of friends of the departed.

We might refer to many other cases in which distressing results have been caused by the discharge of dying patients from the metropolitan hospitals. Sometimes, indeed, the people have died on their way home, or before they could be carried to their dwellings. We have often mentioned the subject to hospital authorities, and some of them say that without care a considerable expense would be incurred by the funerals of strangers, and that parishes strive to shift the cost of the interments of those who die in the hospitals, who have only poor relations to care about their remains, upon the institutions; but in many instances before a sick person is admitted into the hospital a guarantee is signed by some responsible person, that in case of death the charity will not be put to burial expenses. There is also to be considered the desire which the medical officers of these institutions have to do as much practical good as possible, so that they make a point of removing those who are past hope to afford room for others. For all purposes for the needful relief of the sick poor, however, there is no lack of money; and if, by way of experiment, one or two of the hospital boards of management were to be willing to retain particular cases until life had passed away; or what would perhaps be better, if it were considered necessary, as we believe it to be, to establish a general hospital for those who are incurable, and whose homes are but ill-adapted for their reception, sufficient pecuniary support, if the subject were brought properly under notice, would soon be obtained.

#### ACCIDENTS BY LIGHTNING.

The casualties during recent thunder storms have been rather more numerous than usual.

At Stamford, the congregation attending St. Mary's Church were greatly alarmed by an exceedingly vivid flash of lightning, lighting up the interior of the church by what appeared to be a sheet of flame, which seemed to emit innumerable sparks, giving out a strong sulphurous odour. The people, after some hesitation, made towards the door, some screaming, while others had fainted; and the falling of masonry from the upper part of the building greatly heightened the alarm, as it was supposed that the spire was tumbling. Great confusion ensued, but no personal injury was sustained. It was found that the spire and tower had been injured in two or three places. The damage throughout the tower and spire is believed to be extensive; but Mr. Browning, the parish architect, being from home, the extent is not known.

At Boston, the electricity struck the lofty tower of St. Botolph, the parish church, and did considerable damage. The entire building was afterwards surveyed, and the official account states that the lightning struck one of the eight pinnacles of the tower, and seems to have descended the spindle of the ram, and then disrupting the stonework at its base in a very dangerous manner, appears to have dispersed itself over the wet surface of the stonework of the tower, and so descended to the earth without doing further damage, excepting that in one of the upper windows of the tower it fused a small portion of the glass. Some little damage has been produced on the tower, apparently by the

concession of the air; for from the top down to fully half-way of the height, many pieces of stone (not of large size) have been detached, and even the font, situated at the west end of the church, did not escape. Three plumbers working inside the church for Mr. Pindar were thrown down by the vibration: one of them remained paralysed for a few minutes.

At Colchester, the lightning struck one of the ornamental Norman turrets, 10 ft. or 12 ft. high over the western entrance to the Roman Catholic chapel, in Priory-street, demolishing the turret, and carrying away a mass of several hundred weight of the stone debris into the chapel yard and priest's garden on the other side. A small copper cross let into a stone ball on the top of the turret is supposed to have attracted the lightning, which then entered the chapel through some fissure, and, passing through the organ gallery, knocked a large hole partly through the brickwork of the inside wall, and melted a leaden gas-pipe near by.

The telegraph office at Thirsk was struck by lightning, which disconnected and twisted the wires inside the office, injured the instruments, and set fire to one of them. No serious damage, however, was done.

The most singular accident took place in a train in transit on the Great Western Railway. The lightning struck a carriage and rendered a woman insensible.
