

THE J. PAUL GETTY MUSEUM LIBRARY

AN

**ILLUSTRATED WEEKLY MAGAZINE,**

FOR THE

*Architect, Engineer, Archaeologist, Constructor, & Art-Lover,*

CONDUCTED BY

**GEORGE GODWIN, F.R.S., F.S.A.**

*Honorary Member of various Societies; Author of "History in Ruins," "Town Swamps and Social Bridges,"  
"Another Blow for Life," &c.*

~~~~~  
"Every man's proper mansion-house, and home, being the theater of his hospitality, the seat of self-fruition, the comfortablest part of his own life, the noblest of his sonne's inheritance, a kinde of private princedome, nay, to the possessors thereof, an epitome of the whole world, may well deserve, by these attributes, according to the degree of the master, to be decently and delightfully adorned."

"Architecture can want no commendation, where there are noble men, or noble mindes."—SIR HENRY WORTON.

"Our English word To BUILD is the Anglo-Saxon *Bjlsan*, to confirm, to establish, to make firm and sure and fast, to consolidate, to strengthen; and is applicable to all other things as well as to dwelling-places."—DIVERSIONS OF PURLEY.

"Art shows us man as he can by no other means be made known. Art gives us 'nobler loves and nobler cares,'—furnishing objects by the contemplation of which we are taught and exalted,—and so are ultimately led to seek beauty in its highest form, which is GOODNESS."

~~~~~  
**VOLUME FOR 1865.**

# The Builder.

## The Condition of London Question.

**EARLY** efforts are being made by many of our contemporaries, and with success, to bring relief to the distressed thousands to be found in our many-sided metropolis.

We cannot better commence our new volume than with some observations bearing on the condition of London, and some of the causes of the sickness, destitution, and crime to be found in it. We are glad to notice that several persons who themselves have investigated Clerkenwell, St. Giles's, Golden-lane, Bethnal-green,

and other parts which are extensively occupied by the poor, are making known through various channels the results of their observations. The accounts, as our readers are prepared to expect, are most distressing.

Mr. G. W. McCree, in a walk during a few hours in St. Giles's, found the following cases:—An artisan, who with his wife and two children have had typhus fever; his wife is dead; two fingers of the man's hand have been poisoned, and he cannot do any work at present. In another place, an aged woman, deformed, gets her living by needle-work; she earns 4d. a day. A mother and two sons, husband dead, have all had typhus fever; and the landlord has taken their bed for rent. A poor man's wife "confined" in a cold cellar.

In another place, a widow, son, and two other children; the boy, his mother's chief support, has lost one eye, and will probably lose the other; could not pay their rent, and had spent two cold nights in the streets. A mother, a Frenchwoman, in a bed on the floor, with her newly-born child beside her; her husband is dead in the hospital, but they dare

not tell her; five children are left; her husband was a refugee. In another place, up a dark pair of stairs, in a hack room, Mr. McCree found the dead body of a man; he was not in a coffin, although he had been dead for four days; "his ghastly face was exposed to the

view of the children, who were playing near the corpse." Such are the views shown by a short walk in this parish. From other places we have similar tales. From Bethnal-green comes the usual weekly report of death from sheer starvation, pestilential rooms, fever close to ill-drained water-closets, and yards on which the surface water stands, short water supply, and those other evil conditions to which we have so often directed attention. Each year's observations show how much our accounts have been under-stated.

A word or two here as to one of those evil conditions. It is a fact, to which we have before directed attention, that during the raging of the cholera the disease was found more fatal proportionately in the kitchens and in the attics of tenement dwellings than in the other parts of houses; and the same may be said of several disorders which depend in a great measure on atmospheric derangement for their commencement and encouragement. It is true that it is in the basement and upper parts of houses of this class the greatest extent of poverty and privation is to be found, and this predisposes to disease; but the main cause of the extra sickness in these places is the want of attention to ventilation. In many such cases, indeed, ven-

ilation in the garret is a window, containing five panes of glass, 8 in. wide by 9 in. high: two only of these squares seem to be made to open. During the summer weather the sun heats on the roof, causing a most unwholesome and intolerable heat, and to this is sometimes added the heat of the fire needed for cooking and other operations. When we consider this, as well as the number of people who, in the present transition state of the metropolitan dwellings, are forced to live together, the insanitary construction of the staircases, and the common practice, even when some amount of ventilation might be afforded, of keeping the windows closed at night, we need not wonder at the unhealthiness of such places. A large part of the vitiated air of the house finds its way into the upper stories. Many of the higher portions of old-fashioned inns, and, indeed, houses of other descriptions, want careful attention as regards the apartments in which the servants usually sleep.

In the metropolis there are numbers of the servants of tradespeople, and of those more opulent, who are removed to their homes or to the fever hospital, stricken with dangerous disease, owing, in many cases, to the bad construction of the apartments in which they sleep.

A reference to the engraving will show, that the floor of the garret is level with the eaves of the roof;

and then a part of the narrow end of the angle formed by the roof is partitioned off, which limits the central space. With a little contrivance those upper stories might be rendered more wholesome: there would often, for instance, be no difficulty in opening another small window on the other side of the roof. In Bethnal-green and Spitalfields, many of the upper rooms are better conditioned than are those in most other neighbourhoods; the cause being that they were used by the silk-weavers as work-shops, and large lights were needed on both sides; so that now those places having in many instances been transformed into homes for families, they have not only the advantage of good light, but also, if the tenants think fit, plenty of ventilation. We not long since urged the heads of families to make sanitary inspection of the back part of their houses. Let us now suggest that advantage would result from occasional visits to the upper regions.

In a house situate as is the one of which we engrave a sketch of the roof, in case fire were to break out, what would be the fate of women and children who might be sleeping in the garrets? In such instances the staircases

tilation is not possible. Take, as an example, the specimen which is engraved. In a large well-built house, part of the front of which is used as a shop, and where the rooms are let to different families—the garret as well as other rooms—the only space for light and ventilation

generally become impassable in consequence of the fire and smoke, and the application of the fire-escape to the back part of the premises which the garret window overlooks would be impossible, owing to the peculiar nature of the ground, the high walls, and other impediments. A clause in the Metropolitan Building Act is supposed to regulate the height of inhabitable rooms in the roofs of houses, but it is altogether inoperative. To return, however,

A woman has been found dead in a room at Horberton, so miserable that the jury and coroner were startled and shocked. Such cases as these are becoming of almost daily occurrence. The parish refuses to give outdoor relief, and the people will not go into the house; so they die.

Still the London workhouses get filled. Some of our daily contemporaries have given valuable figures in connexion with the pauper population now in the workhouses of the metropolitan districts. It is pleasant in these notices to read accounts of the supply of roast beef and gigantic plum-puddings, on the production of which the masters of workhouses seem especially to pride themselves. In the accounts referred to, we find a report of the population of parishes; the increase as given in the last census return; and a comparison of the price of butcher's meat, bread, &c., between the years 1863 and 1864. From the latter it appears that the cost of the staff of life has been almost stationary, but that the price of butcher's meat has very largely increased.

There is, however, one particular part of this report to which we would direct especial attention, viz., the variations which have taken place in the years 1863 and 1864, in the numbers of persons that have received relief from the different parishes. This is a matter for study, inasmuch as it indicates the direction in which the poor have been driven by their removal from dwellings in certain districts which have been pulled down. There are some omissions in the newspaper report, but of the parishes mentioned there show a decrease, in some instances very slight, in the number of persons receiving in-door and out-door relief; and eighteen parishes show an increase, in some cases to a very large extent: we give the figures as they are placed in our hand.

In the City of London Union, the total decrease of the poor receiving in-door and out-door relief is 135. In Marylebone, the decrease, compared with last year, is 141; West-London Union, 12; St. James's, Westminster, 53; St. George's, Hanover-square (no account of the numbers of the out-door poor), decrease of in-door poor, 5; St. Mary Abbot's, Kensington, decrease of poor receiving parish relief, 210; in the Strand Union the numbers remain about stationary; St. Leonard's, Shoreditch, the total decrease is 66; St. John's, Hampstead, 3; St. Mary's, Paddington, 26; Brentford Union, 36.

The increase of the poor receiving parish relief is stated to be as follows:—St. Pancras, 153; St. Martin's-in-the-Fields, 19; St. Mary's, Newington, 131; St. Mary Magdalen's, 67; Greenwich Union, 124; Whitechapel Union (in-door poor: no statement of the extent of out-door relief), 5; Stepney Union, 11; St. George the Martyr's, Southwark, 238; St. Mary's, Rotherhithe, 224; St. Margaret and St. John's, Westminster, 82; Hendon Union (in the house), 3; Holborn Union, 22; St. Mary's, Islington, 62; St. Saviour's Union, no return; Mile-end Old Town, 53; St. Mary's, Lambeth, 691; St. James's, Clerkenwell, 100; Edmonton Union, 30; East London Union, 47.

It will thus be seen that there has been an increase of pauperism to the extent of 113 in the year in the parish of St. Pancras; and in the parish of St. George the Martyr, Southwark, 238; while in St. Mary's, Lambeth, the enormous increase of persons receiving parish relief has been 691 in one year. This is a difference so great that the causes of distress and the particular conditions of the poor in this district require investigation.

The enormous increase of the population of London is telling on all our charitable institutions. Notwithstanding the number of hospitals, for example, there is still a cry for more. Such is the pressure at the present moment in some of them, that it is difficult to find a vacant bed, and it is too often the case that the admitted poor are discharged and sent to their wholesale homes before they have completely recovered or gained sufficient strength. Accommodation is greatly wanted for patients who require care after they have been discharged from the general hospitals. Those who are acquainted with the working of

the London hospitals know well how sadly this is needed. Even the pressure of out-door patients on the hospitals is enormous; and those who have not visited them could not fail to be surprised at the crowds of sick who throng the waiting-rooms for several hours each day, except Sundays. Very varied is the appearance of those who form the groups. There are amongst them people both old and young, hard-working artisans, costermongers and idlers, decent honest-looking persons and those who have no characters to lose, decayed tradesmen, struggling to keep up an appearance, smartly-dressed women and many in thin and tattered clothing; others of the applicants look so respectable that it would scarcely be thought they could need the aid of such establishments, and yet to many of these the charity is the most valuable. Indeed, it is to the well-conducted struggling classes that hospital aid is often of the greatest consequence,—to those who could not in fairness claim the attendance of the parish surgeon, and who are unable to pay for the visits and medicine of the private practitioner. When sickness is in the house, the usual charge to the industrious part of the community for visits and medicine is 2s. 6d. a day. This in a week amounts to 17s. 6d.—a sum which it is almost impossible for persons of small means to pay for any length of time. If the rules be strictly carried out, the parish medical relief is granted only to persons whose income is less than 18s. a week, and it is by those who have families, whose earnings are more than the above-mentioned amount, that medical assistance is often much needed. We have met with many instances to show that there is great want in the crowded parts of the metropolis of an extensive system of free medical visitation and the supply of medicine. There is an establishment with these ends in view in Islington, the advantages of which might be greatly extended if its merits were better known. In connection with this institution, which is situated near the parish church, persons who can obtain letters from subscribers can be attended at home, and have medicine without charge from the dispensary. In such districts as those of East London an institution of this kind would be of immense service. There are many sick persons who are so circumstanced that they cannot avail themselves of the hospitals: some are unable either to pay the cost of cab-hire or to walk to a distance; and there are numerous instances of persons needing skilful medical treatment who would not be admitted as inmates in the general hospitals. In Paris there is a good system of treatment of the sick poor: a paper is delivered to the patient, or his representative, which ensures the regular attendance of the doctor appointed to treat him, and is kept by the bed-side. On this paper the doctor is bound to record the exact time of his visit and the patient's condition, and an inspector from the bureau follows from time to time in his wake to see that due care has been given to the patient. The attendance on the sick poor in Paris at their own houses has been proved to be a great success, and an economy in money; the home patients costing on the average 12s. each, while every hospital-treated patient costs 2l.

Let us look in another direction, and ask for further aid for the thousands of poor children who are being brought up, or brought down, to swell the ranks of the dangerous classes. Thrown into the dirt, and without a guiding friend, they go on from bad to worse, and then society lifts its hands and wonders that there should be so many evil men and women in the world who are positively incorrigible, and go in and out of prison all their lives, as if the occurrence were merely one of the risks of their trade;—and so in fact they do regard it. "Why, Hal," says Falstaff, when reproached by the Prince with purse-taking, "tis my vocation, Hal; 'tis no sin for a man to labour in his vocation." And so think the outcasts of our streets, the spawn of our slums.

The world does not recognise the connexion of cause and effect. Let us endeavour to illustrate it. We shall be pardoned for those referred to for the sake of the cause we have at heart,—the mighty interests that are at stake.

In the chapel of Buckingham Palace, one Thursday not long ago, amidst a royal retinue, our beloved Queen assisting, and all the kingdom sympathising, an infant boy was christened Albert Victor Christian Edward. Love watches over his cot, carefulness hundred-handed protects his life, and develops his powers of mind and body. In due time competent men will conduct him to knowledge: he will be taught

his duty to God, his duty to his neighbour, his duty to himself; and no one doubts that being so taught he will become an honourable, upright, and noble man, acting through life as befits his high position. Accident, strong passions, half teaching, may lead him in the heyday of youth to what calmer and more tutored spirits would know to be irregularities or excesses, but (this is the merciful chance; and knowing the examples this honoured child will have before his eyes, and the intelage which awnits him, the whole country is justly confident as to the result.

On the same Thursday, too, Mrs. Henry Smith's son was christened John. Papa had a dinner-party, invested 1,000l. in New Three, through the well-known brokers, Dale, Spigot, and Dale, in Master John's name, to accumulate quietly till he should be old enough to spend it properly; and, moreover, did several generous acts marking at once his comfortable affluence and state of personal delight. In due time John will have a private tutor, perhaps go to Rugby (his mother would like to get him some fresh connexions), will adopt a profession, marry an estimable young lady, and, if not a genius or general benefactor, will most likely discharge his duties as husband, father, and citizen, at all events respectably. If he should not do so, he will be an exception to be pointed at—the one John Smith out of a thousand who, well nurtured, well taught, and well placed, yet went to the bad, and brought the law down upon him.

On that same Thursday evening, in the back two-par of a house in Lincoln-court, Drury-lane, a well-formed, beautiful little boy was born in public—at any rate in the midst of two families. The mother is a poor dissipated wretch, whose husband had left her four months before, and who will drive the child into the streets to beg, who will do anything, nothing, as soon as it can go alone. If this child (should it happen to live) do not run a career of vice and crime, and be the cause of expense and sorrow to the community, it, too, will be an exception in its class.

To educate is better than to punish. Prevention is better than cure. The neglected children of the streets should be made the property of the State.

#### THE GENTLEMAN'S HOUSE.\*

In an article on House-Planning, in our last volume, wherein were noticed one book that had endeavoured to deal with the general subject, and another that treated of cottages, we adverted to the fact that "houses are productive of good or bad influences in conformity with the manner of their planning," and went on to remark that there was then need of a perspicuous statement, "both didactically and for after-reference," of the points that ought to be considered in that branch of the process of architects' design. The still wider subject of iconographic distribution, and in its relation with the scenographic, or the production of *delight*, no less than with the attainment of *commodity and firmness*, is still left to the commendation in lectures at the Royal Academy, or, it, as a study, and to the exercises resulting in those arrangements of plan, some times called academic, wherein the satisfying of material wants, and the conditions of actual sites, are little recognised,—educational methods which may be considered to have their chief representation in the Ecole des Beaux Arts. But something has at length been done towards the purpose of the whole subject, and by a book that goes far to supplying the want that we originally referred to.

Mr. Kerr's volume, by the scheme and manner of its treatment, may be said to comprise but one portion of what is architectural design, but one of planning, and the planning of but one division of the class of buildings included under the head of habitations; but the scheme itself is worked out in a manner that may be called nearly exhaustive of principles and of detail for the same time suggestive of these lines of further thought and study that belong to the vocation of the individual architect in the particular house upon which he may be engaged. It is a book eminently designed for those who will read thoughtfully,—that class of progressionists,

\* "The Gentleman's House; or, How to Plan English Residences, from the Parsonage to the Palace," with Tables of Accommodation and Cost, and a Series of selected Plans. By Robert Kerr, F.R.I.B.A., Architect, Professor of the Arts of Construction in King's College, London. London: John Murray, Albemarle-street, 1864." 8vo.; pp. xxix & 484; 44 plates & 20 cuts.

always ready to be searchers,—to carry on the "increasing purpose" from, and therefore after the ascertainment of, what there may be already of basis of legitimate precept and recorded fact,—the only readers by whom an author who has expended great pains can be appreciated, and the only public, perhaps, that he should care to address. Thus taken, the book will be found to suggest much in the matter of planning of dwellings below the class of "the gentleman's house," in that of all buildings for habitation, whether of the residents in towns generally, or in suburban and agricultural districts, and in those suited to the condition of the sections of the community generally included under the "lower middle" and "inburing" classes. By the exposition afforded of the requisites of the superior sort of house, also it may conduce to an ultimate great advance in the art division of the architecture,—in art-architectural, wherewith Mr. Kerr, in his early exertions, occupied himself chiefly.

In this age of hurry, whilst abundance, whoever sets himself to ascertain, and who records, what has been discovered, is a benefactor in his field, and beyond it. He prevents that repetition of working out the same problems, that wastes the time of those who labour, but do not record; waste which, we apprehend, has characterized our profession, when compared with other professions,—that of the civil engineer as one,—and which still distinguishes the pursuit of architecture in this country from the practice of the profession abroad. Whether in France, Germany, or America, there seems to be a consistency of purchasers and readers of books on architecture or building, sufficient to justify publication of such works to a larger extent than in Great Britain. In Paris there are several shops entirely devoted to the publication and sale of books on architecture and engineering; in London there is hard work in maintaining one dépôt of the kind. There have been those acquainted with the publishing trade, who have declared that architects were neither buyers nor students of books. If they are not the latter, they are in error. We marvel that no enterprising person has had his eye upon the ground-floor of the Architectural Union Company's premises in Conduit-street, to establish there a place of sale for English and foreign architectural works, including photographs. The book now before us, we are glad to hear, has had an exceptional sale.

Mr. Kerr carries into effect the purpose of his treatise chiefly by an exposition of the arrangements and details required for the plan of a "Gentleman's House;" but he also enters into the history of the subject, and gives many examples; and he treats of site and cost, and of style and connected with plan. Prefixed to the body of the work is an elaborate "Index," or *Table des Matières*, respecting which we have to say, that had our author published nothing else under the title of his book, he would have deserved well of the profession and the public. The scheme in fact, of the book, constitutes much of its merit, or adds thereto. The actual arrangement in parts, divisions, sections, and short chapters, has helped to swell out the volume considerably; but it certainly assists the comprehension of the ordinary reader and the professional student. Not only the architect, but one who has had occasion to consider his own occupation of a house or a room, that is to say every one, may find in the work much that he is perfectly familiar with; and this circumstance perhaps gives an impression of diffuseness or repetition; but we should not have been disposed to omit much of what the author has set down. Indeed he has made some omissions. In particular, he does not make sufficiently clear to a non-professional reader, that planning, as of a "gentleman's house" or other building, includes much more than this book could teach. As to staircases, flues and smoke-conduction, drainage, and some other items, we might have desired a more pointed allusion to the minute attention which they require, to prevent the notion of a single *plan* drawing being sufficient, or without sections, to show what the architect had to design. Staircase-planning, the subject of distinct works by other authors, must be considered as quite inadequately treated; though we note, with approval, the remarks on the inconvenience of winders. The value of the book would have been enhanced by reference to works on the separate subjects, as on stables. Where the author does name in the text, an authority, as Parker, he should have quoted the title of the book at length. The authorities for the plans given, are quoted. Mr. Kerr has added to many of these plans,

"suggestions" of his own, as on the original occupation of many of the rooms. More precise reference than he gives in some of the cases, however, would be needed, seeing that what he characterizes as a defect, might turn out to be different, were there the complete illustration of the building. Even in the case of Somerleyton, a badly-arranged house, where the windows of the drawing-room open into the conservatory, the one plan does not suffice for our seeing that there are no other windows: we dare say, the case is as bad as the author puts it; and he cannot be far wrong in saying that the room "could not possibly be wholesome;" but there might be windows in the upper part of the room above the level of the conservatory-roof, and there might even be arrangements for admission of fresh air in the lower part of the room. We have so often had to say to committees that one drawing of a set, as a plan, is but like one of the parts of speech in a sentence, that we must not allow any present possible inference to the contrary; particularly as we do not gather that our author has described in all cases, with advantage of actual observation of the buildings. Amongst the omissions is that, in some of the plans, of an indication of the points of the compass, given clearly enough in others, and important for all, seeing that aspect has occupied much of Mr. Kerr's attention. But when we have said that reference to plates, in the body of a work, should give their pages, and directions to binder be added, we have mentioned all the omissions that here call for notice.

The matter of the volume is divided into six parts, which are headed,—“A Sketch of the History and Development of Domestic Plans in England,” “Exposition of Plan as now practised,” “Notes on Site and the Grounds,” “Notes on Architectural Style,” “Notes on Accommodation and Cost,” and “Critical Notes on the Plates.” The last part, “or Appendix,” is connected with both the historical and expository portions of the book; though of the forty-four plates, the first twenty-two are given more especially for the history of plan. They include, in chronological order, Castleton Castle, and the White Tower, London, each of the eleventh century; Castle Acre Priory, twelfth century, and Castle Rising Castle, of about the same date; Charney Bassett Grange, thirteenth century; Kenilworth Castle, fourteenth; Wolterton Manor House, and Oshburgh Hall, fifteenth; Hengrave Hall, and Hatfield House, sixteenth; Inigo Jones's Ambresbury, and Stoke Park, seventeenth; Marlborough House, Blenheim, and Holkham Hall, commencement of the eighteenth; and Longleat, of the sixteenth century, as modified by Sir J. Wyattville in 1809, and Toddington, 1819; whilst to these are added, in seven plates, four expositions of contrast in later planning between what the author regards as Classic or Palladian, and what he considers Mediæval. In five plates, to the fourth part, which is on style, he gives ten sketches, to one plan, of as many different styles, all now having, or having recently, had favour shown them.

The first part of the volume is merely divided into chapters, chiefly of the centuries from the eleventh to the nineteenth inclusive. But the second part, or “Exposition of Plan as now practised,” gives a classification into “the Family Apartments,” “State Rooms, &c.” “the Domestic Offices,” “the Stabling and Farm Offices, &c.” The first division of these four is sub-divided into sections, as “General Considerations,” “the Day Rooms,” “the Sleeping Rooms,” “the Children's Rooms,” “the Supplementaries,” and “the Throughfares;” and the third division similarly into sections, which include “General Considerations,” “the Kitchen Offices,” “the Upper Servants' Offices,” “the Lower Servants' Offices,” “the Laundry Offices,” “the Bakery and Brewery Offices,” “Cellars, Storage, and Outhouses,” “the Servants' Private Rooms,” and “Throughfares, Supplementaries, and General Arrangement.” The part which gives the “Notes on Site and the Grounds” is divided into sections headed “the Choice of Locality,” “the Choice of Site,” and “the Arrangement of the Grounds and Adjuncts.” But each of the other parts, and the sections of the divisions of the parts which we have named, are divided into many chapters. In some of these, guiding principles are dismissed; and in others, the requisites of the separate rooms are described. The plans are drawn to one scale.

Although the question of style of decorative architecture has one part of the volume devoted to it, that branch of the extended subject of “the

gentleman's house” does not make any large portion of the whole. The discussion of two opposite systems of plan, the Mediæval and the Classic, as the author designates them, however, is frequently entered upon; and there may be those who would find fault with Mr. Kerr for the surrender of a preference that has been ascribed to him. Indeed he, we think, allowed it to appear that he has a greater preference for the Mediæval arrangements than he feels. The truth is that there was a regular progression from the commencement of the period embraced by his historic sketch, down to the seventeenth century, in the arrangements for convenience and the several objects of good planning, and that in the latter period plans were adopted rather with a view to the production of decorative features, imitated from those of architecture on the Italian soil, than to that of convenience and to the English climate. The question is, how far regularity of the Classic plan, with the symmetry of corresponding halves, which looks well on paper, may not be made to serve directly convenience; and indeed how far some concession even, though a slight one, of convenience to effect, would not be defensible. There is a decorative treatment which can serve convenience. It is evident that the symmetrical arrangement assists persons in finding and remembering routes from point to point; and the advantage of this seems to be recognised by our author. There remains, however, the fact that the progression which had continued up to the time of the Tudor and Elizabethan buildings, and had at last supplanted corridors as passage-way,—instead of continuing to make use of rooms, or of the open air,—was stopped by the foreign importation, to be resumed only in this present century; so that the preference is that which an architect should have for what is matter of the use of a building. Buildings on the one system may be made decoratively good; certainly those sacrificing convenience cannot belong to good architecture. Mr. Kerr gives the plan of Marlborough House as an illustration of the system wherein convenience was sacrificed to symmetry, and suggests an amusing inquiry as to the route that would have to be taken by the dinner in passing from the kitchen to the place where it might be eaten. He says,—

“Now the Kitchen is on the ground-level. The Dining-room is on the ground-level also. But to carry the dinner across the Entrance Court and in at the front door (see the plan) would never do. To carry it round by the garden and in at the saloon-door would never do. We might contrive a third route, that is, along the colonnade, in at the library window (or sash-door rather), and so through the rooms and main thoroughfares; but this, although the best that could really be accomplished on the ground-level, is still a jest. The actual route was this: first down-stairs to the basement; secondly, through the basement Corridors (probably dark as Palladian basement Corridors generally were); thirdly, up-stairs again by any one of three equally awkward means; and, fourthly, so on to the Dining-room in a manner (whichever of the three stairs might be preferred) still as awkward as the rest. And why all this inconvenience? Merely, it would seem, because the idea fixed itself on the architect's mind that the Kitchen would make a good wing. That the Kitchen must form an obtrusive and pre-emptive wing, with a sham reflection opposite, was no matter; that its windows must look out upon the Entrance Court, and that it must actually have a door opening into the Court (under a sham reflection), were acceptable conditions; that the unhappy footmen, for a hundred years or more, must stumble downstairs and upstairs, and through infinite tortuosities besides, with their soup-tureens and basins of beef, was not to be helped; let the kitchen be a wing, and it was a wing. Such was Palladian plan.”

As an example of block-plan, he thinks Marlborough House exquisitely good, and that the artistic hand of Wren it is which is therein seen; but he says, such merit or “paper-deep beauty” may prove to be itself a fault.

The making convenience secondary to symmetry, or to an idea of effect, led to faults in other plans which Mr. Kerr gives. The Mansion House would have afforded him an excellent illustration. There, there was originally a central open-court, as there is still above the ground-floor; and the way to the Egyptian Hall was across this court, with exposure to the weather, or through the state-rooms at the sides. Mr. Kerr however speaks favourably of some modern plans, which seem to be imitative of Mediæval arrangements rather than designed to meet convenience. One of these has an “irregularity of the thoroughfare lines” which we cannot consider with him as “especially interesting and ingenious,” and reproduces the arrangement on plan of the Mediæval hall, in a manner in which there is more of mere imitation than of the art and planning which the author desiderates.

In his opening chapter of the book, Mr. Kerr observes that each nation possesses its own pec-

lar model of plan; and the villa of Italy, the *château* of France, and the country-seat of England differ from each other just as their owners differ in habits of life. The entire recognition of this fact might perhaps have led him to give a higher place than he has to French plan, of which he has one example. The "test of progress in domestic buildings throughout Europe," he says, is greatly "involved in the question how far any particular nation has set aside the academical Palladian manner in favour of something more properly its own." The development of the English system is the course of advancement "from the Hall of the Saxon Thane to the Mansion of the modern gentleman."

The Saxon house of what Mr. Kerr calls "average degree" was mainly, a single large apartment, the Hall, which became the great feature in houses throughout the Mediæval period. As a covered inclosure, it was the opposite of the Roman atrium. The one room served for dwelling, cooking and eating, and sleeping in, for lord and lady, guests, serfs, and bondsmen. There was, however, under the same roof, another place called a *Cellar*, used for storage of provisions and beer; and this may have formed a basement-story; and there was an apartment in the dwellings of the better class, known as the *Chamber*, cut out probably by an outer door. In royal abodes, there would be rather more accommodation, which would include a kitchen, a detached building. After the Norman conquest there were two descriptions of building, the house of the *Hall and Chamber*, for the husbandman; and the "gentleman's house," which was the castle.

In the twelfth century, the author finds a certain progression evidenced in a monastic building, Castle Acre Priory. There were manor-houses which were occupied occasionally by the great land-owners, who generally dwelt in castles, but were obliged themselves to consume the produce of their estates. The monasteries had their granges. The ordinary houses of the country were of the same description. A manor-house of the day appears to have contained a hall; a chamber, or private room, called *solar*; a kitchen; a larder; a *sewey*, or buttery and pantry; and the "cellar" for stores. The "cellar" and hall seem to have been on the ground level, but the former was only half the height of the latter, and had the *solar* over it. The "cellar" and *solar* were at one end of the hall,—the entrance to the hall being at the other: both were entered from the outside. The larder and *sewey* were placed in an attached building at the entrance-end of the hall, which was also a passage to the kitchen, which was removed to a little distance to avoid risk of fire. A porch to the entrance, and a back-door to a court-yard in which were the stables and out-buildings, were amongst the other features of the plan. The king's houses possessed a chapel, which was used for business as well as worship. Generally they seem to have had but one "chamber." But, the twelfth century manor-houses included or shadowed forth some of the leading features of plan of the best-known buildings of the succeeding periods.

In the thirteenth century, in the reign of Henry III. numerous licences for the fortification of manor-houses were given; and this fact is taken to show that even the owners of castles were beginning to prefer the other sort of habitation. The group of the hall, chamber or *solar*, kitchen, *sewey*, larder, and "cellar," with perhaps a chapel, was added to or altered thus. The *sewey*, or general service-room, was amplified and divided into the "buttery" or butler's store with wine and beer cellars, and the pantry, or bread, butter, and cheese store, and the chandlery. A distinct room called the *wardrobe* seems to have been substituted for the use of chests. Other chambers were added to the principal one, though the hall was the general dormitory. Screens are spoken of as in the royal chamber, and placed between the door and the bed, thus leading the way to the future introduction of separate bed-rooms.

As the manor-houses came to be more and more preferred to the gloomy and inconmodious donjon-keep of the castle, as a residence, the keep was even left to decay; and a complete manor-house was erected in the inner bailey, the wall of which formed one side of the buildings. In the time of Edward I. we have the well-known castles that are called after him. The plan was the old Norman keep amplified into a citadel, or a court fortified by a wall and towers, and surrounded by an outer line of circumvallation, or several lines. The central enclosure was

then occupied by a complete manor-house. In the houses of this thirteenth century, thoroughfares through rooms, even through the private chamber of the sovereign, were common. Fire-places were few in number, and the hall was still warmed by a fire in the centre.

In the fourteenth century, a step is considered to have been made towards securing domestic privacy, although the chamber had been added previously. The provision made was that of a "priest's chamber," which Mr. Kerr describes as "the first properly private apartment in an Englishman's house,"—the chamber of the lord even, at the commencement of the century, being "but a species of Family Parlour and bedroom, withdrawn from the turmoil of the 'great house-place,' and the Lady's Chamber 'generally a luxury to come.'" But offices were added, and arrangement was improved. The hall was now perfected. The chapel was placed near the dais. It was sometimes of two stories. The chamber, parlour, or *solar*, became the withdrawing-room; inside-stairs generally were substituted for the external; and rooms were set apart as bed-chambers, though not to the exclusion of use of the sitting-rooms also for sleeping in. Our author however concludes that "the art of convenient disposition" of apartments was "not keeping pace with the increase of accommodation," but adds that that "we could readily believe in any case." The difficulty of planning must necessarily increase with the number of apartments for separate purposes, and with the extension at the same time of the total area. Mr. Kerr gives the plan of Keulworth, as illustrative of the fourteenth century additions, on the model of the manor-house, to the inner bailey of a Norman keep.

In the following period, important effects upon domestic plan, from the events which make the fifteenth century remarkable, and from the improved social condition of England, are noticeable. The hall, having much of its original purpose lost, was reduced, whilst existing features were retained; but the bay-window was added. The plan of Wolcorton Manor House is a good example of this period. A gate-house, originally flanked by out-buildings, leads to a fore-court space to the main range of buildings, of which last the central feature is the porch to the hall. In the plan of Oxburgh Hall, the several apartments are grouped together surrounding a square court,—the entrance gateway, and the hall with its porch, being in the same relative positions as in the former case. In neither of these examples are there continuous corridors: in the latter case, there are a large number of external doors towards the court; and in both plans, internal doors of communication between rooms are substituted for corridors.

But, for the sixteenth century, the plan of Hengrave Hall would seem to supply the needed features, or unless its corridors be additions. They surround the square court; the main entrance and the hall being still in the same relative positions as before, but the latter not having any porch. In the case of Oxburgh, there had been a carriage-throughfare through the gateway, and crossing the quadrangle, to the porch of the hall; but in that of Hengrave, the quadrangle is only an area for light, the hall being reached by the corridors. The offices form a separate wing, attached at one corner to the general quadrangular group of the domestic apartments which surround the court. In the time of Elizabeth the hall either disappeared, or an inferior sort of hall was provided for the servants. The provision of a separate dining-room for the family, the increased importance of the Withdrawing Room, and the number of the Bed-rooms, are some of the items by which progress is marked; and in Hengrave Hall there are 120 separate apartments catalogued, including all that would be required at the present day. Mr. Kerr says:—

"Hitherto the multiplication of apartments had produced, besides the requisite doors of intercommunication between rooms, first an increased number of external doors, and secondly the addition of internal passages (although not many of these), narrow, defective, and tortuous. Now, however, although such doors and passages still remained in general use, yet in the better class of houses it was only in inferior parts; and the chief thoroughfares were made in the novel form of Corridors. That peculiar feature of Elizabethan plan, the 'Gallery,' was also introduced, some examples being not only important in respect of size, but almost magnificent in design. The staircase also became much amplified and elaborated."

The plan of Hatfield House is given as perhaps the most characteristic of the final Elizabethan manner. The plan is perfectly symmetrical.

The most distinctive feature is the gallery which extends along the line of the recessed front, for more than the whole length between the wings, and supplies the place of an entrance-hall; though the entrance directly into the middle of a side of the gallery, involves some waste of effect.

In the seventeenth century, the revived Classic style of architecture was brought into England by Inigo Jones; and, says Mr. Kerr, there appears to be "no reason to believe that any other than Jones introduced Italian plan." He continues:—

"Nothing could be more decidedly a revolution than the change which now took place in the arrangement of an English Gentleman's House. In a word, the old English mode was made obsolete, and a new Mansion, to be in the fashion, must be an Italian Villa, copied out of Palladio's book, reason or none. Under the Mediæval system, including the practice of the Tudor period, we see a large variety of apartments gradually grouped together, without much regularity of disposition; the chief Dwelling-rooms and the Offices forming the ground-story (as in Hengrave, rather than the sleeping-rooms, which were on the floor above, or in occasional instances two. The new mode, on the contrary, as a rule, elevated the house upon a complete Basement, composed of the whole of the Offices, the Principal floor constituting the Family Dwelling-rooms, and one story above accommodating the Bed-chambers. In the matter of staidness of design, the utmost endeavours of the Tudor time had been limited to an elaborated Porch at the Hall-entrance; a resuscitation in the Hall itself, in the form of some metretroscopic ornament, of the kind that dignify which all besides it had lost; and a corresponding magnificence, quaint rather than imposing, in the new Galleries and Staircases, which had been copied, perhaps at the Elizabethan time, but not the old Mediæval Hall was entirely surrendered; upon quite another principle there was formed a central Saloon (a modification of the open Cortile of the Palazzo), adapted to the Villa, or Country seat, in Italy, reaching in height to the roof of the building, lighted from above, and surrounded by the apartments generally; instead of the comparatively insignificant Elizabethan Hall there was a majestic Portico of columns, with a broad ascent of steps; other entrances from the various quarters were disposed with little regard to economy of space, but with a constant study of imposing symmetrical effect; and, whether the design was on a large scale or a small, there was no longer any toleration of irregularity or pictoresque, or any other unskilled grace, but the situation, beside which the rambling old Elizabethan mansion was in a manner dwarfed, while at the same time it must be confessed, that beside the Elizabethan mansion the new Villa too often might have been charged with seeming more like some temple of the gods than the home of an English family."

Comparing the plans of Stoke Park, and Ambresbury with those previously considered, no contrast could be more complete.

"The change is not one of details or of parts, but of radical elements. Hall and Chamber, Parlour and Bower, Quadrangle and Gallery, are all gone; and in their place there are to be the great Saloon of Italy, the Portico and Colonnade; these for display; and for dwelling-rooms a series of symmetrical compartments into which the bulk of the house is divided at haphazard, to be appropriated at discretion." "In short, we may almost say that the sense of grandeur was the first consideration, and the properties of convenience and comfort decidedly the second."

In the eighteenth century, the same system was continued. If the offices were not on the basement, there was some form of collarage as an under-story; and a pair, or even two pairs, of wings were attached to the main building, to accommodate the guests. The great central apartment, the Saloon of early Palladianism, became in name at least the hall, the "saloon" being a compartment immediately in the rear, the centre of a suite of drawing-rooms, but having a garden-door and a portico. The communications were defective; and thoroughfares again came into use. In some of the requisites of plan, compactness perhaps excepted, there had been no progress, whilst in certain respects there had been even retrogression. But there was much done towards the completion and organization, says Mr. Kerr, of "that catalogue of rooms which constitute a modern Gentleman's House," and of course he does not omit to recognize the "pictorial magnificence" of Blenheim, and the "dignity" of Holkham, arising from its plan,—adding, even that "as much as the rule throughout the whole period, that it is questionable whether in this respect the best works of the eighteenth century have ever been equalled in the nineteenth."

To the produce of this nineteenth century we shall next give attention.

INDUSTRIAL EXHIBITION AT THE POTTERIES.—We are very glad to hear it is proposed that an exhibition of the productions of the workmen in the district shall be held. Arrangements have been so far made that it is considered probable that the exhibition will be held in the month of April. Individuals will thus be enabled to show what they can do.

TOWN SEWAGE AS GUANO.

In considering the sewage question people have, perhaps, not attached sufficient importance to the enormous consumption of guano and artificial manures generally, as an indication of the form in which it would be most useful. The secret of this successful sale and large use lies, in one word, in the portability of the article. Guano and most artificial manures are dry powders, easy to pack in bags, easily conveyed from place to place, and easily laid upon the land. Indeed, the last-mentioned process is performed with as little labour as the sowing of seed broadcast. A man takes as much as he can carry in an apron before him, and, stepping out with long strides, scatters it in handfuls as he paces up and down the land. While it is yet time, we may open the question as to the practicality and advisability of manufacturing town sewage into similar dry, powdery, guano-like compositions.

Phospho-Peruvian guano sells for 11l. per ton. Its competitor, phospho-ammoniacal guano, sells for 9l. 10s. per ton. The component parts of these manures are identical, the difference in the value being determined by the respective quantities of those parts; the Peruvian guano containing more than double the quantity of organic matter held in the latter. Next on the list stands bone meal in esteem; this is sold at 8l. 10s. per ton; half-inch, or dust and drill bone, realizing 10s. per ton less. Superphosphate of lime, in which the insoluble phosphate is guaranteed to be pure raw bone, fetches 7l. per ton; dissolved bones and superphosphate of bones, 7l. 10s. and 6l. 10s. respectively. Concentrated acid costs 10l. per ton. These prices place figures before the eye which render it difficult to believe but that the converting of sewage into a portable commodity would be a profitable proceeding.

Happily it is no longer a question whether we shall waste our sewage or not. That is settled. All that is now required of us is to insure its most economical and remunerative management. We do not refer particularly to the London sewage, because this exceptionally enormous quantity may call for, and pay for, especial treatment. Nevertheless, the remarks we are about to make are equally applicable to the metropolitan sewage as to any other. Of the places where utilisation has been attempted, Coventry has approached the nearest to a manufacturing process. At Croxson, Carlisle, Edinburgh, and Rugby, the irriguous portions of the sewage are dealt with; but here the fluid parts are suffered to discharge themselves into the river, and the solid residue is regarded as the valuable part of the matter. This is, as we have elsewhere stated, mixed with all the scavenge of the town, till it assumes the character of a thick pulp, when it is shovelled into the carts of the purchasers. And here the Coventry people stop. The objection to the present stage or development of this plan is the sloppy weight of the commodity and its unsuitability for conveyance.

It would be well to inquire, of what are the manures composed that at present monopolise the market? Phospho-Peruvian guano and ammoniacal guano contain unequal proportions of water, organic matter, soluble phosphates, insoluble phosphates, sulphate of lime, alkaline salts, sulphuric acid, and sand. Dissolved bones contain, according to Professor Penny's analysis, precisely the same component parts as these, only in different proportions, the sulphate of lime predominating. Superphosphate of lime, recommended by Liebig to be added to all sewage before use, contains less organic matter and more sulphate of lime than either of the manures mentioned. We should not shut our eyes to the fact that town sewage is rich in organic matter, the very large quantity of which held in guano is the cause of its extra value.

After centuries of waste of sewage, we cannot expect to grasp the right mode of dealing with it without a wrong guess or two at first. We must look at the subject from every point of view, and keep the fact that we have by no means arrived at a perfect system always before our eyes. The irriguous processes limit the use of the sewage to the lands in the neighbourhood of the town in which it is accumulated; and as these cannot be under irrigation all the year round, there must be waste in this plan. In the mode adopted at Coventry, the watery particles are drained off, and avowedly disposed of by discharge into a river; here, although it is contended that this fluid is useless, must be more waste. There should be no waste whatever. The golden axiom, "waste not, want not," applies

to sewage as well as to everything else. If rendered portable, the sphere of its usefulness would be so much extended that the supply could not exceed the demand. That anything capable of increasing the yield of field crops should be thrown to the dogs, or to the fishes, is as extravagant a proceeding as throwing bread into a pig-tub. Not only some, but all of the sewage should be turned to good account; with precisely the same frugality as that which directs the good housewife to require that not a crust of bread should be wasted. And whether we can ensure this economical utilization without its intermediate manufacture into cakes or coarse powder, is a matter for consideration. Dealers in manures regard the full consumption of town sewage on lands as a hopeless business till it is rendered portable, and so vendible.

It will be observed that all the manures now on the markets contain sand, or insoluble silicious matter, as it is somewhat grandiloquently called. Sewage would require a similar arenaeous stamina, or ingredient, calculated to solidify it. Although we do not compass to dictate details, we may suggest that it is in some such sufficient manner as that with which some of the difficulties attending the formation of the Metropolitan Main Drainage were grappled, that the present design should be undertaken. When a large quantity of gravel was required for concrete, the contractor purchased several acres of ground close by, and there and then dug out the requisite in question; in another place he ran out a pier for the landing of lime; and laid down several railways for the conveyance of his materials. The consolidation of sewage would call for similar ready, comprehensive, wholesome measures. Steam-power and the regular organization of a manufactory should be brought to bear.

Dublin and Birmingham are on the eve of an installation of improved economy in the disposal of their sewage. Would it not be a wise investment to spend a few pounds in experiments before a final, and, perhaps, second-rate, step be taken? If a private firm possessed a raw material that appeared likely to yield a remunerative profit by the application of a manufacturing process, we question whether there would be two opinions as to the advisableness of a test. And, again, if guano, or dissolved bones, or superphosphate of lime, were only applicable to certain contracted areas of land within the radii of a certain number of hose, we doubt whether there would be the large sale there is now for both.

The greatest difficulty there would be to contend against would be the ceaseless, catastrophic flow of the sewage. Taking one hint from a successful experiment, and another from a failure, we might combat this. It has been found that sewage collected in tanks for irrigation leaves a deposit of a thick pulp-like consistency, which every now and then has to be removed. In one case—mentioned in our survey of towns—this pulp is wastefully carted away or thrown into the river, so as to leave the tank free for the more watery portions. In another instance, also detailed in our survey, when one tank is full the flow of sewage is diverted to another, and the contents permitted to harden. Thus, we are assured, that whether it is wanted or not, there is a tendency now to be insisted upon, to consolidate itself. We might assist this tendency. Perhaps if the stream, instead of falling into a brick or stone tank, precipitated itself into a bed of highly-absorbent matter, we should gain the desired end. If we suggested lime as an absorbent, we would, of course, be reminded of the failure at Leicester. There are, however, other absorbents which might be mixed with this, such as sand, saw-dust, loam, &c. Arrived, by these additions, at the consistency of guano, the same process that pulverizes the one could be applied to the other.

In reply to those who advocate the use of sewage in a "slop" state, we admit that as a manure, it is at certain times of the year as useful in that form as in any other; but as an article of sale it is so confined to a limited locality that it is comparatively valueless. It would certainly not pay to convey trucks of slosh by rail. Converted, however, by additions and by processes, into a dry powder or concentrated essence, the cost of carriage would be trifling; and the expense of conveyance removed, the most inaccessible outlying lands can be benefited, as well as those lying along the line of communication.

There is, and always must be, an enormous market for manures. The owner of the smallest bit of back garden, or allotment, as well as the

farmer who tills his hundreds of acres, knows that the land is no good to him without manure. It must be had. The small gardener or working man, with an allotment, turns to the pig as the fertilizer of his soil now that the new town sewage conveys all the sewage into the river; and, accordingly, knocks up a pigstye as close to his back door as he can find room for it, thus creating a new sanitary evil. This he contends is the cheapest manure he can get, because he can feed the pig nearly for nothing upon the garden produce, and then sell it after it is fat; so he takes no account of the sickening smells emitted in the hoiling of the garden and table refuse that forms the pig's diet, nor of those emanating from the sty. Now, if the town sewage were rendered concentrated and portable, either in a cake or powder, much of the pig-keeping nuisance would be done away with, and one source of disease and discomfort removed. It is, however, in its great bearing as a national question of economy that we now look at the question. It appears not unlikely that if we are to get the full value of our sewage we must pulverize it.

This mode of dealing with the sewage would by no means interfere with works already laid down. For, alluding, now, to that of London, it would be difficult to get a less objectionable place for the establishment of a vast manufactory than the dreary unpopulated place near Barking, where the sewers discharge their contents. Or, treating only of country-town, or city refuse, the present outlets all indicate the sites suitable for future manufactories.

The vast consumption of guano and artificial manures points distinctly to the fact that portability is a matter of the first consequence. Their component parts tally in kind, though not in quantities, with those of sewage; for what is there that is not to be found in sewage, even into bones and dyes? And then, again, the earth's stock of guano cannot last for ever, albeit it has been accumulating for thousands of years; consequently, the price will have a tendency to rise instead of fall. It behoves us, therefore, to manufacture an article that will answer the same purpose. How to do it at a cost that will make it pay and produce no injury is the question.

"BLOCK-SINKING;" OR, BRICK-AND-MORTAR REMINISCENCES IN THE EAST.

DURING a roving tour in Northern India, some years ago, undertaken for the combined purpose of seeing a little more of the world, and escaping the much-dreaded rigours of an English winter, I happened to visit, on my way to the "Hills,"—that Paradise of Anglo-Indians,—a somewhat dull but profoundly philosophical little station far away in the north-west (shame on me for forgetting the name of it!), and thus became acquainted with the particulars of some very important engineering works going on in the immediate neighbourhood. Though but in an embryonic stage of existence when I saw them, these brick-and-mortar performances were so different from anything of the kind I had seen before in my wanderings about the world, and the circumstances connected with them so particularly interesting, that I shall endeavour to give the reader—not already over-primed on the subject, it is hoped—a brief account of what I saw on that occasion; and again on another one some years afterwards, when on a flying visit to the Western Presidency, that steaming, suffocating, odoriferous haven-of-hells for "land-reclamation companies (limited)," and money-making Parsees, unvisited.

The noble art of block-sinking is brought into play, it seems, for constructing the foundations of buildings, under circumstances which, in other and more civilized parts of the universe, would necessitate a recourse to pile-driving, or some wonderful mechanical arrangement involving the use of steam-power, and which, as far as the latter are concerned, would be wholly unsuited to such an out-of-the-way part of the world as that secluded name-forgotten abode of the brick-and-mortar art so especially was in those days of yore. Complicated machinery of any sort would be sure to go wrong in the hands of the unsophisticated Hindoo, and then everything would be at a stand-still for want of the necessary means to repair damages. So, for matters to go on smoothly and uninterruptedly in that part of the country, simplicity, I was easily convinced, must clearly be the order of the day. As an instance of native genius for misunderstanding the use of common things

beyond their ken, it may be mentioned that a friend of mine had indulged in the luxury of very ordinary brass locks for his hungalow-doors; and sure enough every one of them became quite useless before long; and, in many cases, the handles wrenched off in trying to do what any one of our own blessed infants acquires a knowledge of as soon as it is old enough to reach the much-coveted object.

The works that came under my observation, and on which swarms of natives were working away as busy as bees—though such instinctive industry is by no means a remarkable attribute of that interesting people—were the foundations of a gigantic aqueduct, compared with which all other conduits of water, ancient and modern, were very not to be mentioned in the same breath; in short, nothing like it on the planet. Operations were being carried on in the bed of a river of some considerable width, as dry as the table I am writing at for several consecutive months in the year; and during the rainy season the scene occasionally of such very heavy torrents, that it was difficult for uninitiated man to conceive by what scientific means anything could be constructed to withstand their violence, especially when it is known that the integrity of the river bed, consisting of sand and water of unknown depth, can be only permanently secured by the most consummate skill and good management; failing which, it would be scooped out here, there, and everywhere, and every blessed thing along with it.

The difficulty of laying in the foundations of a work 20 ft. deep by any other process than the one to hand can be easily understood, from the fact of the perennial spring water lying so near the surface that it was utterly impracticable digging down more than 5 ft. or 6 ft. in the usual way, and that by no means an easy matter. It is true that the means employed for overcoming a difficulty of this nature are extremely simple, and, after all, but an improvement on the plan that has been in use by the natives of India from time immemorial; but it is on this very account they are so well worthy of notice, as not only being admirably adapted to the comprehension of the Asiatic and the undeveloped resources of his charming but very tepid part of the globe, but also as being so desirable of introduction elsewhere.

It may be stated, in a few words, that the native method of obtaining foundations for their bridges and such-like, is sinking a number of brick cylinders,—or “wells,” as they are generally called, I believe,—which are afterwards filled in with earth or concrete, domed over, connected together, and built upon as they best may. In the work that I am presuming to scribble about, the choice was said to lie between pile-driving and “locks,” the relative merits of which, and the reasons of preferring the latter to the former, though duly impressed upon my bewildered mind at the time, is really much too serious and reconditate a matter to take in hand just at this moment—much to the reader's satisfaction, no doubt.

The advantages of rectangular blocks over circular wells, to build upon, are far too manifest, one would think, to need any special discussion on that head, substantially and their adaptation to the form of superstructure being not the least important of them; and yet these wells have since been extensively used on some important works now in progress in another part of the country, which will be noticed hereafter. In regard to the system adopted on this occasion, the style of procedure appeared to be as follows. After divers optical feats had been performed with level and theodolite, to fix with mathematical accuracy the position of piers and abutments, operations were commenced by clearing away as much of the sand as the walls below would admit of, and this appeared to be about 2 ft. or so below the surface of the river bed, a damp, uncomfortable-looking place being now exposed to view. The next part of the business was to lay down enormously-massive timber frames, consisting of roughly-squared trunks of common jungle trees, firmly fitted and bolted together, all arranged in apple-pie order for the walls of the locks which were to be built upon them.

To make the matter sufficiently intelligible, and speak in round numbers—though very near the mark—we will assume the foundations for one of the piers to be 200 ft. long, 20 ft. wide, and 20 ft. deep; this would consist of nine cubes of 20 ft., placed between 2 ft. and 3 ft. apart, and which are built up first of all to a height of 12 ft. The walls of each block are so constructed as to form four cavities, or “wells,” as they are called,

6 ft. square, for the convenience of getting out the sand, as will be seen further on. Common trestle windlasses are next placed on the top of the blocks, one over each well, and strong wooden troughs laid in a slanting position against the walls, to perform the twofold office of an inclined plane, and a slide for the sand that is to be scooped up from the bowels of the earth.

Coincident with the later operations is the very important one of digging away the sand as deep as can be managed from a distance of 20 ft. or 30 ft., parallel to the lines of blocks; for the sand not so excavated, be it known, would, in the course of undersinking (as the operation is called) find its way into the wells, which, for obvious reasons, would be a much more troublesome and expensive way of getting rid of it than by digging after the usual manner of mortals. Each of the windlasses is provided with a large ponderous iron spade, scoop, or whatever the correct interpretation may be of the tool called, in Oriental parlance, a “jham” and to manipulate late which a pole is used, varying in length as necessity requires, from 12 ft. to 24 ft. or so.

Sinking operations are commenced by inserting the end of the aforesaid long handle into the uzzle of the “jham” as it hangs dangling from the windlass; the men then let go the latter, and the whole affair, pole and all (not including the windlass, of course), is allowed to fall to the bottom as fast as it can go, and woe betide the incautious Hindoo who gets in the way of the handles, which spin round with a force enough to pulverize even a much thicker cyanium than his. The long-handled apparatus is now worked vigorously to and fro, with a downward pressure, in order to get a good hold of the bottom; after which the pole is disengaged from the jham, and rested against the inside of the well, preparatory to being hoisted up, hand over hand, for another good dig.

It may be remarked that this very effective iron implement, though dropping down as a matter of course vertically, is by a delightfully simple self-acting contrivance, drawn up horizontally, and when fairly loaded, may be considered to hold about 2 cubic feet of sand. On this reaching the surface, after the customary hauling, shouting, and frantic attitudinizing, so essential to the success of any combined muscular efforts on the part of Indian workmen, it is tumbled out of the jham, shovelled into the trough, and carried away,—not in wheelbarrows exactly, but after the fashion of the East, in baskets, on the shaved and thickly covered heads of her Majesty's faithful and loyal black lieges. Speaking of wheelbarrows, reminds me of having seen or heard it mentioned, that on occasion of their being introduced for the first time on some work in that country of solar influence and “sola topes,” these simple-minded people, after filling them with earth, proceeded to put the whole affair bodily on to their heads—basket fashion. Oh, ye navvies of England, think of that!

It has been remarked that the sand is cleared away to some distance all round the lines of blocks, and this is a territory carefully preserved from sandy encroachments of any sort, for reasons already stated. As the work proceeds, the sides of the cutting subsides with serious intentions of sloping towards the blocks; but this can be prevented by taking a hint from the premonitory cracks as they appear, now and then. The cavity occupied by the sinking block is called the “crater,” but the term to my limited understanding was vastly more suggestive of Vesuvius than anything so decidedly aquatic as lock-sinking; but this may be considered hyper-criticism, perhaps, by the learned in such matters.

Something often goes wrong down in the lower regions of the well: either the rope breaks in one of those frantic efforts above spoken of, or, what is worse, a piece of drift-wood, of unknown antiquity, gets athwart the timber underneath. This was evidently a fruitful source of tribulation to every one concerned, always excepting of course the insouciant operatives, who instantly assume the sitting attitude of our alleged quadrumanous primogenitors, and are soon oblivious to everything around them in the transcendent delights of the beloved “hubble-bubble.” At this critical juncture in block-sinking operations, a primitive-looking functionary,—if not *in parvis naturalis* exactly, at all events something alarmingly near it,—steps forward to the rescue.

This amphibious specimen of the order Vertebrate, yclep'd the diver, though a more com-

monly useful member of the well-sinking community at one time, when improved jhams were not, than he was at the time I first beheld the sight of his countenance, is nevertheless a very indispensable personage in cases of accident,—in fact, he seems to have been wisely and specially created to get well-sinkers out of their scrapes, and that, too, without the aid of Siebe's or any other wonderful patent diving-apparatus.

It struck an outsider like myself very forcibly that no self-denying, cylindrical-tiled, swallow-tailed Feringhee would wish to change places with this “man and a brother,” on a cold windy morning, as he stands on the edge of the well preparing to slip down the rope on his watery errand; or again, when reappearing from the deep, after a wonderfully long time it appears, dripping, shivering, and the very picture of misery, to warm himself by the few embers always kept at hand for these resuscitating purposes.

The locks above described take from twelve to sixteen days sinking the first 12 ft., after which, the remaining 8 ft. are built up, and the under-sinking recommenced as before. This last is a much more tedious operation than the first, for several reasons, and occupies from twenty to thirty days. Blocks are always found difficult to start again after a long rest, from being so tenaciously gripped by the sand which has settled about them in the interim: herein, though, consists the secret of their future immovability and perfection as a means of support for any weight that may be put upon them. The jham-poles, moreover, become of unwieldy length; much of the sand, too, gets washed off—has to be hauled up again, of course,—in its ascent through the ever-increasing depth of water; add to this the friction against the sides of the monster when deeply submerged.

Blocks are often capricious in their movements, and, from some unexplained cause or other best known to themselves, will stick hopelessly, even unto being abandoned sometimes after months of patient and unremunerative toil, as may be gleaned from the ancient chronicles of block-sinkers. Various intriguing expedients are resorted to for leading blocks, as weight is an element of the first importance in helping them down to their salutary destination: in fact, but for the inconvenience in various ways of sinking locks 20 ft. high, and their provoking tendency in so doing to get out of the perpendicular—especially in their first or tottering stage—they should on this account be built up first of all to their full height, and thus derive the benefit of their whole weight.

The foregoing remarks have been confined to locks with four wells in them, and which are comparatively easy to sink, as by an intelligent use of the windlasses they can be kept straight: but there were a number of disorderly, narrow two-well blocks which seemed to resist in a most pertinacious and obstreperous manner all attempts to get them down: some of these gentry were as much as 4 ft. and even 5 ft. out of the perpendicular, as ascertained from actual measurement: the fellows managing the crazy-locking craft were obliged to hold on by the main-brace. Most of these blocks were fitted up with the outrigger apparatus above mentioned, and heavily loaded with sand, one side or the other, in the vain hope, alas! of restoring them to their lost equilibrium, the sand only holding them up. To follow up the metaphor with a simile, the grotesque appearance, from a distance, of these leaning towers, with their strange-looking appendages, reminded one of ships with straggling sails set rolling about in a heavy sea. I prefer this, at least, to the “drunken man” simile which was current at that epoch.

Another essential element of success in block-sinking, I found to be the prevailing idea, is uninterrupted progress day and night. Some of the ill effects caused by stopping work to build up the last 8 ft. have already been noticed, and they must be proportionally less, no doubt, when sinking operations are suspended at the end of the day, and not resumed until the following morning, especially when a Sunday intervenes. Any cessation of work then must cause a loss of time in re-starting the block, which, when once on the move should, as far as its own interests are concerned, have no repose, no truce, or Sabbathical, until finally disposed of. Night sinking is dearer, of course, than day sinking, for the simple and universally-believed reason, that Blackey never works properly unless he is well looked after; and a dark night, with the darkness rendered more visible by torchlight, is not very favorable, it

must be admitted, for exercising the vigilance of the watchful eye. If any sinking economise time, to what extent, if it is pecuniarily profitable deponent sayeth not, because no one could enlighten him.

It has been observed that these under-sinking operations are necessarily restricted to the dry season of the year, and, as enterprising people are generally ambitious of doing more than they can well get through within a given time, the latter commodity is therefore very precious with our block-sinkers, and their brick-and-mortar pets are always on the move long before they are sufficiently hardened for the trials in store for them: the consequence is that, as the four walls cannot all be operated upon exactly alike, an unequal strain is thus brought to bear upon the timbers underneath, and the walls are given to splitting in divers directions. On looking aghast at these cracks of ominous import, I was assured, with unexpressed equanimity, that they would all close up again as the blocks went down, and that the cracks were really only formidable in a superterrestrial point of view. It need only be said, then, that the results fully justified this disregard of any such trifles as would drive a house-builder to commit suicide on the spot. If a block *did* come to grief, however, when far down, its *disjecta membra*, I opined, would be an insuperable obstacle to sinking a new one in its place.

To the practical mind, "hoop-iron" boud had of course suggested itself as an antidote for this disorder, and had been used in considerable quantities, it appears, but was afterwards discontinued on the important discovery being made that blocks *did* always fulfil their destiny somehow, no matter how much cracked; under which happy circumstances it was quite immaterial whether they had hoop-iron in them or not, and that using it, therefore, would be a sheer waste of the sinews of war. Thus another proof had to be recorded that there are many more wondrous things in the world to be noted than were ever dreamt of in this poor traveller's philosophy.

When the blocks have been sunk to their full depth of 20 ft., the wells are filled in with sand (there was certainly no necessity for using anything else that I could see, all things considered, but which there is no use enumerating here); then strongly arched over inside by means of the notches—cacophonously styled "skew-backs"—left for this purpose with such exquisite forethought when building the last 8 ft. of the block. The spaces between the blocks are also filled in with brickwork, and presto! the whole foundation is then complete, and approximates to what is so neatly delineated on the plan. But why not exactly? Simply because it is invariably found that the blocks when sinking have shifted more or less from the positions originally assigned them, though, generally speaking—with the four-well blocks—to no very embarrassing extent. With the narrow nautical-looking affair, though, whenever they *did* get a chance of going down properly, they turned about to every point of the compass, utterly uncontrollable members, in fact, of the block fraternity.

To an individual who, situate like myself, had never seen anything of the kind before, several long rows of these sinking blocks, with the crowds of people working on them, present a very curious spectacle, even in daytime; but at night, by torch-light, the scene is indescribably odd and picturesque; the effect being so much enhanced as it is by the whole of the *tableaux* being reflected from the still surface of the lake in which the blocks have become gradually and totally isolated. A distant view of these nocturnal well-sinkers, with all their paraphernalia of office, working away "by the light of the moon," when there is one, and always with torches, whether there is or not, might be likened, for want of something better, to swarms of belligerent black ants illuminated in their conflict by an army-works corps of fire-flies. Something better and more appropriate than the above may suggest itself, perhaps, to the more fervid imagination of the reader.

Speaking of scenic effect, though, let me pay a passing tribute to the marvellous view from the place where all these interesting works were going on. About ten or twelve miles off were the low rugged outlined hills of the Siwalik range, so full of geological interest; these were backed by the "hills,"—*par excellence*,—and on a fine day could be seen some forty miles off, dotted about on their summits between

6,000 ft. and 7,000 ft. above sea-level, the comfortable domiciles of that very celestial retreat already spoken of, and happy indeed the man who can fit thither from all the turmoil and abominations of life in the plains. The finest features in the landscape, though, are the magnificent peaks of the "Snowy Range," standing out in such bold relief against their background of blue sky,—altogether, in fact, as pretty a picture as can well be seen, and highly refreshing to the poor wretches with "liver" and blue-devils who can't get there.

The end of the working season, *i.e.*, a little before the middle of June, in the beds of rivers, is characterised by all the hurry-scurry usual in mundane affairs when preparing for any great event, and when something or other *will* always be left to the last. All the "*res impedimenta*" of brick-and-mortar life are now cleared away from the scene of action, and everything supposed to be in readiness for the burst of the rains, and one of those terrific-looking floods or "raos," as they are called in the vernacular, which so seared the poor writer once when he was caught in one of them, and with not a moment to lose in reaching *terra firma*: a decided case of *sauve qui peut* it is on such occasions, let me tell you. On the river bed being deserted in favour of its legitimate owner, nothing but the tops of the submerged blocks, and the huge mounds of sand excavated to make room for them, remain to show how much has been made of irrecoverable opportunities.

These mounds are fortunately but perishable relics of human industry, and their soft masses soon yield to the first rush of mighty waters, leaving the surface of the river bed afterwards as if nothing had happened to disturb the serenity of its repose.

To convey some idea of the importance of the work for which all these 298 blocks were required, and which, if put one on the top of another, would make a column above 9 furlongs high, it is necessary to state that they were intended to carry the piers and abutments of a work comprising fifteen tunnels, each 192 ft. long, and through which the rainfall on 216 square miles of country was to flow by fits and starts,—if not for all eternity, at all events, long past the anticipated advent of that mythical New Zealand celebrity who is to come some fine day and sketch the perishable remains of our fine brick-and-mortar metropolis! Over this row of tunnels, 24 ft. above the river bed, was to be a noble channel for conveying the body of water 170 ft. wide, and, when necessary, 10 ft. deep, destined to feed the canal and its branches, aggregating, when all finished, no less than 850 miles in length!

Now, considering the incalculable value of water in a country like India, the utter dependence of the people on the periodical rains, and the terrific famines that result occasionally from a total failure of that uncertain supply, it is impossible to over-estimate the boon that will be—and, as one of those awful events has already proved, has been—conferred on the country by distributing over one million acres and a half this magnificent supply of water, which has been running to waste in the sacred but much polluted stream of the Gauges ever since—when shall I say?—India rose from the sea,—if geologists have no objection.

On being informed of the bewildering fact that 122 millions of bricks (not the small English ones either) were required for building this wonderful structure, it instantly became necessary to cudgel my brains to pack all this material into some intelligible shape before being able to comprehend how much could be done with it. Put end on end, these bricks would reach 23,106 miles, which is not far short of three times and a half the circumference of the moon. Or if an idea less lunatic than this be preferred, the material could be represented by a brick-and-mortar pyramid, 400 ft. square at the base, and 280 ft. high. Compared bulk for bulk, with some of the first-class works in England in these days, this aqueduct would make very nearly seven Britannia Bridges, barring the tubes of course,—a little above five Tweed Viaducts, and something over twelve Newcastle High-level Bridges.

The whole of the work was calculated to cost 300,000*l.*, and to give some idea of the difference between the cost of brick and mortar in England and in India, calculated at the Newcastle rates, the bill for this little job would have run up to something about *two millions* sterling. Since the mutiny, however, what with the introduction of railways on all sides of India, and the

unpleasant consequences attending the universal greed for cotton, prosperity has made such giant strides throughout the land, that cheapness, even in the item of brick and mortar, is no longer the order of the day. The changes that have been brought about by the above causes are more remarkably exhibited in the case of all the common necessaries of life, which in many parts of India have more than quadrupled in cost, much to the disgust of my poor exiled friends on fixed incomes; at least so, from "Over the sea, over the sea," that's what my "little bird whispers to me."

But I have not done with those everlasting blocks yet, though such a long digression as the above may possibly have encouraged such an idea.

Regarding the comparative merits of rectangular blocks and cylindrical merits, to which an allusion was made in a foregoing paragraph, I may mention that the latter have been used in the foundations of the East-Indian Railway Bridge across the river Jumna, at Allahabad, and were constructed under very different circumstances from the foundation blocks of the "Solani aqueduct." Ah! that's the name of my old friend.

Whilst the bed of the Solani, as it has been seen, is dry during the working season, and thus affords every facility for building operations, the river Jumna on the other hand, at the site of the bridge which was selected on account of the river being so shallow thereabouts, has, it appears, an average depth of 15 ft. in it at low water.

Here, then, was a formidable obstacle to contend with, and it was cleverly overcome by forming artificial islands on which to lay the iron curbs (not timber frames in this case), of the ten cylinders, 13½ ft. diameter required for each pier. These wells are sunk 43 ft. below low-water level, and consequently at an average depth of 28 ft. below the bed of the river. This is 8 ft. deeper than the foundations of the Solani aqueduct, and certainly not more than sufficient, considering, as I understand it, their totally unprotected condition, and the enormous body of water that will impinge upon the piers during high floods.

The heaviest floods in the Solani are provided for by piers 12½ ft. high to springing of arch; whilst the rise of the Jumna in ordinary floods is no less than 45 ft., and, on more occasions than one, as much as 51 ft. During the last *débacle* of this sort, in 1861, the sand supporting the cylinders got washed away, and four of them toppled over to their sides. Great must have been the fall thereof! and it is very certain that all the king's horses, and all the king's men, will never put those Humpty-Dumpties on their legs again.

It has been stated somewhere in this paper that extraordinary care had been taken to protect the foundations of the Solani Aqueduct from the action of the current during floods. This was accomplished by building a solid flooring 3 ft. thick over the whole of the waterway between the two abutments: and a precious long tough job it must have been, besides no end of churning devices on a very extensive scale on the up and down stream sides of the work. By these measures, then, the whole of the foundations are hermetically sealed, as it were; and it may safely be predicted, I think, that the stability of the structure is positively beyond all reach of danger.

Although the body of water that passes down the Solani during floods is, beyond all comparison, less than what it is in the Jumna, still it must be remembered how the current is affected by the fourteen piers, each 216 ft. long, 10 ft. thick, and only 50 ft. apart. Hence the necessity, no doubt, for the wise precaution in making the foundations of this work so impregnable to attack.

Now, in the case of the Jumna Bridge, there are fourteen piers 205 ft. apart, and, as nearly as I can ascertain, 74 ft. long, and 25 ft. thick. There is no flooring, of course, as in the case of the Solani aqueduct, and, like that work, the foundations are sunk in sand of unknown depth. The foundations of the piers are thus isolated, as far as the bed of the river is concerned; and their future safety must depend upon the depth (28 ft.) to which the cylinders composing them have been sunk proving sufficient; or, in other words, upon the river being good enough not to scoop out the sand below that depth in any of its uncontrollable vagaries. The piers of this noble bridge have an abundance

of elbow-room, it is true; and experience has doubtless settled the important fact long ere this, that the stability of their respective tentacles is not dangerously affected in any way, even by a flood above 66 ft. deep, going at the easy pace of 9 miles an hour.

It used to be a favourite remark at one time, that on the annihilation of British power in the East,—and in the general order of things, such must be the case some day, I suppose; to wit, when our friend, the New Zealander, will be taking a trip to India, to sketch all the fine ruins there,—the only trace left behind him by the enterprising Anglo-Saxon would be his empty beer-bottles. To these vitreous remains of fallen grandeur might be added, perhaps, the melancholy fragments of a "grand trunk road." The construction of the Ganges Canal was decidedly the first thing accomplished towards removing this standing reproach from a power, in whose dominions, to use another favourite expression, the sun never sets. All honour, then, to the man who originated the idea and boldly carried it out. Since then the railroads, with their magnificent and unvaried viaducts, are in a fair way of impressing the land with some indelible marks of British pluck and enterprise.

I can honestly recommend my travelling countryman who have "done" the Continent, just to take a passage in a Peninsular and Oriental steamer, and "do" Bombay (I'll warrant they can get the compliment returned), and delight their eyes with a sight of the Bhore Ghant incline, on the Great Indian Peninsula Railway; for this alone would the trip repay him, to say nothing of the renowned antiquarian wonders of Ellora and Ajanta, the former only forty, and the latter but twenty miles distant from that line of railway. Why, that incomparable old fort at Dowlatabad, close to Ellora, and such a pretty road to it, with its labyrinthine tunnels, and matchless scenery of 150 ft. (it looks double this when close to it), all cut out of the hard trap rock, its picturesque ramifications of old fortified walls, and the lovely view from the breezy summits—surely these sights alone are worth going all the distance to see.

But, for a few parting words about the Bhore Ghant Incline, if only to tempt the reader to go and judge for himself. I have the most pleasing recollection of going over this astonishing work shortly before it was opened, in company with the intelligent contractor, Mr. C. We took our seats on a trolley early one fine morning, at Kandalla, the station situate on the summit of the incline. "But, before going on any further, Mr. Scribblor, pray say what is a trolley?" Well, the simplest looking form of conveyance in the world—nothing, in fact, but an unprotected platform on four wheels, as I saw it; and the novel sensation, let me tell you, of being whisked along at some fearful pace, with hut imperceptible confidence in the means of checking it, down this inclined plane, by the mere force of gravity, through pitch-dark tunnels, along giddy precipices, and over unfathomable-looking abysses, was as nearly like going to perdition in a dogcart as anything I can possibly imagine.

The incline traverses a hilly region composed of the toughest basalt: so the difficulty of boring the twenty-five tunnels through it, aggregating some 4,000 running yards, may be easily imagined. The road altogether is 15½ miles long, rising in this short distance a height of 1,832 ft. The steepest gradient is 1 in 37, and the whole work occupied a period of seven years and a half, costing at the rate of 68,750l. per mile.

One of the cleverest engineering devices yet seen in railway work is the "reversing station," as it is called, where the position of the train in regard to the engine is reversed, i.e., the head of it becoming the tail.

The wildness of the scenery on this road is something charming to behold. There are several commanding peaks about Kandalla, and one of them would be very appropriately surmounted with a colossal statue of the eminent engineer, Mr. J. J. Berkley, whose decease not long before the completion of his magnificent work was a source of such deep regret to every one connected with it.

Hoping that all the foregoing prosaic details of my wanderings from "far away in the north-west" to the Bhore Ghant Incline have not been found too overpowering, I shall now reward the reader's patience by subscribing myself, in the language of my little bird "over the sea," his very obedient servant,

RAJ MISTRAL.

### THE MASTER BUILDERS AND THE OPERATIVES OF THE MIDLAND COUNTIES.

The feeling against the proposed "Discharge Note" increases: further meetings have been held in Birmingham, Manchester, Malvern, Nottingham, and London, the object of those in the last place being to raise money for the support of the men on strike in the county. At Nottingham, the meeting resolved,—

"That we, the members of the various branches of the building trades in Nottingham in general meeting assembled, pledge ourselves to oppose by all lawful means the discharge-note, better known as the ticket-of-leave system, now attempted to be forced upon us by the Master Builders' Association.

As the carpenters and joiners of Birmingham have been the first to take action in opposition to the discharge-note, and no doubt before long the whole of the various branches of the building trades will be drawn up in battle array against the proposed system; we therefore pledge our trade to organize themselves and assist by contributions those who are or may be on strike until the withdrawal by the Association of the discharge-note."

Besides the statement from the secretary of "The General Builders' Association," and the communications from two builders, printed in our last, we have received several angry letters, from master builders in the Midland Counties, reprimanding us for not advocating the acceptance of the "Discharge Note" by the men, and calling upon us (one with a childish threat), immediately to retract the opinion we had expressed. On the other hand, two very respectable members of the Builders' Association, of a course in a quite different tone, inform us that they see they are asking for a power they ought not to have; and moreover one they are not likely to get,—at any rate, without a long and costly struggle; and have determined on not striving for it with their men.

We have been sneered at in St. Martin's Hall, and yelled at in Smithfield, when, in times gone by, we had expressed opinions adverse to unwise and unjust steps taken by the operatives; and our course was as much affected by those thoughtless demonstrations as it will be by the master builders' letters now,—that is, not at all. We can fully appreciate and lament the injury inflicted on the masters by acts of the trade unions, and the poverty and demoralization often resulting to the men themselves; but we cannot think that the "Discharge Note" will prove the remedy. The Resolution of the masters' sets forth that the determination to require the production of the "Discharge Note" from a workman before taking him on is come to with a view to counteract "the evils resulting, both to masters and operatives, from unjustifiable strikes and combinations." It is to be effective, however, in the case of all strikes, and all strikes and combinations are not unjustifiable, as the masters of course admit by themselves combining, as they have a perfect right to do. Combination is the secret of the day: men combine that they may enjoy a fine house in Pall-mall, instead of uncomfortable lodgings; we combine to insure; we combine in companies "hunted" to trade; the lawyers combine in Chancery-lane, the architects in Conduit-street, and the trades in every town. Men in all positions cease to be satisfactory. What the great combination, Society, has to do is to see that these minor combinations are not turned to evil account, and by the dissemination of knowledge, to prevent unnecessary and injurious strikes. All strikes and combinations, then, are not unjustifiable, but, *quoad* the "Discharge Note," would be considered so. The more we think of the matter, the more thoroughly do we feel convinced that the operatives will never accept the proposed note; and we earnestly exhort the Builders' Association to withdraw it at once, before had feeling be engendered and money wasted. We agree with their secretary in hoping sincerely that some means may be adopted, arbitration or otherwise, to adjust

• The following, as we understand, is the present form of the resolution come to by the "General Builders' Association":—

"That with a view to counteract the evils resulting both to masters and operatives from unjustifiable strikes and combinations, the following plan be adopted:—That on and after the 1st day of January, 1865, every member of this Association shall, upon paying off any operative, deliver him a discharge-note (in form to be supplied by the committee), which shall state the man's name, and of the Association, pledge himself not to take into his employ any operative who (having previously worked for a member of this Association) does not first produce and deliver to his proposer an employer's former discharge-note, or, in case of his loss, the name and residence of his previous employer, for reference."

differences between capital and labour, and prevent the occurrence of strikes, with their fearful accompaniments of poverty, demoralization, and not seldom death.

### OBSTRUCTION OF LIGHT AND AIR.

A case was tried lately in the Court of Common Pleas, Westminster, before Chief Justice Erle, a report of which may be useful to some of our readers. It was an action for the obstruction of an ancient window in a room built out at the back of the house No. 9, George-street, Hanover-square. The house belongs to Mr. Dodson (the plaintiff), who is one of the members of Parliament for the county of Sussex. This room and window had existed upwards of fifty years. It had been used as a library by Sheridan, who had written his plays in it. Dr. Pearson had lectured in it on medical subjects more than twenty years ago. Artists had used it for a studio; and for the last sixteen years it has been used by Miss Pace as a workroom for the young ladies in her millinery establishment. The window looked north, across the back yards of the adjoining houses in George-street, with little or no interruption as far as Maddox-street, and the light admitted through it was sworn to have been extremely good, and to have enabled Miss Pace to carry on her business, to match ribbands, and to work to a late hour. But in the course of this year the defendant (Mr. Cowland), who occupies No. 10, George-street, and whose back yard is immediately north of the window, put up a new building covering the whole of his back yard, except a space of the length of the window in dispute, and about 6 ft. wide, which was left unoccupied. The walls of his building were of such a height as to leave unobstructed the light coming to the window at an angle of 45 degrees to the horizon.

On the part of the plaintiff, Mr. Penfold and others gave evidence that light was obstructed, as did the tenant and some of her workpeople, to the effect that colours could not now be matched in the room as was formerly the case.

Mr. C. Barry, for the defendant, deposed that the new building was placed at such a distance (6 ft.) as to allow the light to the bottom of the window at an angle of 43°, and expressed his opinion that amongst the profession generally the admission of light at an angle of 45° was considered to suffice to prevent opposition. Mr. H. Curry and others concurred in this evidence. Stress was laid on the fact that, to allow of the erection of the new building, trees which had formerly obstructed the light, had been cut down, so that the room, it was asserted, was as light as ever.

The jury found a verdict for the plaintiff. The mode of obviating the evil has now to be settled, perhaps with fresh litigation.

It is desirable that it should be clearly understood (what the result of this trial confirms), that in law the 45° theory has no weight. The real question always is with the jury, has sufficient light been obstructed to make the room less valuable than it was before for a purpose to which it has been applied for twenty years? In the case of a special adaptation to a purpose for any shorter period, damages cannot be recovered for a deprivation of light which would reduce the room to its previous condition as to light. To put a case: if a room, used for twenty years for ordinary purposes, be appropriated for part of this time, because of its unusually good light, say to some artistic purpose, an obstruction which unfitted it for this purpose could not be prevented; but if it injuriously affected the room for its older purpose, the judge would have to direct a verdict for its abatement. The condition of the law in respect of light and air is not satisfactory, but improvement is not easy. It has been contended, that persons wishing to raise buildings or cover their own land, should have power to do so by compensating in money to an extent to be settled by a proper tribunal for any injury done to neighbour's rights; but it may be fairly asked in reply, Why should the adjoining owner be forced to sell that which he wishes to retain? Why should a rich and powerful man be permitted to buy up and override his perhaps poorer and weaker neighbour?

MEMORIAL SCULPTURE.—A marble bust of the late Duke of Richmond has been placed in the Assembly-room, at the County Hall, Lewes, under the personal superintendence of the sculptor, Mr. F. McDowell.

THE MANUFACTURE OF PERFUMES.

HORTICULTURAL SOCIETY.

AMONGST the popular lectures which have been lately delivered in the Conservatory, Mr. Septimus Piesse has given one on "Perfumes and the Methods of obtaining the Odours." The lecturer pointed out that, contrary to general belief, nearly all the perfumes derived from flowers are not made by distillation, but by the processes of *enfleurage*, or inflorescing, and by maceration or infusion. The odours of flowers do not, as a general rule, exist in them as a store or in a gland, but they are developed as an exhalation. While the flower breathes, it yields fragrance; but kill the flower, and fragrance ceases. It has not been ascertained when the discovery was made of condensing, as it were, the breath of the flower during life: what we know now is, that if a living flower be placed near to lutter, grease, animal fat, or oil, these bodies absorb the odour given off by the blossom, and in turn themselves become fragrant. If we spread fresh unsalted butter upon the inside of two dessert-plates, and then fill one of the plates with gathered fragrant blossoms of clematis, covering them over with the second greased plate, we shall find that after twenty-four hours the grease has become fragrant. The blossoms, though separated from the parent stem, do not die for some time, but live and exhalo odour, which is absorbed by the fat. To remove the odour from the fat, the fat must be scraped off the plates and put into alcohol: the odour then leaves the grease and enters into the spirit, which thus become "scent," and the grease again becomes odourless.

The flower farmers of the Var follow precisely this method on a very large scale, making but a little practical variation, with the following flowers—rose, orange, acacia, violet, jasmine, tuberose, and jonquil.

The commercial importance of this branch of perfumes may be indicated by the quantity of flowers annually grown in the district of Cannes. Flower harvest: orange blossoms, 1,475,000 lb.; roses, 530,000 lb.; jasmine, 100,000 lb.; violets, 75,000 lb.; acacia, 45,000 lb.; geranium, 30,000 lb.; tuberose, 24,000 lb.; jonquil, 5,000 lb. The quantity produced at Nice has not been ascertained; with violets and orange there are more, but with cassie less than here stated.

The market season for orange-flowers at Nice lasts for more than a month, as an average, and during that time there are sold about fifteen to eighteen tons of flowers daily! and a ton of flowers will yield more than a kilogramme of otto (say forty ounces), worth 20*l.* sterling; and the residuary water, highly saturated with odour, is worth another 10*l.* note.

A surface of land, equalling an acre of planting, yields a hundred and eighty to two hundred pounds weight of flowers, valued as an average at two francs the pound. Violets may always be looked upon as an extra crop, growing as they do under the orange and lemon trees. The kind grown is the double Parma. About twenty-five tons weight of violet-blossoms are produced annually at Nice.

In France, the commerce in perfumes has risen to the annual value of 3,000,000*l.* sterling.

THE EMPLOYMENT OF YOUNG CHILDREN IN DANGEROUS MANUFACTORIES.

A SAD case, which clearly shows the necessity for interference with the manner in which the health and lives of children are risked, has just been brought under the public notice. The facts, as they were laid before the coroner's jury, are briefly as follow:—At a match manufactory in Stratford-New-Town, an explosion took place which destroyed the life of a boy twelve years of age, blew out the windows, and did other damage to the premises. Philip Debor, a German, who was the manager of the match manufactory, said Vesuvian lights were being made with a compound of gun, phosphorus, nitre, chloride of potash, Venetian red, and plaster of Paris. [A potent chemical brewing to be allowed to be made in an inhabited neighbourhood!] Witness had to dip the wood for the Vesuvians into it. He gave the stick to the boy, and said to him, "You stir him von leetle bit." He turned round to go into the factory, and before he got two steps the whole affair blew up; the stuff struck him on the back; the windows were blown in; and on looking he saw deceased lying on the ground all in a blaze. In Germany, he said, boys were not employed to stir

the composition or turn the frame; but it was usual to employ them in England. Old men are employed in some manufactories; but he supposed that children were cheaper, and "competition is keen." This was the main evidence.

It transpired that the superintendent of the laboratory was a *military* gentleman. We should have thought that a *chemical* superintendent would have been the most fit for this office. It is to be feared, however, that neither the one nor the other will prevent the employment of very young children in this description of work until fresh powers of interference are given. In this case alone there are fifteen children employed, deceased having been the oldest.

There is one thing, however, which can now be done, after a grace of twenty years which has been allowed for the removal of dangerous trades from populous neighbourhoods: they can now be legally removed; and this is necessary for the public protection.

In the present case of death, the jury, after recording the especial cause, said they considered that the manufacturer was open to censure for entrusting such combustible materials to children of so young an age, and they recommended that in future chloride of potash should be melted with water, and so rendered non-explosive before being mixed with the other ingredients of the composition.

So far the jury have done their duty; but no practical consequences worth naming will result from this verdict. No doubt the parents of the deceased child are poor people, and comparatively helpless. Many, however, think that if a few cases of this description were brought for consideration into the courts of law, damages would be awarded which might be the means of partially stopping this wrong and careless waste of human life.

THE SCOTTISH MEMORIAL OF THE PRINCE CONSORT.

THE designs sent in are now open for inspection in the National Gallery at Edinburgh.

No. 22. Design by Mr. Robert Matheson, is for a bronze equestrian statue of the Prince in front of the new General Post-office, on a pedestal of two stages; one enriched by bas-reliefs, and the other by allegorical figures.

No. 23, by Mr. J. Noel Paton, takes the form of "a memorial cross." The first stage of the structure is a platform of large dimensions and composed of six steps. From the base rises a square central shaft for the support of a statue of the Prince, and at the angles of this shaft are pillars with floriated capitals.

No. 49 is a temple, by Mr. J. T. Rothead, architect, and Mr. J. Steel, sculptor, Glasgow. The design is elaborate, and consists of numerous parts.

No. 7, by Messrs. William Slater and R. Herbert Carpenter, London, is an ornamented Gothic cross of three open stages. The lower compartment of the structure is occupied by a statue of the Prince.

Nos. 9 and 10, by Mr. D. Milne Holme, of Milne Graden, Berwickshire, are granite obelisks, and are illustrated by numerous drawings and two models. The obelisks are proposed to be 170 ft. in height, and in the base a chamber is formed to contain a statue of the Prince.

No. 21, bearing the motto, "The memory of the just is blessed," is a square tower, rising to a height of 380 ft., and resembling in outline the clock-tower of Westminster.

Nos. 24 and 25, designs, and model No. 53, illustrate design, accompanied by a model, by Mr. W. Calder Marshall. Mr. W. Calder Marshall has chosen as its main feature a Venetian shaft or column of polished red granite, surmounted by a statue of the prince, with a foliated capital, and a base illustrated by allegorical figures. In two stages, the first series being seated on projected pedestals, and the second,—like the first, four in number,—standing around the shaft. The lower series appears to represent those arts, and the upper those virtues, which may be held to be peculiarly associated with the career of the illustrious personage whose effigy surmounts the column.

In No. 34, Mr. David Bryce proposes to construct the Prince by the erection of a great tower, or keep, on the Castle Rock, to be called the Albert Keep. It is proposed that in its interior should be a hall, specially appropriated to a statue of the Prince, so that the building might, in all time coming, be associated with his memory.

Mr. John Steel sends three designs, one a drawing (No. 38) for a pedestrian statue, and two rough models, or rather sketches, in plaster, for equestrian statues. In the drawing, the Prince is represented as contemplating a globe, which he holds in his hand, with reference to his project of an International Exhibition, the pedestal being ornamented with allegorical figures of Manufacture, Art, Science, and Religion.

No. 39, a design by Mr. David Rhind, is for a memorial column. The base is made ornate with bas-relief and sculpture; the capital breaks into Gothic pinnacles; the whole being surmounted with a statue.

Mr. Cousin's design and that of Mr. Joseph Durham, we have already described.

ART-WORKMEN AND THE SOCIETY OF ARTS.

LAST Monday evening, the art-workmanship competitors met the council and other members of the Society of Arts, and talked over the terms of the present competition, with the view of learning if they were satisfactory. The general inference to be drawn from the conversation was, that little alteration was desirable. No adjudication has yet been made. The council have invited the same three gentlemen who acted last year as judges, to serve again in that capacity.—Mr. John Webb, Mr. M. D. Wyatt, and Mr. R. Redgrave. The exhibition of the works sent in continues open. Amongst the wood-carvers, Mr. Gerard Robinson occupies a prominent place from the variety he exhibits. "Hope for the Future," a child's head, by Mr. Wallis, is a charming work. "Cain preparing his Sacrifice" (91), James Griffiths, is well intended. A pair of carved frames, G. Ball, and a fruit panel, W. Taylor, show skill. Mr. Baylis's ink-stand will not escape notice. Mr. G. Lock exhibits a double festoon of flowers (90), excellently carved in parts. The carvings in marble are very indifferent. Of the three stone brackets we prefer No. 8, by Leon. The *reposus* work in metal, by Septimus Beresford (15) and H. R. Batchelor, is very creditable. There is an excellent piece of chased ornament in bronze by H. J. Hatfield, and a good engraving on silver by Gilles Mackenzie (31). The wall mosaics give hope, and we may say the same thing of the specimens of gem engraving, an art sadly neglected in this country.

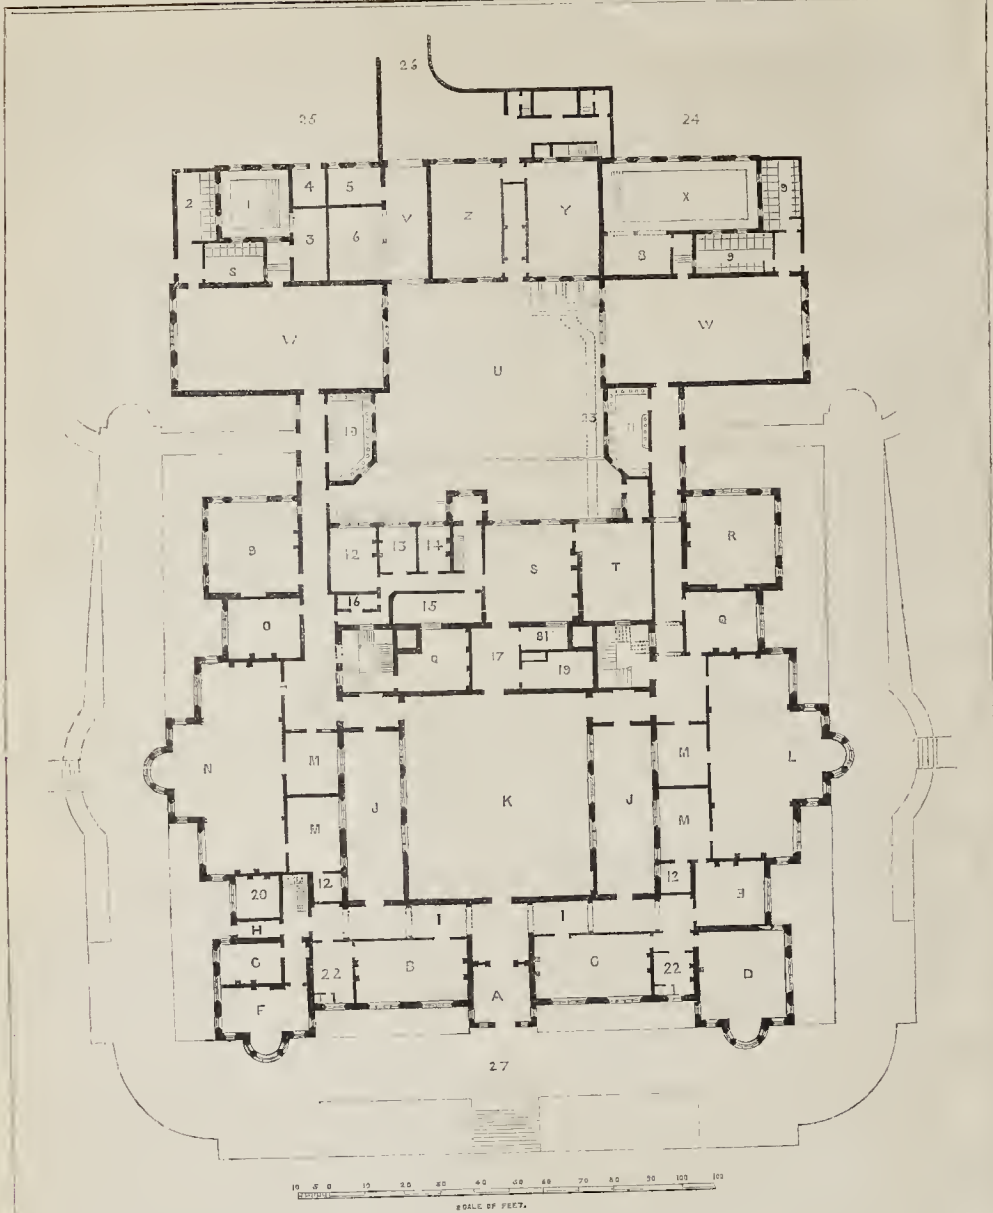

THE CROSSLEY ORPHAN HOME AND SCHOOL, SKIRCOAT MOOR, HALIFAX.

THE Yorkshire town of Halifax has been peculiarly favoured of late years by substantial proofs of the benevolence and wealth of its "merchant princes," as well as by the public spirit of its leading men. The recently-erected town hall and the stately piles of commercial buildings and public institutions in the principal streets are proofs of the latter; whilst the ecclesiastical edifices at Haley Hill and "the square"—the almshouses, the public park, the model dwellings for the industrial classes, and other works (the majority already illustrated in our pages), are proofs of the former; and to these a remarkable addition has just been made in the erection of the Orphanage shown by our illustrations.

The building was commenced several years ago, by Mr. John Crossley, and was intended for purely educational purposes; but shortly afterwards the scheme was abandoned and the works were stopped. In 1861, the firm of Messrs. John Crossley & Sons (consisting of Mr. John Crossley, Mr. Joseph Crossley, and Sir Francis Crossley, bart.), determined to complete the structure, and adapt it to the purposes of an orphan institution. They entrusted the work to Messrs. Paull & Ayliffe, of Manchester. Active operations were resumed three years ago, and have just been brought to a successful conclusion.

The exterior of the building was carried up to the first-floor before the suspension took place. The architects of the Orphanage had therefore to make the best of existing arrangements, and to adapt the exterior treatment to the portions already erected. Internally, little except the enclosure walls of the main structure was retained. The buildings in the rear are wholly additional, and the space now occupied by the dining-hall, &c. was completely cleared and re-arranged.

The whole of the masons' and joiners' works,

THE CROSSLEY ORPHANAGE, HALIFAX.—Ground Plan.

and nearly all the works connected with other trades, have been executed by "day-work," under the superintendence of the architects and the clerk of works, and the entire building is spoken of as a good specimen of materials and workmanship in every department.

Accommodation is provided for 450 children, viz., 200 boys, 200 girls, and 50 infants. The cost may be stated in round numbers to be 50,000*l.*, exclusive of land. The clerk of works was Mr. Gregory Gill.

The building stands on the crown of Skircoat Moor, about a mile from the town, and in the same vicinity as the residences of Mr. John Crossley and Mr. Joseph Crossley.

THE CROSSLEY ORPHAN HOME AND SCHOOL, HALIFAX, YORKSHIRE — MESSRS. PAUL & AVISPE, ARCHITECTS

THE LONDON AND GENERAL WATER-PURIFYING COMPANY.

EVERY one knows that under present arrangements, in proportion as our towns become properly drained, the pollution of our rivers is increased. Such is the magnitude of this evil with respect to the Thames, that notwithstanding the enormous outlay made of late years in providing filter-basins to purify the water taken from the Thames by the Metropolitan Water Companies, the water delivered is little if any purer now than it was in 1851. It holds in suspension both mineral and organic, as well as other impurities, which must remain to be separated by domestic filtering. The cistern-filter of Mr. F. H. Danchell, which is well spoken of, has recently become the property of a company, under the presidency of Viscount Ingestre, a nobleman who has largely interested and successfully exerted himself in the promotion of sanitary reform. The operation of Danchell's cistern-filter is both mechanical and chemical: there is a large bulk of animal charcoal used for purifying the water; and, by the means of disengaging mechanical impurities by ascension, whereby they are, for the most part, separated without entering the filtering matter at all, the filter it may be expected will remain in good working order for a great length of time, whilst the charcoal is easily renewed when necessary. By this means the Danchell filter is free from the common objection to ordinary filters, which, being easily clogged, require to be frequently cleaned; and being self-acting, it is moreover rendered independent of the attention of domestic servants, who, if it is well known, will evade, if they can, the tedious operation of filling into the filter all the water to be purified. Again, the water is purified just at the moment it is wanted, so that impurity that follows upon stagnation is entirely obviated.

WELLS.\*

THE art of well-sinking is common to all countries, and was probably one of the earliest artificial means adopted to furnish a supply of water. From the earliest periods of history the records of both sacred and secular writ go to prove that the art was pursued alike by the savage who roamed the desert and the citizen who inhabited the town; yet it should be here observed that there is a marked difference between the mere hole the savage may scratch in the sand, and the highly-finished wells of some Eastern cities. So ancient are wells that Ewbank observes they must have been of antediluvian origin; and that such useful works remain long after the destruction of those more splendid edifices that have been erected more for the glory than the usefulness of mankind. The buried cities of Nineveh, Herculaneum, and Pompeii, abound in wells of excellent construction, containing good water, and which at the present day supply the inhabitants living in those localities. It is probable that the first wells were shallow holes excavated in the loose soil in moist places, such as are found at the present day to be executed by uncultivated or uncivilised nations or tribes. After the discovery of the metals, which is supposed to have taken place in the seventh generation, as Ewbank observes, rock and indurated strata no longer offered an impediment to the well-sinker, and, consequently, wells were sunk to greater depth in such strata. As the art of well-sinking developed itself at an extremely early period, and long anterior to the commencement of history, no very great advance has been made in it; indeed, the mode usually adopted at the present day when sinking wells to great depth in loose strata, by first forming a curb on which the ordinary steining is placed, and which settles down as the work of excavation is carried on within, and thereby preventing the loose soil falling into the well, was practised ages ago in sinking wells in the East; and from them we have copied the mode in more modern times. Wells of excellent construction abound in Hindostan, China, Japan, Tartary, Egypt, and elsewhere. When the British took possession of Hindostan, the number of wells in use in that country was estimated at 50,000. Many of the ancient wells were of great depth. The wells of Cabul are from 300 ft. to 350 ft. deep, and many of them are but 3 ft. in diameter. The famous well at Tyre is said to be 630 fathoms in

depth. Jacob's well, at Samaria, is 105 ft. deep and 9 ft. diameter. The well Zem-Zem, at Mecca, is 210 ft. deep, and that of Joseph, at Cairo, 300 ft. deep. This well of Joseph is a fine example of the skill and boldness of design of the well-sinker. Although called after Joseph by the Arabs, it is by no means of so ancient a date as the name would imply; for the well was probably sunk about 700 or 800 years ago, but by whom is a disputed point; some attributing it to a vizier of the name of Joseph, others to Saladin, the intrepid defender of his country, whose name was Yussef (Joseph). The well consists of two shafts, one above the other, but not in the same vertical line. The upper shaft is an oblong excavation, 24 ft. by 18 ft., and 165 ft. deep, descending into a large and capacious chamber, in the floor of which is constructed a basin or reservoir for containing water that is raised from the lower shaft. In this chamber a lower shaft is sunk, which is an excavation 15 ft. by 9 ft., and 130 ft. deep. Round the upper shaft a spiral passage, 6 ft. 4 in. wide and 7 ft. 2 in. high, is cut, separated from the well by a partition wall of the solid rock, only 6 in. in thickness, through which loopholes are pierced for lighting the passage. This passage is made use of by parties who draw water, and also for the descent of mules or other animals that are employed in the large chamber below, to give motion to a system of chain-pots by which the water is raised from the lower shaft and poured into the basin in the chamber. There is also a spiral passage round the lower shaft, but it is not inclosed from the well, as in the case of the passage round the upper shaft. The water of this well is procured from a bed of gravel, after penetrating the strata to the depth before mentioned. Wells are common in Greece, and in the olden times of its classic glory were the places of public resort; just as in modern times men congregate at their clubs and such like places, so did the sage Athenians meet together at their wells, and at them orators declaimed, and the music and dance lent their charm to make them places of pleasure and amusement.

The Romans had a clear knowledge of the art of well-sinking; and wells executed by this people are found in every country they once possessed. Many of the successes of their arms were due to their knowledge in this branch of engineering, as when every other source of water failed or was cut away by their enemies, they had recourse to well-sinking to obtain their supply. It was the knowledge of well-sinking that enabled Cesar to retain Alexandria when all the water of the cisterns had been spoiled by the Egyptians. The same knowledge enabled Pompey to procure a supply of water when holding a position of great advantage against Mithridates, who had abandoned it for want of water. Imperial Rome (prior to the time of Appian Claudius) was supplied with water principally from wells.

The water procured from wells is rain that has descended by the minute interstices of the earth's crust, and is stored in the numberless interstitial spaces of porous strata.

Wells may be classified under two heads, viz.—*Ordinary Wells*, or those sunk into permeable or water-bearing strata; and *Artesian Wells*, or those sunk or more generally bored through impermeable strata until a water-bearing stratum is tapped, when the water is forced upwards by virtue of the hydrostatic pressure due to the superior level at which the meteoric water was received.

*Ordinary Wells* may be again classed under the respective heads of *Shallow* and *Deep Wells*. The water from both classes is procured under precisely the same circumstances, but differs often very materially in quality and quantity.

*Shallow Wells* include ordinary domestic wells sunk a few feet into the permeable strata of the earth's crust, and, owing to their shallowness generally, only catch the adjacent percolating water; consequently cannot be depended upon to give a large supply; and, inasmuch as they are generally contaminated with the contents of sewers and cesspools when sunk in the superficial deposits under cities and towns, which are honeycombed with such offensive receptacles, or tunnelled with imperfect and leaking sewers, their waters are not to be recommended for general use.

*Deep Wells* sunk into permeable and water-bearing strata derive supply from a more remote and extensive drainage area brought into action by the depth given to the wells, and the quantity yielded by them is limited by the friction of the water in passing through the interstitial

space and the molecular attraction of the strata for retaining the water, which practically limits the area draining into the well.

*Artesian Wells* have ages ago been in use, and the antiquity of boring wells of this class is so great that the precise period of their introduction is unknown. They are common to Syria and Egypt. China abounds with them, many being upwards of 1,800 ft. deep and but 6 in. in diameter. They are common in Italy and France; and in the province of Artois, of the latter country, they are so abundant that one may be found at nearly every door; and it is from this province that the art of sinking or boring such wells, came into this country, and they are named by us after that place. Artesian wells are artificial springs, and the same remarks that apply to deep-seated springs will apply to Artesian wells.

The quantity of water yielded by wells cannot be absolutely computed, as it is dependent upon so many varying circumstances; but in considering this part of the question we must have regard to the area of drainage, the nature of the stratum, its dip, strike, faults, absorbent properties, and the nature of the underlying and overlying strata, the rain-fall, and the depth of the well itself.

The theory of the probable quantity of water yielded by wells is called the cone theory, i.e., the drainage area contributing to the supply of a well is represented by an inverted cone, the apex of which is at the bottom of the well; so that if the strata were perfectly uniform, and the flow through it equal, the quantity yielded by wells sunk to various depths would be represented by the area of the different cones; but inasmuch as perfectly uniform strata of any great extent are rarely met with in nature, it is impossible to lay down any but general laws in studying the probable yield of water by wells.

*Physical Properties of the Strata.*—The yield of water from a well depends upon the nature of the strata; thus, if the strata be of a close texture, having but few and small interstitial spaces, the drainage area will be limited by the friction of the water in flowing through them, and by their capillary attraction; consequently, in strata of this character, the area contributing to the supply of a well will be represented by an inverted cone of acute irregularity; while, on the other hand, if the strata have large and numerous interstitial spaces, they will yield water rapidly, and the area contributing to supply such well becomes practically infinite. And just in proportion as strata approach one or other of the descriptions of the strata mentioned (all other things being equal), so will the supply of water capable of being procured from wells sunk into them vary. The construction of a well will also influence the flow of water; as, for instance, when a well is sunk into dense but permeable strata, containing much water, naturally yielding it slowly, owing to the fineness of the interstices; by special arrangement an increased supply could be procured. These arrangements consist generally of long tunnels or headings, driven or extending horizontally, sometimes to great distances of the shaft. They have the double advantage of not only offering a greater surface to allow of the escape of water into the well, but they also act as reservoirs for storing it, which is a great advantage in all cases, but more especially when the water is required at intervals, and not continuously. The nature, character, and position of the water-bearing strata, from which wells derive their supplies, must be carefully considered by every person who desires success to crown his labours in practising the art of well-sinking. It has been already shown, under the head of Absorption, that the quantity of water sinking deep into the ground is influenced by many circumstances, and is not alone dependent upon the character of the strata; yet it is quite obvious to the most casual observer, that the nature of the strata has the most important bearing upon the quantity and quality of water yielded by wells; thus, chalk, from its absorbent nature, has been found by observation on the steep chalk-hills around London to absorb a rainfall of two inches per hour; the red sandstone formation, under suitable circumstances, also absorbs rainfall very rapidly; while the more impervious strata absorb it but slowly. The dip or strike of the strata will also have an important bearing upon the amount of water yielded by a well, as it may occur that the natural inclination of the strata may be unfavourable to the yield of any great quantity of water in a particular locality.

*Faults* have a material influence upon the flow of water in the subterranean passages of the

\* From paper by Mr. Baldwin Isthamb, upon "The Supply of Water to Towns," read at "Society of Engineers."

earth, and, consequently, have much to do with the amount of water capable of being yielded by wells. The level of the water in the same strata, when disjoined by a fault, is no longer the same, but may vary considerably; and it may also often happen that a well may turn out to be a failure owing to the near proximity of a fault cutting off and diminishing the drainage area. The careful study of the strata should always form an important point in considering the desirability of well-sinking, and the want of such study often entails failures which we ascribe to faults; but the probability is that, with further insight and clearer knowledge, many of these failures, which are rather the fault of the engineer than any fault in nature, would not arise. Water flowing in the bowels of the earth follows the same laws as water flowing on the surface of the earth, except when modified by some disturbing cause. The line of saturation, or the level at which water may be procured, varies in different strata, and is affected by various causes: thus, the effect of continuous pumping in a district is to lower the water-level of such district. Generally the water-level in strata has an inclination in the direction of its flow: thus it has been established by the Rev. Mr. Chatterback and others that the inclination of the line of saturation in the chalk in the north of London is 13 ft. per mile. In other places it varies according to circumstances: thus, it is not improbable that the flow of some intermittent springs is due to the elevation in the line of saturation, as in the Bourne at Croydon, which breaks out occasionally after very heavy and continuous rains. As a rule, it will be found that in those districts in which the flow of water from springs and the flow of rivers is equal, or neither subject to excessive floods nor droughts, but is always discharging a quantity very near the mean flow, so will it be found that wells sunk into the particular strata from which these rivers or springs derive their principal supplies will yield the largest quantity of water.

#### COST OF THE GOVERNMENT AIDS TO EDUCATION.

SIR DAVID BREWSTER, the principal of the University of Edinburgh, in a recent address, complains of the smallness of the sum which is yearly granted by the Government in aid of the Scottish universities. Amongst other matters bearing upon this subject, Sir David remarks, that the sums granted for Protestant middle-class education in Ireland was, during the last year,—Queen's College, 21,000l.; Queen's Colleges, 6,900l.; Queen's University, 3,608l.; Belfast Theological Institution, 2,700l.—in all, 38,908l. The learned principal says, "this magnificent sum is for the education of far fewer than 1,000 students; while all the universities of Scotland receive only the paltry allowance of some 10,000l. for the education of 8,500 students." Respecting this, "A Scotchman in London," in writing to a contemporary, remarks, that the 10,000l. a year, which is so little thought of, is equal to a capital of 300,000l. in Consols; and the above sum is additional to former grants, and last year the payments in connexion with the Scottish universities (including a special grant of 2,362l. for Aberdeen) were 22,267l.: this is about 6l. 10s. or in three years, 19l. 10s., paid by the State in assisting each student in the Scottish universities. In Ireland, the bounty granted by Parliament for each student is about 34l. a year, or 102l. in three years, the usual time for young men to remain in these colleges. We do not complain of these grants, and have only referred to them for the purpose of contrasting the extent of the Government aid afforded to the education of the poor and working classes in Great Britain. The sum granted for the common schools last year was 704,002l., and the "Scotchman in London" remarks, that in a tolerably well educated country there is, or ought to be, one-sixth of the population at school. Supposing this to be the case, the Government allowance to each scholar amounts, on the average, to only about 3s. 6d. a year; or, supposing the average attendance to be three years, the total sum paid to each child will be 10s. 6d.

In Ireland, the common schools received a Parliamentary grant of 906,821l. One-sixth of the population of Ireland would be 950,000, representing the children who were, or who ought to be, at school; and this sum divided amongst them would average about 6s. 6d. a year for each, or 19s. 6d. in three years—about

twice as much as the sum allowed for common school education in England and Scotland.

In connexion with the common schools, a payment is now made according to Mr. Lowe's plan,—not a certain sum for each scholar, but at the rate of 8s. for each child who passes a creditable examination in reading, writing, and arithmetic; and it appears that in Roman Catholic schools 21 per cent. of the children examined failed to pass their examination in reading (and consequently the school lost the offered 8s. on account of each child that so failed); 23 per cent. failed to pass their examination in writing; and 33 per cent. failed to pass their examination in arithmetic,—the average of the three branches being 25½ per cent. In Church of England schools 13 per cent. of the children examined failed to pass their examination in reading; 15 per cent. failed in writing; and 24 per cent. in arithmetic,—the average of the three branches being 17½ per cent. of failures.

In the British and Foreign Society's schools, where the education is more of a secular description,—taking the Wesleyan, Presbyterian, and other Protestant Dissenters' schools together, the results are as follow:—The failures in reading were only 10 per cent., in writing, 12 per cent., and in arithmetic, 19 per cent.—the average of the three branches being 13½ per cent. We thus find in Roman Catholic schools there are 25½ per cent. of failures; in Church of England schools, 17½ ditto; and in the British and Foreign Society's schools, 13½ ditto. The above figures show a marked difference, and confirm an opinion we have before expressed, that in the National schools it is necessary to direct attention more exclusively than is done at present, to the simple teaching of reading, writing, and arithmetic.

#### AN ILLUSTRIOUS FOREIGN VISITOR.

A VISITOR, well known and highly appreciated in many of the waters abroad, has, by the means of the Acclimatization Society, been introduced into our own. This is a remarkable event, for it is said that there has been no new fish useful for food added to those which before existed in England since the time the carp was brought here more than 200 years ago. The present stranger is the *Silurus glanis*, specimens of which have been brought alive to the station of the Society at Twickenham by the exertions of Sir Stephen Lakeman and Mr. Lowe, from a distance of nearly 2,000 miles. In all, fourteen of these young fishes were brought from Kapochein, in Wallachia, where Sir Stephen Lakeman has an estate. The Argish river, which flows past here, abounds in these and other valuable fish, which are found more or less throughout central Europe and in Scandinavia; in the Danube and many of its tributaries the number is abundant; and in those wide waters the *Silurus glanis* is said to reach the enormous weight of 300lb. Its appearance is not pleasant, the large flattened head having a capacious mouth, which is capable of seizing the largest kind of prey; so that if this fish he successfully propagated in our streams and lakes, the pike, the water-wolf of the British waters, will meet with more than its match. The habits of the *Silurus glanis* are said to be most ferocious, and its growth, provided there be a sufficient supply of food, very rapid. The body is less elongated than the eel, and there are, stretching from the head, long tapering barbels; the eyes are frog-like, and there are many other points of general resemblance to the frog.

The new fish is like the eel in its habits, being a wallowing fish, fond of hurrowing in the mud, and hiding amongst the rotten roots of trees. There are dark charges made against some of the largest specimens of the *Silurus glanis*, in the stomachs of which it is reported that portions of human bodies have been found. However, this is probably an exaggeration. There can, however, be no doubt of the extraordinary appetite and fierceness of this fish. In the floods which cover the neighbourhood of the Danube, the silurus finds a plentiful prey in the multitude of frogs which pass into the river; but at other times, fish, small animals, worms, indeed anything which comes near, afford a supply of food; and there may be fear that, notwithstanding the valuable qualities of the silurus as a means of supply to our tables, it may more than balance its value in this way by the immense destruction of fish which is needed for its support.

It is said that the silurus, when the prey is plentiful, will attain over 56 lb. in four years;

and Englishmen who have tasted it report that in flavour it is superior to the salmon. An eminent authority remarks that this is the only foreign fish which it would be worth while to introduce into this country; and thinks that, into several of our lakes, particularly those in peat soil, this fish might be usefully placed. To increase the quantity and variety of the food of a nation is an indescribable advantage; and the greatest praise is due to the Acclimatization Society for their earnest labours in this way.\*

We may note that there is a sea-fish which somewhat resembles the cod; and the pike is making way as an article of food in the London market: the flavour is excellent, either when boiled, fried, or baked.

#### COMPETITION FOR GOVERNMENT BUILDINGS AT NELSON, NEW ZEALAND.

THE Government authorities advertised for designs for a Government House, a Supreme Court-House, and a Custom-House, with post-office combined. The cost of the first was to be 23,000l., and each of the others 20,000l. A premium of 200l. was to be given for the best design of each of the three buildings, and a second premium of 100l. for the second best design. So far the terms of the competition were unobjectionable. The architects, however, were required to send in carefully prepared estimates with the several tenders stated separately, including all fittings, the drawings being all made to one-eighth scale, comprising plans, elevations, and sections, perspective views from two points of view being desirable, and models also admissible;—the premiated designs to become the property of the commissioners;—the architect of each of the best designs not necessarily to be employed to carry out the work;—and no premium to be paid until the building contracts were taken; and not claimable at all, if the building tender exceeded 15 per cent. above the architect's estimate. Notwithstanding these terms, and that an experienced architect pointed out the unreasonableness and absurdity of them in the *Nelson Examiner*, "an immense number of designs were sent in,"—from would-be architects at least; all the designs, of course, being obviously defective, and not in accordance with the conditions. Two, however, were selected, one of which it is estimated will cost 10,000l. above the stated amount, and the other 8,000l. The design selected for the first premium and for execution, is said to be in the style of a baronial residence of castellated Gothic. This building is estimated to cost 33,000l.; but even according to the commissioners "it may be feared that the cost will greatly exceed this amount." The second design is that of a Tudor Gothic mansion.

#### NEW THEATRE, BRADFORD, YORKSHIRE.

THE new theatre in Bradford was opened on the 26th ult., under the management of Mr. J. B. Buckstone, of the Haymarket, and Mr. White. It has been built by a limited liability company. The building is 50 yards long, and 20 yards wide; and at the front is set back some distance from the line of road, so as to give greater facility for ingress and egress. This space will be covered with an ornamental portico or verandah, forming a desirable shelter in case of wet or inclement weather. In consequence of the inclination of the ground, the architects have been able to arrange the levels of the floor in a convenient manner. Parties visiting the boxes, obtain admission to them without the necessity of ascending a flight of steps. The boxes are entered from corridors, and are furnished with chairs, of ebonyized wood, covered with crimson Utrecht velvet. There are also two private boxes on each side of the stage. The seats of the pit are comfortable, every alternate seat having a back. The gallery is approached by a stone staircase. There is also a second one, of the same size, as an extra means of egress. All the interior doors are arranged to open outwards. The proscenium is 26 ft. wide, by 27 ft. high. At the rear of the stage are suites of dressing-rooms, green-room, property-room, &c. Externally the building is somewhat plain in appearance. Internally, the fronts of the boxes and galleries (three tiers), are decorated with a wide diaper enrichment, each tier of a different design. The

\* There is an account and a good engraving of the new fish in a recent number of Cassell's Family Paper.

proscenium is supported by clustered twisted columns, on each side, having a guilloche enrichment between. The top is of an elliptical form of arch, decorated; over this are the Royal arms and scroll enrichments. They are enclosed in a broken circular pediment, gilded and decorated. From the centre of the ceiling hangs a chandelier, the work of Messrs. Ostler, of Birmingham. The stage is constructed by Mr. James Neill of Bradford, from plans furnished by Mr. J. G. Hilton, of London, and its erection has been carried out under the superintendence of Mr. Oliver Wales, of the Haymarket Theatre. The accommodation is as follows:—Pit, 600; dress boxes, 200; upper boxes, 250; gallery, 750; total, 1,800. The architects of the building are Messrs. Andrews, Son, & Pepper, of Bradford. The execution of the works has been entrusted to local tradesmen. The clerk of the works was Mr. Benjamin Roberts. The opening night was a success.

ROCKWORK.

Bad rockwork is oftener seen than good. Making some observations on the formation of such work, the *Edinburgh Courant* says:—There are two leading objects to be kept in view in the construction of artificial rockwork. One is an imitation of the surface, broken and disturbed, and intermingled with Alpino vegetation; the other an imitation of the natural stratification of some particular section of rock geologically arranged. The rockwork which most usually occurs in park scenery (we do not here refer to it as entering into combination with other objects in flower gardens), is by the sides of the approach where cuttings have to be made through rocky strata. Than this nothing is more simply accomplished, as all that is required is to bare the natural rock so as to bring into view pieces of its most perfect formation, to cover the spaces between with turf or creeping plants, and with a few stunted bushes of birch, or such other tree as is indigenous to the spot. Care must be taken that no tool-marks be left visible on the rock, and that all traces of art be obliterated, leaving the whole as if it had been a natural opening through which the road has been taken. Lay bare prominent pieces of natural rock here and there in dingles and banks near which walks or drives pass, so as to bring them into contrast with the vegetation that surrounds them, and plant with creeping plants here and harsh lines that may have been formed by quarrying, landslips, &c. Artificial rockwork may be sometimes employed to hide objects not wished to be seen, and where the space is not sufficiently broad to admit of this being effected by planting.

THE LONDON DRESSMAKING COMPANY (LIMITED).

The agitation of the question as to overworking, overcrowding, ill-health, and mortality amongst the poor dressmaking girls at the West-end of the metropolis has resulted in the formation of a reformatory or model company under highly influential auspices. The patrons of the association are Lord Shaftesbury and the Bishops of London and Oxford, and among the patronesses are many of the leading ladies of the Ladies' Sanitary Association. The capital of the company will be 20,000*l.*, in 2,000 ten-pound shares. They have already taken offices at 19, Langham-place, and are negotiating for the purchase of a first-rate West-end dressmaking business to begin with, although there are already nearly 200 shareholders on their list. If we have any misgiving as to the result, it is not that the undertaking will be pecuniarily a profitable one. The dividends, however, are restricted to 8 per cent. per annum, and the surplus profits are to be devoted to the improvement of the condition of the poor workwomen. The hours of work are to be restricted to ten, or from 8 a.m. to 8 p.m., with two hours intervals for meals. Great exertions are still, we understand, being made to increase the list of shareholders, although the intention is only to begin on a small scale; but have the company the power even now to begin on a small scale, with 200 shareholders, patrons,—customers, in short, and a first-rate dressmaking business already established to begin with? We should think they would be overwhelmed with orders even at the very outset. This, in truth, is virtually a great West-end co-operative establishment, and it certainly sets out with the brightest of prospects and possibilities

as regards material success and the amelioration of the condition of the poor needlewoman. The company have no desire to act competitively or antagonistically against the present order of dressmaking establishments, but rather to induce them to adopt those improvements as to accommodation, hours of labour, and general good treatment, of their workwomen, which it will be the aim of the company to set before them as a model.

ART-UNION OF LONDON.

CLAUDE DUVAL is the title of the print provided by the council for the subscribers of this Society for the current year, and it is undoubtedly one of the most interesting as well as one of the most ably engraved of the numerous fine plates produced under the auspices of this corporation. The scene depicted is one that was of no infrequent occurrence in the days of our second Charles. Claude Duval, the dissipated foreign valet of a nobleman, took to the road, and, in the course of his campaign against the goods and chattels of the travelling community, he, on one occasion stopped a carriage which yielded booty to the amount of 400*l.* Touched, however, by the beauty of the fair mistress of the party, and with that humorous caprice, which often swayed gentlemen of his profession, the bandit contented himself with 100*l.* out of the 400*l.*, on the condition that the lady should dance a *corante* with him on the heath. This is the moment selected by Mr. Frith for the subject of his picture. The forced gaiety of the lady, contending with the mortal fear which she cannot conceal, combined with the graceful action which bespeaks high culture,—the open-mouthed amusement of the men who evidently enjoy the joke,—and the suppressed indignation of the old man who sits bound on the ground, are all admirably given, while the negro escaping on the right-hand side, unnoticed by the gang, through their interest in the progress of the dance and the contents of the caskets, suggests the possibility of a rescue; and the gibbet in the far distance, with a Hogarthian touch, foreshadows the probable exit of some of the performers in the scene. Mr. Stocks has executed his portion of the work with great success. The laying in of the lines and their hold continuous sweep, are worthy of some of our old masters in this style, and the texture of the lady's satin dress and the robber's coat is very skillfully rendered. There is no doubt that this print must secure a very large number of subscribers anxious to possess it.

The council announce, amongst other novelties, a bust of the Prince of Wales, to pair with the one of the Princess given last year. If the likeness be as good as that of her Royal Highness, it will be a success.

We have seen a silver vase in repoussé work, executed by Mr. Barkentin, on which are given two scenes from the story of Cupid and Psyche: two nymphs very gracefully poised form the handles, and the whole thing is of good design, and a creditable specimen of an art at present much neglected. The Art-Union has bought the model and copyright, and a number of the vases reproduced by electro-deposit will be given as prizes in the next distribution.

THE ARCHITECTURAL ASSOCIATION.

The ordinary meeting of members was held on Friday evening (the 23rd ult.), at the House, in Conduit-street. The chair was taken by the president, Mr. J. H. Christian.

The following gentlemen were elected members of the Association:—Mr. Demain, 4, Haringford-road, Barnsbury; Mr. Somers Clarke, 20, Spring-gardens; Mr. John Eastly Goodchild, jun., 8, Regent-street; Mr. Walter Evill, 27, Elgin-crescent, Notting-hill; Mr. Walter Lonsdale, 1, Horshy-crescent, Notting-hill; Mr. G. Fredk. Payne, 63, Great Queen-street, Lincoln's-inn-fields; Mr. E. J. Maddock, 9, Conduit-street; and Mr. A. Hopkins, 10, Gray's-inn-place, Gray's-inn.

The Chairman said, a letter had been received from the Science and Art Department, South Kensington, transmitting, for the information of the Association, a minute recently passed by the Lords of the Committee of Council on Education on the subject of architectural decorations. Their lordships expressed a hope, that as the subject was one of interest, not only to the public,

but especially to architects, the Department might be favoured with any suggestions which it might be in the power of the Association to afford for the promotion of the object in view. The letter in question was dated the 19th inst., and was signed by Mr. Henry Cole. The chairman added, that as some portions of the minute appeared to be extremely valuable, the better course might be to refer it to the committee.

In reply to a question, The Chairman said, he was of opinion that the Architectural Museum should not be permanently located in so distant a place as South Kensington.

Mr. G. H. Birch then (in the absence of Mr. Bayn) read the prize essay, written by the latter gentleman, "On Iron as applied to Architecture."

On the 6th of January Mr. Lacy W. Ridge will read a paper "On Boxgrove Church, Sussex."

BUILDING NOTES AND QUERIES.

TILING.

In the early times of periodical literature, a column of the *Tattler* or the *Spectator* was devoted to correspondence, and contained questions and answers; sometimes, no doubt, genuine and authentic, but often merely covering editorial opinions under a pseudonymous signature. Correspondence of this nature may still be traced in the columns of certain sporting papers and of journals that deal almost exclusively with some isolated department of public news. With the increase in the number of readers, and the augmented circulation and daily issue of the newspapers of a later period, correspondence entered on another phase. Too voluminous to be printed, even in abstract, the letters daily received supplied to the conductors of the daily journals a convenient method of testing public opinion; and when, here and there, a letter of more than ordinary interest was laid before the public, it generally might be taken to represent a large unprinted mass of more or less unreadable correspondence on the same subject.

Instances have indeed occurred where, whether from a misconception of the real value of miscellaneous correspondence, or from a wish to secure subscribers by the hope that an easy means of appearing before the public in the envied garb of print was offered by the paper which sought their support, a disproportionate space of a public journal has been allotted to the reception of letters, as to which no principle of selection appeared to have been applied. But even apart from the intolerable inanity of these miscellaneous pages, the correspondence of the literary and scientific journals themselves is too apt to be made the medium of private opinion, or even of acrid dispute. The object appears too often to be the exaltation or the vindication of the writer, rather than the attainment of truth; and many otherwise able letters, whether bearing known literary signatures, or subscribed by simple initials, are obnoxious to this reproach.

In our own journal, in which, offering a wide medium of correspondence, the above-named inconveniences seldom arise, much information has been in this way elicited; and if, enlarging the system, the many practical and scientific readers of the *Builder* will devote a few minutes of their time to the asking and answering questions of the nature of "Building Notes and Queries," the result can hardly fail to add to the interest of the journal.

As an instance of one of the practical questions on which the collection of sound information may be of good service in many quarters, let us instance the subject of tile roofing. In one of those religious edifices that have sprung up in great numbers in the suburban districts within the last few years, there is one which was completed in the last spring, and the roof of which already shows signs that it will but ill resist the impending winter. Of course, in all such cases the right, and usually the cheapest, course to adopt, is to place the case unreservedly in the hands of some professional man—the original architect if accessible, or, in his absence, some respectable substitute. In the case in question, however, whether from a view to economy or otherwise, the persons interested in the management of the building sought the advice of the builder.

It should be mentioned that the roof was covered by flat tiles laid in mortar, and that on confining a small quantity of water by a clay edging on the top of one of these tiles, the water rather

\* This will be found in the *Builder*, p. 303, ante.

rapidly percolated, and dropped from the underside. This seemed to account for the damp ceiling of the building, by laying the blame on the use of porous tiles; but the person who conducted this experiment was of opinion that it was too severe, and that any tiles would behave in the same manner.

Then there arises query the first,—what amount of impermeability may be fairly expected from roofing-tiles, and what is a fair test of this impermeability?

Then, query 2.—Is a plain tile the best, or one of the best, for roofing purposes? or is a necking, or slight projection on the upper part of the tile, an improvement with regard to the manner in which it will discharge its proper function of turning water?

The person whose advice was taken on the subject declared that the reason that the roof was damp was, that the tiles had been laid in mortar; he therefore recommended that the tiles should be removed from the roof,—that the mortar should be scraped from the upper surface of each tile, and that the tiles, thus cleaned, should be relaid in hay.

Then there arises query No. 3.—Has mortar ever been known to render roofs wet; and, if so, why?

Query 4.—Is the practice of bedding roof-tiles in hay modern, and found to answer?

It would be easy to argue that, while any irregular use of mortar which would prevent natural drainage, would promote damp; the removal of a fair bed of mortar from the under surface of a square of tiles would only be the removal of so much material that offered at all events some resistance to weather. And it might be urged that the bedding of hay, not laid regularly like thatch, but merely crammed under the tiles as it is crammed into the rack of a stable, would only aid in conducting the external moisture to the upper side of the ceiling. Lastly, it may be said, wait and see how the hay-packed roof stands the winter.

But the object of these lines is neither to express nor to solicit opinion of a theoretical kind, but to furnish an example of that sort of question the clear statement of and the practical replies to which will not only much interest the readers of the *Builder*, but give valuable information to professional men, and tend to prevent much useless waste of money.

The practical lesson to be drawn from the experience of the present instance shall be a future contribution to the note and query department of the *Builder*.

#### ENTRANCES TO PUBLIC BUILDINGS.

##### BRIGHTFUL ACCIDENT AT DUNDEE.

ANOTHER proof of the necessity for some inspection of the modes of ingress and egress to and from buildings where meetings of the public take place, has just occurred at Dundee. A press of people were standing at the entrance of a concert-hall, below the United Presbyterian Church, in Bell-street, Constitution-road, waiting the opening of the gate, which was on a level, not with the concert-room, but with the church-floor above, so that it opened directly on a descending staircase, down which, so soon as the gate was opened, the people were pushed and fell, one on the top of another, till they formed a mass below, from which self-extraction was impossible, and out of sixty or seventy persons so placed, nineteen were taken out, in about three-quarters of an hour, dead, and many others more or less seriously injured. One of these has since died. The flight consisted of fifteen steps, and was 7 ft. wide. The space at the foot of the stairs where the mass of people, chiefly youths of twelve to eighteen years of age, lay, is only about 7 ft. by 9 ft.

There are two accounts given of the precise manner in which the accident took place. One is, that those forced in on a sudden opening of the gate were able to keep upright until near the bottom, where one or two lost footing, and having fallen, those behind rolled over them; while the other is, that a mass of persons were hurled from the top of the stairs to the bottom by the sudden impetus which they had received. The whole affair, however, was so instantaneous that no reliable account can be given of the manner in which the disaster occurred. When the advertised hour had, it appeared, arrived, the man in charge opened one-half only of the gate, but the pressure of the crowd from without was so great that the man was overpowered, and the

other half of the gate was then burst open. The entrance is evidently a trap of a most dangerous description.

There are places of amusement in London where as dire a disaster may occur any evening.

#### QUESTION UNDER THE BUILDING ACT.

Mr. EDWARD COCK, builder, No. 94, Wardour-street, appeared before Mr. KNOX, at Marlborough-street police-court, to answer a summons taken out by Mr. Robert Kerr, district surveyor of St. James's, for an alleged violation of the Building Act, in erecting two buildings in the stoneyard of the workhouse, for vagrant wards (being dwelling-houses) having their walls formed of combustible materials; and also in erecting these buildings so as to prevent them from being lighted and ventilated in the mode prescribed by the Act, by communication with the open air; or otherwise for refusing to obey the requirements of the district surveyor, who, considering these wards as public buildings, had required the same to be constructed with incombustible walls and in direct communication with the open air.

Mr. Kerr gave evidence to the effect, that the stoneyard in question was a space about 90 ft. long and about 60 ft. wide, entirely covered, at a height of about 13 ft., by the public baths overhead, and receiving light and air from the ends; that the two new wards, being about 40 ft. long, were built of timber-work and boarding, about the middle of this covered area, one on each side, removed altogether from the open air, and devoid of windows; that he considered the timber walls to be dangerous as regarded fire, and the deficiency of ventilation to be also dangerous to health; and he explained that if these new wards were considered by the Court to be not public buildings, he required the application of the ordinary provisions of the Act; or otherwise, if they were considered to be public buildings, or works done in a previously-existing public building, that his demands were still the same under the provision for his special authority over public buildings, subject to an appeal to the Metropolitan Board of Works. The danger from fire he considered to be serious, looking at the character of the intended occupants; and the risk of injury to health he thought was especially to be regarded, because of the site being an old graveyard, and there being no proper circulation under the superimposed building.

Mr. Pearce, barrister, instructed by Mr. Buzard, the clerk of the Board of Guardians, said, the question was one of great importance, not only to that but to other parishes, inasmuch as it had reference to an Act lately passed, the Houseless Poor Act; and should the decision be unfavourable, it would tend very materially to obstruct the beneficent intentions of the Legislature. In compliance with the provisions of the Houseless Poor Act, the parish authorities had erected two buildings in the stoneyard, at the back of and adjoining their workhouse, for the reception of casual vagrants. The cost of the buildings was 300l., and they had been approved of by the Poor-law Board under their certificate, which certificate was necessary in order to enable the parish to get from the Metropolitan Board of Works the amount of the outlay as soon as it should have been incurred. It put in a plan of the wards bearing the general preliminary approval of the Poor-law Board, and the final approval was expected daily. Now he contended that the buildings did not come within the Building Act as all, having been erected in conformity with the provisions of a later Act, to meet a temporary emergency. He contended, that the later Act would override the earlier Act, and leave the responsibility of the buildings with the Poor Law Board alone, and not with the district surveyor; that the new wards were not public buildings; and that they were not buildings at all, directly or indirectly, but temporary enclosures in an old building. He would also remark, that if the parish were obliged to pull down the buildings, or to make such alterations as to prevent them from being used for the purposes intended, the object of the Houseless Poor Act would be defeated, and the casual poor would sustain much hardship.

No evidence was called for the defence, and the district surveyor made no reply.

Mr. Knox deferred deciding till next day, that he might inspect the place. His decision was ultimately given thus:—He had come to the opinion from personal examination, that the new

wards were but interior apartments partitioned off. He could not agree that the Building Act was in any degree set aside by the Houseless Poor Act; he read both Acts together without difficulty; moreover, he was of opinion that the new wards were public buildings in the sense of the Building Act; and he held that the Building Act had full authority over them but for the circumstance that they were situate within the covered building which constituted the stoneyard. If built in the open air he should have considered them in every way subject to the rules of the Building Act, but as they were formed by merely erecting partitions in what was previously in fact a room, he must dismiss the summons. The district surveyor, if dissatisfied, knew what course to pursue; but as that officer had relieved himself of all responsibility by his application to that court, this, he supposed, was all that he desired.

Mr. Kerr intimated to the clerk of the Board of Guardians, that it would be necessary for him to report the case to his superiors, the Metropolitan Board of Works, and that he would leave it entirely in their hands.

#### ARCHITECTURAL COMPETITORS.

Sir,—An inquirer's queries on this subject may be fairly met by the question,—Is it customary for architects to bind themselves by the conditions imposed on them? I think not. Nor is it right that they should do so. Nine times out of ten a building committee knows very little of the business they have undertaken. An architect, an originator and director by profession, should set as such, and work out what he conceives to be most suitable as a man of business, and not as a man of the commission. If he chooses to lay three designs (gratis) before the judges, they will, if wise men, certainly avail themselves thereof. The question of scale and some other should be settled by the profession; and, I believe, that with proper regulation, detail drawings will not be called for. As present they are supposed to show the author's competitors.

I suggest that a code of competition rules be prepared and circulated among the members of the profession, to regulate, mainly, the number of competitors; scale; who shall be the judges; how many competitors shall be remunerated; the scale of remuneration; and if stated requirements can be held as absolute conditions.

First, as to number of competitors, and their remuneration. It is but fair that if a building committee desire an unlimited number of designs, we should impose a condition that a certain percentage of the competitors should be remunerated, since the outlay by our members is largely increased. The scale for the drawings should be a small one, to economise labour as far as possible. The judges should consist of five persons,—three architects and two members of the building committee. A list of architects willing to undertake this really arduous duty should lie at the Institute, and its subscribers should serve to rotation. The instructions should be issued by them.

By thus securing competent judges, many of the present difficulties would vanish, and the profession would be taking steps to save its members from the disappointment caused by local chicanery, and by a want of compliance with conditions which are perhaps illogical or ridiculous.

A. GARDNER BARR.

#### MONACHIAN AND CAVAN LUNATIC ASYLUM.

Sir,—Many of your readers will remember that architects were invited, more than a year ago, to submit designs for the above, and that a large number were sent in from English and Scotch, as well as Irish architects, in which it was said at the time that much ability was displayed. Those who engaged in the contest will remember that a selection was made, chiefly on the ground of economy, of a design which the author estimated could be executed for 25,000l., or at the rate of about 80s. per patient, the number to be accommodated being 300.

The tenders for this design have only just been received, and I am informed that the lowest eligible tender reaches the sum of 35,000l., exclusive of a number of indispensable items which will probably bring the amount to 40,000l.

It is clear from the above that those architects who sent honest estimates with their designs, were placed at a great and unfair disadvantage by the low, and as now appears, deceptive estimate sent with the selected design; and it appears to me that the committee are bound in honour to re-consider their decision.

ONE OF THE COMPETITORS.

#### THE SIR TATTON SYKES COMPETITION.

Sir,—It is more than three months since the designs for the above memorial were sent in, and not a word has been heard about the decision of the committee. It is quite time that the unsuccessful designs should be returned, and the names of the "successful competitors" made known.

A COMPETITOR.

ORNAMENTING IRON AND STEEL.—Mr. Christian Weidmann, jun., of Offenbach, Hesse Darmstadt, has patented an invention, which consists in ornamenting, by drawing, or otherwise marking, on the surface of steel or wrought-iron, which must be first polished or bright, or "matted," any desired spots, pattern, or device, and according to different temperatures so will the effects differ.

METROPOLITAN BOARD OF WORKS.  
THE RIDLEY TENDER.

At the last weekly meeting of the Board the correspondence as to Mr. Ridley was read by Mr. Bazalgette, after which Mr. Doulton moved that the letters be printed and referred, with the rest of the correspondence, to the Main Drainage Committee. He was sure, he said, that when the letter of Mr. Bazalgette and the confirmatory letter of Mr. Gregory were placed before the public they would be prepared to say that they entirely exonerated the Board from the charge of acting in opposition to the interests of the ratepayers of the metropolis. He was certain it would be felt that the chairman had acted with prudence and judgment, and that the engineer's character was entirely vindicated.

Mr. Legge seconded the motion. He hoped the correspondence would go to the public, and do justice, not only to the engineer, but to Mr. Ridley and the Messrs. Waring. It would prove that Mr. Ridley at the time of sending in the tender was a man capable of carrying out the contract, and quite willing to do so. The inquiry was not as to his private character, but as to his capability to carry out the contract. It regarded the man's credit. It showed that, if he had taken his employer's money, when Providence placed him in a position to repay it, he came forward voluntarily to do so. The sum was 100*l.* He calculated that the interest would double it, and he said, "Here are 200*l.* to make ample amends for any wrong I have done you." The public would come to a just conclusion at the end, and would judge whether Mr. Ridley was or was not capable at the time of carrying out the contract.

Mr. Lowman (Dorset) thought that on that day the engineer was simply to be asked for information, and that they would not go into any discussion. They were not prepared for it, because they had not till now the papers in their hands, and justice could not be done to either party. It was difficult to determine the question between the two parties, and they should not go into it that day. The information contained in the report of the engineer appeared to be rather incomplete, and there might be a complaint that something was withheld because there were blanks in it.

The Engineer, in reply to the question respecting the blanks, said the information was given to him in confidence, and, therefore, the blanks were in the report.

After a few words from Mr. Tito and Mr. Freeman, the motion was agreed to.

PROVINCIAL NEWS.

*Eye (Suffolk).*—An extensive flax manufactory has been erected in the outskirts of the town, on the Hoxne-road, to replace old works which were burnt in May last. The walls are of clay-lumps, faced with brick. The bricklayers' work was done by Mr. Ramplin, of Eye, and the carpenters' work by Mr. Gooderick, from Sir E. C. Kerrison's estate. All the bricks and the wood were supplied from the estate, and the work generally was superintended and carried out by Sir Edward's own people. Messrs. Chase hire the building from Sir E. Kerrison. In the internal arrangements rooms have been provided in which the workpeople can get their meals, separate accommodation being given to the men and boys, and to the women and girls. At present only the female meal-room is completed, and the males will therefore use the foreman's house, which stands within the enclosure of the works. The total cost of the building and machinery has been from 7,000*l.* to 8,000*l.*

*Woodbridge (Suffolk).*—The railway company have erected a grain warehouse here, 130 ft. long by 50 ft. wide, capable of holding 3,000 combs of grain. The building is of red and white bricks, and was erected by Messrs. Perry & Judson, of Stratford, contractors, the brick-work being done by Messrs. Cullingford & Forsdike, of Woodbridge. It is lighted by ten fanlights on one side, and four roof-lights, and fitted up with gas-burners.

*Bristol.*—The subject of new assize courts has been much discussed in this city. Among the proposed schemes is one by a corporate official, who proposes using a site on the Grove, Queen-square, and building handsome courts. Plans are in preparation, and they will shortly be laid before the council.

*Bath.*—The foundation-stone of the new bank premises at the top of Milsom-street, for the National Provincial Bank of England, has been

laid. The building, when completed, will be similar in style to the centre houses in Milsom-street. The elevation in this street will comprise four stories. The attic will be terminated with open stone halustrading and vases. The main cornice will be supported by four Corinthian three-quarter fluted columns, resting on a rusticated basement. There will be two entrances, one in the centre of the elevation facing York-buildings, and the other in the rounded corner between the two streets. The York-buildings elevation will be similar to that in Milsom-street, the only difference being that the main cornice will be broken by a large pediment supported by six Corinthian columns, the tympanum of which will be carved with the Bath arms and a group of emblematic figures. The attic will be similar to that in the Milsom-street elevation. The banking-office will be large, and lighted by three windows, looking into York-buildings, and by a circular dome lantern supported by four polished marble pillars, in Caen stone, of the Ionic order. The ceiling will be decorated by Messrs. Green & King, of London. All the fittings will be of oak, enriched by moldings and carvings. In the basement there will be a strong room, under the banking-office, fitted up with lift and all modern appliances. The building will be fireproof, iron joists and girders being used throughout. The design is by Messrs. Wilson & Willcox.

*Middlesborough-on-Tees.*—Mr. H. W. F. Bolekrow, a member of the firm of Bolekrow & Vaughan, ironmasters, has intimated his intention of making a gift to the inhabitants of 100 acres of land, in a convenient position, which is to be completely laid out as a public park, at the sole expense of the donor. There are now 25,000 inhabitants in Middlesborough, and they labour in many factories, mills, furnaces, and other works of the great iron industry, where, thirty years ago, a solitary farm-house stood,—the rise of the town has been so rapid.

FROM SCOTLAND.

*Greenock.*—The old west church has been restored and re-opened. The work of restoration has been executed from designs by Mr. James Salmon, of Glasgow, by the following tradesmen:—Mr. P. Crum, mason; Mr. J. Black, joiner; Mr. G. Burns, slater; Messrs. Brownlie, Buchanan, & Co., plumbers; Messrs. Finlay & Weir, gasfitters; Messrs. Johnstone & Lochhead, painters; Messrs. R. Blair & Son, upholsterers; Mr. J. Chalmers, smith; Mr. J. M'Dougall, master of works. The edifice has a new tower and spire, but the building generally was not found to be so dilapidated as to require re-erection. Stained glass windows have been executed for it by Messrs. Ballantine & Son, of Edinburgh. The subject represented in the large north window, is the "Adoration of the Magi." That of the large south window is "Jesus calling his first Disciples." In the dexter side of the twin-light north window, is a representation of "Jesus teaching Mary," and in the sinister light he is "Blessing little Children." The church is lighted in the evenings by two gaseliers, and brackets under the galleries. The warming is by a Gill stove.

GAS.

The report of the directors of "The Pará Gas Company (limited)," has been issued. From this report it appears that the contractors, Messrs. Peto & Aird, have nearly completed the works at Pará, in Brazil, and that the city has for some time been lighted with gas. Messrs. Peto & Aird have been paid 81,517*l.* for the works, and the expenses of the engineer, Mr. Thomas Rumball, amount to 3,666*l.* The capital of the company was 100,000*l.*, and they have still a balance of 4,226*l.* at their bankers'. The income of the company from the supply of gas to the Government and the city is not yet available; and the directors only recommend a dividend of 5 per cent. per annum for the last half-year. The streets, churches, and private dwellings are all being lighted up with gas. The affair promises very well.—The city of Alexandria has been lighted by gas, the works having been erected by a French company. The lamp-lighter is nightly followed in his rounds by a crowd of wondering Arabs, who insist that the marvellous blaze following the touch of his torch must be provoked by the will of a genie, or "djinn," as Mr. Lane would have us spell the familiar word of the Arabian nights.

Heretofore a municipal regulation required everybody going abroad after nightfall to carry his own lantern, but this is no longer necessary.—The directors of the Sheppy Gas Consumers' Company have resolved to reduce the price of their gas from 5s. to 4s. 6d.; and the directors of the Hythe and Sandgate Gas and Coke Company have also announced their intention of making a further reduction of one shilling per 1,000 ft. The price will then be 6s. 6d., and the allowance of discount at the rate of 6d. per 1,000 ft. on prompt payment will further lessen the sum to 6s.

RAILWAY MATTERS.

The forty-seven railway schemes which will next session be submitted to Parliament in reference to London are said to represent no fewer than 151 separate lines and branches, with a total length of 349 miles. Of these, twenty-three relate to the south side of London. The longest on the list is the London, Bucks, and East Gloucestershire, 59 miles 6 furlongs.

We understand, says the *Railway News*, that the appointment of a select committee of the House of Commons will be moved for immediately after the assembling of Parliament, for the purpose of inquiring into the whole question of railway management, and for considering whether any and what steps are necessary with a view to their being made more conducive to the interests of the public. It is further stated that the proposal will not be opposed by Government.

The traffic receipts of railways in the United Kingdom amounted for the week ending the 17th December, on 11,732 miles, to 607,586*l.*; and for the corresponding week of last year, on 11,395 miles, to 583,826*l.*, showing an increase of 337 miles, and of 23,760*l.* in the receipts.

The wear and tear of wooden sleepers have led several of the railway companies in France and other Continental States to adopt iron ones. Of all the processes yet adopted for arresting the decay of wooden sleepers, not one has been found to succeed. They expect a great saving both of time and capital by the use of metallic bearings.

The French commission for examining different questions relative to the service of railways has just issued its report. Among the improvements suggested is that of a more convenient disposal of the interior of the carriages. The American long carriage, with a communication from end to end, is preferred, with saloon, reading and smoking compartments, water-closet, &c.

The Rome correspondent of the *Morning Post* mentions a rumour that Mr. Pope Hennessy, M.P., has obtained from the Papal Government the concession of the recently-projected railway from Rome to Tivoli.

General McClellan has been appointed chief engineer of a railroad in New Jersey, upon a salary of 15,000 dollars per annum, the sum which he would have received had he been elected to the Presidency,—at least, so we are told.

CHURCH-BUILDING NEWS.

*Cambridge.*—The chief stone of a new church, dedicated to St. Andrew, has been laid here, in the Derwent-road, on a site given by Mr. Thomas Cook. The edifice will consist of nave, north aisle, transept, and chancel, with organ chamber on the north, and vestry on the south side. The tower, with spire, is at the north-west corner, and communicates with a cloister porch, the whole width of the west front, and with a porch entrance at the south side of the nave. The space between the tower and north aisle, will be occupied by a side porch, containing a staircase to the west gallery across the nave. Exterially the building will be constructed of Kentish rag walling, in drop courses, with Bath stone dressings and red Mansfield bands, with the exception of the spire, which will be of slate in bands. The roofs will be covered with red and brindled Staffordshire tiles. The interior will be lined with bricks, with bands and arches of white and yellow brick, the walls being finished in stucco. The extreme exterior dimensions will be 120 ft. 3 in. from east to west, and 65 ft. from north to south. The height to apex of nave gable will be 56 ft., and of spire 140 ft. to top of vane. The accommodation will be for about 900, and the cost will be 5,300*l.*, inclusive of chancel fittings and font. The architects are Messrs. Keeling & Tyrie, of London.

**Rusthall.**—St. Paul's Church, Rusthall, has been re-opened after enlargement. The sittings, which were before 366 in number, are now increased to 620, of which half are free, the best seats in the church being set apart for the working classes. The original church was erected in 1850, from the designs of Mr. Stevens, of Derby. The architects have effected the enlargement by the addition of a north aisle, a prolongation of the north transept, and the erection of a north porch at the extreme east bay of the new aisle. The extreme internal width of the body of the church from south to north is now 48 ft., and the length 77 ft. The new aisle is connected with the nave by a pointed arcade of five openings, the easternmost being less than the other on account of the required abutment of the central tower. Each pier is a cluster of four shafts of dark serpentine marble, with caps and bases of Caen stone. The west gable is perforated by a three-light transition window, and exactly opposite thereto the side of the transept has a double-light opening, of a similar character. The additional requirements of light have been met by doubling the lancet on three of the side windows, which have central marble shaft supports. The transept has a new roof, with diagonal ribs forming a groin over the large arch and each window. The covering is of round-ended New-castle tiles. Several painted glass windows have been added. The heating-apparatus by hot water has been extended throughout the new work, by Mr. William Catt, of Tunbridge Wells. The works have been carried out by Messrs. G. Mansfield & Son, of London; Mr. G. Moat acting as clerk of the works. The architects were Messrs. Stevens & Robinson.

**Stratford (Essex).**—The new church of St. Paul, in the new town, has been consecrated by the Bishop of London. The site, which was given by the Great Eastern Railway Company, is in the Maryland-road. It contains space also for schools and parsonage. The church will accommodate over eleven hundred adults on the ground-floor, and it has a west gallery for children. The walls are of brick, with Bath stone dressings, and arches of black and red bricks. The roofs, except that of the chancel, are celled to the underside of the rafters, and are covered externally with blue and pink Bangor slating, excepting the turret, which is covered with green Westmoreland slates, with lead rolls. The nave roof has terra-metallic shark's tooth cresting tiles, and the chancel roof a wrought-iron ornamental ridge railing, about 2 ft. high, supplied, together with the iron terminals to the gables, by Messrs. Peard & Jackson. The nave and chancel aisle arches are of yellow, red, and blue brick, with stone keys and springers, and are supported by cast-iron columns, with polychrome decorations in oil. The arches to the windows throughout are in coloured brickwork, and the interior is otherwise finished in stucco. The carving is of natural foliage, emblematic in character. It is the work of Mr. Williamson. The plan consists of nave and chancel of equal width and height, and north and south aisles, also chancel aisles in three gables. The roof over the chancel (which is semi-octagonal), is boarded diagonally to the underside of the rafters. There is at present no tower or spire, though they are provided for in the design separate from the main building. The extreme external dimensions are 139 ft. 6 in. from east to west, and 60 ft. 6 in. from north to south, and 45 ft. in height to apex of nave gable. The actual cost has been a little short of 4,000l. Mr. E. B. Keeling was the architect.

**Bury St. Edmund's.**—A new church, erected from the designs of Mr. H. F. Bacon, of London, architect, formerly of this town, has been consecrated at Whitwood Mere, near Castleford, by the Archbishop of York. The church is built upon a site given by Mr. T. P. Bland, of Kippax, and the Queen contributed 20l. towards its erection. Its architecture is in the Early English style, and it contains sittings for 320 persons, including accommodation for 96 children. The cost up to the present time has been rather more than 1,000l. The tower has only been carried a sufficient height to form a porch. It will be raised higher, and surmounted with a spire, when sufficient funds for the purpose have been obtained. The church is built of stone got in the neighborhood, but the walls are lined with brick.

**Yardley Gobion.**—A new church has been consecrated at Yardley Gobion, a hamlet on the Northampton and Stony Stratford road. The Duke of Grafton has defrayed the entire cost. The church is a parallelogram 60 ft. by 28 ft.,

with a chancel 22 ft. by 16 ft., and a small vestry or robing-room, and is capable of seating about 150 adults. The style is Geometrical, but the tracery of the windows varies in design. The edifice is built of the native stone, left rough on the face, with Bath stone dressings. Over the windows are relieving arches of stone alternating in colour; an admixture carried out exteriorly by the introduction of coloured stone shafts to the porch and priest's doorways, and stone labels over windows of porch, &c. There is a porch on the north side next the street, and a bell campanile, or turret, at the west end of the nave, on the wall dividing it from the chancel. The interior is simple and plain. The nave and chancel have open roofs of yellow deal, with collar beams and curved ribs resting on stone corbels. The walls of the interior are stuccoed, the colour relieved by arches over the windows in red brick. The chancel arch is a recessed one of brick, red, black, and white, resting upon short pillars, with carved caps and corbels of Bath stone: the pillars are of red Duston stone. The "recedos" is of Bath stone and red brick, all flush, but panelled. The seats are of yellow deal, stained and varnished, as are also the pulpit and prayer-desk. The floors of the passages in the nave are of red and black tiles, and that of the chancel red, black, and buff. The church is heated upon the plan of Mr. Fitter, of Woolston, near Coventry, and that part of the work has been executed by him. The whole of the roof timbers are exposed to view, and are stained and varnished. The whole cost of the church has been about 1,750l. The architects, from whose design, and under whose immediate superintendence the building has been erected, were Messrs. Law & Sons, of Northampton. Mr. Bailey, of Stony Stratford, was the builder. The carving has been executed by Mr. White, of Northampton, the artist employed at the new town-hall.

**Belvoir (Leicestershire).**—The tower of the old Gothic church at the village of Belvoir has given way. It has been shored up with beams, pending more durable repairs. The services of Mr. Scott have been retained to insure the proper execution of the work, which, we understand, will cost about 1,400l. Mr. Wilson, of Grantham, builder, will carry out Mr. Scott's plans.

**Coventry.**—The late Mrs. Hill Morgan, of Cheltenham, we understand, has bequeathed the sum of 10,000l. for the erection of a new church at Coventry.

**Thursford (Norfolk).**—We are requested to state that Mr. T. Gidney, of East Dereham, supplied the warming-apparatus to Thursford Church.

#### DISSENTING CHURCH-BUILDING NEWS.

**Liverpool.**—A new Presbyterian Church is to be erected for Everton, at a cost of about 4,500l., if the funds can be raised by subscription for the purpose.

**Salburn-by-the-Sea.**—The foundation stone of a New Wesleyan Chapel has been laid here, on a site at the corner of Emerald-street, facing Milton-street. The design was prepared by Mr. Peachey, of Darlington. It represents a structure of the Early English style, estimated to cost about 1,000l., and calculated to seat comfortably 300 on the ground floor; and provision is made for the erection of galleries, when needed, to seat 200 more. Tenders for the building have been let as follows:—Brickwork, &c., Mr. W. T. Spencer, of Salburn; joiner-work, &c., Mr. John Wallace, of Brocton; plumber, Messrs. Russell & Sons, of Darlington; slater, Mr. R. Preston, of Sunderland.

**Shields.**—The new United Methodist Free Church, Queen-street, South Shields, has been opened for divine worship. The new church occupies the site of the former chapel and vestries, which were pulled down to erect the present more commodious edifice. The new church is in the Italian style of architecture, and is built of stone. The size of the edifice on the ground-floor is 58 ft. 6 in. by 46 ft. 9 in., clear of the walls. Behind the pulpit are three vestries, under one of which is the hot-water apparatus for heating the chapel. In the gallery, the church is 47 ft. 3 in. by 68 ft.; and from floor to ceiling the building is in height 32 ft. 6 in. The gallery is supported on cast metal Corinthian columns. The ceiling is flat, with an enriched cornice. In the centre of the ceiling is a sun-light, containing thirty-four burners. The pews are without doors, and are grained. The building contains accommodation for 800 persons, and

the cost of it is about 2,200l. The architect of the building was Mr. John Tillman, Sunderland; mason, Mr. J. Hirst, Sunderland; plasterer, Mr. J. Charlton, Newcastle; carpenters and joiners, Messrs. Surtees & Forrest, North Shields; slater, Mr. W. Wylie, South Shields; plumbers, &c., Messrs. Glaboth & Co., Sunderland; painter, &c., Mr. J. Scott, Newcastle. The decoration has been done, under Mr. Scott, by Mr. Thomson, of North Shields.

#### STAINED GLASS.

**Norwich Cathedral.**—The nave of this cathedral has recently had a memorial stained glass window inserted. It is the easternmost of two windows, of precisely similar design, situate on the south side of the nave, in what is called Bishop Nykke or Nya's chantry, a side chapel formed by two bays, and separated from the centre aisle by an altar tomb. The glass tells one continuous story, representing the history of the "Good Centurion," as related by St. Luke (vi. 1 to 10), and St. Matthew (viii. 5 to 10). Commencing with the upper portion of the eastern light, there are—1. "Jesus entered into Capernaum;" and below, in the same compartment,—2. "A certain Centurion's servant was sick;" 3. "He sent unto Jesus the elders of the Jews;" 4. "And they besought Him instantly;" 5. "Then Jesus went with them;" 6. "The Centurion sent saying, Lord, trouble not Thyself!" 7. "I am not worthy that Thou shouldst come under my roof;" 8. "For I am a man under authority;" 9. "I have not found so great faith, no not in Israel;" 10. "And his servant was healed in the selfsame hour." By this arrangement and order the narrative is preserved in sequence. Natural forms, the oak and the vines, have been used in the details of the diaper in the spaces between the groups. The artists were Messrs. A. and W. H. O'Connor, of London. The window has been erected by Mr. R. J. H. Harvey, of Crown Point, to the memory of his father, Sir Robert Harvey.

**Upperthorpe Church.**—A stained-glass memorial window has lately been put up in this church, to the memory of five infant children of Mr. Jas. Charlesworth, of Holmfirth. It is perpendicular in style, and consists of two compartments, with tracery. The subjects, Christ Blessing little Children, and the Presentation in the Temple, occupying the main openings, are inclosed within foliated canopies. This window was also from the establishment of Messrs. R. B. Edmundson & Son.

**Sowerby Bridge Church.**—This church has lately been enriched by the addition of a series of stained-glass windows. The three principal ones, which are placed in the chancel, are memorial windows, and consist each of one large opening. The subjects are the Nativity, Crucifixion, and Ascension, and are inclosed within borders and foliated canopies. Erected on the south side of the nave are four three-light windows, the centre light of each having a full-size figure of one of the Evangelists, inclosed within a canopy and border. The side lights of each of these four windows are in grisaille. The first window (St. Matthew) is also a memorial window. In the baptistery is another window of three lights, similar in size and character to the above. The centre light contains the Baptism of our Saviour, under a canopy. The whole of the above series were executed by Messrs. Edmundson & Son, of Manchester, who are also engaged to decorate the chancel.

**Bolton Church, Cumberland.**—A stained glass window has been recently erected to the memory of the late Rev. John Sherwin, curate of this church. It comprises two lights, and is in the Decorated style. The subjects are, "The Presentation in the Temple," with text, "Mine eyes have seen thy salvation," and the "Raising of Lazarus," with text, "Lazarus, arise, and come forth." These are inclosed within borders, and surmounted by foliated canopies. This window has been executed by Messrs. R. B. Edmundson & Son, of Manchester.

**St. Ann's, Highgate Rise.**—This church has been lately enriched by another stained glass window, the gift of Mrs. Ryder, and erected as a memorial of her late husband. The window consists of two openings, each containing a separate subject. In one the subject is "Nanman coming to Elijah to be healed of his Leprosy," with the text from the Old Testament, "Behold now I know there is no God but in Israel." In the other the subject is, "Our Lord healing the Impotent Man at the Well of Bethesda," accom-

panied with the text, "Arise, take up thy bed, and walk." Both are surmounted by foliated decorated canopies, and inclosed within a horder in character. The arms of the deceased have been emblazoned in the quatrefoil at the head of the window, and a memorial brass at the base bears the inscription. The window was from the establishment of Messrs. R. B. Edmondson & Son, of Manchester.

**Glasgow Cathedral.**—The minor windows in the cathedral, not included in the grand series now completed, are quickly being filled. Six windows have just been erected in the clerestory of the cathedral, five of them triplets and one lancet. Four of these windows are in the transept, two are in the choir. The subjects are, Zechariah and Elizabeth, Simeon and Anna. The choir lancet is the gift of Mrs. Ramsay and Miss Davidson, in memory of the late Professor Davidson, of the University, and father of those ladies. The subject is Martha. All are from Munich.

ROMAN CATHOLIC CHURCH-BUILDING NEWS.

**Greenhithe.**—A new church has been opened at Greenhithe. The church is of small dimensions (the interior being about 50 ft. by 22 ft.), and accommodates about 200 persons.

**Newton-la-Willows.**—A new church at Newton-la-Willows, dedicated to St. Mary and St. John, has been consecrated by the bishop of the diocese. The new church, which has been erected by Mr. J. Middlebnst, of St. Helen's, from the designs of Mr. Gilbert Blount, of London, is in the Gothic style, and when finished the cost will be about 4,000l.

**Runcorn.**—The first stone of a new Roman Catholic Church at Widnes, near Runcorn, to be dedicated to St. Mary of the Assumption, has been laid. The building, which is to be erected in Frysedale-street, will be set back several feet from the parapet, and the north side will run parallel with the road. It will present an elevation of about 108 ft. in length, and the nave will be divided by buttresses into seven compartments or bays, each having two single-light windows, with arched heads. In the first bay will be the great doorway of the church. The west end will come within a few feet of adjoining cottages. It will have lofty single windows in the ends of the aisle, and three single-light windows in the nave. Above will be corbelled out a holly of stone, with high leaded roof, to be surmounted by two crosses, which will be 80 ft. above ground. The chancel at the east end will have a semi-octagonal end, with two windows on each face, placed high up, so as not to interfere with the effect of the altar. The interior will be divided by pillars and arches, nearly 30 ft. high, into nave and aisles of six bays. The north aisle will terminate in a side chapel, with a tracery wheel-window at the end. In the south aisle two confessionals will be built out, each of three compartments. Under the windows of the aisles will be panelled recesses for sculptured representations of the Passion. The aisle-roofs are to be open, and the timbers exposed. They are to be supported by arched principals, resting on the capitals of the pillars and corbels on the outer side. The roof of the nave is to be carried by seven arched principals, resting on stone corbels. The timbers will be exposed to view nearly the full height of the roof. The clear height from floor to ceiling will be 48 ft., and to the ridge of the roof, 56 ft. The chancel roof will be a continuation of the nave roof, but divided into panels by moulded ribs. At the west end of the church is to be an organ-gallery the width of the nave, and 14 ft. long. It will be carried by an arch in one span. The interior dimensions of the church will be as follows:—Nave, 26 ft. wide, 83 ft. long, and 36 ft. high to the spring of the roof; aisles, 11 ft. 6 in. wide, 83 ft. long, and 25 ft. to the spring of the roof; chancel, 26 ft. wide by 19 ft. deep. The total length of the church will be 103 ft., and breadth 49 ft. It is calculated to seat about 500 persons. The exterior is to be brick, with dressings of Appleton stone sparingly used, and relieved by bands of blue brick. The general effect of the church will be very plain, owing to the small amount to which the architect was restricted. The cost of the entire church will not exceed 3,000l., though, at present, it is to be feared that, owing to want of funds, the chancel will have to be left to a future time. Mr. E. W. Pugin is the architect; and Mr. Middlebnst, of

St. Helen's, is the builder. The building will be completed in about nine months.

**Durham.**—The "solemn opening of the church of our Lady of Mercy and St. Godrie of Finchale," has taken place here. The church is situate in Framwellgate. The site was purchased about seven years ago of Miss Williams, for 1,800l. A large brick mansion—at one time the principal hotel in Durham—has been fitted up as a convent, and occupied, during the last three or four years, by a community of Sisters of Mercy. Up to the time when the foundation stone of the new church was laid, 3,000l. had been raised towards the erection. The plans were provided by Mr. Pugin. The style is Decorated Gothic. The building consists of a nave and north aisle, 120 ft. in length, and 38 ft. in breadth. The east end terminates in a hexagonal apse. On the south side there is a chapel for the Sisters of Mercy, and a large vestry. A covered cloister connects the church with the convent.

THEATRICAL.

**English Opera House, Covent Garden.**—We have no hesitation in calling *Cinderella* the best pantomime of the season. The story is compact; the Paynes, especially Mr. F. Payne, are inimitable; the appliances magnificent; and the scenery, by Mr. T. Grieve and his assistants, includes three admirable works in different departments.—"The Butterfly Hunt," a landscape; the Vestibule leading to the Ball-room, as an architectural interior; and the transformation scene, titled the "Flight of the Hours." For grace, elegance in the forms and movements, and harmony of colour, this scenic and mechanical composition has never been surpassed, and the veteran artist, the Nestor of scene-painters, is justly called forward every evening to receive the thanks of the audience for the delight afforded them. Donato's performances show a victory over nature of the most remarkable kind; and the pas of three legs, which immediately follows him, is a lucky thought, well carried out. In half a dozen more words, the pantomime hero is a great success.

**Her Majesty's Theatre.**—The want in Mr. Harrison's pantomime ("The Lion and the Unicorn") is a want felt in most of the pantomimes and burlesques this season,—the want of real fun. The dancing is pretty, the scenery is gay, the transformation scene, indeed, very elaborate. The "Eidos Acides," as they choose to call an optical illusion introduced, is effective. "And what," says Juvenis, "is Eidos Acides?" *Eidos* is a noun from the root *eidō*, to see (Latin, *videre*); and means that which is seen,—the form, shape, figure, &c.: *Acides* is from the same root, with the *a* privative, and means the reverse of the former; *vidē*, unseen, without bodily form, and immaterial. In fact, the advertisement explains itself. The visible invisible being a very good translation, and all they want to convey.

RECENT PATENTS CONNECTED WITH BUILDING.\*

**FIRE-PLACES.**—*E. B. Wilson.* Dated 16th January, 1864.—The patentee closes the bottom grate, and introduces between the front bars and the back of the fire-place a diaphragm, extending upwards to meet the upper part of the front of the stove, so as to divide the fire-place into a front or combustion chamber, and a back chamber or fue. When a fire is lighted in front of the diaphragm, the gaseous products of combustion are caused, by the chimney draught, to pass through holes or open space into the fue behind the diaphragm, fluted hollows in the front of the diaphragm forming channels for their passage.

**LIME-KILNS.**—*H. Robinson.* Dated 18th August, 1864.—The patentee claims, first, the application of bent to lime-kilns for the purpose of burning limestone by means of a fire or fires placed outside and around the kilns, and having access to the limestone by means of apertures in the walls of the kiln in connexion with the flues of such fire or fires. Secondly, the use of steam jets either behind the fire and within the fue, or within the chimney or stack, whether detached from or a part of the kiln, though he does not claim the use of steam jets for aiding the draught of an ordinary fire or fires, but simply its application to lime-kilns where the flames and the heat

require to pass through a compact mass of lime-stone. Thirdly, the application of a steam jet for the cooling of the grate bars of lime-kilns. And, lastly, the combined arrangement of air drifts or galleries, external fires (that is to say, fires that are placed without the kilns), and the steam jets before named, substantially as described for the purpose of burning lime; and also the use of double doors in the front of the discharge-hole, all as described.

**CONSTRUCTING SEA AND RIVER EMBANKMENT WALLS, PIERS, AND OTHER STRUCTURES WHOLLY OR PARTLY IMMERSED IN WATER.**—*B. P. Stockton & J. S. Scott.* Dated 3rd March, 1864.—The patentees propose to form a foundation platform of iron, stone, timber, or other suitable materials, supported upon and securely fastened down to cylinders or piles, or other suitable supports, and made sufficiently strong and water-tight to admit of the superstructure being erected thereon, and resisting the upward pressure of the water. A tank dam is to be attached to this platform, of which the platform itself forms the water-tight bottom. By this arrangement a secure and dry chamber is obtained, within which the structure can be erected. As each section or length of the structure is completed, the sides and ends forming the tank dam may be removed, leaving the structure supported by the foundation platform. In cases where the platform might be liable to oxidation or rapid decay, or required to be removed, "relieving" or "groined" arching, or concrete, or stone blocks, may be used in the lower part of the structure, which would form a sufficient foundation or support, bearing directly on the cylinders or piles, in the event of the platform being entirely destroyed or removed.

Books Received.

*Specimens of Early French Architecture, selected chiefly from the Churches of the Ile de France.* By ROBERT J. JOHNSON, M.R.S.A. Published by the Author, 15, New Bridge-street, Newcastle-upon-Tyne.

CONSIDERING that a dozen or so copies of this work, now completed, alone remain unsold, it may be useful to some of our readers to bring once more to their notice this, to Mr. Johnson, very satisfactory fact. During the progress of the work we have at various times mentioned it with great commendation,—commendation fully justified up to its close. In its completed form it consists of 100 plates, geometrical and perspective; measured, sketched, and lithographed by the author, and which illustrate some of the best examples of the earlier Painted architecture of France.

Mr. Johnson has great mastery over the pencil, and we have good reason to believe in his accuracy, after comparing some of his plates with our own sketches from the same subjects, made years ago. We cordially congratulate him on the successful completion of his undertaking.

*The Old City, and its Highways and Byways.* By ALEPH. London: W. H. Collingridge, City Press. 1865.

This is a much better book than "London Scenes and London People," by the same author, and if that has met with "an unexampled success," as stated, this should certainly not do less. The writer has trusted more to himself, to his own recollections and experiences, and the result is a very readable and interesting volume about persons and places in the Old City. A sad mistake is made at starting by giving opposite the title-page an engraving of Wren's scheme for rebuilding London after the fire, never carried out, as a "plan of London in the time of Wren." However, this has nothing to do with the merit of the book itself. The illustrations are well engraved by Mr. Sheears.

VARIORUM.

"Bacon's Railway and Commercial Map of the British Isles" (Paternoster-row), is certainly the best for the money we remember to have seen. It forms one of the "Popular Series" based on the Ordnance surveys, newly engraved on steel in the good style, and contains all improvements to the present date. It is remarkably clear and satisfactory.—Mr. Stanford has issued a new Map of proposed railways and miscellaneous improvements for session 1865; also the sanctioned lines of railways in operation

\* Selected from the *Engineer's* Lists.

within London and ten miles round. An enlargement is given of the proposed lines in the eastern part of the Metropolis, which includes a pretty piece of involvement in the neighbourhood of New-cross and Deptford. The map will be found useful.—“Transactions of the Institution of Civil Engineers of Ireland, 27th session, 1861-2, vol. vii., parts 1 and 2 (Dublin: Falconer, 1862 and 1864). Among the various papers here given, are a Description of the Cranlin Viaduct, by Mr. A. McDonnell, on the Action of Sea Water on Lime Mortar, by Mr. B. B. Stoney; Description of the Madras Railway, by Mr. T. H. Going; and various others of a more or less useful description. The letter-press is illustrated by engravings.—“A Dictionary of Chemistry and Allied Branches of Science.” Parts 21, 22, and 23. (Longman & Co.) The word Menthol concludes the last of these parts, the chief subjects in which are Light, Limestone, Lignins, Madder, Magnesium, Magnatium, Manganese, and Manure. The last is a very elaborate paper, in which Liebig's views are severely handled.—“The Popular Science Review,” edited by Henry Lawson, M.D. (Hardwick, Piccadilly.) This popular review, of which every one speaks well, contains, as usual, a variety of specially interesting papers. The first is by Mr. R. Hunt, F.R.S., on the Source of Heat in the Sun, with engravings of the total eclipse of the sun, and of solar spots, one on a large scale and showing the curious willow-leaf phenomena. Another of the papers is by Dr. B. W. Richardson, on waves of heat and waves of death, in which the author treats of the influence of cold in increasing human mortality after middle life. In alluding to sanitary matters, Dr. Richardson (incidentally, merely, it is true) says,—“In regard to spreading diseases we hear now almost exclusively of one cause,—drains and the smell thereof; and he makes no allusion whatever to overcrowding, want of ventilation, close bed-rooms, and other causes of the spread of fevers, which sanitary pioneers assiduously now press on the public attention at least fully as much as drains and their foul emanations,—if not more so, and for this simple reason that they have already fully established a public opinion in favour of thorough drainage as a preventive of fevers of the typhoid class, and are now more particularly drawing warning into the public ears as to such evils as that of foul air from close bed-rooms by night, from overcrowding and uncleanness, and from want of ventilation generally, as in workshops, &c., these being all causes of the spread especially of typhus fever, and of at least the aggravation, if not of the origination, of many other causes of illness and of death.

### Miscellanea.

**WORKMEN'S HALL AND EXHIBITION, STRATFORD.** For the purpose of erecting a workmen's hall for meetings and social converse, a sum of 600*l.* has been raised; and for its increase a workmen's industrial exhibition has been opened in the National School-rooms, Station-street, Stratford. The number of articles exhibited is 431.

**FOREIGN ART FOR DUBLIN INTERNATIONAL EXHIBITION.**—We find that from Brussels the list of demands already numbers 110 applicants in the Industrial Department, and 117 artists. Forty of the best artists of Düsseldorf have given their adhesion, and a large number of the Scandinavian painters, headed by M. Adolph Tidemand. Munich will furnish cartoons of the most celebrated artists, and all the leading painters will contribute, including Kaulbach, Schwind, Piloty, Fritsch, and Schraudolph.

**SURVEYING AND PHOTOGRAPHY.**—At the Academy of Sciences, Paris, in the *séance* of the 12th ult., General Morin presented, on the part of M. Laussedat, professor of the Polytechnic School, a new and perfectly successful application of photography to topographical and other surveys. In this instance, the plan was one of Grenoble and the environs, to a scale of  $\frac{1}{50,000}$ , extending over 20 square kilometres, obtained by two photographic lenses of 50 and 25 centimetres focal distance. With these, in 60 hours, at distances varying from 1,500 to 4,500 metres, 29 views were taken from 18 stations. These views were transported to Paris, and studied and reduced in the office, a plan having been laid down as perfectly as could have been done by the ancient mode, after several weeks' or perhaps months' labour on the ground.

**SOUTH KENSINGTON MUSEUM.**—During Christmas week the visitors numbered 35,984.

**LIVERPOOL ARCHITECTURAL SOCIETY.**—The weekly meeting was held on Wednesday, December 28th, Mr. Joseph Bonlt presiding. A communication was read from the secretary to the Committee of Council on Education, asking for suggestions as to what additional examples of architectural decoration, as well of British as of foreign origin, it is desirable should be obtained to complete the collection in the South Kensington Museum. The paper of the evening was read by Mr. W. H. Picton, on “Architectural Reminiscences of Florence.”

**UNIVERSAL EXHIBITION IN PORTUGAL.**—A letter from Oporto in the *Monitor* says:—“The Crystal Palace, in which the International Exhibition is to take place, and the opening of which is definitively fixed for the 21st of August, 1865, is situated on a vast eminence called the Torre da Marca. By the side of the Torre da Marca is a quinta or country-house delightfully situated. The Crystal Palace Company has purchased a part of the park attached to the villa, and its fine shady walks will afford a pleasing recreation to the visitors of the Exhibition.”

**PRACTICAL SURVEYORSHIPS.**—The Slough local government Board advertise that they are in want of a practical surveyor and inspector of nuisances for the Slough district, salary 50*l.* a year; and the Henley local government Board give notice that they are in want of a similar officer at a similar salary. “An Architect's Clerk” who writes us on the subject in a somewhat jocular vein, suggests that either office might prove an eligible one to some meritorious messenger or errand-boy. Doubtless the advertising boards knew precisely what sort of men they want.

**SHEFFIELD SCHOOL OF SCIENCE.**—We are glad to learn, says the *Sheffield Independent*, that the School of Practical Science is not actually dead. The attendance of the “paying” pupils at the lectures at the Collegiate School has been so small that the project has proved a failure, as was very generally anticipated at the time when so important a public movement was started by being grafted on to a private speculation. The committee appointed at the town meeting have recently decided to take steps to carry out the plan of evening classes at some suitable place in the centre of the town. If this be done we have little doubt that an institution so valuable to the town will be well supported.

**WORKING MEN'S INDUSTRIAL EXHIBITION AND BAZAAR AT BATH.**—A sort of preliminary exhibition has been opened at Weymouth House. It is not pretended that it represents in anything like a complete and fitting manner the skill and industry of the industrial classes of Bath. The originators are the Working Men's Hospital Fund Committee, and they have endeavoured to copy the example set by the London Industrial Exhibitions from two motives,—a desire to encourage, as they express it in their rules, “inventive skill, excellence of workmanship, and the workmen's social improvement,” and a wish to help the funds of the United Hospital. There are some 150 exhibitors, and 250 articles exhibited, but many of the latter are not the production of those who send them.

**TELEGRAPHIC.**—The French Council of State is about to introduce a new system of telegraphy into operation through France. Hitherto only two sorts of apparatus have been in general use, viz. the needle and the alphabetic index instruments. The new one, invented by Caselli, is to be autographic, so as to produce the telegram in the handwriting of the sender. The tariff is therefore regulated, not according to the number of words, but after the size of the sheet employed, and it is to be as follows:—30 square centimetres (4.65 square inches) pay 6 francs, and so on in proportion, the sizes being 30, 60, 90, and 120. On these sheets of paper the public will be allowed to figure any correspondence, trade-mark, or drawing,—anything except secret writing. It was stated that this system would probably be in operation on the 1st of January. —A miniature telegraph office, designed as a present to the Emperor of Russia, has been constructed by a citizen of New York. It consists of a complete telegraphic apparatus, capable of transmitting messages between Boston and New York, all embraced within the compass of a morocco case, 8 in. in length, 6 in. in width, and 3½ in. in depth.

**MANUFACTURE OF PORTLAND CEMENT.**—The prospectus of a proposed Cement Company just now issued says, with reference to works near Great Yarmouth, “The total cost of manufacture, including wear and tear of plant, is 17s. 6d. per ton. The wholesale price on board vessels at the works is 30s. per ton, giving a profit of 12s. 6d. per ton.” The extent of the exportation of cement from the United Kingdom may be estimated from the statement that,—in the year 1862 (up to which time the returns have been made) the quantity of cement exported from the United Kingdom, in British and foreign vessels, amounted to 80,632 tons, value 202,050*l.*

**THE BRIGHTON WORKHOUSE QUESTION.**—The Poor-Law Board, on being informed by the Brighton Guardians of their reference of this question back to the vestry, and of the vestry's refusal to carry out the design, drew the attention of the Brighton Board to the fact that the vestry are not legally empowered to decide upon the extent of the workhouse accommodation which is necessary; and they urged the guardians to carry out the plans already sanctioned by the Board. Thereupon the Brighton guardians held a meeting, and they have resolved, *nem. con.*, to accept the tender of Mr. Jabez Reynolds, Brighton, for the execution of the whole of the works, for 30,500*l.*

**POISONED WITH BAD WATER.**—During the short space of one week, Mr. Freeman, the proprietor of this journal, has been robbed by death of three of his children, aged respectively six, four, and three years of age. This event is more harrowing from the cause to which it must be assigned. Not quite three months since, Mr. Freeman moved into a new abode at Twickenham. The system of drainage has proved to be so defective, that in one pint of water, pumped from the well by which the house is supplied, the analysis of the Royal College of Chemistry, in Oxford-street, found enough decomposed organic matter to account for the catastrophe. Mr. Freeman's children, in short, have been literally poisoned. Other members of the family are still suffering from this dreadful state of things; and it is greatly to be feared that the full weight of this calamity has not yet been realised. —*Christian Times.*

**STONE-LIFTING BY FUNGUS.**—At Rickmansworth, Herts, according to a correspondent of the *Clerkenwell News*, the stone floor of a tap-room and kitchen was lifted from its bed, and on the stones being removed some hundreds of mushroom-like fungi of various sizes and species were discovered, varying from 3 in. diameter to 1 in., they being variously—*Agaricus campestris*, *Agaricus Georghi*, and the *Orealis*, or Fairy-ring Mushroom. A still more remarkable instance was seen in the big-say at the rear of the premises. There were discovered under the stones several large specimens of the *Agaricus Georghi*, some of which were of the enormous weight of 16 lb. 2 oz., 14 lb. 7 oz., and 9 lb. 3 oz. The *Agaricus Georghi* has been known, according to Dr. Badian's work, to weigh 14 lb., but here this was exceeded by two pounds.

**DISCOVERIES IN CONNECTION WITH PEAT MOSS.** We hear from Stornoway, says a Glasgow paper, that a product likely to prove invaluable has been successfully extracted from peat moss by Mr. H. Couster, manager of the extensive works erected by Sir James Matheson, bart., M.P., for the utilisation of the peat on his estate at Lewis, by converting it into oils and paraffine. Mr. Couster was struck with the apparent lubricating property of a preparation made by him of the tar distilled from the peat. By way of experiment he resolved to test its powers on the axles of his own gig, which was driven from 16 to 18 miles daily for above three months, and on examination, at the end of that period, it was found to answer beyond his most sanguine expectations, the axles and bushes being in capital working order, and containing enough of the material to last as long again. He immediately took the precaution of protecting it by a patent, and it is now used on railways, and consequently well adapted for all descriptions of vehicles such as carts, waggons, carriages, &c., being equal to any other grease in the market, and infinitely cheaper. Subsequently Mr. Couster discovered that the product of the distillation of peat possessed qualities of still greater value, having found, as we are informed, by an actual experiment, that it acts as an excellent preventive of the fouling of ships' bottoms. This discovery has also been covered by a patent.

# The Builder.

VOL. XXIII.—No. 1145.

## Continental Activity.

**M**

UCH activity in Building and Artistic matters is obvious abroad, and has been so for some time, as our readers must have observed. Notices of fresh works and doings have reached us from various quarters, and we will throw some of them together here, to

give the feature prominence. Let us look first to

*Italy.*—The municipal authorities at Florence are at this moment very active in taking the preliminary steps for a considerable enlargement of what may, for the present, be considered the Italian capital. These steps seem to be the result of well-digested plans based upon the opinions of numerous local architects and engineers, whom the authorities have been neither too wise nor too proud to consult. In the direction of Fiesole both San Domenico and Badia will become part of the city. A further extension in this direction would not be practicable, as the valley north of the Ponte Alla Badia becomes so narrow, as barely to allow of the passage of the Mugnone, which often, particularly in the winter, comes rushing down with great violence between the Lastra and the heights of Fiesole; whilst the hills themselves are too steep for convenient thoroughfare. Towards the south, the extension will include the Villa Poggio Imperiale, which is now reached by the beautiful *alle* of cypresses leading from the Porta Romana. The old walls and fortifications will be laid out in walks and gardens, after the manner of Vienna and other continental cities; the streets leading to the Pitti Place, the Via dei Martelli towards the Riccardi Palace; and, lastly, the Bridge alla Carraja, are all in process of being considerably widened. For those who know or have known Florence well, we may quote from the *Nazione* a list, showing how it is proposed to utilize existing buildings for Government offices, Chamber of Deputies, the Hall of the Five Hundred; offices of the Deputies, Palazzo Vecchio; Senate, Hall of the Dugenti; Foreign Affairs, Palazzo Vecchio; Public Education, Riccardi Palace; War, the Bishop's College beyond the Arno, with additions in present garden; Finance, Casino di Medicis; Home Office, the buildings known as the Santa Caterina Barracks; Public Works, Institute of the Santa Annunziata; Admiralty, Barbetti Monastery; Justice, Palazzo Ceparello; Agriculture and Commerce, Poggio Imperiale; Public Debt, Santa Croce Convent; State Council, a palace now in course of completion; Committees of Artillery and Engineers, Monastery of Santo Spirito; Post, Monastery of San Firenze; the Royal Carabinieri, Military College of Borgo on the Pinti.—Leghorn has just received a new Protestant church, built by the Congregatione Olandese-Alemanna. It is Gothic in style, and

will accommodate 400 sitters. The "Congregation" is an old one, being originally composed of German and Swiss merchants, who, in the year 1607, obtained a kind of charter of rights from Ferdinand of Medicis, then Grand Duke of Tuscany. For the first few years one chapel in the Church della Madonna was placed at their disposal; but this joint possession did not last long, and they built a small chapel, which, however, has long been too small for the increasing congregation. The Gustavus-Adolphus Society, and the Princess Marianne of the Netherlands, were the chief helpers in this new work, which cost 150,000 francs.—The City of Milan is about to erect a monument to Meyerbeer by public subscription. The amount collected at present is about 3,000 lire.—The Church of San Tommaso, at Almecno, is about to be restored by the authorities of Bergamo.

From Vienna, news comes that about a fortnight ago the last stone of a new and very large hospital, to be called the "Rudolf Stiftung," was laid by the Emperor in presence of the Empress, several grand-dukes, and a large assembly of the Austrian aristocracy. It is one of the largest institutions of the kind in this city, and presents three very imposing fronts. All modern appliances, sanitary and economical, have been introduced, and the arrangements for ventilating, heating, and lighting are said to be very perfect.—Two days later the Emperor was present at the ceremony of laying the last stone of the new buildings erected by the Horticultural Society of Vienna, which was first constituted in the year 1832. The first exhibition of flowers and fruit in Vienna took place in 1827. We learn this from the speech which the president of the Society made on the occasion.—The committee appointed to select a design for a Haydn monument, from a number which were submitted to them, have chosen that by Mr. Vincenz Pilz. The composer is represented seated, and in the act of composing. On three sides of the pedestal bas-reliefs are introduced, representing Creation, Symphony, and Harmony. The fourth side will bear an inscription. The genii of the Four Seasons appear at the corners of the pedestal, riding on swans, which emit water into a basin below. The judges were Professors Von Fühlich and Rahl; and Mr. Hansen, architect. The Society of Arts of this city have adopted the designs of Mr. August Weber for a new academy, which it proposes to erect. The buildings, which are on a large scale, will be commenced immediately.—The Imperial commission for exploring and restoring buildings of historical interest throughout the empire, have just ordered the restoration of the Castle of Meran, in the Tyrol. This was the cradle of the lords of Meran, and their territory fell to Austria when the last of the line, Margaret Maultasch, married an Austrian prince.

In Munich, the committee entrusted with the execution of a national monument to the late king, have decided on erecting it in the Maximilian Strasse, and invite public competition for designs. It is, however, limited to Bavarian artists only.—A very fine wooden pulpit has just been finished here under the direction of Mr. Marggraf, architect, for a chapel at Würzburg. It is 45 ft. high, including a pinnacled sounding-board, and is very elaborately carved with tracery, foliage, texts, and figures in niches.

From Hamburg, we learn that the magnificent church of St. Michael, built in the middle of the last century, and considered the *chef-d'œuvre* of the architect, Sonnin, has now been furnished with gas, the want of which has long been severely felt, as, from the immense size of the erection, it was found totally impracticable to light up the church in an adequate manner with candles or lamps. To cover the expense, a subscription was set on foot among the

parishioners, to which, singularly enough, the poorer and middle classes subscribed with much greater liberality than the rich. But all the exertions of the indefatigable members of the committee voluntarily formed for collecting subscriptions were unavailing, and it was found that the contributions were not nearly sufficient to meet the expenses, which amounted to 9,000 marks. Notwithstanding this drawback, the committee resolved to proceed with the work, and it was successfully accomplished on their own responsibility. When finished, it was resolved to get up an oratorio in the church for the purpose of defraying the deficiency; and Miss Titiens, the eminent vocal *artiste*, who happened to be giving a set of operatic performances at the Hamburg Theatre, with her usual benevolence, volunteered to sing the principal part. The oratorio selected for the purpose was Handel's "Messiah," a great favourite with the Hamburg public, and it proved such a perfect success, that the sum wanted was more than covered. As the church in question is of a very peculiar construction, being built without side aisles, the difficulty of lighting it adequately was greater than usual, and it required much larger jets of gas to make the centre of the church light enough for reading. This is, however, satisfactorily done by 214 burners, which consume each from 5 to 7 cubic feet of gas per hour, according to their situation.

Getting now to France: some interesting discoveries have been recently made at Autun, where the remains of an ancient Gallic town have been found, at no great depth from the surface. It was the Bibracte of Cæsar's time, and was known in the last days of imperial Rome as Augustodunum: hence, doubtless, the present name, Autun. Amongst the localities and objects discovered are, parts of the old citadel, the foundations of about seventy houses—some round in plan, some square,—hollow brick walls, stone doors, ovens, pottery, amphora, nails, &c. The remains of a theatre, having a diameter of more than 150 ft., have also been opened up.—Bayard, "*sans peur et sans reproche*," is to have a monument on the ruins of his ancestral castle, near Grenoble. The emperor has forwarded a subscription of 1,000 francs to the committee.

In Paris, at the Buttes Chaumont, considerable works are being carried on for the construction of a new park, and two new boulevards partly bounding it, the total area of the whole being about 850 acres. The gypsum quarries of the Buttes Chaumont have been worked from time immemorial, and on a larger scale within these last few years, the greater portion of the produce being sent to America. It is a work of no ordinary difficulty to convert into a well-laid-out park a tract of land consisting of enormous elevations and depressions, presenting sudden differences of level, in some places as much as 70 ft. or 100 ft. But this is not the only difficulty: the nature of the soil, which consists of a few inches of vegetable mould immediately covering extensive beds of indurated marl, then beds of plastic clay, and the gypsum underneath, is another. The difficulty of making earthworks with plastic clay in bad weather; and the rapidity with which the marl decrepitates under the influence of the air, have rendered it impossible to make use of the ordinary means used in earthworks in Paris, such as the cart, wheelbarrow, &c.; so that the work is being done all by temporary rails and waggons. There are from 250 to 300 waggons now at work, 50 horses, and two locomotives. The latter are exclusively employed on the new boulevards, one of which has to traverse a knoll 270 yards long and 56 ft. at its highest point, over the roadway. This has been attacked by a heading driven through it, at the level of the boulevard, and into which the waggons are sent to be filled from enormous funnel-shaped holes overhead. There are in these works more than

ten cuttings opened, employing 600 men. In order to utilize as far as possible the rough character of the ground in embellishing the park, a great cavity left by one of the plaster quarries is to be converted into a lake, with an island towering to a height of 164 ft. above it. This island is to be joined to the park by an ornamental suspension-bridge, and is to be surmounted by a piece of architecture representing the temple of the Sybil at Tivoli. It certainly promises well.

On the Montignon and Limoges Railway, lately opened, one of the principal structures worthy of note is the viaduct of La Cruse, 190 ft. high, and 87½ yards long, in six spans of 164 ft. It is of iron, the superstructure being of lattice-work, similar to that of the Kehl Bridge over the Rhine, and resting on piers of wrought and cast iron open framework, supported on masonry bases. The originality of this construction consists in the piers having been raised by means of the girder itself. The whole beam, when completely put together at the side of the valley, was, as in the case of the Kehl Bridge, pushed over in one piece, not, however, on to the piers, but into space. When it arrived at the site of the first pier, the several tiers of the metal framework were dropped one by one from this cantilever upon the masonry foundations, and bolted together. This pier being terminated, the girder was advanced over to the site of the next, and so on till the beam reached the opposite side of the valley. The viaduct is expected to be completely finished in a few days. The whole of the work, this being the first iron viaduct in France, will cost under 1,500,000*fr.* (60,000*l.*), including iron, timber, and masonry. This is at the rate of about 4,424*fr.* per lineal metre, or 161*l.* 15*s.* per yard run. The Fribourg Bridge, similarly constructed, cost 6,000*fr.* per metre, or 219*l.* 9*s.* per yard. The ironwork of the Creuso viaduct was constructed at Grenelle, in Paris, by the united companies of Parent, Shacken, & Co., and Cail & Co.—The town of Saintes (Charente inf.) proposes to raise a statue (Clarente inf.) Palissy, and a commission has been formed of the most celebrated local men of letters and artists, to carry out this patriotic and artistic design.

And so we might long go on noting evidences of activity abroad; but here for the present we stop for want of space.

#### SOMETHING ABOUT A HOD OF MORTAR.\*

MORTAR, designated calcareous cement, or some such name, has been used for building purposes, by all civilized people, in all countries, during all ages. The palaces of Assyria, and those temples and pyramids along the Nile, of world-wide celebrity, which were raised long before the ages of historic certainty, and seem likely to reach the latest eras of mortal existence, are constructed with calcareous cement, as far as relates to hedging and jointing the stones.

Notwithstanding all these considerations, I venture to offer some remarks and experiments bearing upon this useful and valuable substance, for this reason,—that, as mortar is a very important material for forming a solid construction, it will bear describing in a variety of ways, in order that it may be well understood and make a lasting impression on the minds of the junior members of the profession. It is quite out of the question to suppose that an architect can be a sufficient judge of the quality of the numerous materials used in the construction of a large and elaborate edifice, in all countries, should be so fortunate as to practise in the north, east, west, south, or midland counties of the British Isles, where the mineral substances of each neighbourhood may vary considerably, according to the geological formations of the district.

The same specification of mortar for a London building might be unsuitable, perhaps almost impracticable, in a remote locality.

The water of Tunbridge Wells is highly charged with iron. In Hertfordshire it contains a solution of chalk; at Harrogate, sulphuretted hydrogen may be unmistakably smelt at all the springs; and salts are abundant in the waters of Epsom and Cheltenham. I believe none of

\* Amongst the unfinished papers left by the late Mr. C. H. Smith is the following, which was intended to be read, with illustrations and experiments, at one of the popular institutions in the metropolis.

these substances remain neutral when in contact with lime. They either improve or deteriorate the mortar, perhaps more than at first might be imagined, notwithstanding the high authority of Susecoto, who has stated that he could not discover any difference in the strength of mortar, whether it were made with sea or fresh water.

Before attempting to improve a defective foundation by introducing a bed of concrete or cement of any kind, it may be as well to investigate the necessity for improvement—why one foundation should be considered solid, substantial, and satisfactory; another soft, yielding, and unfit to be trusted with a lofty ponderous erection. All mineral substances may be said to remain in their natural situations during very long periods, without undergoing any important change. They are always sufficiently moist, while undisturbed in the ground, to be beyond the influence of shrinkage by drying. Clay, in its natural state as we find it in the earth, is, as always, to a certain extent, laminated. If its strata are tolerably level, it forms a pretty good foundation; but if inclined to the horizon—that is to say, if the beds are much out of the level,—there is a tendency, especially during a wet season, for the beds, with their weight of buildings, to slide downwards, and thus cause disturbances in the superstructure. Compact earthy sediment, sand, gravel, chalk, and rocks of all kinds, almost invariably, have been originally formed at the bottom of the sea, or in the estuary of some large river, and afterwards left as dry land: the component parts of such terraqueous formations have been compressed into a tolerably solid state, under the influence of water and great superincumbent pressure. As a general rule, such undisturbed foundations are sufficiently solid and compact to bear any weight likely to be placed thereon by the skill and industry of the architect, engineer, or builder.

All organic substances, whether of animal or vegetable produce, certainly undergo a somewhat rapid change when exposed to the atmospheric influences of air and moisture. During this fermentation and decomposition, a very large proportion of the soil is converted into gases, and gradually disappears in an æthereal state, leaving only a fraction of the original mass in a solid earthy condition, more or less, sooner or later, according to the amount of organic matter in the ground. While this decaying process is going on, however hard and compact the soil may be, it will certainly shrink into a smaller compass. For these reasons, we all agree that garden mould, and surface soil generally, must be removed before a building is commenced.

All attempts at improvement in human affairs must be based on natural laws. The mixture of lime and sand, to form a cement, is one of the combinations, amongst the prodigious number of nature's works, which we are in some degree enabled to understand and to imitate successfully. Every hard substance which we meet with in this world may be considered as a cement, because it presents evidence of having previously been in a fluid or soft state. Modern chemistry recognises nothing unchangeably solid, liquid, or æthereal. The hardest materials of which the colossal statues, obelisks, and fragments of Egyptian grandeur were executed several thousand years since, were at one time undoubtedly in a liquid or molten state; the same remarks will apply to the materials of the Parthenon at Athens, the Roman Colosseum, and the stone of St. Paul's Cathedral. Each separate material with which all these edifices are erected is unquestionably natural cement of a very durable quality, which the chemist or geologist can manage to analyse, and in some cases to understand; but with our present knowledge the most learned philosophers are not able to imitate, nor to compose, even approximately, a cement possessing similar qualities of hardness and durability.

Time is an important element in nature's operations. What is deficient in power is made up in time; and effects are produced during myriads of ages, by powers far too weak to give satisfactory results by any experiments which might be extended over perhaps half a century. In nature these changes proceed by slow degrees, and an apparently insignificant cause will produce a surprising effect if continued without

\* "Eddystone Lighthouse," p. 105.

† Dry sand alone will take in a large quantity of water, without any increase of bulk; or, rather, with a remarkable decrease of bulk. It seems that wetting or lubricating the grains facilitates their sliding on each other, to fill the vacant spaces.

interruption during periods of immense but unknown duration. Generally, in our hands, experiments are distinguished by suddenness of action; in nature, chemical power is distributed over a long period of time, and the process of change is scarcely to be observed. By art we concentrate chemical force, and expend it in producing a change which occupies but a few hours or days at most. Many of the more striking phenomena of nature are still mysterious to us, and principally because we cannot, or do not, take the element of time into our calculation. There is a prevalent impression on the minds of many persons, that the mortar used by our ancestors was far better than that which is used by modern builders; this, I am disposed to consider, is a great mistake; sea lime and sand, mixed in due proportion, as is now generally used by respectable builders, will in due time become as hard and adhesive as any to be found in the edifices of former times; but time acts a most important part in the consolidation, and good calcareous cement will gradually increase in hardness, rapidly at first, but slower and slower, without interruption, as the centuria roll on, until it has attained a degree of induration equal to many varieties of real stone.

The various productions of nature offer evident proofs of her industry in all ages; changes have been going on, from the remotest antiquity to the present time, on every substance that comes within our observation. All the actual combinations of matter have had a former existence in some other state; nothing is to be found in nature but what is likely to change its present condition; the most solid and compact bodies have not such a degree of impenetrability and so close a union of the parts which compose them, as to be exempted from ultimate dissolution; they possess the materials of which they are composed only for a limited time, during which some powerful agent effects their decomposition and sets the elementary particles at liberty, once more to form other equally perfect combinations. In some bodies these changes are not so frequent and remarkable as in others, though equally certain at a more distant period. They seem to have their ages of maturity and decline the same as animals and vegetables, but whether this condition remain for only ten years or during ten thousand, is only a question of relative duration.

In thus alluding to elements generally, whether in a natural state, as rocks and stones, or produced artificially by man, they are all formed or governed by unerring physical laws. We may observe extraordinary influences, from the first appearance of force; in the adhesion of two atoms each solitary molecule is invested with peculiar properties and regulated by very surprising forces, which belong to the same class of substances; and although busy meddling man may interfere or create a disturbance amongst a few grains of sand, he has no power to alter or change their natural condition. Each atom is involved in its own atmosphere of properties or powers, which it obstinately retains. Considerable diversity is exhibited according to circumstances, but through all things the most perfect order and harmony are manifested. We may study the grand in what at first sight appears the simple, and learn in the mysteries of a particle of dust the divine truths which science has to relate of a planet.

The smallest grains of earthy or mineral matter, whatever may be their form or condition, are for ever under the operations of certain physical forces. One of the most important is called cohesion, or the attraction of aggregation, which is a power employed by nature in holding the particles of matter together; operating only on surfaces, or within distances too minute for the mathematician to measure or describe. Then we have caloric or heat, as a repellent force, in opposition to cohesion; so that each grain of matter, as well as the entire mass, is in a state of disturbance: from the centre to the surface all is in an active condition: a sort of mutation prevails with every created thing, and science clearly shows that influences are constantly in action which prevent the possibility of absolute repose. This law of nature exists amongst objects of microscopic dimensions, the same in principle as it is with those mighty spheres which the telescope reveals to us in the stellar universe,—that is, perpetual motion and alteration.

In the British Isles and a large portion of Europe, calcareous rocks are very unequally distributed; in Ireland and Scotland they are rather scantily supplied, although there may be

more than sufficient to supply the wants of animal and vegetable existences; but in England, limestone is superabundant, either as chalk, oolite, dolomite, or lias, especially in the south-eastern parts, extending towards the north-west as far as the counties situate between Yorkshire and Dorsetshire. The purest and most compact limestone may be defined as a transparent, colourless, solid substance; although it is generally quite opaque, of many different colours, various degrees of hardness, and not unfrequently adorned with an infinite variety of patterns: yet, notwithstanding they differ so much in appearance, the very materials that nature has appled to form such apparently opposite creations are almost identical; the whitest chalk and the blackest marble, the softest stones and the hardest spars, together with shells of the most beautiful colours and shapes, are all formed of very nearly the same elements, scarcely differing except in the manner in which they are developed, by containing a minute portion of colouring matter, or in the nature and extent of their duration when exposed to the weather.

Pure lime, or such as we usually obtain fresh from the lime-burner's kiln, is certainly never found in that condition in nature; it is invariably chemically combined with some other substance, generally with an acid, and most frequently with carbonic acid, forming chalk, Portland, Bath, and many other building stones; also most of the ornamental marbles. At every quarry, where limestone is obtained for building purposes, the greater portion of refuse material is regarded only as worthless rubbish. At the Isle of Portland, from whence all the Portland stone is procured for the principal buildings in London, there are at least 50,000 tons of excellent limestone chippings annually thrown into the sea, or buried in an old quarry, not being worth the trouble of carrying to a distance to convert into lime; whereas it would be valuable in Holland, and all those low countries where they have neither chalk nor any other calcareous earth. I am not prepared to say from whence the Netherlanders now obtain lime, but formerly their practice was to drag the shallow parts of the sea with nets, drawn by horses, for fish-shells, which they burnt for lime. In many islands of the southern hemisphere, the natives collect fragments of madreporæ and other species of coral for the same purpose.

Notwithstanding these various substances differ so much in outward appearance, they all produce equally good lime, if sufficient care be taken in the calcination and preparation of them. Lias, and some others, may contain clay or iron in small quantities, which, when burnt, may improve the quality of cement for certain works. If a very soft stone be used for lime, such, for example, as common white chalk, it is liable to this disadvantage, that the cores or centres of the largest pieces, which probably have been only superficially burnt, remain of the same colour and in the same chalky condition after a certain amount of calcination as that which is burnt, and are thereby not taken notice of; and being equally soft, are easily broken into powder and mixed with the other ingredients,—consequently a weak and perishable mortar is produced. Whereas, if hard limestone such as lias, Portland stone, or black marble be used, the parts which are not sufficiently burnt or converted into lime, will still remain as hard lumps of the same black or brown colour, and must be rejected as "core," because they cannot be mixed with the well-burnt material: hence a far superior and more durable cement will be the result. So different may be the proportional quantities and chemical properties of apparently similar substances, that no rules or results, however definite, or however successful in one locality, can safely be trusted to in another. The precise mode of burning or manufacturing a newly discovered limestone for cement, must depend upon circumstances, experiments, and practice.

Although the before-named limestones may be considered to produce equally good lime in consequence of their containing very little foreign matter, there are many others which are not so well adapted to the use of the builder, or, more probably, not used because they cost a trifle more in preparation, as they take a longer time and a greater quantity of fuel in burning. Magnesian limestone is sometimes rather reddish, but usually is of a pale yellowish brown, and, without attentive inspection, may be mistaken for a fine-grained variety of sandstone. On analysis, however, it proves to be a compound of carbonate of lime and carbonate of

magnesia, the relative proportions of which, though subject to considerable variation, may be stated at about three-fifths carbonate of lime and two-fifths carbonate of magnesia. If a piece of this stone be put into cold dilute nitric or hydrochloric acid, it will dissolve very slowly, with hardly any effervescence, although, in hot acid, the effervescence will be as vigorous as with common limestone. When burnt to lime it retains its causticity much longer than common lime does, and therefore no doubt modifies, to a certain degree, the properties of the mortar, into the composition of which it enters, although its precise action has hitherto been very little investigated. These limestones which contain in their composition a certain proportion of iron and clay seem to be superior, in their consolidation and cementing properties when burnt into lime, to such as are purely calcareous. The iron and clay, when calcined, give the cement the property of becoming solid under water, and, therefore the cement is peculiarly valuable in subaqueous constructions. The gray chalk, which is obtained from the neighbourhood of Dorking, Mersham, and Halling, is of this description. It contains various proportions of ferruginous clay, from 6 or 8 up to 25 per cent., and after burning has a pale brownish yellow colour.

The most valuable variety of limestone for mortar, and especially for water cements, is the blue lias, which is generally of a dove colour when fresh broken; by long exposure to weather, it becomes brown on the surface. The lias formation is one of the most remarkable of the English strata; it passes obliquely through the entire country, from the sea-coast at Whitby to the cliffs at Lyme Regis, in Dorsetshire; there are also detached patches in the counties of Monmouth and Glamorgan. The quarries of Watchet, Aberhaw, and Barrow were celebrated for their excellent blue lias limestone long before it had been ascertained by experiment, and from geological surveys, that they produce similar substances on different parts of the same formation. By analysis, the blue lias of Watchet and Aberhaw contains about 11 or 12 per cent. of iron and clay; that of the Barrow about 14 or 15, or, according to Smeaton, 21·3 per cent. of the same ingredients. The lias limestone used by the London builders is brought from Lyme Regis.

Although lime and some hard granulated substance, such as sand, are the most important ingredients in all this class of cements, it seems to have been long and generally known to architects and builders, that if a certain quantity of oxide of iron and burnt clay be added, a vast improvement will be obtained in the cementing and hardening qualities of the mortar. Vitruvius and Pliny allude to the powder of Puteoli (*Pulvis puteolanus*), now known as puzzolana, a substance of a porous, rusty-coloured, half-concreted matter, a sort of natural brickdust, thrown out of Vesuvius during its eruptions; or, at any rate, it is, clay altered in some measure by volcanic agency, which, when reduced to powder and mixed with lime and sand, or with common mortar, has the property not only of attaining much greater induration by atmospheric influences, but also the valuable quality of hardening under water. This material seems to have been in great repute with architects and engineers during all ages, down to the present time; for I am informed that puzzolana, brought from the neighbourhood of Vesuvius, is now being used in the Government works at Portland; notwithstanding the same elements are found in the blue lias stone of Lyme Regis, which is within a few miles of that enormous work, the Portland Breakwater, now in progress. I have very carefully examined, analysed, and experimented upon these different substances, and cannot discover any elements or qualities in the volcanic product differing in an appreciable degree from ordinary brick-dust, or the argillaceous or ferruginous part of the blue lias formation. During the Anglian age, when chemistry and geology were neither known nor thought of, and in a country with probably only a trace of blue lias limestone, there would be great credit due to those architects or builders who discovered the improvement which puzzolana gave to their calcareous cements; but in our country, where, in numerous places, nature has furnished us with the same elements, mixed in the most suitable proportions, almost ready for use, I cannot comprehend why architects and engineers, in the middle of the nineteenth century, should send two or three thousand miles for that material which may be obtained,

in every respect equally good and fit for their purpose, in many cases, within the very neighbourhood of the works they are about to undertake. If the practice of using puzzolana has nothing to recommend it more favourable than prejudice in favour of a material long in use, it must be important that the subject should be fully investigated, and forthwith made known to the profession.

Various opinions have long been entertained by chemists and others respecting the effect of sand and lime upon each other in the formation of calcareous cement. If the subject has ever been investigated, I am not aware that it has been made known to the public. The general impression is, that the slaked lime and sand in contact have a chemical affinity for each other; that the lime decomposes the surface of the sand, and the atoms or molecules interpenetrate each other, forming a sort of silicate of lime. This is an extremely ingenious theory, which has never been proved. The most powerful microscopic examination will display nothing in favour of such a hypothesis. In the year 1843 I commenced an experiment to determine whether any, and to what extent, chemical action proceeds between the lime and sand in ordinary mortar. For this purpose I selected from a heap of gravel a common flinty pebble of about 2 in. superficial area, such as when ground or broken into small fragments, would be considered as ordinary sand. I had it rubbed down to a flat surface, and polished as brilliantly as possible. The piece of flint was then ready for the lime, and to perform its part as a grain of sand. In procuring the lime for my experiment, it was important to be sure that it was of a fresh, pure, and genuine quality. I had long previously ascertained by experiments that the most perfect lime, or that which contains scarcely a trace of iron, clay, or other foreign matter, is to be obtained from the best kind of black marble, wherein the colour is merely carbonateaceous matter, and is readily driven off in a gaseous state, during calcination. I was my own lime-burner, and from a fragment of the blackest marble obtained pure lime of the most inconceivable whiteness, which I slaked with water in the usual manner before it was quite cold, and made it into a paste sufficiently solid to be spread with a knife about the twentieth of an inch thick, on the polished surface of the flint. But, in order to observe more conspicuously the amount of change, if any, on the flint, I spread the lime only on one half of the polished part, leaving the other half wholly independent of the experiment. In this state I placed it on a projection of the wall of an open shed, where it lay protected from rain and snow, but freely exposed to all the usual atmospheric influences of damp and dry, summer and winter, during eleven years.

In March, 1854, at one of the Friday evening meetings of the Royal Institution, in Albemarle-street, a small portion of the lime was scraped off, and no alteration whatever could be observed on the polished surface of the flint. At one of the meetings of the Institute of British Architects a few years since, a little more of the lime was removed, presenting the gloss as brilliant as ever; and now, after twenty years that this experiment has been tested, upon clearing off the remaining fragment of lime, there does not appear to be the slightest deterioration of polish: in fact, it would be impossible for the most scrutinizing eye to determine with certainty what part of the flint had been subjected to the influence of the lime.

In the construction of a wall, whether of brick or rough stone, it should be clearly understood that there is an important distinction between mere drying and the ultimate process of induration. The mortar may become sufficiently set, dry, and solid, in a few days or weeks, to enable the wall to bear a very considerable weight and pressure; but it does not acquire the maximum degree of hardness till after the lapse of many years, and even of centuries. The process of slaking quick-lime by throwing water upon it, causes a sudden chemical change, combining the two, thereby forming hydrate of lime.\*

\* Mix a certain quantity of water,—say a pound weight, with a pound of dry plaster of Paris; in less than an hour the mixture will have become a solid mass, although extremely damp. If this be gradually and thoroughly dried before a fire, or in a moderately-hot oven, until all the surplus water is evaporated, it will be found to weigh considerably more than the plaster did before it was wetted, or mixed with the water. This extra weight arises from the water being converted into one of its solid states, and is then called a "hydrate." The same process takes place in slaking lime; after which, the substance should be more correctly termed "hydrate of lime." For example, spurious, 1 of a pound

After the hydrating is performed, the chief utility of all the water that is applied in mixing the mortar was to make the mortar in a state fit to be most conveniently applied to the building by the bricklayer. The water is also unquestionably useful in making the mortar, when dry, very porous, and thereby rendering it more susceptible of induration by atmospheric influences through the entire mass, and not merely on the surface.

One of the causes of the durability of old buildings, especially the ruins of abbeys and monasteries in the south-eastern counties, where chalk and flints abound, may be attributed to the long period during which the mortar has been exposed to the hardening influence exercised upon it by four, five, or six centuries. It is far beyond my attainments to explain the mode of proceeding which nature employs in the induration of mortar. A chemist can tell to a certainty that mortar which has been used only a few weeks or months in a building, contains a large proportion of hydrate and a very small amount of carbonate in its composition; whereas, we now find the proportions are reversed in the mortar of old buildings; the greater their age the less hydrate and the more abundant is the carbonic acid, which is the material source of hardening. We know, by investigation and experiment, that such change has taken place, but we are rather ignorant of the time and ceremony which occur between two atoms while they are changing places; and science does not encourage the faintest idea that hydrate may ultimately, by some unknown process, be converted into or form a component part of the carbonate.\*

#### ENGRAVING AND OTHER REPRODUCTIVE ART PROCESSES.

To the antiquity of the art of engraving it is not my intention to do more than allude; it is abundantly evident that it was known to the Egyptians, and used long prior to the Christian period. The art was probably one which grew out of the necessity of attaching some distinguishing mark to individual works, or from the custom of recording the history of the early ages by cutting them in stone, many examples of which have been preserved to us. Soft bodies were also impressed with the makers' marks, as in the case of ancient bricks and other plastic bodies; and thus, what was in the first instance an isolated mark, led to and became a reproductive art. From a sculptured or monumental art a refined art grew up, of which, and the perfection to which it attained at an extremely early date, the engraved gems and seals preserved in our museums give ample evidence. Engraving on metal was early employed as a means of ornamenting articles of dress; and the coins preserved to us show how the skill of the die-sinker and engraver in metal became the basis of another reproductive art. Engraved metal plates have been found in the coffins of mummies, and are preserved in the British Museum. In India, engraving on plates of copper appears to have been practised long prior to the Christian period. It was there customary to ratify grants of land by deeds of transfer actually engraved on copper, and a copy of one of such relics, with an English translation, is given by Mr. Wilkins, in the 1st vol. of the "Asiatic Researches," page 123,—an early proof of the commercial use of engraving. To trace the history of engraving on stone and metal to the period when the art of printing was discovered, would only be to repeat an oft-told tale, and tend to prove that the one object which all appear to have had in view has been to facilitate the means of reproducing, at a cheaper rate and by a more ready means, copies of the works of the artist and engraver. It has appeared to me that the present is not an inopportune time for reviewing some of the changes which have been either introduced, or proposed for introduction, during the last half-century, and which have

of water upon 11 pound of quick-lime; the lime will swell, become hot, and crumble into fine powder; when cold, it will be quite dry, and increased in weight about half a pound; the missing quarter of a pound of water having passed off as steam. Thus 2 pounds of slaked lime have been produced from 11 pound of quick-lime. Quick-lime has two powerful and distinct affinities: first for water, and afterward for carbonic acid. On exposure, it absorbs moisture from the atmosphere, and is thus slaked into hydrate. If this is mixed with a larger quantity of water to about the consistency of cream, it will be in a state fit for whitewashing or limewashing; and, when dry, after a day or two, it will no longer be hydrate of lime, but decidedly chalk, or carbonate of lime as it originally existed in its natural state.

\* To be continued.

placed us in our present position with reference to the art of engraving, or its substitutes, for illustrative commercial art purposes. With a view, however, of making what I have to say more clear, it is necessary that I should state what were the peculiarities of the art processes in common use prior to the beginning of the present century. The earliest specimens of prints from engravings were those obtained from wood blocks on which the design was cut in relief, but the art of engraving on wood, though greatly improved, continued in an extremely imperfect state till within the last half-century. The perfection to which the art had attained in the year 1803, is printed a specimen showing the great progress which the art had made at that date; and at page 13 of the Preface, we find the following:—"It has been frequently asserted that the art of engraving on wood is not, at the present day, equal to what has been done by some of the ancient masters, but when the emblematical performance of young Austin, in this line, prefixed to the present list of premiums, is considered as the work of so young an artist, it may probably appear that it cannot be excelled by many artists in Europe of a similar age, and the reward assigned is likely to excite his emulation to progressive improvements in that art." The reward given was the silver medal and ten guineas—and the block was for many years used by the Society as a specimen of the art, and was printed at the head of the secretary's letter announcing the election of new members. The art was, however, carried to considerable perfection by Bewick, who applied it in the illustration of his "Natural History of Beasts and Birds," and the commercial condition of wood engraving may be seen by a reference to that work. The earliest specimen of a print from a wood block is one known as the St. Christopher, and dated 1423.

The earliest use of engraved metal plates in England probably dates from the time of the Conquest; but Mr. Stuart states that he has not seen any with a date prior to 1284. They were then used as monumental brasses or tablets, and were executed with the graver, and arc assumed to have been produced by ecclesiastics. The same principle which was applicable to the production of monumental brasses, viz. the removal of a portion of the surface of a metal plate by cutting it away, according to any desired design, by means of the graver, was applied by goldsmiths in the production of Niello work. The earliest known print from a metal plate, is one which can be seen at the Imperial Library, Paris; it is attributed to Tomaso Finiguerra, the Florentine goldsmith, and bears date 1452; and the earliest known book illustrated in this way bears date 1478, and was printed at Rome. The next step in the improvement of the art of engraving is said to have taken place at the beginning of the sixteenth century, and is attributed to Albert Dürer, to whom is ascribed the invention of the art of etching, or drawing with a metal point or tracer, upon a metal plate, the surface of which was protected from the corrosive action of acid, by means of which the etching or drawing was permanently engraved in the metal plate. The process of etching afforded an opportunity of exercising any required amount of freedom of hand in the production of foliage or landscape, and soon led to a combination of the two processes, and was the means by which engraved copper-plates were usually produced at the beginning of the present century. This process is known as line engraving; it is a slow, tedious, and costly means of copying works of art; its peculiarity is, that it affords facility for giving a large amount of drawing and minuteness of detail, at the same time that it admits of the greatest possible gradation of light and shadow, and the most perfect artistic effect. The process of etching was largely used by Rembrandt. The most perfect works executed in the early days of this art are, however, to be found in the portraits and historical subjects, for the reproduction of which it was especially suited, though in later times it was largely and most effectively employed in the copying of architectural, monumental, and landscape art. Copper-plate engravings were printed in England, in "Vesilius's Anatomy" as early as 1545; but the English school of engraving cannot be said to have existed till about the middle of the eighteenth century, at which period efforts were made to advance the interests of artists in this country. It was during the reign of George III. that the

Royal Academy was established; and as art advanced, so with its advancement grew up the use by our artists of the etching-point and the graver in a more refined and skillful manner. But the mere reproduction of copies of pictures from engraved plates printed in black inks, did not long continue to satisfy the public, and efforts were soon made to print in colours from the engraved plates; but no thoroughly satisfactory results were obtained from line engravings in this direction, and recourse was had to the next process, to which I shall call attention.

Line engravings were executed (as before stated) by cutting away the surface of the copper-plate by means of the graver, which, for this purpose was made concave in its length, and varied from a square to a thin V-shape in its width; thus enabling either a narrow or a broad line to be cut; while by a slight variation of pressure, or by depressing the hand of the operator, the point of the graver was gradually driven along the metal, or freed from the plate altogether.

Chalk or stippled engraving, the next process to which I have to refer, was, on the contrary, executed by means of a graver of an arched or convex form, and when applied to the surface of the copper-plate could not relieve itself from the surface of the metal, the whole tendency, where ever pressure was applied, being to thrust itself deeper and deeper into the metal, leaving a punctured dot, varying in breadth or delicacy according as the graver itself was more or less square or V-shaped on its face. This mode of puncturing the face of a metal-plate was known as "chalk engraving," from the clusters of dots being so arranged as to imitate the granulated effect of lines drawn upon cartridge paper with Italian chalk. This process was especially suited to portraiture, owing to the softness of its gradations from light to shadow, and the production of landscape effects, though admirably suited for copying the delicate effects of light and shadow, and giving precision of drawing, either to portraits or groups of statuary.

The *Mezzo-tinto* is a method of engraving the discovery of which is attributed to Prince Rupert; but on this I would refer to a letter by Dr. Diamond, which was communicated by him to the Society of Antiquaries in 1838, and to which is appended a catalogue of the earliest known works in mezzotinto. The catalogue will be found in vol. xxvii, pages 405 to 409, of the "Archæologia." I have before me, through the kindness of Dr. Diamond, a copy of a letter addressed by L. de Siegen to his Highness the Landgrave of Hesse-Cassel, and which I believe has never before been printed in this country, and appears to substantiate his claim to be recognised as the inventor of the mezzotinto art.

Dr. Diamond says in his letter:—

"In the last session I had the honour of laying before the Society of Antiquaries several remarkable specimens of early mezzotinto engraving; which prove beyond doubt that the generally received opinion as to Prince Rupert being the inventor of that style of engraving is erroneous. From the examples then exhibited, it appears that the person to whom the merit of the invention is due is Louis von Siegen (or L. de Siegen), a lieutenant-colonel in the service of the Landgrave of Hesse-Cassel. The works of this amateur artist are of considerable rarity; and it is not improbable that they were merely distributed among his friends and patrons. Baron Heineken, in his 'Idée Générale d'une Collection complète d'Estampes,' printed at Leipzig, in 1771, says decidedly that Siegen was the inventor of mezzotinto engraving, and observes that the first specimen which appeared was the portrait of the Princess Amelia, Landgrave of Hesse; he adds, that Prince Rupert learnt the art from Siegen, and that eventually it became public."

"Huber, the compiler of Vinkler's Catalogue, tells us that Theodore Caspar de Firschenberg, a Capitulary Canon of Mayence, was an engraver in mezzotinto; and that his works are contemporary with those of Siegen; and expresses a doubt as to which was the disciple of the other; adding, if Firschenberg learnt the art of Siegen, he excelled his master. But there is no evidence whatever to warrant this doubt; on the contrary, the portrait of the Queen of Bohemia, which is exhibited in February last, bears the date of 1643, while the earliest known specimen of Firschenberg is dated 1656. It is only necessary to add that Rupert's earliest effort in mezzotinto through etchings of this Prince are earlier, and one is known inscribed Rup. Pr. 1637 is of the year 1668."

The mezzotinto is a process altogether distinct from those previously mentioned, and was effected in the first place by puncturing or tearing up a uniform burr over the entire face of a copper plate, from which, if a print were taken, an impression in density of colour would be obtained equal to that required in the darkest parts of the picture to be copied. Upon this ground the subject to be engraved was traced, and by scraping and burnishing away the burr or dotted lines impressed in the face of the plate, either in part or wholly, the necessary gradations of light and shadow were obtained. This process, although affording facilities for

covering large surfaces, did not admit of being applied on a small scale, so as to give detail of drawing or delicacy of outline, and was in the main inapplicable to the production of foliage, and when first practised was grey in colour and flat in effect. At a later period, with the view of facilitating the operations of the engraver, an instrument called a roulet was invented, and was used for the purpose of impressing a series of dots into the metal.

The first person who applied the mezzotint process on steel was Mr. T. Lupton, who, in 1822, submitted a specimen of his work to the Society of Arts, and stated that in order to obtain the necessary ground on the steel plate he had been obliged to lay his ways in eighty or ninety directions, whereas in preparing or breaking up the surface of a copper plate from twenty-four to forty ways were all that were required. The use of steel necessitated a much stronger hand and an increased number of ways in laying the ground, but the advantage of steel over copper was that from eight to ten times the number of prints could be taken.

*Aqua tinta*, a process of engraving which was extensively used at the beginning of the present century, but which is now rarely employed, was executed by a process of the following description:—The surface of the plate of metal to be engraved was equally covered with a finely-powdered resin. The plate was then warmed, to attach the grains to the surface of the metal. A tracing of the design to be engraved was laid upon the resin, and the surface of the plate, after the whites had been stopped out, was submitted to the corroding action of acid, which, acting between the grains of resin, produced a grain in the face of the metal plate. The light parts of the design were next stopped out, when the acid corrosion had been carried far enough. The darker parts of the design were again submitted to the action of acid, and this process was repeated till all the gradations from light to shadows, required by the design, were produced in the metal. A slight amount of burnishing and scraping of the plate so bitten in was then resorted to, to blend the several parts of the picture, and to heighten the lights where necessary. This process was carried to great perfection by Mr. Sandy, about 1799. Such were the various processes in general use at the beginning of the present century, the whole being originally executed in copper. A growing demand for book illustrations, and a necessity for producing the engraving in a more durable metal, and one that would consequently yield a greater number of impressions, led to the introduction of the next process.

*Steel Engraving.*—The invention of steel engraving is due to Mr. Perkins, who first introduced the art in America; his object being to increase the facility, cheapen the cost, and produce absolute identity in the manufacture of bank-notes. In order to effect this, he etched or engraved a steel plate, or, more properly, a block of soft steel, by the ordinary process of line engraving. The plate, or block, was then hardened. A cylinder of very soft steel, of from 2 in. to 3 in. in diameter, was then rolled backwards and forwards under pressure on the surface of the steel plate, until an impression from the engraving was obtained in alto-relievo on the face of the cylinder. The cylinder so obtained was in its turn case-hardened; and by rolling the hardened die over the surface of a flat plate of copper or soft steel, an exact copy of the original engraved plate, with all its sharpness, was secured. This process being repeated, any desired number of plates could be obtained from the die. As the object first sought was the production of bank-notes, and the cost of elaborate designs was great, a machine was invented in America by Mr. Asa Spencer, which was called a geometric lathe, and this was employed in the production of geometrical figures in combination with line engravings, as borders and ornaments on the face and back of notes. Mr. Perkins brought his invention to this country, where it was introduced and known as the "soderograph" process for multiplying copies of engravings. Soon after his arrival in this country he was joined in working his process by Mr. Heath; and they state, in 1821, "we cannot yet say how long a well-hardened steel plate will last, having never printed more than 500,000 impressions from the same plate. It should, however, be observed that this plate consisted principally of writing, or work quite as strong. It may also be observed that the impressions are yet good." The first steel-plate engraved in this country is attributed to Mr. Raimbach, who

was soon afterwards followed by the chairman of the Fine Arts Committee of the Society of Arts, Mr. Charles Warren. Engraving on steel, beyond necessitating a change in the nature of the acids used, and a better and more perfect graver, involved but little alteration in the process of engraving itself. Steel-plates admitted of an increased commercial product, in the form of prints; but they also demanded more time in their execution, and, as a consequence, a higher rate of remuneration for their production; and thence arose a class of men whose works as artists gave fashion to the art of engraving and book illustration; and out of their labours came such works as "The Forget-me-not," "The Keepsake," "The Book of Beauties," &c., &c., coupled with which works are the names of the Findons, Charles Heath, Rolls, Lacy, the Le Keuxs, Goodall, Willmore, Doo, and others, a school of engravers which has now entirely passed away. With the extended use of steel, however, came a proportionately heavy charge for printing, which, where large numbers were required, it was desirable to reduce as far as possible. This charge was not material as affecting high-priced works; but I have said that it gave rise to a fashion in book illustration, and a reader and cheaper means of illustration was demanded. We accordingly find that "Hone's Every-day Book," and "The Penny Magazine," which were popular works, and amongst the earliest examples of cheap literature, were illustrated with wood-engravings, which, being produced in relief, and capable of being printed with the type, saved the ordinary extra charge due to printing from steel plates. But, however artistic and effective wood-blocks were, they lacked the refinement of the steel engraving.

Concurrently with this spread of art in England, came the opening of the American, and the creation of an Australian market for English literature; and the adoption of a German discovery, which has done more to revolutionise art in this country than any other previously introduced, viz., the invention of lithography by Alois Senefelder, who, about 1795, while in search for a cheap means of printing the pieces which as a dramatiser he produced, by an accident discovered that, by writing on a slab of Kelheim stone with ink prepared with wax, soap, and lamp-black, and then biting in the stone with *aqua-fortis*, a surface in relief could be obtained, from which prints could be taken in the same way as from wood-engraving. This discovery led to the art of lithography as now practised. To the growth of the lithographic art I shall return hereafter; but for the present I would merely say that its introduction and the great cost, as well as the time involved in printing from steel or copper plates, led to numerous attempts to cheapen the cost of engraved plates, and also to multiply the plates when produced. The process introduced by Mr. Perkins was inapplicable to a large surface, both on account of cost and the difficulty and risk of injury in applying it. But machinery had been applied in the form of the geometric lathe, and a desire was created to possess a machine of a simpler character which might be employed to produce skies and backgrounds to portraits, without involving the skilled, and in many cases monotonous, labour of etching. This want was soon supplied by Mr. Lowry, who was speedily followed by Mr. Porter, Mr. Taylor, Mr. Storker, and others. By the first-named a machine was invented for ruling either straight or wavy lines, which, when used separately, produced flat or graduated tints, and when used in combination produced the effect now so generally seen on the face of bankers' cheques.

The result of these machine processes, coupled with the introduction of lithography, was to create serious competitors with the aquatint and mezzotint processes; which may be said to have been swept away by the great advance which lithography has made, and to the consideration of which we will now return. I have stated that Senefelder discovered, about the year 1795, the principle upon which lithography is based, but it was not till 1819 that much progress was made in the art; but at that date, owing to the fostering care of Baron Aretin, in Munich; Count Lusterick, in Paris; and Mr. Rudolph Ackerman, in London, an account of the art of lithography, showing its then state, appeared. The establishment of the art of lithography in England is, however, due to Mr. Hullmandel, who not only drew upon stone with crayons and printed from them in black ink, but soon carried out the process by drawing on two or

three stones, and printed from them with ink of a neutral tint; he also drew on several stones, and printed from them in colours. Mr. Hullmandel introduced the process known as litho-tint, the drawing being made upon the stone with a brush and liquid ink, and he also applied the process of stamp drawing. The facilities which drawing with the crayon, the stamp, and the brush, afforded for the production readily, and at a moderate cost, of a surface from which to print, soon gained for the art a large amount of public support, and enlisted the sympathies of the late Mr. Milneady, Mr. J. D. Harding, Mr. Louis Hagie, Mr. James Ward, Mr. J. Lane, and other Royal Academicians and artists, who applied themselves to the production of sketches on stone. There was, however, in the early attempts at lithography, a crudeness of effect and a want of gradation from light to shadow. To overcome this, Mr. Hullmandel made a material between ink and chalk, which, being applied to the hard edges, carried the full tints by gradation into the high lights. The effect thus obtained advanced the art in the estimation of artists, as it increased the facility for producing artistic effects, which was greatly helped by the use of tinted paper and printing in neutral tints from several stones. Printing in colours was practised by Senefelder, but his early specimens give but a faint idea of the richness and beauty of the productions of Mr. Owen Jones, who applied himself to develop the powers of lithography, and who not only drew upon stone, but also printed in gold and colours the entire of his work illustrative of the Palace of the Alhambra. In addition to drawing on stone and printing in flat colours, Mr. Jones introduced a method of printing from graduated tints drawn in ink only upon the stone, graduating his tints by stippling upon polished stones with a fine camel-hair pencil.

*Litho-tinto* is a method of drawing, in which washes of ink are applied to the surface of the stone; but it is not largely in use, though many artists have employed the process in the reproduction of their own sketches. The process of stamp drawing, by Mr. Hullmandel, afforded great facilities for the production of even and graduated tints over the stone, and soon became a process in general use. The cost and inconvenient weight of the lithographic stone led to a desire to find a substitute, and for a large amount of commercial work, drawing on zinc has been found to answer, and is now extensively in use. This fact leads me now to refer to the commercial, rather than the artistic use of lithography.\* S. T. DAVENPORT.

POST-OFFICE STATISTICS.

The tenth annual report of the Postmaster General (for 1863) has been issued. It differs from previous reports; reviewing progress during the last ten years, as well as during 1863. It also shows, on the whole, that the correspondence of the country has risen from about 70,000,000 of letters in 1839,—the year before the penny-post system was introduced,—to upwards of 610,000,000 in 1863.

The total number of letters delivered, in 1854, throughout the three kingdoms, at 4,847,983 inhabited houses, to 27,967,565 persons, was 443,649,301, or at the rate of 15 to each person. The total number delivered in 1863, at 5,212,723 inhabited houses, to 29,335,318 persons, was 642,324,618, or at the rate of 22 to each person. Thus the increase in 1863 over 1854 was 198,675,317 letters, delivered to 1,367,753 persons, at 394,740 inhabited houses, or at the rate of 7 to each person. The increase in England and Wales alone was from 358,300,696 letters, to 529,325,455, or 171,024,759, delivered at 421,739 inhabited houses (or at an increase of houses from 3,440,112 to 3,562,181) to 1,921,452 persons (or to an increase of persons from 18,711,016 to 20,632,498); being an average increase of 7 letters to each person (or from 19 to 26). The increase in London alone was from 103,000,000 letters to 161,000,000, or 58,000,000, delivered at 62,838 inhabited houses (or an increase of houses from 382,949 to 445,787), to 484,982 persons (or to an increase of persons from 2,831,950 to 3,316,932); being an average increase of 12 letters to each person (or from 36 to 48). The increase in Scotland alone was from 44,114,009 letters to 61,401,678, or 17,287,669, delivered at 20,701 inhabited houses (or at an increase of houses from 377,208 to 397,909), to 156,329

\* To be continued.

persons (or to an increase of persons from 2,940,516 to 3,095,845); being an average increase of 5 letters to each person (or from 15 to 20). The increase in Ireland alone was from 41,234,596 letters to 51,597,455, or 10,362,859, delivered at 47,700 inhabited houses (or at a decrease of 16 letters to each house, from 1,000,333 to 982,633), to 709,058 persons (or to a decrease of persons from 6,316,053 to 5,606,975); being an average increase of 2 letters to each person (or from 7 to 9).

The foreign and colonial letters coming into the United Kingdom for delivery are about one-fifth of the whole number of letters delivered; and the letters despatched to foreign countries and colonies are nearly equal in number to those which are received. The most remarkable increase is in the case of France. In 1854, before the reduction of postage thither, the correspondence amounted only to 3,000,000 letters; in 1857 it was 4,200,000; and in 1863 it had reached 6,373,000.

It is believed that 15 per cent. of the total number of letters posted in London contained printed enclosures, mostly advertisements. During 1853 an account was taken in London of 3,957,000 letters, which were obviously circulars, and of which 3,485,000 could be assigned to various trades and societies in the proportions shown in an accompanying table. The number of letters recorded as circulars, however, is much below the actual number of them posted in London, as circulars which are posted in small quantities escaped notice. Of the number above recorded, 1,690,052 were from drapers; and in 1859, 400,000 circulars with regard to the projected Handel Festival were despatched in one day to the Post-office, in two vans, which they filled.

The tables show that there has been a marked proportionate increase of facilities for posting letters within a convenient distance from the homes or places of business of the writers. This great extension of accommodation has been effected mainly by the introduction of pillar and wall letter-boxes, which first came into use in 1855, and now form nearly one-third of the whole number of receptacles for letters. Throughout the country these receptacles have been increased at the rate of 52 per cent. since 1854, while the number of inhabited houses has only increased at the rate of 8 per cent. In 1854 the London district had only one receptacle for letters to every 813 houses, but in 1863 it had one to every 426 houses. Perhaps the chief if not the only objection to the pillar and wall receptacles (unless letters be occasionally longer in these than in the post-offices before delivery), is that the public are not sufficiently warned not to put lock packets into them, as these are often tediously detained, and sometimes are altogether lost.

There are one or two other points in connexion with the Post-office regulations to which we may here refer, as being worthy of the attention of the authorities, as well as of the public, who ought to be more fully informed as to them either by means of advertisement in the most widely-circulated newspapers, or by sending to the journals, in both town and country, paragraphs, which, in nine cases out of ten, the editors of newspapers, in their wish to do good, would gladly insert. But even if it were needful, for the right publication of the most important of the Post-office regulations, that advertising should be resorted to, extra expense should not be a consideration; for the Post-office should rather be considered as a public convenience than as a source of revenue. Sir Rowland Hill's system is amongst the wonders of the age, but its very thankfulness which we feel for it canes a wish to make all the arrangements as complete as possible.

One of the matters to which we would desire to draw attention presses hardly upon the industrious and poorer classes. We refer to the passing of coin in letters through the Post-office. It is well known that this practice has been the cause of dishonesty amongst the letter-scooters and carriers; and it is most desirable that the practice, now that a Post-office order can be obtained for 3d. for any sum less than 2s., should be put an end to. The difficulty, however, is, that in consequence of the want of a more extended publicity, there are thousands of these very persons upon whom the rule presses very hardly who know nothing about it. It has been usual for poor people to send to friends at a distance very small sums of money: sometimes these remittances, which are most valuable in time of need to

those to whom they are addressed, consist of 1s., 1s. 6d., or even less, and those who know the condition of these people are aware that the receipt of even a very small sum is sometimes a matter of life or death. Now the regulation of the Post-office is, that if any coin can be felt to be enclosed in a letter it is registered at the Post-office. The charge for registering such a letter is 4d.; but in consequence of the person posting the letter containing money not having paid this sum, 8d., or double the amount, is charged to the person receiving it. In many ways this regulation presses severely, and on those, too (the receivers of the money), who are not blameable in any way. In many cases, the person to whom a letter of this kind is sent has not 8d. to pay for it; often there is no right address of the sender forwarded; and there can be no doubt that a large amount, consisting of small sums, is thus added to the profits of the Post-office. We could mention many instances that have come to our own notice of the way in which this regulation works. A mother, whose little girl was in an hospital, sent her 6d. in a letter: the porter of the establishment paid 8d. for it; so that the child, instead of receiving any money, was left 2d. in debt! A woman on the brink of starvation had a shilling sent to her by a friend. With the greatest difficulty she managed to raise the 8d. requisite, and after this was paid of course her shilling was reduced to 4d. We could give many other instances, but these will suffice to show our meaning.

We do not complain of the attempt which has been made to stop the transmission of coin through the post-office; but the way in which the present regulation works should be more extensively made known. It is not those who send bank-notes and other valuables, to a large amount, who feel the pinch; but the poorer people, to whom every 8d. is of serious account; and these should be instructed that a post-office order can be got for 3d. But then people say, why pay this for the transmission of a small sum? Why not 2d. for 10s., and 1d. for 5s.? A letter containing coin can be registered for 4d., or a very small amount may with perhaps less risk be sent in postage-stamps, which may, if necessary, be exchanged at the post-offices at a charge of 3d. for 10s. worth.

Nor has the registration system served to diminish the evil of pilfering which it was mainly established to prevent. True, "the number of registered letters has risen from 1,457,000 in 1860, to 1,965,000 in 1863; and the number of applications for missing letters containing coin has fallen from about 6,000 to about 2,000 per annum;" but, "on the other hand, the good effect of these measures has to a great extent been neutralized by the growth of the practice of transmitting postage-stamps through the post; the applications for missing letters containing postage-stamps having risen precisely in the proportion in which the applications for missing letters containing coin have fallen."

As regards the transmission of little matters through the post to our soldiers and sailors who are serving their country at foreign stations, there seems to be the same want of information as that to which we have alluded. Many who have sons and dear friends in India and other distant lands send little articles in the shape of keepsakes; and the rule is that for any letter or package under the weight of half-an-ounce sent to India or any of the English colonies, the postage is 1d.; but if a fraction over this weight, the charge is one shilling! And if in ignorance any one post a letter without the payment of this sum, and it gets to its destination, double the charge of the postage is made. A case has been mentioned to us of a woman who has a brother on board H.M.'s ship *Zebra*, which is stationed on the west coast of Africa, engaged in the prevention of the slave trade. She sent several letters including little articles. The postage was paid for at the rate which would be charged, in proportion to the weight, for sending to any part of Great Britain; but, after the lapse of a long time, it was found that they did not get into the sailor's hands at all: and, on inquiry, it was found that they were detained at Sierra Leone, in consequence of the postage not being sufficient. Such matters require to be seen about; and many think that in the present management, since the retirement of Sir Rowland Hill, the authorities of the Post-office are drawing the reins rather too tightly; and, in their anxiety to increase the revenue, are not showing the same kindly disposition that was formerly shown to serve the public.

The number of money-order offices in the

three kingdoms has been increased from 1,872 to 3,005 since 1854; the amount issued from 10,462,411, to 16,493,793. The increase for England alone has been from 1,221 to 2,150 offices, and from 8,567,136, to 14,087,883, in issues. For Scotland the increase has been from 278 to 352 offices, and from 814,461, to 1,305,871, in issues. For Ireland it has been from 374 to 503 offices, and from 690,809, to 1,100,039, in issues. The increase in London has been from 96 to 373 offices, and from 1,798,957, to 3,181,874, in money-orders issued.

The Post-office savings-banks returns show that on the 31st March, 1864, there were in the three kingdoms 3,024 banks, 372,955 depositors, and 4,097,492, due to them. The total number of depositors in the old savings-banks prior to the establishment of the Post-office banks was 1,609,103; and the increase in the number of savings-bank depositors since the establishment of the Post-office banks has been 278,407. In Scotland there were on the 31st of March last 354 post-office banks, 18,683 depositors, and 107,832, due to them. In Ireland there were 570 banks, 14,639 depositors, and 160,756, due to them. The number of banks in London was 374, the number of depositors 117,955, and the money due to them 1,143,377. The number of savings-bank depositors in London previously to the establishment of the Post-office banks was 332,798, and the increase since has been 89,874.

The report congratulates the country on the fact that "by the establishment of Post-office savings-banks the Legislature has effected not a mere transfer of depositors from one establishment to another, but a real and considerable increase in the total number of saving persons throughout the kingdom." In the London districts there is one depositor (taking the depositors in old banks and those in Post-office banks together) for every seven persons; and in the 106 postal districts of England and Wales, which are specified in the tables, there is one for every thirteen persons; in the rest of England and Wales, one for every fifteen persons; in Scotland, one for every seventeen persons; and in Ireland, one for every sixty-eight persons.

The effective force of officials connected with the Post-office throughout the country in 1854 was 21,574; and in 1863 it was 25,492. The total cost of the service was 2,312,681, in 1854, and 2,956,486, in 1863. To meet this the gross revenue in 1854 was 2,619,786, and in 1863 3,730,073. Thus the net revenue in 1854 was 389,181, and in 1863 it was 1,042,969, remaining, of course, after deduction of the total cost of the service.

France, we may here remark before concluding, is to be divided into six postal districts, the centres of direction being Arras, Alençon, Toulouse, Poitiers, Lyon, and Nancy.

## COMPETITIONS.

*Metropolitan Meat and Poultry Market*.—Though two premiums were offered for the first and second best designs, viz., 300l. and 200l., only seven sets of drawings have been sent in, and three of these are incomplete works. This result is due to the supposed intention of the Corporation not to employ the author of the selected design to carry it into execution. The designs are marked as follows:—No. 1. "A Key." Estimated cost, 100,000l. No. 2. "For the use of the Citizen, and the Decoration of the City." 150,000l. No. 3. "Citizen Stationer." 122,000l. No. 4. "Semper Paratus." 75,000l. No. 5. "Invicta." 90,000l. No. 6. "Fortuna Segnatur." No estimate. No. 7. "Spero." 20,100l.

*Hospital, Wimbledon*.—The governors of St. George's Hospital, desiring designs for the hospital about to be built at Wimbledon in connexion with their institution, invited plans in competition from Mr. Huxewell, Mr. Meo, Mr. T. H. Wyatt, and Mr. M. D. Wyatt. The design by the last-named architect was selected, and will be carried out by the Messrs. Wyatt conjointly.

*Bath Forum House*.—Under this title a hotel and bathing establishment are to be erected in Bath. Designs being sought for, twelve were sent in by nine architects. From these four have been selected for further consideration, all the work of architects resident in Bath. The architects whose designs are selected are,—Mr. C. E. Davis, city architect; Messrs. Giles, Hicks, & Isaacs, Mr. C. J. Phipps, and Messrs. Jas. Wilson & Wilcox. The instructions with which each competitor was furnished, before preparing his plans, specify that the form of the building shall be

"a centre, with two wings enclosing a quadrangle, the whole to front towards Stall-street, which must be increased in width as much as 10 ft." A Gothic design was forbidden, because it would not harmonize with other architectural features of the city, and the cost was not to exceed 15,000*l.*, exclusive of pipes and extra fittings, heating apparatus of the baths, &c. All the designs are, therefore, in the Italian and Classic styles. The cost of, at any rate, two of the designs would probably exceed the stipulated amount considerably. Since this was written the first premium (200*l.*) has been awarded to Mr. C. E. Davis; the second (100*l.*) to Messrs. Wilson & Wilcox.

*The Tatton Sykes Memorial.*—A design submitted by Mr. John Gibbs, architect, Oxford, has been selected.

*Medal for the South London Industrial Exhibition.*—In reply to the offer of 5*l.* for the best design for prize medal proposed to be awarded to meritorious productions at the close of the forthcoming exhibition, twenty-one designs were sent in by twenty-one competitors. The judges selected four in the following order:—1. The design marked "*Nisi Dominum frustra.*" 2. The design marked "*Fleur-de-llys.*" 3. The design marked "*The Talents.*" And 4. the design marked "*Conatus.*" The committee then proceeded to break the seals of the envelopes containing the names of the artists, and it was found that the successful competitor was Mr. R. Wallace Martin, sculptor's carver, of No. 5, John's-terrace, Olney-street, Waltham. To him, therefore, the prize of 5*l.* was awarded. The design for which the prize has been given is modelled in brown cement. On the reverse is a figure of Fame holding a laurel wreath in each hand; beneath which on either side are figures of men—on the right an architect seated upon a Corinthian capital, surrounded by architectural specimens, and engaged in preparing a design; on the left, the figure of a mechanic leaning against a horizontal steam-engine, and intently studying an open book. On the obverse are inscribed the names of some fifteen or twenty men who by labour have risen to eminence.

*Fembroke Dock Congregational Chapel.*—The committee have chosen the design submitted by Mr. R. C. Sinton, Bromley House, Nottingham.

*New Wesleyan Chapel, Belfast.*—The committee appointed by the Wesleyan conference to make arrangements for this building, having invited the following architects to submit designs in competition, viz.—Messrs. Lanyon, Lynn, & Lanyon, Belfast; Mr. Alfred G. Jones, Dublin; Mr. William Fogerty, Dublin; and Mr. William Hill, Leeds; after careful consideration have selected the design of Mr. Fogerty as best suited to the requirements. The institution is to consist of two departments, one academic and the other collegiate, with accommodation for professors, students, and boys, on an extensive scale. The selected design is in the Gothic style, with red brick facings and stone dressings. The immediate outlay proposed is 10,000*l.*, with provision for future extension. The committee very honourably voted the sum of 40*l.* to each of the unsuccessful competitors.

*Burnley Market.*—Sir: I enclose you particulars of the Burnley Market Company (Limited), and I have underlined the percentage part of the business.

It now appears to me a fact, that there are architects who will work for 2*l.* per cent., and furnish all detail drawings, elevations, plans, &c. &c. As for the 100*l.* premium, it merges into the commission, and thus the Company will doubtless have forty or fifty sets of designs to select from, and for the low charge of 2*l.* per cent. get all they need except superintendance. Again, if the Company think (supposing them to be competent to judge) the designs of not sufficient merit, they will not give the premiums.

Now, sir, let us take notice who will send in for this affair; there will be no difficulty in getting the competitors' names, and then they ought to be made public.

I quite concur in all "*B.*" states in your recent number, and I think, as we are now beginning a new year, it would not be amiss to try and find out how many architects would send in their names to you as willing to support the proper professional charge of 5*l.* per cent. and abide by it.—ONE OF THE CAFT.

BOLTON TOWN-HALL COMPETITION.

Out of the thirty-eight designs submitted, Professor Donaldson, to whom they were referred, selected for special consideration, six, marked as follows:—24, "*Experientia docet.*" 3, "*Manchester.*" 25, "*Nil Magnam Utile Bonum.*" 19, "*Do you like it?*" 26, "*Nisi dulci.*" and 10, "*Experiar.*" These are in the order as the referee considers of their respective merits, 24, 3, and 25 being recommended for

the premiums, 120*l.*, 80*l.*, and 40*l.* In his report, Professor Donaldson says:—

"I have been met at the outset with this great difficulty, that hardly any, if any, of the designs contain the full number of rooms and accommodation of the sizes therein specified. But as there are the words appended (or as near as may be,) 'I have felt that there was a latitude left to the discretion of the competitors, which put it out of the question to reject any on account of non-conformity, and that I was limited in the judgment of the committee, who are left free to decide as to any omissions in that respect, the consequences of which would rest solely with the competitors themselves. Were this not the case, and if I were limited in my selection to those projects which strictly adhered to the instructions, I might have had to omit many, which, for general convenience in the arrangement of the plans, or for beauty in the treatment of the elevations and decorative architecture, are most worthy of your attention, and alone suitable to the occasion. Mere technical conformity to the instructions is not what you require; but a masterly grasp and comprehensive treatment of the whole subject. At the same time I have considered it necessary to note where the designs, which I have the honour to submit to your consideration, conform more or less to the requirements stated, and I leave it for you to decide how far the deviations should weigh in affecting your judgment, when making your ultimate selection for the three prizes."

"If the committee should be pleased to confirm my opinion of the relative merits of the designs, I venture to suggest whether a combination of the plans of No. 24 or 3 with the elevation of No. 26 may be advisable, so as to produce the most convenient and effective design, and thus most successfully carry out the expectations of the town council, producing a monument that shall as a whole reflect credit on the borough throughout all times. I must venture to impress upon the committee the necessity of having a lofty clock tower as an essential part of the design."

He suggests to the corporation that they should not expect that the total outlay for the structure, including a tower, and exclusive of site, will be less than from 70,000*l.* to 80,000*l.*

We are glad to see the *Bolton Guardian* protesting in strong language against allowing the selected design, whatever it may be, to be carried out by any other than the architect who produced it. The writer properly says:—

"Feeling, as we do, a deep interest in the Town Hall scheme, we are anxious that both in relation to its cost and adaptation to public business, as well as its architectural finish, it should reflect the good sense, the taste, the liberality, the honour of our municipality, and be in all respects in keeping with the rising character of the borough."

We understand that the recipient of the first premium is Mr. Hill, architect, Leeds; of the third, Mr. Cutburt Brodrick, also of Leeds. The award of the second premium has not yet reached us.

THE LATE MR. JOHN DOBSON, OF NEWCASTLE, ARCHITECT.

We record with very great regret the unexpected death of Mr. John Dobson, of Newcastle, which took place on Sunday last, in the 78th year of his age. Bronchitis was the fatal complaint, and carried him off suddenly, although he had long been ailing. Mr. Dobson was born at Chilton, near North Shields, on the 9th December, 1787. His father had the discrimination to perceive that his son was gifted with rare talent, and gave him what in those days was considered a good education.

At the period of Mr. Dobson's youth, architects were not so plentiful as they are now, nor was the distinction between design and construction so well defined. Mr. David Stephenson was the only architect in Newcastle, and he was a builder as well as an architect. To him Mr. Dobson was sent as a pupil, and he soon exhibited signs of aptitude in the acquisition of his profession. While with Mr. Stephenson he found in the person of an Italian refugee named Muss, a master capable of imparting to him valuable instruction. He studied perspective with him, and had for fellow pupil John Martin. He afterwards studied under John Varley, at that time one of the most distinguished artists of the day.

When Mr. Dobson returned to Newcastle he found that he was the only architect in the county of Northumberland, as Mr. Bonomi was the only architect in the county of Durham. He received some commissions, and in the intervals of his employment he travelled in England and France, studying church architecture. He soon got well to work. Chipchase Castle and Haughton Castle, both on the North Tyne, were improved by him, and the pile designed by Sir John Vanbrugh for Sir Ralph Delaval, at Seaton Delaval, was enlarged by Mr. Dobson for Sir Jacob Astley.

A catalogue of Mr. Dobson's works would be the history of nearly every territorial residence in the county. One of his earliest works was a

house for Mr. Nicholson, at Earsdon, Northumberland, in 1813. This was speedily followed by Bradley Hall and Birtley Hall, Durham; Prestwick Lodge and Cramlington Hall, Northumberland; Benwell Grove and Villa Real, near Newcastle; Belford Hall and Doxford House, Northumberland; Biddleston, Flotterton, Longhurst, Newburgh, Acton, and Cox Lodge, large mansions in the same county.

As Mr. Dobson's reputation began to extend beyond the limits of his own county, he was called in to design houses, churches, and castles in other parts of England. He built a large house for Mr. Harrison, at Whitehaven; another for Mr. Beadle, and one for Mr. John Dixon, both near Carlisle; Inglethorpe Hall, near Wisbeach, for Mr. Metcalfe; Ostland Park, near Windsor, for Mr. Hewison; and another house in the same locality for the Rev. Dr. Hawtry; Sitlington House, in Yorkshire, for the Rev. Mr. Long; the Scar House, in Arlendale, for Mr. Gilpin; the Parsonage, at Stockton, and Pennythorn House, Yorkshire; Greenwood Park, Hampshire, &c. Besides these, Mr. Dobson made extensive additions to Wynyard House, Durham, for the Marquis of Londonderry; and to Sudbrooke Holme, near Lincoln, for Col. Ellison, and received from a German nobleman a commission for a castellated mansion on the Rhine, the plans for which he partly furnished, but from the great distance from his own place of business he could not conveniently complete the work. The following mansions in his own neighbourhood, in addition to those already named, were also either entirely rebuilt or received large additions from his designs:—Cheeseburn Grange, Unthank House, Falldon, Backworth Hall, Hamsterley Hall, Musters-aeres, the Museum at Wallington for Sir Walter Trevelyan, Nunykick, Gosforth, Shadon, Blenkinsopp Castle, Whitburn, Hollyn Hall, &c.

The churches built from Mr. Dobson's plans were very numerous. When he first began his career Gothic architecture was lightly esteemed, and the same taste which induced Sir Christopher Wren to replace one side of the cloister at Lincoln with an arcade of Roman design, was still rampant. The church of St. Thomas, Newcastle, one of the first designed by Mr. Dobson, bears marks of the timidity with which architects then ventured upon the Medieval style. It was, however, in advance of the period. The first church built from his design was the Scottish church at North Shields, in 1813. In 1817 he furnished the design for the restoration of Tynemouth Priory, the repairs of St. Nicholas' steeple, and the warming of the church, which work was succeeded after some interval by the beautiful florid Gothic window at the end of the north transept. In 1817 Mr. Dobson was called in by Col. Beaumont to restore the east end of Hexham Abbey Church. The private chapel of Mr. Riddell, Cheeseburn Grange; the Independent chapel, Sunderland; churches at Belford, Haltwhistle, Gilsland, Greenhead, North Shields, and chapels at Heworth, Gloucester, Eghlington, Dinnington, Cowpen, Monkwearmouth, and restorations of Hartburn and Marsdale, showed how industrious he was. He built a church at Carlisle for Mr. Peter Dixon; Trinity Chapel, Gateshead, and Alwinton Church; and in 1843 he began St. Peter's Church, Newcastle. Josmond Church, a church at Monkwearmouth, another at Hendon, Lynn Church, at Warrington, Cheshire; St. Stephen's, South Shields; St. Mary's, Jarrow; and St. Mary's, Rye Hill, were built, and a number of others repaired or restored, besides schools built, cemeteries laid out, and some restorations of difficulty such as those of Houghton-lo-Spring and Warkworth, were completed.

The restoration of Lambton Castle for the Earl of Durham offers an instance of the invention of the architect. The coal-workings under the castle had been filled with water at the time when some of the more modern additions were made; and this work, by the drawing off of the water in subsequent mining operations, was dislocated from top to bottom. Parts of the ruin were not worth preserving, and Mr. Dobson condemned them to destruction; but he has succeeded in restoring the parts worthy of preservation by going down into the mines, building up from the bottom where he found a solid foundation, in no less than three distinct and completely excavated seams of coal, with solid brickwork, and wedging up the walls to the perpendicular. Before, however, the whole of the additions to the building were completed, Mr. Dobson's health became impaired, and his

NEW FONT FOR BOMBAY CATHEDRAL.

plans have since been carried out under the direction of his son-in-law, Professor Smirko, R.A., who will doubtless now act elsewhere in a similar capacity.

The laying out of the new cemetery at Jesmond, Newcastle, afforded Mr. Dobson scope for the display of his ability both as an architect and a landscape gardener, and the result is well worthy the attention of the student as an excellent example. The versatility of Mr. Dobson's talent in turning his hand to work of any kind deserves to be mentioned. The timber frame-work used as stais for shipping coals on the Tyne, showed that Mr. Dobson was master of carpentry; the graving-dock designed for Messrs. Smith, at St. Peter's ship-yard, proved him an engineer; and the warehouses built at the docks at Sunderland and Jarrow showed that the most massive construction came as easily to his hand as the Gothic church or luxurious mansion. The Central Railway-station of the North-eastern Company at Newcastle is perhaps Mr. Dobson's most important work; and though the work as actually executed falls far short of the original design, it is still a fine and imposing structure, and shows the skill with which the architect met and overcame the difficulties of the situation, and the foresight with which he made arrangements for accommodating the additional business which he clearly knew was likely to result from the development of the railway system.

The construction of the High-level Bridge and the passage of the Newcastle and Berwick

Railway through Newcastle, involved an immense destruction of house-property; and here Mr. Dobson's services were called into requisition, in the settlement of compensation to the owners of the property destroyed. His knowledge of its value, and the implicit confidence placed by the owners and occupiers in his honesty and impartiality, enabled Mr. Dobson, in conjunction with the late Mr. Robert Wallace, the town-surveyor of Newcastle, to adjust all the claims for compensation, without carrying (with one exception) any of the claims into a court of law. In these respects, no less than in respect to his skill in architecture, the death of Mr. Dobson will leave a blank not easily supplied; for in the settlement of all kinds of disputes within a very wide range from Newcastle, the sound judgment and dispassionate temperament of Mr. Dobson were successful in extinguishing litigation. When Mr. Grainger was changing the entire aspect of the town, by the erection of the streets and public buildings which have shed a lustre upon his name, Mr. Grainger never failed to award to Mr. Dobson his obligations for the advice and valuable suggestions that gentleman gave him whenever he was consulted.

One of the earliest of Mr. Dobson's miscellaneous works was the Royal Jubilee School, Newcastle. In 1819 he planned, for Colonel Birch, additions to the fortifications of Tynemouth Castle, which have been lately supplemented by a fosse, also, it is said, designed by a civil engineer. Mr. Dobson was also employed by the Government on extensions or alterations

of the Custom-houses at Glasgow, Newcastle and Liverpool. The Royal Arcade, Newcastle was from his designs. He prepared plans and sections for the Newcastle and North Shields Railway. Of hydraulic works, Mr. Dobson executed several. He designed St. Peter's Dock, near Newcastle, for Messrs. T. & W. Smith; a dock for Mr. Robson, at North Shields; and Seaham Harbour, for the Marquis of Londonderry. In connexion with ornamental park-like grounds, ornamental water was a necessity, and the lake at Bolam, the seat of Lord Deedes, in Northumberland, was his principal work in this department. Mr. Dobson also executed for Mr. George Hudson, baths, streets, terraces, and the general arrangement of the new town at Whitby, and designed for other proprietors the baths and terrace at Roker, near Sunderland.

Many of the mansions designed or altered by Mr. Dobson are of large size, and would be worthy of an extended notice. The design for the Central Station at Newcastle procured the honour of a medal at the Exhibition of Paris, in 1855; but this appears to have been the only public recognition his services ever received. He was the first president of the Northern Society of Architects.

We have here given but a meagre sketch of a most industrious, prolific, and valuable life; but we must not close it without bearing witness to Mr. Dobson's upright conduct as a man; his generous and kindly nature. The profession has lost a very eminent member, and Newcastle a distinguished and most respected citizen.

LAMP AND VENTILATING SHAFT ERECTED OVER THE SUBWAY, SOUTHWARK STREET, LONDON.

EXECUTED BY MESSRS. WALTER MACFARLANE & CO, UNDER THE DIRECTION OF MR. BAZALGETTE.

**THE LATE MR. EBENEZER TROTMAN, ARCHITECT.**

MR. TROTMAN died, we regret to say, at his residence in Park Village East, Regent's Park, on New Year's Day. He was in his 56th year. His name was probably better known a dozen years ago, young as he was comparatively than it is now. Mr. Trotman was the son of a Baptist minister at Wrexbury, and was a nephew of Sir John Easton, Bart. He was educated at the Mill Hill Grammar School, and was subsequently articled to Mr. William Wallen, a well-known surveyor, in Little Moorfields. Soon after he left him he attended the office of Mr. Tite, first as a junior clerk, but finally Mr. Trotman became his principal assistant, and had much to do with his large business, being greatly employed by him, and representing him in very extensive works in Edinburgh and Perth in connexion with various railways, as well as in London. His health failing him, he gave up his position with Mr. Tite, and was succeeded by the late Mr. Charles Porden. Mr. Trotman was an excellent draughtsman, and had obtained a great mastery in the details of Gothic architecture, which he exhibited in a paper read by him at the Institute about thirteen years ago, wherein he showed the results of his curious researches in hundreds of our country churches. He wrote, amongst other contributions, an article on Tudor architecture in "London's Encyclopædia," which attracted much notice at that comparatively early period.

His health was feeble, and before he left Mr. Tite he showed symptoms of the disease which finally terminated his life, viz., softening of the brain. He was in every sense a gentleman.

**NEW FONT FOR BOMBAY CATHEDRAL.**

WE have much pleasure, on the present occasion, in placing before our readers a faithful representation of a new font, that now is on its way towards a baptistery which awaits it in the Cathedral of Bombay. The font is a gift, a thank-offering from an English gentleman, a resident in Bombay, who for many years has devoted himself, with energy and gratifying success, to the promotion of various important public works for the improvement of that great city. To the senior chaplain of the cathedral, the Rev. W. B. Fletcher, was intrusted the duty of seeing that the wishes of the donor of the font should be carried into effect. Acting upon the advice of a common friend, Mr. Fletcher placed himself in communication with a brother clergyman at home, an experienced student of ecclesiastical architecture, with a request that he would send out to Bombay a design for the required font. His design having been received with cordial approval by the Bishop of Bombay, Mr. Fletcher, and the cathedral architect, as well as by the donor, the Rev. Charles Boutell was requested to commission a sculptor to execute the font under his own superintendance in London. Mr. James Forsyth received this commission, and he has produced this new font for Bombay Cathedral in a very satisfactory manner.

The cathedral of Bombay is an edifice built in conformity with what we know as Norman architecture, the new font, accordingly is designed with a view to harmonize with the Norman Cathedral of Bombay. This font, which is of full cathedral proportions, is formed from a single block of Caen stone, the cluster of five dwarf shafts which support the bowl being sculptured upon a basement also of Caen stone, and, in its centre, this basement is supported by a plinth with steps executed in basalt. The basalt portions of the work have been produced in Bombay, from drawings sent out for that purpose.

The bowl of the font is banded midway with two passages—the letters being carved in relief—"Sancti Little Children to come unto me," and "Go and baptize all Nations." In connexion with these texts are four circular medallions, severally containing groups representing "The Baptism of Our Lord" and that of the Ethiopian prince, with the sacred monogram "I.H.S." and the date "1864." Below the font is encircled with lotus-leaves, emblems of purity; and above, a wreath formed from another variety, the Lily of the valley, is typical at once of the purity and of baptismal innocence. The capitals of the four smaller shafts exhibit—sculptured with much freedom and vigour—the sig-

nificant union of the flowers of the Indian lotus with the roses of England. Above, the font is finished with a plain chamfer; and the present cover, which is of oak, with a brass central ring, is of a simple character.

We have a view of the cathedral, as about to be recast, in progress, and shall publish it shortly.

**LAMP STANDARD AND VENTILATING SHAFT, SOUTHVARK STREET, LONDON.**

THE lamp-standard and ventilating-shaft represented by our engraving has been recently erected over the subway, Southvark-street, London. It is executed in cast-iron, for the Metropolitan Board of Works, by Messrs. Walter Macfarlane & Co., of the Saracen Foundry, Glasgow, and Bedford-street, Strand, London; and was done under the direction of Mr. Bazalgette, engineer to the Board.

This work shows, in a very marked degree, the improvement that is taking place in the cast-iron productions of our country, to which improvement in the ornamental branch of the trade the firm of Messrs. Walter Macfarlane & Co. have largely contributed. In the Exhibition of 1862 their works (to which we at the time drew attention) were sufficiently excellent to gain for them a prize-medal, their castings being characterized by the jury as "admirable, sharp, clean, and full of character." The work before us combines strikingly those qualities. The erection consists of a red sandstone base, about 5 ft. high, surmounted by ventilating shaft, lamps, &c., in cast-iron, about 27 ft. high, the whole forming a handsome central feature to the street crossing.

We must compliment Mr. Bazalgette, and all the parties concerned in this work. The cost of the lamp, without the stonework, will be about 255*l*.

**THE SANITARY CLAUSES OF THE METROPOLITAN BUILDING ACT.**

ON many occasions we have pointed out the failure of the sanitary clauses, few in number, of the present Metropolitan Building Act, and that, too, without any reflection on the District Surveyors. The following observations in the last report of the medical officer of health for the Whitechapel district (Mr. John Liddle), relate to the same subject:—

"The most important defect in the present Building Act is that which relates to the requirement of providing an open space of at least 100 square feet at the rear or sides of those houses in which all the rooms cannot be lighted and ventilated from the street or alley adjoining. But as nothing is said about the arrangement of such open space, it may consist of a slip of ground, being only 1 ft. in width and 100 ft. in length; or it may be of any other shape, if only the 100 square feet, required by the Act, has been provided. Not a word is said in the Act respecting the necessity of there being a window opening into this space. The Act is also silent upon the size of the windows in any of the rooms in a house, and of the height of the rooms, except those in the basement and attic, when these rooms are let as separate tenements. Every room, used as a sleeping-room, should be at least 8 ft. in height.

To show how the spirit of this Act has been evaded in this district, I may, in addition to the instance in Osborn-place above-mentioned, bring to your recollection the fact, that in 1861 four new houses were erected in Bear's Head-yard, upon a space of ground, on which only two houses should have been allowed. One of these houses, No. 2, has a narrow passage by the side of it, in addition to the open space forming the court in front, so that all the rooms in this house are said to be lighted and ventilated, and therefore an open space at the rear is not required. The yard at the rear of this house is apparently common to it and to No. 1, but as No. 2 does not, according to the Act of Parliament, require an open space in the rear, the yard, which is exactly 100 square feet, is said to belong exclusively to No. 1. As it was found to be impossible, by any contrivance, to give to the house No. 3, which was intended to contain two rooms on a floor, a space of 100 square feet at the rear, the builder was compelled to make only one room on a floor, whereby all the rooms could then be said to be lighted and ventilated

in front, consequently it was not necessary to provide any space at the rear of this house. The yard, therefore, which ought to be common to it and the next house, is said to belong exclusively to No. 4.

Again, in Queen's-place, Whitechapel, two dwelling-houses, of six rooms in each, have been erected, with a space at the rear of only 50 ft. to each. It was obvious, in this case, that the buildings were not in accordance with the requirements of the Building Act, and on complaint being made of the want of sufficient space at the rear of these houses, the owner caused a doorway to be made in the party-wall, between these houses. This arrangement was said to be legally sufficient to convert these two houses into a single house, whereby the entire space at the rear, which is 100 square feet, is all that the Act requires.\*

Upon the same principle, half a dozen or more houses may be converted into a single house, while the open space in the rear for lighting and ventilating the back rooms may not exceed 1 ft. in width, provided that the building extends 100 ft.

The following case will further show how the provisions of the Building Act have been evaded. The landlord of some old houses in a court in Spitalfields thought it expedient to rebuild and enlarge them; but instead of pulling them down at once, as he ought to have done, he first took down the front walls only, and rebuilt them. He then took down the back walls, and rebuilt them. He subsequently took off the roof, and replaced it with a new one. By these proceedings he evaded the requirements of the Act relating to the structural arrangements of new houses; besides which, he was enabled to build two small rooms, 6½ ft. only in height, at the back of each house, without his being under the necessity of complying with the twenty-ninth clause of the Act, which relates to the providing of an open space of 100 square feet for the purposes of lighting and ventilation.

The width of all courts in which houses are to be built should be regulated by Act of Parliament. It appears, that in old courts, in which, perhaps, a warehouse, stable, or shed, has existed for a few years, the owner may erect upon the sites of these buildings dwelling-houses, and may let them out in tenements, without any regard being had to the width of the court, because it is said to be an old court, and no power is given to any authority to limit the height of the houses built thereon; but in a new court, a bye-law of the Metropolitan Board provides, that an open space of 20 ft. shall exist between the houses on each side of it.

The present Building Act does not require a parapet-wall to be made. The want of such a protection to the public may be productive of danger to life. A tile, slate, or a quantity of frozen snow may fall from the roof and injure persons in the public streets. Neither is there any provision made to afford safety to the public in enabling them to make a speedy exit from places of public entertainment in case of an alarm of fire.

The law relating to the building of houses appears to be in this anomalous state, viz:—That houses can be built without suitable provision being made for the proper ventilation and height of the rooms; but after such houses are completed and let out in tenements, then, by virtue of another Act, the local authority may institute proceedings before a magistrate to prevent the occupation of any room which, in the opinion of the medical officer, is unfitted for the health of the occupants. It rarely would be much better to prevent houses being built, unless every arrangement suitable for preserving the health of the occupants be first made, than to allow houses to be completed, and then to prevent the landlord from letting them.

At the present time large sums of money are being expended by some philanthropists, in erecting improved dwellings for the labouring classes, in the hope that such dwellings will not only directly benefit the occupants themselves, but will contribute indirectly to the general welfare of the whole community; but, unless the provisions of a new Building Act forbid the extension of buildings in unsuitable localities, and at the same time enact that all the rooms in dwelling-houses shall be sufficiently lighted and ventilated, the labour, time, and property of such kind-hearted persons will be, to a certain extent, thrown away."

\* We must conclude that the two houses were in the same occupation, or the arrangement would be illegal.—Ed

ART-WORK IN THE FUTURE.

SIR,—I must call attention to some remarks made by you at a recent meeting of the Society of Arts on the subject of "Art Industry," as it is to be greatly feared that without it they will not accomplish the good which you doubtless intended they should do. To my mind they seem to be most important and pregnant of consequences.

The first is, "that it is a most lamentable fact, that notwithstanding what has already been done, the great body of building artisans of the present day are inferior in skill to the same class of artisans of seventy years ago." It is, as I think, simply impossible to say more than this. It condemns modern art as the production of the workman, and, as well as this, all our present means of art-instruction, as attempting to influence the art results of the age in which we live. Now, the first questions are,—is this true? and can it be proved, that our workmen are inferior to their fellows of seventy years back?

I do not think it possible for any one to look attentively at any object left us from the days of which you speak, "seventy years since," without acknowledging at once that the art-skill of that time found its way to material; and was not, as it now so unfortunately is, wholly expended on paper; and in efforts at representing objects on a flat surface, and in mere drawing. Almost any of the objects left us, as articles of furniture, chimney-piece ornaments, glass, plaster-work, wood carving, and others, will show this; and, what is more, any attempt now-a-days to get them imitated by our present race of workmen is impossible. Why is this? At that time there did not exist a single drawing-school of any kind to which the workman could go; all were under the baneful system of the old drawing masters, simply to be described by saying that the mode of work was not to imitate any natural thing whatever,—its virtue was the touch of the drawing-master. Without any kind of art-instruction, therefore, what was the secret of the success achieved? It was, as I conceive this: that the executive workmen were looked to as the sole means, individually, of producing the art result whatever it was. Any object of that date will evidence the fact that but one workman was employed on it. The object was commenced and completed, i.e., its artistic portion as a picture, by one art-workman. And that the object itself was the sole subject of interest; and, what is more than all, and is in reality the key to a new system of art-action, it was designed in material. It was all the very reverse of the present method. The art-action is now wholly expended on paper, and the object itself left to be manufactured,—no one looking at it or caring about it until it is too late to alter or amend,—until it is finished and ready for its destination. I consider, therefore, your remark to be capable of absolute and ocular demonstration; and if so, that it demands an entire change in our present complicated and costly system of art-instruction, whether supported by public money or the result of private efforts. It is, if you are right, both false and useless.

To those to whom this subject is new, a great deal of explanation and detail would doubtless be required to convince them of the necessity of organic change in the whole modern system of art-production, and this cannot be done within small compass. I can only hint at the means of change, and indicate, as you have done, its true direction. But as an additional proof of the correctness of your view, I need but repeat your other remark, in which I entirely concur,—that the withholding the promised prizes for the wood-carvings, by the Architectural Museum committee, did not meet with your concurrence. How unfair this! We are all now, to a man, engaged in the indication on paper of what is to be, and in afterwards knocking the object together anyhow by the modern system of manufacture, wherein one man is appointed to undo what his predecessor in the work has already done. In cabinet painting only do we ever see what the artistic power of the time can do; and now we are beginning a great change—we are asking for the signature of our common and unlettered and untaught workmen. They give us their handwriting, rough and ignorant as it is, and it is simply and rudely thrown aside as worthless rubbish! I have been many years at this work, and I protest against this injustice and this unkind rudeness. I have no hesitation whatever in saying, that some parts of the panels exhibited, especially in the details of the foliage, and even in some signs of animal life

shown, Ghiberti himself need not have been ashamed of. Such work, as a whole, is new, as I take it, beyond the power of our Academician sculptors; they would only succeed in bits here and there; they could not rival the past: how much less a workman with every modern art, influence, and help flying away clear past him, and missing, as it does, both him and everything else capable of affording a practical art result? More might be said. I agree with your dictum.

You say, further on, that lectures are good things in their way, but not enough,—"there must be actual practice in the studio and workshop." It is in this short sentence that I think the workmen themselves will in the future have good cause to thank you for showing them the way; but they must demand it, and perhaps plead for it. It is in the workshop and the studio, and, I would add, in our great public collections, that the workman must seek for help, and must practise the fine art of his trade. The whole of the present paper system of art-work must be abandoned before any material will consent to slow what nature it is of, and how the art power in humanity can impress itself, and become visible either to the artist-workman's own eye or to other men's. It is pitiable to think of the cost to the public of our museums, and the little good they are doing, or can do, as things now are. In place of the dull and stupid school-room and the worthless reams of paper and cardboard wasted in them, the artists and workmen of to-day must be encouraged to seek instruction and help in the museums and in the midst of their collections of fine-art handwriting. And each artist and workman must be led to express himself in his own individual way in material inspired by the works about him. This but once commenced, we shall soon see the value of the individual experiment of it; and, perhaps, in time look down on those who now as art capitalists are so unrighteously using this art faculty at second-hand and without acknowledgment, and reaping from the toil of others both wealth and fame—wealth from the work of their hands, and fame from the work of their brains. It is only public ignorance that permits this, or can perpetuate it for another hour.

I must, therefore, again repeat that I think your remarks at the Society's meeting were most valuable, and that they should be acted on and enforced; and it is to help in this that I have ventured to trouble you with this letter.

C. BRUCE ALLEN.

ARCHITECTURAL INSTITUTE OF SCOTLAND.

The following abstract of the treasurer's accounts with the Architectural Institute of Scotland, for the year ending 31st of October, 1864, is given in the report just published:—

CHARGE.	
I. Balance in account with British Lincen Company's Bank at close of last account	2100 10 8
II. Annual subscriptions for 1863-64, received	88 4 0
III. Arrears of former year's subscriptions received	3 3 0
IV. Interest on account with British Lincen Company to 15th April last	3 6 10
V. Special fund for endowing a Chair of Architecture, consigned in British Lincen Company's Bank, dated 31st October, 1863	£10 14 8
Interest thereon to Oct. 31, 1864	0 15 3
VI. Miscellaneous receipts	20 0 11
Balance due to Treasurer at Oct. 31, 1864	6 0 0
	2233 4 11
DISCHARGE.	
I. Balance due to treasurer at close of last account	£17 1 1
II. Rent, taxes, &c., paid for rooms	26 10 0
III. Expense of prizes	15 9 0
IV. Expense of lithographs of Roslin Chapel	49 8 0
V. Accounts paid for printing, advertising, &c.	
1. Printing	£21 0 0
2. Advertising	1 6 6
3. Books, stationery, &c.	2 0 0
	23 3 0
VI. Miscellaneous general expenses: including expenses connected with meetings, insurance, secretary and treasurer's outlays, postages, carriages, and expenses of collections	32 2 5
VII. Amount in deposit receipt of British Lincen Company, on account of fund for endowing a Chair of Architecture, dated 31st October, 1861	20 9 11
VIII. Balance in British Lincen Company's Bank at 31st October, 1864	59 1 6
	£233 4 11

Mr. Miller having resigned the office of honorary secretary, Mr. John Fleming Rodger has undertaken the duties.

A general meeting of the Institute was to be held on the 12th inst., "To consider the question of a site for the Scottish Memorial to his late Royal Highness the Prince Consort; and, if need be, to memorialize the Royal Committee of Advice on the subject."

THE BIRMINGHAM ARCHITECTURAL SOCIETY.

On the 4th, the members of this Society commenced the business of the year by a dinner. The chair was occupied by Mr. Thomson Plevins, president of the Society, and there were also present Messrs. A. B. Plippson (vice-president), J. H. Chamberlain (hon. secretary), J. R. Botham (treasurer), J. G. Bateman, J. G. Bland, J. A. Chatwin, J. Cranston, B. Corser, W. Harris, E. Holmer, W. Martin, T. Naden, C. J. Newey, F. B. Osborn, E. J. Payne, H. Yorville Thomson; and J. T. Bruce and Allen E. Everitt, honorary members.

The President, when proposing the toast "The Birmingham Architectural Society," read an address, in which he named Mr. Botham as the founder of the society.

"For the information of those who, like myself, did not belong to the Society in the early years of its existence, it is perhaps well for me to notice that it was started in 1851, and when I tell you that immediately upon its foundation twenty-one gentlemen became members, and that at this period the number of architects practising in Birmingham was only about twenty-six, you will agree with me that it was started under most favourable auspices, and that many thanks are due to Mr. Botham, and those who worked with him. When the Society was formed it had in its ranks a majority of the profession, and its conductors, therefore, fairly represented the views of the architects of the town. But since then its position in this respect seems to have altered, and now, although knowing an I do, that amongst us some of the most respectable members of the profession, yet, seeing so many as worthy not in our Society, I cannot flatter myself that the meetings of our little unexceptionable body have so much influence as they should have, either with the profession generally or the public."

"One good result which I hope for, in connexion with the extension of his Society, is an understanding amongst all the respectable members of the profession, as to the uniformity of percentage for certain work, and a conviction in the minds of the public that it is not even to their interest to pay less. The profession to which we have the honour to belong is certainly deserving of more consideration than the public sometimes accord to us; for I do not hesitate to say that many of our members would far rather sacrifice their own interests than those of their employers; but this high state and honourable feeling have only been cultivated, and can only be perfected by the public generally treating architects as they deserve to be treated—with consideration and confidence; as men having a reputation at stake and an independent position to maintain."

The toast was duly acknowledged by Messrs. Chamberlain, Bateman, and other gentlemen. The various speakers strongly urged the importance of reviving the Society, widening its basis, and including amongst its members the leading architects of the district as well as of the town.

SOME OF THE CAUSES OF LONDON FIRES.

A CAREFUL inquiry into the causes of those conflagrations which in both the day and the night are constantly alarming some part of the metropolis, would discover curious results, and would show that with carefulness and better management a large percentage of those calamities might be avoided. We will now, however, just glance at a few of the chief means by which property of enormous value is annually consumed, and not a few lives are lost, in the capital alone. In warehouses there is the risk of spontaneous combustion, in consequence of the careless packing of goods; the storing of highly inflammable and other matters in places of such huge dimensions that when a fire once gets head the separation walls are insufficient, and, in spite of the exertions of the firemen, destruction spreads from one range of warehouses to the others, until the whole range of premises is destroyed. This has been shown in a remarkable manner in the great fires at Alderman Humphrey's wharf, London Bridge, and the more recent conflagration at Dock-head. The writer has often heard the late lamented Mr. Braidwood express his opinion very strongly respecting the danger of large interiors for the storing of goods; and the truth of his opinions in this respect has been borne out on several occasions, especially on that when his valuable life was lost. The leakage and explosion of gas are also a prolific cause of London fires. Many accidents of this kind have occurred in drapers', milliners', and other shops of this description; and it is not likely to be known how many mysterious fires are to be attributed to the spontaneous and

accidental lighting of lucifer matches. In the  
 of summer, in over-heated workshops,—  
 on by the falling of a lucifer match, or a box  
 them, from a mantel-piece, or by children  
 lying with them, and other causes,—many  
 accidents occur. We remember a case of fire  
 which was attributed to the firing of lucifers by  
 means of the concentration of the sun's rays  
 through one of the old-fashioned bulls'-eyes  
 window panes of glass. If we could get a cor-  
 rect estimate of the value of the property  
 which has been thus destroyed, it would show  
 surprising figures. Chimneys and flues are  
 not a source of mischief, especially where care  
 is not taken in the cleansing of them. Fire-  
 brick and lucifer-match manufactories, which  
 should not now be allowed to remain in the  
 metropolis, add to the chapter of accidents;  
 does the drawing of turpentine, camphine,  
 and such-like articles, at night-time or in the  
 day, in dark cellars, &c., where candle-light is  
 used. Nine out of ten of those fires might be  
 prevented by the use of proper lanterns. In the  
 London oil-shops gunpowder, even for the blowing  
 up of copper-holes, is not sold after the gas  
 is lighted: some such provision would be useful  
 in connexion with the sale of other dangerous  
 articles. Servants, children, and others often  
 carelessly place lighted candles in cupboards or  
 under shelves, and, forgetting where they have  
 put them, the woodwork takes fire. Drying  
 clothes in front of the fires of tenement  
 dwellings is a cause of damage, as is the  
 arrangement of stoves for glue-melting, care-  
 lessness in casting about shavings, the smoking  
 of lighting of tobacco-pipes, the use of candles  
 without lanterns in stables and the stores  
 of cord-chandlers, &c., &c. We have known  
 two or three fires to have occurred in conse-  
 quence of placing hot ashes in the dust-heaps  
 adjoining premises. Crinolines have added to  
 the number of fires, and been the means of the  
 loss of life and property. The cause of many  
 accidents which occur about rent-day, or where the  
 premises are well insured, will for the most part  
 remain amongst the mysteries of London.  
 It would be well if the stacking of immense  
 quantities of wood in populous neighbourhoods  
 were prevented. Some of the largest of the  
 London fires have occurred from this cause. In  
 connexion with this matter much remains to be  
 done in the arrangements needful for the public  
 safety.

SANITARY MATTERS.

**Stamford.**—Scarlet fever is very prevalent in  
 Stamford at the present time, chiefly on the  
 left side of the river. In one house in  
 Water-street, one day last week, three of a  
 family named Ingram lay dead, and two others  
 were in a dangerous state. The village of  
 Bingham is also suffering severely from fever.  
**London.**—The town council have unanimously  
 resolved—"That a committee of three, together  
 with the corporation surveyor, be formed for the  
 purpose of obtaining all necessary information  
 which has for its object the improved drainage  
 of the city; and for this purpose the committee  
 authorised to go and inspect works in other  
 places where the drainage has been improved,  
 and ascertain the expense which has been in-  
 curred in forming them, and carrying them out,  
 and report to this council on the subject; and  
 that the following persons form the committee:—  
 the Mayor, Alderman Foster, and Mr. Doughty."  
**Great Ormesby.**—For eight months or so past  
 this parish has been scourged with diphtheria.  
 During the hot weather fourteen deaths occurred  
 from this cause among 800 inhabitants. Since  
 then there have been many cases, though for-  
 tunately not fatal. Now, however, this disease,  
 in its most malignant form, has reappeared in the  
 baby part of the parish called Wapping.  
**Bury.**—Malignant fever is reported to be very  
 prevalent at Bury at present. Two or three  
 persons in a house have, in some instances, been  
 carried off by it. One of the measures taken by  
 the authorities was to send the bellman round  
 the town, directing the people, among other  
 things, to keep their children in the house at  
 night, as a precautionary step. The precise  
 reason for this is not stated.  
**Houcester.**—The number of registered deaths  
 in this city, during 1863, including those in the  
 public institutions, amounted to 1,066, being at  
 the rate of 29.54 per thousand of the population,  
 and 4 deaths in 24. The average number of deaths  
 in a annum, for the last twelve years, has been  
 1,065.16, being at the rate of 20.28 per  
 thousand, the average rate of England being

22.14 per thousand. The enormous excess  
 (9.26 per thousand) of the death-rate of 1863  
 over the average annual death-rate is attribu-  
 table to the epidemic of scarlet fever, which  
 raged with great severity during the year, and  
 caused the deaths of 192 persons. The deaths  
 of children under five years of age amounted to  
 61.13 per cent. of the mortality at all ages. For  
 the last five years the average annual mortality  
 had been at the rate of 37.89 per cent.

THE UTILIZATION OF SEWAGE.

The Local Board of Health at Tamworth  
 have awarded to Mr. J. S. Benest the first  
 premium for his plan for works to utilize  
 the sewage of that town. The plan is as fol-  
 lows.—The whole town is drained into one  
 culvert, deep enough to intercept all the smaller  
 sewers. This culvert is carried beyond the town  
 to a point sufficiently distant to cause no nu-  
 isance to house occupiers. It there discharges  
 into one or other of two reservoirs, or tanks, one  
 of which fills while the other is being deposited  
 and emptied. When deposition has taken  
 place,—and it does so very rapidly,—the liquid  
 will be conveyed away by pipes, and spread over  
 the adjacent meadows. The thick deposit which  
 remains in the tank will speedily become so hard  
 that it may be carted away as ordinary farm-  
 yard manure.

The Bill which is about to be brought in by  
 Lord Robert Montagu will probably contain the  
 following permissive powers:—

1. It will extend to England, Ireland, and Wales, and will give increased powers to towns for the utilisation of sewage and its application to land.
2. Power to acquire land by means of loans raised by mortgage of the rates.
3. Power to carry sewers and other ducts under and across roads, railways, and private lands.
4. Power to sell sewage to companies and others.
5. Power to advance capital, or to grant mortgages on rates to companies or persons contracting for sewage.
6. Powers to take forebears and waste lands for reclamation.
7. Powers to the Crown, &c., to grant leases of land.
8. Prescription on reasonable terms secured to local husbandmen.
9. Power to take up Government loans.
10. Power to enable local authorities to combine for joint outfall and other purposes.

The Bill will also probably contain the following  
 prohibitory clauses, chiefly with reference to  
 the purification and conservation of streams  
 and rivers:—

1. Water-ward Boards to be appointed for the conservancy of rivers.
2. The constitution and representation of local jurisdictions, &c., to be locally determined.
3. The Water-ward Boards to make by-laws to bind Boards of Health and other local authorities.
4. Power to remove obstructions from rivers and outfalls.

SEWAGE AS MANURE.

Sir,—I observe the paper on sewage in a solid form in  
 the *Builder*. I pointed out a year ago that might be, and  
 was (on a large scale), put into a solid form for carriage  
 when collected; and also, how it might be collected fit  
 for the purpose.

This you thought a return to the "night-stool system"  
 of France. It is indeed no such thing. The intercepting  
 vessel may be outside the house; it may be in the drain  
 beneath the ground. And I believe yet, when the bubble  
 of making use of liquid sewage has been blown big  
 enough to burst, that the best way of securing and using  
 the solid matter in its best state will come to receive the  
 notice it deserves.

I still say, that for all public buildings the new system  
 now practised in several towns of France, Italy, and Bel-  
 gium, is quite and easily applicable.

Private houses are another consideration, more diffi-  
 cult, doubtless. Jas. EDWARDS.

\* \* We are sorry to differ from our correspondent;  
 but our objection to the system of retention advocated  
 remains in full force.

"PLEASANT APARTMENTS"

Sir,—My attention has just been called to a paragraph  
 in the *Builder*, headed "Pleasant Apartments in Pad-  
 dington," which contains a very entertaining description  
 of an underground dwelling in North-street. The writer  
 concludes by suggesting the expediency of a sanitary in-  
 spection. In order that this state of things may be  
 brought under the notice of the proper person, I beg to  
 state that North-street is not in Paddington, but in Mary-  
 lebone. J. BENSON SANDERSON, M.D., F.R.C.P.,  
 Officer of Health for Paddington.

THE CHIEF CLERKSHIP IN THE CITY ARCHITECT'S  
 OFFICE.—The candidates for the office of  
 principal clerk in the architect's department,  
 Guildhall, so far as we have heard, are these:—  
 Mr. T. Baker, who has been an assistant in the  
 office for some years; Mr. C. Bailey, of Grace-  
 church-street; and Mr. C. L. Eastlake, of Upper  
 Berkeley-street West.

OUR HIGHEST SPIRES.

ST. JOHN'S, BURY ST. EDMUNDS.

As Mr. Denison, in his interesting statistics  
 respecting our cathedrals and largest parish  
 churches, has named among the "highest spires"  
 two which are less than 160 ft. high, perhaps  
 you will allow me to claim a place in the list for  
 the spire of St. John's Church, Bury St. Edmunds,  
 the height of which is 160 ft. to the top of the  
 stone cap, or finial. (It has no weather-cock.)

The construction of this spire renders it es-  
 pecially worthy of mention, as, with the exception  
 of the finial and stone ribs at the angles, it is  
 entirely built of Suffolk white brick, together  
 with its eight pinnacles and flying buttresses.  
 The same material has been used throughout the  
 church, even to the deeply-moulded ribs of the  
 arches and capitals of the pillars, the stylo being  
 Early Pointed. In giving 160 ft. as the height  
 of the spire, I follow an account of the building  
 published at the time of its consecration (October  
 21, 1811). In the architect's plan it was 165 ft.

C. J. GEDDE.

LINCOLN CATHEDRAL.

On several occasions comments have been  
 made in our columns on the mode in which the  
 works have been carried on about Lincoln  
 Cathedral. In reply to these and other floating  
 objections, apparently, a semi-official statement  
 has been made in the local papers. It says  
 the works at the west front of the Cathedral  
 are to be cautiously proceeded with under the  
 advice of the same architect, Mr. Buckler,  
 of Oxford, who has been employed for many  
 years by the Dean and Chapter, and who has  
 sanctioned and directed what has hitherto  
 been done. Mr. Buckler had been desired care-  
 fully to inspect the whole, and he declares him-  
 self fully prepared to justify what has been done.  
 What is now being done is to collect the remains  
 of the old columns removed so long ago, and  
 copy them in the minutest details in Lincoln  
 stone (the original material), in order to replace  
 the columns of Yorkshire grit; and at the same  
 time to put in fresh pieces in those parts of the  
 Norman doorways which are absolutely perishing  
 from age, these parts being also copied by the  
 masons employed. This done, the question was  
 whether the new joints thus necessary to be  
 inserted, unless the whole were to become a ruin,  
 should remain a piece of patchwork, or whether  
 the "scum" of age should be carefully removed  
 from the old work that remains. Mr. Buckler  
 affirms that it is a peculiarity of the Lincoln  
 oolite, unknown to architects who have not  
 employed it, to become coated with a hard sur-  
 face which preserves it, and that all that is done  
 at Lincoln is to remove the black sooty matter  
 by which this surface is overlaid. This is done  
 by first wetting the stone with water from a  
 bush, and then taking off the black with a  
 small tool, without either mallet or hammer,  
 leaving the tool marks of the old Norman work-  
 men. Not even this process, it is said, has been  
 or will be applied to the Norman carvings.

FEVER CASES.

In the last report of the Registrar-General,  
 ninety deaths from typhus fever in the week,  
 are recorded in the metropolis; eleven of these  
 in the Greenwich district, which contains Dept-  
 ford and Woolwich; and "eighteen deaths from  
 typhus were recorded in Islington West," in  
 which sub-district the London Fever Hospital is  
 situate. But for the knowledge that this useful  
 and extensive hospital was situate in West  
 Islington, the number of deaths would be  
 startling, and reflect discredit upon the sanitary  
 state of this district. It is, however, not always  
 that in the Registrar's report reference is made  
 to the Fever Hospital as a means of increasing  
 the death-rate from fever in this locality; and  
 many persons even in Islington either do not  
 know, or else forget, that the hospital to which  
 the most serious fever cases are brought from all  
 parts of the metropolis is in their neighbour-  
 hood. We have before referred to this, and  
 suggested that in order to arrive at a truthful  
 record of the deaths from zymotic diseases,  
 which will show the sanitary condition of dis-  
 tricts, that the deaths which occur from fever  
 in such hospitals as this should be accredited to  
 those parishes from which the cases are taken.  
 Some time since we made inquiry, and found  
 that the cases treated in this hospital were

brought from all parts of the metropolis, some of them from long distances; and a reference to the books of the hospital which record the names, places of residence, and other particulars of the patients treated there, would be a useful indication to spots which require sanitary improvement.

We read of eleven deaths from typhus in the Greenwich district, and, it would perhaps be found on inquiry that some of the eighteen persons who died from typhus in the hospital were brought from the same locality. Whether this may be so or not in the present instance, it is clear that West Islington should not be charged with the cases brought from elsewhere. We say this, although well aware of the extensive operations of the Registrar-General's office; and that it must cause a considerable amount of extra labour to introduce new divisions in the death reports. But, in a matter of this kind, we should not spare labour or even extra expenditure.

#### HOW WE MANAGE OUR ROADWAYS.

For months Long Acre was passed through with difficulty by reason of the new sewers that were being tunneled for and built. At last, however, the heaps of earth and elevated windlass here and there disappeared, and drivers thought it all right again. So it was for a few weeks; when down came fresh invaders with enormous iron pipes, and the ground was again broken up, the traffic interfered with, the trade of the shops injured. The pipes have been buried and the men have departed; but will the thoroughfare now remain open, the business of the district go pleasantly on? Not a bit of it. Look at the condition of the roadway: the surface is destroyed, a passage over it is dislocating. An army of paviers must be called into action again to block up the roadway, and by the time they have restored the paving, an underground railway, a pneumatic despatch tube, or some new gas pipes will be ready for laying. And so we manage our roadways!

#### NEW CEMETERY FOR ASHTON AND DUKINFIELD.

THE Corporation of Ashton-under-Lyne, and the Local Board of Dukinfield, have united in the purchase of about 38 acres of ground, for the formation of a joint cemetery. The land was formerly a park, belonging to "Dukinfield Lodge," and in the days preceding the erection of cotton-mills, was a very delightful locality. It occupies an elevated position above the banks of the river Tame, and the cemetery, when laid out, will be a prominent feature in the surrounding scenery for miles. The works have been entrusted to Messrs. Pannell & Ayliffe, of Manchester, architects, whose designs for the buildings and the laying-out have been formally approved. It is intended to employ distressed operatives on the earthworks, &c., and application has been made for a loan, under the Public Works Act.

The proposed outlay, exclusive of land, is about 17,000l.

#### THE BUILDING TRADES MOVEMENT.

THERE is great commotion amongst the operatives as to the "discharge-note," as the Master Builders' Association calls it, or the "ticket-of-leave," as it is called amongst the men. In Birmingham about 800 carpenters are on strike; in Coventry about 400 men, comprising all branches; in Walsall, about 400 of all branches; in Nottingham, about 700 ditto; in Malvern, about 100 ditto; and about 1,000 in other towns of the midland counties. In the meantime several meetings of the masters have taken place, and the subject of the "note" is understood to have occasioned warm and angry discussion. Some influential masters say they think it quite necessary that there should be a masters' association, to aid as a check upon the combinations of the men, but consider the "discharge-note," as proposed by the Birmingham executive of the association, an un-English weapon of warfare, to which they are entirely opposed. In the face of the opposition of the men, and the disapprobation of many of their own members, the Association will do well by at once abandoning the "note."

At Hull the subject of the "note" has been warmly discussed by the men, who have formally

and unanimously protested against it, and resolved to support the men now out in opposition to it in the midland counties.

The carpenters and joiners of the Potteries and Newcastle-under-Lyne have published an address to the members of the Master Builders' Association, in which they declare that they have a desire to prevent the recurrence of unjustifiable strikes and combinations, and, for the sake of peace, request the Association to abandon the "discharge-note" which they have agreed to adopt, and to consent to a conference for the formation of a code of laws for the regulation of the trade.

It seems to be not merely unionists but non-unionists, also, who have resolved in many cases to resist the introduction of the "note," so that the unions are likely to be greatly strengthened by the threatened measure; and what looks no less serious as against the masters, is the fact that the disinterested feeling of the press appears to be everywhere against the "note."

The operative joiners in Nairn, Scotland, have petitioned their employers for a rise of wages. Their present wages for a week of sixty hours is only 16s.; and, as this amount is much below the general average in Scotland, they desire an advance of 2s. per week, and also that a regular pay-day be observed.

At the Warwick Quarter Sessions on Thursday, two brickmakers, named Stone and Gregory, were each sentenced to fourteen years' penal servitude for killing three and stalling four horses, the property of Messrs. Lewis, brick manufacturers, at Aston. It seems that Messrs. Lewis had determined not to employ any men belonging to the trade union, and the destruction of the horses is supposed to have resulted from this decision.

#### FROM SCOTLAND.

*Edinburgh.*—The town council and railway companies meeting there have under consideration a scheme for a great central station at Waverley Bridge, but nothing definite has yet been decided. The scheme, which seems to have originated with the council, is of a very comprehensive and rather costly character. It embraces the removal of the present Waverley Bridge, its place being supplied by a new bridge—probably of iron.—The statue of Professor Wilson is now ready, and a general meeting of the subscribers was held on Monday last, at the Messrs. Blackwood's, to receive the report of the committee, and to make arrangements as to the inauguration and future preservation of the statue. Dr. Robert Chambers, as secretary, read the report, which stated that the bronze statue was now finished, and the pedestal nearly completed, and that an early day might be named for the inauguration. Several gentlemen present remarked that Mr. Steel had succeeded in producing a striking likeness. It was remitted to the sub-committee to make the necessary preparations for the inauguration, which will probably take place on an early day in February, and on the same day as the inauguration of Mr. Steel's marble statue of Allan Ramsay.

*Glasgow.*—At the present moment, according to the *Citizen*, eight churches are in the hands of the builders here, and rapidly approaching completion; and if to these be added the churches opened within the last eighteen months, there is a total of eighteen added within the last two years to the number of churches in Glasgow, and at a cost of nearly 100,000l.

*Dundee.*—A deputation from the directors of the projected Albert Institute had a meeting with the town council to submit the plans of Mr. G. G. Scott, architect, for their approval. Mr. Baxter stated that it was Mr. Scott's opinion and that of the directors, that the Institute, if erected in the centre of the ground purchased (at a cost of 8,050l.), would prevent the Royal Exchange from being seen from the top of Reform-street. The plan showed the best position for the new building. From Mr. Scott's last communication to the directors, it appeared that his estimate for the great hall and the library together as shown on the plans—that is, for the main portion of the building fronting the west—was 8,400l.: for the corridor division—the portion of the building which it is proposed should front the north, consisting of the circular staircases, and the corridor—his estimate is 3,000l.: for the committee-room division—that which fronts the south, consisting of a variety of

rooms above and below—his estimate is 3,000l. His estimate for the external staircase is 1,100l., and for the ornamental spire 700l. The total estimate for the work, which includes the expense of piling, is 16,500l. The portion which is to be appropriated for the public library is on the ground-floor of the great hall section of the building, and the estimated cost of that will be 4,400l. As there was not at present sufficient money for the completion of the whole design for erecting all the buildings, the long building behind for the picture galleries and museum was abandoned in the meantime. It was proposed to take estimates for the work in sections,—for the great hall, the corridor, the committee-rooms, and other accommodation, and the external staircase. The subscribed funds up to this time amount to 23,260l. The council at a subsequent meeting unanimously approved of the plans, as amended.

*Wick.*—The new Free Church here, recently opened, is in the Perpendicular style, from a design by Mr. Gray, of Berwick, architect. The front elevation looks into Bridge-street. It is divided into three compartments. In the middle compartment there is a large central window of five lights, with pointed tracery; in the interior it is in great part concealed by the gallery. From the street view, however, this arrangement detracts nothing, as the windows are all filled with corrugated glass, not seen through. On the north or right-hand compartment the front elevation stands the tower and spire, supported by diagonal buttresses, surmounted by crocketed pinnacles. The spire is angle-ribbed, and terminates in a sculptured finial, surmounted by a gilt copper cross and spear. The entire height of the spire from the foundation is 123 ft. From the position of the building, situated between the walls of adjoining houses, the front and spire are the only parts visible from the main street. The front measures 63 ft., and the length of the building backwards is 90 ft. The front is all built of Burghhead freestone smooth-dressed. Messrs. Dunbar had the contract for the joiner work; the building contract was executed by Mr. Williamson; and the hewn work was done by Messrs. Hood & Henderson. The plumbwork was executed by Mr. Johnstone.

#### Books Received.

"Hardwick's Science Gossip: Hardwicke." This fortnightly monthly is intended as a medium of interchange and gossip for students and lovers of nature. The first number only is out. It has an extensive field of subjects, and ought to interest a very numerous class of readers. The "Gossip" in this first issue is zoological, entomological, piscicultural, botanical, geological, microscopical, &c.; and it besides contains little papers on the Viper or Snake (illustrated); on Duckweeds (also illustrated); and on several other subjects, as well as reports of societies, notes and queries, &c.—The *Dublin Builder* has commenced the new year with vigour. The first number contains a lithographed view of Whitworth, Drogheda; architect, Mr. Burre, of Belfast.—The principal papers in the current *Gentleman's Magazine* relate to ancient monuments. The first is an account of the curious ancient slab which stands on the north side of the churchyard of Kirk Michael, in the Isle of Man, by the Rev. Dr. Dodds.—"The Garden Oracle and Floricultural Year-book, 1865. Edited by Shirley Hinder, F.R.H.S., author of 'Rustic Adornments for Homes of Taste,' &c. London: Groombridge." The present issue is the seventh of this useful garden book. A leading feature of it this year is a list of stove and green-house orchids, arranged to exhibit certain kinds in bloom every day throughout the year. This is accompanied with hints to beginners in orchid culture, which seems to be likely to become the next popular mania that will follow in the wake of the aquariums and fern-cases.—"The Land and the Agricultural Population. Arundel: Mitchell, West Sussex Gazette Office." In 1863 Messrs. Obden and Bright delivered speeches at Rochdale which the newspapers discussed, from the *Times* downwards. In the questions of entail and primogeniture, and parish settlements, brought forward in these speeches, the *West Sussex Gazette* took part, and the pamphlet under notice is a reprint of the correspondence published in this paper on the subject.—"The Concentration of the Courts and Offices of Law in London." The council of the Association for the Promotion of Social Science conceives this sub-

ject to be one of such great national importance that it resolved to address the members of both branches of the legislature, the municipal corporations of England and Wales, and the chambers of commerce, in connexion with the Association, as well as others, upon it, in the hope of exciting sufficient attention and interest to secure the acceptance, in the ensuing Session of Parliament, of the two bills which the Government have announced their intention of bringing forward for the fourth time. The pamphlet under notice is issued by the Law Amendment Society, in connexion with the Association, and one of the chief purposes in view is to show that the present condition of our courts and offices of law is not to be looked at as a professional grievance, but as a source of serious injury and loss to all suitors, and therefore detrimental to the value of all property; and that the proposed remedy will not add to the public burdens.—“The Brown Book” (Samders & Outley) has been improved by the adoption of the suggestion we made last year,—the addition of the artistic societies. The Art Union of London should be added to those given, and in the list of benevolent societies the Newspaper Press Fund should appear.

Miscellaneous.

ANOTHER CHURCH DESTROYED BY FIRE.—(Dipton parish church, midway between Great Yarmouth and Lowestoft, was destroyed by fire on Sunday. It was partially insured. There was no loss of life.

THE WEST CHURCH, GREENOCK.—To give credit where credit is due, we would add to our little notice of this church in our last intimation that the carving about the pulpit and elsewhere was executed by Messrs. Roddis & Grassly, now settled in Glasgow.

LIVERPOOL ARCHITECTURAL SOCIETY.—At last week's meeting of council a letter was received from Mr. Charles Herdman, secretary of the Liverpool Architectural and Archaeological Society, applying for the use of the Town-hall for a series of lectures in behalf of the Architects' Benevolent Society. The letter was referred to the finance committee.

THE LIVERPOOL BUILDING SURVEYORSHIP.—The special committee as to the office of building surveyor submitted a recommendation to the council that the salary of the officer to be appointed be 300*l.* per annum, and that Mr. G. H. Rollet be appointed to the office at that salary. Eventually a resolution was unanimously adopted, referring the subject back to the special committee for reconsideration.

RESTORING ENAMELS.—Mr. Hatfield, who is known as a worker in bronze, has been lately applying himself, and with great success, to the restoration of Chinese enamel work. We have seen two or three fine jars previously black, damaged and ugly in consequence, that have become out beautifully under his hands. He appears to work down the whole surface to the fine partitions of metal that divide the enamels, grinding the edges of these lines, and filling in with coloured composition where the enamel has been injured.

PROPOSED INDUSTRIAL EXHIBITION IN BRISTOL.—A meeting of delegates of trade and other societies, in Bristol, has been held, to consider the propriety of holding an industrial exhibition in this city. The matter has been taken up with spirit by the working classes, and several influential gentlemen have promised their aid. At the meeting a preliminary committee was appointed, to confer with the sub-committee of the Working Men's Club, and to attend a public meeting, to be held on the 1st of February.

SANITARY CONDITION OF OUR IRON SHIPS.—The *Caladonia*, iron-clad, has been docked at Devonport yard, and taken into the basin at Keyham, after having been in dock for several months past, getting her sides pierced for ventilation, and other arrangements made for the discharge of waste water. One cannot help expressing a little surprise that, while in the construction of our navy the minor details relative so much attention, this essential provision should have been overlooked, especially in iron-clad ships. It is said that in some vessels, particularly in passenger ships, the iron beams have been caued over with wood, with very great advantage to the health and comfort of the persons on board.

THE VOLUNTARY EXAMINATION, 1865.—The number of candidates who have sent in their applications for voluntary examination, this session, is three in the Class of Proficiency, and one in the Class of Distinction, which being less than that required by the printed regulations, no examination will take place in January, 1865.

WALTON SURVEYORSHIP.—At the monthly meeting of the Walton Board, the chairman stated that the committee appointed to consider as to the proposed surveyorship had made inquiries, and they had agreed to recommend one of the firm of Reade & Goodison, architects and surveyors, Liverpool. He understood that although they could depend upon the practical services of both those gentlemen, it was only necessary that one of them should be nominally appointed. The recommendation of the committee was approved of, and the name of Mr. G. W. Goodison was entered on the books as surveyor.

MEMORIAL TABLE.—Mr. S. C. Hall, during a lecture he recently delivered in Wexford, suggested to the people of that town that they ought to erect a marble slab in front of the house in Corn-market, where was born the mother of Thomas Moore, the poet. The idea was a good one; but the necessity for any joint action in the matter on the part of the people has been rendered unnecessary by the mayor, Mr. John Greene, J.P., who has put up the slab at his own expense. After stating that Mrs. Moore had been born in the house, the legend on the slab goes on to state that, on the 26th of August, 1835, the poet returned to it “in the zenith of his imperishable fame, to render homage to the memory of his mother, whom he venerated and loved.”

THE LAST-FOUND STATUE, ROME.—Contradictory rumours have been circulated with regard to the colossal statue found in the excavations of the Righetti palace. It is true that the *Ozar* offered 370,000 scudi for the piece, and other high personages followed suite; but it was an error to state that Signor Righetti, obeying a sentiment of patriotism, had offered it at half the above price to the Pope. The truth is that the spirited proprietor, from a feeling of patriotism, would not allow the statue to be sold to a strange country, so he simply and purely presented it to the Pope, who, not to be outdone in generosity, inscribed Signor Righetti on the civil list for an income of 2,500 scudi, representing a capital of 50,000 scudi. The Pope has also presented Signor Righetti with a superb gold snuff-box, and each of his children with a roulet of 1,000 scudi in gold.

THE LATE MR. BRASH, BUILDER.—Died at his residence, Monkstown, Cork, on New Year's day, Mr. William Neesham Brash, builder, aged fifty-four years. He deceased was, for a period of thirty-two years, one of the most eminent builders in the south of Ireland, and was greatly esteemed for the honesty and unflinching integrity of his character. He was a man of great practical knowledge and skill in every department of a business now too often intruded upon by men ignorant of its commonest details. The last works executed by him were the National Banks at Cork and Clonmel, and a large villa residence at Queenstown. On the completion of the first-named edifice, he was presented by the directors with a gift of one hundred sovereigns, as a testimony of their appreciation of the fidelity with which he had discharged his engagements to them. Mr. Brash had just retired from business, having realised a comfortable independence.

A NEW “SEVERN BORE.”—It is proposed, says the *Bristol Times and Mirror*, to tunnel under the bed of the Severn for a distance of three miles; and through this subterranean or rather sub-fluvial gallery to carry a railway, so as to connect the South Wales Union line with the Principality. The promoters and the engineer of the South Wales Union declare it can be effected, and, as the estimated cost, name 750,000*l.* It is argued that the nature of the soil is particularly favourable to the work, being a substratum of marl, with a roofing of red sandstone. It has a rival in another project, namely, a bridge to span the river from Aust to the Chepstow bank, to be two miles in length, and laid with a double line of rails. This structure is to be supported on piers, which, from sunken base to summit, shall be each as high as the London Monument, and with a span between each of 600 ft., the estimated cost being 1,800,000*l.*

THE SHEPHERD INUNDATION COMMISSION.—An important judgment has been given by the Inundation Commissioners on one branch of the numerous claims for consequential damages. The Court decided that the claim of a tradesman for damages in consequence of the loss of his customers, who had either been drowned or driven from the neighbourhood, could not be sustained. The judgment has, in other points, an important bearing upon the construction of the statute. We may state here a fact which is equally creditable to the claimants and to the company—namely, that out of the total number of upwards of 7,000 claims, no less than 4,707 had been settled up to the 28th ultimo. Of this number, 1,500 have been settled since the previous sitting of the Court.

THE ARCHITECTS OF HALIFAX AND THE CORPORATION BUILDING BY-LAWS.—Recently, a meeting of the architects and land surveyors of Halifax was held on the subject of the new building by-laws of the corporation, and a deputation was then appointed to wait upon the corporation to lay their complaints before the proper authorities. On Wednesday the interview in question took place with the Improvement Committee. Among the architects composing the deputation were Mr. Councillor Nicholson, Mr. Horsfall, Mr. Bull, Mr. Jackson, Mr. J. E. Oates, Mr. Davis, and Mr. Booth. The objections of the architects and land surveyors to the new building by-laws, which were confirmed by the Home Secretary a few weeks ago, are, that a great many plans and copies of plans of intended new buildings and streets must be deposited with the corporation,—more, in fact, than are necessary. Next, the carrying out of the new by-laws will seriously affect the cost of the erection of second and third class dwellings, on account of the greater quantity of land required, and the increased thickness of the walls, &c. Again, an asphalt and gravel area to be crected for every cottage, and this, too, they consider unnecessary. Were those by-laws to be carried out, the cost of cottage property would, it is said, be increased at least 25 per cent. The committee promised to further consider the objections advanced.

TESTIMONIAL TO A RAILWAY CONTRACTOR.—A short time since, Mr. M'Henry, the contractor of the Atlantic and Great Western Railway, presented to the city of Philadelphia a battery of artillery of Whitworth guns. The friends of that gentleman in America now return the compliment in the shape of a testimonial, by American artists, which has been exhibited at Messrs. Hunt & Roskell's. According to the *Railway News*, it consists of a dinner, dessert, and tea service, composed of silver, richly chased and gilt; and there is with it a tall column of silver-gilt, round which there winds a spiral and continuous band from the base to the summit, and upon this is engraved the section of the 200 miles of the Atlantic and Great Western Railway, which were completed in as many days by Mr. M'Henry. Every cutting, and embankment, and bridge is shown upon a scale of 18 ft. to 200 miles, and there are engraven upon it 30,000 words and figures—some of them so minute as to require a microscope to decipher them. The summit of the column supports an allegorical figure of America. The cost of the testimonial was about 20,000 dollars. American artists, continues our authority, will not be displeased to hear that this eminent firm of English goldsmiths, so far from being actuated by any desire to depreciate the work, candidly declare that it is one of which they would have been proud to have been the producers.

RAILWAY MATTERS.—The line of railway to unite the London and North-Western with the South-Eastern at Charing-Cross is about to be commenced. It will be an underground line, and, indeed, will cross the present underground on the New-road, at Tottenham-court-road, on a still lower level. New streets will be formed in connexion with this line, as we have noticed on previous occasions, opening up the close streets between Oxford-street and the Strand. This will be the third line of connexion between the North and South of London lines, the three Thames bridges of connexion being Blackfriars, Hungerford, and Kensington.—The traffic receipts of railways in the United Kingdom amounted, for the week ending the 24th of December, on 11,732 miles, to 675,291*l.*, and for the corresponding week of last year, on 11,365 miles, to 612,748*l.*, showing an increase of 337 miles, and of 62,543*l.* in the receipts.

**THE LADIES' SANITARY ASSOCIATION.**—The seventh annual report of this excellent Association states that no less than 90,240 of their popular and useful sanitary and other tracts have this year been distributed amongst the poorer classes, making a total of 703,740;—a moral force which implies a vast extension of really public and popular opinion in favour of ventilation, cleanliness, sobriety, and many other domestic improvements. The lectures got up by the Association also cannot but be of very great importance towards the same desirable ends. The Ladies' Sanitary Association constitute a powerful auxiliary legion in the army of sanitary pioneers. Their benign and subtle influence gains access where no rougher and more masculine power can reach.

**ALARMING OCCURRENCE IN A LIVERPOOL THEATRE.**—An occurrence, happily unattended with serious consequences, but which shows the necessity of having ample means of egress from the places of amusement, took place last week in the Adelphi Theatre, Liverpool. The house was crowded, and an alarm of fire was raised. The greatest excitement immediately took place, and a large number of persons made for the doors. The crushing that ensued was terrific, and several persons were trodden under foot and injured. On order being restored, it was found that the alarm was entirely groundless, and that no fire had taken place.

**MONUMENTAL.**—Some time ago it was determined to erect at Derby a monument to the late Mr. Alderman Johnson, in recognition of his exertions in promoting improvements in the town. The monument has now been erected on the south-east part of the old cemetery. It is of marble, and is in the form of a Gothic memorial cross, on an hexagonal pedestal, with a moulded base elevated on a step. It stands in the centre of an oblong stone plinth covering the entire grave. The front face of the pedestal contains the inscription. The total height is 13 ft. Mr. Hall, marble cutter, designed and executed the work.

**PROGRESS OF BELFAST.**—In December, 1860, says the local *News Letter*, the total valuation of the town was 270,930*l.*, and in the following year 730 new buildings were erected, valued at 7,877*l.* In 1862 the new buildings numbered 840, but they were rather of a poorer class on the average, and the total valuation of them was but 7,618*l.* In 1863 no fewer than 1,260 new buildings were erected, the total valuation of which was 10,864*l.* In 1864 the new buildings numbered in all 1,403, or very nearly double the number erected in 1861, and the valuation is also nearly double, being 13,667*l.*

**VESTRY REPORT OF PARISH OF CHELSEA.**—The eighth report of this vestry, for 1863-4, under the Metropolitan Local Management Act, 1855, has been printed by order of the vestry. It is, as usual, a comparatively voluminous document, occupying, with the appendices, no less than 175 octavo pages. The medical officer's report states that fever, not unfrequently epidemic typhus, continued to prevail more or less throughout the year, though, on the whole, not of a malignant character. It generally seized the majority of the inmates of any house among the lower orders which it entered, and in the worst localities spread to several adjoining houses. The deaths attributed to fever, many of which were not typhus, numbered only 39, against 51 in the previous year. These returns, however, end in March last, and therefore do not include cases which have since occurred. Scarlet fever, measles, and whooping-cough carried off 179 children: the mortality from these causes in the previous year was 131. In all the ordinary forms of disease an increase was observed when the death-rate of the year was compared with that of the preceding one.

**HORTICULTURAL EXHIBITION IN AMSTERDAM.**—It is announced that a universal horticultural exhibition is to take place at Amsterdam in the middle of April next, when a congress of botanists and horticulturists will probably be held. All horticultural produce will be admitted, as well as all the industrial objects relating thereto. The prizes are to consist of thirty gold medals, of the value of 100 florins; ninety-two medals of fifty florins; 127 medals in vermell, eighty-four large and seventy-seven other silver medals, and money prizes to a considerable amount.

\* A Holland florin = 2/10 francs = 20/16 pence.

**DOING THE RIGHT THING.**—I mean to try to show, and believe I can show, that a simple and sure conviction of our having done rightly is not only an attainable, but a necessary seal and sign of our having so done; and that the doing well or rightly, and ill or wrongly, are both conditions of the whole being of each person, coming of a nature in him which affects all things that he may do, from the least to the greatest, according to the noble old phrase for the conquering rightness, of "integrity," "wholeness," or "wholesomeness." So that when we do external things (that are our business) ill, it is a sign that internal, and, in fact, that all things, are ill with us; and when we do external things well, it is a sign that internal, and all things, are well with us. And I believe there are two principal adversaries to this wholesomeness of work, and to all else that issues out of wholeness of inner character, with which we have in these days specially to contend. The first is the variety of Art round us, tempting us to thoughtless imitation; the second our own want of belief in the existence of a rule of right.—*John Ruskin, in the Art Journal.*

**A NEW CAB.**—We lately drew attention to the dangerous nature of the "safety cabs" called Hansoms. Since then we have heard of four-wheeled Hansoms, if they can still be so called. Whether the following, extracted from a Liverpool paper, be of this kind we do not know; but the notice shows that the subject is under the consideration of mechanical minds:—"Mr. Gorst, formerly a coachbuilder in Liverpool, has invented a new patent safety-cab, the principle of which is to facilitate the draft by the use of wheels of increased diameter, and to admit of the centre of gravity being lower than in ordinary vehicles. Mr. Jones, car proprietor, of Liverpool, has introduced a Hansom cih built by Mr. Findlater, of Birmingham, on this principle, which seats four persons, and has wheels 5 ft. 7 in. in diameter. The motion is very smooth and easy."

**TEMPERATE IMPROVEMENTS AT KNARESBOROUGH.**—The Rev. James Fawcett, vicar, at a tea meeting in the Town-hall, Knarborough, referred to certain objects which must be brought before the parishioners. He instanced the remodelling and enlargement of the present organ at the parish church as being a necessity, and the complete restoration of the church itself. At Trinity Church, he said, a letter approach was much needed. A paper was read on "Bells," by the Rev. H. Fawcett, in which he said that if the peal of bells at the parish church were not quarter-tuned, they would become seriously injured, judging from the deep indentation already made by the clappers in the parts where they strike. It is stated that the six o'clock bell is now half worn through: The value of the present peal, even as ordinary bell-metal, is upwards of 600*l.*

**METROPOLITAN BENEFIT SOCIETIES' ASYLUM.**—The annual treat to the inmates of this Institution, in the Ball's-pond-road, was given on Monday, when they were regaled with a dinner of good old English fare. The chairman, Mr. J. T. Slater, stated the Asylum had provided a home for 165 persons, of whom 34 now remained, and he was glad to say, living very happily. The Society had now 7,145*l.* capital invested in the Public Stocks. In proposing "The Friendly Societies of Great Britain," the secretary said that about 130 of those in the metropolis and neighbourhood subscribed, and he wondered that more did not see it to their interest to give the Institution substantial support, being for the benefit of their members only.

**TENDERS.**

For alterations and addition to Mr. Bowly's House, High-street, Swindon. Mr. Thomas S. Landow, architect:—

Hopkins	£50 0 0
Hobbs	548 0 0
Barrett (accepted)	530 0 0

For a new house and offices on the Kilrush estate, near Limerick, for Mr. Thomas Bevington. Mr. William Fogarty, Dublin, architect. Quantities supplied by Mr. E. P. Gribben. Amounts exclusive of plate-glass, chimney-pieces, and ironmongery:—

W. & Roberts	£5,500 0 0
Meade	5,195 0 0
Crowe, Brothers	5,000 0 0
Flunter	4,700 0 0
Ryan & Son	4,642 0 0
Scanlan (accepted)	4,340 0 0

For the erection of artist's studio, No. 83, City-road. Mr. Dennison, architect:—

Garrod	£293 0 0
Auley (accepted)	530 0 0

Accepted for the erection of farm buildings at Rudelife Hall, Shelfield, for Mr. John Brown. Messrs. Flockton & Abbott, architects. Thirteenth contract:—

<b>Mason's Work.</b>	
Wade	£1,200 0 0
<b>Carpenter's Work.</b>	
Gibson	£390 0 0
<b>Slater's Work.</b>	
Brown & Sons	£117 15 0
<b>Plumber's Work.</b>	
Harrison	£16 9 0
<b>Plumber, a Glacier, and Painter's Work.</b>	
Townsend	£110 10 0
<b>Smith's Work.</b>	
Ellis	£143 10 0

**Thilham Cemetery.—Contract No. 1.**

For erecting and finishing Episcopal chapel, Nonconformist chapel, entrance lodge, boundary wall, and piers. Mr. A. W. Blundell, architect. Quantities supplied by Mr. J. A. Banker:—

Kelly	£3,546 0 0
Smelling	3,196 0 0
Chamberlain	3,191 0 0
Turner & Sons	3,071 0 0
Wright	3,020 0 0
Harris	2,841 10 0
Eydmann	2,838 0 0
Adamson & Sons	2,790 0 0
Holland & Son	2,700 0 0
Robinson (accepted)	2,666 0 0
Palmer	2,643 0 0

**Contract No. 2.**

For laying out, draining, and planting. Quantities not supplied:—

Turner & Sons	£299 6 0
Armstead	420 0 0
Rutty	412 15 0
Peasey	395 0 0
Leeks	340 6 0
Ball	320 0 0
Clarke	319 0 0
Peasey	307 10 0
Neal	295 0 0
Cole & Co.	280 0 0
Robinson (accepted)	249 0 0

For wrought iron railings and gates. Quantities not supplied:—

Johnson, Brothers	£1,120 0 0
Smith	940 0 0
Hill & Smith	895 0 0
Robinson	835 0 0
Selden	790 5 0

For police station at Northcote, Kent:—

Higgins	£2,138 0 0
Naylor	1,811 0 0
Phillips	940 0 0
Norris	1,710 0 0
Chambers	1,700 0 0
Blake	1,635 0 0
Stamp	1,680 0 0
Gould	1,684 0 0
Ansecomb (accepted)	1,667 0 0

For the erection of a school-room, &c., Love-lane, Shadwell:—

Thompson	£787 0 0
Hall	684 0 0
Holmes	648 0 0
Stone & Pearce	650 0 0
Nagle	665 0 0
Palmer	610 0 0

For addition to schools, Hackney Union. Henry Norris, architect:—

Thompson	£1,200 0 0
Holmes	1,014 0 0
Harding	987 0 0
Nagle	903 0 0
Smyth	874 0 0
Sweeney, Brothers	867 19 6
Masters	849 0 0
Wood	839 0 0
Skinner	834 0 0
Stone & Pearce	823 0 0

We are compelled to decline pointing out books and giving addresses. All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender; not necessarily for publication.

**TO SUBSCRIBERS.**

The TWENTY-SECOND VOLUME of "THE BUILDER" (bound), for the year 1864, will shortly be published, price One Guinea.

CLOTH CASES for binding the Numbers are NOW READY, price Two Shillings and Ninepence. In ordering, it is necessary to state whether the Advertisements are, or are not, to be included.

A COLOURED TITLE-PAGE can be had, Gratis, on personal application.

SUBSCRIBERS' VOLUMES will be bound on being sent to the Office, at a cost of Four Shillings each.

# The Builder.

VOL. XXIII.—No. 1146.

The Designs for the Meat and Poultry Market, Smithfield.

ON September last, the Corporation of the City of London advertised for designs for the Metropolitan Meat and Poultry Market, proposed to be erected at Smithfield on a plot of ground, measuring 625 ft. by 240 ft., which is intersected by the line of the Metropolitan Railway extension from Farringdon-road. Premiums, one of 300*l.* and one of 200*l.*, were offered to the authors of two designs that might be selected. These premiums were to entitle the City to the copyright, but without any engagement on the part of the Corporation to carry out either of the designs, or to employ either of the authors in the execution of the works. The designs received have been exhibited at Guildhall, during a fortnight; but it does not seem to have been considered necessary that we should be informed of the fact.

The result to the Corporation, from the expenditure of 500*l.* in premiums, will hardly be the possession of a design that can be carried into execution. Only seven designs were sent in; and of these, two or three afford scarcely a suggestion in any matter of the arrangement or construction, and are indeed not to be considered as matured productions. The remainder of the designs, even, cannot be accepted as supplying a solution of the problem,—not a difficult one, comparatively,—of a meat-market; though, amongst them, one design at least has merit and decorative, and in a high degree. We think that the slight response to the offer of premiums must be taken as evidence additional to what we have noted of late, that competitors, at least those which are "unlimited," are becoming viewed with disfavour, as means of professional success. It is true that, in this case, there was no reason for an architect who might receive a premium to expect he would derive much further advantage, and that always the chance of benefit beyond a premium has been rated higher than it should be: it is however satisfactory to us to be able to believe that our professional brethren are beginning to see, not the general miscalculation on their own part, and on that of public bodies, promoters of competitions,—the question of which we do not care to argue,—but the necessity for stipulations to secure to themselves some advantage, as for example that which might be derived even by competitors not successful in gaining premiums, through an exhibition, managed as we have often explained, but as we have scarcely yet witnessed.

The seven designs submitted to the Corporation of the City, in answer to the advertisement, have, owing to their small number,—but, to that circumstance alone,—been tolerably well seen by those who could procure cards of admission. Some of the two rooms over the Comptroller's Office, where the designs were hung, is hadly lighted; little publicity was given to the exhibition; and the motto-system being adopted, a last

chance of benefit to the majority of competitors was denied them. Credit must be given to those who managed the competition, for having worded the "Instructions" so as to leave scope for suggestions, and also for having printed the competitors' particulars of their designs. The "Instructions," of necessity, stipulated for attention to certain conditions, chiefly arising from the relative positions or levels of the intended market and the railway. The shops and avenues, and the general structure of the market,—the floor-line to be 3 in. above the paving surrounding the building, or 5 ft. 11 in. above Trinity datum,—will have the railway as a haemorrhage; and openings will be left in the flooring of the market, at about a dozen points, already fixed,—and that very irregularly as to the whole area,—for the hoists required for raising the meat from the railway, for the ventilation of the railway, and for stairs for the passenger-traffic connected with the market. The "Instructions" also directed that a central roadway, 50 ft. in width, from north to south, that is on the transverse axis of the ground, covered over, should be preserved. One-sixth of the total area was to be reserved for the poultry-market. The markets and roadway were to be well lighted, and protected from the sun. No part of the main building was to be less in height than 30 ft.; and provision was to be made for flushing, for heating the shops, and for some other requirements. Cement and soft stone were to be avoided.

It is curious that whilst one or two of the competitors refer to the Halles Centrales of Paris, none of them appear to have noted the exact features of those structures, unless for the purpose of a deviation and on the hypothesis that there is a difference, greater than in fact exists, between the climate of London and that of Paris. As to humidity, and clearness of the atmosphere, there is great difference; but as to heat and cold alone, there is none that needs much attention; and the precedent of the Paris markets may be fairly taken without deduction or modification. It so happens that the first-built *pavillon* of the Paris markets, was for the meat-salesmen; and that, there, a structure with solid walls, and considerable decoration in masonry, was found quite unsuitable,—so that it has since been removed. Now, the new *pavillons*, though not all for hutchers' meat with poultry, are little more than sheds, connected with wide roadways and avenues that are roofed over at sufficient height to allow of clerestories; but the whole external enclosure of the market, or *pavillon*, is constructed with a large area of louvres or other provision for ventilation. Skylights, and glass generally, are eschewed.

Ventilation and the avoidance of direct sunlight have been regarded as important, by the authors of the best of the designs for the City Meat Market; but ventilation, at least, in each of the designs to which more especially we refer, does not seem to have been adequately provided for. Besides the provision of louvres in the clerestory of an avenue, that of apertures for admission of air through the lower portion of the outer enclosure of the market, should be considered,—and we are not undervaluing space already given in different entrances, some of them wide, closed up with iron gates; whilst the adoption of skylights, or the Crystal Palace system, in some of the designs, may be undesirable, even allowing that direct rays of the sun would not fall on the meat. It has been said that the best arrangement for a market is as little as possible removed from that of stalls in the streets, though there there might be inadequate provision against frost; but we apprehend that the arrangement for a meat-market, should approach rather to that of the old shambles, than to that of the central avenue of Covent Garden Market, which, with or without the addition of skylights, seems to have been the model of more

than one of the designs. There is, however, room for discussion as to some of the principles to be laid down for the arrangement of meat and fish markets,—as for that of many other descriptions of buildings, to the principles of planning of which attention is being given just now, and seemingly for the first time. The salesmen are by no means agreed, unless as to disadvantages of structures such as the building in Warwick-lane, once the old College of Physicians, where there is little or no means for admission of air in the lower portion of the walls. Yet the subject cannot present one tithe of the difficulty that there is in the planning of an ordinary house. In the Paris markets there is a vast area below-ground for storage, and furnished with tramways. Like storage for the London Meat Market does not seem to be necessary or desirable, the position of the railway being taken into account, and rapid sale being calculated upon. Ventilation would be difficult in a haemorrhage. The competitors' plans, and the plan of the ground, are deficient of information on main points of the connexion of the railway and the market. The latter plan just indicates the apertures for hoists, a staircase, and the centre lines of columns of the haemorrhage. Generally the designs do not show that the subject has received the amount of study that was required.

The set of drawings, No. 1, marked with a key, includes in fact two alternative designs, the difference being chiefly in the arrangement of the shops, and by the omission, in one design, of certain features in the 50-ft. transverse roadway, and its entrances, which might obstruct to some extent the access and circulation of air. The principal design has a central avenue of 20 ft. wide, on the longitudinal axis of the ground, and connected with the 50-ft. roadway. Parallel with this avenue are two others of 15 ft. These three avenues are lined by the shops, which are arranged in groups of four or six. The groups are separated, and the longitudinal avenues connected, by transverse passages, which however would be apportioned with the shops and kept private. All these passages, public or private, are carried up with clerestories above the level of the roofing of the shops; and their ends form features of effect in the elevations. The entrances to the central transverse roadway have each a great arch beneath a pediment, the lunette-head, or tympanum, of the arch being filled with sculpture. The whole of this central feature is very effectively composed; as indeed are also the features of the wings of the north or south front, and those of the east and west fronts, some of which we have referred to. The character of style resembles the German, or rather the recent French, version of Greco-Italian, of which we have often had occasion to speak as adopted in Paris, more especially for the buildings designed by the architects of the municipality. At the intersection of the 20-ft. avenue with the 50-ft. roadway, a tower in several stages is proposed as the central feature of the building; and the grouping of the whole, as shown in a well-drawn perspective view, is very clever. But the tower is proposed to be carried on sixteen points, or four at each of the four angles, each pier of the sixteen being intended to be 2 ft. 6 in. square on plan, and some of the piers having to carry the ends of girders of 35 ft. span. The girders would support the floor of the chief refreshment-room, intended to be at an upper level here, over the portion of roadway. The clerestories throughout, are proposed to be furnished with louvres,—these to be of glass; and the slopes of the roofs would be glazed. The shops would be generally 30 ft. in height, with a flat roof-covering; but the full height, internally, is given to the shop only in one-half of its area, the other half having an upper-story room. The number of shops required by the "Instructions" was 200 or thereabouts;

the number provided by the author of the design before us is 186; though in his second design it is 200. The shops next the street would open thence, and be protected by pan-house roofing covered with ornamental tiles. This feature, continued round the building in the middle of the height, adds to the good decorative character of the whole, already spoken of. The dimensions proposed for the shops of the group of four, are 23 ft. 6 in. by 22 ft. 10 in. The arrangements for ventilation, as of the railway, are alluded to by the author; but they are not clearly shown. The roofing would be supported on iron columns built into the 9-inch brickwork which forms the divisions of the shops, the columns being intended to act both as soil-pipes, and pipes for the rain-water. The sun would be excluded from the avenues by blinds made to travel horizontally, or beneath the glass-roofing. The estimated cost of this design is 100,000.

The author of the design, No. 2, marked "For the Use of the Citizen, and Decoration of the City," considers that whilst the Palais Centrales are "admirably adapted by their lightness and openness for the mild climate of France, they are inapplicable, if exactly reproduced, to the cold and variable climate of England," and that a meat-market "to be erected in this climate, should be of a substantial character," so as to keep out "the extraneous of heat and cold," but that advantage should be taken of modern improvements connected with iron and glass, to give "lightness and airiness," and to reduce the points of support to the minimum, a matter of the utmost importance in an erection of this nature." This is something like the original Paxtonian notion, that iron and glass would supersede all other materials, wherein no thought was given to the defects of iron columns for strength, and to the claims of masonry or brickwork, and of vaulting, or of tiled roofing, for consideration, as favouring an equality of temperature.

The chief provision for this last, in the design which is before us, consists in an external space, 15 ft. in width, on the north and south, throughout nearly the whole length, to be occupied by shops and offices over them, and serving to inclose the market and protect it, as supposed, from the extreme cold on the north, and from the sun on the south. The east and west ends of the market would be left almost open, the chief features of these ends being three large arches, wholly or in great part filled in with iron-work. The elevations there, by the crowning mouldings, carry out the idea of an ordinary low-pitch centre roof and side lean-to roofs; but the market itself is roofed over in three similar spans with eaved principals of wrought and riveted iron. These principals are carried by piers which are formed of a group of four shafts around a central square column, the shafts being ornamented by spiral fluting, and a lozenge pattern. These piers also carry arches for the support of the cornice-lines and the two gutters between the roofs. The centre span would be 90 ft. in width, and the same in height; the others would be 60 ft. Whereas in the first-noticed design, the bulk of the area was appropriated to shops, with private ways, it is here given to the avenues. The shops are arranged in continuous lines, interrupted only by two transverse avenues, the greater number of the shops being about 15 ft. square. A tramway across the centre of each wing of the building, is proposed, with gates at the ends, north and south; so that the central 50-ft. way could be left free for street-traffic. The decorative character of the building may be described as Italian. The shafts exhibit a range of small arches and flanks, with brickwork-diapering below, a division into bays by square piers, and towers to the centre of the front. The light is admitted through the roofs, along the centre, except in one roof, where the opening is placed in the side-slope away from the direct rays of the sun. The centre, or "nave," has a clerestory, the louvres to which are glass on the north side, and iron on the south. The walls of the aisles rise above the external building, north and south, and have also louvres, in one case glass and the other iron. The semi-circular opening at the west end of the building is proposed to be glazed with ground glass. In general character, though not in detail, the design differs little internally, from many recent productions. There is some decorative effect in all these works; but there is not the picturesque effect noticeable in some very simple timber-roofed structures,—for example, St. John's

Market, Liverpool. The cost of design No. 2 is estimated at 150,000.

We are looking at the designs in the order in which they have been arranged and numbered, which often in competitions has some reference to an idea entertained of merits. The author of the design, No. 3, marked "Citizen Stationer," has prepared much the largest number of drawings, and otherwise has taken considerable pains with the subject. He claims to have studied, besides other points, the rental to be received from shops; and of these his plan would afford 214 in number. The ground on each side of the covered 50-ft. central transverse roadway is divided by two longitudinal avenues and one transverse avenue, each being 30 ft. in width, except for the Poultry Market, and 32 ft. in height. The avenue is divided down the centre by a row of iron columns, not for the support of the roof, but to carry hooks for meat. Louvres are inserted in the roof, and the author claims to have taken care to avoid heat from the direct rays of the sun. He provides, however, dome of iron and glass, at the intersections of the avenues, but open at the top. This arrangement he thinks will conduce to ventilation. The shops vary from 30 ft. by 20 ft. in the market for meat, to 16 ft. by 15 ft. in that for poultry. The divisions are of enamelled slate let into grooves. Four shafts are specially provided for ventilation of the railway. There are upper rooms attached to the shops; and these receive direct ventilation from the open air. The lavatories, closets, and animals are connected with the shafts before referred to. The decorative treatment of the design, Italian in character, is inferior to that in the design first noticed. The estimate is 122,000.

No. 4, "Semper Paratus," calls for little remark except as to its differing from other designs, by giving the greater height of roofing to the area over the shops, and the less to the passages.

No. 5, "Invicta," not sufficiently explained, has the Crystal Palace character, but provides open areas ventilating the backs of shops in a block, and in which the closets and animals are placed. A tramway leads from the hoists, to the back of every shop.

No. 6, "Fortuna Sequatur," is an unfinished set of drawings. The best features of the design are decorative; but they are not consistent with the expression, or altogether with use, of a market. A screen wall with an order of three-quarter columns, and enriched doorcases, are what they mainly consist of.

The design, No. 7, "Spero," we can hardly do justice to; for it is shown by tracings which are hung in a bad light. The author suggests a description of carriage, for the tramway, by the use of which turn-tables would be unnecessary.

Some of the competitors have materially damaged their plans by placing iron columns in avenues where they would be exposed to shocks not favourable to the endurance of the structure. There are hints to be gathered from nearly every one of the designs; but it can hardly be said that the Corporation have gained what was expected, or that the question of the arrangement and construction of meat-markets has been much advanced.

#### PROFESSOR SMIRKE'S OPENING LECTURE ON ARCHITECTURE: ROYAL ACADEMY.

On a former occasion, in this place, I dwelt on the paramount importance to an architect of the study of general composition of his designs; and I expressed the opinion that however admirably executed the details may be, however gracefully the subordinate and smaller parts of a design may be treated, if the general outlines of the building are unsatisfactory, it will surely fail to please the educated eye. I told you of instances of the impressive effect produced by the simplest and rudest constructions—works, perhaps, composed of mere scaffold-poles and tarpaulins, owing to a judicious and artful arrangement of lights and shadows, and to the general proportions of the various masses. We might look around us and not be at a loss to find instances where a superabundance of swags and scrolls, and other like objects of minute decoration, display an excessive attention to details, to the total neglect of the far more important consideration of the general composition of the design. I will not deny that I am the more disposed to repeat this warning, because the very least observant of us must perceive that this inordinate and too exclusive elaboration of details is one of the vicious tendencies of the

present day. We are prone to run into the error of supposing that, be the outline of our masses ever so tame, ever so deficient in symmetry, we shall yet not fail to secure admiration if the surface of our work be covered with intricate enrichment, so as to captivate the eye with a sumptuous display of elegant friezes and delicate embroidery.

Such were the warnings which I deemed it my duty to address to you on a former occasion; but in doing so let me not be so misunderstood as to be supposed to have encouraged carelessness or inattention to those minor objects of ornamental design which, whilst we depreciate the habit of attaching too much importance to such superficial details, are, nevertheless, the source of real beauty and pleasure when used with moderation and judgment. It appears to me, indeed, of so great importance that these lesser matters of art should not be disregarded, that I purpose to devote this evening wholly to the consideration of them.

I believe that the best teachers of the sister-arts, whether their teachings be written, or conveyed by the still more impressive mode of example, and by their own actual practice—we shall find whilst they have of course paid their first and deepest attention to general composition, and to the great elements of beauty of style, yet have never permitted themselves to forego the attention to the execution of details.

It is always with very great diffidence that I venture to allude to the sister-arts, but I feel sure that I am justified in saying that the greatest masters of painting, such as Michelangelo and Correggio, whose genius was especially conspicuous in their grandeur of conception and greatness of manner, never slighted their smallest details, never laid themselves open to the comments of criticism on this score, by showing any want of thought or care in those minor matters, which more slovenly or less competent painters might fancy to be beneath their attention.

Raffaello, in an especial manner, illustrates this truth. Remarkable as he was for all the loftiest qualities of artistic genius, he never failed to pay delicate attention to his accessories, and to the careful painting of all his details. It was the remark of one of our former presidents, Sir T. Lawrence, when enthusiastically recording his admiration of Sir Joshua Reynolds, that delicacy of finish and careful imitation as much distinguished his works as that noble breadth and largeness of style which placed him at the summit of his art in this country. And again, when advertising to Michelangelo, he said that "whilst the ceiling of the Sistine Chapel was wonderful for its unequalled breadth and for loftiest conception, and might be regarded as the noblest work ever yet projected, yet even the miniatures of Julio Clovio were not more lightly finished than some of the studies of the great master."

Again, with great deference to my better informed colleagues who cultivate the art of sculpture, I would venture to say that there also the best sculptors have ever shown a scrupulous regard to the subordinate portions of their work. It has often been deplored by the warmest admirers of that truly great genius, Flaxman, that he should have dimmed the lustre of his works by a too frequent disregard of finish.

If we look back to the brilliant era of ancient sculpture few things present themselves more calculated to excite our surprise and admiration than the surpassing excellence of their details. The horses in Phidias's friezes are not only wonderful for the spirit and truth of their design, but we shall find on examination that the sculptor has with loving and lavish hand thrown art into the minutest details—the representation of the veins and the delicate execution of the manes and tails. Although the work was destined to be placed upwards of 60 ft. or 70 ft. from the eye, yet these extraordinary men loved their work too well to admit of their leaving unfinished or unconsidered these small matters, although they must have been well aware that no eye could appreciate them when raised to the position assigned to them in the main work.

I have dwelt long enough on the evidences of the value attached by the highest authorities to a careful attention to detail in the cognate branches of art; but certainly to no branch of art does the observation apply more forcibly than to that which engages our attention this evening. The works of the architect are usually on a far larger scale, and therefore subordinate parts may not infrequently derive even more importance from their size and unavoidable con-

spaciousness. In our art the high quality of grandeur is more dependent on actual magnitude than is the case in the sister arts. The architect may even be able to win applause by the forcible effect obtained from mere bulk and extent. Yet still our art has this in common with the sister arts, that whatever praise a building may obtain by reason of its meritorious proportions, or of the grandeur of its general effect, those merits are so greatly increased, and the pleasure derived by the critical eye is so materially enhanced by the discovery of those smaller beauties of design that are revealed only by a close and critical examination of the subordinate parts, that we can never venture to be indifferent to the value of such details.

Now, it would be easy to show to you that such has been the opinion of most men of great artistic genius at all periods. The same niceties that I have been adverting to as forming one of the great charms of Greek sculpture, are equally observable in the *chefs-d'œuvre* of Greek architecture that have survived for our study and instruction. Perhaps it would be difficult to cite a more remarkable instance than the entasis of the shaft of a Greek column. It was found that, owing to some optical illusion, the shaft of a pillar of which the sides are parallel appears to be larger at top than at bottom, and such appears to be the case in the remarkable Egyptian example at Beni Hassan, which has often been referred to as the prototype of the Doric order. To remedy this defect, the Doric architects diminished their shafts upwards of 1-5th of their bottom diameter. But then, owing to some other optical illusion, it was found that where the sides of the shaft were diminished in straight lines from the bottom to the top, those sides appeared to be slightly concave: this gave rise to the adoption of what is called by Vitruvius the *entasis*, by which expedient this disagreeable *descriptio visus* was at once obviated.

This has always been known, but it has quite recently been found that even this expedient was not sufficient fully to satisfy the excessive refinement of the Greek eye, and that the boundary line of the Doric shaft, in the best examples, was made not merely a convex line, but a part of a true hyperbolic curve, a hyperbola, no doubt, of an extremely small axis minor, but, nevertheless, a hyperbola drawn with exact mathematical accuracy. Many of you are probably well aware that, although this fact had been previously surmised by others, the ascertainment of the truth with precision has been the result of the very careful observations and measurements of Mr. Penrose, made under the auspices of the Dilettante Society. Here is an instance of the extreme delicacy and fastidiousness of Greek taste, and an evidence of the value attached by the Greeks to what probably appears to most of us to be a very trifling matter. We may, however, learn to set a higher value on a rigorous attention to such trifles, when we contemplate the mischievous results of a neglect of them. The later imitators of the Classic style saw this entasis, but, being utterly unable to feel as the Greeks felt, they presumed that all they had to do was to swell the shaft, and so they swelled it, but to such a preposterous extent that, as Evelyn frequently observes, their columns appear to be sick of a typhoid.

A similar evidence of nicety of taste is presented to us in the mathematical precision with which the Greek echinus is carved. The artists of that wonderful period were not content with an ordinary and simple curve, which might have satisfied a less sensitive taste, commencing the contour with a straight line and gradually giving to the upper part of it a curvilinear form resembling that of the natural echinus. But the careful measurements of Mr. Penrose prove the curvature of the Athenian echinus to be strictly and exactly hyperbolic, as the Greek sculptor felt that his curve should be.

Now I would call your attention to another instance of the really wonderful delicacy of the Greek eye. Most students who have looked over the pages of the earliest expounder of the laws of architecture,—Vitruvius, will have been deeply perplexed by the instructions given to us by him touching the "*Scamilli imparis*" in a Greek order. Much as the question has been exercised, I do not know that any expounder of the text ever so satisfactorily explained or ascertained the exact meaning of those words by the aid of the plumb and level, until Mr. Penrose did so, when engaged on the minutely critical examination of Athenian remains, made by direction of the Dilettante Society. That most careful observer has shown us that the course of masonry

forming the base line on which the columns of a Doric portico were placed, was studiously laid with its upper surface very slightly but appreciably convex; and though Vitruvius, on laying down this rule, does not give us the reason for it, yet there can be no doubt whatever that, like the other minute observances of the Greek masons to which I have adverted, the "*Scamilli imparis*" which were the result of this very peculiar mode of construction, were intended to correct an optical illusion similar to that which the entasis of the column shaft was intended to correct;—thus furnishing another illustration of the extreme fastidiousness of these accomplished art-workmen. It is in like manner shown by the measurements of Mr. Penrose that the sciffite of the entablature is executed with a very faint concavity. We can well understand the motive for this. Every one will have observed, that through some visual deception any large surface of flat ceiling appears depressed towards the centre—such an effect on the eye was sure not to have escaped the observation of Greek builders, who adopted this natural mode of correction.

I am tempted to add one other illustration. On a former occasion I pointed out to you a slight, but very delicate instance of that fastidiousness to which I have been adverting, in the faint concavity which was wont to be given sometimes to the fæcetes of a Doric triglyph. The motive for this concavity may readily be surmised to be a wish to render the drawing of those triglyphs distinctly perceptible, without resorting to too deep or sharp indentations, which might by their shadows have interfered with the effect of the sculptured metopes, and detracted in some degree from the *breadth of effect*, that quality which is one of the distinctive charms of all Greek art.

Perhaps there is no lesson which those artists inculcate by their example more emphatically than that manifest love of their art for its own sake which constantly led them to take what ordinary minds might have considered *superfluous* trouble. The same unsparing prodigality of labour which they showed in giving to the unseen back of their pedimental statues as high a finish as the front, and the same scrupulous attention to truth in the anatomical minutiae of their bas-reliefs, however remote from the eye, to which I have already adverted;—that same feeling extended even to the subordinate details crossing cyana of their cornices, and to the antefixes on the eaves of their roofs,—interesting instances of which we possess in the British Museum.

We will now pass over the Roman period, which was but the dim sunset of art, and hurrying past the still dark shades that followed that period, we will seek illustration in the best period of Mediæval art. We shall there find, that if the more refined æsthetic niceties may be wanting, there yet existed, without doubt, a high appreciation of the value of a careful attention to details.

The mouldings of the thirteenth century are of themselves sufficient evidence of the strong artistic feeling that pervaded our art at that period. While a forcible effect was studiously sought by deep undercuttings, and by a brilliant sharpness of execution, the best Mediæval artists never lost sight of the value of that breadth which had been, as I have said, the peculiar merit of Greek mouldings. Their mouldings were massed together in groups kept forcibly distinct, but deep, undercut hollows, producing powerful lines of shadow.

The custom prevalent in the thirteenth century of banding the shafts of columns is another evidence of nicety of taste. The practice was quite original, and was admirably adapted to obviate what might otherwise have been a meagre effect of the somewhat excessive slenderness of those column shafts.

Another instance of delicate perception, very worthy of observation, is presented to us in the execution of their spires. Although the Greek Gothic of columns was wholly unknown in the Gothic school, a feeling exactly similar taught them to give an entasis to the spire; so delicate as to be scarcely perceptible, and yet, I believe, never wanting in the best examples.

Time will not permit me to pursue this subject much farther; but the sketch would be unparadoxically imperfect were I to omit allusion to the really wonderful attention paid by the able masters of the Renaissance period to the whole subject of architectural detail. I do not mean that in the practice of those masters there was

any excessive resort to ornamental detail. On the contrary, the best artists of the quattrocento school usually aimed at producing good effects by very simple means, although undoubtedly they showed themselves to be complete masters of ornament when they thought proper to resort to it. The architecture of L. B. Alberti, of G. Romano, of Raffaello, and others of that early and pure school, is marked by consummate sense of beauty of proportion, and of general outlines, but no masters knew better,—I believe I should say none but the Greeks knew so well,—how to enhance that beauty and to enrich those outlines, by details of highest purity and simplest character.

I may, perhaps, be permitted to extend my observations on the susceptibility of good taste in the minor objects of design, by referring to the subject of futile vases.

When we regard those ancient works in the early purity and youthful freshness of the Greek style, the beauty that pervades those insignificant objects of the potter's art appears to me truly surprising. It would be difficult to illustrate the power of art more forcibly by contrasting the exquisite outlines of that very early Greek earthenware with the pots and pans of this vulgar modern world. There is, perhaps, no greater manual dexterity, no more mechanical skill, shown in one than in the other; there may, indeed, be less exactness of execution in the old than in the new works; but the one has those peculiar qualities which the educated eye at once recognises as the elements of beauty, whilst the other lays claim to no attention, and has no æsthetic merit. Certainly it is a phenomenon that would be very surprising, were not the fact so familiar to us, that during the 2,400 or 2,500 years that have passed since the heat of those futile works were produced, a period which comprehends the whole history of human civilization from the period of primal simplicity down to the vulgarities of the nineteenth century, there has been an unceasing struggle to alter, vary, and improve: after indulgence in every species of rovelty, excess, and caprice, we have never succeeded so nearly in producing forms beautiful in shape and colour as when we have copied the old Greek type. Beautiful things of this nature have been found in Oriental art; beautiful in Mediæval art; beautiful, too, in the age of the Renaissance; but analyse those several beauties, and you will find that those please us most in proportion as they approach the nearest to that wonderful type.

This is not encouraging to modern invention; it is not gratifying to modern vanity; but it is true, and therefore demands our observation. At all events, it should teach us *modesty*, and stimulate us to respect and to study those examples which our earliest teachers have set before us. Whatever may be the cause, I think the fact is undeniable that, though the arts and sciences are usually regarded as kindred pursuits, and are supposed to be intimately associated, they are in truth widely different in their history and in their destiny. Science has been progressive: step by step men have advanced in the knowledge of the exact sciences as time has advanced. The step of to-day helps us on to the acquirement of a further step to-morrow; and the horizon is thus ever widening as we advance. Quite otherwise seems the destiny of art. The small objects of art to which I have been adverting illustrate this anomalous fact, and so perhaps may be said of almost every other object of design, in the sister arts as well as in architecture. Has Raffaello yet been surpassed? Have the works of Phidias yet been rivalled?

But I must return to the humbler theme of my lecture of to-night. It is not of statues that I have to speak, but rather of the pedestals they stand upon; and indeed of these pedestals I have much to say.

I should be pronouncing a very unmerited condemnation of sculpture were I to say that statues and their pedestals have, in modern times, shared the same fate. One might have expected that the same taste and talent which an artist exercises in the production of a fine statue would distinguish equally the base it stands upon. Can we admit that such has been the case? Have we, during the last 200 years, made great progress in the art of designing pedestals? Has the work at Charing Cross been thrown into the shade by any subsequent work of like nature? Have we gone on, step by step, improving on our ancestors, in form, or in proportion, or in graceful decoration? But I am not about to enter critically into the masonic

efforts of modern pedestal builders. It will be a more agreeable as well as a more profitable task to invite your attention to the pedestals of other times and of other countries. Few exist of classic times; very few of them indeed are standing where they were originally placed. After barbarian violence has thrown down a fine statue, and after time or accident has hurried it, its own merits or value may cause it to be disinterred. Not so, however, the masonry on which it stood; and thus we are left in general ignorance as to the exact character and proportions of classic pedestals. We have, fortunately, in the British Museum, a few examples of the highest quality of Greek art, and although the overcrowded state of our galleries there forbid the public exhibition of them, they are well worthy of your careful study. They are, it is true, of but small size, and of very simple design. Indeed, it does not appear to have been the practice of the sculptors of that refined period to place their groups upon pedestals of any pretensions or proportions. It would appear as if they desired these pedestals to attract notice as little as possible, so as not to divert attention from the nobler work which was placed upon them. They had usually, perhaps always, a moulded capping and a plinth; but these mouldings are kept the very reverse of forcible in their effect. Even the inscriptions on these pedestals are tenderly treated; the letters are small, regular, and uniform in size, and in form always extremely slender, and always of very moderate intaglio, presenting a singular contrast with the pompous lettering of later days.

Were it not likely to lead me astray from my proper subject, I might suggest that, analogous to this deterioration in the treatment of their inscriptions, is the style of their composition. In the best times of art these inscribed records are condensed in style, and severe and simple in their mode of expression. It is only in later and degenerate times that we find the lettering bold in size and violent in depth, the lines capriciously varied in their length, and the sentences "exhausting the pomp of woo" in inflated and grandiloquent words.

I would request your attention to the beautiful monument of Colonne, one of the great Venetian Condottieri, of the date of 1495. The statue, by Verocchio, is by no means to be despised; but the pedestal I regard as one of the most ornate, as well as one of the most elegantly-proportioned, pedestals that I can call to mind; it is a noble example of the quattro-cento style, a style of which you have so often heard me express my qualified admiration.\*

#### SOMETHING ABOUT A KID OF MORTAR.†

It is a question of little moment to the architect or builder, from whence Nature obtains the materials for her innumerable productions. All agree that exposure to atmosphere is essential to fully develop the requisite properties of mortar; but many high authorities entertain an opinion that the quantity of carbonic acid in the atmosphere is so small, that the hardening of calcareous cements cannot reasonably be attributed to that source. However small that proportional quantity of carbon may be, we know that immense supplies are momentarily and eternally being exhaled from all animals, and generated by combustion of all kinds. The growth of forests and the produce of meadows demonstrate that an inexhaustible quantity of carbon is furnished by the carbonic acid of the atmosphere; also, that an apparently trifling or unimportant cause will produce a wonderful effect if continued, without interruption, during ages. Another requirement for the induration of mortar is the presence of moisture, or a certain amount of dampness, without which the mortar will not become firm, except perhaps during a much longer period; if he dried rapidly, as in setting a stove or building an oven, it will not easily harden, but will remain a long while friable.

It has been stated that the hardening of mortar arises from the presence of carbon and oxygen formed into carbonic acid, which is absorbed by the lime; but from what source the carbon is obtained, is until this time rather mysterious. Oxygen is abundant in the composition of water and atmosphere; and that quick-lime has an astonishing affinity for it is evinced by the practice of using a little powdered

lime, tied up in muslin, to beat out a minute portion of dust on the surface of polished steel or iron goods, such as fire-irons, fenders, and fronts of stoves of a superior quality, when not in use, to prevent their rusting. A more delicate instance is that of the manufacturers of needles, watch-springs, cutlery, &c., who generally put a small packet of quick-lime in any box or parcel of polished steel goods they may be sending to a distant customer, or with goods which may be put away as not likely to be wanted for some time, as security from rust. The following is very different, yet bearing upon the same principle. When bricklayers leave off work for a couple of days or two, as from Saturday till Monday, they push their trowel in and out of the moist mortar, so that the bright steel may be smeared all over with a film of mortar, finding this plan an effectual remedy against rust. In Wren's "Pantologia," page 206, there is a passage bearing upon this subject:—"In taking out cramps from stonework at least 400 years old, which were so bedded in mortar that all air was perfectly excluded, the iron appeared as fresh as from the forge."

A genuine fresco painter is well aware how soon a hard film of shiny carbonate of lime forms on the newly-stuccoed surface on which he is to exercise his art. In order that the picture shall be thoroughly or properly frescoed, it is indispensable that the artist should begin to paint the moment the plastering is finished, and that he undertakes no more than he can complete in the time of one day; for on the day after a shiny glaze of pure crystalline carbonate of lime is formed on the surface over the painting. Those who are about buildings in progress must have observed that, if a standing pool of water lay within the influence of a quantity of mortar without being disturbed for a day or two, it will be covered with an exceedingly delicate film of solid transparent carbonate of lime; which, if not removed from the surface of the water, may be gently disturbed in large flat sheets, displaying most brilliant prismatic colours. These are some of the instances of incrustation and hardening which must be produced by the carbonic acid of the atmosphere.

Pure lime alone, or, more correctly, mixed with water, and used in rather considerable masses, acquires only a very slight degree of hardness, and that chiefly on the outside of the bulk; hence, if used in considerable thickness, it is almost worthless as a cement for building purposes. The more minutely the lime is spread, the stronger will be the mortar, as an extremely thin pellicle in immediate contact with stone, sand, or other hard and compact substance, adheres with the required firmness, owing to that interesting law of nature known as the attraction of cohesion. I cannot discover that there is anything peculiar in the nature of silicious granulated sand to render it particularly suitable for the composition of mortar, beyond that of its being hard, compact, and free from porosity and absorption; and, above all these qualities, its abundance in almost every locality renders it procurable at so reasonable a price that no other material possessing these estimable qualities can be put in competition with it.

Quick-lime alone will not combine with carbonic acid, however long it may be exposed to its action; nor will mortar or cement ever acquire the hardness which it is capable of attaining, were it not for the water, which first converts the lime into a hydrate, and is then ready to be disturbed, to make way for the carbonic acid. This process may be termed "substitution," or that power which a body possesses, under certain conditions, of turning out one of the elements of a compound, and taking its place. But in order to effect this, the atoms must be in immediate contact with each other, or at immeasurably short distances; and water acts as a sort of "go-between," a vehicle of communication to bring about an intimate molecular contact. On the same principle, lime and sand might be mixed and blended for ever, without showing the least tendency to form a compact solid mass; but by the addition of water, either from the atmosphere or intentionally supplied, they acquire the property of gradually hardening, and in due time forming excellent cement.

If the grains of sand, or rather their surfaces in contact with each other, be sufficiently numerous within a given space, and uniformly dispersed, then the effect of the film of hydrate of lime will be sufficient to unite the grains of sand to each other, and bring the whole mass into active combination, not only with the sand,

but also with the surfaces of the bricks or stones, especially with sandstones. It is impossible, or extremely difficult, to determine the best proportional quantities of lime and sand to make the strongest mortar. A superabundance of either one or the other is equally objectionable: the most advisable mixture in one case may be wholly unsuitable under different conditions; so much depends upon the purity and freshness of the lime, the cleanliness of the sand, the size and varied bulk of its grains. If each separate piece of sand be covered with lime about the thickness of an ordinary coat of paint, I should be disposed to consider such an amount as very near the perfection of quantity.

Smeaton has stated, from his own experiments, that unburnt clay, even in very small quantities, materially interferes with the hardening of mortar, and disposes it to perish in a few years; it is, therefore, obvious that the use of dirty, clayey pit sand should be avoided as much as possible. This remark applies especially to the present time (February, 1863), because large quantities of gravel, obtained from subterranean railways and main drainage works, are now being used in London for concrete and mortar, without any attempt to get rid of the clay, by washing or other means of separation, from the flinty portions; consequently, all buildings constructed with mortar or cement made with such objectionable sand or gravel must be contrary to the intention of the architect, and against the interest of his employer.

The usual practice of making mortar, intended to be of the best quality, is to mix three measures of sand with one of lime; but if the grains of sand were of two or three different sizes, a much greater quantity might be introduced with advantage, as I am inclined to think it would form a firmer cement than if a larger proportion of lime were used. With ordinary river sand, a coarser variety might be added; and then shingle, or moderately-sized broken flint, in grains or pieces about the bulk of usual dinner peas: the component parts would be one bushel of lime, three bushels of common sand, one of coarse sand, and one of shingle; or collectively, five bushels of silicious matter to one of lime. To make sure that the various sized flinty grains shall take their respective places in the mass, I propose the following mode of preparation: the lime to be slaked as usual with water, if practicable within a day or two after it is removed from the kiln, and reduced to the consistency of cream, to which the fine sand should be first added, and intimately mixed, until every grain has been immersed in the cream of lime; then the coarser sand to be equally well mingled with the previous compound of lime and sand; after which the coarsest sand or shingle to be added, and thoroughly intermingled with the entire mass, which will then be ready for the bricklayer.

Judging from the many technical habits and customs in every trade, known only to the manufacturers and their workmen, it would seem advisable to hear what the operatives themselves have to communicate about the art and mystery of mortar; but, under present circumstances, I fear we should not derive much useful information from the bricklayer or general builder: in fact, these individuals are only required to do as they are told, and to conform strictly to the full intent and meaning of the architect's specification. Consequently, I refer to the writings of the most eminent architects and engineers upon this important chemical or scientific subject; but, instead of finding something like uniformity of general principles, and a little approximation towards the same proportional quantities of the materials which are to compose the mortar, we find the most unaccountable and contradictory directions, and, to all appearance, a vast amount of ignorance, about one of the most valuable matters in the construction of a well-built edifice. The fertile imaginings of one age are considered matter of fact in the next; error steals imperceptibly into practice, and the most conflicting usages are the result. One architect of established reputation has specified that the mortar is to be composed of equal quantities of lime and sand; others of equal celebrity will have two, three, or even four measures of sand to one of lime.

Some architects have no objection to fine gravel full of clay, or muddy sand in all its genuine dirtiness, being used in the composition of mortar, provided that an extra portion of lime be added to the mixture; presuming that, as lime forms the most important and most extensive ingredient of the cement, an extra allow-

\* To be continued.

† By the late Mr. C. H. Smith. See p. 22, ante.

ance of that article will compensate for the large amount of delaterrous rubbish in the sand. This is unquestionably an error of judgment. A superabundance of either lime or sand, no matter how good it may be, is, under any circumstances, objectionable.

Formerly great importance was attached to the continued manual labour of heating mortar. Vitruvius says, "When the plaster is mixed, cause it to be beaten with wooden staves by a great number of men, and use it after this preparation." Smeaton reckoned it a fair day's work of a labourer to mix and beat up two or three hods of mortar fit for use. At the present time, beating has become obsolete. The pug-mill, or the mill-stones of modern practice, will mix the materials more completely, and do a day's work of a labourer, according to the heating process, in two or three minutes; yet, as if wonders would never cease, we find in the specification of a celebrated bridge builder, that "the mortar shall not be mixed in a pug-mill, but shall in all cases be beaten up to the proper consistency, as practised in former times."

Pliny decidedly states that the older the mortar the better it is for building purposes. The same author informs us that the old Roman laws, which provide for the permanence of buildings, expressly state that "the undertaker to build a house at a certain price shall use no mortar that has not been kept in a covered pit for three years;" and remarks that buildings erected during the operation of such law were not liable to cracks. Compare the above with modern practice. Within my own recollection, Sir Robert Smirke, who had just returned from foreign travel, and was at the time quite a young man, consequently not very deeply versed in practical building, yet being engaged in the rebuilding of Covent-garden Theatre during the year 1808 or 1809, ordered the lime to be brought from the kiln without delay, to be immediately made into mortar, and used "smoking hot" by the bricklayers, greatly to the astonishment of the sapient builders of that time, who arrived at the conclusion that the "young and inexperienced architect had adopted some wild scheme of holding the lime, instead of baking or burning it," as heretofore in general use. Although I was merely a lad at the time this hot mortar was used, I have the most perfect recollection of seeing it in progress, and hearing the remarks and wonderment of those who felt interested in such matters; consequently, when the opportunity offered of examining that brickwork, after half a century's erection, namely, when the walls were demolished after the fire a few years since, I was much pleased to find that the mortar was as hard and solid as any reasonable person could either wish or expect it to be.

Many other cases are recorded wherein the lime is to be used as fresh as possible. At the new prison, Tothill Fields, "hot lime" was specified to be used. The Royal Exchange was built with lime thoroughly and freshly burnt, with strict injunctions that it should be kept in an inclosed shed, and no more mortar to be made at one time than was sufficient for each day's consumption.

THE DESIGNS FOR THE SCOTTISH MEMORIAL OF THE PRINCE CONSORT, EDINBURGH.

In answer to the requisition of the Committee of Advice appointed by her Majesty, sixty designs have been sent in, as already mentioned in the *Builder*, and are now exhibited in the Scottish National Gallery. As is usual in general competitions of this nature, some of the designs are unworthy of notice, and many of them commonplace and indifferent. In the present notice it is proposed to glance at those most worthy of remark, and the order of the catalogue will be followed.

No. 3. J. B. Edinburgh.—A design of considerable merit. It is in its detail of the Italian Renaissance, as seen in the library of St. Mark's, at Venice. It is square in plan; of three stages; proposed height 200 ft. The first stage is of four arched openings, flanked by coupled columns, the spandrels filled in with figures. Under the canopy thus formed stands the statue of the Prince. The second stage is similar to the first, reduced in breadth; and the third is solid, and crowned by a small dome.

No. 6. W. L. Moffat, Edinburgh.—A plain Gothic column, grided by a wreath half-way up its height; at the base semicircular projections, showing sculpture. Above the capital are niches filled with figures, from the centre of which rises the statue. This design is somewhat novel in treatment, but dumpy and ungraceful in its proportions.

No. 7. Messrs. Slater & Carpenter, London, exhibit four drawings of a monument of the same character and detail as that projected for Hyde Park, but more resembling in outline the Scott Monument in Edinburgh; and that resemblance is the objection to its erection in that city. The details are carefully worked out, and the general effect decidedly good.

No. 12. J. Anderson Hamilton, Edinburgh.—Four Byzantine arches raised on granite pillars support a dome, ribbed and crocketed, which is crowned by an open lantern. Detached columns to the right and left support winged figures. Mr. Anderson's conception is good, but badly carried out; the parts are ill-adjusted, and want balance and repose.

No. 20. J. Starforth, Edinburgh.—Similar in outline to No. 3, but better in detail. The stages are solid, and the statue is placed in a niche in the lowest. There is a considerable amount of sculpture well distributed. If placed in West Prince-street Gardens, a monument of this description would form a good companion to the Scott Monument.

No. 23. J. Noel Paton, Edinburgh.—Mr. Paton exhibits drawings of great beauty, and the public are apt, on that account, to give more heed to his design than its merits as a composition would perhaps obtain. It is square in plan, and consists of four Italian Gothic canopies, under which are seated gracefully-conceived figures. From the centre of the canopies passes a square shaft, rising to a small height above them, and on its capital stands the effigy of the Prince. On the base are bas-reliefs, composed in a truly artistic style. The great objection to this design is, that the architectural part of it is unmeaning, and that it would be swamped by the sculpture, neither enhancing the value of the other.

No. 25 (with reference to model No. 53). W. Calder Marshall, London.—This is a red granite pillar (similar to Mr. Scott's Crimean Memorial at Westminster), supporting the statue of the Prince. The base is of blue granite, and is flanked by figures at the angles. The general arrangement and proportions are good. If placed on a suitable site, it would be a great acquisition to the adornments of the city.

No. 33. D. Cousin, City Architect, Edinburgh, gives a Corinthian Temple, of which particulars have already appeared in the *Builder*.

No. 34. David Bryce, Edinburgh.—A keep of the Scotch baronial type, to be placed on the Castle rock; the statue in a vaulted chamber in the basement. Admirable in itself, this design appears inappropriate as a monument to a Prince whose life was one of peace.

No. 39 & 40. D. Rhind, Edinburgh.—The first, a classical design, too much like a mausoleum, and good as such. The second, a shaft from a Gothic church, with a scroll running spirally from base to cap; above the capital a series of canopies, and the statue at the summit, the base surrounded with sculptured figures and couchant lions.

No. 43. Joseph Mitchell, Westminster.—A copy from Nuremberg, not improved by the artist's additions.

No. 49. Model. J. Rothead and J. Steel, Glasgow.—A very grand classical design, the cost of which would be very greatly beyond the amount at the disposal of the committee.

No. 67. Model. J. B. Philip and R. Edgar, London.—An elegant circular Corinthian structure, similar to what Edinburgh already possesses, although on a larger scale.

No. 58. Model. R. Baldie, Glasgow.—Of the same character as the last.

Besides the designs above referred to, there are several equestrian statues (one of them hoisted atop of a Gothic cloister); numerous obelisks, more or less elegantly proportioned, especially one by Mr. Durlinn, already noticed; a few St. Eleanor crosses of some merit; and two or three indifferent Gothic towers.

The committee called the attention of intending competitors to several sites, and particularly recommended one on Arthur's Seat. This recommendation excited considerable surprise at the time, as a more unsuitable place for a monument could not have been fixed upon. The chief beauty and charm of the hill consist in

the peculiarity of its outline and the aspect of wild nature which it possesses. Near to the city, it yet appears not to belong to it. The pedestrian may in a few minutes place himself in as wild a solitude as if he were in the heart of the Pentlands; he may scramble through thickets of furze, startling the linnets from their retreats, and sometimes a rabbit may scud across the green sward to a place of shelter. Once begin to dot this quiet retreat with monuments, however beautiful, and its charm is gone.

The newspaper press has spoken out strongly against such a piece of vandalism; and the Architectural Institute has been equally emphatic on the subject (as shown on another page); and it may be said that the mass of the public who know or care aught about the matter acquiesce in this decision. If the selected design be one intended for an elevated position, the Calton Hill affords several such; but there are no lack of sites, and good sites, within the city; and any of the others enumerated in the advertisement of the committee would be decidedly superior to the one they express a preference for. It is pleasing to observe that the best designs appear to be intended for one or other of the sites within the city.

DIRECT COMMUNICATION BETWEEN LONDON AND CALCUTTA BY LAND IN A FORTNIGHT!

Sir,—When last I visited the Mont Cenis Tunnel, I sent you an account of the works, with all details; and the article, which you published in a prominent part of your useful and well-known paper, gave the English public the only true account of the progress of that great work ever published in this country. I therefore write to inform you that the works have been steadily continued ever since I last wrote; and when I passed there, a month or so ago, I saw great advance had been made in the interval.

On the Italian side, last year, the average advance has been 5½ ft. per day of twenty-four hours, and on the Savoy side 3½ ft. during the same period. The result is, that about a third of the whole distance to be pierced has already been tunneled, and out of the eight miles which is to be the length of the whole tunnel, more than two miles and a half have already been completed, so that there remain better than five miles and a half yet to be excavated, and lined, and laid, before the trains can pass beneath the Alps; and the late minister of public works, General Menabrea, stated it as his opinion that it would take yet twelve years to finish entirely.

Your readers will remember that I made a calculation which led me to very nearly the same results; and if it is done in anything like that time, it will certainly be the eighth wonder of the world.

Wild on this subject, I cannot omit to state, for the benefit of general readers, that no part of a railway is so safe as a tunnel, provided it has been properly constructed. Embankments are liable to slip after heavy rains; and even if they remain in good order, to my thinking they will never be safe until it becomes the invariable custom to put a "guard-rail" alongside one of the rails, so as to prevent the flange of the wheel from mounting, especially when the embankment is of any great depth; and this should be made obligatory on embankments of every kind; for in such parts of the line immense danger may and is almost sure to result, if a train should ever get off the line.

Again, in open cuttings, pieces of rock or loose earth often give way, and (especially in wet weather or after rainy seasons, or after periods of heavy frost) detach themselves, and either obstruct the way or cause obstacles to the advance of the trains; or else portions of them may fall upon the carriages or on the rails, and do harm to the passengers and do infinite damage.

In a tunnel, I repeat it, there is less likelihood of accident than on any other part of a railway, *ceteris paribus*; but they proper precautions should be taken, and should be made obligatory by legislative enactment, and one of the principal conditions which should be imposed upon all railway companies should be to have gas lamps constantly lighted in every tunnel, as is the case on the Continent; and in addition to this there should be lamps in every carriage, first, second, and third: without this, danger will always be inevitable. Some persons may urge as an objection, expense; but this should not be listed

\* Pliny states that the Greeks had a method of beating or tempering their lime and sand for mortar, in a large mortar with a great wooden pestle.

to for a moment. Whatever is proved to be requisite to the safety of passengers by railroad, it is as much the interest of directors to provide, as it is the interest of the public to see them provided, and of the Government to enforce them.

Directors, engineers, shareholders, and all who have any interest in upholding the new state of things, should do all that lies in their power to make railway travelling as safe a means of locomotion as possible. They have also the interest to make their property as good as possible,—not by parsimony or by stingy saving, but by providing the public with all accommodation really requisite sincerely and honestly.

Their property will be sadly depreciated if they omit to do so in time, for otherwise perhaps the public and Government would find it incumbent on them to interfere if the responsible administrators went on longer in a careless manner. Their plan should rather be to forestall all improvements, to offer premiums for new and useful inventions, and to make use of them before even popular clamour has made itself heard on the subject.

It is better to have the public too well served than to have to pay large sums as indemnities; and it might find their property hampered or interfered with.

In my next I shall describe how railway property may be enhanced in value, and how it may be made, more than it has hitherto been, a safe and very advantageous investment; but the scope of this article is to draw attention to a subject which I was the first to bring under public notice, namely, *direct railway communication with India.*

Railways are our own peculiar invention; and although we claim no monopoly, yet still we ought to take advantage of the system to put ourselves in direct and speedy communication with our great Indian Empire. I wrote on this subject to Lord Clarendon many years ago. He brought it under the notice of Lord Palmerston, who transmitted my letter to Sir Charles Wood, who, in his turn, placed the whole matter, with my plans and suggestions, before the local Government of India.

The line of route I then proposed was across France and Austria, Turkey in Europe, and Turkey in Asia, down the Euphrates Valley, and then skirting the Persian Gulf and passing through Persia, thus join this great European-Asian Railway to our own network of Indian rails. This must eventually be carried out, so that it will be as well to keep this grand idea constantly in view.

But as, in order to be practical, we must not aim at too much at once, I proposed temporarily to cross France, taking advantage of her railway leading to Switzerland, and then go on to "Chur," or "Coire," and there passing the "Lukmanier," to get into Italy, make use of the lines of that country, and so arrive at Brindisi, the old Roman port Brindisium, whence a line of steamers should be at once established between that port and the nearest point on the Asiatic shore to the Euphrates valley.

This route might be somewhat modified by taking the valley of the Arc, in Savoy, and crossing the "Mont Cenis," either through the tunnel or over the Pass.

Since I made these suggestions, which were favourably received by practical men everywhere, and by the governments interested, a new plan has been suggested by Mr. Fell, which, from experiments he has made, bids fair to be very successful. His plan is to go over mountains instead of travelling through them, and the Emperor's government has authorised him to make experiments on the most difficult part of the "Mont Cenis" road.

To these experiments, which are to be made on French territory, are to be invited representatives of the Italian, Austrian, and Indian governments. I sincerely hope they may be successful, and really believe they will; but, be that as it may, however, we must lose no time in bringing our Indian possessions into connexion with the British Isles by quick and uninterrupted transit.

The glories of the East, the beauties of the Vale of Cashmere, the wealth and the art of India, the vast treasures of an unexplored mine of silver, of gold, of diamonds, and all kinds of precious stones, the produce of extensive tracts of rich and readily cultivated territories and illimitable domains,—all these may be brought within a fortnight's journey of London, the real metropolis of the world, by energy, perseverance, and determination; but the matter is urgent in

the extreme. I have planned the means of raising the capital, and made many of the arrangements for carrying out this grand undertaking, which will be a credit and advantage to our own country, and will form an important epoch in this great world's history. I therefore hope the public will take that interest in it which so important a subject requires.

WM. H. VILLIERS SANKEY, Civil Engineer.

#### ENCRAVING AND OTHER REPRODUCTIVE ART PROCESSES.\*

I HAVE said that the discovery of lithography gave a means of printing from the surface in a manner similar to the process of printing from type or wood blocks; but, owing to the slight relief of the drawing on the stone, and the necessity of wiping with a wet sponge, and gumming the surface of the stone to prevent the absorption into the stone of the grease from the ink, the process is, nevertheless, a tedious one. But this evil is in a measure compensated for by the facility which the lithographic process affords for multiplying copies of a drawing when once made, by the process of transferring an impression taken from the drawing first made to a second portion of the stone; and as this can be repeated to any extent, a number of copies can be printed at one operation—the only limit being the size of the stone, and the nature and size of the design to be printed. The want of an efficient substitute for steel and copper plates, in the form of a surface block from which to print with the type in ordinary type printing-presses, still remains a desideratum, notwithstanding all that lithography has done, and the many attempts which have been made to find one. Casts in relief from engraved copper plates were among the earliest efforts in this direction, but the cost and labour of producing a uniform surface fit for the printing-press has not hitherto led to a commercial success. We now come to a period in the history of engraving at which another new discovery was given to the world, and which has since played an important part in the arts. I refer to the discovery of the process of electrotyping. In the year 1800, Volta, in a communication to the Royal Society, announced his discovery of the Voltaic pile. By its means Nicholson effected the decomposition of water and of several metallic salts. Cruickshank next invented the galvanic battery, to the positive poles of which he attached silver wires. The other ends of the wires were placed in a glass tub containing a solution of acetate of lead. When the electric current had passed through the solution for some time, metallic lead was found deposited on the negative pole. Brugnatelli observed the transfer of the elements of a decomposed compound from one pole to another. In 1801, Wollaston made the following observation, viz.:—That if a piece of silver, in connexion with a more positive metal, he put into a solution of copper, the silver is coated over with the copper, which copper will stand the operation of burnishing. It was not, however, till after the discovery, by Daniel, of his constant battery, in which copper is continually reduced upon the negative plate, that it was observed that the newly-deposited copper, when stripped off, had upon it a counterpart of every scratch on the plate upon which it was deposited. In 1837, Mr. Spencer, of Liverpool, discovered that if a portion of the surface of the negative plate was covered with varnish, then no deposit took place upon those parts. He next conceived the idea of applying this process to the arts, by coating a piece of copper with varnish and wax, and of cutting a design through it so as to leave the copper bare, and then to deposit a metal upon these parts, so that on removing the varnish the design would be left in relief; but no account of these experiments was published till September, 1839. In May of that year, it was announced in the *Athenæum* that Professor Jacobi, of St. Petersburg, had discovered a method of converting any line, however fine, if engraved on copper, into a relief by a galvanic process. This announcement was followed by a letter from Mr. G. J. Jordan, which appeared in the *Mechanics' Magazine* in June of the same year; and it is due to Mr. Jordan to state that the suggestions he then made have since been acted upon with considerable success. Mr. Robert Murray next discovered that if the surfaces of plaster casts and similar non-conducting bodies were covered with plumbago or black-

lead, it was no longer necessary to use metallic moulds, which had hitherto proved the great barrier to the progress of the electrolyte art. Chemists and artists were not slow in their endeavours to apply this newly-discovered process as a means of multiplying copies of engraved plates, both of copper and steel. In the latter case, an impression was taken from the steel-plate, by covering it with a sheet of tinfoil, and passing it through the printing-press. The result was a print obtained in relief in metal. Upon this a deposit of copper was made of the required thickness, and the required plate from which to print was obtained. In the early experiments the plates were thin, and curled in printing; this defect was, however, soon overcome, and the practice of engraving in copper, where large plates were to be produced, as in the examples issued by the Art-Union of London, was again soon reverted to, thus affording facilities which are now largely availed of, for multiplying copies of costly engravings at the same time that the quality of the works produced can be maintained against wear.\*

The next application of the electrolyte art to which it is necessary to refer, was that patented by Mr. Edward Palmer, and introduced under the title of "Clyphotography, or engraved drawings for printing at the type press after the manner of woodcuts." The process was a compound of drawing and engraving on a plate of copper, the surface of which, having been stained black, was then covered with a thin layer of a white opaque composition. A tracing of the design to be drawn or engraved was made. Needles, of various degrees of breadth and form, were then employed to remove the composition from the surface of the copper, beginning with the greatest breadths of shadow, and gradually working up to the lighter and more delicate parts of the design. When finished, an electro deposit was taken from the drawing so made, and a block in relief was thus obtained, which, being mounted in the same manner as an ordinary stereotype plate, was capable of being worked in with the type, and printed from in the machine and steam printing-press. This process is not so generally known as its merits and capabilities entitle it to be, and the problem of how to obtain with facility a substitute for the wood block still remains unsolved. Among the numerous other plans proposed for use in the production of engraved plates or blocks, may be mentioned voltatype, electro-tint, daguerrotype, and etching by galvanism.

Etching by galvanism was suggested by Mr. Alfred Smee; it was similar to the ordinary process of etching, but instead of being bitten in by a direct acid action, Mr. Smee suggested that the etched plate should form the positive pole of a battery, and being dipped in a galvanic trough of sulphate of copper through which a current was passed, particles of copper would be given off from the etched lines of the engraving; the plate was to be removed from the bath from time to time, for the purpose of stopping out, and graduating the tints required, as in the usual etching process.

I must now retraced my steps and recall attention to the discovery of Mr. Murray, who, having succeeded in giving a conducting surface to non-metallic bodies by the use of plumbago, placed within the reach of the scientific man a new and as yet unheard-of process of engraving, which is now known as Nature-printing. The first examples of this art were also due to the discovery and use of a substance made known to the world, through the Society of Arts, in 1813—I mean gutta percha. Nature-printing, as it is called, was first introduced to the notice of the public through the Society of Arts, which, in its notes of proceedings for the year 1819, printed a communication from Dr. Ferguson Branson, of Sheffield, in which he stated he had ascertained that by embedding a fern leaf, or any other flat body, in softened gutta percha, and then allowing the gutta percha to cool, upon removing the leaf a perfect mould was obtained, from which mould an engraved copper plate, fit for the printer, could be secured by means of the electrolyte process. A plate so obtained, with prints taken from them, accompanied the communication. Nature-printing, however, did not long remain in this normal condition; for in the Exhibition of 1851, in the Austrian department, were exhibited specimens of plants, flowers, &c., printed in colours from copper plates. It had been ascertained that if a rolling pressure was

\* The Art-Union of London soon abandoned the use of electrolyte plates.—E.N.

\* See page 24, ante.

employed to imbed the object to be copied, then soft sheet lead could be used; and that process was subsequently introduced into this country, and employed by Mr. Henry Bradbury in the production of his work on "Ferns and Mosses." Nature-printing did not stop here, for in a communication read before the Society of Arts in 1854, by Mr. Aitkin, of Birmingham, we find that, by means of a rolling pressure, objects of various kinds, and of the most delicate description, such as thread-lace, the down of a feather, &c., could be made to engrave themselves in Britannia metal, copper, brass, German silver, or tin plate; and, to use Mr. Aitkin's words, "more wonderful still, on what we are led to believe is the most dense and darkest metal in ordinary use,—namely, steel." I must not, however, here enter upon the industrial and manufacturing uses to which electrotype-deposits and nature-prints have been applied, but will direct attention to another process, in which the principle of nature-printing has been proposed to be applied as a substitute for engraving,—I mean the process submitted to the society by Mr. George Wallis, and called by him "Auto-typography." In this process Mr. Wallis substitutes for, or in combination with, a natural object, a drawing made upon a surface of gelatine. This he selects as it has no grain, and is to a great extent non-absorbent. His drawing is made with an ink or fluid, which, when dry, either crystallises or forms a naturally granulated body in relief upon the surface of the gelatine. The drawing, having been carefully prepared, is then passed through a press, in contact with a metal plate, into the surface of which the drawing becomes embedded; and the result is a transcript in copper of the artist's own drawing, from which prints may be worked in the usual manner. Notwithstanding the suggestions above related, I regret to say we are still without the great desideratum, a surface block, or a ready means of obtaining one at a commercially economic rate, by a process which will give to the artist a true translation of his sketch or finished drawing, to the commercial world an economic means of extending a knowledge of art, and of cheapening the cost as well as extending and facilitating the means of book illustrations, and to the public the advantage of a ready means of cultivating economically a knowledge and a love for all that is elevating and beautiful both in nature and art, as well as a means of educating the youth of our country by means of cheaper, more numerous, and better examples than are at present generally attainable. But before I close this communication, which I propose to do by referring to other processes which I think deserve more attention than they have hitherto received, and which I believe to be capable of helping to solve the problem of how to obtain a surface block, I must in justice refer to the photo-galvanographic process of Mr. Paul Pretch, the photo-lithographic process of Colonel James and others, and the process for enlarging and reducing drawings and engravings, patented by Mr. H. G. Collins. The aeriage process is thus described by M. Joubert:—"Mr. Grove made efforts to engrave the image obtained upon the daguerrotype plate, and it is due to Mr. Archer, who was the first to propose the use of collodion as a medium upon which light might be made to impress an image, that I should state that it is to that gentleman's discovery that the world owes its present advanced position in the art of photography. Without the collodion film, Mr. Paul Pretch's galvanographic process of engraving would not have existed, as light could not be transmitted through the daguerrotype plates, and the paper processes of Mr. Fox Talbot and others would have been inadmissible. Mr. Pretch, knowing that gelatine, if treated with bi-chromate of potass and submitted to the action of light, possessed a power of expansion; and availing himself of that fact, used a photographic image taken on collodion as a means of partially intercepting the rays of light, thereby regulating their action upon sensitized gelatine, and as a result he obtained a positive photographic image in relief in gelatine. The image, being allowed to dry, was then coated with linseed oil, and served as a mould in relief upon which to deposit, and from which he obtained, by electro-deposition, an engraved copper plate of the original collodion photograph, from which plate-prints could be taken, as in ordinary copper-plate printing; and it is right to add, that some of the best specimens of prints from chemically-engraved plates ever seen were so obtained and introduced into commerce. But

the fault which attached to the aquatint and mezzotint processes of engraving, also attached to Mr. Pretch's process,—viz., the surface or grain of the plate was too fine to yield a large number of good impressions, and that is, no doubt, one of the many causes which have impeded its extended use. The aeriage process of M. Joubert, for coating copper plates with an iron surface, was not introduced at the time Mr. Pretch was working his invention. Mr. Pretch succeeded in producing surface-blocks by his photo-galvanographic process. In order to obtain a surface-block, it must be borne in mind that the process, as compared with the intaglio plate, is reversed. In the engraved plate, the impression is printed from the lines cut into the plate; but in the case of all surface-blocks, it is the portions which are not to be printed from which have to be removed by the graver. In like manner, Mr. Pretch used a negative photograph in one case, and a positive in the other, thus reversing his results. Colonel James, of the Hydrographic Department of the Government, has introduced and used a process of photo-lithography, to which I cannot do more than allude. It is similar, in many respects, to the photo-lithographic and zincographic process described by Mr. John Walter Osborne, in the *Photographic Society's Journal*, vol. vii., pages 163 and 213.

Mr. Collins's process for enlarging and diminishing drawings or engravings was chiefly mechanical and lithographic. The plan was as follows:—A print from any engraved plate, wood-block, or lithograph, was taken in the ordinary manner, but in transfer ink, and upon a sheet of vulcanized india-rubber, covered with a composition of equal elasticity, and of a non-porous character. If it were desired to enlarge the design, the india-rubber upon which the impression had been taken was attached to a frame by means of books passing through holes made at equal distances round the edges of the india-rubber. Four bars were then passed through the body of the books, and the sheet was thus prepared for the extending machine, which consisted of two parts—viz., a table and screws,—the latter being used to stretch the rubber equally to the required dimensions. The impression was then transferred and printed by the ordinary litho- or zinc-ographic processes. If the design was to be reduced, the india-rubber was stretched before the impression was taken upon it, and afterwards allowed to contract to the required dimensions in the regulating machine. Mr. Collins considered that his process would afford a ready means of adapting a design, when once made, to the size and character of the same work when printed in editions of various size of page. Mr. Collins, however, found the lithographic process of printing a great impediment in the way of his progress, and attempted to obtain a surface block by building up the impression transferred to the stone, by depositing a succession of layers of printing ink mixed with suitable dryers; and when such building up of the ink had been carried sufficiently far, a cast in wax or other material was taken, and from the cast so obtained a copper block was secured by electro-deposition. This process was tedious and uncertain in its results, and, like its predecessors, failed to secure the object aimed at. I cannot help expressing an opinion that one great source of failure in the majority of the plans proposed has been, that the authors of them have been too ambitious in the selection of subjects, or almost entirely ignorant of the art of engraving. They have endeavoured to arrive at perfection at once, and have consequently failed. By beginning with art in outline, experience in manipulation would be gradually acquired, and a chiaro-oscuro effect ultimately attained to if desired; and I have little doubt that blocks in outline can be readily produced, either by the electro-magnetic or mechanical process of Mr. Hansen, or the more recently-discovered process of M. Vial.

The last processes to which I have to allude are those recently submitted by M. Dulos to La Société d'Encouragement, Paris, and a full report of which will be found in the *Journal of the Society of Arts*, vol. xi., second series, page 3. The report is accompanied by prints illustrative of the results obtained by the methods which he employs.

\* \* \*

My object in writing this paper will have been attained if I have succeeded in showing the relation of the various art-processes to each other. I have endeavoured to point out how each succeeding process has aimed at facilitating the means of producing and giving permanence

to art, and a larger commercial product at a smaller cost to the producer, and consequent advantage to the public. Each process has been applied in the attempt to produce a surface block from which to print. Hitherto, a commercial success has not been attained, and my hope is that a knowledge of what has been done may cause others to carry on the investigation of this subject to a successful issue.

S. T. DAYENPORT.

NIGHT SCHOOLS.

It is satisfactory to find that the subject of night schools in the metropolis is gaining an increased share of attention. The matter is most important; for on this question depends, to a great extent, the intellectual culture of a very large number of the rising generation. It is unfortunately the case that there are thousands of scholars who yearly leave the National schools at the age of about eleven or twelve years; and, in many cases, so imperfectly is their education grounded, that when the boys get to work they often forget the little they have learnt. There is a great difference of opinion respecting the means by which an effective system of supplementary night schools for such boys is to be carried out.

At a recent meeting in the room of the Society of Arts, there was a long discussion; but it does not seem that any clearly defined or practical plan was suggested. The Rev. Henry White submitted for discussion, the need of night schools specially suited to boys of thirteen to nineteen; and the desirableness of changing the name of "night school" for that of "youths' club" or "institute." He would add, inopportunities for instruction, the means of innocent amusement and pleasant fellowship. He would propose to have a reading-room, supplied with popular magazines and draught-tables; and would desire that the teachers should make themselves the friends of the pupils. He was also in favour of cricketing and boating clubs in the summer months.

While agreeing with Mr. White upon the advantage, when possible, of combining amusement with education, there are certain reasons which cause us to doubt whether a large amount of amusement would not be liable to lead the attention of such scholars from the main point. Mr. White thinks that these schools should be self-supporting. This, too, is a most desirable thing; but we fear that the experience of the past is not such as to show that this can be depended on. For the purpose of rendering the night schools serviceable to the class for whom they are so much needed, the weekly payments should not be more than 4d., or, at the most, 6d.—that is, 4d. for boys under fifteen, and 6d. for those over that age. In many districts in the metropolis it would not be easy to get a regular attendance of from 50 to 100 scholars. The revenue, in such instances, would be insufficient for the payment of a good master and two efficient assistants. There would also be the cost of firing and gas-light; or, if distinct buildings are to be provided, as Mr. White hints at, there would be a large additional expense for rent. If, however, the attendance of unpaid assistant-teachers could be depended on, and the National school-rooms were devoted to the use of the night schools, the payment of the boys might be brought to cover the charges, and allow a sum which would consider the masters of the National schools would consider worth the trouble of trained superintendence; and without this the night establishments would be of but little service.

Mr. Smith, diocesan inspector of Canterbury, remarked that night schools were on the increase; but added that what was applicable to London was utterly inapplicable to most country places. He had come to a conclusion that there should be an endeavour in the night schools to continue the control and superintendence of the youths after the age of twelve; and that it would be successful in that respect he would undertake to say from his own experience and that of others. The night schools were useful not only as a means of keeping up the attainments acquired in the National schools, but were also a means of re-sifting society, and admitting only those who were deserving into the educated body of the country. He was convinced that many night schools failed from the want of proper teaching.

The Rev. Mr. Suter, Mile-end, gave an account of night schools in his district; and Mr. Curry announced that at a night school in the neighbourhood of Poplar, 300 men attended, who paid their

fees, and were taught arithmetic and reading and writing.

It is very desirable, in connexion with this subject, that the facts connected with the night schools which have been already established, should be known; for the experience will be most valuable to those who are intending to make local experiments in the opening of such schools.

Mr. G. M. Murphy, of 55, Finchley-road, writes to the *Star*, to mention that, for the last seven winters, he has, on two nights in the week, conducted large classes of adults; and this gentleman thinks that, if large classes of men and women are to be educated,—and thousands of them are conscious of their need of teaching,—it can only be done by much less of formality and simpler machinery than is generally thought sufficient for the purpose. The classes referred to by Mr. Murphy are conducted in Hawkstone Hall, Waterloo-road, on Wednesday and Friday evenings at eight o'clock. The teachers are working people. The instruction is free. The men and women are in separate classes, although in the same room. There has been only one case of misconduct calling for expulsion. Class-teaching closes at half-past nine, when an address is given on some interesting subject; or, occasionally, the time is occupied by reading some interesting paper, or in singing. The evening is closed by a short devotional service; but persons who object to attend this service are not obliged to do so. The average attendance last winter was sixty, and the expenses incurred only amounted to 11*l.* 8*s.* 6*d.*,—a very small sum in comparison with the opportunity which is thus afforded of doing a considerable amount of good. Mr. Murphy is of opinion that less advantage would have been derived if the teaching of children,—that is, those of twelve or thirteen years of age,—had been conducted at the same time with those of older age. An opinion founded on the experience of seven years is worthy of the most careful consideration; but it is feared that instruction of a practical kind during only three hours of each week, and that only during the winter months, will be a slow means of providing against the difficulties of a greatly neglected education. Moreover, while acknowledging the need there is for teaching those who are over nineteen years of age, we maintain that there is a far wider field which needs to be skilfully and energetically worked in connexion with lads of from twelve to seventeen or eighteen years of age.

The immense size of the metropolis, the peculiarities of its population, and other causes, make social matters of this kind difficult to work. There are a few excellent night schools in London to which we may hereafter more particularly refer; for such schools are hidden in the multitude of educational and other establishments, and do not meet with the attention which they deserve.

#### MR. LAYARD ON THE HISTORY OF ART.

At the Lambeth School of Art last week, Mr. Layard, M.P., delivered an address on this subject. True art he defined to consist in a perfect appreciation and combination of form and colour. Some nations had one, some the other; but without a combination of the two no nation had ever been great in art. The arts of a nation depended on the character of a people, and represented its characteristics and peculiar circumstances, and his first illustration was drawn from the dissimilarity of Assyrian and Egyptian art. Egyptian art, in its massive invariable character, corresponded to the character of an exclusive, unchanging caste people, possessing unlimited command of stone materials; while, on the other hand, Assyrian art represented a conquering, ambitious people, given to assimilating the characteristics of the different peoples with whom they came in contact. From these two peoples the Greeks collected the chief features of their arts, and developed out those beautiful forms which were still the admiration of the world. The great specimens of Doric art were all clearly drawn from Egyptian models, and recent discoveries in Assyria had furnished a remarkable fulfilment of Niebuhr's prophecy, that Ionic art would be found, some day or other, to have an Asiatic origin. The decay of art in Greece was contemporaneous with the decay of Greek freedom, as was the case in every other country in which art had flourished. Passing to Italy, Mr. Layard pointed out that Etruscan and Roman art was merely a reproduction

of Greek art, and that architecture was the chief art by which the Romans were distinguished. Nothing gave a greater idea of their power than the magnificent public buildings which they had erected in their colonial cities, and which far exceeded anything this country had ever produced. The first great classic architect of modern Italy was Nicholas Pisano; the first great Christian artist was Giotto; and the basis of Italian art might almost be said to be the church of Assisi, the walls of which Giotto was called upon to ornament with passages from the life of St. Francis. The perfection of Christian art was attained almost by Ghirlandajo, though it could hardly be said ever to have been brought to perfection, owing to the decay of freedom which followed the German and French invasions, and the rise of a false classical taste. Of modern schools, Mr. Layard touched chiefly on the English; and, after criticising severely our shortcomings in architecture as evinced in the National Gallery, the British Museum, and the House of Commons, and in sculpture as shown by our public statues, he drew a hopeful picture of the future which English art and art schools had before them in applying the principles of form and colour to the new materials of iron and glass which had been brought into use, and to the structures, such as the railway stations, the great warehouses, and the Crystal Palace, which the wants of modern civilization and commerce were calling up on every side.

#### COMPETITIONS.

*Bolton Town-hall.*—At a meeting of the Town-hall committee on the 10th, accounts were passed amounting to 78*l.* 1*s.* 11*d.*, including 60*l.* to Professor T. L. Donaldson,—charge for report on competition plans for Town-hall. It was then resolved that of the six sets of designs selected by Professor Donaldson, the author of the design numbered 24, and bearing the motto "Experientia docet," is entitled to the first premium of 120*l.* That from the same selection, the author of the designs numbered 25, bearing the motto "Utile dulci," is entitled to the second premium of 80*l.* That also from the same selection, the author of the designs numbered 3, and bearing the motto "Manchester," is entitled to the third premium of 40*l.* It was also resolved that the authors of the designs numbered respectively 24 and 26 be jointly engaged as the architects for the erection of the Town-hall, but subject to such conditions as the council may annex to their appointment. Professor Donaldson, it will be remembered, had placed No. 24, No. 3, and No. 25 for the first, second, and third premiums respectively. When the committee took up the report to the town council, the council tried to find out what grounds or in deference to whose superior opinion the committee had advised a departure from the referee's decision, and not being satisfied on this head, very properly refused to ratify the report, and sent it back to the committee for reconsideration. A long and animated discussion took place at the meeting of the town-council on Wednesday. The question was introduced by an influentially-signed memorial, disapproving of the increasing expenditure of the borough; and a resolution was passed that 50,000*l.* were sufficient for the building complete, including site, cost of erection, and fittings; and this was carried by the chairman's casting-vote. A further amendment, however, was adopted, referring the whole question of site, &c., to the town-hall committee, to report to a future meeting of the council. The subject of awarding the premiums for the three best sets of designs then came under consideration. The committee, at a meeting on Monday, had passed a resolution, "That inasmuch as, by the instructions, architects, in sending in designs, are requested not to exceed 40,000*l.* as the cost of the building complete, this committee determines that no premium be awarded to any architect who does not give satisfactory proof to the committee that the building, according to his design, can be erected for a sum not exceeding that amount." This resolution was laid before the council for confirmation; but there being a slight difference between the resolution on the minutes and that actually adopted by the committee, which had only reference to the six architects whose designs had been selected giving satisfactory proof, &c., the minutes were negated by unanimous consent. The entire question of the premiums is therefore in a state of uncertainty.

*The Sir Tatton Sykes Memorial.*—We mentioned last week the name of the successful competitor for the design for this memorial. We can now add there were about 150 designs sent in; and that the second premium, 10*l.* was awarded by the committee to Mr. E. A. Heffer, architect, of Liverpool, for a pair of designs, one being an obelisk, and the other a column; the obelisk having recumbent dogs at the faces of the pedestal, and the column having lions at the angles.

#### A ROYAL IMITATOR OF JOHN HOWARD.

If we may judge from the following, there is great hope that the Emperor Maximilian will work much good in his Mexican dominions. From an order addressed by the emperor to the director of the Mexican prisons, it appears that the emperor, during the course of a journey into the interior, adopted the praiseworthy course of making use of his own eyes; and, amongst other matters, inspected the condition of the prisons, which at this day appear to be in much the same state as the English prisons were when they were described by John Howard and Oliver Goldsmith, a century or so ago. The emperor desires information of the moral and material state of the prisons, and of the persons detained there; also information respecting the kinds of employment, and the religious and secular education provided, the extent of these establishments, the size of the dormitories with respect to the number of prisoners, and also the state of the ventilation and the cleanliness of those apartments; also whether the prisoners are well fed and clothed. The inspector is to listen with attention to the complaints of the prisoners, and to make all inquiries necessary to ascertain if their grievances are well founded, in order to redress them as speedily as possible; the inspector is also called on to devise the means of immediate remedy, while measures are being taken, to carry out a thoroughly improved system of prison discipline; "and," says the emperor, "as the stay of children in the prisons, with their parents, witnessing examples which are highly corrupt, is most prejudicial to the young, you will take care that they do not remain there under any pretext. You will take care also, that the very young prisoners are, wherever this is possible, in a department separated from the rest, in order to prevent them from being still further corrupted by the contact of individuals who have grown old in crime."

#### FRANCE.

For the last two years a considerable modification has taken place in the pavement of the Paris boulevards, quays, and other great thoroughfares, by diminishing the width of the macadamized portion, and enlarging the stone roadway on each side. This has been attended with a considerable economy in the maintenance of the streets, the macadamized roadways having cost the towns enormous sums to keep in repair. Perhaps this is mainly owing to the departure from the right principles of a good macadamized road, as it is evident that gravel and sand mixed with water to the consistence of cream is only fit to be swept into the gullies.

It was announced a few days ago that the commission appointed by the Minister of Public Works to consider the improvements in railway traffic had recommended the adoption of the American system of carriages. This was a mistake; a special commission was named to examine in detail the numerous inventions of this class communicated from time to time to the Minister of Public Works. Of these very few, unfortunately, are capable of practical adaptation, and the sub-committee, so far from recommending passenger-carriages with a continuous communication throughout the train, has pronounced against them.

It is very probable that a rectification or straightening of the Paris and Lyons Railway will shortly be carried out, in order to quicken the transit between Paris and Marseilles. When the general group of railways in France was approved, local and personal interests prevailed to such an extent that the most direct or most economical line was not always followed.

*INDUSTRIAL EXHIBITION FOR WAKEFIELD.*—Preliminary measures are being taken to hold a working men's industrial exhibition at Wakefield.

HANDEL COMMEMORATIVE WINDOW.

ST. MARY REDCLIFF, BRISTOL.

SOME time ago, on the occasion of a musical entertainment in Bristol, commemorative of the first centenary after Handel's death, a number of gentlemen there, including Mr. William Powell, Mr. W. Frooter Baker, Mr. William Proctor, and others, determined on setting up a window in memory of the great composer, in Redcliff Church. Some little delay occurred, but ultimately three artists were invited to submit designs, from which one by Messrs. Clayton & Bell was selected. This has been executed, under the direction of Mr. Codwin, and is now set up at the east end of the north aisle of choir.

The glass is designed in pointed allusion to Handel, by setting forth eight incidents to which he composed music in his "Messiah," thus:—At the base of the window, on the left hand, is illustrated the passage, "Behold, a virgin shall conceive;" above this is treated the passage, "Unto us a child is born." The subjects follow on in the other lights in this order:—"There were shepherds watching;" above this, "He shall feed His flock;" "Behold, and see if there be any sorrow like unto His sorrow;" above this "Surely he hath borne our griefs;" "He was cut off out of the land of the living;" above this, "Thou didst not leave His soul in Hell." The whole of the openings in the tracery are filled with angels, singing and playing "Alleluia." Groups of angels also take the place of canopies and divisional members in the lower lights, and by these the Handelian spirit of the design is sustained by their musical scrolls being inscribed with the music of the composer's great work as it applied to the incidents above enumerated. At the base of the window is the following inscription:—"In Memory of Handel. Erected 100 years after his death."

The window is one of the most successful works of the artists. Some parts of it, for example, the head of the Saviour (bearing the cross), may fairly be described as beautiful.

DESTRUCTION BY FIRE OF THE THEATRE ROYAL, EDINBURGH.

ON Friday in last week, about four p.m., a fire broke out in the Theatre Royal, Edinburgh, at the head of Leith-walk, which, within an incredibly short space of time, destroyed the entire building; and, in the falling of the walls, knocked down the cloister and part of the main building of St. Mary's Roman Catholic Church, and caused the loss of six lives. The disaster has caused a gloom in the city of Edinburgh, deepened by the loss of the well-known and much-respected architect, Mr. George Lorimer, Lord Dean of Guild, who fell in the discharge of his public duty.

The Theatre Royal, formerly the Queen's Theatre (until the name was transferred from the old Theatre Royal, in Shakspeare-square, removed some time ago to clear a site for the new General Post-office), was opened only nine years since. It occupied the site of the Adelphi Theatre, which was destroyed by fire in May, 1855.

The fire originated, it would appear, in the top shifts of the scenery, which were so badly protected that on several occasions they had taken fire, although in the previous instances the men had been able to extinguish the flame promptly by cutting away the drapery. In the present case, the gas-man, who had just been putting on the lights, at a subdued height, to be ready for the illumination of an early evening performance, had succeeded in lighting the second row of top lights, and was lighting the first when the drapery caught fire. The flames spread so rapidly that he was unable to get the border down in time, and rushed along the "flies," or wooden stages upon which the men walk when regulating the scenery, and called to his assistance the head carpenter, an assistant, and the fireman. These men had been adjusting the scenes for the pantomime when the alarm was given, and they at once used every possible means, by cutting down the borders and hacking away the side scenes, to prevent the fire spreading in the "flies." Meanwhile, the flames spread with almost incredible rapidity, and the scenes were in a few minutes in a sheet of flame; the wooden "grooves" and stagings aloft quickly caught the flames, and the fire was speedily roaring to the roof, fed by the draughts which open flames necessarily produce. So rapid was the configuration that the few men in the house

had barely time to escape, after they saw their attempts to extinguish the flames were hopeless. The fire, at its height, is reported to have been seen from Dunfermline, in Fifeshire, about 15 miles distant.

The flames, evidently stimulated by a great draught, broke fiercely through all the windows to Broughton-street, and raged for some time with great fury. From the state of the walls further danger was apprehended. A part of the south wall had been torn down in the fall of the roof, and the boxes and galleries having given way in a series of loud crashes, the side walls, which were 40 ft. to 50 ft. high, stood unprotected, and showing a great inclination outwards. The north wall particularly, overhanging the cloister of the Catholic chapel, was seen to be in a very threatening condition, and on this side already a sad and fatal occurrence had taken place. A little after five, one of the chimney-stacks of the theatre fell outwards, and smashed in the cupola and a large part of the roof of the cloister chapel. A good many people were in this part of the chapel at the time, as it afforded a point for operating on the north side of the burning building. In the fall of the chimney, two men in the cloister were struck down. An old man, who had for eighteen years been in the fire brigade, was killed on the spot; a young man, a clerk in a painter's establishment, was thrown down with a great stone on his back. He called loudly and piteously for help, which could only be rendered by others at the greatest peril, for the north wall threatened every moment to give way. Several men courageously endeavoured to get him out. One of the most active in the benevolent and heroic labour was the Dean of Guild. He felt confident in his own calculations for his safety. He was repeatedly called to come away; but his reply to one was, that he knew the theatre walls well, and that they would not give way; and to another, who urged him still more earnestly, that he would rescue the man at the peril of his life. The firemaster, Mr. Mitchell, who had been observing the increased defection of the wall, conjured Mr. Lorimer to yield, and even tried to drag him away. In a second or two the greater half of the north wall fell with a terrific crash. Mr. Lorimer and three others were in the act of escaping when they were overwhelmed in the ruins. A number of gentlemen, who were in the lobbies of the chapel, lost no time in making an effort to get at the buried men; and, under the direction of Mr. Nichol, architect, they, along with a body of labourers who were immediately called in, proceeded to remove the debris, getting into the cloister by a private door leading from a room underneath the chapel. The men wrought with great earnestness, but it was not till ten o'clock next morning that the site of the cloister was finally cleared, and the number of persons killed ascertained to be six, including the two first struck down. The north wall in falling broke through a large portion of the roof of the church, besides destroying some of the parapets and pinnacles.

The Theatre Royal, or Queen's Theatre, was opened in December, 1855. It was built from a design by Mr. Bryce, Edinburgh, and had 1,700 seats, having three tiers of boxes and galleries. The front lines of the different tiers formed a semicircle with an ogee curve outwards, while the stage-boxes within the Corinthian columns of the proscenium curved inwards. The stage was from a design by Messrs. Crieve, Telbin, & Co., and might be opened up from the footlights to the wall to the depth of 58 ft. The breadth of the proscenium was 32 ft.; and as the height from the stage to the roof was 54 ft., scenery could be drawn upwards out of view of the house, or helow into the area of 22 ft. below the stage. There were ten dressing-rooms, besides green-room, property-room, store-room, workshops, &c., and ladies' cloak-room in connexion with the audience department. The theatre had for the last few years been in the hands of Mr. and Mrs. Wyndham. We understand that the loss is for the most part covered by insurance, both on the part of proprietors and manager, but one office at least had declined the insurance some time ago on account of the want of protection of the top-shifts against fire.

The late Mr. Lorimer was justly esteemed for his sound practical talents and high personal character. In November last he was appointed to the office of Dean of Guild, or by ancient courtesy Lord Dean of Guild, with a seat in the Town Council, in which he had previously served for three years as a Common Councilor. In his official capacity he was convener of the Fire-engine Committee,

and was always sent for on the occasion of fire breaking out. Mr. Lorimer, whose life is said to have been largely insured, was in his 54th year. At a meeting of the magistrates, on Saturday, it was unanimously resolved to ask leave for the magistrates and Council to attend the funeral in their official capacity, and the Guildry intended to make the same request.

It is rather remarkable, that of all those killed only one did not belong to the building trades. The list is as follows:—Mr. George Lorimer, Dean of Guild; Mr. John Taylor, builder; Mr. Thomas Henry Lecke, clerk to Mr. Tod, painter; John Clark, mason, and who had served eighteen years in the fire-brigade; Bernard M'Vie, labourer; George Sweeney, gentleman's servant.

The procurator-fiscal was instructed to take out warrant for removal of dangerous walls, and adopt any other measures necessary for the public safety.

CONDITION OF STIRLING, SCOTLAND.

THE provost of Stirling, Mr. John Murrie, writing with reference to our articles on that town, says:—"At a recent meeting of the police commissioners last week, regarding certain improvements in our town, I brought your remarks before the meeting. Whilst I admit a number of them to be correct, and which I desire to carry out as speedily as possible, there are others which are erroneous; but I do not find fault with you, as very much would depend upon the parties from whom the information was obtained. I, as well as a number of the magistrates and commissioners, have been most desirous to introduce the New Police Bill, which would rectify much that you deprecate, but we have twice been thwarted; yet you make us all appear as if we opposed reformation and cleanliness. I sincerely trust your strictures may be the happy means of aiding us to carry on the many improvements required in our town."

It will be a cause of extreme gratification to us should it prove so. It is to such ends alone that our labours are directed; and with a chief magistrate holding such views as those expressed by Mr. Murrie, we may fairly anticipate changes for the better in the ancient and picturesque town of Stirling.

"LAST WINTER IN ROME."

THESE words have a pleasant sound, especially to those who have spent a winter in the wonderful city, serving to recall what most have found a happy time; and Mr. Weld's book, of which they are the title, will be found pleasant too, as well as instructive.\* It is not a guide-book; says nothing of the stock antiquities and works of art to be found there; but sets forth in an agreeable and piquant way the condition of Rome during the year, and what was said and done there, with many scholarly and apposite references. The more recent works are mentioned; one of them thus:—

"Whew! what is that vile erection deforming the Piazza di Spagna, which has sprung up since we were last in Rome? We approach a pillar of Cippolino marble, reared in front of the Collegio di Propaganda Fide, and read that it has been erected by Pope Pius IX. in commemoration of the dogmas of the Immaculate Conception, established by his Holiness in 1854. Erected too, it might be added, to testify the low state to which art had fallen in Rome. The Cippolino shaft, fine in itself, is entirely spotted by trumpet bronze tracery, which, in the form of lattice-work, coats a considerable portion of its base. Turning away vexed and disquieted, we pass at the foot of the steps leading to the Church of the Trinita di Monte, observe that the quaint old box-shaped fountain is sadly in need of repair, and that the broad steps leading to the church are no longer the resort of artists' models."

Of the investigations by Father Mullooly, at San Clemente, of which we have spoken at some length on various occasions, an interesting account is given. The great marble wealth of Rome struck our author as it does most persons, especially on visiting the museum in the Collegio della Sapienza. In this institution, placed in glass cases, are no less than 607 specimens of various marbles and alabasters used by the ancient Romans. It is, indeed, only by examining these that you truly realise the magnificence of that people in their buildings.† Many

\* "Last Winter in Rome." By C. R. Weld. London: Longman, Green, & Co. 1865.

† This collection was made and arranged by the late Professor Sanguinetti, a gentleman of great scientific acquirements, and professor of mineralogy in the college. Many English families, who have benefited by Professor Sanguinetti's instruction in Rome as an Italian master, will learn with regret that he fell a victim to fever in the spring of last year.

CAMPAÑILE OF THE CHURCH OF SS. GIOVANNI E PAOLO, ROME.

varieties are so beautiful that they seem like precious stones; and so indeed they are, for we know that the Romans incurred enormous expense in quarrying and conveying them from distant parts of Africa. Among the most beautiful marbles are Verde Rannoecchia, Breccia Verde di Settebasi, Rossastra, Pavonazzetto, Africano Principe, Africano Rose, Giallo antico (che ha sofferto l'azione del fuoco), Lavagna Antica di giallo, Basalto di bronzo, Breccia a seme santo; and of the thirty-one varieties of alabasters, Corallino, Fiorito a pecorella, Occhi, Rosa, Giallo, Verdognolo, Sardonico, and Chiaro may be especially cited for their curious markings and exquisite hues. Looking at this unique collection, you can well understand how, ruined as Rome has been by earthquakes, conflagrations, and the effects of time, there are still thousands of marble columns in her churches and palaces, and who shall say how many underground? Good yielding veins of fragmentary marbles run parallel to the Apian and Latin ways. Near the aqueducts you are also likely to find several varieties; for these "camels of the Campagna," as they have been called, rough in their exterior when far from the city, were often clothed in marble when near Rome, that they might be in keeping with the architectural grandeur of that city. Perhaps, however, the richest quarry lately opened is that around the recently discovered Villa Livia. Mr. Weld advises marble hunters to be provided with a sponge and a

bottle of water, in order to wash the surface of the marble fragments, for often a piece that coated with dirt seems worthless, turns on being cleaned to be rare and beautiful; and, on the other hand, what appears rich hued may be only stained by vegetable matter.

The works of Michelangelo impressed him greatly:—

"It is only in Rome that you become really aware of the greatness of Michelangelo. Desirous of studying and understanding the works of that great master, I devoted several days to an examination of the sculptures and paintings by him in that city. The impression left on my mind is, that the works of Michelangelo are stamped with the characteristics of unity of thought, sublimity of conception, and a grandeur of design possessed by the works of no other artist. Goethe observes: 'In design the soul gives utterance to some portion of her inmost being; and the highest mysteries of creation are precisely those which rest entirely on design and modeling; these are the languages in which she reveals them.'"

Mr. Weld has the impression that life was in much more danger last year in Rome than was generally supposed, and gives evidence in support of his view. Everything is ill managed. Feelings of the deepest discontent prevail, and the "National Committee" are active and urgent. Science is at a stand-still; justice a farce. He calls attention, and not before it was necessary, to the miserable state of the Pantheon, foul without and filthy within; no pains seem to be taken to preserve it from corroding influences.

Of the statue of Augustus, found amidst the ruined walls of the Villa Livia, Mr. Weld says,—

"Among the numerous masterpieces of sculpture which arrest your steps, as you pace the halls in that treasure-house of art, this statue holds the highest rank. It represents Augustus as he has been made familiar to us by history, the type of a man who possessed the rare tact of exercising absolute power over a people who, though jealous of their freedom, became not only his willing but also his grateful subjects. Psychologically similar in many respects to the first Napoleon, who had the power of moulding multitudes to his will, the countenance of these men bear a great similarity, especially in the prominence of their chins, and the massiveness of their foreheads.

Ancient sculptors were always extremely careful to embody whatever attributes appertained to the subjects of their statues, and which were at all likely to identify them. Thus, the statue of Augustus is highly emblematic of the man, but the various insignia with which it is covered, and its great artistic merit, can be only properly seen and appreciated by viewing it by torchlight. I saw it twice by this light, and on the last occasion was even more struck by its excellence than when I first examined it. And I have entertained a higher idea of the aesthetic taste of the Pope, since hearing that his Holiness spent an hour before the statue last winter, seated at a small table, on which was placed hot coffee—a great luxury on a winter's evening in the Vatican—an attendant meanwhile exhibiting all the excellences of the statue by means of a small light properly screened."

Mr. Weld sought to obtain leave for a company to search the Tiber, a desire that has occurred to others before him. The reason given for the refusal he obtained in an interview with Cardinal Antonelli was, that any derangement of the bed of the river would be certain to engender malaria. Some few slips are apparent in the work here and there, such as "chair" for "choir" (p. 104), "off leather" for "don leather" (p. 248), which we mention merely that they may be corrected in the next edition. The book is illustrated partly from Mr. Weld's own sketches.

Here is one of them which we are enabled to present, a view of the most picturesque campanile in Rome. It is attached to the church of SS. Giovanni e Paolo on the Caelian, and is interesting as the base is formed of a portion of the Temple of Claustris. You cannot mistake this, for it consists of enormous blocks of travertine, into which the masonry of the tower is built. The tower dates from the twelfth century. Beneath the church is a vivarium, where it is supposed the wild beasts were confined before being introduced into the arena of the Colosseum. It is not possible at present to penetrate through the passage to the Colosseum, as it is choked; but there is every probability that it might be easily opened so as to admit of being explored throughout its entire length. Shafts were pierced in the rock to admit light, and a pool of water is still shown where the beasts are said to have slaked their thirst. Adjoining the vivarium are various large arches, forming vaulted chambers, in which prisoners destined for martyrdom in the Colosseum are stated to have been confined. But all this is mythical.

We must break off here, but our readers will probably think that we have given sufficient evidence that "Last Winter in Rome" is a book to be read.

#### MALVERN PROPRIETARY COLLEGE.

IN our present number we give a general view of the new Proprietary College at Malvern, just completed from the designs of Mr. Charles F. Hanson, of Clifton. We propose, in a future number, to give plans of the two principal floors, and an enlarged elevation of entrance-tower, which is the principal feature of the building.

The college is situate on a gentle slope, at the foot of the Malvern hills, a little to the south of the village, and commands beautiful views of the Worcestershire valley on the east, and of the far-famed range of hills on the west.

The college contains all the necessary accommodation for 600 boys, with ample provision for a full staff of masters, secretary's offices, board-room, &c., &c. The plan is in the form of the letter E, the eastern side being left open, to secure ample light and ventilation to every part. The west, or principal front, is 210 ft. long; the north and south fronts 140 ft. The entrance-tower is in the centre of the west front, 35 ft. by 25 ft., and 100 ft. high, flanked by a low range of buildings on each side, which connect it with the wings, in which are waiting-rooms, secretary's and clerk's offices, master's rooms, &c. The board-room and library are immediately over the entrance-hall, above which are the museum and clock chamber.

The north and south wings are devoted to class-rooms on the ground floor, all entered from spacious cloisters running round the interior of the building. At the four corners of this cloister are stone staircases, leading to the upper floor, on which are the principal school-rooms, 97 ft. by 35 ft., and 57 ft. high. The classical school

MALVERN PROPRIETARY COLLEGE—MR. CHARLES F. HANSON, ARCHITECT.

on the north can be increased to 135 ft. long, by opening the sliding-doors between it and the drawing-school. The modern school, on the south, is fitted up as a temporary chapel, the permanent one shown in the view not having been erected as yet.

The basement extends about half-way under the wings, from which access is gained to the lower terrace and play-ground. On this floor are lavatories, closets, and the apparatus for warming and ventilating the buildings, supplied by Messrs. Haden & Son, of Trowbridge. The contractors for the building were Messrs. Warburton, Brothers, of Manchester, the cost being about 16,500*l.*, exclusive of furniture, roads, boundary walls, &c.

In addition to the above, a residence has been erected for the head master, at a cost of 2,500*l.*; a porter's lodge, 450*l.*; and shortly will be added racket and five courts, gymnasium, &c.

Two masters' boarding-houses, capable of containing forty boys each, have been erected by an auxiliary company, called the "Malvern College Building Company," on land immediately adjoining the play-ground, one of which is ready to receive pupils, and will be occupied on the 25th inst., when the first term commences: the other house will be ready for the Easter term.

The head master is the Rev. Arthur Faher, M.A., late Fellow of New College, Oxford. We understand the college will commence with the goodly number of nearly 100 boys for the first term.

#### SCHOOLS OF ART.

*The Leeds School.*—The annual meeting of this institution, and the distribution of medals, prizes, and scholarships to the successful candidates at the recent examination, has taken place in the Mechanics' Hall, the works of the successful competitors being exhibited upon the walls of the building. There was a large audience. Lord F. C. Cavendish occupied the chair. The report of the committee stated that at present the usual number of 7,430 students received instruction either directly or indirectly from the masters, and that the numbers had more than trebled during the past six years. Mr. Walter Smith, the head master, next read his report, which concluded with the following summary:—

—The Leeds school has, during the last five years of its existence, taught 20,000 children in National schools at a nominal fee; given instruction to 5,000 pupils of the middle classes; taught 2,500 working men in evening classes; has educated four art-masters; has been referred to in evidence given before a commission of Parliament by the chief inspector of art-schools as the type of a successful school of art; is now carrying on art-work in all the great towns of the West Riding, teaching thirty National schools, thirteen middle-class schools, five evening classes in mechanics' institutes, two branch schools of art, and its own classes in the central school. In course of his address, Lord F. C. Cavendish said he believed that there had been implanted in the nature of man by his Creator, a taste for and a love of the beautiful. This taste, like all other natural tastes, was meant for a certain use, and they would all agree with him when he said that this use was to refine and elevate the nature of man. But no taste could exist and grow unless there was something to feed and nourish it. The tendency of modern civilization, crowding vast masses of human beings into towns, where the long rows of streets and the dusky canopy of smoke above shut out the beauty of nature, to a great extent prevented this; but they must not sit down and think that because civilization had certain disadvantages, nothing could be done. Marvellous things might be achieved. Thousands might be sent by cheap trains to the most beautiful parts of the country; and the cheap illustrated hooks and prints were carrying to the homes of many artisans copies of all that was most beautiful in art; but still he believed there was a wide field for institutions like that, which, by means of their galleries, in which exhibitions could be held, and by means of their teaching in popular schools, might nourish that taste, even in spite of the disadvantageous circumstances in which they were placed.

*The Exeter School.*—Sir Stafford Northcote, M.P., who presided at the annual meeting of this school, said, in allusion to the complaints made as to the central school:—Attention has been drawn to complaints made, not altogether without reason, of the unequal division of funds

between the central institution at South Kensington and the provinces, although it should be considered that the institution had an immense influence upon the country. He believed that a great deal more would in a few years be effected in disseminating the advantages of the central institution, although more was being done than some persons perhaps were apt to think. Expensive foreign works of art had been purchased by the Government at large prices; and these had been lent, or copies or casts had been made of them, so that they had been reproduced and rendered saleable at prices fabulously low. Mr. Cole mentioned to the committee an instance in which a majolica plate, originally purchased by the State for 200*l.*, was lent to Messrs. Minton, and had been reproduced so as to sell at 35*s.*; and when the copy was compared with the original, there were hardly any members of the committee who professed to know which was which. In this way it would be sought to circulate these valuable articles that would create a taste for art which fine works of art were capable of engendering. It must, therefore, be acknowledged that South Kensington was doing a great deal of good in the country. Mr. Cole had suggested a plan of organising a system under which fine works of art could be lent from the great national institutions centralised in London to the different provincial museums for limited periods. The more the department of South Kensington was stirred up the better, and he did not regret having been on the committee that had called them to account for having monopolised too much of the Parliamentary grant.

*The Kidderminster School.*—At the annual meeting of this school, Sir John Pakington, M.P., who presided, thus spoke of the ruling authorities of the schools of art:—"I am not one of those, as you may perhaps be aware, who are very enthusiastic admirers of the Committee of the Council on Education. But I must, at the same time, say that I think the encouragement which they have on the whole given—which that department of the Committee of Council intrusted with the conduct and management of these schools of art has given to the cultivation of art in this country—is highly to be commended; and I cannot help thinking that although there may be defects in some respects, yet, as a whole, the management of the Science and Art Department has been such that it has given a great stimulus to the cultivation of art in this country."

*The Birkenhead School.*—A meeting of the subscribers and friends to this school has been held at the school, Hamilton-street, in order to receive from the committee explanations as to the present position of the school, and to take such measures as might be thought desirable for carrying it on, provided sufficient funds could be raised for that purpose. Mr. John Laird, M.P., presided. The chairman said it had been found necessary to call that meeting because the amount of fees received from the students had not been sufficient, under the system hitherto adopted, to meet expenses. He thought they must, under the circumstances, look to the town to provide 150*l.* a year in subscriptions to carry on the school in an efficient manner. A committee was appointed to endeavour to carry out the object of the meeting.

*The Sheffield School.*—The council of this school have presented to Mr. Benjamin Wightman, for twenty years the honorary secretary, a mark of their appreciation of his services. The testimonial consisted of a silver tea and coffee service.

#### THE ARCHITECTURAL ASSOCIATION.

The usual meeting of members was held on Friday evening, the 6th inst., at the House in Conduit-street.

The chair was taken by the President, Mr. J. H. Christian.

Mr. J. T. Hanson, of 10, Old Jewry Chambers, and Mr. W. Wade, of Deau-street, Soho, were elected members of the Association.

The President called attention to the drawings which Mr. R. P. Spiers had submitted to the Royal Academy in competition for the Travelling Studentship and Gold Medal, and which were exhibited in the room. Although he (the chairman) was a Gothic man, he could not but appreciate the affection which Mr. Spiers entertained for the Classic school, and which had evoked the admirable drawing to which the Royal Academy had awarded the studentship. Mr. Spiers had produced a fine façade,—a land-

some group, and a plan which was at once simple and well adapted for the object in view. The subject selected for illustration was not an easy one; and when the very short time which Mr. Spiers had devoted to his drawing was taken into consideration, the success which he had achieved was the more remarkable. He thought the Association ought to congratulate Mr. Spiers on the very creditable manner in which he had competed for the prize of the Academy.

After a few words from Mr. J. D. Mathews, to the same effect,—

Mr. Spiers observed that the advantages held forth by the Royal Academy were not so generally understood by students of architecture as they ought to be. All that was now required to gain permission to compete, was to send in a drawing, which, if considered of sufficient merit, entitled the author to be admitted as a probationer. The design to be submitted for a studentship now occupied but twelve days in the preparation instead of three months as heretofore. For the travelling studentship of 100*l.*, but thirty days' work was required. He regarded these prizes, as also that given by the Royal Institute of British Architects, as most valuable, because they afforded the many means by which young architects could get their ideas on paper before they got into practice. There were, he believed, about 2,000 architectural students in the metropolis alone, and yet last year but three out of that large number offered themselves as competitors for the gold medal. He hoped that students would for the future exhibit a spirit of greater emulation in this respect, and thus encourage the Royal Academy and the Institute to do yet more for the profession.

The Chairman said that until he had heard the statement of Mr. Spiers, he was not aware of the altered rules of the Royal Academy in reference to the prizes offered by them for architectural designs. The subject, however, was one of such great importance to students of architecture, that he hoped the Association would take some means to make the regulations of the Academy familiar to its members.

Mr. Lacy W. Ridge (hon. secretary) then read a paper on Boxgrove Church, Sussex, which has already been described in detail by the Rev. J. L. Peil, the Rev. Mr. Turner, Professor Willis, and others. The priory of St. Mary the Virgin and St. Blinze, at Boxgrove, was founded by Robert De La Haye, the lord of the manor of Hahnaker, or, as it occurred in some ancient documents, "Halfnaked," whose residence was in the immediate neighbourhood. The monks were of the order of St. Benedict, and were originally three in number. They were subsequently increased to thirteen, at which number the establishment remained until 1414, when it was reduced to nine, and remained so until the Reformation. The priory was subject to the abbey of St. Essay, in Normandy, but was within the diocese of Chichester. The village of Boxgrove was four miles north-east of the cathedral town. It consisted at present of a low central tower, transept, and one double bay of the nave. The ruins of the latter extended beyond the present west wall, the whole foundations of which were uncovered in 1853, when the Archaeological Institute of Great Britain and Ireland visited the spot. The excavations then made showed that there were five more double bays towards the west. There did not appear to be any record of the precise date of the building, but, judging from the style of the architecture, it was erected most probably within the last quarter of the twelfth century. Mr. Ridge then proceeded, with the aid of the drawing-board, to point out the most interesting details of the building, which he said he had measured very carefully, and subsequently sketched on the spot. The church was a conventional building, of simple but tasteful construction; and although it was evidently built with a view to economy, the architect had, by judicious proportions and appropriate though not costly ornamentation, shown that he thoroughly understood his business. The walls were faced with flint, and filled up with rubble; but as the dressings were now completely coated over, he could not tell of what stone they were composed.

A member observed, that as there was no stone in the immediate neighbourhood, the dressings were probably of Portland stone.

The Chairman said, he did not think the Portland quarries were known in the twelfth century. It was, he thought, more probable that the stone was imported, and similar to that used in the adjoining cathedral—namely, Caen. He also observed curious perforations in the doors

(which opened outwards) forming a sort of grille, which were ornamented, but for the use of which he was at a loss to account, unless they were intended to give alms through.

A member here remarked that precisely similar openings were to be found in the doors of an old red brick house (formerly a monastic building), with pointed roof, and very strong walls, near the village of Prittlewell, in Essex; the tradition with respect to which was, that the inmates had made a gallant stand against the soldiers of Cromwell, when on their "reforming" campaign, and had fired through the grille upon their assailants.

In reply to a question, Mr. Ridge said, that he had not been able to obtain any clue to the name of the architect who had built the church and priory of Roxbury; but that the natural supposition was that they were the work of the same architect who had built the Cathedral of Clerichester.

After some further discussion a vote of thanks was passed to Mr. Ridge for his paper.

THE ARCHITECTURAL EXHIBITION.

We desire to call the attention of architects and others to the approaching Architectural Exhibition, which will open as usual in March; in the hope that we may lead them to contribute to it. The committee notify that,—"Although pictures in perspective are the most suitable, still absolute working drawings, merely put together on a strainer, or in a frame; details, mouldings, or parts of buildings, are all most desirable." Two *conversations*, besides the opening one, will be held during the Exhibition, and the committee want assistance in that direction also.

THE ARCHITECTURAL INSTITUTE OF SCOTLAND.

THE EDINBURGH ALBERT MEMORIAL.

At a meeting of the Scottish Institute on the 12th, Mr. Seton, advocate, in the chair; Mr. Rodgers, the honorary secretary, read a letter from Mr. D. Cousin, urging somewhat strongly that the Institute had no right now to interfere in respect of site; and maintaining that it was not actually Arthur's Seat that was proposed for it, but a ridge quite distinct from what is properly so called. Mr. Lessels, Mr. Peddie, Mr. Thomas Stevenson, engineer, and several other gentlemen, spoke in condemnation of the proposal to make Arthur's Seat the site; and the meeting unanimously decided to memorialise the Committee of Advice, to that effect.

The following has been accordingly presented:—

"Petition of the Architectural Institute of Scotland," humbly shewing,—That at a public meeting of the Institute, held in the Hopetoun Rooms, Edinburgh, on the evening of Thursday, the 12th inst., it was unanimously resolved that the site on Arthur's Seat, proposed by the committee, is unsuitable for any monument, and that the erection on it of the Memorial to the Prince Consort would be inexpedient. That this meeting of the Institute was attended by a large number of influential citizens of Edinburgh, who were invited to take part in the proceedings, and who unanimously and cordially concurred in the opinion of the Institute; and the Institute is fully satisfied, from the statements of the press and otherwise, that this opinion is entertained by the public at large. May it therefore please the Royal Committee of Advice to take this petition into consideration, and to adopt such steps as may be deemed desirable to prevent the proposal above referred to from being carried into effect."

THE CROSSLEY ORPHANAGE, NEAR HALIFAX.

We are requested to mention what, if we had been informed, we should certainly have stated in giving the illustrations of the orphanage—namely, that the original architect of the building was Mr. John Hogg, of Halifax. The alterations made by the architects who rearranged the interior, and completed the work, appear to have been confined mainly to the upper part of the building, including especially the clock-tower. Mr. Hogg appears to have just cause of complaint that his name was kept out of sight.

STRIKE AGAINST AN ARCHITECT.—At the moment of going to press we received a printed account from Mr. A. Waterhouse, of Manchester, of the treatment he has received at the hands of the Manchester Union Bricklayers. A hasty perusal seems to show that he has been treated scandalously. We must return to it.

BRISTOL SOCIETY OF ARCHITECTS.

At the annual meeting of this society, held recently, Mr. E. W. Godwin in the chair, Mr. Chas. J. Phipps, hon. secretary, read the report, from which it appears the society now consists of 21 fellows, 18 students, 13 amateur members, 9 corresponding members, and the artist members of the Academy. The gentleman who has filled the office of president for two successive years, Mr. P. W. S. Miles, now retires, in accordance with the rules; and the council have elected their oldest member, Mr. Charles Underwood, to fill the office. The council desire to impress on the members generally the necessity of maintaining the library in an efficient condition, and would invite donations of books for that purpose. They have also under consideration a proposal for offering prizes to art-workmen. A balance-sheet of the receipts and expenditure since May last was presented, showing receipts to the amount of 46l. 4s. 8d., and expenditure, 46l. 13s. 8d.

The chairman referred to the present prospects of the society, and of art in this locality; and observed that one feature was now occupying the thoughts of a good many persons,—architects among others,—viz., the new Assize Courts for Bristol. If Bristol acted in the matter of those assize courts as she had hitherto acted in all matters of public interest, she would only add another had mark to her name on the list of the cities of England. An opportunity was now afforded for Bristol to redeem all the bad things she had hitherto done, by erecting the assize courts on some suitable site to begin with, not to cram them up where it was impossible for the angle of vision to take them in.

Mr. Charles Pooley read a paper on "The Crosses of Gloucestershire," which was illustrated by a number of drawings of ancient crosses to be met with in different places in the county, amongst them being representations of those at Bisley, Calmsden, Cirencester, Lydney, Clearwell, and Aylburton, contrasting with the high crosses of Gloucester and Bristol, and the preaching cross at Iron Acton.

A BRISTOL NEW CLOTH WAREHOUSE.

THE establishment of Messrs. Crowe & Co., clothiers, adjoining Colston's-hall, Host-street, is a very extensive one. The cloth room is 90 ft. by 24 ft., a staircase in one direction leads to the cellars, and another flight of steps conducts to the made-up goods or stock-room, which is 150 ft. in length and 26 ft. in width, and the fittings here are of mahogany and pine, French polished, and supported by bronze standards. The cutting-room, which is immediately over the stock department, is about 150 ft. long by 25 ft. broad, and contains accommodation for some forty cutters. Attached to this room is a ponderous cutting-machine, which in a separate compartment will be worked by steam-power. The trimming-room, an apartment adjoining, is 50 ft. by 25 ft., and fitted up with a great number of shelves and drawers. The out-workers' apartments have separate entrances and places of exit; and there are also in this part of the building a cash office, and a room in which the goods manufactured out of the premises can be examined, whence they may be removed to the brushing-room, and then deposited in the stock-room. The large work-room, capable of accommodating between 400 or 500 hands, is directly over the stock-room, and is similar in extent to it. Upwards of forty sewing-machines, driven by steam, are here ranged, and also great lengths of tables. There are immense stores for heating the irons used by the tailors, and likewise a considerable quantity of shafting for working the machines. By a very simple arrangement—the invention of the architect—the sewing-machines are put in and out of gear, and the stitches can be regulated so that a machine will work very slowly, or produce 500 stitches per minute. Adjoining the apartment just noticed, is a room, 50 ft. by 30 ft., to be used for the manufacture of juvenile clothing. The whole of the different apartments are approached by a fireproof staircase. Above the staircase is fixed a tank, nearly 20 ft. square, which will be required in working the hydraulic machinery, and will contain a general supply of water for the building. Extensive and improved lavatories, &c., are on each floor. In the cellar is an enormous gas-meter, for the supply of 500 lights. The whole of the building is ventilated by a shaft in connexion with the engine-chimney, and which is capable of carrying off

about 6,000 cubic feet of air per minute. The place is warmed by steam. There are about 130 windows in the whole building. Attached to the business premises is a dwelling-house, with an entrance from Trenchard-street, to be occupied by some of the clerks, a housekeeper, &c. Mr. Masters, of Bristol, was the architect, under whose superintendance the work has been carried out. This gentleman also designed the extensive premises of Messrs. Walsh, clothiers, Quay-street, which have been recently erected. The following tradesmen executed the work:—Mr. M. Kingstone, mason; Messrs. Eastbrook & Son, carpenters and joiners; Mr. D. Taylor, plasterer; Mr. J. Palmer, plumber and glazier; Mr. J. Smith, smith; Mr. H. Harris, gas-fitter; Mr. E. Roach, engineer; Mr. R. M. Bryant, fittings; and Mr. J. Edbrooke provided the smith's work for the fittings.

NOTES FROM YORK.

A CORRESPONDENT writes,—The improvements in Little Blake-street, consist in laying out the cleared space of ground near the new Masonic hall with grass sods, and railing it off with a sort of Gothic open rail, ornamented at intervals with the *fleur-de-lys*. By having the rails open, it interrupts as little as possible the seeing York Minster from pinnacle to base,—a most desirable matter, and very grand it looks. There have been measurements taken and drawings made, for a restoration of Belfry church; and it is to be hoped that if it is restored, the frightful modern Gothic windows will be taken out, and windows of a character corresponding with the age at which this ancient building was built substituted. It will be desirable to open the ancient doorway, which is a beautiful one, and which can easily be used now there is such an ample space before it. The next building, the guildhall of the ancient city of York, is going to have a series of stained-glass windows, placed in the old windows now filled with plain glass. The subjects, I should suppose, will be connected with the history of the city. The walls of the guildhall are whitewashed. I would suggest the plan mentioned in the *Archæological Journal* of the Archæological Institute, vol. xix., p. 220, where it says, "St. Cuthbert's church, the ancient cathedral of Cologne, situate to the north of the cathedral, on the bank of the Rhine, has recently been carefully restored and decorated in polychrome, with great effect. The semicircular apse has been painted in imitation of tapestry, with a grand figure of the Saviour in the upper part. The stained glass in this church is considered to be the oldest in this part of Germany." There is another matter in the decoration of this old hall which ought to be remembered. It had before the memorial window erected to the memory of Alderman Meek, a good window, by Giles, a glass stainer of the time of James II. Besides having the royal arms of James II., it had figures of Justice and Abundance, and a representation in a lower compartment of a stag or hart, and a waterfall, most likely allusive (in a covert way), to the verse in Scripture, Psalm xlii. 1.—"As the hart panteth after the water brooks, so panteth my soul after thee, O God;" meaning, no doubt, King James II.'s preference for the Catholic religion. It is supposed a window cannot be found, when all the new windows are arranged, large enough to contain this old window; and as the painted glass "Giles" is rare and fine, I would suggest that one of the windows of the Minster now filled with plain glass be the place to put this interesting and very curious old window of the time of James II. The old chapel of the Bedern had some painted glass, which was taken out of its windows to preserve it from destruction. It is now in cases in the Minster; and I would also suggest that it be put up in one or more of the windows of the Minster at present filled with plain glass. Of course, a label at the base of the window should describe, in Gothic characters of the same age as the glass, whence all these windows were brought, and the date of their putting up in the Minster. Mr. Verrill, the homonger, on the Railway-station side of the Ouse bridge, is extending his handsome Gothic shop and warehouse front, which well deserves to form an illustration in one of the numbers of the *Builder*.

A most desirable thing as an improvement to the city of York would be to have a central station (as stated some time ago in the *Builder*) in Little Blake-street, where, if the houses that

remain were pulled down, a square would be formed before York Minster similar to the landing "Citadel station," at Carlisle. Then the line might be carried down Parliament-street, which might be covered with glass. From thence it might proceed through the White Swan-yard; cross, I believe, the Fusse, pass York Castle; and joining the cattle line down the moat, outside the City walls, at Micklegate-bar, join the Cattle-market near Walmgate-bar. The river Ouse might be crossed by an American bridge, wood or stone piers, which might be put across the river at St. George's-fields, for (say) the expense of 3,000. I need not say how much this would benefit all the property in the neighbourhood, as well as the city at large.

It has been proposed to change the name of Mincem-street, from the new bridge to Great Blake-street; and from Great Blake-street to Little Blake-street, to Duncombe-street. Now, I declare, as an antiquary, I cannot agree to this changing of the names of streets. They have changed Jubbergate, the Jews' quarter, where we can imagine Isaac of York, mentioned in Sir Walter Scott's novel of "Ivanhoe," to have resided,—into Market-street, thus confounding its identity; and as I detest this, neither can I agree to the substitution of the name of Duncombe-street in the city that James II. took his title from as Duke of York. Let us preserve the names mentioned by great authors and hallowed by great events; for (to alter Longfellow).—

"These are the grand old masters,  
These are the new suburbs,  
Whose distant footsteps echo  
Through the corridors of time."

#### CONDITION OF THE MANCHESTER POOR.

A COMMITTEE appointed by the Manchester Statistical Society have been investigating the social condition of the Manchester poor, and they have published a number of statistics on the subject. The inquiry has been prosecuted from house to house, and such information as the people could give has for the most part been very readily imparted. The numbers representing the density of the population show that for the whole district inquired into there are 231,167 persons to the square mile, or an average of 13.26 square yards of ground for each individual. The average number of rooms occupied by a family is 2.46; but there are no less than 297 families, or 28.15 per cent. of all the families in the district, living in one room: many of these families consist of four, five, and six persons, and in several cases of seven persons each. In one case there are five persons in the room, their total earnings are 4s. and the rent is 1s. In another case there are four persons living in a one-roomed cellar, consisting of a widow and her lodger, and a spinster and her child. In another case, a man and his wife and two lodgers are living in one room: the man earns 18s. a week. In another, the family consists of seven persons, the children being two boys and three girls, two of them over twelve years, and their earning, 4s. 2s. a week. Many other cases of a similar kind have occurred in the inquiry.

In 574 cases the occupation of the head of the family is described as permanent, in 398 occasional, and in 82 cases as none at all. There are 571 families which consist of father, mother, and child or children. The number of lodgers who pay for their lodging is less than half the whole number. Very many of those who do not pay take care of the house or the children as an equivalent for their lodging: in some cases the lodgers are parents or other relatives of the head of the family, but in many cases they are no doubt prostitutes. The number of those who have money in the savings-bank is extremely small, viz., twelve, and of these only three are strictly working people.

In reference to the articles of food which form the staple of the family, considerable difficulty has been experienced, and it was found that in most cases the people were either unable or unwilling to tell what their principal food consisted of, or what was the cost of it. In forty-five cases, however, the principal food was stated. In one case a man and his wife and five children, whose total income is 19s. and rent 2s., spend 8s. 9d. a week in bread. Another family of six persons whose income is 26s. and rent 2s. 3d., spend 5s. for bread, 2s. for potatoes, 2s. for bacon, and 1s. for coal. In one family they never have any meat, their chief food being bread and tea. Another family of four persons,

whose income is 4s. and rent 1s. 9d., have for five months had only one meal a day; and another, of three persons, where the husband and wife both work, and earn between them 3s. a week, and pay 1s. rent, have also but one meal a day.

#### THE CENTRAL CO-OPERATIVE STORES IN MANCHESTER.

THE new central co-operative stores in Downing-street have been opened. The building depends externally for architectural effect on a mixture of coloured and moulded bricks, stone being sparingly used. The shop-fronts are carried on box lintels of cast-iron, visible, and constructionally treated. The pediment by the line of main cornice. The facade is in Downing-street, from which entrance is effected by a stone staircase as the reading-room and library, which are special features connected with the stores. The large hall above is capable of seating nearly a thousand people. Another entrance leads to the drapery establishment and to the show-room on the first-floor; and on the ground-floor is the shopping warehouse, divided into two compartments, one for groceries alone, and the other for bread and food stores. In the cellar is a lakehouse, admirably fitted up.

Messrs. Pennington & Bridgen were the architects. The cost, including the fittings, supplied by Messrs. Statham & Sons, of Pendleton, has been over 3,000l. The builder was Mr. Johnson, of Ancoats.

At the inauguration, Mr. Percival gave some facts as to the progress of the society since its establishment, a little over five years ago. During that time, he said, the business done had been to the extent of 150,000l., and the working expenses amounted to 6,900l., leaving a net profit of 8,022l. The latter sum had been expended in interest to the members, 3,089l.; allowed for depreciation on fixed stock (costing the society 1,400l.), 771l.; devoted to the purposes of reserve fund, 125l.; applied to educational purposes, 111l.; 50l. had been given for various benevolent objects; and 5,870l. had been divided amongst the members and non-members. The society commenced with a capital of 100l., which had accumulated to 3,000l.; and, during the year, 2,000l. had been added.

#### THE BUILDING TRADES MOVEMENT.

THE strike and its cause still remain unsettled, and the men are everywhere protesting against the "discharge note," and resolving to assist those on strike in the Midland Counties. The masters at Birmingham are said to be wavering, but a series of resolutions by the Association, published in the *Birmingham Journal* of last week and elsewhere, do not give much indication of a disposition to abandon the "discharge note," although the resolutions "strongly recommend to the whole body of the operatives that all future disputes in the building trade be settled by arbitration." They also urge the formation of a national union of masters, and joint attention to the "discharge note" as a chief object to be kept in view by such a union at its meetings. Others of the resolutions are explanatory of the intentions of the "note," and (uselessly, we will venture to say) endeavour to persuade the men that they misunderstand its objects and its consequences, and that these are not hostile to their interests. The last resolution is, "That the original address read at the Birmingham meetings, the president's speech, and these resolutions, be sent to the *Times*, the *Builder*, and all the leading provincial papers in the Midland Counties." As to this resolution we feel it requisite to explain that, if these documents were addressed to the *Builder*, they failed to reach us, otherwise we should not have allowed our last issue to appear without any allusion to them.

Since these resolutions were passed, however, the aspect of the dispute has, it seems, undergone some change. Several of the masters, it is understood, are dissatisfied with the action of the general body, and are disposed to sever their connexion with it. The various trade societies throughout the kingdom, as we have already noted, are organising subscriptions in aid of the men on strike, and the leading organs of the newspaper press—London and provincial—have unanimously taken an adverse view of the policy of the masters, as we stated last week. The men, we believe, will agree to settle all other

questions by arbitration, in accordance with the resolution adopted by the masters, but they will admit of no arbitration and no compromise as to the obligations "ticket-of-leave," in respect to which their adverse feeling is very strong. The carpenters and joiners, the only class at present on strike, have formally signified their assent to the proposal of arbitration as a rule, and the other branches would, no doubt, follow their example were the "discharge note" withdrawn. At Malvern, one of the members of the Masters' Association has already formally renounced the "discharge note," in a written agreement with his men, who have accordingly returned to their employment, on the terms of a three months' natural notice of change. At Sheffield, Halifax, Stockport, and other places, the workmen have had meetings protesting against the "note," and resolving to aid those on strike. A delegate meeting of the London carpenters and joiners, have also done the same thing, and forwarded 100l. in one week to the Midland districts on strike. At this meeting the propriety of calling a general meeting of the London trades was discussed.

#### THE "DISCHARGE NOTE."

Str.—Knowing that you adopt the motto of bearing both sides, I am somewhat surprised that no workman has forwarded his reasons for opposing the above project of "The Master Builders' Association." The masters have shown that they care for a national union, which will embrace every village and town in the kingdom. It is too late in the day for such a farago of nonsense to pass current as that read from the chair by the president of the Builders' Association, at Nock's Hotel, Birmingham. The talk about the oppression and dictation of operatives is mere booby, whilst the operative can point to builders who a few years ago had not, as the saying is, a fishing in the world, but who now have their carriages and establishments, which outdo those of the aristocracy and merchant princes. The operative begins to understand and hear the masters' idol called "accumulated labour." The masters seem to forget that the schoolmaster has seen abroad, and that the works of Adam Smith, McCulloch, Morrison, J. S. Mill, the *Edinburgh* and *Westminster Reviews*, and other politico-economic writings, are found upon a large number of the building operative's book-shelves, and the master builders or their secretaries be as familiar with the economic doctrines they are always prating about as many of the operatives are, fancy they would have the tact to introduce "the master and ticket-of-leave." Adam Smith says,—"The property which every man has in his own labour, as it is the original foundation of all other property, so it is the most sacred and inviolable. Capacity to labour is to the poor what stock is to the capitalist. Now, a hundred or a thousand capitalists may form themselves into a company to combine their like all their means in common, and dispose of their property as they may, in their collective capacity, judge most advantageous for their interests; and why should not a hundred or a thousand labourers be allowed to do the same by their stock? Of all the species of property which a man can possess, the faculties of the mind and the powers of his body are most particularly his own; and to fetter him in the mode in which he is to exercise or dispose of these faculties and powers, is a manifest encroachment on the most invaluable of all rights." The masters reverse the above, and make capacity to labour less than that of the Middle Ages. Because the character of a builder's workman is seen in his first piece of work; and as a door, sash, and frame take but a short time to complete, and the materials are in hand and the finish of them constitute character sufficient for a three weeks' or a month's engagement with a master builder. I might cite other objections did space permit, but I think the basis in the above sufficient to justify a unionist opposition of the "ticket." A JOINER.

"PATENT BRITISH CEMENT."—As a cement to unite either similar or dissimilar substances, such as glass and stone, marble and wood, and so on, this certainly seems to be a valuable material, and likely to be useful. At any rate, a number of specimens of such "joinery" have been laid before us, exhibiting remarkable adhesiveness.

• We print the following, as representing seven or eight communications to us on the subject, received from Joiners, bricklayers, and masons.

MONUMENTAL.

A GREAT memorial work is to be raised on the spot lately occupied by the *Barrière de Cléchy*, Paris, to commemorate the defence made there under Marshal Mouton, in 1814, and the project has been submitted to public competition. Twenty-seven designs were sent in, and six were chosen, the authors of which were invited to compete again amongst themselves. The prize has fallen to M. Doublemard. The principal group represents the marshal protecting with his sword an allegorical figure of the City of Paris, and being supported by four other figures—a garde national, a man of the people, a polytechnic student, and a pensioner.

A colossal statue of Vereingtorix, the celebrated Gallic chieftain, is about to be raised in the town of Alise, the ancient Alesia, where that hero made a desperate resistance to Julius Cæsar. This statue is about 20 ft. high, and the work of M. A. Millet. The difficulty and expense of executing such a gigantic work, either in stone or bronze, have led to the adoption of gessoed work. A considerable portion of the work is done, and report speaks highly of the effect, as far as it can be judged at present. The gessoed work has been entrusted to M. Aubert.

A granite obelisk, 15 ft. in height, has been sent out to Shanghai, to be erected over the grave of Mr. Alexander Bremner, C.E. The obelisk is of Aberdeen granite, sculptured by Mr. Keith, of Aberdeen, and prepared under the directions of Miss Sarah Bremner, sister of the deceased gentleman. The inscription on the base of the obelisk is,—“In memory of Alexander Bremner, C.E., of Wick, Gairness, N.B., who was cut off by cholera, when preparing to return to his native land, after a temporary sojourn in Shanghai, on the 14th October, 1862, in the 44th year of his age.”

Sir George Abercromby, of Forglan, bart., says an Elgin paper is about to have a memorial erected at Forglan, from plans by the Messrs. Reid, architects. It will cover 45 ft. square, and contain thirty coffin-shelves, of marble, on the sides, and six sunk compartments in the floor. The style will be Decorated Gothic, having parapet and raking parapet, pierced with quatrefoils.

PROPOSED TECHNICAL EXAMINATIONS FOR ARTISANS.

As growing out of the paper on Art-workmanship, recently read at the Society of Arts, and no discussion that followed it, Mr. Thomas Whiting has proposed to the Council of that society the establishment of examinations for testing the abilities of certain classes of workmen who may desire to be examined, and granting certificates of competency; offering to defray the cost of preparing the text-books required, and the examination fees for the first experiment. We shall doubtless hear more of it.

SANITARY MATTERS.

Liverpool.—Under the new Liverpool Sanitary Improvements Act, the Deputy Recorder, at St. George's Hall, has received a presentation from the grand jury upon premises reported to them by Mr. Trench, the medical officer. The present report upon twenty-nine different lots of property, mainly situate in close courts and alleys, to the effect that “they are in a condition, state, and situation prejudicial to health, and ought to be improved; and that the houses, privies, and ashpits thereto belonging, and specified in the report of the medical officer of health, dated the 7th of December, are in a condition, state, and situation prejudicial to health, and unfit for human habitation.” The present report extends to the erection of water-closets, &c., in the places named, and concludes as follows:—“That they (the grand jury) find that many courts and alleys within the borough of Liverpool are rendered prejudicial to health and unfit for human habitation by reason of the same being open middens, ashpits, and privies, and that such courts and alleys should be improved, and the above objections thereto removed, by trough water-closets being substituted in the place of such open middens, ashpits, and privies.”—At the last weekly meeting of the Liverpool Workhouse Committee, it was stated that the typhus fever epidemic prevalent in the town was almost entirely amongst the indigent and dissolute classes. Tho

melancholy announcement was made that of the six workhouse surgeons attending on the patients in the fever hospital, one had just died, two others were seriously ill, a fourth was absent on sick leave (all from typhus), and that only two remained fit for duty.

Stamford.—The fatal prevalence of scarlet fever in this town has called into action the Sanitary Committee of the Corporation. At a meeting, the Mayor in the chair, it was resolved that a notice be sent to the owners of property in Water-street, &c., recommending, “as an essential step, that the landlords and tenants in the affected localities do immediately cause the said tenements to be cleansed, whitewashed, and properly ventilated; also furnished with a liberal supply of clean water; and that they should prevent, as far as possible, overcrowding in their tenements.”

RAILWAY MATTERS.

The estimated cost of the proposed high-level railway bridge over the Severn, just above Old Aust Passage, is 1,800,000. The river at this point is nearly two miles wide, but the main channel is not more than one-third of a mile. In order to bridge over this channel, and not interfere with the navigation, it is proposed to construct a bridge at a height of 110 ft. above high-water of ordinary tides, and of three openings—one of 600 ft., and two of 250 ft. respectively. Mr. H. H. Fulton, the engineer, in conjunction with some influential coal and iron masters, is the originator of the movement which has led to the adoption of the project by the Great Western Company. Mr. John Fowler, the consulting engineer of the Great Western, and Mr. Fulton, are now acting as joint engineers.

A compensation case, *Wyld v. The Manchester and Sheffield Railway Company*, has been decided in the Court of Queen's Bench. The plaintiff, a contractor and quarryman, was a passenger from Glossop to Newton, and the train being an exceedingly long one, part of it shot beyond the platform, and many of the passengers had to get out in the dark beyond the platform. The plaintiff, in getting out, received serious injuries from falling against a pump-handle, and the jury awarded him 1,250l. damages. The Lord Chief Justice, however, considered the damages excessive, and stayed execution on the payment into court of 500l. Subsequently, Mr. Temple, Q.C., obtained a rule nisi to set aside the verdict, and for a new trial, or to reduce the damages. At the suggestion of the Lord Chief Justice, it was arranged that the damages should be reduced to 1,000l., without costs on either side for the rule.

The total railway receipts for 1864 amounted to 33,182,490l., being an increase of 2,638,430l., or about double the average increase per annum. The increase of traffic on the Caledonian Railway amounted to 100,900l.; Great Eastern, 105,000l.; Great Northern, 201,000l.; Great Western, 209,000l.; Lancashire and Yorkshire, 191,000l.; London and North-Western, 449,000l.; London and South Coast, 32,000l.; London and South-Western, 61,000l.; Manchester, Sheffield, and Lincolnshire, 84,000l.; Midland, 237,000l.; South-Eastern, 51,000l.; North-Eastern, 309,000l.; and North British, 62,000l.

The traffic receipts of railways in the United Kingdom amounted, for the week ending the 7th of January, on 11,786 miles, to 565,249l.; and for the corresponding week of last year, on 11,460 miles, to 530,292l., showing an increase of 326 miles, and of 34,957l. in the receipts.

METROPOLITAN BOARD OF WORKS.

THE RIDLEY TENDER.

At the last weekly meeting of the Board, the Main Drainage Committee presented a statement on this subject, which they submitted to the Board, as a reply to the charges made against the Board and its officers respecting the non-acceptance of Mr. Ridley's tender.

Mr. Upton moved that the statement be adopted by the Board. Various amendments were moved and negatived; and after a long discussion and an adjournment, the motion of Mr. Upton was finally adopted by a majority of 21 to 6.

It was then ordered that copies of the Drainage Committee's report and statement be sent to the members of both Houses of Parliament, and to the members of vestries and Court of Common Council.

PLAIN-TILING.

Sir,—In answer to your query on plain-tiling, thirty-five years ago I was employed to tile the roof of a mansion containing over 100 squares. The tiles were all laid in mortar; the mortar was laid at the bottom of the tiles; and the cross joint of each tile was carefully struck from top to bottom, thus preventing any water getting under the tiles. There was no symptom of wet getting in on any part of the house, nor any repairs for many years afterwards. There are very few bricklayers in the London district who can be safely entrusted to do plain-tiling in mortar unless strictly looked after, they using too much mortar, and not being careful with the cross joints, in which lies all the mischief. The mortar should not be laid more than 2 in. wide, and the tiles rubbed close together. All red tiles, as they are more or less porous, should be thoroughly saturated with water before using; it makes them tougher, and they will not absorb so much a second time.

With respect to laying plain-tiles in hay (I have done a great deal that way, as in the part of the country in which I resided slates was the exception, plain-tiles the rule), I consider if a roof is lathed with heart-of-oak lath fixed on with tenter-hooks bent in lined-off,—the hooks not driven through, but at the under edge of the lath,—loose hay litter spread evenly over the tiles, kept on with flat-headed iron pins, boiled the same as the hooks,—you will have the best kind of plain-tile roof for buildings where there is no walking over; but where there are gutters and trap-doors in the roof, I consider laying in mortar is the best, it not being so likely to get damaged by walking over. As to laying in hay being a modern practice, my father, who is seventy-six years old, and in the trade, says it was common in his youth, and considered the best method.

PRACTICE.

Another correspondent says, in the course of a letter on the subject:—

“In answer to query No. 3. Has mortar ever been known to render roofs damp; and, if so, why? My experience goes to show that tiles bedded in mortar always render the roof damp, from several causes. First, there are always hollow places, or cups, in the mortar underneath the tiles, which serve as reservoirs for the water, which escapes only by percolation or evaporation; secondly, in bedding tiles in mortar, the mortar squeezes into the vertical joint, which prevents the water running freely down the edge of the tile, and causes it to spread along the bed of the tile, to be again impacted in its descent by the mortar which forms the bed of the tile above; thirdly, mortar encourages moss to grow in the joints, as, when it decays, it forms a soil for the moss to root in, and the moss, again, impedes the escape of the water. The best method of tiling is to hang the tiles on to the laths without any bedding of any description; and when the roof is covered in, to touch them on the inside with stout hair mortar, run along on the top of the laths and the heads of the tiles, which prevents the snow drifting up, and holds every tile down to the lath. But all tiles should be made an eighth of an inch wider at top than bottom, which prevents the tile from pushing the bottom end of the joint open, which forms a channel for the water to run down, which is very important; for if the edge of one tile touch the other, the first of the roof washes into them, and stops them up; thus the water is impeded in its natural channel, which causes it to spread on the bed of the tiles and run through the joints, which would not be the case if the joints of the tiles were an eighth of an inch wide, as the water would prevent them from gluing up.”

H. P.

COLOURED BUILDING STONES.

Sir,—It has occurred to me that a very good opportunity has arisen for treating our building stones from a polychromatic point of view, through the medium of a lithographic publication. Great service might thus be done in assisting architects in the introduction of colour into their buildings.

There can be no doubt that, with the great variety of stones within our reach, greater effects, and those of a more artistic sort, might be produced than at present. The continued use of the positive colours, so much in vogue, has a tendency to vitiate taste by a crudeness of tints, and coarseness of feeling, nowhere to be found in our great instructor, Nature.

We have works in abundance illustrating the effects of our old architecture as questions of form, but very few in regard to their effect in colour; and while we may readily study these works in one direction, we are deterred from considering them in another.

It has been argued that the natural mode of using stone is to take it as it occurs in any particular part of the country, and so confine its use to that district. The fallacy of this our artificial atmosphere will at once demonstrate. Of course, as nature did not take into account, in the formation of rock, the various combinations of air would have to submit to, by reason of smoke, &c., the argument becomes rather more ingenious than sound. It is, therefore, no reason why we should not have the full use of any stones that may be harmoniously combined in our buildings. Of course, another question than colour would have to be considered,—durability, and the capabilities of the various stones to stand different atmospheres of the various generalities to be taken into account,—the ultimate general effect which a particular stone will have after a certain length of exposure, independently of the colouring influences at work through smoke, &c.

G. S. A.

## THIN SHEET IRON.

THE American specimen which we some time since noticed in the *Builder* has naturally led to attempts in this country to ascertain the thinness to which British iron can be rolled; and Messrs. Murrall & Stohort, the metal brokers, of Cardiff, are said to have produced some sheets which, it is claimed, surpass the American specimens, both in quality and thinness. The plates are less than the 1,000th part of an inch in thickness, and a plate 8 in. by 5½ in. weighs 2 dwts. 14½ grs. only, without the slightest flaw, either at the edges or elsewhere. They are manufactured by Messrs. T. W. Booker & Co., of the Melingriffith Works, near Cardiff, from their celebrated R. G. "tagger" or "button iron," and are one-tenth thinner and lighter than the American plates to which such great consideration has been given. "The thinnest sheet of iron yet rolled in the world" (1,000th part of an inch) has elicited numerous competitors in this country. We mentioned that iron had been rolled at Cardiff considerably thinner, and since then some iron still thinner has been rolled by Messrs. James, of Bilston. A sheet has been rolled from common iron of the ordinary sheet mill by Messrs. Robert Williams & Co., of Swan Village, West Bromwich, which is only 1,015th part of an inch thick, is very tough, and has a good even surface. Another specimen consists of two sheets, measuring 8 in. by 5½ in., weighing respectively 49 and 49½ grains, and being the 1,400th part of an inch in thickness! These marvellous examples of iron rolling were produced by Messrs. Nevill, Everitt, & Co., of the Marshfield Iron Works, Llanelly.

## ACCIDENTS.

DURING the late storm of wind, about 60 ft. of the great chimney at the factory of Messrs. Pontifex & Wood, engineers, in Shoe-lane, London, was broken off by the gale, destroying a smaller shaft, and falling into a dwelling-house in Plumtree-court, injuring six of the inmates, who were asleep at the time.

At the Peterborough station of the Great Northern Railway, a locomotive boiler has exploded, killing two persons, and injuring seven others, besides destroying a shed, 100 yards long by 40 yards wide. The damage to property is estimated at between 2,000l. and 3,000l.

At Liverpool, one of the 44-in. mains, connecting the Prescot with the Kensington reservoir, at Rivington, burst, flooding the neighbourhood, and destroying the road and footwalks. In about half an hour the water was shut off, and new pipes were immediately forwarded from Prescot. The double line of mains will shortly be completed to Kensington from Prescot.

A builder, named Jacks, of Lambeth, has been dashed to pieces, whilst crossing the line at Clapham Junction station.

An explosion of firedamp, attended with terrible loss of life, has occurred in a coal-pit at Hainault, in Belgium. Forty-two dead bodies had been got out of the mine, and sixteen or seventeen more remained to be found.

The tower of the well-known church of St. Lawrence, at Nuremberg (Bavaria), which is 300 ft. high, has been struck and set on fire by lightning, destroying the whole of the upper part.

## CHURCH-BUILDING NEWS.

*Pett (near Hastings).*—The Church of Pett is designed in the style of the architecture of the fourteenth century. The building is erected with the stone of the neighbourhood, but the window dressings, door jambs, and other ornamental parts are executed in Bath stone. The church consists on plan of a nave, chancel, and vestry, and a tower standing at the north-west corner of the nave, the ground story forming a porch to the church. The tower is square on plan to the belfry stage, when it changes to an octagonal plan, with couplet belfry windows. The tower is surmounted by a lofty spire covered with shingles. The roofs are covered with local tiles. Internally the church is fitted with deal stained seats, and open timber roof stained. The edifice is visible from the road between Hastings and Rye for a great distance. The church accommodates 250 persons, and costs about 2,500l. Mr. B. Ferrey was the architect; and Messrs. Dove, Brothers, were the builders.

*Roads (Northants).*—The Parish Church of Roads has been re-opened for Divine service, after having undergone extensive alterations. The south wall and porch have been rebuilt, the west wall restored, the nave re-roofed, the south door of the new south porch restored, the galleries taken away, and the pews have given way to open seats. The cost of the restoration is about 800l., the expense of all, with the exception of the pews, being covered by a rate extending over six years. The seats have been put in by voluntary subscription. The restoration has been carried out under the superintendence of Mr. Whitney, of Northampton; Mr. Shakeshaft, of Ashton, being the contractor.

*Mentmore.*—Baron Rothschild has erected a Protestant church here for the benefit of Protestants in his employment.

*Bournemouth.*—The new chancel and burial-ground of St. Peter's Church have been consecrated by the Bishop of Winchester. The newly-added chancel, and its aisles and transepts, are in the Early English style. The carving, including reredos and pulpit, was executed by Mr. Earp, of London, under the direction of Mr. G. E. Street, architect. The contractors were Messrs. Rogers & Booth, of Gosport, and the clerk of the works was Mr. Davison.

*Cricklade (Wilts).*—St. Sampson's parish church has been re-opened for divine worship. The former ruinous and dilapidated condition of the structure is well known. The Earl of Radnor offered to restore, at his own cost, the Widhill aisle; and the vicar, the Rev. F. Dyson, assisted by the churchwardens and the leading inhabitants of the town, at one set about the work of restoring the remaining portion of the work, under the direction of Mr. Christian, architect. The expense of these works was at first estimated to amount to 2,000l., but as the work proceeded it was found necessary to extend the sum to 3,450l., or nearly double. With the exception of a large new east window in the chancel, which replaces a very small and inadequate one, the works have been strictly confined to a restoration of the building. The old plaster ceiling of the chancel has been taken down, and the open roof exposed. The lath-and-plaster partitions which separated the Hungerford Chapel from the chancel and the south transept have been removed, open wooden screens being substituted. The old irregular pews have been replaced by low open seats. The whole building has also been ventilated, heated, and lighted; the gas-fittings being by Skidmore, of Coventry. The contractors were Messrs. Pedley & Son, of Highworth.

*Stoke Bishop.*—St. Mary Magdalene Church, Stoke Bishop, has been re-opened by the Bishop of Gloucester and Bristol, after having undergone some alterations and additions. The original structure was erected in the year 1560. The drawings for the building were supplied by Mr. Norton, architect. It consisted of a nave, chancel, and aisle, with a porch on the south side, and was capable of seating about 300 persons. The congregation, however, became too large for the building, and it was found necessary to increase the accommodation. Mr. Norton advised the addition of an aisle on the south side of the structure. The work was commenced about six months ago, under the superintendence of Mr. Baker, of Stoke Bishop, builder, who had been the builder of the church. By the increased space which the addition affords about 100 additional sittings have been gained. A series of subjects, four in number, and illustrative of events in the life of St. Mary Magdalene, to whom the church is dedicated, have been worked into corbels of the new arcade. Besides the aisle a vestry has also been added, and an entrance doorway has been opened at the western end. The cost has been moderate. A tower and spire are wanting to give finish and proportion to the exterior.

*Compton Pussycot (Somerset).*—A new north aisle has been added to the church of St. Mary Compton, and the roofs of the nave and south aisle removed, and now they form three nearly equal gables. The chancel roof has been restored, and a vestry added on the north side. The church has been re-seated with open seats of deal, and the nave being very narrow, there is no central passage. The chancel seats are of oak, and were carved by Mr. Forsyth, who has also executed the figures of the Virgin and Child, placed in the niche on the south porch. The reredos is of stone, and the central panel is filled with Dr. Salviati's mosaic, executed from the architects' designs. The floor is laid with Poole tiling. The chancel windows are to be filled with stained glass, executed by a Brussels firm.

The works have been carried out from Messrs. Slater & Carpenter's designs, and under their superintendence, by Mr. Clarke, of Bruton. The chancel roof is now being decorated in colour, by Messrs. Clayton & Bell.

*Torquay.*—On consideration of some additional figures being sculptured in the reredos at St. John's, Torquay, the Bishop of Exeter has now given his consent to its remaining in its place. The object of the alteration was to make the work a more exact representation of the actual figures of the Crucifixion than it was originally. This has been accomplished without any alteration of the figures first of all sculptured.

*Tupplesley (Herefordshire).*—St. Paul's Church, commenced in July, 1864, is now making rapid progress. It will contain 537 sittings, all free; and will cost 2,300l., towards which sum only about 1,600l. have been promised. The *Hereford Journal* of December 31st gives a view of the edifice. Mr. R. Kempson, of Hereford, is the architect.

*Knutsford (Cheshire).*—A font, in Grinshill stone, has just been put up in the Parish Church, Knutsford, by the family of the late Mr. Roscoe. The shape is octagonal; round the shafts are carved in relief figures of St. James, St. Peter, St. Paul, the Virgin Mary, and the four Evangelists; and on the basin are representations of the Baptism and Confirmation, Crucifixion and Ascension; Christ blessing little children; the Marriage Feast; Christ walking on the Sea; and the Last Supper. The floor is laid with Minton tiles, raised about 6 in. The font is about 5 ft. high, and is approached on one side by two steps for the minister during baptism. It bears the inscription "In memory of James and Hannah Roscoe, A. D. 1864." The work has been designed and executed by Mr. Harrison, of Chester.

## DISSENTING CHURCH-BUILDING NEWS.

*Loughborough.*—The new Unitarian chapel, lately erected in Loughborough, has been opened. The chapel, which fronts towards Victoria-street, is an adaptation of the style prevailing in the early part of the thirteenth century. The walling is of undressed random stone, from Charnwood Forest, pointed with black mortar, and dressings of Hollington stone, the inside of the wall being faced with white bricks, for distemper and diapering hereafter, when the work shall have become thoroughly dry. The nave is flanked by buttresses on either side, and lighted by six lancet windows, together with a circular window over the doorway, in the gable, filled in with plate tracery, the whole being glazed with leaded panes. Three lucerne lights are also introduced in the roof, on the Park-street side. Accommodation for the choir is obtained by an arched compartment, projected from the south-west corner of the nave, finished externally with a slated spire (in green and blue bands), terminated by a wrought-iron finial, in colour and gold, 72 ft. from the ground. The chapel is fitted up with open red deal benches, stained and varnished, affording accommodation for 176 hearers. The roof is open-timbered, of interlaced rafters, and a layer of felt is introduced between the slates and the boarding. The nave of the chapel measures 42 ft. 6 in. by 26 ft., independent of the choir. In the rear of and adjoining the chapel is a school-room, 42 ft. by 23 ft., with boarded floors, and with an independent entrance from Park-street, and having three class-rooms, and underneath, the ground-floor an apartment containing the boiler which heats both chapel and school. The school buildings are built of red brick, relieved with a sparing introduction of blue bands, and the windows, gable copings, &c., are of Hollington dressed stone. The premises are entirely enclosed by a walled fence, that of the chapel being of stone, in character with the fabric. The stone walling, and bricklayers' and plasterers' work, have been carried out by Mr. Wm. Moss; the carpenters' and joiners' work by the firm of Messrs. Lamb & Stevenson, of Nottingham; the masonry by Mr. Walpole, of Loughborough, with the assistance of Mr. W. P. Smith, for the carved work; the glaziers' work and heating apparatus by Mr. Messenger; the painting, &c., by Mr. Greening, of Nottingham; and the gas-fittings were furnished by Mr. Rhodes, of Nottingham. Mr. Jno. S. Norris, of Nottingham, was the architect, from whose designs and under whose superintendence the works have been carried out; and the total outlay, exclusive of site, amounts to something over 1,200l.—The Victoria-street

Chapel of the Presbyterians has been opened. The new building fronts towards Victoria-street, and is an adaptation of the style prevailing in the early part of the thirteenth century. The walls are of dressed Forest slate, and the dressings of Hollington stone, the inside of the walls being faced with white brick. The nave is lighted by six lancet windows, with a circular window over the doorway, filled in with plate tracery. Accommodation for the choir is obtained by an arched compartment, projected from the south-west corner of the nave, finished externally with a slated spire, the finial of which reaches 72 ft. from the ground. The chapel is fitted up with open deal benches, varnished in the natural colour, and affording accommodation for 176 persons. The lighting is effected by ten gas brackets projecting from the walls and the usual branches to the pulpit. The heating is by means of hot-water pipes under continuous gratings on the aisles. The roof is open-timbered, of interlaced rafters. Adjoining to the chapel in the rear is a school-room with an independent entrance from Park-places; also a vestry and an upper and lower class-room. The school buildings are of red brick, relieved by a sparing introduction of blue bands, and the windows, gable-copings, &c., are of Hollington dressed stone. The stone walling, bricklayers' and plasterers' work, have been carried out by Mr. W. Moss, of Loughborough; the carpenters' and joiners' work by Messrs. Lamb & Stevenson, of Nottingham; the masonry by Mr. W. Walpole, of Loughborough, assisted by Mr. W. P. Smith for the carved work; the glaziers' work and heating apparatus, by Mr. Messenger, of Loughborough; the painting, &c., by Mr. Greening, of Nottingham; and the gas-fittings were furnished by Mr. Rhodes, of Nottingham. The architect was Mr. John S. Norris, of Nottingham. The total cost of land, buildings, and other charges will be little short of 1,450l.

**Mexbro' (Yorkshire).**—The new Primitive Methodist Chapel, Mexbro', has been opened. It stands on a conspicuous site, and can be seen from the railway, rising above surrounding buildings. The rapid elevation of the ground from front to back necessitates flights of steps to the principal entrances and lobby. From the lobby, stairs lead into the chapel on either side, and galleries are approached by means of separate staircases. The inside dimensions of the building are 46 ft. in length by 36 ft. 6 in. in width, and 25 ft. from the floor to the ceiling; a vestry also 15 ft. by 10 ft., is built at the back, over which is arranged the gallery for the singers, which can be used as a rostrum. The galleries surround either side of the chapel, as well as over the front portion. The building presents an Italian elevation, the semicircular and segmental arch being prominent features both in the interior and exterior arrangements. The walls are built of stone from the neighbourhood, and the quoins rusticated and clefted similar to the stone dressings, architraves, friezes, inscription stone, and tablings. The ceiling is a flat one, with a cornice running round the walls. The chapel is capable of seating 600 persons. The works have been designed and carried out under the direction of Mr. A. Fippard, of York, architect, by Mr. Arnold, of Doncaster, builder. It is the fifth Primitive Methodist chapel built by Mr. Arnold in the Doncaster circuit. The gas-fittings were executed by Messrs. Smith & Son, of Doncaster.

STAINED GLASS.

**Cobridge Church (Staffordshire).**—A stained glass window, to the memory of the late Rev. R. H. Bentley, the former incumbent, and Mrs. Bentley, has just been placed in the chancel of this church. The subject is "The Sermon on the Mount." In the highest part of the central light our Saviour is represented sitting under a palm-tree, while beneath and around him are grouped the multitude, who fill up the lower part of the central and the two side lights. Several of the disciples are prominently introduced. The window has been supplied by Messrs. Cox & Son, of London, and is the production of a French artist. It has cost about 200l.

**Kingswinford Church.**—The parish church of Kingswinford, at Wordsley, has just been beautified by an east window, presented by the Misses Parrish, in memory of their late brothers, John and Richard Parrish. The window is a large one, containing ten compartments besides the upper tracery. The middle upper light is occupied by a medallion of our Lord's Ascension,

taken from a picture of Raffaele's; and the three middle lower lights contain Leonardo da Vinci's well-known representation of the Last Supper. The tracery and the other lights are filled in with quarries of a geometrical pattern, the prevailing colour being blue. The window is the work of Messrs. Powell & Sons, of London.

**St. Stephen's Church, Norwich.**—The large west window of twelve lights in this church has recently been filled with stained glass. The subject illustrates the life and death of St. Stephen, each subject being carried through two openings, as follows:—1, St. Stephen ordained; 2, Distribution of Alms; 3, Preaching; 4, Cast out of the City; 5, Stoned; 6, Burial. The ornamental portion is Perpendicular in character. In the tracery are the twelve apostles, angels with emblems, &c. Two other windows of four lights each, have also been filled with stained glass, the subjects being "Abraham's Sacrifice" and "Rebecca and Abraham." A fourth window, having for its subject, "Christ blessing little Children," has also been erected. These are all memorials given by a lady in memory of deceased relatives. The whole of this work has been executed by Messrs. Heaton, Butler, & Bayne, under the direction of Mr. R. M. Phipson, Norwich.

**Hove Church, Norfolk.**—A window of three lights has just been filled with stained glass as a memorial, the figures of Faith, Hope, and Charity, with their emblems, being introduced. This window is from the works of Messrs. Heaton, Butler, & Bayne, under the direction of Mr. R. M. Phipson.

PROVINCIAL NEWS.

**Hulme.**—The completion of the Town-hall for the township of Hulme has been celebrated by a public dinner. The building, designed by and erected under the direction of Mr. Lynde, the city surveyor, is in the Italian style of architecture. The completed facade, in Halifax stone, presents a rusticated basement, comprising the cellar, rock-faced in Bolton stone, and the ground-floor, smooth or polished. In the centre of the ground-floor is the principal entrance, a segment-headed doorway. Carved modillions support a cornice which divides the ground-floor from the first-floor. This contains seven balustraded and semicircular-headed windows: the arches, containing an enrichment of the laurel-leaf pattern, spring from a moulded entablature, resting upon ionic columns. The three central windows are slightly recessed. The middle window is between two Corinthian columns; and these and four corresponding piers support a cornice, surmounted by a balustrade, having in the centre the city arms, and further relieved by four vases. In the frieze are carved floral festoons, and over the three central windows are heads of Oratory, Justice, and Mercy. The principal front, in the Stretford-road, is 184 ft. in length. The design comprises a centre and two wings; the central portion, 94 ft. in length and 66 ft. high, being appropriated for the Hulme Town-hall and township offices. The west wing, 45 ft. in length and 50 ft. high (now in course of erection), is appropriated to a branch free library; and the east wing, also 45 ft. in length and 50 ft. high (not yet commenced), will be appropriated to the overseer's offices. The central building comprises, on the ground-floor, the township offices, committee-room, fire-proof room, and surveyor's department, together with a public weighing-machine and office at the back, in Dale-street. In the basement are a spacious kitchen and offices, with serving-room, and hoist to the upper floors, as well as workshops and other conveniences connected with the township business. The principal floor is approached from the entrance in the centre of the principal front of the building by a vestibule and grand staircase, lighted by a stained glass window bearing the Royal arms in a central compartment at the top, and the arms of the Duchy of Lancaster, the hundred of Salford, the city of Manchester, and the township of Hulme, in the four corners, the central divisions having emblematical figures of Industry, Commerce, Peace, and Plenty. The hall is paved with encaustic tiles. On the principal floor is the public room, 90 ft. long, 45 ft. wide, and 38 ft. high. It is lighted by day by the seven windows in the principal front, and by night by three sunlights suspended from the ceiling. In connexion with this room is a refreshment or supper-room, 35 ft. long by 22 ft. wide, and 18 ft. high, with dressing and retiring-rooms. On the upper floor is another supper or committee-room, of the same dimensions, with

dressing and retiring-room in connexion with it. The area of the large hall is double that of the Manchester Town-hall. The contractors were: for the excavation and drainage, Messrs. Naylor & Son; for the brickwork, Mr. Wm. Healey; for the masonry, Messrs. Ellis & Hinchliffe; for the joiners' work, Messrs. Clark & Jones; for the iron work, Messrs. Kitchen, Brown, & Co.; for the plumbing, &c., Messrs. Harrison & Son; for the plastering and painting, the late Mr. Hood; for the gas-fittings, Mr. Helsby; for the slating, Mr. Kirkley; for the stone carving, Mr. T. R. Williams; for the encaustic tiles, Messrs. Maw & Co.; for the stained glass window, the late Mr. Edmondson; and for the heating apparatus, Mr. Crowe. The whole has been executed under the superintendence of Mr. S. Taylor, the clerk of the works. The cost of the central portion of the building has been about 12,000l.

**Colchester.**—On the part of the Colchester new Corn Exchange Company, communication has been made with owners of property, with a view of providing an extended frontage to the street, and if the entire Public Hall property, including the house and premises in the occupation of Mr. J. B. Harvey, could be purchased on reasonable terms, it would materially add to the accommodation. There appears to be a prospect of facilities being offered for the erection of a corn exchange, in every way adequate to meet the requirements of the district.

**Manchester.**—The proprietors of the Royal Exchange have ratified the proposals of the committee for the erection of a new building, and sanctioned the raising of the necessary funds by the creation of new stock. The probable expense of the undertaking, including the purchase of the property required, the erection of the new Exchange, and the alteration of the present building, is estimated at nearly 200,000l.

Books Received.

*Normandy: its Gothic Architecture and History as Illustrated by Twenty-five Photographs. A Sketch.* By F. G. STEPHENS. London: A. W. Bennett, Bishopsgate-street. 1865.

The title of this book scarcely commends it to the right class of readers: it is not an architectural work, but a very pretty and interesting volume for the general reader or the drawing-room table. The photographs are too small and indistinct to be of value to the architect, but make picturesque illustrations for the tourist and general student. One great peculiarity, however, in respect of the views, must be noticed, that, illustrating Normandy, the photographer has given no example of "Norman" (round-arched) architecture, if we except the interior of the nave of Bayeux Cathedral. The title, "Normandy: its Gothic Architecture," &c., prepares the reader for this; still the omission is a singular error. The historical essay is clearly and agreeably written.

Speaking of the fine church of St. Ouen, in Rouen, Mr. Stephens says,—“The nave was completed about 1340; but such was not the case with regard to the transept until 1430, when the rose windows were inserted by A. Berneval, ‘architect and clerk of the works.’” We should be glad to have these quoted words in the original, and to know their source.

VARIORUM.

It will suffice to mention that "The Builder's and Contractor's Price Book, revised by Mr. G. R. Burnell, is published for 1865 (Lockwood & Co.). Mr. Burnell is well qualified for the task, and is, moreover, of so painstaking a habit, that we should put faith in the result of his labours. The fact that for daywork the charge for artificers (bricklayers, masons, &c.) is put down at 6s. 8d. a day, and for labourers at 4s. 2d., shows that revision must have been made in many of the detailed prices. An Appendix gives a number of useful tables, items of information connected with the various trades, and instructions as to mode of measuring.—“The Engineer's, Architect's, and Contractor's Pocket-book for 1865,” contains its usual large amount of special information. It includes, *inter alia*, a useful résumé of the available knowledge as to cast-iron girders and iron roofs.—“The Railway, Banking, Mining, Insurance, and Commercial Almanack for 1865” (Red Lion-court), contains, with the usual matter of an almanack, a large amount of useful reading, in the manner of the "Companion to the Almanack," bearing on

the departments to which it is devoted. We are disposed to award high praise to the present issue. It is edited by Mr. W. Page Smith.—A new edition of Mr. Septimus Piesse's "Chemical, Natural, and Physical Magic," just now published by Messrs. Longman & Co., contains some fresh tricks and games requiring mental labour. It is a book full of amusement for young people, and well calculated to educe ingenuity and "sharpness," and induce quickness and precision of thought. The recreation afforded by it may be made to administer many good lessons.—The *Literary Gazette* has been revived as a monthly record of literature, in a shape that will be useful to book clubs and buyers generally; but scarcely one to commend it to the reading public. It contains a vigorous letter from William Jerdan, the founder of the original *Literary Gazette*, pointing out what all must feel who think about it, that the present period can scarcely compare for great names in literature with that which has just passed away. The prospect in art is equally, as it seems to us, disheartening.

### Miscellaneous.

**SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.**—The seventh session of this society was opened on the 12th, with a *concertation*, which was held at the Institute of Painters in Water-Colours, Pall-mall. The programme of music for the evening embraced both vocal and instrumental selections.

**LIVERPOOL ARCHITECTURAL SOCIETY.**—At the meeting on Wednesday evening, the 11th, Mr. Joseph Boulton presiding, Mr. A. B. Anderson read and explained his scheme for the river approaches. The chairman alluded to the various schemes that had been brought forward, and expressed his opinion that this was the best he had yet seen. He pointed out that it would be necessary to have more than one system of approach to the river. It was suggested that Mr. Anderson should exhibit his plans publicly. The chairman called attention to the circumstance that, by the permission of Mr. Lyster, the dock engineer, the members of this society would, on Saturday, the 14th inst., view the works in progress at the north entrances, and the sluicing channels of the Birkenhead Docks.

**ASSOCIATION OF FOREMEN ENGINEERS.**—The London Association of Foremen Engineers held their annual meeting on January 7, when Mr. Joseph Newton, of the Royal Mint, was, for the seventh time, unanimously elected president for the year. In tendering his resignation, Mr. Newton observed that during the past year, thanks to Messrs. H. Grissell, Henry Maudslay, Telford, Field, John Penn, and others, the jealousy which their proceedings had for some time previously been regarded by engineering employers had been to a very considerable extent dissipated. Mr. Thomas Sanson was chosen vice-president, and Mr. David Walker, of Messrs. Maudslay's, secretary, for the current year. Mr. C. F. Hayes explained the processes employed in converting solid ingots of homogeneous steel into tubes by hydraulic power.

**LORD S. G. OSBORNE AND THE WORKING CLASSES.**—On Saturday evening the Rev. Lord Sydney Godolphin Osborne delivered a lecture in the temporary church of St. Michael, St. Leonard's-road, Bromley-by-Bow,—the extreme east of London,—to the working men who attend the evening schools in that district. In consequence of the number of artisans and others employed in the docks, the population of the parish of Bromley (the living of which is in the gift of Mr. John Walter, M.P.) increased from 11,000 in 1851 to 24,000 in 1861, and it is now about 28,000. Through the exertions of the clergy, classes have been established for the working people, large numbers of whom now devote portions of their evenings to the study of mensuration and geometry, navigation and nautical astronomy, arithmetic, algebra, history and geography, book-keeping, French, Scripture history, drawing, and other branches of useful knowledge. Lord S. G. Osborne's lecture was introductory to the course of the present year, and his subject was "The Hand and Hands," in which his lordship extolled the human hand as the most wonderful of machines, and expressed his opinion that, to speak of workmen as "the hands" of an employer, was the highest title that could possibly be conferred upon them.

**THE CHURCH AT GILSLAND.**—Sir: I see you include the church at Gislund among those you name as being the works of the late Mr. Dobson, of Newcastle-on-Tyne. Allow me to say the above church was designed by me, and carried out solely under my direction.—JAMES STEWART, Carlisle.

**LOSS BY FIRE IN SWEDEN.**—The library of the cathedral church of Strongnaes, Sweden, has been destroyed by fire. It contained a great number of Scandinavian antiquities, valuable manuscripts, and rare books, which came from the pillage of the convents of Bohemia and Moldavia during the thirty years' war. The library was founded in the fifteenth century, and science and literature have by this catastrophe suffered a severe loss.

**WORCESTER CATHEDRAL RESTORATION.**—The Dean and Chapter, and the committee appointed to act on behalf of the subscribers to the restoration fund, have decided that the organ, the screen, and the canopies of the stalls, shall be at once taken down. A portion of the present organ will be temporarily removed by Mr. Hill, of London, to a site in the north aisle, in order to ascertain the effect of an instrument placed in that position. The local  *Herald*  asks,—“Why not by the great south transept, where it would interfere with nothing, nor hide anything which is worthy of being seen?” By the erection of the stoves in the cathedral, a warm and comfortable atmosphere has been secured.

**NORTH LONDON WORKING CLASSES INDUSTRIAL EXHIBITION.**—The distribution of prizes to the successful exhibitors took place on the 16th instant, at Exeter Hall. The Earl of Shaftesbury, K.G., presided, and distributed the prizes. The large hall, galleries, platform, and orchestra were crowded. The prizes consisted of books and certificates. The certificate is in the form of an illuminated design, commemorative of the exhibition, each signed by the Earl of Shaftesbury, and framed in a gilt frame. The memorial, given to every exhibitor, is a volume, containing a complete history of the exhibition, with a frontispiece portrait of Mr. Watts. In his address the chairman said he had been told that in future exhibitions the exhibitors were to be confined to the branches of industry in which they were daily engaged. To that he responded, Heaven forbid! The exhibitions were more social than financial. Their object was to hold out refined recreation to the working classes, to break the monotony of their labour, and to give a large development to the taste and imagination of the working men. To put the intellect in operation to which he had alluded would be to put an extinguisher upon the efforts of working men, and would stand between them and recreation. Why, they had lamp-lighters and hairdressers and costumers exhibitors. How could such men exhibit if they were to be confined to the products of their usual industry? Let taste and genius have their full scope, and let them not be drowned in the pot-house and gin-palace. The secretary of the West London Exhibition denies the accuracy of Lord Shaftesbury's information on this point. It is nevertheless desirable, as we have said, that artisans should do their best in their own line.

**BEVERLEY NEW CATTLE MARKET.**—A field in the neighbourhood of the railway station has been converted into a market. A wall, 7½ ft. high, protects the railway side, the remainder being hedge fences. The market is divided lengthwise, into two equal divisions, by a road 22 ft. wide. The cattle-stalls are constructed of 9 in. by 9 in. and 7 in. by 7 in. oak posts, with four rails of 1-in. and ¾-in. wrought-iron tubing; the uppermost being ½ ft. from the ground. The number of stalls devoted to cattle is seventy-commodate from ten to fifty sheep each, or 3,000 in all. These are entirely formed of iron, the rails being of 5-8ths iron, and the uppermost of the four being 2½ ft. high. All the roads are laid with chalk foundations, and the drainage is effected by 6-in. sanitary pipes, with a 9-in. fall. The sheep-pens are all paved with bricks, and the ironwork covered with a coating of tar. Within the market stands the market-keeper's office, urinals, &c.; and there are also two or three gas-pillars. The total cost of the market, including land, fittings, &c., will not, it is said, exceed the estimate, 2,200*l.* A banquet has just been held to inaugurate the opening of the new market.

**A NEW USE FOR MAGNESIUM.**—The magnesium lamp (if it can only be made practically useful) promises to become a regular article of furniture in every silk-mercer's show-room. Whether by night or on a dark day, any question as to colour is in a moment set at rest in the flame of a bit of magnesium wire.

**BRADFORD WATERWORKS.**—Mr. Ferrand, M.P., has addressed a letter to Sir George Grey, in which he complains that orders have been given by the Bradford corporation to refill the Doe Park Reservoir before an inspection of the repairs has been made by a civil engineer. The repairs have been made under the sole superintendence of the borough surveyor. Mr. Ferrand alleges that the reservoir is still in an unsafe condition. The mayor of Bradford replies that he thinks the public need be under no alarm after the result of Mr. Ferrand's complaints last session, and gives an assurance that the waterworks committee know their responsibility, and will discharge their duty.

**THE ATLANTIC TELEGRAPH.**—A coil of 279 miles of this cable has been shipped in H.M.'s ship *Anethyst*, for transmission to the *Great Eastern*, in the Medway. Upwards of one-third, or 900 miles of the cable have now been manufactured at the works of the "Telegraph Construction and Maintenance Company," formerly Glass, Elliot, & Co. The entire length will be 2,300 miles; but allowing for slack, 2,100 miles will be provided. A very small space in the *Great Eastern* will be required for the whole, which will weigh about 17,000 tons. In about six months the line will be laid.

**PROPOSED IMPROVEMENTS IN MILAN.**—Some months ago we informed our readers that plans had been approved of in Milan for re-arranging the space, and re-erecting streets and buildings around the cathedral. It seems that a company has been formed, with a capital of 600,000*l.*, in 20,000 shares of 30*l.* each, for the purpose of carrying out these plans. The concession, dated the 28th of July, 1864, granted by the municipality of Milan, confers the grant of the fee simple of about seven acres of land in the heart of the city immediately surrounding the cathedral, for the purpose of re-building the Piazza del Duomo, and connecting it with the Piazza della Scala. The capital is already in a measure subscribed, and English enterprise, it is expected, will soon complete the business. The project is launched under the auspices of the Credit Foncier and Credit Mobilier Companies of England.

**PORTRAITS PHOTOGRAPHED FROM THE RETINA OF THE EYE.**—Our readers for the last few years may remember a notice in the *Builder*, of an instance in which it was alleged that a photograph of a butcher had been obtained from the eye of a bullock which had been killed by him. Some doubts were cast upon the circumstance at the time; but the possibility of it seems now to have been brought up again by the Florence correspondent of the *Morning Post*, who has seen the photograph of a murderer, taken from the retina of a human eye. The photograph appears to be rather a nebulous one; but the general traits of the countenance, such as the wide nostrils, the large mouth, &c., are said to have been sufficient to identify the man. As corroborative evidence, such photographs would be valuable, of course; but it would be perilous to risk a life upon such evidence alone, as the portrait might not be that of the murderer.

**"WORKING THE ORACLE."**—The writer of a paper in the *Social Science Review*, "On the Employment of Returned Convicts," speaking of John Kendrick, who lived in the latter times of James I., says he established in 1624, in his native town, Reading, a manufactory for the production of woollen fabrics. "Into this factory any man who chose might enter and find employment. If a man had other and better employment elsewhere, good; if he had none, then at Reading he had no pretext for idleness or vagrancy, for he knew where he would find work, and receive proper wages for work done. It was a house 'for the begging poor.' For a few years the plan answered well. In course of time, for some curious reason of which we know nothing now, this factory was called the 'Oracle.' 'To work in the Oracle' implied that the workman had resorted to it because he was out of work elsewhere; at last the term became general, and from it we believe sprang, somewhat modified, the slang phrase, 'Working the Oracle,' which we hear to this day."

**INTERNATIONAL REFORMATORY EXHIBITION.**—An exhibition of the products of industrial schools, reformatories, refuges, and similar institutions at home and abroad, is to be held in London, in May, 1865, in the Agricultural Hall, Pall Mall. At the opening, 1,000 children from the reformatories will form a choir, and assist in the inauguration. Under the direction of the committee of the Reformatory and Refuge Union several exhibitions of industrial work have already been held in London. The first of these was in 1856, and was honoured by the presence of the Prince Consort and a large number of the nobility and gentry, and others interested. On the present occasion, however, the managers of similar institutions in all parts of the world will be invited to send for exhibition, and, where desired, for sale, specimens of the industrial work of their inmates.

**THE IRON TRADE.**—Much agitation prevails, and exercises an evil influence. Prices remain doubtful until it is known what the men will do. The *Iron Trade Circular* says with reference to the matter:—"The men must not forget how the Iron Ship Building Trade was driven from Ireland, and how one industry after another has been wrung from that angry hot-bed of strikes. How much our district has already been afflicted by similar insensate agitation, wickedly conceived and ignorantly executed, it is impossible to calculate; but an instance was mentioned on Thursday of a Russian order for 100,000 lbs. of machinery for that Government having been declined during a former strike, and carried over to the South of France, where the connexion has ever since remained, because the manufacturers here, when offered the order for time, declined it as a consequence of the uncertainty of their men at the period. And this is one of many hundred cases."

**VITRIFIED PORTS.**—About forty of these curious relics of the past have been discovered throughout Scotland, including several in Galloway. They are to be found in the great glen of Scotland, and there is a very perfect one in the Kyles of Bute; but, in extent, that of Craighead, near Inverness, surpasses them all. It is remarkable that none have been found in England. The most plausible and generally accepted theory of these structures is, that originally they were built for purposes of defence, and afterwards used as convenient stations for beacon-fires. Now, however, that Mr. Laing's discoveries in Caithness go to show that our "rude fathers" had a tendency to cannibalism, does the old theory seem so improbable that the fires that first fused these massive rocks together were the fires which are said to have been kindled for human sacrifices in honour of Baal or the Sun, who was an object of worship with our barbarous progenitors? — *Dunfermline Courier*.

**Gas.**—The directors of the Hull Gas-light Company have resolved to supply gas at 3s. 9d. per 1,000 cubic ft. The directors of the Sunderland Gas Company have reduced the price of their gas to 4s. per 1,000 cubic ft., with discounts for cash—12½ per cent. under 50,000 ft., 20 per cent. under 200,000 ft., and 25 per cent. above 200,000 ft. The gas movement which the *Builder* set a-going in past years, and which was already so greatly reduced the price and improved the quality of gas throughout the country, is being renewed in London, where meetings of gas consumers are being held for the purpose of either forcing a reduction of price to 2s. 9d. per 1,000 cubic feet from the present companies, or establishing municipal gas-works on the Manchester principle. The announcement of an intention on the part of the Imperial Gas Company, which has a monopoly of the Paddington, Marylebone, St. Pancras, Islington, and Hackney gas supply, to apply to Parliament for power to raise £1,735,000, has startled the London gas consumers, who know pretty well what that means; and they are now organising an opposition to the company's design. They ought to be made fully aware, however, that a good deal of money may be requisite to carry out such an opposition effectually. The Canterbury Gas Company have announced an intention to reduce their price from 5s. 6d. to 5s., but the citizens are dissatisfied, and insist on a reduction to the Maidstone price of 4s. A rival company is talked of. The Worcester Gas Company have reduced the price of their gas to 4s. and also made a considerable reduction at same time in the price of their coke.

**THE WHITCOMB RESERVOIRS, GLOUCESTER.**—The surveyor having reported to the Waterworks Committee of the town council on the 20th ult., that a considerable leak had been discovered in the embankment of the lower reservoir, supposed to arise from some defect in the mains supplying Gloucester, either in the joints or by the bursting of a pipe, he was authorized to open down to the supply main, and found that a defective joint in one of the pipes had caused a leakage equal to 10,000 gallons a day. It was resolved that the surveyor should put in a culvert, 4 ft. 6 in. in diameter and 10 yards long, over the supply main, so as to enable him at all times readily to examine the main and make any repairs necessary, and also to put in a drain from the screen vault. The council have confirmed the resolution of the committee.

**THE CONSTRUCTION OF CHIMNEYS.**—At a recent meeting of the Chester town council, a letter from Richard Parry, chimney-sweeper, Broughton, to the council, was read by the town clerk, on the violation of the Act for the Regulation of Building Chimneys (3 & 4 Vict., cap. 85). The writer stated that "the disgraceful state of hundreds of chimneys in this city loudly calls for your interference, as being quite contrary to Act of Parliament, no sweeping machine being able to clear away the accumulation of soot, and thus giving great cause of danger by fire." The writer further stated that he "was confident that much property in the city was in a very doubtful state on account of the bad state of the chimneys; and most insurance offices, were they aware of the fact, would decline granting the policy of insurance."

TENDERS.

For masonry, stables, &c., at Dover for Mr. I. I. Ellis. Mr. Howland Rees, jun., architect. Quantities supplied.

Bonley .....	£3,161 3 4
Watkin & Son .....	7,835 6 11
Mathews .....	7,598 0 0
Fry & Papper .....	7,295 7 0
Stitt & Co.'s .....	7,173 0 0

\* Accepted, subject to certain provisional alterations.

For rebuilding premises, Ryde-street, St. James's, for Messrs. Christie, Manson, & Woods. Mr. J. Norton, architect.

J. & A. Hermon .....	£5,455 0 0
G. Myers & Sons .....	5,147 0 0
J. & C. Hanson .....	4,990 0 0
Holland & Hansau .....	4,842 0 0

For building a villa, at South Moor, for Mr. Benjamin Levy. Mr. John Tillman, architect.

Hirst & Son (accepted) .....	2,300 0 0
------------------------------	-----------

For the extension of Mr. Cadley's pianoforte manufactory, Liguorpond-street. Messrs. George & Vaughan, architects.

Loss (accepted) .....	£1,079 10 0
-----------------------	-------------

For building Baptist chapel, Canterbury-road, Kibbura Mr. Hall, architect.

Feltham .....	£1,387 0 0
Stevenson .....	958 0 0
Ferguson .....	705 0 0
Manley & Rogers .....	912 0 0
Palmer .....	887 10 0

For alterations and additions to Rutherford Lodge, in the county of Northampton. Mr. R. W. Johnson, architect.

Henson .....	£310 0 0
Birkett .....	209 0 0
Wilson .....	286 0 0
Duswell & Hawthorn .....	282 0 0

For building a Wesleyan chapel, at Lytchett Minster Dorset.

Saunders .....	£593 8 6
G. & J. Curtis .....	404 10 0
Hunt .....	493 0 0
Sharland .....	365 0 0

TO CORRESPONDENTS.

X. (on salt the patent).—M. C. (the supposed discovery is an old one.—W. M. C. for the duties of the "dielict" or "pore") at the Metropolitan Building Ash.—Architect (the application of the "water glass" process to the walls of hospitals, to render them impervious, has been recommended, but we do not aware that it has been tried).—B. R. (it is in accordance with custom for an architect to charge for time occupied in travelling to visit his works (distant 200 miles), in addition to 5 per cent. commission and travelling expenses, should often departed from, by arrangement).—Z. (we do not undertake to instruct our brother architects how to manage their clients).—H. B. (the question is, not what H. B.'s colleagues do, of which we have no means, but what the particular colleague illustrated may be built for).—These (shall have attention).—W. W. P.—A. A list of correspondents received on Thursday necessarily stands over for completion. The press of actual news has compelled the postponement of the continuation of several articles.

We are compelled to decline pointing out books and giving addresses. All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender; not necessarily for publication.

TO SUBSCRIBERS.

The TWENTY-SECOND VOLUME of "THE BUILDER" (bound), for the year 1864, will shortly be published, price One Guinea.

CLOTH CASES for binding the Numbers are NOW READY, price Two Shillings and Ninepence. In ordering, it is necessary to state whether the Advertisements are, or are not, to be included.

A COLOURED TITLE-PAGE can be had, Gratis, on personal application.

SUBSCRIBERS' VOLUMES will be bound on being sent to the Office, at a cost of Four Shillings each.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the author.

The Publisher cannot be responsible for Original Testimonials left at the Office in reply to Advertisements, and strongly recommends that Copies only should be sent. Advertisements cannot be received for the current week's issue later than FIVE o'clock, p.m., on Thursday.

[ADVERTISEMENT.]

CHURCH, TURRET, and STABLE CLOCKS. J. W. BENSON, having erected steam-power and improved machinery for clock-making, at the manufactory, Lodgegate-hill, will be glad to furnish to clergymen, architects, and committees, Estimates and Specifications of every description of Horological Machine, especially cathedral and public clocks, chiming tunes on any number of bells. A descriptive pamphlet on Church Clocks put free for one stamp. Watch and Clock Maker by Warrant of Appointment to H. H. the Prince of Wales, and maker of the great clock for the Exhibition, 1852. 33 & 34, Lodgegate-hill, E.C. Established 1749.

ADVERTISEMENTS.

Now ready, in part 8vo, with Portrait of Silla (a Roman Model), and several Wood Engravings, price 11s. LAST WINTER IN ROME. By G. R. WELD. Author of "The Pyramids, West and East," &c. London: LONGMAN, GREEN, & CO. Paternoster-row.

Now ready, in 2 vols. Imperial 8vo, price 6s. 6d. each, TUSCAN SCULPTORS: their Lives, Works, and Times. With Fifty-aye Enchirons and Twenty-eight Engravings on Wood, from original Drawings and Photographs. By CHARLES G. PERKINS. London: LONGMAN, GREEN, & CO. Paternoster-row.

THE QUARTERLY REVIEW. No. CCXXXIII. is published this DAY.

CONTENTS: I. WILLIAM SHAKESPEARE'S ARTIST. II. ARISTOTEL'S HISTORY OF ANIMALS. III. SIR JOHN ELLIOT. IV. LORD BYRON'S TRANSLATION OF THE ILIAD. V. MEXICO'S SIR ROBERT WILSON. VI. SERIAL LITERATURE. VII. HEBREW'S ANCIENT AND MODERN. VIII. THE UNITED STATES AS AN EXAMPLE. The Quarterly Review is published as nearly as possible on the 1st of January, April, July, and October. JOHN MURRAY, Albemarle-street.

NEW AND ENLARGED EDITION, 1853. BIDDERS' EARTHWORK TABLES, showing the Contents of Excavations, Area of Slopes, &c. By P. BIDDERS, Esq., C.E. Sheets, 8s.; in Case, 3s. 6d. London: VAUGHAN & SONS, 29, Parliament-street.

Now ready, price 7s. cloth. MRS. LOUDON'S COMPANION to the FLOWER GARDEN. English edition. Revised and corrected to the present time. By CHARLES EDMONDS, Esq., Chelsea. London: BRAIDERS & AYNSLIE, 11, St. James's-street.

SOUTHALL, MIDDLESEX.—In the celebrated Cowley district.—To let, in a good position, Public Rooms, Land, Houses, and Offices.—Valuable Freehold Estate and Building, comprising 32 acres, nearly adjoining the station on the Great Western Railway.

Messrs. DENBHAM & TEWSON have received instructions from Messrs. BRAYLEY, Ogilvie & Co., in consequence of their having completed their contract for the Northern Sludge Land, to sell at the GUILDHALL COFFEE-HOUSE, on THURSDAY, JANUARY 24th, at 10 o'clock, in one lot (unless previously disposed of by private contract), the very valuable and important FREEHOLD ESTATE AND IMPROVED HOUSES, with their ample grounds for building the Southern Sludge on the Great Western Railway, with a view from the Sludge on to the land. It comprises in all 29 acres (less more or less, 2 acres of which remain unworked, and contain a quantity of an average depth of 5 feet of sludge, and of superior quality. The land is the Metropolitan Board of Works for the Thames Embankment. Kites are erected on the ground sufficient for making 45 millions per annum, and there is ample space for erecting clamp bricks also. The works may be carried on all the winter, there being extensive sheds heated by flues, which will dry about 50,000 per week. The railway company's heavy bricks either to the Thames, at Brentford, or to Paddington, at a very moderate rate, and a roadway may be formed to connect the field with the Grand Junction Canal, which is within a quarter of a mile. The land after the bricks have been made, will be very valuable for building purposes.—Particulars and plans of Messrs. SWIFT, BLENKINSOP, & Co.'s, 22, Great St. Martin, Westminster; of Messrs. BAYBERRY & HEATH, Surveyors, 4, and 40, and street-buildings, and of the Auctioneers, 24, Chancery.

# The Builder.

VOL. XXIII.—No. 1147.

*Strike against an Architect, Manchester.*

E alluded briefly last week to what seemed to us, and seems still, shameful proceedings on the part of the Manchester Union bricklayers against Mr. Waterhouse, the architect of the Manchester Assize Courts and the County Gaol. The possibility of such an occurrence applies to so many of our readers, that it is necessary, if on no other ground, that we should make the particulars known.

A strike occurred some months ago, and still continues, against Mr. Bramall, the contractor for the Assize Courts and the new gaol in Manchester. The strike related exclusively to

the management of the works. Mr. Bramall employed as foreman a man named Kettle, in whom he trusted; and Kettle, who had been a master, put at the head of the bricklayers' labourers a man who had already served him in the same capacity. This arrangement was resisted by the men. They alleged that, by custom of the trade, the first labourer who offered himself for a job was entitled to be the head man of the gang. There was no written rule to this effect, but it was a custom. It is not disputed that the master has the power, by dismissing all the men above any man whom he may prefer, to place him at the head of the gang, and take on the rest at the tail, so that the utility of the rule is not very apparent. However, Kettle had broken it, and the labourers struck work. This threw the bricklayers off work, and they adopted the labourers' quarrel as their own. To supply the place of the labourers, Kettle engaged "navvies," and announced that the bricks would be wheeled down to the works. This raised the question of hods versus harrows; and harrows were denounced as an innovation. A bricklayers' committee determined that Kettle was "unfit for his post," and insisted upon his dismissal. But Mr. Bramall refused to part with his foreman, and the works were abandoned. The bricklayers induced the carpenters on the Assize Courts to leave work, and the magistrates had to engage workmen from a distance to finish them. The strike still continued on the works of the new gaol, but Mr. Bramall succeeded in obtaining a sufficient number of non-unionists to carry them on.

The bricklayers, finding they were not succeeding, now addressed themselves to the architect, and urged him to interfere with Mr. Bramall; and, as the architect was exceedingly anxious that the work should be done, and moreover had satisfied himself that the primary cause of the dispute was an infringement, on Mr. Bramall's part, however slight, of the ordinary customs of the trade, he did what he could towards bringing about a settle-

ment of the dispute. The men demanded the dismissal of Kettle, and said that if that were conceded they would not press their claim for payment for lost time.

Mr. Waterhouse appears to have taken the men's side to a considerable extent, and did what he could to carry out their views, but without success.

Another deputation, composed of men belonging to different trades, then called on him shortly after, going over the old ground, and complaining that a man had been allowed to work as a bricklayer at the gaol who had never set a brick before in his life, and that the work which had been lately done by non-unionists was not equal to the work which the union men had done. He promised to inquire into the case of the incompetent bricklayer, and assured the men he would pass no bad work, whether done by union or non-union men. They again urged him to endeavour to settle the dispute, and said they believed the contract gave him power to dismiss Kettle. This he denied; but promised he would do what he could to bring about a settlement. He could not, however, succeed, Mr. Bramall being determined to support Kettle.

The bricklayers then concentrated their wrath on the architect. He was informed that if Kettle were not dismissed by a certain day, the other works under his superintendence in Manchester should be stopped; and, in the course of a few days, the threat was carried into execution, and all his other works in Manchester and its neighbourhood, as far as the brickwork was concerned, were suspended.

He wrote a letter to the Association pointing out the injustice of their proceedings, denying their charges, and almost suing them to reconsider their determination. But all in vain, and so the matter still remains. He offered to hand over the works he had in hand to other architects if the men would go on with their work; but without avail. One haulier had all his other works stopped for daring to carry on one of Mr. Waterhouse's buildings. Even limo and brick merchants were prevented from supplying materials for his works, and, as Mr. Waterhouse says,—“If the thing be carried out to its logical results, I suppose I shall find in time that my butcher and baker are compelled to refuse my custom.”

He has offered to submit the point in dispute to arbitration; but this has been rejected: in fact, they propose to ruin him.

It now behoves Mr. Waterhouse, as it seems to us, to take a different attitude towards the leaders in these scandalous proceedings, and at once to institute proceedings against them for conspiracy. If need be, the whole body of the profession should assist him in it.

There are very serious matters involved in this case; matters affecting the well-being and progress of the community. The working-classes have seen, by the unanimity with which the recently proposed Discharge Note was discouraged by the public, that every disposition exists to support them in all just efforts to maintain or advance their position; but they may rely upon it that such proceedings as those to which we have been forced to draw attention will separate from them good friends, and will tend to bring about a public opinion very difficult to be resisted.

## FOGS.

THERE has been a considerable amount of information obtained lately about fogs; and as these vapours affect the architect, engineer, operative, and artist in their respective pursuits, perhaps, more than they do persons following other occupations, we purpose calling attention to the string of facts meteorological observers have patiently threaded. None of our readers who were forced to go into the streets of London

on Saturday evening in last week, will see the word "fog" without a certain amount of personal interest.

A fog is a mixture of air with minute globules of water. Far from being the useless inconvenience dwellers in towns are apt to consider fogs, they play an important part in the economy of the earth's surface. Indeed, it is calculated that if the aqueous vapour contained in the ordinary atmosphere were removed but for one single summer night, every plant upon the face of the globe not capable of bearing intense cold would perish. The minute quantity of water suspended in the atmosphere acts as a warm mantle to the earth, absorbing and radiating heat that would otherwise be dispersed in space, and so lost to our vegetation. It is estimated that the atmosphere under ordinary conditions contains, on an average, but one globule of water to two hundred particles of air, and that this one globule absorbs eighty times as much heat as the collective two hundred particles. Looking at fogs as reservoirs of watery particles from which the atmosphere replenishes itself, we can appreciate their usefulness. Professor Tyndall, who a few weeks ago received a medal in acknowledgment of the addition he has made to modern knowledge on this subject, has made a series of extremely delicate experiments relating to the absorption and radiation of heat by vapours and permanent gases. He writes that but for the aqueous vapours in the air the warmth of our fields and gardens would pour itself unrequited into space, and the sun would rise upon an island held fast in the grip of frost.

Fogs are of two kinds: local and general. For some time Dr. J. H. Gladstone obtained returns of the occurrence of fogs at different stations round the coasts of the United Kingdom. These have enabled him to make several guiding generalizations. General fogs are known to extend over a district measuring from 100 miles to 200 miles in length, and sometimes over still larger tracts. Sea fogs are generally of this character. Local fogs are confined to limited areas not extending beyond the neighbourhood of a single station, except in rare cases, when they have extended to two. Dr. Gladstone's observations have led him to conclude that there is nothing intermediate between those two kinds of fog; they either extend over a space occupied by a great many stations or are confined to one small area; for there is scarcely any record of a fog extending to three or four stations and no more, or of fogs insensibly passing into one another. Probably local fogs are due to certain conditions only existing at the several spots at which they occur; and the prevalence of general fogs at sea to the absence of such peculiarities upon the broad uniform surface of the ocean. The most extensive fog traced by Dr. Gladstone occurred on the 22nd and 23rd of June, 1861. All England, Wales, and Scotland were veiled in one vast mist, except part of the Suffolk and Norfolk coasts, and a few places in the extreme north of Scotland; and the same fog extended across the ocean, and touched various parts of the Irish coast.

Certain places appear to possess an attraction for fogs, or to be peculiarly liable to become the landfall of these wandering vapours. The Suffolk coast, Yorkshire, the headlands of Cornwall and Wales, are some of the landing-places most frequented. The fogs taking up a centre in Yorkshire sometimes pervade the coast as far north as Aberdeenshire, and as far south as Suffolk, and even, occasionally, re-appear at the Fjords; at other times they confine themselves within the limits of Northumberland and Lincolnshire. Now and then, these vast vague visitors make a wingless flight across the mainland, to take water again in the Bristol Channel. Curiously, the Mouth of the Thames is rarely invaded by them. Dr. Gladstone's returns from Ireland, however, are more complete, and extend over a longer period than those gathered at home. From these it appears that the south-eastern corner of Ireland is often the centre of fogs that cover the coasts of Wexford, and obscure the whole southern and eastern shores. Another point of attraction is the western half of the southern shore, where the fogs land within a compass bounded by Minchhead on one side and Valencia on the other. The northern and north-west shores are singularly free from them. Scotland is frequently included in the fogs visiting the eastern coast of England; and sometimes the Shetlands are pervaded by the same palpable presence. The Orkneys are within large fog areas. The architect can apply

the information thus gleaned, and any extension of it hereafter placed at his disposal, to great advantage. In a neighbourhood found to have essential natural attractions for fogs, he will be careful to use no building materials upon which aqueous vapours exert deleterious influences. He would be wise, also, to avoid the use of any material in internal decorations likely to be affected from damp. In those localities shown to be exempt, or nearly so, from fogs, frescoes, and other vehicles of art requiring a dry atmosphere, might be ventured upon with a greater probability of a happy issue than experiments based upon no such reference.

Under some conditions fogs become sources of danger to human life: these conditions, it is almost needless to remark, occur most frequently at sea. Human ingenuity has endeavoured to counteract this tendency by inventing a system of fog-signals, whereby ships can be informed of their neighbourhood to dangers. The lights that mark such places in ordinary weather are not visible in fogs: recourse is therefore had to sounds. These, again, are so much affected by the direction of the wind, and by the density of the fog, that persons interested in the preservation of the life and property committed to the seas are anxiously casting about to obtain improved methods of signalling. They look towards submarine signal by sound as a mode most likely to be more efficacious than any other, from the known power that water possesses of transmitting sound; but the details and development of this scheme yet require to be worked out. Our marine engineers may give the matter thought.

The signal most approved by the matter thought, gun, bells and gongs are also extensively used; but, in some cases, have been abandoned for guns. The ammunition for a single gun costs about 200l. a year. Besides the expense, there is the objection that guns are also fired by ships in distress; and the firing depends upon the punctuality of the signal-men. The intervals at which they are fired is generally half an hour; but, when rapid steamers are expected, as at mail stations, more frequently. The Holyhead gun is fired every fifteen minutes. There is a bell at the Copeland Light, Belfast Lough, which is tolled by machinery. This is stated to have been heard at a distance of thirteen miles, but as its locality happens to be noted for the number of wrecks occurring in foggy weather, it can be of little real efficacy. At Boulogne the signal-bell is placed on a parabolic reflector made of masonry; but this contrivance for intensifying sound does not seem to have answered very well. Some other material for the reflector would probably be more suitable.

The steam whistle has been applied as a fog signal. One is used in the Bay of Fundy, and is said to be heard eight miles off. The air-whistle blown by bellows is not heard at such long distances. Horns and trumpets blown by men are also used. Mr. Holmes has applied steam to these trumpet signals with considerable success. The instrument has a long reed: it is blown by steam of about 20 lb. pressure. One of Holmes's instruments was heard at a distance of nine miles and a half. Mr. Daboll's instruments are said to possess great power. Mr. Robertson, of Poplar, has patented a gun-trumpet as a fog signal.

The loss of the *Anglo-Saxon*, with most of her crew and passengers, in a fog, in June, 1863, occurred only a few days before a memorial was forwarded to the Board of Trade from the British Association urging the national importance of an inquiry that had for its object the saving of human life under similar circumstances, and suggesting that the Board should set on foot a series of experiments to determine upon the best kind of fog signals. This memorial threw out the suggestion that a central station should be appointed for experiments, and pointed out the suitability of the flag-ship at Spithead for such a site; and that coast-guards or other officials should be set to record the results at various points at a series of distances of from two to ten miles, and in all directions, so that the difference in the transmission of sound when with or against the wind should be observed. Guns, bells, gongs, drums, steam-whistles, organ-pipes, Holmes's and Daboll's trumpets were all recommended for test; and it was suggested that the relative efficacy of the various calibre and charges of powder of the guns, the weight of hells, the force of blows, the steam-pressure upon the wind-instruments, should be all noted. It also called attention to the probable superiority of subaqueous signals. But the Board of Trade

allotted the settlement of the question to the marine department. This branch of the public service communicated with the Trinity House: the Trinity House Elder Brethren referred it to Dr. Faraday. The professor recommended the Corporation not to make the suggested researches, on the grounds of the difficulty, the magnitude, and the expense of the investigation.

One of the instruments already invented for the subaqueous transmission of sound is the Siren. This is a box with a lid pierced with numbers of oblique apertures, through which a fluid passes and causes it to revolve with a musical note, which is intensified under water in an extraordinary degree. Bells, too, have been tried. A bell has been struck by a hammer under water and heard at a distance of nine miles across the Lake of Geneva; and Professor Wheatstone has ascertained that a wonderful sound is emitted by tubes fitted with the embouchures of organ-pipes when made to speak under water by a current of that fluid. An American application of the whistle to the revolving cylinder of lighthouses appears to be an ingenious contrivance not yet tried in this country. It is the suggestion of Mr. Wilder, Detroit, Michigan. By this contrivance the signal whistles at regular intervals as the lights revolve: it does not depend upon the punctuality of an attendant, nor does it involve any cost for combustibles or charge. This has several advantages over the subaqueous system (which presents the drawback of requiring a hearing-tube to be dipped into the water) and the ear applied to it to hear signals at any great distance, as sounds made beneath the surface are reflected when they come to the junction of air and water; but it has the wind to contend against as a rival noise, and as a power that sweeps all sound before it in one direction. The economical use of the power of the revolving cylinder, however, is worthy of note. It could be as easily made to toll a bell.

A London fog is one of the sights of the metropolis. Where else does the atmosphere assume the aldermanic tint and density of green turtle soup? In what other part of her Majesty's dominions can be subjects hoast of being invisible to the rest of their fellow creatures beyond arm's length? Where else may we stand by and watch men, women, and children, and vehicles pass into the palpable air as into a stranded, discoloured, "yawning gulf";—taking the latter to mean some open-avaled danger peculiar to the seas? The London fog, too, has ordinances of its own. When its silent approach is perceived, a thousand and more boys are ready, with links and shouts, to pioneer passengers through it. Vehicles seem to muffle their wheels and find their way, warily, to the nearest quarters. The lamplighters turn out and set dots of yellow glare, at intervals, along the streets. The shops are lighted with gas; and as the darkness becomes more intense the silence of a snow-storm, broken only by occasional shouts as the flame of a torch comes into view and is lost again, settles upon the great bome of three millions of people. As the fog vanishes, its retainers, the linkboys, also disappear; omnibuses commence tearing to and fro again; cabriolets whip round sharp corners with redoubled velocity; stall-keepers are "discovered" on the kerb giving finishing touches to the disposition of their wares, or extra polish to their pyramids of fruit, as though some stage-curtain had been withdrawn; careful horseholders turn out the gas, burner by burner, and the population returns to its ordinary pursuits with the sensation of having risen early twice that day. There is nothing like it in the country; a fog towards the coast is scarcely more than a silvery haze, answering well to its name of "sea-fog"; and the white eddies that disengage themselves from inland low-lying grounds, and unfurl their wreaths over field after field till the whole landscape is enveloped in a dewy and almost luminous mist, form a very different visitation to the smoke-laden vapour that tarnishes the gilded ball on the top of St. Paul's and blackens the traciced canopy-work on Westminster Abbey. If the Londoners would consume their own smoke, they might exchange their steamy, clammy, choky, old-brass-coloured fog for a mist scarcely less silvery than that which deposits dew on aphodella.

Thus we find fogs have their beneficial uses like everything else in Nature's domains; that it is its own willfulness that intensifies their density into a metropolitan fog; further that there is a deficiency in the efficacy of existing fog-signals, and consequently an opening for the

exercise of mechanical and scientific genius on a matter that bears upon the ever-important question of the saving of life.

#### THE GENTLEMAN'S HOUSE.\*

IN this nineteenth century, according to the author of the contribution to the subject of house-planning, of which we have already given some account, a new era in domestic plan was entered upon. Whilst as regards architectural the portion now passed of the century, an age of revival, has been accompanied by the open avowal (as he puts the case,) of the styles as "equally good in their way," our practice of planning has come to an adopting "quite indiscriminately and interchangeably" two classes of models, the Palladian and other forms of Italian on the one hand, and the Elizabethan and pure Medieval on the other. Of the "two processes of reasoning involved" in the competition, as in all arts and letters, between Classicism and Gothicism, the Classic Mr. Kerr considers to have had no effect upon domestic arrangement in this century; whilst the Gothic revival, he says, has had much. Indeed, he believes that the "chief consideration which brought the Tudor and Elizabethan Mansion as a whole into fashion, was the obvious superiority of its plan.

Mr. Kerr remarks that it may be of use here to remember a reaction that there was, and of which the tendency is yet observable, from the pretentiousness of the Palladian, which accompanied its staidness; for "it must be looked upon as a rule that an English gentleman will desire to avoid ostentativeness even at the sacrifice of a good deal of that importance which properly belongs to the rank, wealth, education, and character of his class."

Palladian plan went out chiefly as "the solid block of building, generally with wings attached and Basement Offices;" Elizabethan plan came in "commonly, perhaps chiefly," as "the quadrangular system, with the Domestic Offices on the Ground-floor, sometimes separate and sometimes not." As examples of the manner of the first quarter of the century, the author adduces the plans of Longleat as remodelled, and Toddington, both already named, and mentions those of Wallaton (altered), Cassiobury, Foutbill, Hattford, and Eaton Hall, besides "various Castles so called." The arrangement of Longleat he refers to frequently; and he considers the plan of enhanced value by reason of its combination of "freedom from Palladian restraint," with "that perfect symmetry which the professional architects of the time would still necessarily seek after,—." Amongst its noticeable features are a "noble suite of Public rooms" a Principal Staircase, central yet private; the ready communication with the Dining-room from the Kitchen, and "the still almost unimprovable grouping of the chief offices generally;" and, as "last, not least," the complete of the Private Suite of rooms,—nothing so suggestive of comfort according to the habits of an English family, being to be found "except piecemeal," in the eighteenth century mansions. The general block-plan of this building is simply quadrangular, or with projections of the bay-windows,—there being two internal courts. Toddington was a "somewhat extreme case of the development of the Medieval idea as then understood." The main house is quadrangular; the domestic offices take the same form, and are attached to the angle of the first group; and the stables are also quadrangular, and similar in their position with reference to the second group; but the interior arrangement is not so good as in the case of Longleat. The Palladian principle settled into that which is commonly called the "Square-house," with or without a basement of offices,—a form to which a wing is attached at pleasure for the offices, or one wing for offices and one for stables. Sometimes the offices have been more elaborately developed, attached to the rear, and made to embrace a small court-yard; sometimes the pair of wings provides certain principal rooms, and encloses an entrance-court in front. In all these changes, and those more recent, the abandonment of basement-offices has become more and more established. "The present state of the rivalry of style in respect of plan," says the author, may be set forth in a sentence:—

"First, the old Palladian manner has died away, except in the common 'square house'; secondly, the Media-

\* See p. 2, ante.

val principle has been followed out in a great variety of instances, and with perfect success; and, thirdly, although it cannot be said that our Palladian-Italian exterior has brought with them a new system of plan to do battle with the old English manner (which would be needless), yet certainly there has taken place the place of Palladianism in a large number of our best Mansions an equally Classical manner of arrangement which has proved itself a worthy rival to the best Elizabethan, and may even, on certain grounds which is its own, claim a clear preference. The balance of power is perfect. The charming irregularity of unfettered convenience is the Mediaeval merit; and, when duly refined by an educated and skillful judgment, can never be called upon to recede from its position; but there is the stately Classic symmetry, on the other hand, all grace and balance (claiming indeed to be a still greater refinement, the work of a still more highly-educated and more skillful form of judgment), which must not be denied one iota of its pretensions until the price of its elegance is the sacrifice of convenience."

To illustrate the practice of these two systems of arrangement, or "Styles of Plan," four pairs of plans are given,—each pair being considered to present a fair contrast of Classic and Gothic arrangements of their kind. The first pair comprises a plan of Llynnon, Oswestry, and one of Old Connaught, Wicklow, the former a symmetrically disposed plan, having a square top-lighted saloon in its centre, and the latter (to which and to Mr. Kerr's remarks upon it we referred in our former article), a plan with Mediaeval features, such as a hall entered from a porch at one end of it, a passage-way behind "screens," and a hay-window at the end where the "dais" would have been. Both these houses are of very recent date. The second pair comprises plans of Osborn House and Balmoral Castle, these two being considered particularly eligible as having been based on the instructions of the same person, the late Prince Consort, and as having been intended for the self-same occupation. In each, perfect domestic convenience was aimed at; yet the plans present a striking dissimilarity. One is founded upon the Italian Villa, the other upon the Elizabethan Manor-house: in the former, symmetry prevails in spite of a certain purpose of irregularity in the bulk; in the latter, "notwithstanding an obvious desire to provide that regular disposition of thoroughfare lines which is so important a means of convenience, and none the less that simple regularity of partitioning which belongs to good plain modern rooms, yet" Mediaevalism "displays itself constantly in an unaffected but decided disregard of all needless or fictitious correspondence." The next contrast is between the plan of Bridgewater House and that of West Shandon, on the Clyde, which last, Mr. Kerr says, "shows perhaps as much of the disorderly convenience peculiar to Mediaeval plan as could safely be compressed within the space," the "entire composition" suggesting "the idea of a rabbit-warehouse," where you could "get from anywhere to everywhere at a jump—provided" you knew "the way." Finally are given two plans by the author, with the same items of accommodation in each, and "equal stateliness." At the end of the book, moreover, there is a plan, also by the author, intended to represent the modern arrangement in Scotland, "the best ordinary application of the Mediaeval principle, but considered to be deficient in internal refinement" only the irregularity that is inevitable, becoming a merit, whilst intentional, or even unnecessary obliquity is "an affection and an inconvenience." These Scotch plans have many good features, but combined with defects, as in the internal lighting. The reader will not fail to observe that the author's argument in favour of irregularity of disposition, is not all that might be hastily supposed, and that the case in favour of symmetry remains pretty much as we viewed it.

The first Part of the book, or preliminary essay, is concluded with the inquiry, "What may be the more immediate prospects of domestic plan at this moment?" We have a system of plans the resources of which are not understood. Mere accommodation is overflowing; whilst, in convenience and comfort, the best works of our architects leave little to be desired. Yet in our best works, the family apartments are frequently far inferior to the offices,—the reason being, he says—we do not feel sure whether correctly—"that the science of the superior apartments is a superior effort." And he finds that there is "another grievance (of universal prevalence)," "the want of due consideration for the all-important question of Aspect." Niggardiness of space, and insufficient provision for internal salubrity and external disposition, and for cheerfulness of general character, are to be noticed; and the "complex qualities of stateliness wedded to comfort, and comfort to stateliness," are frequent desiderata: but all are "capable of being supplied from a

proper study of the abundant resources of the existing English system." As to which of the two great styles now practised is to displace the other, or how far may a compromise or combination be effected? and, what is the natural style of the soil?—these questions often mooted, and not so often answered, need not be evaded.

"The grandeur, refined balance, and repose, of the Italian manner in its highest efforts are attributes all its own. The piquant utilitarianism of the Mediaeval manner is none the less peculiar to itself. This is so, just as much as in the decorative element the Classic style possesses the same grandeur, refined balance, and repose, and the Gothic the same piquant utilitarian charm. But these characteristics, we must congratulate ourselves, may in plan at any rate compete without collision; we cannot consent to part with either of them. Some of our ardent archaeologist architects may occasionally stretch a point to carry Mediaeval authenticities into practical house-building; but the effort is harmless,—if it pleases the resident and family. Any similar attempt to reproduce the identical glories of some forlorn Roman or Venetian palazzo could only result in the same way."

We stop quotation to express difference with Mr. Kerr as to the harm done, even as taking the meaning of his words to be confined to plan. We say, without reference to Mediaeval or Italian, there is harm done beyond that to the first resident, and to his family,—of whom our author takes little account. Every one who enters the house, or who sees it, is exposed to harm, to a certain extent: moreover the house will not be pulled down on the decease of the first resident; it will pass to others,—perhaps not his family; and the art and the building-practice of some succeeding generations will be prejudiced through the errors or whims of him who thought he had right to do what he liked with his own. No one has the moral right to perpetuate a blunder by his ignorance of architecture. Why is it that general self-education, and the education of his children, are the duty of every man, and should be required of him by the State? Surely not alone that the lack of education may be his misfortune, but because the deficiency will make him a non-contributor to the world's progress, and even a centre from which evil will radiate beyond the limits of his family. Properly viewing a question, whether of house-building, education, or morals, it will be found there is incumbent upon every one who has work to do, the duty that he should accomplish that work in the best manner, seeking counsel if need be. The ground we take, and have taken before, seems to us plain and the only right ground, that he who erects a bad building, even though it be within his park, and hidden for a period by a wall as impenetrable as that with which Beckford surrounded his estate at Fonthill, does a public injury. We do not expect the world at large to assent to this, in the nineteenth century, or to some other truth; but we expect Mr. Kerr to see that "the effort" that "pleases the resident and his family" is not necessarily, as he writes it, "harmless."

Mr. Kerr continues, saying that there are demands of the day, which refuse to recognise mere authority; so that the competition of styles proceeds not only under such modification, but along with their mutual influence and aid. And to "the never uninteresting question, What is our natural style?" he answers by directing attention to his essay, wherein he has "not failed," throughout, to "award to domestic plan of the Mediaeval type its full claim to historical authority on English ground." But the question, he says, is not thus at the end.

"Whatever our national type of the old world, there was superseded, at the birth of the new world, in England only as everywhere else, and in the subject before us only as in a hundred others, a singular majesty-and-grace combined—we call it the Classic—character, which this new world gathered from antiquity in its Italian birth-place, and with which it delighted itself, never to divest itself of again, unless indeed some great change should come over intellect which is far beyond our foresight. Both types, therefore, are our inheritance in modern England; and to suggest the repudiation of either is to imply disloyalty to both."

Our author then proceeds to the "Exposition of Plan as now practised," or "Part Second" of his volume. We have already specified the titles of its Divisions, and those of the subsidiary sections of each Division. It first discusses the general principles to be kept in view, and of which the relative importance must be left to be decided by the individual architect, according to what may be the conditions, as of site, and then gives attention to each feature in the plan of a house, defining its purpose, and its situation most to be desired,—as with reference to aspect, and to the position of other features of the plan,—and treating of the positions for doors, windows, and fireplaces, and the provision to be made for furniture.

Of course, the class of habitation to which the

author restricts his attention, still includes houses in great variety of magnitude, and such may differ considerably through local circumstances and tastes of occupants: so that a scheme of classification of their features, which may be applicable to all the houses, is not easily made. But our author finds that the house of an English gentleman is divisible into two departments, one of them that of the Family, and the other that of the Servants. In some mansions of very superior class, another special department is constituted by the State-rooms. As out-door departments or appendages, there are the Stables and the Farm-offices. Such is the author's primary classification. The subdivision of the Family Department, and that of the Servants' Department, we gave in our last article. With this introduction, he arrives at the general considerations affecting the arrangement of the Family Apartments. But, before specifying what these considerations are, as required to govern the rooms generally, with the supplementaries and thoroughfares, he says,—

"The points which an English gentleman of the present day values in his house are comprehensively these:—

Quiet comfort for his family and guests,—  
Thorough convenience for his domestics,—  
Elegance and importance without ostentation."

"However small and compact the house may be, the family must have privacy and the servants commodiousness, and the whole dwelling must display an unassuming grace."

Even grandeur, he observes, must not be pretentious, or wealth ostentatious: "the attributes of an agreeable English home must never be sacrificed." The general requirements which he enumerates and treats under separate heads, are, Privacy, Comfort, Convenience, Spaciousness, Compactness, Light and Air, Salubrity, Aspect and Prospect, Cheerfulness, Elegance, Importance, and Ornament.

The idea implied under the first head, was the basis of the primary classification. Illustrations of the want of privacy may be found in "houses of the smaller sort," where one entrance admits visitors and tradespeople, thin partitions transmit sounds, and odours from the kitchen fill the house. It should be understood, that the bulk of the volume is applicable rather to country-houses than to houses in towns, where many of his requirements could not at all be answered. However, in any house of tolerable dimensions, a separate staircase for servants' use becomes necessary. Advancing in the scale of establishment, "privacy of corridors and passages becomes a problem," and the lines of traffic of servants and family respectively, have to be kept clear of each other at recognized points. The author says,—

"The idea which underlies all is simply this. The family constitute one community; the servants another. Whatever may be their mutual regard and confidence as dwellers under the same roof, each class is entitled to shut its door upon the other, and be alone."

He considers the Classic model "certainly less" favourable to privacy than the Mediaeval; in other words, "that the open central lines of thoroughfare in Italian plan must favour publicity, whilst the indirect routes of the Mediaeval arrangement must equally favour privacy."

Secondly, there is to be considered Comfort. Much of what it includes might come under the term convenience, which, however, the author prefers to apply to another quality. The comfortableness of a house is described as the "exemption from all such evils as draughts, smoky chimneys, kitchen smells, damp, vermin, noise, and dust; summer sultriness and winter cold; dark corners, blind passages, and musty rooms." As to the separate apartments, it is too frequently considered he says, that any form will make a good room, if space and height be adequate, and doors and windows sufficiently distributed.

"But here lies the cause of innumerable shortcomings in respect of comfort. As a rule, no random arrangements of this kind ought to be tolerated. No room ought to pass muster on the plan until the designer has in imagination occupied it and proved it comfortable. It is too much of the plots upon the drawing every important article of furniture which the room has to receive, and so establishes its capacities and qualities beyond all hazard. A little fastidiousness on paper will save much discomfort on the building. Take, for instance, the case of a gentleman's Business-room of small size, or a Study, and suppose that when the occupant comes to place his desk in it he discovers that he must choose between three evils (and it is not unfrequently the case) whether he shall turn his back to the fire, or to the door, or to the window. He will be told, perhaps, that the reason of this awkwardness lies in the conflicting claims of a neighbouring apartment; or that it is the fault of the access, or the chimney breast, or the prospect, or what not; but the simple fact is that it is the fault of the architect,—the room has not been carefully planned. It is true, it would be dangerous to assert that the architect is bound to pro-

vide for each individual apartment an arrangement as perfect and complete as if itself alone were the subject of plan; questions of compromise must continually arise, and often they will prove hard of solution; but the skill of the designer has its chief task here, in reducing every compromise, by wise patience of contrivance, to a minimum; and the plan can never be considered perfect whilst anything of the sort is so left as to provoke the perception of a radical defect, or even a serious discomfort."

Convenience is distinguished from Comfort, as referring to the active, whilst the latter to the passive,—convenience being the characteristic which results from an arrangement of parts in such relation as may enable the establishment to be carried on in perfect harmony; and it is of two branches, one relating to the family and the other to the domestics. The requirements of the offices are more difficult to fulfil than those of the family department.

In the chapter on Spaciousness, the author says, that this requirement, an element of comfort and convenience alike, ought never to be undervalued, though it often is. It would be better to choose a smaller number of rooms, than a larger with the rooms of questionable size.

"There are many otherwise good houses in which the sense of contractness is positively oppressive; you feel a constant fear of overturning something, a sense of being in somebody's way; you speak in a subdued voice, lest you should be heard outside, or upstairs, or in the kitchen; you breathe as if the place were musty; you instinctively stoop to pass through a doorway; you sit contractly in your chair, and begin even to be contractly in bed; and to step out into the open garden, or even upon the footpath of a street, seems an act of leaping into free space. And there are others, perhaps of much less aggregate size and importance, whose the mind and body, the spirits, and even the self-esteem of a man, seem to expand and acquire vigour under the simple influence of elbow-room."

Compactness, the author calls "the exquisite quality," "opposed to spaciousness, but only in appearance, and by way of contrast." The other provisions combine to give to the plan an extended and struggling character; and this increases more and more with each increase in the establishment.

"In plain language, the more we have, the harder is the task of keeping it well together,—the greater the aggregate the more difficult the preservation of its unity. The very completeness of convenience in one form produces inconvenience in another. The very elaboration of the mechanism disjoins it."

In London houses, compactness as regards site is a primary question; but "the more scientific form of the quality is that compactness of an extended superficies which is chiefly required in Country-houses." The best compacted plan is that which provides the shortest and easiest routes; yet compactness is "not always to be judged of by what may be called the compact appearance of the drawing." Mere regularity of plan, as there seen, may be only "paper-deep beauty;" "in the actual house, such merits are altogether lost; whereas it is frequently the case that arrangements which are in the building both convenient and compact, have on paper an aspect of irregularity and want of repose which strikes the superficial critic as evidence of crandity."

Little is said in the chapters on "Light and Air," and "Salubrity;" but many of the points relating to the latter belong to Site, which is treated of in the next Part of the volume.

On the other hand, much that is valuable is put forth under "Aspect and Prospect"—conjoined subjects, to which the author has paid considerable attention; and he here gives an "aspect-compass," which shows the quarters whence the different winds blow, those in which the sun rises and sets on the longest day, and the shortest, and the ranges of sunshine for different points of the compass. Aspect of a room is properly defined as "the relation of its windows to sunshine and the weather." The prospect of a room has to be considered, "with relation, first, to the landscape; and, secondly, to the light in which that is to be seen." There is no doubt that Mr. Kerr is quite correct in saying that every room has, according to its particular purpose, a better aspect as opposed to a worse. He is not content with this: he says, the room has "a certain very limited range of suitable aspect as opposed to the whole remainder of the compass more or less decidedly objectionable," and there is truth in this also. But here, as he allows, "arises one of the greatest possible difficulties of plan, demanding on the part of the architect so much careful attention to domestic requirements, and so much patient exercise of skill in plotting as to be itself a science." Considerations of prospect are frequently at variance with those of aspect; whilst the former, not to mention other matters, are insisted upon by the person about to build. It results that the choice of aspect ends in a

compromise, generally, or more frequently than our author's chapter seems to imply would be requisite. In towns, he says that questions of aspect and prospect are so entirely "subordinated to others that they may be said to be altogether lost sight of;" whilst he appears not to consider the case of aspect hopeless. It is clear that, in towns, there is little scope for attaining the object unless by varying the disposition of rooms according as the house may be on one or the other side of a street; and even in suburbs it is difficult to escape from "the rule of absolute parallelism to the high road." But "too frequently in the open country," where, he says, "everything in respect of site is perfectly untrammelled," aspect is so little regarded as to raise a question whether the matter of it is understood. There can be no doubt that it should be understood, in order that the inevitable compromise may be effected in the best manner; and Mr. Kerr's chapter, and his frequent allusions to the subject in the volume, should be carefully studied. He considers that when considerations of prospect are allowed to set aside entirely those of aspect, the error of judgment is a grave one; for, prospect, he thinks, loses its charm in the eye that constantly looks upon it; whilst aspect, if radically unsuitable, will never lose its unpleasantness. Acknowledging that there are few things in the whole province of plan more difficult and complicated than the disposal of rooms so that that they may possess the advantages of aspect and prospect together, he notes as simple expedients, the provision of extra windows specially placed, that is for prospect, and the use of bay-windows of special plan; and the rule which he recommends being, in fine, that whenever the considerations of aspect and those of prospect happen to be quite irreconcilable, the proprieties of aspect should be deemed of most importance, and that some mode of turning the prospect to account otherwise should be devised.

The quality next considered is "Cheerfulness," which in our climate he would adopt as a leading idea. The chief element of cheerfulness is the sunshine; so that the question is that of aspect: though prospect is equally important. The other elements he specifies as "Spaciousness of plan, loftiness of ceilings, a slight excess (rather than otherwise) of light and air, a character of decoration and furniture neither too heavy nor too dark [he is here going beyond the field of plan], all coupled, of course, with comfort and convenience, without which it is difficult to make by any means a cheerful house."

Then follows the consideration of the requisite "Elegance." The more advanced the taste, the more fastidious and becoming; and "repugnance to the mercenary or obtusive has sometimes even led to a sort of repudiation of the element of elegance itself." Persons the most exalted seek relief in their private retreats by the adoption of simplicity; but whilst the luxury of grandeur is reduced to a limit, grace need not be quite rejected. The limit is indicated by the term Elegance.

"Grandeur and artistic ambition must be spared even in places of state; mere richness will often be pronounced vulgar; simple grace, and elegance, and perfect finish are generally enough; their absence, if it true, will be at once detected, but any endeavour to reach beyond them will be labour in vain."

It would be a mistake, he thinks, to fancy that the "aesthetic abstemiousness" of English gentlemen is not shared by the ladies; and he says that the "sound principles of criticism upon which the pretensions is discarded" are fully comprehended by the latter.

Under the head "Importance," however, he remarks that there are considerations of dignity essential to the plan of a Gentleman's House. Though removed from ostentation, the house must be comely; removed from meanness. Solid value for the money spent should be provided. The importance of the rooms as a whole will greatly depend upon the means of communication: in fact, Mr. Kerr says, whenever display is allowable at all it should there begin, and that when the quality of Importance has to be carried into that stateliness which is proper for dwellings of the very first rank, Italian plan will offer great facilities for effect.

The recognition of the English taste amongst "the superior orders" as "averse to rich or sumptuous effects," does not lead Mr. Kerr to repudiate altogether, ornamentation. That, he says, would be "an act of morbid archaism which English gentlemen, and still more English ladies, would not approve." There should be no "excessive adornment," which is "almost invariably vulgar, and at the best barbaric;"—"no exuberance;" but there should be "no poverty."

Even in simplicity there may be "an affectation as demonstrative as any other; and when the fastidiousness of excessive refinement takes refuge in a mental blank, it is but an artificial idiosyncrasy." In a "Gentleman's House" there should be neither ostentation nor an opposite extreme; the house, he says,—

"ought to be not merely substantial, comfortable, convenient and well furnished, but fairly adorned. It ought to exhibit a reasonable amount of intellectual liberality, faithfully keeping on the side of simplicity and moderation, and clinging to the grace of elegance as the beauty which will last the longest, but avoiding none the less that poverty of dress which is not self-denial, but inhospitality."

Mr. Kerr's view that *hospitality* requires there should be a certain adornment, is the same as Mr. Garbett's in his Principles of Design in Architecture, that *courtesy* requires it. We are pleased to find the accordance between the two writers: only, we are inclined to add that the possession of means involves the duty not merely of the hospitality and courtesy which may be comprised in abstaining from "poverty of dress," but of the investment of the means so that they may return a positive contribution to the progress of art. Mr. Kerr, however, is much nearer to our view, in his later assertion, than he was in his other, above, on which we joined issue with him.

The several qualities, or requirements, treated of with reference to the Family Apartments, are discussed again,—or the chief of them,—when the author comes to the Domestic Offices.

It is not our intention to follow Mr. Kerr minutely, through the remaining sections of this first division of the second part of his work, or through the divisions headed "State Rooms, &c.," "The Domestic Offices," and "The Stabling and Farm Offices, &c." His definitions under the separate heads "Dining-room," "Dining and Sitting-room," "Morning-room," "Breakfast or Luncheon-room," "Drawing-room," and so on in great detail, throughout the section given to "The Day-rooms," under the heads "An Ordinary Bed-room," "An Ordinary Dressing-room," "Principal Guests' Suite," &c., of "The Sleeping-rooms," in similar detail; under those of "Nurseries," and "School-room," of "The Children's Rooms," under "Clenk-room," "Lavatory, &c.," "Bath-room," &c., of "The Supplementaries," and under divers heads of the section devoted to "The Thoroughfares," and similarly throughout the other divisions,—as the third, where each separate office-room is treated of in a distinct chapter,—are not less valuable than is his minute specification of the conditions and requirements in each case. To appreciate the whole of this part of the work, the book itself should be resorted to. The arrangement of the heads, of which we have before spoken, cannot, even without reference to them severally as treated, be studied without results, as well in the facility in planning which a logical view of the subject will give, as in the improvement of what conduces to domestic comfort. But whilst we may leave a valuable portion of the book comparatively unnoticed, we reserve for future attention portions of the volume which, belonging to the subject of planning, can perhaps be appreciated with less difficulty through the medium of a review, than those for which the appreciation would have to be founded upon an abstract of matter already condensed, and therefore on such an abstract as would with difficulty accommodate itself to our space.

#### PROFESSOR SMIRKE'S OPENING LECTURE ON ARCHITECTURE: ROYAL ACADEMY.\*

DISMISSING now all further reference to the subject of ornamental detail, I would somewhat enlarge the sphere of my observations, and suggest for your consideration the interest that may be given to buildings of small extent, or of unimportant character, by the application of the rules of good art to their design. Beauty and even dignity are surely capable of being impressed upon a building, although it may want prestige of utility in its origin, and although it may lay no claim to the doubtful merit of mere bulkiness. I would be careful to guard myself from being supposed to advocate any attempt at giving an inordinate, or undue, importance to trifling works: what I would fain urge on you is, that they may be made to interest us, and even to excite our admiration, without any attempt being made to stilt them up to a level with great

\* See p. 38, ante.

works. The hand of the *real artist* can never pass undetected.

It has been said of Virgil's rustic swains, such was the natural grace with which he seemed to invest them, that they appeared to perform the humblest and commonest tasks of rustic life with the dignity of gentlemen. So, perhaps, we may say with truth that buildings, even of the very least importance, may be raised high in our esteem by the artistic treatment of them.

It would be easy to multiply to any extent examples of this happy effect resulting from the judicious exercise of taste on minor works of architecture; and to illustrate the dogma that I would press upon your attention, that objects of architectural design do not derive their value so much from their intrinsic importance as from the quality of art bestowed upon them.

Take, for instance, the *bow window*, a peculiarly English feature which well deserves our regard and attention. Though so cheerful and pleasant a feature in dwelling-houses, it was, perhaps, in its origin, designed not *only* for light and prospect, but also as conducive to security in troublous times, as a looking-out place, giving a wider area for observation than would be afforded by an ordinary window. We see the idea of a bow-window carried out, although somewhat timidly, in the Border castles of the North.

Subsequently, however, in Tudor times, when castles began to lose their frowning character, indicating a greater sense of security, and a desire to render home not only a place of refuge and defence, but also, to some extent, of domestic enjoyment, we then find them, as at Berkeley Castle, Kenilworth, and many other examples, assuming that particular character which afterwards became one of the principal attractions of an old English mansion. Indeed, we are justified, I think, in claiming this agreeable architectural feature as *peculiarly English*.

Bow-windows, no doubt, occur, in some form or other, in various parts of the Continent; scarcely even, perhaps, in Italy; not very commonly in France; but in Germany some types of the bow-window are, I admit, common enough. At Nuremberg, that great mine of picturesque architecture which every architectural student should visit and study, some particularly beautiful examples occur. Still there is a manifest local character that distinguishes all these German examples from the genuine old English manner of designing them. The Germans never appear to have so entirely departed from the ancient Gothic type, as we find to have been the case in English domestic buildings.

Their bow-windows are apt to look more like perforated towers than with us; and there seems to have been retained a special disposition to place them at the *angles* of their houses, as if covertly intended to command the sides of the building, as the bastion of a fortification commands the curtain. Our Tudor bow-windows, on the contrary, seem more designed for interior domestic enjoyment. As Bacon says of them, "These be pretty places for a conference," and it is certainly obvious that our ancestors, in building these bows, were far more bent on providing means for the pleasant occupation of a room than on producing any ornamental exterior effect. It is true, they are almost always extremely picturesque, and never fail to contribute to the beauty of the building of which they form a part; but this only tends to prove what on former occasions I have repeatedly urged, that in design, whatever is peculiarly fit and proper for its individual purpose rarely fails to be agreeable in its appearance.

Whilst dwelling on those subordinate parts of a building which the genius of artists has loved to endow with especial beauty, I must not forget to do justice to the chimney-shaft. Out of these trivial and uncleanly smoke-vents architects have taxed their ingenuity to produce really marvellous objects of high aesthetic value. Of classical interest they can scarcely be said to possess any, for it is very doubtful whether architects of classic times recognized the existence of such a feature. Vitruvius does not even name them. The remains of Herculaneum present not a single example of one; nor do the mosaics, frescoes, or bas-reliefs of antiquity show any indication of one, as far as I know. There is every reason to believe that the only means of escape for the smoke of their fires was through a hole in the roof, like the *louvre*s of Medieval times; so that the "smoke nuisance" we complain of at the present day may lay claim to high antiquity. The very name of the large hall in a Roman's house, *atrium*, is believed to be

derived from this nuisance, "*Atrium, enim, erat ex fumo*." The statues in these halls are described by Juvenal and others as "*fumosi*," and Vitruvius advises that there shall be no carved work in the interior of winter rooms, as they so soon, as he says, get covered with soot. I apprehend that the roof-timbers of our old baronial halls must have presented much of the same appearance; and as Horace complains of the "watery eyes" produced by the smoky halls, so our own mailed knights and their retainers could hardly have been better off. You will find that antiquaries are by no means satisfied as to the period of the introduction of this great domestic convenience, the chimney; but it was somewhat late in Mediaeval times before chimneys became very common. Viollet-le-Duc gives us in his "*Dictionnaire Raisonné*" a good example of one of the thirteenth century, formerly existing in the Abbey S. Ló, and in England we have examples of still earlier date; but as civilization advanced, and men's domestic habits refined, the chimney became conspicuous. They lavished art upon the decoration of the hearths below; whilst the chimney above partook of the same feeling, and both gradually grew into favourite objects of design, until, in the sixteenth century, the exuberance of architecture,—especially, I think, in France,—led to the creation of those enormous and elaborate towers which we see provided for the discharge of smoke at Fontainebleau, the Tuileries, and very many other places.

The hypercritical may ask, why clothe these subordinate features with the dignity of art? Why bring out into so great importance and conspicuousness objects which have so mean a use? The artist, I apprehend, will rejoine—why not? Why should we not give to these chimneys any amount of beauty and expression that such objects, trivial though they may be, can be made susceptible of, provided we do so honestly, and keeping within the limit of good sense. To give to a chimney-shaft the air of an embattled turret, with loophole and creellation, would be a falsity and an outrage on that good sense to which all things in art should be amenable; and indeed, to make them appear to be anything but what they are would be a fault which I should be ashamed here to defend or extenuate. But that it should be considered unworthy of the dignity of art to descend to the adornment of even a chimney-shaft, by beauty of proportion, as well as of detail, merely because it is an object subservient to a very humble purpose, is what I feel bound to deny.

At all events, let not the architect think that he can afford to slight any portion of his inventions. "*De minimis hauri curat Prætor*" may possibly be a sound maxim in law,—and even that I apprehend admits of a doubt,—but the arts of design are subject to a far milder, less severe rule; and, I repeat it, an architect cannot adopt such a rule of conduct without abandoning a part of his plainest duties, and at the same time abandoning a large and fruitful field for the exercise of such genius as he may be endowed with. I have now urged this principle upon you by referring to various minor details of architecture. It would be easy to greatly extend the number of similar illustrations, but perhaps we should profit more by enlarging the scope of our observations, and by showing how the same principle applies to the designing of whole buildings as well as of their details. I would wish you to consider that buildings of small dimension, and appropriated to subordinate and even very insignificant purposes, may yet be made pleasing and interesting objects by a judicious application of the resources of art. But before endeavouring to enforce this opinion by special illustrations, let me assure you that I am by no means about to lead you into that vulgar error of which we see so many evidences constantly presented to our view, of that misapplication of art which consists of loading small buildings destined for humble purposes with excessive or obtrusive decoration. On the contrary, that is a practice against which I would strongly protest. In like manner, I would warn you against another error common enough, and perhaps all the more dangerous on that account, of giving, or attempting to give, to those smaller buildings, a *character* that belongs to other more important works. To design a gate lodge so as to represent some classical temple, or to deck out a tavern, or a shop-front, as if it were a temple of Osiris, on a small scale, these are vulgar habits which I beg of you to avoid as repugnant to good sense, and derogatory to your art. No delicacy of finish, no exactness of representation, no excellence of

execution, will compensate for so great a violation of propriety. Indeed, this disregard of the *appropriateness* of style—this ambitious assumption of dignity, incompatible with the size as well as with the character of the building, never fails to bring on the work, and on its author, the condemnation, and perhaps the ridicule, of sound critics.

However, as I have already said, very trivial buildings are capable of beauty and expression, that beauty not being sought in excessive or inappropriate decoration, and that expression not being enforced by resort to theatrical or obtrusive artifices. The idea which it may be desirable to express should be delicately hinted at, rather than forced on the observer. Perhaps I may best illustrate the principle that I am endeavouring to present to you by hypothetical cases. Suppose, for instance, that a halliér's, or a gamekeeper's lodge has to be built, in one of those ornamental and picturesque parks with which English scenery is so often graced. One ambitious architect will overlay his ornaments upon it from plinth to roof; his ridges will be bristled with a luxuriant cresting; his walls will be speckled over with bricks of all manner of colours; he will give it perhaps two or three very port-looking gables; his bow-windows and porch will present a complete storehouse of crockets and corbels; tall chimney-shafts will of course not be wanting elaborated after the types of Hatfield or Knowle; in short, there will be a whole world of art within the compass of this nutshell. Another architect, whilst he gives to his work that careful and even polished aspect that is demanded by the genius of the place, will yet keep it subordinate and unobtrusive. He will not force it upon your notice, but rather would let you perceive it amidst a becoming veil of foliage: like the modest rural hells of Virgil, she is retiring, but not unwillng to be admired:—

"*Fugit ad salices, at se cœpit ante videri.*"

His work will present nothing to your view either ambitious or sordid. Ornament will not be wanting, but it will be sparingly used and suitable in character. There will be elegance, but a total absence of ostentatious ornamentation. In both these supposed cases there may be beauties, but in the one case there is an incongruous display of them; in the other case, its beauties are but modestly disclosed, and have to be sought for in order to be duly appreciated. Which, I ask you, of these two men's works would best deserve the name of *fine art*?

It is, I fear, a deplorable fact that the present day is distinguished by far too great a prevalence of the evil taste to which I advert. Aesthetic cultivation has not kept pace with the accumulation of the means of indulgence in the luxuries of taste. I believe that many an architect finds himself, contrary to his better judgment, constrained to work *down* to the level of his patrons, and erects unsightly examples of misplaced finery to meet the exigencies of such patrons, whilst he is conscious of higher and worthier aspirations. I am treading, however, on hazardous grounds, and must proceed no further. I will, therefore, at once dismiss the subject, merely remarking that, however improvable may be the fine-art education of my profession, no improvement would be so prominent of good, and none so needed, as an improvement in the knowledge and appreciation of the art *outside* the profession. But for the enlightened perception of the beautiful in general—and, indeed, in the Greek culture generally—Greece, perhaps, would never have had a Phidias. It was the ardent love of art, and the earnest study of it, in Lorenzo di Medici, to which may justly be attributed that memorable school which gave us Michelangelo and all the other glories of his age.

I have observed on the capacity of even very small buildings for beauty and expression, without that resort to excessive decorative detail which is supposed by some to be so essential. Examples in endless variety might be adduced in verification of this opinion. The cottages that remain to us of the sixteenth and seventeenth centuries have often a most pleasing character, contrasting painfully with the ordinary cottage of the present day. Notwithstanding the simplicity of design and the apparent absence of all effort at "effect," there is yet a play and variety of form, and breadth of light and shadow, which will produce, by chance, as it were, a most picturesque object; and this desirable result, let me add, will be often found to be brought about without a single *merely* ornamental adjunct. When

these humble yet pleasing structures happen to occur beside a cottage of the ordinary type of the present day, it is impossible not to admit that in matters of taste, at all events, the world makes very slow progress, if it be not retrograde. The utilitarian spirit seems to have completely extinguished the feeling that prompted the cottage builders of former times; so extinguished, indeed, that the rash man that would venture to insinuate a doubt whether we might not derive valuable lessons from these very unpretending works of our simple forefathers would probably meet with far more derision than sympathy.

Do not suppose that I am not alive to the very important improvements that have been made of late years, in the domestic arrangement of cottages. It would be a gross injustice to many able and benevolent men who have laboured in the good cause of bettering the material condition of the humbler classes, were I to deny that great success has attended these efforts: there is not a doubt that the interior economy of cottages has been wonderfully improved, and that the health of their occupants, both moral and physical, has been greatly promoted by those improvements; nor do I hesitate to admit that these are considerations which have a far higher claim on our attention than the merely picturesque consideration which I have been noticing, and to which it is perhaps my duty here to confine myself. My object in touching at all upon the utilitarian view of the subject is to suggest to you, as artists, not that the first place is to be given to artistic excellence in these humble productions, but that art should not be altogether overlooked in them; and to urge upon you the duty which, as it seems to me, devolves on all who love their art, to study seriously and carefully how to reconcile and adopt the high qualities of beauty and expression to the severer virtues of convenience and healthiness.

At the risk of being charged with extending my remarks on this cottage architecture to an unreasonable length, I am strongly tempted to point out the fertile source of profitable study to be derived from the critical observation of the villas and other rural buildings that so often meet the eye of the observant artist who wanders over the campagna of that land of art, Italy. They are for the most part the works of former and better times, and illustrate forcibly the picturesque tendencies of the Italian mind. Every group of these unostentatious structures that we meet with is apt to arrange itself agreeably and to become in itself a picture, attractive to the painter's eye and inviting his pencil. There are not tricked up exhibitions of artistic coxonomy; not theatrical displays, "smelling of the lamp," and betraying the vanity and vulgarity of their authors; but their charm lies in the unadorned grouping together of very simple forms, pleasing us by the accidental beauty of the result. It may be difficult to explain the cause of the pleasure which these rustic buildings produce on the mind of the wanderer who has leisure and inclination to seek benefit from a contemplation of them. The pleasure derived from this exercise of the eye is to be felt, but not described, and will perhaps best be realised by those who will take the trouble to compare these examples with buildings of like nature usually erected by ourselves at the present day, and in our own truly utilitarian country, from the contemplation of which we usually derive anything but satisfaction.

I must not detain you longer with these reflections. I might readily draw and illustrate from the works of the great painters of the Renaissance and later periods. I can assure you that even the architectural student who, in search of the picturesque in his own department of art, will examine the works of the great masters of the sixteenth and seventeenth centuries, will not fail to find the delicate perception of beauty which so greatly distinguished the Italian mind, eminently manifesting itself in the backgrounds and subordinate portions of the refined compositions of that golden period of art.

Now, when endeavouring to enlist your interest on behalf of these minor objects of picturesque architecture, it may seem incense that I should pass by without recognition the almost proverbially attractive form and features of the Swiss chalets; but they are objects so familiar to all that we need not be detained by any special reference to them, except to point to them as a most obvious illustration of what I have been urging on you, namely, that in these smaller works of art those will assuredly please the

critical eye the most which seek to give pleasure, not by multitudinous enrichments, but by an agreeable outline and chiaroscuro. The singular charm of those plain wooden tements consists in their breadth and simplicity, in the unaffected rustic beauty which particularly characterises the Swiss chalet.

It is time to close these desultory remarks on small matters. Let me sum up in few words the perhaps not sufficiently marked or steady aim of all the observations with which I have been soliciting your attention this evening. I would not have you despise small objects of design. Never regard it as beneath you, nor beneath the real dignity of your art, to pay even minute attention to every object, however unobtrusive; for there is in designing nothing to which true art may not be applied with advantage. It is the slovenly neglect of these details which contributes, more than almost anything else, to make a design crude and sometimes even vulgar.

Some may be disposed to regard such inattention as a noble indifference to trivial matters, and as an evidence of true genius; but must we not rather look on this defect as a proof of the very narrow and finite range of human capacity?

Look, as I have often repeated in former lectures, to what Nature does, and no true disciple of art will ever think that he can too carefully pursue that study. In the works of Nature we shall find, in the veriest trifle of organised life,—the tiny moth's wing, the fly's foot, even the dead leaf that is drifted as an utterly worthless thing before the wind,—that there is no less careful adherence to Nature's laws, no less thoughtful adaptation of means to the end, than in the most precious works of the Creation; and yet we shall find that over all these minute though not less noticeable manifestations of Divine power and wisdom, there has been extended an all-pervading spirit of grace and beauty, a manifestation which should prompt the artist to follow humbly yet zealously the example thus set, and never to relax his best endeavours to endue his works, whatever they may be, with such touches of those heaven-born qualities as may be within the reach of his ability.

#### WALKS AND TALKS ABOUT LONDON.\*

"WHICH is the most interesting portion of London?" said a distinguished Fellow of the Society of Antiquaries. "I can scarcely make up my mind to the locality," replied the person thus interrogated. "It is Covent Garden," rejoined the F.S.A., "because its celebrity is just old enough for us to be familiar with the lives of eminent persons who have rendered it so celebrated." This is reasonable: so let us have a little walk and talk about "the amorous and herbivorous parish," along with Mr. Timbs, F.S.A., as our very efficient conductor.

Walter Savage Landor, in one of his imaginary conversations, thus glances at the changes in Covent Garden: "The convent becomes a playhouse; monks and nuns turn actors and actresses. The garden, formal and quiet, where a salad was cut for a lady abbess, and flowers were gathered to adorn images, becomes a market, noisy and full of life, distributing thousands of fruits and flowers to a vicious metropolis." Although the market dates from the reign of Charles II., in 1726, and later, it was called Covent Garden; and by the vulgar "Common Garden" (Sir John Fielding, 1776).

Covent Garden was the first square inhabited by the great, for immediately upon the completion of the houses on the north and east sides, after Inigo Jones's design, they were every one of them inhabited by persons of the first title and rank, as appears by the parish-books of the rates at that time.

The chambers occupied by Richard Wilson, now the Tavistock breakfast-rooms, were portions of the house successively inhabited by Sir Peter Lely, Sir Godfrey Kneller, and Sir James Thornhill. Covent Garden, even so late as Pope's time, retained its fashion, as may be seen in the *Morning Advertiser*, March 6th, 1730—

"The Lady Wortley Montague, who has been greatly indisposed at her house in Covent Garden for some time, is now perfectly recovered, and takes the benefit of the air in Hyde Park every morning, by advice of her physicians."

The parish of St. Paul's was at that time the only fashionable part of the town, and the

\* "Walks and Talks about London." By John Timbs, F.S.A. London: Lockwood & Co., Stationers' Hall-court, 1865.

residence of a great number of persons of rank and title, and artists of the first eminence; and also from the concourse of wits, literary characters, and other men of genius, who frequented the numerous coffee-houses, wine and cyder-cellars, jelly-shops, &c., within its boundaries, the list of whom particularly includes the names of Butler, Addison, Sir Richard Steele, Otway, Dryden, Pope, Warburton, Cibber, Fielding, Churchill, Bolingbroke, and Dr. Samuel Johnson; Rich, Woodard, Booth, Wilkes, Garrick, and Macklin; Kitty Clive, Peg Woffington, Mrs. Pritchard, the Duchess of Botton, Lady Dorchy, Lady Thurlow, and the Duchess of St. Albans; Sir Peter Lely, Sir Godfrey Kneller, and Sir James Thornhill; Vandewelde, Zincke, Lamier, Hogarth, Hayman, Wilson, Dance, Meyer, &c. The name of Samuel Foote should be added.

The Garden became infamous when its opulent inhabitants exchanged their residences for the newly-built mansions in Hanover, Grosvenor, and Cavendish squares, and Holles and the other streets adjacent. It was at that period that Mother Needham, Mother Douglass (*alias*, according to Foote's *Mirror*, Mother Cole), and Moll King, the tavern-keepers and the gamblers, took possession of the dedicated premises. Beneath the church-porch was "Tom King's Coffee-house," shown in Hogarth's print of "Morning." It was a mere shed, as Murphy describes it—"well known to all gentlemen to whom beds are unknown." Upon the south side of the market-sheds was the noted "Finish," kept by Mrs. Butler, open all night—the last of the Garden taverns, and only cleared away in 1829. This house was originally the Queen's Head.

The market was a strange and shabby assemblage of shed and pent-house, rude stall and crazy timent, coffee-house and gin-shop, intersected by narrow and ill-lighted footways, until the site was cleared for a new market, in the year 1829. A sketcher of that date says:—

"Enter it from Russell-street: what can be more unightly—with its piles of cabages in the street, and basket-measures on the roofs of the shops—narrow alleys, wooden buildings, rotting vegetables, andque; and swarms of Irish basket-women, who wander about like the ghosts on this side of the Stix; and who, in habits, features, and dialect, appear as if belonging to another world? Yet the Garden, like every garden, has its charms. The narrow passages through this mart rendered one of the Chinese streets, where all is shops, bustle, squeeze, and commerce."

Of the place, before the new market was erected, Mr. Timbs thus speaks of his own recollection:—

"We have viewed the Market from one of the windows of an adjoining hotel; and a more deplorable picture of wretchedness cannot be conceived than this dual area presented; yet, at stated times, might be seen the collector descending from his curcule, to gather, with outstretched hands, the rests from stall-keepers."

At length the site was cleared, and a new market commenced, from the designs of Mr. Fowler. In digging for the foundations was exhumed a quantity of human bones, on the north side of the area, supposed to have been the convent burial-ground. The market, we may remind our readers, consists of a quadrangle, with two exterior colonnades of shops, and in the central building an avenue of shops for forced articles, the choice fruits, vegetables, &c. At the east end is a quadruple colonnade, with a terrace and two large conservatories, a fountain, emblematical sculpture, &c. At the west end are a colonnade, conservatory, and the flower market.

The market buildings cannot be mistaken for anything else but what they are, unless the inscription, "John Dunke of Bedford, erected MDCCLXXX," over the east end, lead posterity to regard this as a patriotic act; whereas the Bedford family derive a large rental from the market, stated at £5,000 per annum. The area is three acres. The rent of some of the shops is from 400l. to 500l. per annum. The market is said to pay 10 per cent.

Some of the larger items of the market sales are exclusively of modern date, such as the 200,000 pines which come yearly into the port of London, or the hundreds of tons of rhubarb which are now sold in Covent Garden. According to the evidence of Mr. Maynwaring, one Boyce, of Maiden-lane, recollected when Covent Garden was let for 30l. a year. To the Horticultural Society of London much of this progress is due.

It has been said, that there is more certainty of being able to purchase a pine-apple here every day in the year, than in Jamaica and Calcutta, where pines are indigenous. Of curious herbs for domestic medicines, distillers, &c., upwards of 500 species may be procured at the shop of one herbalist. Three millions sterling

FONT, STANDON CHURCH, HERTS.

reward him, would take him to see the giants at St. Dunstan's; and he used to say, that when he grow to be a man, he would buy those giants. Many a child of rich parents may have said the same; but in the present case the marquess kept his word. When the old church was taken down, in 1829, Lord Hertford attended the second auction-sale of the materials, and purchased the clock, bells, and figures, for 200*l*.: he had them placed at the entrance to the grounds of his villa in the Regent's Park, thence called St. Dunstan's Villa, and here the figures do duty to the present day.

Mr. Timbs's excellent gossip, however, makes us forget that our space is limited, and we must close his lively volume without even glancing at a host of book-marks not yet reverted to.

In what we may, without any exaggeration, call "The Timbs Library," there are many books in which we see little of Mr. Timbs himself, besides his skilful selections, compilations, and condensations. Here, however, as in his "Curiosities of London," and others of his writings, we have the author himself before us. Reminiscences of persons, places, and events form the staple of the "Walks and Talks," which, moreover, though complete in themselves, give indications, as we are informed, of the character of an autobiographic volume of collections and recollections yet unpublished.

We may conclude with a list of the general contents of the "Walks and Talks about London." The work is divided into,—A little talk about Lyon's-tan; the last days of Downing-street; walks and talks in Vauxhall Gardens; the last of the old Bridewell, of London; the fair of Mayfair; from Hicks's Hall to Campden House; talk about the Temple, past and pre-

sent; recollections of Sir Richard Phillips; curiosities of Fishmongers' Hall; a morning in Sir John Soane's Museum; a site of speculation; changes in Covent-garden; the last of the Fleet Prison; forty years in Fleet-street; changes at Charing-cross; railway London; Blackfriars Bridge; the raising of Holborn-valley; and an old tavern in St. James's-street.

#### STANDON CHURCH, HERTFORDSHIRE.

St. Mary's, at Standon, near Ware, had fallen into a miserable condition, as we mentioned some time ago, before the works were commenced. Through the exertions, however, of the vicar, the Rev. Charles Fuller, and the good-feeling and liberality of the parishioners and neighbouring landowners, money was raised, and the building has been put into a sound and substantial condition. The accompanying engraving conveys something of the present aspect of the interior of the church, looking east, and the following passages from a circular issued at the commencement of the works show the state in which the building was:—

"The ancient parish church of Standon is a large and has been a very handsome pile of building. Its total length, including the chancel, is 110 ft., of which the chancel occupies 40 ft. The width of the nave and aisles is 50 ft. It has two aisles and clerestory. The chancel has neither aisles nor clerestory. The style of the chancel arch is very beautiful Early English. The nave and aisles are in the Decorated style; and the windows are much admired. The chancel is Perpendicular in style.

The tower touches at one corner the south-east angle of the south aisle. It was rebuilt about twenty years ago, when a large portion of it fell down from decay.

The chancel is peculiar in being raised eight steps above the level of the nave; the rise of the hill having been followed in laying the foundations.

At present the external walls of the whole building are disfigured by bricks and other stones. The stone-work of the windows and buttresses is much decayed, and in many places has been replaced by brick-work.

The old roof has been removed, and a modern one of low pitch screened by a flat plaster ceiling substituted both in nave and chancel.

The internal walls are dirty and ill-faced, and the internal stone-work (and in the chancel the wood-work also) is much disfigured with paint and whitewash. The paving is imperfect and ill-arranged, and in the nave and aisles three-fourths of the area are occupied by high and inconvenient pews."

The face of the external walls has been renewed with uncut flints, the porches are rebuilt, the stonework of the windows, copings, pillars, and so on, is made good, and all the paint and whitewash which disfigured the building have been removed. The church has been re-pewed, the old organ gallery over the west door taken down, and a new high-pitched roof, in stained fir, placed upon the nave. The whole of the seating is of oak, plain but solid. The pulpit is also of oak, formed with open panel-work, and has a cornice of passion-flowers, very well carved. It is entered from off the steps from the chancel. The font, an early one, and of which we give a view, was much battered, and made up with cement. With some care it has been renewed in stone. A piscina and an interesting recessed sepulchre, in the south wall of nave, with a stone coffin below, were discovered during the works, and have been restored.

The Perpendicular windows of the chancel, decayed and ruinous, were insertions; and the chancel has been brought back to its original Early English character, with a tile pavement supplied by Messrs. Maw & Co. The pinnacles is also of tile. The tomb seen against the south wall of chancel is that of Sir Ralph Sadler; and

STANDON CHURCH, NEAR WARE, HERTFORDSHIRE, AS RESTORED.  
MESSRS. G. & H. GODWIN, ARCHITECTS.

the King of Scots' standard, which he took at the battle of Musselburgh, in the reign of King Edward VI., stood by his monument in the church until all had gone but the pole; and now only the sword is left. This is still suspended near the tomb. There are other interesting tombs in the church, and several brasses. The latter have been placed at the foot of the chancel steps.

The cost of the works in the chancel was liberally defrayed by His Grace the Duke of Wellington, lay rector of the parish.

A spacious organ chamber has been added to the church, between the south wall of the chancel and the tower (formerly an open yard enclosed by a dead wall), and a moulded opening communicates from the chamber to the chancel. The window at the east end of the south aisle of nave, left without glass, also opens into the organ-chamber. The stone staircase and the opening to the old roof-lead remain. The new south porch, it may be mentioned, is of oak, and somewhat elaborate.

During the progress of the works, a subscription was raised in the county for the erection of a memorial, or memorials, of the late Mr. C. W. Giles Puller, and part of the amount raised was expended in setting up stained glass in the east window of the chancel, a triplet. The three lights are bound together at the top by a rich hood-moulding, which includes the dog-tooth ornament, repeated from the old work in the chancel arch. The subject in the principal compartments of the three lights, is "The Transfiguration;" in the lower compartments, "The Epiphany," represented by three groups; in the centre, "The Virgin Mary and the Infant Jesus;" on the left, "The Adoration of the Shepherds;" on the right, "The Wise Men presenting Offerings." In the upper quatrefoils are symbols of the Three Persons in the blessed Trinity. A brass plate will be inserted in the north wall of the chancel, notifying that the window is a memorial of the late C. W. Giles Puller, esq. The window was executed by Messrs. Clayton & Bell.

Between the lights of the east window are pillars of Parbeck marble, the cost of which, as well as that of the red Devonshire marble pillars in the chancel arch, was defrayed out of the Puller Memorial Fund.

The opening on each side of the chancel arch is somewhat peculiar with reference to the Early English period. Originally the openings probably went down to the floor of the chancel, but when the present nave was built, in the fourteenth century, they were partly filled in and altered to lancet windows. The old mouldings belonging to them were discovered in the wall, and were reinstated. Standon is an ancient place; it is described in "Domesday Book," and the Abbots of Croiland had a seat here in 1030. It is more than likely that the present thirteenth century chancel was built to a Norman, if not Saxon nave, which, early in the fourteenth century, gave place to the present nave, now by the liberality and continuing piety of the people of Standon fitted to endure for coming generations. The total expenditure, including the Puller Memorial fund, has been something under 3,000l.

The works have been executed from the designs and under the superintendance of Messrs. J. J. & H. Godwin, architects; the nave by Messrs. Dove, Brothers, of Islington; the chancel by Mr. Thomas Ginn, of Puckeridge; and it is but fair to say that both contractors have done their work well. Mr. Henry G. Brown was clerk of the works.

THAMES DITTON CHURCH, SURREY.

The parish church of Thames Ditton was re-opened for divine service on Friday, the 13th instant, by the Archdeacon of Surrey, after having been enlarged by the addition of a south nave and chancel, aisle and porch, affording accommodation for about 200 persons. The walls are constructed of flint and rubble, with flint stone dressings. The east chancel and western circular gable-windows have been filled with glass by Messrs. Lavers & Barrand. The old part of the church is debased fifteenth century work; but the base of the tower is probably Saxon, and it seems likely that a Roman villa stood formerly near its site, courses of Roman brick being built into the walls. The font is considered by some to be Saxon; the bowl was supported on a modern base, which has been replaced by one more in character. The church possesses several curious and interesting monuments and some brasses of great interest, all of

which have been preserved from injury and replacement in their positions. The works were done under the superintendance of Mr. Ferrey, architect; and Mr. Mathews, of Thames Ditton, was the contractor.

HESTON CHURCH.

NOTWITHSTANDING all that was said on the subject, we learn, and with much regret, that the demolition of this ancient church will, in all probability, be begun in a fortnight's time. It only awaits the receipt of a faculty from the bishop, and it is said there is small hope of its refusal. Considerable desire for the preservation of the sacred edifice is expressed in the neighbourhood by many persons of position; besides which, the local press has been active against the apparently uncalculated-for destruction of a relic of antiquity.

THE EDINBURGH THEATRE DISASTER.

Speaking generally and with respect to Scottish and English theatres as a whole, we are afraid there is such a constant and increasing quantity of risk in their construction, and more particularly in their working, that we are induced to think the whole system must, sooner or later, undergo revision and reform. The sensation drama and the imposing spectacles are every day growing more imperious in their demands for dangerous elements. The quantities of gas and gunpowder, for example, which are consumed in a London theatre during some pieces are so enormous and so costly that few would credit the amount who were not, literally speaking, behind the scenes. Then we have the electric light introduced on the stage, the limelight, and every description of red, blue, green, and parti-coloured lights, all of which are composed of materials in the highest degree combustible and inflammable. To make things worse, these materials are consumed or exploded in the very closest contact to timber spars covered with pasteboard, painted canvas, light gauze, and such like inflammable fabrics. Nor do the human creatures who go to build up a transformation-scene or a ballet make the slightest effort to avoid the general danger. A multitude of muslin petticoats fluttering within 3 in. of a glaring gas jet,—long draperies, in interminable festoons, interwoven with artificial lights in enchanted gardens,—these are a few of the situations which a smiling spectator in the boxes of a theatre enjoys during his Christmas holidays. A poor girl, indeed, is now and then burned to death; but this occurrence, he suspects, is a risk inseparable from a profession which is unusually exposed to risks. It is only when the house takes fire, and the lives of the audience are endangered, that it is really seen what a premium the audience themselves hold out for the sacrifice of human life. The fact is, we manage somehow in our modern amusements to kill off as many people as the ancient Romans did in the amphitheatre. But, then, our inhumanity is not so positive, nor our abnormal tastes so conspicuous.

The end of all this, we apprehend, must be something like a suspension of the principles of free trade with regard to theatrical managers. There must be a limit set to their supply of morbid demands. The sensation business must be restricted. The jurisprudence of this country has long recognised a class of official inspectors in other cases, such as chemical works and emigrant ships, where cupidity and self-interest become dangerous to the health of the liges. We have ourselves strenuously advocated the appointment of such officials in respect to overcrowded dwelling-houses; and sooner or later the principle will have to be extended so as to include theatres, dancing-saloons, concert-rooms, and other places of entertainment.

The Edinburgh Theatre Royal occupied a site on a conspicuous corner at the head of Leith Walk, adjoining a lofty tenement of houses on the one gable and a Roman Catholic chapel on the other. There seems to have been no adequate separation from either of these buildings; and if this be the case it was certainly a prodigious mistake in construction. The old Edinburgh Theatre Royal, in Shakspeare-square, on the site of which the new post-office was built, we remember as an isolated building in the centre of the square. Why was the present theatre not also detached? It is surely a mistake to render the inhabitants, or rather, we should say the population, of a long common stair subject

to extraneous risks of this serious character; for in our opinion they stand in great danger as it is. Again, how is it that the Edinburgh municipality possess neither a steam fire-engine nor a common fire-escape? They are, indeed, profusely supplied with one valuable preventive to the extension of a conflagration in the very construction of their buildings. Fires in Scotland, as far as we can observe, are seldom extinguished by the fire-brigade: they are usually circumscribed alone by the solid masonry of the walls. But in the event of high winds prevailing at the time, even this security would be overcome. And what must we say about a possible scarcity of water? Had this fire occurred in Edinburgh in the month of August or September last year, when the reservoirs were empty, what might not have been the consequences? It is all very well to tell us that the danger is over for the present; and there are more theatres in Edinburgh, we suppose: have we any stronger security respecting these than we had in the Theatre Royal? And what meteorologist can secure us against a succession of dry summers?

COMPETITIONS.

Design for Front of Manufactory.—The designs sent to a firm in the Royal Exchange for the front of a building (nearly fifty in number), in reply to offered premiums of 10l. and 5l., are, as might be expected, mostly rubbish,—the efforts of pupils and other tyros. Drawings by Messrs. J. P. Jones, Gilbert R. Redgrave, Chmings, E. T. Eard, Blake, and one or two others, may be excepted.

AWARD OF THE PREMIUMS FOR THE BOLTON TOWN-HALL DESIGNS.

A MEETING of the Town-hall Committee, at Bolton, was held on Monday evening, when the question of awarding the premium for the best designs, which it will be recollected the town council had sent back, came under consideration. After several proposals had been separately made and negatived, the committee, by a large majority, passed resolutions, awarding the three premiums to the authors of the designs which Professor Donaldson had classified as standing first in the order of merit. The first prize will, therefore, be awarded to the design marked No. 24, "Experientia Docet;" the second to No. 3, "Manchester;" and the third to No. 25, "Nil Magnam nisi Bonam." The committee also passed a resolution awarding 20l. to each of the authors of the other three sets of designs included in the selected six, on the condition, that the plans become the property of the corporation. These awards will, of course, require confirmation by the town council, a meeting of which will probably not be held until the 15th proximo; but as the committee have thus acceded to the principle laid down at the previous meeting of the council, no further attempt will be made to disturb the relative positions of the successful competitors. The plans to which the 20l. awards are offered are, No. 19, "As you Like it;" No. 26, "Utile Dulci;" and No. 10, "Experia."

THE DISCHARGE NOTE.

A MEETING of the General Builders' Association was held on the 23rd, at Nock's Hotel, Temple-row, Birmingham. There were about 150 master builders present, and the following, amongst other towns in the Midland counties, were represented:—Birmingham, Wolverhampton, Walsall, Dudley, Burton-on-Trent, Wednesbury, Nottingham, Derby, Leicester, Willenhall, Coley, Leamington, Warwick, Hanley, Burslem, Stafford, Stourbridge, Gloucester, &c. The meeting was called for two o'clock; and at the conclusion of a discussion which lasted about three hours, the following resolution was passed:—

"That, with a view to the settlement of the present differences in the trade, the master builders are willing to withdraw the notice they have given respecting the discharge-note, and at once, through their association, to meet their men, in order to settle all labour questions by the adoption of trade rules; and, in case of any differences arising, are willing to adopt a system of arbitration."

It has been asserted that some resolutions were passed after the withdrawal of the "note" which had excited suspicion, and up to the time of our going to press the men had not resumed

work. We have every reason, however, to believe that all obstacles to reconciliation have been removed.

On this subject we have received a large number of letters from masters and from men, but are forced to put them on one side at present.

#### PROPOSED WORKHOUSE, BRIGHTON.

The Brighton Guardians certainly have a peculiar way of conducting the business of the Poor. At their last meeting, the consent of the Poor-law Board to borrowing money to carry out designs which have been doctored up, as we understand, by various parties having been obtained, the following report from the new Workhouse Committee was brought up:—

"Your committee have had under consideration the question of appointing a competent person as clerk of the works in the erection of a new Workhouse, and they recommend that Mr. James Reed be appointed accordingly, at a salary of 27. 5s. per week.

Your committee also recommend that Mr. George Maynard be employed to prepare the working drawings for the new Workhouse, and to superintend the carrying out of the works at a charge of one and a half per cent. on the amount of contract."

After discussion, in the course of which some of the speakers said that Mr. Maynard was an officer of the Board and must neglect his proper duties if he carried out the design, and others that the payment was much too small, the report was adopted unanimously.

#### CORNISH SERPENTINE FOR EXTERNAL WORK.

The large and lofty structure which was erected a few years ago on Cornhill for Messrs. Sarl, having been purchased by the City Offices Company, and becoming occupied by the "Cylinder Fancier et Mobilier Company of England," the lower part of the front has been altered under the direction of Mr. John Barnett, architect, to suit their purposes. The space between the existing granite pilasters is filled in with work executed in a light green serpentine, combined with some of the darker varieties and red granite. The effect produced is very good, and shows the capabilities of the Cornish serpentine, either alone or combined with granite. In reply to our inquiry as to its resistance to atmospheric influences, it is stated that examples of serpentine have now been exposed to the weather for many years in London and elsewhere, without any loss of polished surface. It was supplied by the Lizard Serpentine Company, St. James's-street. Messrs. Cubitt & Co. were the builders.

#### FALL OF CORNICE AND SCAFFOLD IN GREAT WINCHESTER STREET, CITY.

On Thursday, in last week, a large portion of a cornice in progress at the extensive premises in course of erection, for Alderman S. Waterlow, stationer, in Winchester-buildings, adjoining his London-wall premises, fell, breaking down the scaffolding in front of the building, on which about twenty men and boys were at work, and so severely injuring eight of them that one, a lad of seventeen, has since died, and other three are in a precarious state. Messrs. Lawrence, Brothers, are the contractors for the building, and Mr. Randall is the architect.

An inquest on the deceased was held by Mr. Payne, at St. Bartholomew's Hospital, on Tuesday last. The following evidence was taken:—

Nathaniel T. Randall, on being sworn, said: I live at 28, Great Winchester-street, and am an architect. The building which caused the injury is situated in Winchester-street. Under the Act of Parliament I should term it of the warehouse class. It consists of six stories and attic. The width or substance of the external wall or the basement is 2 ft. 8 in.; ground-floor, 2 ft. 3 in.; one-story, 1 ft. 10 in.; two-story, 2 ft. 10 in.; three-story, 18 in.; and 18 in. up to the parapet. The height of the building from the ground-floor up to the top of the building is about 64 ft. The mischief occurred through the fall of the scaffolding and cornice. The cornice fell first, and brought down part of the scaffolding. If the scaffolding gave way it would tend to rattle up the cornice, but I could not say which gave way first. The height of the cornice from the ground is about 52 ft. to its top. To the lower part of the cornice it would be about 50 ft. from the ground. The cornice is about (in depth from top to bottom) 2 ft. to 2 ft. 3 in. It is made of brickwork and stone. That cornice was nearly level with the floor of the attic. The length of the cornice, extending the whole width of the building, is 99 ft. There is a party wall in the middle. The height of the cornice is 2 ft. 3 in. From the wall to the stone core there are six courses of brick; the stone core is 2 ft. 10 in. in length and 3 in. deep, 2 in. projecting on the inside and 9 in. on the outside. Above the stone core there are 6 in. of brickwork. The last time I was at the premises before the accident was

three or four days ago. I do not recollect how much of the cornice was then up. After the accident, I was on the premises about four in the afternoon, when I saw the cornice and scaffolding had fallen down. I understood about a third of the cornice had fallen. Another third was taken down. The building was erected under my plans and directions, the builders being Messrs. Lawrence. It was expected that the stone core would carry the weight of the brickwork above it, and that the cornice would be perfectly safe. I apprehend the cause of the cornice falling was on account of the "green" state of the work, the cement not having been properly set, and the core not having been braced or shored up in the usual way. It should have been shored up by a raking piece of wood from the wall to the projecting edge of the cornice. I also apprehend the cement was much reduced in quality by the men walking over the cornice. As there was no external ladder connected with the upper part, the workmen went up on the inside and came out over the stone core. There was a plate of iron, placed horizontally, under the cornice, which goes through the stone core. I do not know the dimensions of the bolt. It went to the depth of 1 ft. 9 in. down perpendicularly. There was an iron bolt (fastener) under the top of a stone core. It was a washer and nut, which goes through the stone core. I do not know the dimensions of the bolt. It went to the depth of 1 ft. 9 in. down perpendicularly. There was a plate of iron, placed horizontally, running the whole length of the building over the stone core, and also at the bottom course of the cornice. After the accident, one-third of the cornice was taken down, and one-third fell. If the cement had set, I apprehend the whole would have been safe, and the tie would have acted.

By Mr. Woollett: That portion of the cornice that remains (one-third) is perfectly safe. That confirms the conclusion I have formed, that the cornice was in the green state, and consequently fell. I do not know whether the cornice standing now was done first or last. There is nothing unusual in the size of the cornice.

By Sergeant Atkinson: The part that remains has no brickwork attached to it.

Mr. Edmund Woodthorpe, district surveyor, said: I have seen the work in course of erection, and attended the accident in about one hour. When I saw the cornice five or six days before I did not see the state of it, as I did not go on to the scaffolding. After the accident I found the cornice had fallen, and cut through the putlogs. I cannot give a definite cause of the fall, unless it was carried up green. I have had additional precautions ought to be taken at this time of the year. But I cannot say what should have been done on this occasion. The working men going upon it might have shaken the key of the projecting portion. I do not say that was the cause of the accident. I should not recommend a body of men continually running over the cornice. The Act of Parliament unfortunately gives us no power as to these projections.

By Sergeant Atkinson: The brickwork over the core, had it been carried out according to the first plan, would have been a sufficient counter-balance to the projecting portion. By Mr. Woollett: The part now standing is perfectly secure, and it is very difficult to account for this accident. It is not always customary where there is a core and cement to shore up a cornice.

By a Juror: I saw the iron ties, which appeared substantial. They were 2½ ft. by ¼ in., and bolted occasionally. I should consider them as a substantial character. It is much stronger than many buildings now being erected in my locality.

Several other witnesses were examined.

The jury returned the following verdict:—

"We find that Thomas Pears met with his death from the falling of a portion of the cornice, which cornice, from the insufficiency of the bolts and ties, was not properly secured."

Coroner: You mean that it was an accident?

Foreman: That is what we mean.

The Coroner then made a few remarks, and said that he might suggest to builders that, in such a narrow street as Winchester-street, it would be better to avoid such heavy cornices. An accident of a similar character had occurred in Wood-street some time since.

#### WORCESTER.

Sir,—A few weeks since you were invited to Worcester by the editor of the *Worcester Herald*. Your reply concerning that city is itself quite sufficient to convince me that you have not yet accepted that invitation. It is probable that the prevalence of the small-pox in its latest eruptions may account for your non-appearance. Not through the united efforts of the inhabitants, that fearful malady has almost disappeared. Every one that it cared for, it has mark upon it, has many fallen victims, and that fearful scourge; and if it feels inclined, it may find more victims here next autumn. No investigation has been made into the cause, and no preparation appears likely to be made for its recurrence.

It is especially desirable that you should pay Virginia an early visit, for the following reason:—No one can be more fully aware than yourself that in every city and large town in England, a monster joint-stock hotel has been, or is now being, erected. These hotels are not only remarkable for their size, but for their architectural beauty; for as to come to the present place, the taste of the nineteenth century. One of these is now nearly completed in Worcester; but it resembles the others only in size. Its architecture begs for description. Imagine a smooth brick wall with great number of square holes in it, nearly all one size, and you have the facade. Of course, you do not feel the slightest desire to see the inside of such a monstrous place, and you would do, pray refrain from expecting the interior is not in keeping with the exterior. Do come and see for yourself.

A PASSES BY.

#### THE CLOCK TOWER AT ST. ALBAN'S.

AFTER resisting railways, defying and escaping reform, the venerable little borough of St. Alban's—once all activity, but now rotten,—has now boldly come forward to do something for itself, historically and architecturally. From St. Michael's Mount, in Cornwall, to Berwick-upon-Tweed, commanding the debatable land between England and Scotland, there is not to be found within the Dido-acres it covers a spot of land more rich in what it possesses or more rich in association than the Verulamium of the Romans,—the St. Alban's of ecclesiastical history,—the St. Alban's of the Wars of the Roses. "Who has e'er been to Paris?"—no, not to Paris, as Mat Prier sings, "Who has e'er been to St. Alban's?"—fill of the chronicle-recording monks, Matthew Paris, Thomas Walsingham, and William Rishanger; better still, and the great Lord Chancellor of Science, Sir Francis Bacon, "must needs know John Morgan." No. The clock-tower at St. Alban's, standing hoary with age, filthy through neglect,—defying time, with a clock—defying railway time; and meaninglessly it stands before the visitor who travels un-Murray-handed, or who does not come prepared to see what is to be seen.

Roused at length by the compulsory necessity of doing something, the St. Alban's dignitaries, headed by the Earl of Verulam (the lieutenant of the county) and Mr. Kent (the now mayor), a meeting was called, and a resolution for the restoration of the tower put and carried unanimously.

Before, however, the resolution was put, the following letter from the architect was read:—

"Gentlemen,—I have carefully examined the old clock-tower at St. Alban's, and beg to report the result. The tower seems to have been the old tower helmy, somewhat equivalent to those in the ancient cities of Belgium.

The lower story has evidently been built for a shop, having two fronts with stone benches for the display of goods; the one on the south, the other on the east.

One story over the shop seems to have been in the same occupation with it, and was approached by a separate stair, having also a quadrate or necessary of its own.

It is probable, also, that the use of one or more of the upper stories may have been allowed to the same person, should he have the charge of the bells, though provision is made by a distinct staircase and quadrate for their possible occupation by another party.

The whole is a very curious structure, and unique in this country, so far as my own observation extends. The date is probably about the middle of the fifteenth century, or a little later.

The present state is by no means satisfactory, though quite within the reach of restoration; and I strongly recommend it as well deserving of what it may cost to place it in a sound condition.

The chief object to be aimed at is to avoid over-restoration, and to retain as much as may be the character of an ancient structure.

This is somewhat difficult by the great extent to which decay and mutilation have gone, which necessitates the renewal of very much of the stone dressings. I believe, however, that the original design of them may, in nearly all cases, be recovered.

It should be the object to strengthen the structure wherever it is cracked or become weakened; to restore its architectural features, retaining all ancient portions that can possibly be retained, and reproducing exactly those which are perished. I will not trouble you with details of all this, but will simply state that I estimate the works to cost about £700.

The tower, so restored, will be a very handsome object, and an ornament to the town, recalling a feature in its past history which should by no means be lost. I have no doubt that any case can be found for the restored tower, just as heretofore, as a clock tower, to which chimneys might with advantage be added; secondly, as a helmy for public uses; thirdly, perhaps as a depot for arms of volunteers, &c.

I would not recommend the use of the lower story as a shop, as its difference for modern usage would cause constant desires for alteration, which would be most injurious to its antiquated value.

JAN. 9th, 1864. GEO. GILBERT SCOTT."

After a conference on the letter, and much wise talk, magisterial and architectural, the following resolution was put and carried, with acclamation:—"Resolved, that Mr. Gilbert Scott's plan and report be adopted, and that measures be taken forthwith to obtain the necessary funds to carry out the same."

The resolution carried, the committee commenced their labours, and the following subscriptions were announced:—The Earl of Verulam, 21 l.; W. James Loyd, esq., 10 l. 10s.; Rev. M. R. Southwell, 10 l. 10s.; H. E. C. Staryton, esq., 10 l. 10s.; T. Bagnall, esq., 10 l. 10s.; T. W. Kent, esq., mayor, 5 l. 5s.; H. Parsons, esq., 5 l. 5s.; J. Gulston, esq., 5 l. 5s.; T. W. Blagg, esq., town clerk, 3 l. 5s.

That the committee will get the seven hundred pounds there cannot be a doubt. Hertfordshire, though a small county in the acreage of England, has many landed noblemen and gentlemen in its shire. In addition to those already received, subscriptions are sure to be obtained from rich

residents in Hertfordshire, like the Marquis of Salisbury (from Hatfield), the Earl of Essex (from Bessingbald), Earl Cowper (from Panlunger), Lord Dacre (from the Hoo), Sir Bulwer Lytton (from Knebworth), and Mr. Baker (from Bayfordbury).—

"So thousands more, but I want rhyme and room." Gay. Including, no doubt, the Duke of Marlborough as Baron Sandridge, and the young Duke of St. Alban's, who, strange to say, has not an acre of land in the whole county.

The successful stops just taken for the restoration of the clock tower, had their origin in the following concerted correspondence of four years ago:—

"To the Editor of the St. Alban's Times. Sir,—Passing the clock-tower several times a day, and being a deep interest in the historical associations of the locality, will I trust be accepted as an apology for intruding on your space.

The tower is a substantial ornament to the town, and a point of standing as many centuries as it has already stood. To still improve it, place a neat and strong iron fence round the tower—east and west—to the extent of Mr. Wortons premises, and south sufficiently in front not to interfere with the 'Eleanor Cross.'

Having a gate and tiled path up to the tower doorway; if not gravel, or a side up to the fence.

Then restore, not destroy, one doorway or more up to the first strong course, as the funds will admit.

The manifest improvement would induce ladies and gentlemen to visit the Restoration Fund.

The feeling of St. Alban's is very different in 1861, than when 'the authorities pulled down' the Eleanor Cross in 1222.

Archæologists might wish to have the two foundations of this Cross, now placed in front of the pump, removed where they were taken from, and the exact site of it marked over.

The restoration should be done except under the direction of the 'local architect.'

June 18, 1861. SAMUEL CUNDY."

"Sir,—The clock-tower of your disfranchised borough full of historical and architectural associations. England has not elsewhere anything to show of the kind. The clock-tower of St. Alban's does not belong to St. Alban's; it belongs to a people,—it is national; it belongs to those who utter

Words which wise Bacon and brave Raleigh speak. Its state at present is not even outwardly clean; indeed, it is all but useless.

The masonry of the tower is strong enough to outlive any mayoralties, and if handled with skill and skilled care, may not only be restored to St. Alban's, but to all England.

Let it not be said of St. Alban's, that having destroyed the Eleanor Cross,—that having concurred in the destruction of the house of 'The Great Lord Chancellor 'Human Nature' (as Bishop Warburton called Lord Bacon),—it will now endure a third demolition, and allow a clock-tower of so far famed a borough as St. Alban's to share the fate of its Eleanor Cross.

The high court of Parliament (whether properly or not at the present moment) has destroyed some of the many charms of St. Alban's. Let not St. Alban's lose all its associations; and by so doing drive visitors away.

Let an ready to find an accomplished architect who will restore your clock-tower to what it was, without drawing the cup of ruin from your borough, but by the aid give the corporation through the hands of its active and intelligent mayor.

June 18, 1861. PETER CUMINGHAM."

"The fine old curfew bell of the St. Alban's clock-tower is inscribed with the words 'De Passi Celis Hæc Nonen Gabrielis.' Men and women still alive remember its tolling 'the bell of parting day' at curfew time, with a welcome and pleasant sound. It will soon resume its labours in Mr. Scott's restored and appropriate architectural casing.

THE CEILING OF HER MAJESTY'S THEATRE.

At a recent discussion at a public meeting on the subject of Theatres, a suggestion was made by Mr. J. W. Papworth that some one should ascertain whether the ceiling of Her Majesty's Theatre is really a wooden one, or is plastered over. As nearly the whole of the decorations of the ceiling, as well as many other parts of the house, were re-painted by us (Green & Co.) two years ago, I am in a position to state that the ceiling consists entirely of thin boards nailed to the framing; and that these are again covered by stent canvas, on which are painted the decorations. The same remarks apply to other portions of the auditorium, the box seats being lined on both sides. I cordially concur in mainly attributing the wonderful acoustic properties of Her Majesty's Theatre to this fact; and I may mention that the ceiling of Exeter Hall is treated on precisely the same principle, and with nearly equal success. With regard to a question mooted by Mr. Papworth, as to whether the effect at Her Majesty's might be owing to the pigeon-holes and draperies,—

the acoustic quality of a building appears to me to depend on a proper balance of its resonant and absorbent capacities. In Her Majesty's, when empty and denuded of all draperies, there is a thorough echo; and even when fully draped, if at the same time free from the covering cloths, the resonance at a rehearsal is unpleasantly marked. The same thing occurs at Exeter Hall. Human beings, and draperies, in a resonant building, seem to have the quality of simply absorbing the excess of sound, while projections and ornaments in relief confuse and destroy it. JAMES GREEN.

Baker-street.

RECREATION FOR WORKING MEN'S CLUBS.

Sir,—As perhaps there is no paper in which the interests of the working men are more fully discussed than in the Builder, will any of your readers do me the great favour of furnishing a list of sports, round games, or any contrivance which will promote mirth, or where strength of muscle and skill are required?

As almost every county has its own particular amusements, I shall feel exceedingly obliged for any suggestions, however poor or simple; and, if desired, I shall feel a pleasure in forwarding either sketches or a list of those we find most successful.

I would not thus trouble you, but my apology must be, that we hope by the experiment to keep up our reading, drawing, and music classes, but more particularly to gain the interest of those for whom the club is established.

A MEMBER OF THE WORKING MEN'S CLUB, DATCHET, BUCKS.

P.S.—Perhaps some gentleman can kindly recommend a book containing an account of "Old English Games and Pastimes."

LABOURERS' COTTAGES.

Sir,—There is much merit due to Mr. Birch for his design for a labourer's cottage; but there are a few suggestions, from experience, that I should wish to point out.

In the first place, it is desirable, if possible, to avoid a direct communication between the sitting-room and scullery. The fire-places should be built in a position to prevent smoking. An oven should be attached to each cottage, either as forming part of the grate, with a small boiler, or an oven built detached. A dining-room, to be convenient, should not be less than 14 ft. by 12 ft., or even 14 ft. by 14 ft.; scullery about 12 ft. by 9 ft. or 10 ft. The height of the rooms on the ground-floor should be 8 ft. Each chamber should have a small fire-place for ventilation. The height of the rooms should be 7 ft. to the wall-plate and 9 ft. to ceiling or collars. W.

\* \* \* The design in question was controlled by a limited sum: and the question is if even that would not be exceeded in carrying it out.

"INSTRUCTIONS TO ARCHITECTS."

Sir,—It appears almost impossible to put an end to the liberties which are taken with the members of the architectural profession; and your correspondents may I fear, write in vain, so long at least as we find one member of our profession a party to the following "instructions to architects," issued by the Cheltenham Boarding-houses Company (Limited). The following are quotations from the "instructions":—

"Commission, &c.—The architect whose plans are selected will probably be employed to carry out his design; but the directors do not pledge themselves to this. Should the architect whose plans are selected be employed, the premium of 50l. will merge in his commission. The plans for which the premium is awarded to be the property of the directors."

May not I and others fairly ask,—1st. Why these "instructions" are framed in such a tone? 2nd. Who are to be the judges of the fitness of any plans offered to these directors, and of the ability of their authors to direct the works contemplated by them? 3rd. Why any body of directors, with a professional man amongst them, ventures to offer such terms to the profession as they would propose to artists who prepare drawings for sale? AN ARCHITECT.

COPPER VESSELS.

Sir,—It being requisite in my vocation to make use of copper vessels or utensils, these, as every one of course is aware, become furred or incrustated if water is boiled in them. What I wish to enquire is the course that should be taken to prevent this incrustation or deposit taking place, or even adhering so very tenaciously to the bottom and sides of the utensil; and again, how to remove it with facility and quickness without in any way injuring the copper when it is already formed? INQUIRER.

SOME QUERIES RESPECTING THE NUMBERING OF LONDON HOUSES.

In a recent number of the Builder there appeared a most interesting letter, purporting to be from a wood-carver, written during the building of St. Paul's Cathedral. It is stated that the document, which has been printed, is in the library of the British Museum. I for one would be glad to have an opportunity of inspecting the original. It would, therefore, be doing a service if you could obtain the mark by which the letter can be found in the library.

You do not vouch for the genuineness of the carver's letter; that, however, might be easily decided by an inspection of the paper; but, without doing this, there is a matter which throws further doubt upon the truthfulness of this document; or, if this paper should be found to be authentic, would give it a rare interest. I refer to the circumstance of the number of the house in which the carver lived in Ivy-lane being distinctly given. Are there any authentic accounts of the numbering of the houses in London at the time of the rebuilding of St. Paul's? Any particulars respecting the general introduction of numbers on the houses of the metropolis would have great interest. In the time of Dr. Johnson the address of letter-writers seems to have been given as over against some well-known tradesman's sign; but, without going further into this matter, I will venture to ask the following questions, in the hope that some of your readers may feel disposed to throw light upon the subject, the introduction of street numbering being rather an obscure one:—

1. Are there any other letters in existence which profess to be of as old a date as that of the carver's, on which the numbers of houses are given?

2. Are there any such letters to be found of the date of Dr. Johnson's and Oliver Goldsmith's times?

3. At what time do we find the use of house-numbering commencing? Is it known in what part of London this took place? Are there instances of this plan being introduced in any provincial town sooner than in the metropolis? and, is there any note of the name of the person who introduced this system?

At a date which I cannot give, having not just now the means of reference, the numbering of houses, together with some other metropolitan improvements, was enforced by an Act of Parliament; but, for some time after, the plan seems to have been very imperfectly carried out; and, although there has been considerable improvement made during the last few years, there still remains a great deal to be done, especially in the suburban and outlying streets.

It is difficult at the present day to imagine what would be the state of things in the metropolis but for the systematic numbering of houses. The tax-gatherer would be sorely bothered; cabmen would be almost unable to ply their trade; and the present plan of penny-postage and parcels delivery would have been impossible.

AN ANTIQUARY.

HIGHFIELD SCHOOLS, HUDDERSFIELD.

The new schools in connexion with Highfield (Independent) chapel, are nearly completed. On the ground-floor are the assembly-room, 76 ft. by 32 ft.; the lecture-room, 42 ft. by 28 ft.; and the infants' class-room. Between the assembly-room and the lecture-room is the principal staircase (of stone), with main entrance from the street, and this conducts to the class-rooms—twenty-one in number—and to the ladies' room and library. These rooms extend over the assembly-room and lecture-room, the latter having two stories above it. Those over the former are arranged in a double series with corridors between (vertically lighted), and in both cases are separated by lath-and-plaster trussed timber partitions. They vary in size, the greater number being about 14 ft. by 12 ft., and some are 22 ft. by 14 ft. All have external windows and a few have fireplaces, and all are boarded 4 ft. high, and have fixed seats against each side. In the assembly-room a gallery has been constructed, 4 ft. wide at the sides, and 24 ft. deep at the lower end of the room. All the arrangements are adapted to a division of the sexes throughout. Underneath the end gallery of the assembly-room, is a class-room for 150 infants, semicircular in plan, and having raised seats arranged in the form of an amphitheatre. This room averages 14 ft. in height. The lecture-

room will seat 200 adults, and is 16 ft. high. Beneath the lecture-room are chambers for preparing tea for tea meetings, &c. The ladies' room is the "drawing-room" of the building. It is placed immediately over the lecture-room, and is 28 ft. by 16 ft. The windows are on two sides and command a view of the New North-road. Adjoining the ladies' room is the library. Every apartment is warmed and ventilated. The system adopted is that of Messrs. Haden, of Trowbridge and Manchester, which in this case is a combination of hot water and warm air, and is the same in principle as has been successfully adopted in the Manchester Assize Courts, the reading-room of the British Museum, and nearly all the prisons and asylums in the kingdom.

The style of the structure is Italian. The exterior is of local stone throughout. The parts are all simple.

The contractors of the various works are all Huddersfield tradesmen, viz.—A. Graham, mason; Goodwin & Son, slaters; R. Whiteley, carpenter and joiner; W. H. Chadwick, plumber and glazier; W. Henthwaite, painter; I. Jowitz, plasterer (who has also acted as clerk of works gratuitously).

The cost of the entire undertaking, exclusive of land, which is freehold, is expected to be about 3,500l.

#### FOREIGN AND ACCIDENTAL.

*Moderate.*—According to the *Independence Belge*, of the 14th inst., the works of the New Opera House have been interrupted by an incident. It has been discovered that a corner of the Grande Hôtel, on the Boulevard des Capucines, will mask the facade of the new building. Overtures have been made to the proprietor of the hotel, which is known to be in the hands of M. Pereira, with a view of removing the offensive portion of the pile of building in the way, and he has demanded no less a sum than twenty-four million francs.

*St. Maclou, Rouen.*—Considerable damage was done to the Église St. Maclou, at Rouen, during the storm of the night of the 13th inst.: two bays (each 33 ft. high) of one of the high windows of the lantern of the steeple fell with a dreadful crash, carrying in their fall the stones of a massive cornice: they fell into the nave, breaking the grille of the choir and a seat: one of the stones, striking the head of one of the sculptured angels, was thrown against a lustre, which it demolished.

*Iron and Water.*—At the iron-works of M. Revollar (in the Loire), an accident took place, by which one of the men nearly lost his life. Wishing to cool a considerable mass of scoria just taken from the fire, he threw some water over them without taking the usual precaution to prevent the water getting under the mass. The consequence was the explosion of the generated steam underneath, and the dispersion of the burning mass over the man.

*The Mont Cenis Pass.*—The works are still progressing for the temporary railway which is to enable the Mont Cenis to be traversed in four hours only. For the Italian side of the mountain, on which the descent is more rapid, the rope system of the engineer, Agudio, is to be adopted, on condition that the Italian Government grant a subsidy of a million and a half francs (60,000l. sterling) for the expenses of the construction of a special direct roadway. Though the Government may be ill disposed to saddle the budget with this sum, yet it is thought that it may do so out of compassion to the town of Turin, which would then be the principal entrance from France into Italy, in a commercial point of view.

#### IRELAND.

The foundation-stone of the Cathedral of St. Fin Barr, in the city of Cork, was laid on Thursday, the 12th inst., by the Lord Bishop of Cork, attended by several members of the Masonic body, the Dean, and Chapter. Some time since a view and description were given, in this journal, of the approved design, selected from a large number submitted in competition, the author of which proved to be Mr. W. Burgess. It will be sufficient to say at present, that the design will be carried out in its main features, but that the proposed outlay has considerably swelled in amount, the belief being general that 30,000l. not 15,000l., as originally intended, will be the ultimate expenditure. Mr. Robert Walker is the contractor. This new building will re-

place an unsightly old structure, wholly unworthy of the city of Cork, of the age, and of the sacred purpose to which it was dedicated. But around and about it hang interesting relics of antiquarian lore. There is every reason to expect that the new pile will prove worthy of the city, which, at least by its own inhabitants, is called beautiful.

The parish church of St. Peter, situate in what is considered the most fashionable parish of the city of Dublin, is about to be restored, we might more properly say rebuilt,—from the plans, and under the supervision of Mr. E. H. Carson, architect. The old building, of which but little will remain, is a harm-lice edifice, not requiring preservation. The proposed works comprise an extended chancel, with choir, vestry, robing-room, with heating chamber below; transepts, these latter provided with galleries; and a handsome tower, with angustian case building. It is not intended to carry out the spire yet, but when funds have been collected, one will be added. The entire of the seating will be formed with open benches, with plain bench-ends. A reredos and a pulpit, both in Bath stone, will be erected in the chancel. The lectern will be in red timber: the entire cost will be about 4,000l.

A correspondent from Dublin comments on the doings of builders, who act in the double capacity of architect and builder:—

"These," he says, "obtaining a job, or securing a client, whichever you like, doubtless tell their employers that they 'need no architect'—it is better to leave the arrangement of all such matters as planning, design, specifying, &c. to them. There is evidently some remedy required here; the question arises and ought to be easy of settlement, who the builders who act in such manner, to the detriment of public taste and to the prejudice of architects, should be disqualified for tendering for the execution of any work with which an architect is entrusted. The practice alluded to is one that deserves suppression let the individual that practices be ever so trustworthy."

#### METROPOLITAN BOARD OF WORKS.

##### METROPOLITAN IMPROVEMENTS.

At the last week's meeting of the Board, a report was brought up from the Works and Improvements Committee, recommending that the Board do contribute 3,030l., being one-half of the cost of a further improvement to be carried out by the Commissioners of Sewers of the City of London in connexion with the widening of Newgate-street, by setting back the houses Nos. 71 and 72, as shown on the plan submitted to the committee, at a cost of 6,060l., independent of professional charges. The report, after some discussion, was adopted.

The following contributions to improvements were also sanctioned—1,500l., being one-half of the cost of an improvement in connexion with the widening of Leadenhall-street and St. Mary Axe, at a cost of 1,000l.—2,616l. 10s., being one-half of the cost of the improvement carried out by the Limehouse District Board of Works, by setting back the premises Nos. 98, 99, and 100, and the removal of a projection at Eagle Wharf, High-street, Wapping, at a cost of 1,233l.—3,100l. towards the cost of setting back the premises No. 29, Queen's-road West, Chelsea, estimated at 200l.

#### DRAINAGE AND WATER SUPPLY.

*Tamworth.*—The Town Council are taking measures for the drainage and water supply of the borough, and 57 owners, ratepayers, and occupiers of property memorialised them to the effect that the present Nuisance Removal Act, if strictly enforced, would suffice for the public health without wasting the public money on such needless and unnecessary schemes as those contemplated. The memorial was rejected on a point of form, and a public meeting was held, at which a resolution was unanimously passed agreeing to a memorial to Sir Robert Peel, requesting his intercession in the matter. A resolution was also passed requesting the Town Council to open their meetings to the public.

*Graham.*—The local Board of Health have proposed to the hamlets of Spittlegate and Little Gonerby to take combined action for the removal of the sewage from the river Witham, by obtaining a common outlet, each parish retaining the management of its own sewers. Meetings have accordingly been held, and there is a prospect of carrying out the object in view. Spittlegate has already offered 400l. towards the expense, Graham disposing of the sewage, and making a profit of it if it can.

*Chalmersford.*—An offer for the sewage has been made by Mr. F. Marriage, of Barnes Farm, Springfield, paying a rent of 30l. for it after the first two years, under certain conditions. The local Board of Health have decided to accept of the proposal, also conditionally; and the matter has been left for further arrangement to their sanitary committee.

#### Books Received.

*Memorials of the late Francis Oliver Finch, Member of the Society of Painters in Water Colours, with Selections from his Writings.* London: Longman, Green, & Co. 1865.

As a solace in her bereavement and at the request of many of her friends, the widow of the late Mr. F. O. Finch has provided them with an acceptable remembrance in compiling these selections from his writings, with written opinions of him by others, and adding an admirably-words little memoir of his career, which, with no extraordinary events to chronicle, is both pleasant and instructive to read. No biographer could he preferred to one who must so thoroughly have sympathized with him in all his relations; and although there are, doubtless, many as affectionate wives equally desirous of securing general recognition of their own well-established convictions, few could have invested the simple record of an earnest, well-spent life with so much graceful tenderness, and rendered interesting an account of every-day experiences that differ so little from the common lot, only varying, in their effect of making those they act upon good, bad, or indifferent, wise or unwise, just as their lesson may be heeded or disregarded.

In this case they are proved to have afforded opportunities enough for enunciating the better qualities with which our nature is endowed, and Mr. Finch must have merited the high estimation in which he was held by so many for rectitude of purpose and kindness of disposition. One of the best purposes of biography is fulfilled when it inculcates the doctrine that even the humblest have a sphere of action and an equal opportunity of doing right or wrong as the greater; and that if it is possible for all to do a great amount of good if the desire be only proportionate to the capability. Indeed, there may be far more probability of deriving benefit and encouragement from the story that includes but the results of industry, conscientiousness, patience and amiability to make an existence valuable,—throughout which duty has been the paramount consideration, and regard for others more conspicuous than selfishness,—than from the history of heroes, military or civil, whose very eminence as exemplars leaves such an impression as would forbid all idea of emulation in some minds that would be more easily influenced by the direct example of how to make serviceable less rare possessions than art indispensable to the performance of brilliant exploits or other triumphs of exceptional genius.

As an artist Mr. F. O. Finch will be most regretted by those who appreciate those true principles that actuate the painter to become something more than a mechanical imitator of common-place fact; his organization was essentially artistic; his pictures bore evidence of how much he loved music and poetry, and how his refined taste had assisted to leave him almost singular at last at a period when the selective and ideal are so much ignored as to be recollected now in distinction between the older and new schools. Still his name will be remembered chiefly in connexion with his associates,—John Varley, Barret, David Cox, Copley Fielding, De Wint, and the rest,—for owing probably to his occupation of teaching, which absorbed much of his time and attention, he was prevented in great measure from attaining that position his classic feeling and homage for all excellence, with the ability he possessed of expressing his ideas, might have seemed to promise for him.

#### VARIORUM.

"RAILWAYS: A Plan of Systematic Reform by Legislative Enactment. London: Longman & Co. 1865." The author of this volume is anonymous, except as "the Author of 'The People's Blue Book.'" He here addresses the President of the Board of Trade in the form of a letter, in which he mainly urges a tariff reform analogous to the Penny Postage system, to be brought

but by legislative enactment. Cheap passenger transit, he maintains, would be beneficial to the public and to the companies. He advocates, as has been done in the latter years, the erection of working-class dwellings, model or otherwise, in the urban districts, with cheap facilities of access by the railways. On the subject of cheap fares, the author says, "The railway companies may depend upon it that they will find it more for their own interests in the long run to look for their profits in a low mileage rate and a large number of passengers rather than from a high mileage rate and a small number of passengers;" and so they would. The principle is identical with that upon which the gas companies now so generally act, after it had been forced into their unwilling heads by the *Builder*, whom they long looked upon as their latest enemy, whereas it has turned out to be their friend, no less than the public's, so far as gaslight is concerned.—"Railways, their present-way and Rolling Stock. By W. Adams." This is a reprint from the *Journal of the Society of Arts* of 2nd December. It contains some important suggestions as to the improvement of locomotives. We wish Mr. Adams could bring about some improvement in the hideous and dreadful screechings by night of railway luggage-trains, before the further extension of railways throughout the metropolis. A sleep of thousands is already murdered by these far more diabolical than anything heard of on railways by day; and, although a howling (or a crowing fowl) can be put down as a nuisance, here is a monster nuisance which, instead of being put down, is growing worse and worse, and is really most shameful and intolerable. The more central metropolitans are as yet blessed ignorance of the purgatory which is awaiting for them.—"Observations and Evidence on the Value of Sewage Manure. Mr. J. Kirkman's Tender." The intention of this pamphlet is to establish the advantages of the liquid system. Mr. Kirkman has obtained the sewerage for ten years. He gives the population 5001. for the first five years, and 6,000 a year for the last five years. The cost of the machinery, coals, and deodorizers, and the delivery of the sewage to him as he requires it, is £1,000 to the metropolitan sewage, he says.—"An estimate of the solid refuse from the flow of sewerage at 536 tons per day, which, at one shilling per ton, is £536. per annum; it has been estimated at a much lower rate by men of science, viz., 1,000 tons per day; Professor Volcker has said that the dry deposit of sewage is worth 6s. per ton, or 2,150,000l. per annum. If it could realize so much to me, the Board would get by selling the terms I offer, 430,000l. per annum for the next seven years. I offer to guarantee only 10,000l. as a maximum, because I do not see my way clear to the larger sum." Mr. Kirkman petitions Parliament for a continuance on his system, and on the sewage question generally.

Miscellaneous.

WORKS FOR INDIA.—On the 20th of this month, a quantity of Little Casterton freestone was loaded for India, by the *Tweed*, sailing for Bombay.

THE INTERNATIONAL EXHIBITION MOVEMENT IN INDIA.—Bombay has determined upon having an International Exhibition, and a company has already been formed with a capital of 500,000l., to order to carry out the project.

MONUMENTAL.—It has been determined to erect a monument in remembrance of the late William Speke, the discoverer of the great Equatorial lake of Africa, the Victoria Nyanza, who, in his gallant companion Grant, followed its waters to the mouth of the Nile. The Geographical Society of Paris have contributed ten guineas towards the fund.

THE CITY ARCHITECT'S OFFICE.—Mr. Charles Barry has been elected chief clerk in the architect's office, in the room of Mr. Allen, who has resigned that office. There were originally five candidates, namely, Messrs. Baily, Baker, Eastlake, Strudwick, and James. Mr. Eastlake, however, withdrew prior to the election, and, as the final result, Mr. Baily and Mr. Baker were the two candidates submitted to the Court for its decision. The former was elected by a majority of 10 only; the numbers being, Baily, 55; Baker, 54.

STEAM OMNIBUSES.—An omnibus drawn by a locomotive, instead of horses, is now running at Clontarf, in the south of France. It can be turned and stopped with ease, and both inside and outside passengers travel by it without fear.

THE JOHN WEST METER MANUFACTORY.—It will be seen in another column that this flourishing concern is to be carried on hereafter by a limited liability company. The tendency seems to be to hand over every undertaking of any magnitude to a "limited" Company.

CRISIS IN THE TIMBER TRADE.—The crisis which was first felt in Birmingham, and which has affected various parts of the country, has touched Liverpool with a heavy hand, the failures during the last month having amounted to nearly half a million of money. The dividends vary in amount from 6s. 8d. to 15s.

STAINED-GLASS WINDOW, COBRIDGE CHURCH, STAFFORDSHIRE.—We are informed that the window recently put up in this church by Messrs. Cox & Son was executed on their own premises by their own people, and that "no French artist had anything to do with it." We may add that we saw the cartoons, made for the execution of the window, and were much pleased with them.

A TURRET CLOCK FOR ST. PATRICK'S CATHEDRAL, DUBLIN.—There is now erecting in St. Patrick's Cathedral, Dublin, a turret-clock (presented by Mr. Guinness), showing time on two dials, each 8 ft. in diameter, and striking the hours on a bell of 36 cwt. and chiming four times in twenty-four hours. Mr. J. W. Benson, of Ludgate-hill, London, is the maker of the clock.

NEEDLES AND PINS POINTED BY GALVANISM. M. Caudey, of Lausanne, engineer, has applied the galvanic battery to the sharpening of needles and pins, by connecting a bundle of wires with the negative pole. The process is said to be cheaper than the present method, which is also very injurious to the health of the workpeople, in consequence of the fine metallic dust disengaged.

POPULAR UNION.—The guardians having decided to enlarge the workhouse, have arranged to obtain additional ground of the East and West India Dock Company, in the rear of the present house, to enable them to erect buildings to accommodate 1,000 inmates, exclusive of infirmary, fever and infantic wards, and have appointed Mr. W. Dohson and Mr. J. W. Morris, the architects, to prepare designs and superintend the works.

PHOTOGRAPHY IN NATURAL COLOURS.—The *Cemeus*, a newspaper published at Port Louis, Mauritius, contains the following extraordinary announcement, according to *Galignani*:—"M. Chambay has succeeded in fixing the colours of the object. The picture is taken instantaneously, as in other kinds of photography. The modelling and relief are marvellous: the blood appears to circulate beneath the skin; the colour is fixed; and the portraits, which present a surprising resemblance, are equal to the finest pastels, miniature, or water-colour drawings. M. Chambay is about to remove to Paris."

WANDSWORTH WORKING CLASSES INDUSTRIAL EXHIBITION.—An Exhibition organized by the Wandsworth Working Men's Club is to be opened on the 2nd of June. Persons eligible as exhibitors must live within the radius of three miles from Wandsworth, and belong to the working classes. Prizes for skill in design or execution will be awarded to—1. Producers of articles calculated to promote domestic, sanitary, and social advantages. 2. Producers of useful, artistic, scientific, and ingenious designs, works, models, &c. There will be two classes,—one for mechanics and artisans; the other for the unskilled and self-taught.

INSPECTION OF NEW STREETS IN THE METROPOLIS.—The Metropolitan Board of Works having directed Mr. Hart, one of their officers in the superintending architect's department, to inspect the new streets formed from time to time under their sanction, 313 new streets have come under his view. In general, it was found that the regulations of the Board have been faithfully carried out. A few exceptions have been observed: They consist chiefly in ignoring the condition requiring narrow streets or footways to be flagged over the entire surface, and the omission of posts at the entrance. The Board has given orders for enforcing their regulations in cases where they have been violated.

THE RAILWAY DEPOSITS.—The Parliamentary deposits this year on account of new railway projects have amounted to 4,272,010l., of which 189,235l. was in cash, 258,500l. in Exchange Bills, and 3,824,275l. in stock. This total is 2,050,879l. less than that of last year.

RAILWAY RETURNS.—The traffic receipts of railways in the United Kingdom amounted for the week ending the 14th of January, on 11,786 miles, to 570,570l., and for the corresponding week of last year, on 11,460 miles, to 540,471l., showing an increase of 326 miles, and of 30,099l. in the receipts.

SALE OF CORDIER'S SCULPTURES IN PARIS.—A great sale has attracted the notabilities of the artistic world to the *Hôtel Drouot*. It comprises all the sculptures of Cordier, as well as his museum of curiosities, collected during his travels in Algeria and the East. Cordier's statues reproduce the Moorish, Arab, and Chinese types. They took the world of art by surprise when first exhibited.

"STEAM SUPERSEDED."—The model of a new electro-magnetic locomotive is now exhibiting at Versailles. Its inventors, MM. Bellet & Rouvre, assert that locomotives constructed on their principle could travel on ordinary railroads at the rate of 124 miles an hour! The power is obtained by magnetising and de-magnetising by means of a current supplied by a fixed battery; and, it is said, only a small part of the force developed is thus utilized.

THE GRANITE FOR THE ALBERT MEMORIAL.—The blocks of granite intended for the base and pedestal of the memorial of the late Prince Consort are about to be polished at the works of Mr. Kelk, the contractor. The granite comes from the quarries of the Scottish Granite Company, in the Isle of Mull. We are informed that several of the lighthouses on the west coast of Scotland which have stood well are constructed of this granite, and that it has been used in the building of the Liverpool Docks, the harbour at Greenock, in the foundations at Westminster Bridge, and the Thames Embankment.

THE FALL OF THE CHIMNEY IN SHOOLANE.—Mr. Vulliamy, superintending architect to the Metropolitan Board of Works, having been directed to inquire into the nature and circumstances of the fall of the chimney belonging to Messrs. Pontifex, in Shoolane, has made a report, in which he states that Mr. Parkinson, the district surveyor for the western division of the City, reports that the chimney in question was built about thirty-five years ago, and that about twenty-five years ago, it was raised to the height of about 120 ft., at which height it stood at the time of the accident. The force of the wind during the late gale, acting directly upon the sides of the shaft, which was square upon plan, was sufficient to snap off the shaft immediately above the roof of the building in which it was situated, leaving about 20 ft. of the shaft still standing. The portion which fell in its course struck a smaller furnace-shaft of about 80 ft. high, which, not being able to resist the blow, also gave way, and the two then fell upon the roof of No. 23, Plumtree-court, a building let in tenements, crushing in the roof and floors of the building, and leaving the northern half nearly ruined. The Board has referred the whole matter to the Building Act Committee.

SANITARY MATTERS.—A Hasty correspondent of the *York Herald* says,—“During the last three years we have had as visitors the small-pox, low fever, and typhus, and at the time I write the scarlet fever is present in many houses, and has been for some time. The cause has been hinked long enough, viz., the defective state of its drainage, which is really a conserve of stenches.”—The *Norfolk Chronicle* says of the Fleggs, at Yarmouth,—“From time to time we have reported meetings in which reference was made to the unhealthy state of several of the parishes in the Fleggs, and have inserted letters which have drawn public attention to the progress of disease in those localities. The defective drainage in the districts pointed out has long been notorious, but Mr. Waller's brief but truly appalling statement at the Balesby meeting, on Tuesday, must convince the most indifferent that if speedy measures be not taken in order to remedy the evils which have so frequently complained of, the result will be an increase in the rate of mortality upon that of last summer, when by diphtheria, small-pox, fever, and other contagious disorders spread havoc and dismay throughout the infected places.”

**PNEUMATIC DESPATCH.**—The report of the directors of the Pneumatic Despatch Company to the shareholders explains the difficulties with which the directors have had to contend in obtaining possession of required property, and states that all obstacles have now been removed, and that there now only remain 5-8ths of a mile of tube to be laid in order to complete the communication between the General Post-office and Euston-square.

**ANCIENT GREEK STATUES DISCOVERED IN CANDIA.**—In digging for the foundation of a mosque near the village of Hieropetros, on the site of some ancient ruins, three ancient statues have been found. One appears to be the colossal statue of a warrior, unfinished, but of excellent workmanship. The second seems to be Oceanus, with a small stag crouching at her feet. The third is a male figure; but at present it does not appear whom it represents. The figures are considered to be, in all probability, of Greek workmanship.

**THE COAL-TAR COLOURS.**—The trade in the coal-tar dyes, which began in 1860, continues to expand, amounting probably at present to from a quarter to half a million annually. The colours are, magenta, various shades of blue and violet, purple, yellow, orange, and green. The dyes are sent from London to Lancashire and Yorkshire, and various other places, to be used in the preparation of silk and cotton velvets, printed calicoes, delaines, merinos, finished cottons, silks, ribbons, flannels, and fancy and flannel shirtings. An export trade is beginning to China and the United States, the dyes being sent in their solid form to save freight. It is said that several thousand pounds are annually spent in defending the patent.

**LINCOLN ARCHITECTURAL SOCIETY.**—The first meeting of the committee of the Lincoln Diocesan Architectural Society was held at the office on the 6th instant. An account of the progress made in the restoration of St. Mary's Church, at Stow, was read, whence it appeared that that interesting work was progressing satisfactorily. Great regret was expressed by the members of the committee that the cathedral pulpit, which had been so long in hand, will not be finished in the early spring of this year, as was expected. The various first-class artists employed, it appears, require four or five months more to complete their labours upon the sculptured panel subjects, the canopy work, the iron work, and, above all, on the numerous statuettes of apostles and evangelists with which the pulpit will be adorned. Of the statuettes, we understand that about half are presented by societies or distinguished persons connected with the diocese, among whom are Mr. Alfred Tennyson (the Poet Laureate), Professor Conington, Mr. Anthony Trollope, Chancellor Massingberd, Mr. Lewis Fytche, the Rev. W. Smyth, the Lincoln Diocesan Architectural Society, the Yorkshire Architectural Society, &c. These statuettes are ten in number, and each will bear the name of the donor. They will represent Apostles and the Evangelists, &c., to be carved by the best wood-carvers that can be found.

**FALL OF A NEW WAREHOUSE AT SHADTHAMES.**—At Butler's Wharf, on the south side of the river below London Bridge, a new block of buildings, only very recently completed, and upwards of 100 ft. in height, 140 ft. in width, about 70 ft. in depth, containing four floors, with iron girders and supporters, and fire-proof throughout, gave way, and the entire front of the building fell into the river. Happily there was no one in the building at the time of the occurrence. As to the cause of the accident, it is stated that a large quantity of rice had been recently stored in the third floor, but whether the iron ties had given way, or the brickwork was insufficiently set, does not appear. Owing to the influx of business, the firm were compelled to warehouse cargoes of vessels before the building was actually completed. Indeed, there were masons and bricklayers still engaged on it at the time of the accident. A loud cracking was heard in the river frontage wall, and on the men looking upwards they saw the floors bulging downwards, and succeeded in getting into the street, when the whole fabric fronting the river fell into the water, bringing with it several thousand bags of rice. The land side of the structure remains entire. The excessive weight on the raw structure, no doubt, caused it to give way.

**A NEW ENGINEERING AND REVOLVING SHUTTER MANUFACTURING COMPANY, LIMITED.**—The well-known firm, Messrs. Bunnett & Co., have transferred their business, as "manufacturing engineers, founders, smiths and machinists, manufacturers and patentees of revolving shutters, drawn brass and cast-iron shop-fronts, lifts, and hoists," to a new limited company, under the same title. The capital of the Company is 30,000*l.*, divided into 500 shares of 60*l.* each, 150 being preference shares, and 350 ordinary shares. The shares have all been taken amongst the families and connexions of the old firm, and the new company are building new factories, and greatly adding to their machinery.

**PUBLIC WORKS AT STOCKPORT.**—According to a return prepared by the borough surveyor, it appears that 21,411*l.*, has been expended in the execution of public works in that town. The average daily number of skilled and unskilled labourers employed has been 250, and out of this number only an average of twelve were skilled, the remainder being, with very few exceptions, cotton operatives. The average earnings of the skilled men were 3*s.* 10*d.* per day, and of the unskilled 2*s.* 2*d.* per day.

**Gas.**—The Ipswich gas company have reduced the price of their gas from 4*s.* to 3*s.* 9*d.*—The Nottingham gas company have reduced the price of theirs from 3*s.* 2*d.* to 3*s.*, and farther to large consumers in proportion. The company have seen it to be for their own interest to do so, as they have had no pressure from without. After such reductions as those at Ipswich, Nottingham, Plymouth, &c., what can the metropolitan companies say in defence of their present charges?

**BUILDING IN BIRKENHEAD.**—At a recent meeting of the Health Committee of the Birkenhead commissioners, Mr. Mott submitted the following returns of the number of buildings and alterations to buildings within the townships of Birkenhead and Clanghton-cum-Grange, for the ten years ending the 31st December, 1864, according to the notices given to the building surveyor:—

Years.	Places of Worship, Schools, and Public Buildings.	Dwelling-Houses and Shops.	Cottages.	Offices, Workshops, and Alterations.	Total.
1855	3	41	26	13	83

Average per annum	2.3	65.9	240.9	49.2	376.8
Increase in year above average of ten years	1.2	20.1	...	11.8	...
Decrease	...	...	83.9	...	50.8

The total extent of passage and court flagging which has been done by the commissioners (at the cost of the owners) during the past year, amounts to 1,680 square yards, or 1,066 lineal yards. The total extent of private drainage also done by the commissioners at the cost of the owners is 508 lineal yards of 9-in. pipe drain, and 340 lineal yards of 6-in. pipe drain; the drainage of ninety-one hack-yards, seventy ash-pits, and ten water-closets being connected therewith; the whole of this work involving an outlay of 822*l.*

**TENDERS.**

For building chemical works at Hackney Wick, for Messrs. Simpson, Maule, and Nicholson. Mr. Cooper, architect:—

Dalby	28,400 0 0
Hack & Sons	7,967 0 0
Sawyer	7,633 0 0
Henshaw	7,323 0 0

For the erection of a parsonage-house and offices, at Berwick Bassett, Wilts, for the Rev. E. J. Vicary. Mr. Weaver, architect:—

Barnden (accepted)	1,130 0 0
--------------------	-----------

For alterations to the Barclay Mow public house, No. 59, Long-lane, West Smithfield, for Mr. Robins. Mr. C. Foster, architect:—

Ballard	2440 0 0
Terry	345 0 0
Sinclair	301 8 0
Smith	273 10 0
Davey	272 5 0
Barker	267 0 0
Palmer	267 0 0
Gadsby	227 0 0

For alterations and additions, conservatory, &c. to East Hill House, Frome, Somerset, for Mr. H. C. Lopes. Mr. Weaver, architect:—

Barnden	1,007 0 0
F. & G. Brown (accepted)	1,084 10 0
May	996 0 0

For additions and alterations to dwelling-house at Streatham, for Mr. J. J. Frost. Messrs. George & Vaughan, architects:—

Mason (accepted)	1,761 0 0
------------------	-----------

For building an intended public-house, for Mr. Richards, at Leytonston, Essex. Mr. John M. Dean, architect:—

Ricci	2613 0 0
Hick	690 0 0
Harris (accepted)	585 0 0
Arber	535 0 0

For building fire houses and shop, for Mr. George Park, in Fox-street, Hallsville, West Ham. Mr. John M. Dean, architect:—

Cordery	2845 0 0
Hick	890 0 0
James	792 0 0
Hovell	750 0 0
Holmes	720 0 0
Heritage (accepted)	723 0 0
Fernie	720 0 0

For the erection of a new bank, at Basingstoke, for the London and County Bank. Mr. F. Chaceolour, architect:—

Budden	2,750 0 0
Martin	2,750 0 0
Mann	2,475 0 0
Harris	2,425 0 0
Sawyer	3,338 0 0

For sundry works to be done in building thirty-two almshouses at Reading:—

Dover	41,500 0 0
Biggs	4,510 0 0
Simmons	4,228 0 0
Barnecoat	4,267 0 0
Pyther	4,255 0 0
Senic	4,130 0 0
Matthew	4,119 0 0
Randel & Son	4,069 0 0
Rendell	3,650 0 0
Wheeler & Sons	3,498 0 0
Norris	3,920 0 0
Gwyer	3,910 0 0
Shepard	3,897 0 0
Sawyer (accepted)	3,841 0 0

For restoration after fire, Haberdashers' Hall, Greenstreet, exclusive of all painting and decorations. Mr. W. Snook, architect:—

Ashby & Horner	24,140 0 0
Holland & Hannan	3,928 0 0
Mansfield	3,621 0 0
Trollope & Son	3,362 0 0
Brass (accepted)	3,622 0 0

For the erection of warehouses, Down's Wharf, Lower East Smithfield, for Mr. Charles Jack. Messrs. Snooke & Stoe, architects:—

Downs	236,360 0 0
Lawrence & Son	34,830 0 0
Hart	33,973 0 0
Ashby & Horner	32,860 0 0
Holland & Hannan	32,845 0 0
Rider	32,810 0 0

# The Builder.

VOL. XXIII.—No. 1148.

Baalbek.—The City of the Sun.

When you occupy a country, and wish to hold it, carry roads through it. The force of this maxim of the Iron Duke has been duly recognized by our Continental neighbours, or, at least, by their ruler. Napoleon III. has also proved himself a man of metal, for he has carried his macadamized boulevards right through the strongholds of the vanquished Parisians. No more paving-stones to play with, my little gamins,—no more narrow lanes for ambuscades, my gentlemen of the red,—but broad imperial ways, easy for the passage of artillery, and affording elbow-room for indigènes, who will fall to work with a will on the first occasion you afford them. From these premises we may infer that the French, or, rather, he, the embodiment of the French will, intends, or, intended, permanently to hold Syria; for he has carried a noble road, also macadamized, right over the summit of Lebanon, through the centre of the country from Beyrout to Damascus, and has established khans at proper intervals, with relays of horses for the diligences which have commenced running. Whether or not this road was begun by the French army, during its temporary occupation of Syria, or by the company who are finishing it, we know not; but we do know, that in whatever way it will be accomplished, it will be a great and good work, tending greatly to the comfort and security of travellers in that insecure and comfortless country. It is the path by which civilization will penetrate to the very edge of the desert; for that great civilizing power—Commerce—is already covering it with her caravans.

At the time of our visit to Damascus it was only completed three parts of the way, and the diligence only travelled half the way, the rest of the journey being accomplished on horseback. On our return from that interesting city we left the road in the great plain of Bekaa, which lies between Lebanon and Antilibanus, and is from six to ten miles wide and one hundred long, stretching from above Hums to Mount Hermon. We left the road in order to visit the ruins of Baalbek, which were situate a day's journey to the northward. A conveyance was to have met us at the branch road to Zakleh, but, as the Americans say, we "missed connexions," and proceeded to the town on foot, leaving our dragoman in charge of our saddle-bags. The plain of Bekaa is quite flat, well cultivated, but without trees. In this part of it the French army was encamped many months, so the Christian boys of the neighbourhood fluted us in our progress with "Bon jour," much at first to our astonishment. Zakleh, the largest Christian town in the district, is recovering its splendor after the depressing results of the massacre; and we noticed that new convents were being built upon the sites of those

that were destroyed, and in a manner to resist the attacks of Arabs and Druses. We found there a hotel, dignified by the name of hotel, where we had breakfast, and where we were shortly joined by Michael, our dragoman.

We went then into the market-place to hire mules; and, having at last been successful, mounted in haste in order to reach Baalbek, if possible, before sunset. Our road lay athwart the plain to the north-east. For some miles cultivated fields without hedges or other inclosures were visible on both sides of us, and we passed at first through villages inhabited by those sons of Ishmael who had become domesticated, had relinquished "the road" to their brothers the Bedonins, and had taken to the field instead. After a time the cultivation and villages ceased, and we had around us the usual sand, stones, and brushwood. Though our progress was but slow, the wonderful grandeur of the scenery consoled us. The snowy range of the White Mountain on the one side, and on the other the red peaks of Antilibanus,—which seemed to have been burnt by the sun's rays until they had the appearance of mountains of brass,—kept company with us all day long, and, as evening approached, overshadowed us,—too soon, alas! for they obscured the great pile of the temple of Baalbek a few minutes after we came in sight of it. We had but time to gain a glimpse of its grandeur in the short twilight, for night overtook us while we were yet miles from the ruins. It is not pleasant to be benighted in the East, for the roads are stony and difficult to follow, as there are in general no boundaries to them; but fortunately Michael knew the road well, and, after a few stumbles, we at length reached the village which adjoins the ruins in safety, and obtained quarters in the house of a Christian family. At the end of a courtyard there was an oblong building, consisting of two living-rooms, divided by an open archway like the *lewan* of the houses of Damascus. Unfortunately one of these rooms had no floor, as it was but newly built, and consequently while some of our party occupied the remaining apartment, others had to seek rest in the open archway,—to seek, but not to find it, for myriads of fleas held their revels there and banished sleep. But "it is an ill wind that blows nobody good;" for to these little tormentors we were indebted for one of the most lovely sights eye ever beheld. They were the cause of our being roused at daybreak in time to see the sun rise over the ruins. Hurrying to a hill in front of the house, we gained a perfect view of the whole plain.

Looking over the flat-topped houses in the foreground, we beheld the broad plain of Bekaa still wrapped in grey shadow. Beyond it rose the lofty chain of Lebanon, whose jagged summits were just lighted up by the rosy light of morn; every ravine in its indented sides by degrees became distinctly visible, even to its purple depths. In the foreground of this majestic picture of nature rose the huge dark mass of masonry, one of the grandest of man's works, apparently an immense fortress, rising high above the houses and groves of trees which surrounded it, and surmounted by six slender columns. At first it looked gloomy and sombre, but little by little the sun's rays painted cornice and capital with rich rose madder, bringing out clearly every detail, admirable in contrast with the mass of green foliage beneath. Rapidly the shadow fled across the plain before the pursuing ray, till it was finally gathered up into a small space at our feet, and old Baal resumed possession of his early inheritance—Heliopolis, the City of the Sun—to reign there royally for the next fifteen or sixteen hours. We have seen the sun rise upon the Alps from the summit of the Superga, near Turin; we have watched it tip with gold the minarets of Stamboul; we have seen it gild the sides of the

Pyramids; but we never remember to have beheld such a splendid effect as when we witnessed his return to the city which bears his name,—and we owe all this to the fleas!

Upon descending to breakfast—for we early birds are always ready for our matutinal worm—we were glad to find that Michael had provided a substantial meal. After heartily discussing it, we made our way to the ruins. Upon approaching them, we found that they consisted of temples and other edifices, erected upon an immense platform, some 20 ft. or 30 ft. above the level of the ground, and enclosed by a wall heightened in Arab times, so as to form altogether a vast fortress, 1,000 ft. in length, from east to west, and 500 ft. in breadth, from north to south, with walls varying from 60 ft. to 80 ft., or even 100 ft. in height. The platform was originally reached by a flight of lofty steps, at the east end, removed by the Mahometans, and replaced by an embattled parapet. There appears to be no mode of access to the terrace except through a breach at the south-west angle, though there is in reality another through a subterranean passage. But before entering we will walk all round the pile,—which may be called the acropolis,—and remark the construction of the platform, looking especially for the three great stones mentioned by all travellers, which, from their dimensions, have given the temple at Baalbek, the name of *ἱεροὶ τάλιθοι*.

The east end is entirely occupied by the propylæa. The columns of the portico no longer exist, but their bases and pedestals have been built into the embattled parapet. There were originally twelve columns, which were flanked by a pylon, 25 ft. square at each end. These pylons stand entire, and have four pilasters on each face; the cornice of the podium is returned on both the north and south sides. Upon the entablature surmounting the pilasters, a wall has been erected by the Arabs, so as to make the total height of the building at this point almost 100 ft. above the level of the ground.

On the south side the wall is continued for the full height, to a distance of 30 ft.; here it juts out at right angles to some 50 ft. In the east face of the projection there is an entrance to subterranean passages, which run through the basement. These we shall afterwards describe. The remainder of this side is formed by the walls of a Saracenic palace, which occupies the corner of the platform; beyond it the barrier is formed by the south wall of the cella of the Temple of Jupiter and by the columns of the peristyle: eleven of these have fallen, but four remain standing. Roberts chose this point for one of his most beautiful sketches. Beyond the Temple occurs the breach already mentioned, as existing at the south-west angle.

On the west side we find a plain unbroken wall, and at the north-west corner the three enormous stones that we were seeking form apparently one unbroken course, 186 ft. in length by 13 ft. in depth, for they are so nicely laid that the joints are not easily to be discerned. We should suppose the temple to have been built upon rock levelled to receive it, if these stones had not other smaller courses beneath them, and if we did not see, on turning the corner, at least six other stones of large dimension, ranging with them, and forming with them part of the original temple, built by the Phœnicians, or by Solomon, as the Arabs say. According to them, this edifice was built by that monarch as a sort of country mansion, where he could retire to divert himself with his 1,001 wives: no great sin in their eyes. We wonder that they do not associate in their imaginations these stones with the time of the giant Nonh, whose tomb was visited on our return, at Nely Nonh, near Zakleh. It is a coped tomb, about 4 ft. above the ground, and 100 ft. long, showing the full stature of the truly great patriarch. We are giants in science and inven-

tion, but we have never moved a stone weighing 1,000 tons a mile's distance: perhaps because we never had occasion to do so. The quarry from which these stones were hewn is almost a mile from the temple, and there is another stone lying in it of still greater dimensions than these, being 68 ft. 4 in. long, 17 ft. wide, and 14 ft. 7 in. high, according to those who have measured it. It is tilted up at one end, all ready to be moved by rollers or whatever means were employed by primitive builders.

On the north side there is an outer wall, composed of the above-mentioned large blocks. It is about 15 ft. or 20 ft. high, and is some 20 ft. or 30 ft. distant from the higher wall, which supported the peristyle of the Temple of the Sun, leaving a sort of fosse between. Beyond the peristyle of the temple the main wall juts out at right angles, passing beyond the end of the lower wall. The cornice of the podium begins here, and is continued round to the eastern side. In the west side of the projection is another entrance to the subterranean corridors, and there are two pilasters above it, ranging with those of the portico.

If we clamber through the breach at the north-west angle, we find ourselves on a platform lower than the general level of the enclosure. Upon it stands the Temple of Jupiter, which, after the Temple of Theses, is the most perfect existing; and which in its dimensions exceeds the Parthenon. It is octastyle and peripteral, and of the Corinthian order. The portico had three rows of columns, and was larger than that of the Pantheon at Rome. Most of these columns are standing; those on the north side stand entire, with their entablature and with a great part of the ceiling of the peristyle, which consists of a flat segmental curve, formed of single stones laid side by side. The soffits are most elaborately ornamented with hexagonal compartments, each filled with a group of figures. Three columns of the portico are also standing, but those on the south side have for the most part fallen down.

The doorway of the temple has been so often described by able pens, and delineated by able pencils, that we shall not attempt to picture it in detail; suffice it to say, that the architraves are single stones 42 ft. high. The lintel is of three stones, the centre stone of which slipped down 3 ft. or 4 ft., but remains suspended, as though ready to fall upon the intruder into the adytum of the temple. The internal walls were engaged columns, the spaces between them being filled with two rows of niches. Inscriptions inform us that this temple was erected in the time of Antoninus Pius.

Such being the smaller temple, what must the larger have been in its pristine state? Now there are but six columns of the southern peristyle remaining. These stand upon a supporting wall on the general level of the upper platform. Wood and Dawkins restored this temple, and from their plan it appears to have been decastyle, peripteral, and most probably hypæthral, standing upon a high podium, which upon the north and west sides rose straight from the level of the ground. The shafts are 62 ft. 4 in. high, and the total height, with the entablature, is 76 ft. Thus they were the highest in the world. This stupendous structure was approached through an atrium about 350 feet square, lined with *exedrae* and ornamented with numerous columns and niches. This again was approached through an outer and smaller court, likewise lined with *exedrae* and niches. Portions of the former, and a great part of the latter still remain. The decoration is extremely rich, though not what we should consider pure in style. This outer court terminates in the grand eastern portico, which had twelve columns, 4 ft. 4 in. in diameter. We quote these dimensions from various authorities, as we had not time to measure, but simply to explore. After a general survey of the ruins on the platform, we visited the subterranean corridors—not the least interesting or curious part of the structure. There are two long vaulted passages running the full length of the platform, or nearly so, connected by transverse galleries. They are partly built of immense blocks, evidently of the same date as the large stones at the north-west corner; the greater part, however, is Roman work. These passages have never been thoroughly examined. Dr. Robinson appears simply to have peeped into them; others seem to have devoted their time exclusively to the examination of the upper work. We observed in our exploration an opening in the south wall of the southern corridor about 6 ft. from the ground, and, with the assistance of

Michael, managed to scramble into it; but not being furnished with lights, did not venture to descend on the other side. It was too late in the day to go for candles, so we unwillingly deferred our visit till the next day, and retired to our flea-haunted mansion, had actually procured and cooked chops for dinner—an unusual luxury in a country where hatcher's meat is rarely to be obtained by hungry travellers.

Early the next morning, having supplied ourselves with candles and the only ladder in the village, we returned to our underground researches, and were rewarded by the discovery of an arched chamber about 20 ft. square. The ceiling was semicircular, elaborately enriched with caissons filled with rosettes, and at the sides of the room there were rich niches with pedestals over them. This chamber had evidently been open to the exterior at one time, as the end wall was of more modern days, and the crevices between the stones admitted faint rays of light. What this chamber could have been it is difficult to say. We have not met with any notice of it either in Wood, De Sauley, Robinson, or any other writer, and we therefore feel ourselves at liberty to suppose that it was not remarked by them; the whole building is a fine study for the archaeologist, and has to be thoroughly explored, measured, and explained by some future traveller, for it is without doubt the finest pile of ruins in the world as far as grandeur and completeness go.

Not far from the acropolis, as we may venture to call the fortified enclosure, stands an elegant little octagonal structure, which Miss Beaufort aptly terms the *baudoir* of the gods; each side is curved concavely, and at each angle there is a detached column, about which the entablature is returned. It is circular in the interior, 38 ft. in diameter, and has had a domical roof, the lower courses of which remain.

There are many other objects worth a visit in Baalbek: for instance, the quarry where is the great stone, and in which there are various rock dwellings, apparently those of anchorites; the magnificent source of most limpid water forming a small river which fertilizes this part of the plain; a ruined mosque with three rows of pointed arches springing from classical columns, and the walls of the ancient town, which, with their gates, are almost entire, enclosing a great tract of ground, a corner of which is occupied by the modern village. All these are well worth visiting; indeed, a residence of several weeks would be necessary to enable a person to see the place thoroughly. But Michael was inexorable, and, after the second day, we unwillingly mounted our mules, and turned our faces with regret towards the Neby Noub.

## ENGINEERING ARCHÆOLOGY.

### THE HISTORICAL LOCOMOTIVES AT KENSINGTON.

PEOPLE talk very glibly about invention and its progress, but we have often had occasion to notice that but few have any clear notion of what industrial invention really is, while a philosophic history of invention has yet to be written. Invention has been termed the poetry of science, and one popular belief about inventions would maintain that they are struck off like the stanzas of a poetical improvisatore. But very few inventions, however, could be traced to such a source, and the history of the arts shows that time, accident, and tentative experiment are, after all, the greatest inventors. One of the chief features observable in the maturity of any invention is its gradual and slow evolution, by the work of many brains, of many hands, of many circumstances of time, place, and chance. So slow and gradual is this progress, that the different stages in its history are as difficult to note as would be the progress of the hands of a clock unprovided with a dial-plate; and the different stages are difficult to determine, not merely with regard to entire machines or processes, but also with respect to the different details or these processes. As a natural result, when inventors or their descendants do at last come to understand the importance and value of what they have been doing, there take place endless controversies as to priority of invention. Witness that of the blast-pipe, for which there are several claimants. The importance, for reasons of social and commercial policy, of determining the laws of the deve-

lopment and progress of industrial improvement is scarcely recognized,—although the patent law and other laws bearing on inventions may be supposed to have some such theoretical basis. A generalization of this kind could only be conducted on a firm groundwork of historical truth, and there are many difficulties in the path of an investigation in this direction. To mention only one. There is scarcely one important modern invention which is not claimed for a distinct and different inventor in each of the more important civilized countries of Europe. The first originators of many of the different important steps in the elaboration of the steam engine are thus subjects of fierce contestation between the savants of England, France, and Germany. It would be scarcely possible to get at any true account of a question of this kind without studying the records and claims in these three languages at least. It is the French who show the greatest ardour and vivacity in these discussions; and we regret to say these patriotic sentiments have not in all cases been tempered with many scruples as to the means of maintaining, or rather of annexing, honour of this kind. We say this advisedly, having in our memory some yet unpublished discoveries as to the history of the steam engine.

We thus look upon the Museum of Patents at Kensington, mainly founded by Mr. B. Woodcroft, and greatly extended by the zeal of the present Curator, Mr. F. P. Smith, as being of yet greater importance than is generally acknowledged. This Museum, even in its comparatively undeveloped state, is not merely an historical record of inventive progress,—is not merely a museum of engineering archæology,—but is also a place where lessons may be drawn some valuable lessons towards a philosophic theory of the development of invention. One lesson, apparent to the most casual observer, is that an invention is not a thing of spontaneous, inspired, production, but is rather a plant of slow growth,—sown, nourished, tended, and reaped by many different hands. This view is a rather disenchanting one to take, however true it may be. The popular imagination seems to always require a corporeal object for the embodiment of its fancies. It delights in a hero, its sight does not range so far over the intellectual horizon as to perceive a principle,—it can only see a person. It is forgotten that men's powers—the term being used in the widest sense—differ but little in extent from the physical stature of a given number of persons. The popular belief of this, for instance, invests Watt with that of spinning machinery; Fulton with marine propulsion by steam; George Stephenson with the first invention of the steam locomotive. A brief account of the locomotives already existing in the Kensington Museum of Patents, would dispel this last belief, and even without greatly shortening George Stephenson's status. At the time we write too, the celebrated "Sanspareil," the rival engine to Stephenson's "Rocket" built by Stephenson's rival, Timothy Haekworth, is just now being re-erected in the Museum, in company with its former competitor of the famous contest on the Manchester and Liverpool Railway, in 1825.

In the matter of priority of invention in, or rather of attempts at, land propulsion by steam, the French may well claim to be our *devanciers*, and we do not think that any true Englishman will be inclined to grudge them this honour. The first steam carriage seems to have been made by a Frenchman, Cugnot, in 1769,—that same marvellous year which witnessed the birth of Napoleon I., Wellington, Humboldt, Mehemet Ali, Lord Castlereagh, Sir M. L. Brunei, Cuvier, and the first patent of Arkwright, the first patent of Watt, as also some other events almost as great in their eventual influence on the present era. An engine made by Cugnot is still in existence in the Conservatoire des Arts et Métiers at Paris. It has a copper boiler, very much like a common kettle without the handle and spout, furnishing with steam a pair of 13-in. single-acting cylinders. The engine propels a single driving-wheel, which is roughened on its periphery. Altogether, this engine bears considerable testimony to the mechanical genius of its inventor. It was unsuccessful, having got overturned once or twice on the very bad roads then existing in France, and it was put on one side in 1781, to put it to work in the presence of Napoleon Bonaparte. The departure however, of Napoleon for Egypt, prevented the trial,—a circumstance which recalls Fulton's subsequent unsuccessful ne-

gations with Napoleon for aid in attempting marine propulsion by steam. Wait then, in 1784, patented a locomotive engine, the boiler of which was to be "of wood," hooped like a beer-barrel. Watt, however, had not much faith in steam carriages, and he objected to the attempts made in this direction in 1784 by William Murdoch, his very able assistant. The miniature engine made by Murdoch in that year is still carefully preserved at Soho. Careful and elaborate researches, such as those lately made by Mr. Zerah Colburn\* into the history of the locomotive, seem to more and more confirm existing impressions as to the great part done by Trevethick in the introduction of the locomotive engine. In 1802, he and his moneyed partner Vivian patented the application of the high-pressure engine to steam carriages, and one of these was made, put to work in Cornwall, and exhibited in London. A model locomotive, made by Trevethick in 1802, is now in the Museum of Patents, at South Kensington, having been found out in Cornwall by the present curator, Mr. Francis P. Smith. The boiler is fitted with an internal double flue, and a chimney of small diameter. Mr. Colburn has shown clearly enough, in spite of previous misstatements, that Trevethick understood the value of the blast formed by the exhaust steam when turned into the chimney, and the practical sufficiency of the adhesion between smooth metallic surfaces for propelling the locomotive and its load. Trevethick's engine of 1804 was able to work over a rough tram-road at the rate of 5 miles an hour; but in Cornwall, where fuel was then so dear, the comparatively high quantity of coal consumed rendered this performance of inferior commercial value. The Northern districts of Newcastle-on-Tyne clearly offered the fairest opening for the childhood of the locomotive, and accordingly, Mr. Blackett, the proprietor of Wylam Colliery, wrote in 1809 to Trevethick respecting his locomotive. It appears that, at the time, Trevethick replied that he was too much engaged; but in 1811, however, he sent an engine to Newcastle. It was not put on the Wylam railway, but set to drive a foundry.

At this time a locomotive was being made by Murray, of Leeds, at the order of Mr. Blenkinsop, of Middleton Colliery, near that town. It will be remembered that Mr. Blenkinsop's name is connected with the employment of a strong rack rail on the line, into which worked a toothed pinion driven by the engine. A horizontally-placed cylindrical boiler was used, in which were placed two vertical steam cylinders. The boiler had a single internal flue, containing the grate at one end,—like a Cornish boiler,—while the chimney rose out of the other end of the flue. A pair of cranks on each side of the engine drove a toothed wheel, and these two wheels themselves propelled a larger toothed wheel, on the axis of which was a pinion with coarse teeth working in the rack rail. With such a light engine as one of 5 tons, and working at the slow rate of only 3 miles an hour, Mr. Colburn considers that we should be obliged to use a rack, and that thus Mr. Blenkinsop did not deserve the ignorant ridicule which has been directed against his rack and pinion. In fact, Murray's engines on Blackett's plan were the first locomotives ever worked permanently and on a commercial scale, and this line between Middleton and Leeds is in reality the first commercial railway. It is not, perhaps, generally known in England, but it is stated by Mr. Colburn, that as late as 1848 the rack rail was adopted upon an incline of 1 in 17, on the Madison and Indianapolis Railway, in the United States. "This incline, which has since been superseded by a line with practicable gradients, rose from the north bank of the river Ohio at Madison, and was about five-eighths of a mile in length." The engines provided had five steam cylinders in all, and, in a way not to be made clear without a sketch, a cogged wheel working on a rack rail.

The next step was the commercial working out of the adhesion of the driving-wheels. This was done by William Hedley, the colliery viewer of Mr. Blackett, of Wylam; but it is probable that this would have been done by any one who first built a rather heavier engine than that of Murray's. Hedley thus, in 1813, constructed the engine now in the South Kensington Museum, but which has been at work near Newcastle down to such a recent date as 1863. It has been known many years under the name of the "Puffing

Billy"—a nickname given to its maker, Mr. William Hedley, by the colliery bands, from the fact of his being rather stout, with a consequent shortness of breath. Mr. Hedley first of all made an engine somewhat like that of Trevethick's, with a cast-iron boiler, provided with a single internal flue, and working by adhesion on a smooth rail. This engine was not very successful, from a deficiency of hoiler power, and from the fact of its having only one cylinder; but it clearly proved the possibility of doing away with the expensive and cumbersome rack. The "Puffing Billy" was then made. The inscription on it states that it was built in 1813, by Jonathan Foster, engineer, of Wylam colliery, under the superintendence of Mr. Blackett, owner, and of Mr. Hedley, viewer of the colliery, in order "to haul coal-laden waggons along a railroad to Lemington, where the coals were shipped in keels." This railroad was a substitute for the old tramroad, and was laid down on the site of the latter, between the years 1807 and 1811. The "Puffing Billy" has a wrought-iron boiler, containing a return flue,—the chimney being at the same level as the fire-door. There are two vertical cylinders, driving beams centred each at one end, termed the "grasshopper" beam—a plan first due to Oliver Evans. The motion of the wheels is given to the four wheels by toothed gearing. An original document of great interest and instructiveness, is framed and glazed and hung to this engine. It appears that the noise and smoke made by this engine were considered a nuisance by some of the people living in the districts it traversed. They accordingly threatened to indict the "Puffing Billy" as a nuisance, and Mr. Blackett found himself obliged to take counsel's opinion on the matter. The barrister, who had noted one in his day, evidently agreed with the neighbours in their bad opinion of Mr. Blackett's engine. The case being put to him, he writes on the back of the document, that,— "It does not appear to me that there is any objection arising from the noise itself, to Mr. Blackett's conveying his coal-waggons by means of his steam-engine; but I think that the use of such an engine may be deemed a nuisance to A, if the smoke and noise occasioned thereby render his habitation unhealthily or uncomfortable; but this must entirely depend upon the quantity of smoke and noise so occasioned, and the distance of the house of A, from the waggon-way."—(signed) R. Hopper Williams, Newcastle, 12th September, 1814. But the most amusing bit is a note, apparently the result of an after-thought of the learned lawyer,— "If the noise of this engine disturbs the cattle grazing on the land adjacent to the waggonway, so as to injure them with regard to their feeding, I think it may be considered a nuisance." In all probability Mr. Williams's capacity was rather above than below the average; but this is one of many more instances that shows the difficulties to be encountered in the introduction of any new thing. It is not very likely that such an opinion would now be given, or that we shall ever abolish locomotives for fear of disturbing the digestion of grazing cattle; but the first thing has been done, and the introduction of traction engines is just now greatly impeded by the same difficulties which beset the Puffing Billes of 1813. At the same time, it is clear that horses are more liable to be frightened by an engine on common roads than on a line,—or, rather, more properly speaking, the engine is brought within sight of a greater number of horses when it is made to travel on a common road. But it is well known that horses very soon get accustomed to a railway locomotive, and there is no doubt that they would just as soon forget their fear with a traction engine.

About a couple of years after the construction of the "Puffing Billy" Mr. Hedley built a yet more efficient engine for the Wylam Railway. In the same way as he had first put to commercial use the adhesion of smooth surfaces for railway traction, so did he first apply the return-flue boiler and the narrow chimney. By the way, talking of "adhesion" we think that this term is often used very improperly. Adhesion only takes place between two surfaces of the same substance, of the same—or of nearly the same—molecular structure, and consequently similar surface. Adhesion thus does not take place between a cast-iron surface and a wrought-iron surface,—between (say) a cast-iron wheel and a wrought-iron rail. The grip is in this case produced by simple friction without any adhesion, properly so called.

A careful observer of the doings on the Wylam Railway was George Stephenson, and he persuaded his employers at the Killingworth Colliery to construct an engine which was finished towards the middle of the year 1814. Its boiler, 8 ft. long and 34 in. in diameter, was carried on four 3-ft. wheels, and provided with a single internal flue. Two vertical cylinders were placed for half their length in the boiler. The motion for driving the wheels was almost the same as that in the "Puffing Billy." It is stated by Mr. Smiles that the speed of this first engine of Stephenson's was only three miles an hour, and a year's trial with it showed that it had no advantage in point of economy over horse-power,—being thus much inferior to Hedley's engines. This weakness of Stephenson's first engine was due to the low boiler power produced by the use of a single flue and a chimney of large diameter with its weak blast, nullified by exhausting the waste steam into the chimney. In 1815, Stephenson made his second engine, according to the patent which he took out in that year. A different kind of gearing was adopted for driving the engine, and additional adhesion was obtained by coupling the wheels of the tender to the engine by means of an endless chain. Stephenson also used springs, according to a suggestion of Mr. Nicholas Wood. George Stephenson also applied a strange and even absurd scheme to some of the Killingworth engines as a substitute for springs. This consisted in adapting a number of pistons sliding in cylinders fixed to the bottom of the boiler, and in communication therewith. Stephenson, in his own words, supposed that as they "acted upon an elastic fluid, they produced the desired effect with much more accuracy than could be obtained by employing the finest springs of steel to suspend the engine." Of course, the plan had to be at last abandoned, after some unsuccessful trials. At this time, and some years previously, the placing of steam-carriages on common roads was being attempted,—a feat which is now being carried out in our own time mainly for agricultural purposes. The wedding of the wheel and the rail put an end for the time to the experiments in this direction, conducted by Griffiths, Gurney, and others. Mr. Colburn remarks on these experiments, that while road locomotives had ample adhesion, they only lacked evaporative power. "The steam blast, which for railway engines running at a slow speed, and having insufficient adhesion, was as yet hardly required, nor, for some of these engines, even admissible, was therefore of great importance to the road locomotive engineers. Goldsworthy Gurney, then a surgeon and lecturer at the Surrey Institution, has claimed the discovery of the properties of the steam-jet in 1820,—the year, by the way, in which Nicholson's patent for various applications of the steam-jet expired. In 1820 and 1821, Gurney employed the jet for promoting combustion in laboratory furnaces, for decomposing various compound bodies, and for working platinum; in 1824 he applied jets of steam, taken directly from the boiler, to increase the draught in the chimneys of the steamboats *Albatross*, *Duchess of Clarence*, &c.; in 1826 he applied steam in the same manner to increase the draught in the chimney of his road-locomotive; and in an *ex parte* statement not long ago published by Mr. Gurney, he alleges that he "supplied Timothy Hackworth with the blast-pipe employed by that engineer in the locomotive 'Sanspareil,' which so nearly won the Liverpool and Manchester prize in 1829." It would seem, however, that Hackworth used the single contracted blast orifice about two years previously to 1829. Timothy Hackworth was a practical engineer of much ability, and, though not so successful as George Stephenson, it is probable that his mechanical powers were little, if at all, inferior. He helped to make the "Puffing Billy" at the Wylam Railway; in 1824 he was the manager of George Stephenson's locomotive foundry at Newcastle; becoming, in the following year, the locomotive superintendent of the Stockton and Darlington Railway. The engines of this line, opened in 1825, were made by Stephenson, and they gave such bad results that it was stated that the directors, as late as 1827, were thinking of altogether giving up locomotives. Hackworth, however, took in hand one of the engines on the line, made by Wilson, of Newcastle. Hackworth applied the return-flue to the boiler, and, above all, he applied to it the blast-pipe. The "Royal George" was thus the best locomotive of its time, as it was, besides, fitted with the then novelties of "a cistern into which, a portion of

\* "Locomotive Engineering," Glasgow: W. Collins, 1864.

the exhausted steam could be turned to heat the feed-water: it had short-stroke force-pumps, worked by eccentrics; adjustable springs, instead of weights, upon the safety-valves; and a single-lever reversing gear.\*

Two years after the application of these improvements to the "Royal George," in 1829, took place the Rainhill trials on the Manchester and Liverpool Railway, which had the effect of bringing to a head most of the existing knowledge in locomotive traction. One of its most important results was the first application of the multitubular boiler to the locomotive. The invention of this important form of boiler has afforded, and still affords, a field for both intestine and international wars as to its priority of invention. The English claim the multitubular boiler; so do the French; and so do, we believe, the Americans. Perhaps a Chinese claim may be yet put forward. In the mean time, Mr. Colburn shows that it was first prepared by a London engineer, Mr. James Neville, of Shad-Thames, in specification No. 5,344, A.D. 1826. This is an important document in engineering archaeology, as it annihilates the pretensions of the French claimant, M. Marc Séguin, who only patented the multitubular boiler in France in 1828.

Thus were combined and brought into practice all the essential points of the present locomotive, which has only been since improved by, in the main, the mere effect of time,—of time and experiment, eliminating inferior forms of detail. Nevertheless, the then existing locomotives were by no means very successful machines; such distinguished engineers as Messrs. Walker and Rastrick reported against their use on the Liverpool and Manchester Railway; and they were confirmed in their impressions by a man of such ability as Mr. Nicholas Wood, who (just as Smeaton firmly believed that steam-engines could never do better work than pumping up water for water-wheels), gave it as his conviction that no locomotive could be made to go faster than 8 miles an hour. Thus, even so late as the spring of 1829, the directors of the Liverpool and Manchester Railway were thinking of applying fixed engines and ropes for working the line. Fortunately, however, the counsel of two or three members of the board prevailed, and it was decided to make a last trial of locomotives. As one of George Stephenson's engines had already failed on the line, a prize of 500*l.* was publicly offered to all comers on the 25th of April, 1829.

The conditions that engines had to fulfil have been often published. One of these was, that the engines should burn their own smoke; and it is a pity that this "condition" has not even now, been fulfilled, as every railway passenger knows to his cost. The only engine ready at the appointed time was the "Rocket," entered by Robert Stephenson; Haekworth's "Sanspareil," Braithwaite and Ericsson's "Novelty," and Mr. Brandreth's "Cyclops" were not ready at the appointed time. The "Rocket" and the "Sanspareil" (both somewhat altered) are now in the Kensington Museum, the last, as we have stated, being just now here re-erected. Both are four-wheeled engines. The boiler of the "Rocket" is traversed by a number of copper tubes, and its two inclined cylinders work crank-pins on the driving-wheels at the front or smoke-box end of the engine. The honour of the application of the tubular boiler is not due to the Stephensons, but to Mr. Booth, the secretary of the Liverpool and Manchester Railway. The diameter of the driving-wheels was 4 ft. 8½ in., and that of the travelling-wheels, 2 ft. 6 in.

With regard to the "Sanspareil," it is stated that this was the second engine to which was applied the blast-pipe; the "Royal George" (1827) being said to be the first.\* The exhaust steam from each engine is taken into the chimney through a blast-pipe. It also appears to have been one of the first engines with conical wheels, of which it had four. The most striking peculiarity to the eye accustomed to the present locomotive is, that the driver stood beside the chimney, the boiler being completely traversed by a return flue. The boiler is cylindrical, about 4 ft. in diameter and some 6 ft. long. The fact that the apparent front end is in reality the hind portion which was coupled to the tender, has misled some of the writers of treatises on the steam-engine, causing them to figure the tender in front. An inspection of the engine would ap-

pear to show that the driver stood on the tender in order to fire the boiler. The cylinders are vertical, and, in the original engine, were 7 in. in diameter, the stroke being 18 in. The two front wheels are fitted with crank-pins, driven by the connecting-rod of each engine. The "Sanspareil" was tried on the 13th of October, 1829. The total weight of the engine and load being 19 tons 2 cwt. The failure of the feed-pump, however, led to its stoppage, as the boiler could not be kept filled with the necessary water. It was also unfortunate with regard to one of the steam cylinders cracking through the bore into the steam vent. The rate of evaporation, and consequent tractive power of the "Sanspareil," was, however, higher than those of the "Rocket," the successful engine. It is stated by Mr. Hick of Bolton, the donor of the engine to the Kensington Museum of Patents, that it was purchased by the Liverpool and Manchester Railway after the trials. In 1831 it was sold to Mr. T. Hargreaves, of Bolton, in order to work on the Bolton and Leigh Railway. In 1837 the old cylinders were replaced by new ones of larger dimensions, and the original wheels with wooden spokes were replaced by cast-iron wheels, with hollow spokes. It continued till 1844 on the Bolton and Leigh Railway, but was, by that time, found too small and weak. Mr. Hargreaves then removed it to his colliery at Cophall, near Chorley-lane, and fixed it over a coal-pit, in order to drive a pumping and winding apparatus, a pair of wheels being removed for a set of looted gear. The boiler was not used, the engine being driven from a stationary boiler. It thus worked up to the end of 1863, when it was removed solely in consequence of the coal-pit being exhausted. Mr. Hick of Bolton, happened to pay a visit last year to the Kensington Museum, and, having seen the other engines there of historic fame, he determined to add the "Sanspareil" to the number. Mr. Hargreaves then presented the engine to Mr. Hick, who, in his turn, gave it to the Museum, where, in the words of Mr. Hick's letter, the engine, after all its chequered and eventful career, may end its destiny "in peace and not in pieces." It may not be uninteresting to state, that the railway company on the road from Bolton to Liverpool carried the old engine free of cost, according to the suggestion of Mr. F. P. Smith, that the venerable engine which had carried so many, should, in its turn, have its own carriage franked to its last resting-place.

The "Novelty," though very unsuccessful—as it was very soon disabled by an accident—displayed high constructive power, and is considered by some good judges as being in many respects the best designed engine of the four. It was a four-wheeled tank engine; its boiler consisted of an upright cylinder for the fire-box, and a horizontal barrel 15 in. in diameter, and about 12 ft. long. The flue was taken from the fire-box through the barrel by means of a tube hole chimney. The two steam-cylinders were placed vertically in the flue, being 6 in. in diameter, with a 12-in. stroke. The diameter of the wheels was 4 ft. 2 in. Mr. Burstall's "Perseverance" very soon gave up, and was found unfit for the trials.

It would be a natural remark to make, that the greater number of the engines and machines which have been so long at work have been greatly altered from their original construction by the exigencies and accidents of practical wear and its attendant repairs. Like John's old knife, which still remained "John's old knife," though it had received about a half-dozen new blades in succession, and about as many new handles, it might be doubted whether these engines really represent their original construction. In one sense this may be true, and it is probable that only a portion of the original raw metal is still in combination. But then it must be remembered that in piecemeal repairs any part repair is in a great measure tied to the original form. The new blade of the old knife has to conform to the existing handle, and the new handle has to be made to the shape of the blade. The same must be, more or less, the case with repairs to an engine or machine. At the same time, such a consideration points to the absolute necessity for a correct history—or rather engine biography—being appended to each engine, pointing out where and what alterations and repairs have been made.

The Patent Museum, at South Kensington, only yet needs the "Novelty" to complete the trio of the engines which figured at the great Rainhill contest. It is not now known where the

"Novelty" at present is, or, indeed, whether it is even still in existence. We believe that Mr. F. P. Smith is anxiously looking about for it, and we hope that he may be successful in his search. What lessons of the way in which "Fortune turns her wheel" may be read by a look at these old engines,—the progenitors of its impress upon present life in so many direct and indirect ways. The two Stephensons are now dead, but their engine, which killed Mr. Haskinson, raised their fortunes above those of perhaps any other engineers of their time. Timothy Hackworth is now dead, but his works at Newcastle, like those of the Stephensons, are still flourishing. The Messrs. Braithwaite are now living, but their factory has been given up, and their partner of 1829, the Swedish engineer, Ericsson, is now building "Novelties" in the way of gun-boats, for the Federals. In centuries hence, time will have thrown its halo of distance round these engineers, and their doings will be scanned with a kind of romantic interest. Let us hope that, in the course of the next century, the Government will have provided a decent building for the objects which represent such important interests, but which are now sheltered in the crowded and dark shed at South Kensington.

#### OUR DOMESTIC FIRE-PLACES.\*

On the strength of the aphorism of "every man to his trade," we may inquire who should be a more competent person to give us information about fire-places than a well-informed practical man who has manufactured thousands of them, and made an examination of their respective merits a life-long study? But it is so generally admitted that, as in love and war, all sorts of stratagems are fair in trade, that the public are apt to eye with reserve any production dealing with the writer's own wares, and to regard it as an oblique or disguised advertisement. We would, however, gaily apply the application of this opinion to Mr. Edwards's work on "Our Domestic Fire-places," which, although it may answer the purpose of an ordinary trade-book, belongs to a higher order of things. Thus Mr. Edwards has not confined himself to a scale of prizes upon the particular grades manufactured by his own firm, but has fairly weighed the merits of many that are patented by their inventors, and are therefore inaccessible to him as a source of profit. He gives a chronological account of the improvements made in fire-places in modern times, and particularly of the various contrivances that have been introduced to render fires smokeless,—the simple device known as "the Builder's fire" among others;—and beyond this, makes several useful recommendations, to the most striking of which we shall refer. Seventy-four illustrations of different forms of fire-places assist the reader very materially. And a supplementary chapter on the Patent law brings up the rear somewhat lamely, as a foreign contingent is apt to do.

Some of the principal fire-plate manufacturers have been required so frequently to remove old-fashioned fire-places and fire-dogs from country seats, when quaint collections accumulating in spare ware-rooms. A selection from these would be very curious. But Mr. Edwards takes up his subject at the period when the had draught of the wide chimney-openings then in use, and the great waste of fuel they entailed, attracted the attention of Count Rumford. He remarks that exceedingly little progress has been made in the method of warming apartments by open fires since the Count published his essay, towards the close of the last century. The cause of this stagnation he attributes to two circumstances. In the first place, to the fact that the Count has had no successor of equal influence in the public; and, in the second, to the circumstance that builders deal principally with the great empiricisms in Thames-street, who do not enter into details or trouble themselves about improvements, but continue to manufacture what they find to be saleable articles. The efforts of Count Rumford to improve our comforts should be gratefully acknowledged, if it were only for the single suggestion to use firebricks for the backs and sides of our fire-places instead of metal; but he has a

\* See the London Quarterly Review for 1858, and the Practical Mechanic's Journal for 1850 and 1851.

\* Our Domestic Fire-places; a Treatise on the economical Use of Fuel and the Prevention of Smoke. With Observations on the Patent Laws. By Frederick Edwards, jun. Second edition. London: Robert Hardwicke, 152, Piccadilly, 1863.

further claim upon us, which, perhaps, the next generation may allow; for Mr. Edwards believes that his *Rooster* for the use of the poor, which is an admirable contrivance, in which economy of fuel is practised to a very great extent, is likely yet to become a favourite with the industrial classes. We think of the Medes and Persians when we consider that the hundreds of thousands of grates distributed from Thames-street are all made of metal, and that their manufacturers altogether ignore the great economy and comfort of firebrick backs and sides, and the propriety or advantage of adapting the width of the bars to the size of the coals in general use. Many of our readers will, doubtless, remember that Count Rumford declared that metal of any kind is the very worst material it is possible to employ in the construction of fire-places; and that fire-stone and common bricks and mortar were the very best that he had been able to discover. In reality, the next best metal registers now so generally inserted in every room in the rows of small houses growing up like garden-stuff upon the sites of suburban fields and market-gardens, are in fact monsters of extravagance. Mr. Edwards suggests that district surveyors should be empowered to condemn such grates whenever they find them in new houses!

Sylvester's patent introduced a new idea. The fire was placed nearly on a level with the floor, and each bar of the grate extended some distance into the room, so that it might conduct the heat there. King's patent and Stephens's patent next appealed to the public; they embraced the principle of directing the smoke to escape through an aperture at the back of the grate, and differed chiefly, from one another, in the mode of regulating the draught. Messrs. George Wright & Co. hold a patent which is also modelled on this construction, with the addition that the whole of the recessed arch extending from the point of junction with the front of the fireplace to the back is suspended on a hinge in addition to the door used in the former patents, so that the opening into the chimney can be enlarged at pleasure. Another novelty works out the principle enunciated by Cardinal de Polignac 150 years ago. It presents a chamber behind communicating with the external atmosphere, which, after being heated by its contact with the back of the grate, is admitted into the room through ornamental apertures in front. Mr. William Pierce made a great advance when he invented a little grate composed entirely of fire-lamp except the bars. The grand problem, however, with regard to the domestic fire-place is the same as that over which furnace-builders ponder,—how can the fire be made to consume its own smoke? This has been endeavoured to be accomplished in various ways. Altogether forty-eight plans have been proposed to effect this piece of economy. These Mr. Edwards has divided as follows:—

1. Rotating grates the first of which was invented by the American Dr. Franklin, and for which ten different patents have been taken out.
2. The use of a chamber contiguous to the fire, from which fuel can be introduced below or behind the burning fuel when required. (Six patentees have adopted this principle.)
3. The use of a contrivance, not forming part of the grate itself, to introduce coal at any time below the fire.
4. The use of a double fire. The fresh coal being introduced into the lower division is supposed to get its smoke consumed in the upper one.

5. For the prevention of smoke by a downward current for the products of combustion. (The first grate aiming at this result was constructed in 1680, and exhibited at St. Germain, near Paris.)

6. The use of a chamber to contain coal for a day's supply, a fire being made on the top of the fuel, which burns gradually away as it is exposed to the action of the air.

The grates, the use of which Mr. Taylor advocated in a paper printed in these columns, falls under the fifth of these divisions. Mr. Edwards, who deprecates the supposition of rivalry, finds several objections to them. It will be remembered that Mr. Taylor has two modes of dealing with the products of combustion. In the above the grate, and to pass off by separate channels to the chamber under the fire bars, and then to unite in an ascending flue into the chimney; in the other the heated products are carried down a single flue behind the grate, and are then intended to divide, and to pass by two ascending flues into the chimney. Mr. Edwards

states that the first of these suggestions is a very unfortunate one, as it affords indubitable evidence of the scheme having been devised without practice or experiment; for no person familiar with the working of flues could have proposed to carry off the products of combustion from a register grate by opposite descending currents of air. The single or descending flue he considers a happier thought. In this, he says, "the products of combustion are carried off as they should be in the same direction as that from which the air enters; but it must be remarked that after passing from the descending flue into the space below the fire-bars, they would scarcely ever be known to separate, as Mr. Taylor would lead us to suppose, but would pass at once to that flue in which the ascending current happened to be the strongest, which current would become thereby accelerated." It is our author's opinion, however, that descending flues are only applicable to a very limited number of cases; and that it would be utterly absurd to apply a grate with such an obstruction into an opening which communicated with a short chimney. He doubts, too, whether the smoke is consumed even in an otherwise successful application of Mr. Taylor's grate:—

"How is it possible for smoke to be consumed in passing at a short distance below the bottom bars of the grate? When and how does Mr. Taylor make oxygen combine with the hydrogen and carbon of the smoke so as to decompose the smoke? The space under the bars is simply a chamber which is by no means highly heated. There is no flame there whatever; for irrespective of the fact that under ordinary circumstances there could be no downward current between the bars, we must consider that coal in a full state of ignition, as coal generally is at the bottom of a grate, has lost most of its hydrogen, and is therefore flameless."

Dr. Arnott's popular grate belongs to the sixth division of inventions aiming at the consumption of smoke. It was based upon the patent of Mr. John Cutler, the principal feature in which was a movable bottom, made to rise or fall by means of chains and wheels worked by a handle. When lighted in the morning the bottom was to be lowered, the chamber filled with coal, and a wanted all that was required was to raise the bottom by winding up the chains attached to it. This plan was patented in 1815. Thirty years afterwards Mr. George Tillot took out a patent for an improvement upon this device. He added a contrivance by which fresh fuel could be put into the bottom chamber when the supply was exhausted. He made a little recess at the top of the grate, into which the remains of the ignited fuel and the front fire-bars could be pushed while the process of lowering the bottom and refilling the chamber went on. When this was accomplished, the fire-bars were restored to their place, and the ignited fuel drawn forward on to the top of the fresh supply. Mr. Tillot proposed also to raise the bottom of the chamber by springs. Eight years later Dr. Arnott stepped into the arena with an additional contrivance and some simplifications. He provided a similar chamber for the fuel, but made a point of preventing air entering it, and provided the effective instrument, the lever, as the means of raising the movable bottom. The upper part of his fire-place he contracted into a metal hood, in which he placed a damper, to regulate the draught. Two firms manufactured the doctor's invention,—that of which Mr. Edwards is a member, and the Messrs. Bailey.

Dr. Arnott may be said to have been the successor of Count Rumford as a reformer of the fireside. He read a paper upon the subject of his improvement to the Society of Arts, in 1854, which was very well received. *The Times* and *Quarterly Review* approved of the new suggestions; and orders began to flow in. Mr. Edwards does not state the number manufactured by the Messrs. Bailey, which, by the-by, presented some small differences in the details from those despatched to the present Archdeacon of Dorset, in 1854, to the end of the year 1863, Messrs. Edwards had supplied 2,617. The advantages expected from the mode in which the fuel was treated were, that there would be no smoke after the coal was properly ignited, and scarcely any soot; that the fire, and, consequently, the heat of the room, could be maintained at a certain point with less variation; and that it could be left from five to eight hours without attention. To ascertain whether these results were actually obtained, Mr. Edwards took the trouble to address circulars to about 650 persons to whom his firm had supplied these grates, omitting wholesale houses dealing in grates, exporters, and builders, as they were not expected to have used them.

156 persons replied. Of these, 83 wrote favourably of them, and raised no objection; 30 wrote favourably, but mentioned certain objections; 21 passed neutral opinions; and 22 condemned them.

The pith of Mr. Edwards's experience is to be found in his deductions and recommendations. Allowing that our insular traditions are not likely to be superseded by the acceptance of any other mode of heating our habitations than open fires, and that our latitude and longitude require that the majority of these should burn from eight to sixteen hours a day for, at least, seven or eight months of the year, he compresses into seven heads, the gist of the national requirement. 1. What is the best form for a grate? 2. Of what materials should it be composed? 3. What should be the general arrangements of the fire receptacle? 4. What provision should be made for checking the escape of the heated air? 5. How should air be supplied to the fire? 6. How are the heated products escaping into the chimney to be utilized? 7. How should coal be supplied to the fire? With regard to form, the grates that are provided with sloping surfaces from the fire-bricks to the metal fronts, radiate or reflect, according to their material, the most heat. The square forms exposed to the most heated surface, and are on that account to be preferred to the more popular circular form. On the subject of materials, Mr. Edwards says,—“It is much to be desired that the use of tiles in a fireplace should become very largely extended, for few persons have an idea how cheerfully, elegantly, cheaply, and usefully their fireplaces can be arranged with the aid of a few tiles, some fire-bricks, and a little ironwork, instead of the usual chesses black grate.” The most economical receptacles for the fuel is that of a dish-shaped fire-brick below the fire, and fire-brick back and sides extending to the chimney-opening. A few small holes are perforated, tapering downwards, at the bottom of these fire-brick basins for the purpose of allowing a little air to enter the fire on certain occasions. (Should, however, the fire be lighted from the top, as in the *Builder's* fire, these holes might be dispensed with.) Our author makes a useful suggestion when he insists that every ordinary register stove should be fitted with the means of regulating the size of the opening into the chimney. As most of them are already provided with racks on which their doors can recline at any angle, all that is wanted is a communication from the outside with the door. There should be a handle outside the fireplace, by which any one could adjust the door without soiling their hands. When he comes to the question of supply of air, the author admits that in a common way there is too large a supply of it from below the grate, and that the sheet of iron over the bottom, prescribed by the *Builder*, is one of the best antidotes to the waste arising from a too rapid combustion that can be devised. He thinks, however, that an ash-pan in the same place would answer the same purpose and do double duty. Although it may be against the manufacturing interest to recommend so simple and costless a contrivance, Mr. Edwards candidly admits that the mode we have so frequently advocated is very efficacious and economical,—that “it will burn with great steadiness, give considerable heat, and require no attention.” After this recommendation, we find him poaching upon our manor, counting probably upon not being ordered off on the ground of extending the utility he acknowledges our plan to possess. He says that the system can be so elaborated that the fire need not be replenished for a whole day. This is to be done by making an extra depth for the bottom layers of coal by means of an extra bar or two added to the top; and to provide against the ignition of the mass a sheet of iron is to be suspended by two hooks before the lower bars. A still more elaborate method, makes this metal cover or air excluder to the lower front of the fire, to be suspended by chains in grooves, at each side of the grate, instead of merely hooking on to the bars or fitting on to hooks projecting from the sides. Mr. Edwards says, assuming that the objection advanced to Dr. Arnott's plan of want of simplicity is disposed of by the above propositions, that “the cover or blind to shield the coal can be as ornamental as any one can wish; the fire-bars can be substituted by ornamental lattice-work of the required depth, and a polished steel ash-pan, such as is used to an ordinary grate, can improve the appearance of the hearth and receive any fine dust falling in front.” We must sum up these elaborations by repeating that our recommendation of this mode of dealing with a fire is based upon its economy, cleanliness,

readiness, and efficacy, more than upon its capabilities for ornamentation.

Mr. Edwards finds a great many faults with the Patent Laws, and, as we have indicated, devotes a long chapter to their blemishes. He first stumbled upon his grievance in visiting the library of the Patent Office in Southampton-buildings, for the purpose of ascertaining the merits of any suggestions for improvements in grates which might have been patented but not brought into public notice. It was certainly an aggravating circumstance that for one patent, or application for protection by patent, of which he had heard, there were not less than ten that were new to him; and, perhaps, still more so, that the atmosphere of the library,—or, as he names it, *the long passage*, in which his investigations were conducted, was such that, though the fortunate possessor of an excellent constitution, he was unable to remain in it for two hours without discomfort; but these facts scarcely warrant the opinion he has formed of the working of the Patent Laws. But, although we do not agree with his extreme views, we can admire the continuance of purpose that prompted him to examine three hundred of the specifications relating to grates, and appreciate the industry with which he collected every particle of information relating to his subject that was of value. The total number of patents connected with fire-places, stoves, &c., down to 1852, when the Patent Law Amendment Act came into operation, was 169; the number of patents, or of cases of provisional protection only, from that date till the last day of December, 1863, was 348, making a total of 517. The year 1862 was the most prolific in that period; as many as thirty-five applications for the various terms of protection having been made for new ideas connected with the improvement of our fireplaces. In the following year they fell to thirty-one. Mr. Edwards made a digest with a view to ascertain in how many cases patentees were able or willing to extend their period of protection. Of the 183 applications made up to the year 1857, inclusively, 63 received provisional protection only; 87 obtained powers for three years, which they did not renew; 26 obtained protection for seven years; and 7 only for the full term of fourteen years. He notes, too, as a significant fact, that the inventors of the best improvements, such as Count Rumford, Mr. Stephens, and Dr. Arnott, gave their discoveries to the public; and that, while a French nobleman and a hatter may be found among the patentees, the names of the well-known London dealers seldom or never occur. He concludes by suggesting that the system of protection by patent should be swept away, and a permanent museum of industrial art established, as a better means of bringing inventors and their suggestions before the public. Mr. Edwards is, doubtless, *great* upon fire-places; but he is lost in the Patent Offices.

One consequence of taking up the history of our fireplaces at so late a period, is the fact that we appear, upon the face of it, never to have had any other mode of heating our houses; whereas we know that, during the four hundred years of the Roman occupation, buildings were warmed by hypocausts. Supply this link in the experience of man, and a new train of thought arises. The modern Italians have gradually modified the ancient Roman plan into a system of zigzagging their fires to such an extent that they serve as heating apparatus to the rooms they skirt. Is not this a rational mode of utilizing the heat we waste?

#### THE DOCKS AND WAREHOUSES AT MARSEILLES.

INSTITUTION OF CIVIL ENGINEERS.

On January 24th, Mr. John Fowler, V.P., in the chair, the paper read was "Account of the Docks and Warehouses at Marseilles," by Mr. T. Hawthorn.

It was stated that the port of Marseilles comprised five docks in actual use, and one in course of execution. The old dock, or old port as it was generally termed, constructed about the time of Louis XV., was formed out of an inlet of the sea. It was 1,100 yards in length, with a mean breadth of 120 yards, and near the entrance the depth of water was from 21 ft. to 22 ft. The dock de la Joliette, the first constructed basin of the new port, was 500 metres in length by 380 metres in width. The dock du Lazaret, which served exclusively for customs purposes, came next; and then the dock d'Arène,

succeeded by the Napoleon dock, 380 metres in length by 300 metres in width, recently completed by the State, who were at present engaged in the construction of the dock Impériale, as well as graving docks, which would be executed to the level of the quays by the Ponts et Chaussées, and then he handed over to the "C<sup>e</sup> des Docks et Entrepôts." All these basins were formed by constructing moles in the sea, a pier, or breakwater, parallel to the shore, constituting the seaward side of the enclosure. The earthwork for the moles of the Joliette and Lazaret, as well as for filling in the space upon which the magazines and warehouses were built, was taken, for the most part, from a bill immediately to the east of the docks. This bill, of nearly 100 ft. in height, might literally be said to have been thrown into the sea; two million cubic metres of "deblais" having been thus employed. The mole Arène was formed with "deblais" from the Rue Impériale, a new street cut through the old town to the level of the new town, which involved the excavation of 1,200,000 cubic metres. Previously to the filling in of the Lazaret, excavations to the depth of from 8 to 10 metres were made in some places, to remove a mass of slimy earth, that had accumulated at that part for many years, from the residue of old soap works. This earth was so impregnated with a green coloured matter, that obnoxious fumes were frequently given off, producing illness among the labourers.

In the construction of the pier and breakwater, an embankment was first formed of hard calcareous stone, mostly taken in barges from the islands opposite the port. This stone was sorted in classes thus: rubble weighing from 20 lb. to 250 lb. each piece, first class from 250 lb. to 1 ton 2 cwt. each; second class, from 1 ton 2 cwt. to 3 tons 15 cwt. each; and third class, from 3 tons 15 cwt. and upwards. The smallest material was used for the core, or hearting, of the embankment, the larger pieces being successively added. This embankment was levelled<sup>a</sup> at a height of 2 metres (6 ft. 7 in.) above low water, the surface being 7 metres in width, and the slopes having an inclination of 1½ to 1 in height. At a depth of 8 metres under low water, the width of the embankment was increased to 7-3½ metres, horizontally towards the sea, in order to receive the large concrete blocks, placed on it promiscuously to break the force of the sea. The artificial blocks had a width of 10 metres at the level of low water, and they attained a mean height of 3-8 metres above the same level. On the inside of the pier, a quay, 30 metres in width, was formed of natural blocks, with a wall in front, the latter having its foundations 6 metres below the water-line. The embankment had a slope towards the dock of 2 base to 1 in height, and as its formation progressed, it was from time to time solidified, by placing on it artificial blocks, in tiers one above another, by means of a floating crane, or derrick. These blocks were generally allowed to remain about three months.

It having been ascertained by experiment, that blocks weighing 20 tons each, and measuring 10 cubic metres, could not be moved by the most violent sea in the Mediterranean, artificial blocks of concrete were made of an average weight of 23 tons; their dimensions being 2-4 metres long, by 2 metres wide, and 1-5 metre deep. These blocks were composed of two parts of hard, broken limestone, to one part of cement; the cement consisting of five parts of sand to one of lime. These materials were mixed in portable iron cylinders, made to rotate by means of a belt connected at pleasure with a steam-engine, which also drove the stones for mixing the cement. After the concrete had been well worked, the mixture in the cylinders was emptied into wooden moulds, which could be detached from the blocks. The moulds were so constructed as to form a groove at each end of the blocks, for facilitating the lifting and setting of them. The contents of each cylinder were beaten down by two men, an operation which occupied half a day for each block. The moulds were allowed to remain for at least three days before the cases were removed; but the blocks were not considered to have attained sufficient solidity and hardness, for those that were to be thrown promiscuously into the sea until after a lapse of three months, and for those that were to be employed in forming the foundations of the piers and quays until after a period of six months. The blocks attained, in course of time, a hard-

ness almost equal to that of stone; those first used, about sixteen years back, being very little worn by the action of the waves. The cost of the blocks was 12s. 8d. per cubic metre, or, including setting and other incidental expenses, 15s. 10d. per cubic metre. The entire cost of the breakwater had amounted to from 2901. to 3101. per lineal metre.

In the construction of the quay-walls of the docks Lazaret, Arène, and Napoleon, the system of building on artificial blocks, somewhat similar to the inside of the pier, was adopted. At 6 metres under the level of low water an embankment was formed of second and third class stones, having a base of from 8 to 9 metres in width, and an inclination at the sides of 1 to 2. Upon this embankment, and up to the level of the water, four rows of artificial blocks were placed longitudinally side by side, making a total height of 6 metres, with a width on the top of 3-4 metres. Two rows of blocks were usually placed on these to consolidate the embankment, and were allowed to remain for about six months. When they were removed, a masonry wall was built up to the level of the quay. At the back of this wall there were other artificial blocks, from the upper side of which a further embankment of stones was formed, having an inclination of 1 to 2. The quays of the Arène and Napoleon docks were 2-4 metres, and those of the Lazaret dock 3-4 metres, above the water-line. In several places the embankment beneath the artificial blocks had moved, generally slipping forward, and causing the artificial blocks, as well as the quay walls resting on them, to incline over towards the dock. This usually arose from an insufficient time having been allowed for consolidation, and most frequently occurred in the quays or the moles, where it had caused some of the walls to yield. Owing to the instability of the quay walls, and from the nature of the embankment behind them, the quay cranes simply rested on platforms of heavy timbers, which had sufficient base to insure stability during the "slewing" of the jibs. The entire length of the quays, at present constructed, belonging to the Dock Company, was 2,840 metres. The cost of the quays above the embankment, that was of the quay walls with the artificial blocks supporting them, was 241. per lineal metre.

Sheds 14 and 10 metres in width, extended completely round the dock du Lazaret. These sheds were covered with a simple roofing of double T iron, the rafters for supporting the tiles being also of iron, of an A section. The sides towards the dock was closed by sliding or rolling doors of corrugated zinc, the roof resting on this side on cast-iron columns, and on the other on the walls of the magazines. These magazines were of one story only at present, and were constructed of rubble masonry, with dressed piers and quoins, and wrought-iron roofing, with vaults in brickwork. The amount of covered space, including the floors, was 67,132 square metres. The flooring for all the magazines and sheds was composed of a layer of asphalt half an inch in thickness, costing 2 francs per square metre; but including the levelling of the ground and the bed of cement below, the cost was about 6 francs per square metre.

The bonded warehouses, or "entrepôt commercial," formed one block of buildings, to which were attached the company's offices. Two lines of railway, and a public thoroughfare which ran parallel to it, separated these buildings from the Dock du Lazaret. On the east side were the sheds from the Paris, Lyons, and Mediterranean Railway, a junction with this line having been made by means of an incline and a tunnel under the town. The length of these warehouses was 365 metres (1,200 ft.), with a breadth of 37-5 metres, and a height of 35-7 metres. The offices were of the same breadth, with a length of 37-6 metres. The warehouses were divided into four quarters, each containing an interior court with two doorways. There were six stories above the ground floor, with vaults below; the whole having been constructed in stone and iron, the concession requiring that all the materials should be fire-proof. The masonry was for the most part a better class of irregular rubble; but the piers, arches, quoins, windows, and ornamental work, were of dressed ashlar. The cost of the several kinds of masonry and brickwork per cubic metre was, hard limestone dressed and built in place, 41.; less hard quality, 31. 8s.; soft calcareous stone from Miramas, 21. 8s.; rubble, 12s. 6d.; and brickwork, whether of solid or of hollow bricks, 21. 8s. The thickness of the

<sup>a</sup> The level of the Mediterranean varied at Marseilles about 18 in., according to wind and other influences.

top an opening to be left, to serve as a chimney for the escape of the combustible air or gas. The reason for elevating this hold-covering so considerably is to preserve the cargo from heavy seas washing into the hold and destroying very frequently the greater portion of its contents. The office or chimney might, perhaps, be judiciously fitted with a tube, whose lowest end, or that terminating in the hold, might have a "rose" top, similar to those attached to the watering-pots used in gardening operations. Should a fire break out in the hold, a hose could be fixed to the upper end of the chimney, and a stream of water thrown down, which, by means of the "rose" top, would be spread over a larger extent of surface.

In prisons, in poor-houses or unions, and in every large public or private establishment, serviceable fire-engines should be kept, and arnateur companies or brigades organized to work them. A course of training would be physically and mentally valuable in all cases, and especially relieve the dreariness of a pauper's existence. For safety as a means of escape from fire, and indeed in all other respects, I maintain a preference for flat roofs, or, at least, but slightly inclined or sloped at each end of a roof. This should suffice to carry off the rainfall; and each end might be kept inviolate from its neighbour by means of a high and close railing. At some part of this there should be a gate, and kept conveniently locked, the key to which should be conveniently accessible. An iron ladder should be hung up or fixed against the wall at the top of a house, so as to be readily detached and available for passage through the team door, in a fire.

It has been suggested that balconies should be constructed at the first-floor windows from the second level, and at every succeeding floor upwards. This has been objected to on the ground that such a means of escape from fire might be improperly used, and also facilitate robberies. It would be easy to obviate such a possible consequence.

It occurred to the writer so long back as 1861, that a telescopic sliding principle might be usefully applied to fire-escapes. Three (or more) flights of ladder, containing one within another, might be wound up by a winch readily; or they might be folded up into several pieces or segments, and in either case be much less unhandy; and, what is still more important, they would, of course, be shortened or lengthened, so as to reach the various floors and elevations of a building.

Our greatly boasted ingenuity and invention have hitherto to have proved but pretence. Such a "Fire Annihilator" is rarely if ever employed. The Duke of Sutherland, the Earl of Athlone, and other noblemen and gentlemen, formed themselves into an association for encouraging anti-significative inventions. Great ingenuity has been shown in the production of commodities; but it would be more conducive to human happiness if at least an equal amount of mental labour were devoted to the origination of a manufacture of such matters as would extinguish fires. A "Fire Preventive Act" should be passed, compelling the attention of all connected with the construction and proprietorship of houses and buildings.

These fire-guards hitherto in use, although they vary in shape, have all been constructed on the same principle, involving the adjustment and removal of the guard in order to diminish a fire with fuel or otherwise attend to its continuance and details. This objectionable feature might be removed, and a properly preventive guard or mechanism devised which would be a fixture, and not require, consequently, the trouble of being continually fixed and unfastened.

In the building up of new houses, the hawking-weight, &c., could be enclosed in a bag on each side of, and within the brickwork, or fire-place; the sash running up a little way to the chimney. The sash should be made of iron or other metal, the guard or blind-like part being a sheet of iron, zinc, &c., perforated with numerous holes, so as to present a gauze or sieve-like texture; and thus allow the fire-heat to pass through to the room, yet protecting clothing and preventing burning coal from flying out and

may here suggest a very cheap and simple life preservative apparatus which could and should be the possession of every separate family, apartment, or temporary indweller of each house apartment. This consists in providing a stout

and moderately thick rope; yet not so thick but that it might be easily tied or affixed. It should be sufficiently long to reach from a bed-post or other heavy article, through a room window, and enough to bear the weight of any person, however heavy, who may be resident in such apartment.

The rope should be kept in one place only, and loosely coiled round a large hook or of a chair, yet not too high up for ready access by means of others, or cats, dogs, &c. to tamper and play tricks with. When needed for use, one end is to be fixed to the post of a bed or any other heavy article of furniture, or even it might be longer and fastened to the room door, by running it through the key-hole and tying it to the edge of the door; the latter being locked would offer a strong resistance to the weight of a descending human body. If the bedstead or other article had posts or projections, a loop or a slip knot might be made, and so being fixed thereto it would obviate any delay from tying it up when a fire happened. A simple contrivance like this would save many lives, if not every life endangered.

For the better protection of firemen, there should be an improvement upon the present helmet or head-covering. At present, the men incur the dangerous possibility of being scorched and injured in the face, and are hindered thereby from rendering greater service than is now possible from their exposure to flame and fire. It is proposed, therefore, that the helmet be made somewhat after the style of the ancient ones worn by soldiers in the days when armour was in use. This is to be provided with glass, or, better still, mica, in the openings for the eyes to see through, and corresponding apertures for the nose and mouth.

Fire brigades attached to each "volunteer" regiment might prove valuable auxiliaries. The system of organization adopted by the firemen companies in New York and in Australia, might probably be reproduced here with advantage, though these would perhaps require modification, to suit with English habits and character.

It has been suggested in the *Builder* to use alum for the suppression of fires. This chemical is a powerful non-conductor of heat, cheap, and readily obtained. At a moderate heat it dissolves, and liberates its water of crystallization in the shape of vapour. Although only recommended to be employed in large buildings, filling in iron hollow cellular houses, joists, &c. It might be beneficially used in all houses and buildings, however small, and where no iron-work is at present made subservient. Between the floor and ceiling of each succeeding room, and between each room and house wall—space being left for the purpose—alum might be filled in, either in a powdered state or in blocks of a suitable size. W. M. M.

OXFORD NEW WORKHOUSE.

The designs for the new workhouse for Oxford were obtained, it will be remembered, in a competition open only to architects residing in Oxford. The accommodation required was for 300 inmates. The building is now completed, with certain exceptions to be mentioned, and is set forth by the accompanying engravings. The foundation-stone was laid on the 6th of April, 1863. The site consists of about 12 acres of clay soil, on the north side of the Cowley-road, and was purchased for about 2,800. The building is of red and white brick, with dressings of Bath stone. Its base being about 20 ft. above the level of the road, it forms a conspicuous object from many directions. It consists of three principal ranges or blocks, parallel to each other, approached by a wide road which leads to the front of the house. The centre portion of the front range of buildings comprises two stories, with entrance archway, surmounted by a bell-cote. This portion is allotted to the porter's day and bed rooms, clerk's and committee rooms; and the other portions of the range, forming wings on either side, contain a board-room and dispensary. Beyond these are the receiving wards and tramp wards for both sexes, with separate entrances to each from without, and also private entrances from within, for the use of the officials. Passing through the great archway, in a straight line, at a distance of 120 ft., is the main building, 258 ft. by 44 ft., forming the northern side of the quadrangle. It has a central corridor extending the whole

length of the building, with a large and lofty hall in the centre, over which is a tower, 90 ft. in height to the vane, serving the purposes of a staircase for the use of the master and matron and of a ventilating shaft. The building is divided into separate day-rooms and dormitories for the several classes of inmates, each class being kept quite distinct, having its own staircase, lavatories, and yards. The aged of both sexes occupy the front, and the able-bodied the back, where yards are already formed, and workshops, laundries, &c., erected.

The kitchen, offices, and dining-hall are at the back of the main building, being approached by well-arranged separate covered ways.

The infirmary, which is not yet commenced, will be at the back of the whole on the higher ground, with the nurses' rooms for each class, the fever wards being on the third story, with separate staircases from the back. The chapel, which is also not begun, will be of a cruciform shape, inclosed by iron railings, and detached from the workhouse.

The staircases in the building are of York stone, and all the internal walls are of brick-work. The dormitories are 12 ft. in height. Bath stone has been used for cornices, brackets, and tabling. The apartments are warmed with hot-water pipes, fireplaces however being provided, and the cooking is also performed by steam. An attempt was made to procure water on the spot, but without much success, and an arrangement was consequently made with the trustees of the City Water Works to lay a main to the cistern. The guardians obtained authority from the Poor Law Board to effect a loan of 9,000*l.*, repayable by instalments, to meet the cost of the site and building, and the contract was taken by Mr. Curtis for 6,000*l.*, besides extra items, making a total of 7,150*l.* Up to the present time the expenditure has been 8,939*l.*, independently of several payments which will fall due, and of the chapel and infirmary, which have yet to be erected. An extra levy of 6*l.* in the pound has been necessary this quarter, mainly on account of the roads, fittings, &c., which cannot legally be charged on the loan; but the old site of 51 acres having been disposed of for upwards of 8,000*l.*, the permanent burden on the city caused by the new house will not be large. The architect was Mr. W. Fisher, of Oxford; and the clerk of works was Mr. John Castle.

MANCHESTER ALBERT MEMORIAL.—The Manchester City News is asking what has become of the Prince Consort's statue with which that city was to be endowed, or what binds its erection?

OXFORD NEW WORKHOUSE.— Ground Plan.

OXFORD NEW WORKHOUSE.—MR. W. FISHER, ARCHTCT.

## POMPEII.\*

THE subject I have chosen for my paper this evening is one which, I think, has not yet occupied the attention of the Association,—at all events, during my recollection; and I esteem myself especially fortunate in having the opportunity of so doing, because I remember that I looked forward to no portion of my route in Italy with greater interest than that which should include Pompeii and Herculaneum. And I am inclined to believe that the same feeling influences us all; and that, not only with a view to any practical hints in architecture or decoration which one might derive from it, as from the simple fact of being able to visit a city hidden from the sight of man for nearly seventeen centuries, and exhumed,—as it were, restored almost to its original state, in all its pristine beauty of form and colour. It seemed almost a dream or fairy-tale to imagine that we could wander through the same streets, look upon the same temples and monuments, enter the same doorways, and tread on the pavement of the same houses, as those who had lived 1,800 years ago; and that all their features should be in the same condition as they were then. Generally the discovery of a wall, a gateway, tower, or temple, is looked upon with thrilling interest, and many are the learned dissertations as to their origin or original use. Here, in England, the finding of some ruin (now devastated by time and age, though still more by the destructive hand of man) constitutes one of the greatest pleasures that can be afforded us; and should its date remont back five or six centuries, it is looked upon with the greatest respect, when we remember the length of time that has elapsed since the stones composing it were quarried, carved, and placed in their respective positions; and be it uncouth in the extreme, its age renders it sacred in our eyes, and we regard it with veneration, if not with admiration. What, then, shall we say when we are able to look at buildings—may, a whole city—bearing no traces of modern restoration and beautifying, not the unweath'ered works of a barbaric age, but of a people far more elevated in the artistic scale than we are even at the present day,—with a greater instinctive knowledge of form and colour, and with a greater power of displaying it in the different materials in which they worked?

Being the first time that this subject has been brought before the Association, I shall do right, I think, to give you a general description of the city and the chief characteristics of its architecture, decoration, and paintings, reserving special accounts of newly-excavated portions for some future occasion, when, after visiting the ruins a second time, I shall be better able to do so.

The ancient town of Pompeii was situated on the volcanic rocks of the Campania; its south and west walls washed by the sea; its east wall bounded by the river Sarno, which was then navigable for a short distance above its mouth. Though Seneca mentions it as a celebrated city, little is known about its early history. Its origin is generally ascribed to the Oscans, and its name is supposed to have been derived from the Greek word *πομπαια*, signifying "storehouses."

From its great richness, the country seems to have had the peculiar property of enervating those who settled there, rendering them an easy prey to invaders, who, enervated in their turn, gave place to some sterner enemy. Hence it was possessed successively by the Oscans, the Ausones (both these of Pelasgic extraction), the Campanians (or Etruscans), Samnites, and Campanians; these latter, in a second attack by the Samnites, threw themselves under the protection of Rome, about 360 B.C., and then sank down into one of the dependencies of that empire. About 91 B.C. they revolted, and then a colony was sent down from Rome to cultivate their territory and keep them in complete obedience.

In A.D. 63 a violent earthquake shook the city to its foundation, causing it to be almost abandoned for some months, at the end of which time the inhabitants gradually reappeared, and set to work to repair the damages done and rebuild the shattered edifices.

In A.D. 79 the great eruption occurred which covered Pompeii with showers of ashes and scoriae, hiding it from sight, and thus preserving the greater portion of it more or less complete for our study and admiration. Herculaneum, situated at the foot of the mountain, was covered also with ashes and scoriae; but the vast

volumes of steam sent up by the volcano caused the deposit of these ashes in a liquid state, which solidifying, became as hard and compact as lava; so that the excavations of this latter town are more difficult to make, especially as subsequent eruptions have gradually poured their lava over the town, which is now found at a depth of 75 ft. below the present surface of the ground. These subsequent eruptions have been almost the cause of Pompeii's remaining more or less intact; for the inhabitants returned again after the burial of their city to search for its treasures; and would probably have settled there up to this present day (as at Portici and Resina, built over Herculaneum, after each successive eruption). As many as eight successive layers, some of lava, have been counted over Pompeii, and it is only the lower one, which first buried the town, that has been disturbed. This accounts for the fact that so few articles of intrinsic value, such as jewels and money, have been preserved. Pompeii remained buried for nearly seventeen centuries, and it is singular that Domenico Fontana, a celebrated architect, who in 1592 was employed to bring the water of the Sarno across the city to the town of Torre dell'Annunziata, and who in the course of the work most often had to encounter the foundations of ancient buildings, should not have had his curiosity awakened as to their origin; in fact, the city was entirely lost till 1748, when a countryman sinking a well discovered a painted chamber, with statues and other objects of antiquity. This brought the attention to it of the king, Charles III., and in 1755 the works of excavation commenced, which have continued up to the present time, more or less slowly; so that after a lapse of 120 years, probably not more than one-third of the city has been excavated.

Before the laying down of the railway, the visitor generally entered Pompeii by the street of tombs; and a more fitting entry to the desolate and empty city could not be well afforded. The street rises as it approaches the walls, and is lined on each side by a series of tombs, some of great magnificence, it being a Roman custom to bury the dead not in cemeteries or spaces set apart for that purpose, but along the principal and most frequented roads leading from the town: thus the Via Appia, at Rome, is fringed on either side with tombs, for upwards of 13 miles away from the city. The Romans, as you are aware, buried their dead, and then, collecting the ashes, placed them in small jars, or urns (the origin of those delightful features in our modern churches and cemeteries); these were deposited in vaults, in the walls of which were small niches resembling pigeon-holes, for which these vaults have acquired the name of columbaria. The tombs consist for the most part of a small altar, either square, oblong, or circular in plan, raised on two or three steps, the whole carried by a pedestal or podium (in the interior of which was the vaulted chamber), and a small inclosure with low wall around.

The upper portion, or altar, of these tombs, was generally in white marble, with bas-reliefs and inscriptions on them recording the virtues and exploits of those buried beneath. The podium was in masonry, ornamented with stucco decorations, and sometimes painted. Near the city gate are some tombs of larger size, one of the Priestess Mamma, built in stuccoed masonry adorned with columns, the walls of the interior covered with arabesque work: two large exedra or semicircular seats in stone, and a hemicycle or large niche very richly decorated, are still in very good preservation. In this street of tombs are also one or two villas or suburban residences; of one of which, "the Villa of Diomedes," I shall have a word to say farther on.

The walls surrounding the town have been traced throughout their whole extent, so that the size of the city is known. They are not more than two miles in length; and the space enclosed, about 160 acres, is of the form of an egg, at the apex or smaller end of which is the amphitheatre. The walls were of great solidity and width. They had a double parapet and terrace, the latter about 14 ft. wide, sufficient to admit of two chariots passing abreast. It was carried by two walls, the outer one with a slight batter, 25 ft. in height, the inner wall about 40 ft., and occasional flights of steps on the city side to admit of easy access on to the terraces. The walls are built of large blocks of volcanic tufa and travertine in horizontal courses with inclined joints; and on some of the stones are found Oscan inscriptions, so that these date probably from the foundation of the city. Square

towers are placed at intervals along the walls. The battlements seem to be of later date, being built in that kind of work called *Opus incertum*, the milite work of the ancients.

There are eight entrance-gates to the city, five of which are mere ruins; of the three others, the gate of Herculaneum, through which we enter from the street of tombs, is the most perfect. It is in Roman architecture, built in alternate courses of brick and lava, and consists of a central archway, 11 ft. 6 in. wide, and two side ones for foot-passengers, 4 ft. 6 in. wide each, these latter vaulted throughout their whole length. The central passage, of which the arch is gone, seems to have had an open space in the centre, so that the enemy who had already forced the portcullis might be attacked from above whilst endeavouring to force the second door which swung on pivots. The height of the arch is calculated at 20 ft.

Outside the gate was a niched tomb, long taken for a sentry-box, from the fact that the skeleton of a soldier, in the usual accoutrement and arms, grasping a lance, was found in it, instanced as a proof of the excellent and praiseworthy fidelity of the Roman soldier, who remained faithful to his duty to the last.

The streets are for the most part straight, and run at right angles to one another. They are not wide, many of them not admitting of the passage of more than one chariot at a time; and probably these were not much used, taking into account the small extent of the city (only three-quarters of a mile in length, and half-a-mile in width), though the deeply-worn ruts in the stones would seem to indicate the contrary.

The roadway is composed of huge polygonal masses of lava, from 9 in. to 18 in. in diameter, and 9 in. in depth, closely fitted together. The stones were worked in a wedge shape, so that they spanned the roadway like a vault, each stone resembling the voussoir of an arch. All the streets have pavements for foot-passengers, even those where chariots could not pass, consisting of curbs-stones of lava, with the pavement composed of bits of marble and stone, set in cement, the whole rubbed flat. In places where the curb-stones have broken away, they have been cramped together with iron. These foot-pavements are elevated sometimes more than a foot above the roadway. It is supposed that the latter, in times of rain (which falls very heavily in those countries), became a kind of sewer, as all the streets are slightly inclined one way or the other; and this supposition seems well founded, because there exist everywhere huge stepping-stones from pavement to pavement, the wheels of the carriages and the horses (always two) passing on either side of the stone. The way in which the solid refuse of the city was carried away is still a mystery, scarcely any traces of sewers having been found. Mazois gives us a drawing of one, the position of which he does not state; but it seems only to have served to carry the waters from the street under the walls to outside the town. It is just possible that the streets may have been the only sewers, as they are still in some towns in the East.

Though traces of aqueducts are found in the country around, it is not known with any great certainty from whence Pompeii was so plentifully supplied with water, there being no wells.\* A very large number of leaden and earthenware pipes have been found, the former of which supplied the numerous fountains which were placed in all the principal streets. They consisted of a cistern, formed of blocks of lava, cramped together with iron, the water falling into them through a pipe fixed in one of the haek stones of the cistern, which rises higher than the rest.

## Public Buildings.

The public edifices and monuments of Pompeii give more direct information as to its history than might else. The more ancient are essentially Greek, both in plan of building and style; the later edifices show the influence of Roman customs and habits, though always preserving a certain Greek feeling.

In a description of a Roman city, the Forum is the first place to which we should direct our attention, as the centre of business, the resort for pleasure, and the scene of all political and local contention.

The Forum is the largest and most imposing spot in Pompeii, measuring 500 ft. in length, and 150 ft. in width. It was surrounded on three sides by a portico of Doric columns, set

\* Read by Mr. R. Phéné Spiers, before the Architectural Association, January 20th.

\* One deep well has been recently discovered, with good potable water in it.—Ed.

wider apart than usual, so that stones could not be depended upon to span the distance between them; and accordingly wooden beams were used, on which rested the stone entablature; in the back of which holes were cut to receive the ends of joists of a gallery, which extended over the portico round the Forum. Several pedestals of masonry, deprived of their statues and marble coatings, still exist, and some bear still the names of the distinguished inhabitants in whose honour they were erected. At the north end of the Forum is situate the Temple of Jupiter, on an elevated podium or basement, reached by steps flanked on either side by pedestals for statues. The temple has a portico of six columns in front, and three on the side. The columns are about 3 ft. 8 in. in diameter, which would give 36 ft. 8 in. for their height. In the interior of the cella on either side was a row of columns of smaller size, on which probably rested a second row, as at Pæstum, to support the roof, and a gallery, the stairs to reach which are at the further end of the temple, as also three small chambers for the priests. The painting of the interior is not remarkable: the floor is paved with mosaic.

The prisons on the right are approached by an archway in brick, formerly covered with slabs of marble. These prisons consist of dungeons without light, in which skeletons were found, with their leg-bones encircled in iron shackles or stocks.

The Temple of Venus stood in a large arena, 150 ft. by 75 ft., surrounded by a wall and portico. The columns of this portico were originally Doric, but afterwards altered into Corinthian by successive coats of stucco, an anomaly which I will explain further on. The walls of this portico were decorated with a series of paintings on a black ground, representing architectural scenes, landscapes, and figure subjects. The temple itself stood upon an elevated basement; had a portico of four columns in front, and two deep; and a prystyle round the cella, which latter was very small. There was an inscription in it, stating that "Marcus, Holconius Rufus and Caius, Ignatius Posthums, decemvirs of justice for the third time, by a decree of the Decurions, bought again the right of closing the openings for 3,000 sesterces, and took care to erect a private wall up to the roof of the incorporated Venerables;"—the proceedings of that corporation, I suppose, being of such a nature that it was wise to conceal them from the public gaze.

The Basilica, or court of justice, is the largest building in Pompeii, of an oblong form, and measures 220 ft. by 80 ft. It is entered through a vestibule, by five doorways of masonry, in which grooves have been cut for the insertion of wooden door-jambs. From the vestibule the area of the Basilica is reached by a flight of four steps, leading through principal and two side doorways. The roof was carried by a peristyle of twenty large Ionic columns, built in brick and tufa, covered with stucco. The centre was probably open to the sky. At the further end of the building, on each side, are two square chalcidiea; in the centre, the tribune for the judges raised on a basement, and approached on either side by steps. It was decorated by columns, detached and semi-detached; between the latter were spaces for embayments, in which robes or records were kept. There was a gallery round the peristyle, reaching up about half the height of the Ionic columns, with a railing between them, to prevent persons falling over.

The three buildings at the south end of the Forum, opposite the Temple of Jupiter, are similar in plan; two of them are supposed to have been places of assembly for magistrates; the third is an ararium, or treasury.

The Chalcidieum, or Cryptoportico, of Eumachia is the next largest building to the Basilica; it is supposed to have been the Exchange of the cloth merchants. The interior was surrounded by a double gallery of forty-eight very beautiful columns of white marble (only one of which, broken, has been found); a chalcidieum, or enclosed apartment, at the further extremity; and a cryptoportico (a gallery in which the spaces between the columns are walled up and pierced with windows). Behind the chalcidieum was a niche, in which stood a statue of Eumachia, at whose expense the building was erected. The Temple of Mercury now serves as a museum for all those objects found in the excavations, and not taken to the museum at Naples. The House of the twelve pedestals in the centre of its court, in which it was supposed were the *Dii Consentes*, though from the numerous culinary paintings on

the north wall, and the large collection of fish-bones and other fragments of food found in the sink in the centre, it would seem more to have been devoted to banqueting than religious purposes; and, indeed, its contiguous position to the Forum would point it out as a very convenient place for a large *trattoria* or restaurant; the twelve rooms on the south side being private dining-saloons. It is a spacious building, with entrances on three of its sides, the one from the Forum decorated with columns and niches with pedestals for statues. This completes the list of the monuments round the Forum, and we may look upon them as the most important of those in Pompeii.

The triangular Forum adjoining the large theatre, in the smaller part of the town, has a portico of ninety Doric columns round two of its sides. It is entered by a propylea or vestibule, of eight Ionic columns, which, when complete, must have been one of the most beautiful features in Pompeii. The Temple of Hercules in this Forum is the most ancient building yet discovered here, its capitals, columns, and general construction resembling mere the temples of Pæstum than any of the other temples in Pompeii: from its ruined state it is difficult to define exactly its plan; it was 120 ft. by 70 ft. wide.

The great or tragic theatre is placed on the south side of a hill of tufa, in which the steps or seats are cut. It was semicircular, open to the air, and lined in every part with white marble. The seats faced the south, commanding (as in all these ancient theatres) an extensive view, so that the visitor, if tired with the performances, could at all events solace himself with the enjoyment of the fine prospect before him. The walls of this theatre were never entirely buried, and the stage was covered with so slight a deposit only, that here (as, in fact, probably in the greater part of the most southern portion of Pompeii) the decorative parts, such as marble, statues, &c., may have been easily removed after the eruption. The general audience entered the theatre by an arched corridor, on a level with the colonnade of the triangular Forum, and descended thence into the *cavea* by six flights of stairs, which divided the seats into five wedge-shaped portions or *cunei*. The space allotted to each was 1 ft. 3½ in., so that from calculation the theatre would accommodate 5,000 persons. A separate entrance and staircase led to the women's gallery, which was placed above the corridor just mentioned, and divided into compartments or boxes. It seems also that they were protected from the gaze of the audience beneath by a screen of iron wire. In the lowest portions of the theatre, with special entrances, and separated by a low parapet or balustrade, was the *proscenium*,—what we should call the pit or orchestra stalls, reserved for the nobles, Augustales, and patricians. The level space in front of the reserved seats was destined for the magistrates, whose seats, the *isellia* in bronze, with purple cushions, were brought by their slaves. There was also some distinction made between the middle and lower classes, the latter occupying the higher range of seats, and being divided into their respective trades and occupations. The stage or *pulpitum* is a long narrow platform, with seven niches in the front of the wall which carries it, in which it is supposed the musicians were placed. The *proscenium* was decorated with columns, and niches between them for statues, with three doorways, the centre one larger than the others, and only entered by the important characters. Their scenery was very simple, either a door swinging on a centre axis or a triangle, the one having two, the other three different views represented on it, its position being in the central doorway. Behind the stage was the *postscenium*, where the actors' rooms were placed. The exterior of the upper wall round the theatre still retains the projecting stone rings for receiving the poles of the velarium or awning, which on special occasions was spread over the theatre.

The small theatre adjoining is supposed to have been used for musical performances. It is also semicircular, and similar in arrangement to the other, except that a portion of the circle is cut off on either side by walls continued from the side of the stage. The style and execution of the work are very inferior to the other, which is explained by the fact of an inscription, stating that it was built by contract. It seems to have been permanently roofed in, and accommodated 1,500 persons.

Adjoining the theatre is a large forum, surrounded by a portico of columns, supposed to

have been occupied by the soldiers, from the large amount of armour discovered. In the various rooms round these were two floors, the officers occupying the first floor. Inside one of the entrance-gates, also, were found the skeletons of thirty-four soldiers,—the guard, probably, called out on the night of the eruption. Sixty-three skeletons in all were found in the barracks,—more than in all the rest of Pompeii.

In the south-east angle of the city walls is the amphitheatre, intended for gladiatorial shows, the chase, and combat of wild beasts. It was here that the people were supposed to have been assembled when the grand eruption took place. From the number it would accommodate (16,000) and the interest taken in these shows, it was probable that more than half the inhabitants were there. From the sharpness of all its mouldings and little wear visible on the stonework, it is probable that this building was erected not long before the destruction of the city; and, from the absence of the greater part of its stone seats, that access was had to it after the eruption. Its form is elliptical, 430 ft. long by 135 ft. wide. The masonry of the walls is of the *opus incertum* kind, and also of bricks placed diagonally after the Roman fashion. The interior contained twenty-four rows of seats. There were separate entrances in different parts of the theatre, the patricians, nobles, and magistrates, as usual, occupying the lower ranges, the plebeians the upper, and the women the boxes. At each end of the ellipse were entrances into the arena, for the admission of the gladiators and wild beasts, and removal of the dead.

Various inscriptions announcing displays in the amphitheatre are found on the walls in the city: one more especially of them says that "On the occasion of the dedication of the public baths there will be a chase of wild beasts, athletic contests, sprinkling of perfumes, and an awning." The value of an awning will be easily appreciated by those who know either what the heat of an Italian sun is, or the deluge of an Italian rain. It has been a matter of some controversy how a temporary covering could be stretched over so large a space without any intermediate props. The stone rings existing on the upper portions of the exterior wall round the theatre gives me reason to suppose that they were intended to support and hold the wooden masts to which the ropes carrying the awning were attached: there must have been considerable difficulty in keeping the awning stretched sufficiently tight, and we find that on windy days it was impossible sometimes to stretch them. As to the sprinkling of perfumes, Seneca tells us that "the perfumes were disseminated by being mixed with boiling water, so that the scent rose with the steam and became diffused throughout the building." Rimmel's patent vaporizer, therefore, introduced three years ago, at the pantomimes in all the chief theatres of London, was by no means a novel idea.

The Temple of Isis is a small but interesting building, standing on a basement in the centre of a court, round which is a portico of Corinthian columns, in brick, covered with stucco, and painted. In one corner of the court is an *ædiculum* with a vaulted roof, and pediment covering the sacred well of lustral purification, to descend to which there was a narrow flight of steps. Near it was an altar, on which were found the burnt bones of victims. On the south side of the inclosure were the chambers of the priests and a kitchen. In one room a skeleton was found holding a sacrificial axe, with which he had cut his way through two walls to escape from the eruption, but perished before he could penetrate the third. In another room a skeleton was found with bones of chickens and fish, eggs, bread, wine, and a garland of flowers, as if he had been beguiling away the last moments of his life merrily. Many other skeletons were found in the inclosure, testifying to the belief in the power of their deity.

A flight of steps leads to the temple, the front of which is a portico of six Corinthian columns, with niches on either side of the entrance to the cella, the interior of which is small; the entire width of the back, occupied by a long hollow pedestal for statues, having two low doorways at the end near the secret stairs, by which the priest could enter unperceived and deliver the oracles as if they proceeded from the mouth of the goddess herself.

#### Public Baths.

Two large establishments have been found in Pompeii. They are based on a similar system to the so-called Turkish baths lately introduced

in this country, and are remarkable for their admirable distribution.

The establishment first discovered behind the Forum is divided into three portions. The first containing the furnaces and fuel; the second, the baths for men; and the third, those for women. The two sets of baths were similar in arrangement, both heated by the same furnaces, and supplied from the same reservoir. Each set had its apodyterium or disrobing-room, its frigidarium, tepidarium, and caldarium, and court with portico to the men's bath, only these latter were the largest and most rich. The apodyterium has seats of lava on either side. The clothes were hung up on pegs, the holes to hold which are still visible. The roof is vaulted in stone and rubble work, faced with stucco, and painted. It was lighted at one end by a window furnished with small panes of glass, ground, on one side, pieces of which were found on the floor. A cornice runs round the room, under which is an arabesque frieze in relief on a red and blue ground, composed of griffins, lyres, vases, dolphins, &c. A small recess at one end of this room is supposed to have been a wardrobe: at the opposite end is the entrance to the frigidarium, a room circular on plan, with a large cold-water bath in the centre, 12 ft. 10 in. in diameter, and 2 ft. 9 in. deep. The chamber is covered with a conical-shaped roof painted blue, the light admitted by a window in the side of it near the top. The walls are in stucco, painted yellow, and have four semicircular niches, in which are seats for the convenience of bathers. The cornice is decorated with has-reliefs in stucco, on a red ground, representing Cupids and warriors engaged in a chariot race. The tepidarium, or warm bath, is entered from the frigidarium. It has a barrel-vaulted ceiling stuccoed, in low relief, with figures of flying genii and other ornaments, relieved on coloured ground, in medallions and panels.

The more remarkable portion of the decoration, however, is the series of niches divided by terra-cotta figures, representing Telamones or Atlases, who support the cornice. These figures and niches are at a height of 4 ft. 6 in. from the ground. The figures are about 2 ft. in height, stand on square plinths, and are similar in form to the giants of the temple at Agrigentum, which are supposed by Mr. Cockerell to have carried the roof. The object of these figures at Pompeii was simply to ornament the divisions of the niches, which we may suppose contained either the robes or the ointments and perfumes of the bathers. A brazier for coals, and two seats, all in bronze, were found, and still remain, in this room. The windows were awkwardly contrived. We next enter the vapour-bath or caldarium: it terminates at one end with a semicircular niche, containing a marble basin or lahrum, 5 ft. in diameter: at the other end is the hot-bath, 12 ft. long and 2 ft. deep, in white marble. The ceiling is a barrel vault in brick, covered with stucco, and ornamented with a series of transverse fluting in relief. The walls are decorated with pilasters. The walls and floors in this room are hollow, to admit of the easy circulation of the hot air from the furnaces. The floors were of similar construction as those found in the Roman villas in this country, being carried by series of small pillars or piers formed of tiles, 1 ft. 5 in. in height, and about 18 in. apart. The floors are formed of tiles, held by cramps of iron, at a distance of 3 in. from the main wall, by means of small hollow pipes attached to these tiles, through which in fact the iron cramps pass. The women's baths are arranged on a similar system, being somewhat smaller and less rich in their decoration. The second establishment of baths, discovered in 1858, have a very large open court or palaestra, surrounded on three sides by a portico of fluted columns. The walls of the three sides under the portico are covered with paintings; and on the fourth side, there is decoration of a similar design, but executed in stucco relief. The baths were arranged and warmed on the same principle as the others.\*

FALL OF A FLOOR AT WESTMINSTER.

On Thursday night in last week, an accident of the most alarming character, by which nearly 100 men, women, and children were severely, and more than one fatally injured, happened at a Roman Catholic school-room, in Westminster. The Roman Catholic Chapel of St. Mary, Horseferry-road, has recently been repaired and redecored; and, in order partly to meet the

expenditures, the priests belonging to that establishment got up a prize drawing, which took place in the St. Mary's school-room, Great Peter-street. This building, which is of L shape, consists of two floors, and it was the upper one which was selected for the purpose. It was capable of accommodating some 300 or 400 people, and the place appears to have been well filled. While the prize drawing was in progress, a large beam, which supported the centre of the floor suddenly broke in towards one end, and a part of the flooring, about 20 ft. by 18 ft., gave way, precipitating those who were standing or sitting upon it to the ground beneath. After some delay and great excitement, nearly 100 persons were got out, all of whom were injured more or less. Nearly sixty cases were taken to the Westminster Hospital, and of these thirty-eight were found to be casualties which included severe cuts upon all parts of the body, contusions, and some broken arms. There were some sixteen cases of broken limbs, injury to the spine, &c. An examination of the beam, which is about 14 in. square, showed, it appears, that it was a piece of wood which ought never to have been employed to bear a great weight. It was a knotty hulk, of a particularly short cross grain, and very liable to snap, as it did. The wood was also to some extent affected by dry rot. The building was erected in 1857. The beam rested at each end about 4 in. on a set-off, and, as it seemed to us the day after the accident, when we examined the place, the ends were not pinned up. The rest of the floor is unsafe for a crowd, and should be taken down. About 500 persons were on the floor at the time of the accident.

At the Friday's meeting of the Metropolitan Board of Works, Mr. Miller, M.P., called attention to the accident, and moved that the architect be asked to report upon it. This was at once agreed to.

COMPETITIONS.

**Boston.**—The committee of the Primitive Methodist Chapel, Boston, have awarded the premium to design (for new chapel) offered by Messrs. Bellamy & Hardy, architects, Lincoln. The works are to be immediately carried out under their superintendence.  
**St. James's Church, Denton Holm, Carlisle.**—The committee of St. James's Church, Denton Holm, Carlisle, have received designs from competing architects from various parts of the country, and have awarded the first premium to Messrs. Andrews & Pepper, architects, Bradford, who are instructed to carry out the works.

PRIZES FOR ART WORKMANSHIP, SOCIETY OF ARTS.

The following is a list of the prizes awarded. The judges were Messrs. Richard Redgrave, R.A., M. D. Wyatt, and John Webb:—

1st DIVISION.

WORKS EXECUTED FROM PRESCRIBED DESIGNS.

- CLASS 1.—CARVING IN MARBLE, STONE, OR WOOD.**  
(a) *The Human Figure.*—Work executed in marble or stone, after the Boy and Dolphin cast from a chimney-piece, ascribed to Donatello. Four works sent in.—1st prize of £1. to G. T. Sherborn, 59, Posenoy-place, Millbank, S.W.; 2nd prize of 7l. 10s. to Alexander Kenmore, 43, Pancras-square, N.W.  
(b) *Ornament.*—Work executed in marble, stone, or wood, after a carved chair-back in the South Kensington Museum. One work sent in.—1st prize not awarded; 2nd prize of £1. to James Stuart, 7, Pancras-square, N.W.  
(c) *Ornament.*—Work executed in stone, after a Gothic bracket in the Architectural Museum. Three works sent in.—1st prize of 10l. to T. V. Swan, 55, Lambeth-walk, S.; 2nd prize of 5l. to John Barker, 7, Draycot-street, Sloane-square, S.W.  
(d) *Work carved in wood, after a design by Holbein.* One work sent in.—1st prize not awarded; 2nd prize of 10l. to W. H. Baylis, 69, Judd-street, W.C.  
(e) *Work carved in wood after the Head of a Harp of the period of Louis XVI.* One work sent in.—1st prize not awarded; 2nd prize of 7l. 10s. to T. E. Mayle, 17, James-street, Camberwell-new-road, S.  
(f) *Ornament.*—Work carved in wood after an Italian picture frame.—No works sent in.

CLASS 2.—REPOUSSÉ WORK IN ANY METAL.

- (a) *The Human Figure on a horse-back, after Raffaele's "Three Graces."*—Four works sent in.—1st prize not awarded; 2nd prize of 5l. to W. Holliday, 14, Naisior-street, Islington, N.  
(b) *Ornament.*—Work executed after a Flemish salver in the South Kensington Museum. Three works sent in.—1st prize of 5l. to Septimus Beresford, 29, Myddelton-street, E.C.; 2nd prize of 3l. to H. R. Batchelor, 148, St. John-street, W.C.

CLASS 3.—HAMMERED WORK, IN IRON, BRASS, OR COPPER.

*Ornament.*—Work executed after a portion of the Pediment of a Gate (German work, date about 1700), in

the South Kensington Museum. Three works sent in.—1st prize of 7l. 10s. to T. Winstanley, 10, Arthur-street, New Oxford-street, W.; 2nd prize of 5l. to J. Zobel, 139, Fenton-road, N.W.; extra prize of 2l. to W. Lethere, Lansdown Iron Works, Cheltenham.

CLASS 4.—CARVING IN IVORY.

*Human Figure in the Round.*—After an Ivory by Finimingo. Two works sent in.—No first prize awarded. Two second prizes of 10l. each awarded; one to J. W. Bentley, 29, Sherwood-street, Golden-square, W., and one to John Richards.

CLASS 5.—CHASING IN BRONZE.

- (a) *The Human Figure.*—Executed after a reduced copy of "Clytie." One work sent in.—1st prize of 10l. to T. Nichols, 4, Everilda-street, Hemingford-road, N.  
(b) *Ornament.*—Work executed after Goutier, from a cabinet in the possession of her Majesty the Queen.—Nine works sent in.—1st prize of 10l. to R. E. Barrett, 26, Harrison-street, Gray's-inn-road, W.C.; 2nd prize of 7l. 10s. to H. J. Hatfield, 16, Alfred-street, Tottenham-court-road, W.C.

CLASS 6.—ETCHING AND ENGRAVING ON METAL.—NIELLO WORK.

*Ornament.*—Work executed after arabesques by Lucas Van Leyden, 1828. Two works sent in.—1st prize of 10l. to Gilles Mackenzie, 12, Tudor-street, Sheffield. 2nd prize not awarded.

**CLASS 7.—ENAMEL PAINTING ON COPPER OR GOLD.**  
No works sent in.

CLASS 8.—PAINTING ON PORCELAIN.

- (a) *The Human Figure.* After Raffaele's "Two Children," in the cartoon of "Iguera."—Seven works sent in. No prizes awarded.  
(b) *Ornament.*—Executed after arabesques by Lucas Van Leyden, 1828. Two works sent in.—1st prize of 5l. to J. B. Evans, South-street, Mount Pleasant, Fenton, Staffordshire Potteries. No second prize awarded.

CLASS 9.—DECORATIVE PAINTING.

After an ornament, from *Cristof. R. Pandino*, near Lodi, from a drawing in the South Kensington Museum.—Two works sent in.—1st prize not awarded. 2nd prize of 3l. to John Henk, George-street, Stoke-upon-Trent.

CLASS 10.—INLAZS IN WOOD (MARQUETRY, OR BURL), IVORY OR METAL.

*Ornament.*—Executed after a specimen in the possession of the Hon. John Ashurst, Grosvenor-street, in metal.—1st prize of 5l. to E. A. Millward, 33, Little Clarendon-street, Somers-town, N.W.

CLASS 11.—CAMBRO CUTTING.

- (a) *Human Head.*—After Wagon's heads of the Queen and the Prince Consort, on the J. Archer's medal of 1851. Two works sent in.—1st prize not awarded. 2nd prize of 5l. to James Ronce, 156, King's-road, Chelsea, S.W.  
(b) *Animal.*—Work executed after Wagon's "St. George and the Dragon," on the Prince Consort's Medal.—One work sent in. No prize awarded.

CLASS 12.—ENGRAVING ON GLASS.

No works sent in.

CLASS 13.—WALL MOSAICS.

*Human Head.*—After Bertini, of Milan. General competition.—Three works sent in.—1st prize of 15l. to Samuel Cooper, Longdid-place, Hatfield, Stoke-upon-Trent. 2nd prize of 10l. to G. H. Stevens, Lambeth Glass Works, Carlisle-street, S.  
Female Competition.—One work sent in.—1st prize not awarded. 2nd prize of 10l. to Miss E. Mossop, Windmill-lane, Brentford, W.

CLASS 14.—GEM ENGRAVING.

(a) *Human Head.*—After an original in the possession of Mr. John Webb. Three works sent in.—No prizes awarded.  
(b) *Full-length figure.*—After an original in the possession of Mr. John Webb.—One work sent in. 1st prize not awarded; 2nd prize of 5l. to John Wilson, 14, Leicester-place, W.C.

CLASS 15.—DIE SINKING.

*Human Head.*—After the head of the Prince Consort, by Wagon, on the Society's medal. Five works sent in.—1st prize not awarded; 2nd prize of 5l. to John Hatchett, 5, Gloucester-terrace, Kennington-park, S.

CLASS 16.—GLASS BLOWING.

No works sent in.

CLASS 17.—BOOKBINDING AND LEATHER WORK.

*Bookbinding.*—After an Italian specimen in the South Kensington Museum.—One work sent in.—1st prize of 7l. 10s. to Louis Genth, 15, Broad-court, Bow-street, W.C.

CLASS 18.—EMBROIDERY.

No works sent in.

2nd DIVISION.

WORKS EXECUTED WITHOUT PRESCRIBED DESIGNS.

WOOD CARVING.

- (a) *Human Figure in alto or bas-relief; animals or natural foliage may be used as accessories.*—Twelve works sent in. No 1st prize awarded. 2nd prize of 15l. to Mark Rogers, 111, Beechbrook-street, S.W., for a carving, "Spring"; a child's head. 3rd prize of 10l. to James Griffiths, 9, Addison-place, York-road, S., for a carving, "A Child's Head." Extra prize of 5l. to T. W. Wallis, Louth, for a carving of a child's head, "Hope for the Future."  
(b) *Animal or Still Life. Fruit, flowers, or natural foliage may be used as accessories.*—Five works sent in.—2nd prize of 7l. 10s. to T. Wallis, Louth, for a carving of "Wagtail and Fly." 1st and 3rd prizes not awarded.  
(c) *Natural Foliage, Fruit, or Flowers, or conventional ornament in which grotesque figures or animals may form accessories, preference being given where the work is of an applied character for ordinary decorative purposes, as representing conventional value.*—Nine works sent in. No first or second prizes awarded. Two third prizes of 5l. each awarded; one to George Murray, 6, Claremont-place, Hammersmith, for a carving of a vase; and one to W. M. Holme, 10, Dean-street, Soho, W., for a tripod-stand. Extra prize of 3l. to George Lock, 26, Albert-street, Camden-town, N.W., for a carving of a vase of flowers.  
An extra prize of 5l. to Gerard Robinson, 14, Duke-street, Manchester-square, W., for carvings of the human figure in the round.

\* To be continued.

INTERNATIONAL COMPETITION: PALACE FOR THE STATES GENERAL OF THE NETHERLANDS.

The following letter speaks for itself:—

SIR,—A new palace, for the accommodation of the States General of the Netherlands, is to be built at the Hague, open to public competition of all countries.

I have been specially requested by my Government to send to you a couple of the programmes for that proposed building, with the view of making such use of it as you may think best for the information of British Architects. I have the honour to be, &c.

BARON BENTINCK,  
Minister of the Netherlands.

We have placed a copy of the programme at the Office, in York-street, where it may be consulted. We may state briefly, that the edifice is to include two Chambers,—the cost, exclusive of foundations, is not to exceed 1,000,000 of florins of the Low Countries; the author of the selected design will be entitled to a premium of 500 florins; the minister reserves the right of buying, at the sum of 1,000 florins each, any of the other designs which are distinguished by happy combinations or excellence of execution; the selected design is to be made use of as the minister thinks fit; the designs are to be sent in by the end of June.

“COMPETITIONS AND THE ALLIANCE.”

SIR,—The periodical correspondence on this subject having just appeared, I send you a copy of the circular, which I send every Saturday morning to the managers of all competitions advertised in that day's *Builder*, and any more I can hear of. If any of your readers will send me the advertisements of any others, they shall be similarly favoured. I know that the circular has done good in some cases, and hope it has in all. Trusting you will be able to find room for it, I am, Sir, &c.

J. P. PRITCHETT, Hon. Secretary to the Alliance.

“THE ARCHITECTURAL ALLIANCE,”

Embracing the following Architectural Societies:—

1. London Architectural Association.
2. Architectural Institute of Scotland.
3. Birmingham Architectural Society.
4. Bristol Society of Architects.
5. Glasgow Architectural Society.
6. Liverpool Architectural and Archaeological Society.
7. Manchester Architectural Association.
8. Northern Architectural Association.
9. Nottingham Architectural Association.

SIR,—In consequence of your advertisement asking for designs to be submitted in competition for —, I am instructed, as hon. secretary for the Architectural Alliance, to offer for your consideration the views of the Allied Societies on the subject.

Assuming that competition as an abstract principle is good, the working out of an architectural competition is so fenced round with difficulties, that the greatest care is requisite to prevent injustice to competitors on the one hand, and disappointment to promoters on the other; and, feeling sure that you wish to avoid both these evils, the Allied Architectural Societies presume that you will not object to profit by their experience in bringing the matter to a successful issue.

The chief desiderata in every competition must necessarily be—

- 1st. Clear and precise conditions and instructions for the guidance of competitors.
- 2nd. A strictly honourable adherence to such conditions and instructions both by the promoters and competitors.
- 3rd. The offer of remuneration sufficient to induce men of talent and experience to compete.
- And lastly, Provision for a competent and impartial adjudication of such remuneration.

The conditions and instructions should lay down—

A. Either the exact accommodation required and the approximate outlay intended, leaving it to the competitors to send a definite estimate; or the exact outlay intended and the approximate accommodation required, leaving it to the competitors to decide the amount of accommodation they can provide for that outlay.

If both the accommodation and outlay are fixed, the estimate is manifestly the work of the promoters, not of the competitors.

B. The drawings to be submitted should be fixed, as follows, being what are usually re-

quisite:—A plan of each floor; two sections (one longitudinal and one transverse) of each building; two elevations of each building, and perspective drawings and details, at the option of the competitors.

The plans should have the walls coloured with Indian ink, sepia, or neutral tint, with the floors coloured yellow or brown, to show whether of wood or of stone.

The sections and elevations should be either in outline, or coloured, to show the different materials proposed; no shading to be used, except flat shadows in the windows.

The perspective drawings should be either in outline, or etched in black or brown ink, or shaded with Indian ink or sepia; no colour to be used.

Detail drawings should be coloured to show the materials proposed, but no shading to be used.

All drawings to be mounted on strainers, but without frames or glass.

The scale of all drawings, except details, should be fixed at  $\frac{1}{2}$  in. to the foot, if the ground-plan will come in a sheet of paper 52 in. by 30 in.: if not, a smaller scale, to enable it to do so.

C. A plan of the site, the same or half the scale that the designs are required to be, should be furnished to competitors, together with sections, if the ground is not level.

If the required designs are for the alteration or enlargement of existing buildings, plans, elevations, and sections of such parts as are expected to work in with the new buildings should also be furnished.

D. It should be made a distinct condition, supposing our suggestion A to have been followed out, that unless a tender is received from a competent builder to execute the works for the amount of the architect's estimate, the promoters may be at liberty to abandon the design on payment of a moderate sum to the designer (say 1 per cent. upon the amount of his estimate), to cover what he may be actually out of pocket, and to proceed with the next design in order of merit; and should no tender be received at or about the amount of estimate (say within 10 per cent.), this course should be adopted.

The promoters should distinctly state that any competitor violating the conditions by sending any coloured perspective drawings, or any drawings framed or glazed, will be excluded from the competition, and his plans will be at once returned to their author—not merely that such drawing will be excluded, as it may accomplish the designer's object by creating an exalted impression of the design before it is excluded; and in all other matters the promoters should strictly adhere to the conditions, and should give competitors to understand that they will do so, which will not fail to produce an honourable response on the part of competitors.

It is manifest that when architects are asked to compete, the remuneration to the successful competitor should be more than he would receive were he commissioned to carry out the work without a competition; and also that there should be some slight acknowledgment to the next one or two designs about whose merit as compared with the one adopted there may have been a difference of opinion.

It is, therefore, clear that there should be a premium for the best design in addition to the commission for carrying out the work, and that there should be moderate second and third premiums.

But above all, the question, an answer to which decides men of ability and experience whether to compete or not, is,—Will the author of the selected design be employed to carry out his design at the usual rate of remuneration?

No matter how fair the premium, it barely remunerates the receiver of it for the expense and trouble he has been at in preparing his drawings, irrespective of the skill required for designing the building; and is, therefore, by itself, no premium, but merely moderate pay to one competitor only out of a large number for a part of the work done. Competitors look to the commission as their real remuneration, and consider the ‘premium,’ as the term implies, an extra payment for the extra trouble and anxiety of competing.

It should, therefore, be an invariable condition that the author of the selected design should be employed to carry it out at the usual rate of remuneration, should he be a person of sufficient experience to warrant the promoters in entrusting the work to him.

The proper award of the premiums is the most difficult question connected with competitions;

but its paramount importance demands that an attempt should be made to grapple with it.

In competitions for small works the selection must necessarily rest with the promoters, who should appoint a sub-committee to select and report to the general body.

In works involving an outlay of 2,000l. and upwards, it seems desirable to secure a more experienced tribunal than a committee afford; that is to say, to refer the matter to one or two architects of admitted experience, honour, and discretion.

The award of the adjudicator, whether appointed as above suggested or otherwise, to be final and conclusive.

Hoping you will find these suggestions of service to you, I am, Sir, &c.

J. Condit-street, Hanover-square,  
London, W.”

THE ARCHITECTURAL ASSOCIATION.

THE usual meeting of the Association was held on Friday evening (the 20th ult.), at the House, in Condit-street. The chair was occupied by the president, Mr. J. H. Christian.

Mr. Edward J. Lowther, of High-street, Stoke Newington, and Mr. R. S. Wilkinson, of Weighton House, South Penge Park, were elected members of the Association.

Mr. R. Phinó Spiers then read a paper “On Pompeii” which we give elsewhere.

At the conclusion of the paper,

Mr. Spiers stated, in reply to questions, that with the exception of two instances, he had not observed any cases in which gardens were attached to Pompeian houses. The reason probably was, that as the inhabitants passed the greater portion of the day in the open air, and that from the peculiar position of the city (built on the volcanic rocks of the Campania, washed on nearly two sides by the sea, and commanding from almost every point the most picturesque views), it was considered unnecessary to provide that which in England would be regarded as a great attraction to a gentleman's residence.

With regard to baths, two large establishments, on a similar system to the Turkish baths lately constructed in this country, had already been disclosed. That first discovered was behind the Forum, and was divided into three portions. The first contained the furnaces and fuel; the second the baths for men; and the third those for women. The two sets of baths were similar in arrangement, both being heated by the same furnace, and supplied from the same reservoir. Each set had its apodyterium, or dressing-room; its frigidarium, tepidarium, and caldarium. The clothes of the bathers were hung on pegs, the holes into which they were fixed being still visible. The frigidarium was a circular room, with a large cold-water bath in the centre, 12 ft. 10 in. in diameter, and 2 ft. 9 in. deep. In the tepidarium adjoining, a brazier for coals, and two seats, all made of bronze, were discovered, and still remained. The fact that the Pompeians were familiar with glass was also established, in this case beyond doubt, as the baths were lighted with small windows, glazed with glass ground on one side, the fragments of which were found in the building.

The description of the baths having suggested the “sweating system,” a member inquired whether Mr. Spiers had traced any tailors' shops.

Mr. Spiers replied that he had not, as the business of a tailor could be carried on almost anywhere. The Pompeians did not, however, hold the tailors in very high repute, as they were ranged in the Forum very high up, and were generally a noisy and ostentatious lot. They were not allowed to look at the Pompeian ladies of the higher order, who had a gallery of their own in the Forum, and viewed the performances through a grille of metal-work, somewhat similar to that through which ladies in our own day are permitted to enjoy the exhibition presented in the House of Commons. With regard to the supply of water and drainage, although abundance of earthenware and metal pipes had been found in Pompeii, the source of water-supply had not been traced; neither did there appear to be any provision for carrying off the more solid sewage. Possibly the streets were the only drains, as in Eastern towns; and these might have been flushed occasionally by the tremendous showers with which Italian towns are sometimes visited. He had not been able to trace any remains of public baths, although he had found (and produced) scraps of

iron. The Pompeians used bronze largely in fine art productions, but the use of iron appeared to have been restricted to works of construction only.

Having described the manner in which the plaster for fresco-painting was prepared, and exhibited specimens with the colours still fresh, Mr. Spiers stated that he hoped to revisit Pompeii in the course of the present year, and, on his return, to contribute some further information on the subject to the Association.

In proposing a vote of thanks for this paper, the Chairman said, with regard to the architectural features of the city, but little scope appeared to have been left to the architects of those days, except in the construction of the temples, theatres, and other public buildings; as the private houses and shops, though very beautifully ornamented with coloured marbles, presented no great field for the higher qualifications of the architect. In many instances the chambers of the private houses were decorated with paintings, in fresco, of buildings, or rather outlines of buildings, that might be taken as representing iron architecture. He did not, however, believe that the Italians of the period were familiar with the use of iron for structural purposes; and he fancied that the drawings to which he referred were the outlines of buildings suggested to the eye of the artist, and had no reference whatever to any existing structures composed of iron.

#### REREDOS IN PRESTWICH CHURCH.

A RICHLY-SCULPTURED reredos has just been erected in this church by the rector, the Rev. H. M. Birch, and Mrs. Birch. The style is in accordance with the architecture of the church, viz., that known as the Perpendicular. The material of which the reredos is principally executed is Caen stone. It consists of five canopied niches, enriched with carved crockets and pinnacles. The three central niches contain a sculptured representation of the "Last Supper," in alto-relief; and the remaining two, "The Agony in the Garden," and "The Three Marys at the Sepulchre." In addition to the sculptured subjects, there is a large panel at each end; these extend from the base up to the cornice, and contain marble tablets, on which are engraved the Ten Commandments, the letters and ornamental embellishments being painted in various colours. The circumstances to which the church is indebted for this handsome work appears from the following inscription, which is engraved on a brass plate, and fixed behind the communion table:—"To the Glory of God and to the Memory of Henry Arthur Drinkwater, their first-born and fondly-loved child, who died of scarlet fever, April 25th, 1863, in his eighth year, this Reredos is dedicated by his bereaved parents Henry Mildred and Harriet Julia Birch." Mr. W. Smith was the architect; and Mr. James Forstyh, of London, was the sculptor.

#### DWELLINGS OF THE LABOURING CLASSES.

THE committee appointed by the Society of Arts with the view of instituting an inquiry, to ascertain if anything can be done to remedy or to mitigate the evils arising from the want of proper dwellings for the labouring classes, has divided itself into three sub-committees, to proceed simultaneously with various parts of the subject. On the 27th ult. the sub-committees 1 and 2 met; present, Mr. W. Hawes in the chair, Alderman Waterlow, Mr. Bosanquet, Mr. Le Neve Foster, Dr. Greenhill, Mr. Gatliff, Mr. Godwin, Mr. Martin Ware, who is acting as secretary to the committee, and others. The sub-committees discussed jointly at considerable length "the best mode of lessening the burdens on house property of the working classes." The committee includes the names of Messrs. Dyke Acland and Akroyd, Lord Belper, Lord Berners, Duke of Buccleuch, Messrs. Chadwick, Chester, and Cole, Knight Hon. W. Cowper, Mr. J. Bailey Denton, Earl Ducie, Lord Ebury, Mr. Hare, Earl of Harrowby, Messrs. G. W. Hastings and C. Wren Hoskyns, Dr. G. Lankester, Marquis of Lansdowne, Lord Falbot de Malahide, Messrs. M. H. Marsh, M.P., H. Maynard, J. Stuart Mill, and J. Chalmers Morton, Earl of Shaftesbury, Sir J. Kay Shuttleworth, Lord Stanley, M.P., Mr. Twining, the Duke of Wellington, and several others.

#### THE ARCHITECT OF THE CHURCH OF ST. OUEN, ROUEN.

SIR,—In the notice kindly given to my little book, styled "Normandy, &c.: a Sketch" (*Builder*, No. 1116), you ask for the authority for a statement with regard to A. Berneval, one of the architects of the church of St. Ouen, at Rouen, which describes him as "architect and clerk of the works." Having destroyed the notes used while compiling the text in question, I cannot now refer to the authority for the words which are italicised above. Allow me to say that they appear in the text as a quotation,—between inverted commas,—and not as a positive statement of my own opinion. Finding these words so placed indicates to me that I did not consider them beyond question. The position of Berneval is best defined by the inscription on the tomb in St. Ouen, placed there by the monks in consideration of his abilities and services. This is thus given by Pommeraye, "Histoire de l'Abbaye de St. Ouen, 1662?"—"C'est Mr. Alexandre de Berneval, maître des œuvres de maçonnerie au Bailliage de Rouen et de cette Eglise, qui trépassa l'Année de grace 1440, le 5 Janvier." In another place Pommeraye speaks of him as "architecte et conducteur des travaux de l'Eglise de St. Ouen."

With regard to the photographs which my text was intended to illustrate, let me say that they were not made under my direction, either as concerns their subjects, size, or the points of view chosen for them. F. G. STEPHENS.

#### THE SEWAGE QUESTION.

THE Sewage Committee, in their report, have embodied their opinions in the following paragraph:—

"We recommend that the important object of completely freeing the entire basins of rivers from pollution should be rendered possible by general legislative enactment, enabling the inhabitants of such entire districts to adopt some controlling power for that purpose; but it should include a provision for compelling local Boards to render the sewage of their districts innocuous by application to the land for agricultural purposes. The case of the valley of the Thames (where the purification of the river has been sought by the expenditure of enormous sums, is to a considerable extent, counteracted by the increased discharge of sewage from towns higher up the stream) requires special and immediate attention."

Dr. Ackland, of Oxford, who has for some time advocated the necessity of appointing some authority to control the catchment basins of rivers, presented a memorial, in conjunction with other gentlemen, to Sir George Grey two years since, with respect to the particular catchment basin of the Thames. The evidence he gives in the report of the condition of the river near Oxford is certainly disgusting. He states that in one place the deposits of sewage have diminished the depth of the river by 6 ft.

Mr. Rawlinson, the principal inspector in the Local Government Act Office, who has inspected the rivers of Lancashire and parts of Yorkshire, says—"The rivers Irwell, Medlock, Irk, and Bridgewater Canal are more offensive from sewage than the Thames. The Medlock at Manchester is covered with a black scum so thick that birds are able to walk over it! The rivers and streams in Lancashire and Yorkshire are fearfully abused. There are river beds in Lancashire and Yorkshire that are raised 10 or 15 ft. by sewage, ashes, and other refuse. The want of some central authority to deal with the watersheds of districts is illustrated by the case of Salford. The inhabitants of this town wished to carry their sewage by tunnel three or four miles from Manchester at an expense of 80,000l., but were prevented from doing so by the refusal of other towns to co-operate. "Of what use is it," they say, "to expend large sums when Manchester and all the other towns above will continue to foul the river?"

Baron Liebig, the President of the Royal Academy of Science at Munich, has forwarded to the Lord Mayor of London a communication, which would probably occupy four or five columns of a newspaper, and which was evidently intended for national circulation. Leaving untouched the sanitary, engineering, and agricultural questions connected with the sewage, for the reason that they had already been profoundly investigated by the Select Parliamentary Committee, over which Lord Robert Montagu presided, Baron Liebig, in the document in question, aims at putting in their proper light before the farmers, the inhabitants of towns, and the legislature, the facts

and principles which he thinks ought to be taken as guides in any estimate of the worth and importance of sewage. The document is written in English throughout, and that is its key-note. The Lord Mayor convened a special Court of Common Council the day after the receipt of the communication, in order that he might lay it before that body, which has of late taken a prominent part in relation to the utilization of sewage. The result was that Baron Liebig's communication was referred to the Coal, Corn, and Finance Committee, to be printed and circulated forthwith among the members of the Common Council.

#### SANITARY MATTERS.

*Woolwich.*—At a recent meeting of the Local Board of Health, a letter was read from Dr. Simon, F.R.S., medical officer of the Privy Council, requesting to be informed what steps had been taken by the Board to carry out the recommendations of Dr. Bristow, who had been specially employed by the Privy Council to make an inspection of the town with reference to the frightful epidemic which recently prevailed. Dr. Bristow, in his report, strongly recommended the advisability of connecting the sewerage system of the district with the tall shaft at the steam factory department of the dockyard; and it was now stated that the local Board had applied to the Admiralty for permission to carry out the plan proposed, but that some objections had been made, which, it was believed, could be obviated. A reply to this effect was ordered to be forwarded to the Privy Council.

*Glasgow.*—At the last fortnightly meeting of the Police Board it was reported that during the previous fortnight 376 cases of fever had been announced, as against 312 cases during the fortnight before. Mr. Ure said it would be observed that this was the greatest ever reported to the Board. It is proposed to take on lease for a fever hospital, premises in Main-street, Anderson, at a rental of three years for 400l., and for five years, at 350l. sterling per annum.

*Ireland.*—Dyscise is very prevalent in Ireland at present. There is not a town almost where fever is not raging.

#### SOUTH LONDON WORKING CLASSES' EXHIBITION.

The second South London Exhibition, at the Lambeth Baths, was opened on Wednesday, with some éclat. The Bishop of Winchester presided, and the Hon. W. Cowper, M.P., Mr. John Locke, M.P., Dr. Newman Hall, the Hon. A. Kinnaird, M.P., Mr. Donlon, M.P., Mr. Lucas, and Mr. F. Fowler addressed the meeting. Dr. Hall's speech was remarkably effective. To the exhibition itself we may return. Suffice it to say at present, the number of exhibitors is 633.

The space used for the purposes of the exhibition is about 5,000 square feet of hanging space, 1,200 ft. run of table space of various depths, and 800 ft. of floor space.

#### IPSWICH TOWN HALL.

THE town council, after a long and cross debate, have determined not to patch up the old hall, and, in building a new one, not to join with it the museum, as originally intended. They further referred it to the Estate Committee, to obtain a design. In what way the Committee are to set about this, however,—whether they are to put aside altogether the previously selected competitors, invite a fresh competition, or name an architect themselves,—did not appear. Having again determined on having a new building, it is to be hoped the members of the town council will now put aside their different crotchets, and work with something like unanimity towards the one end in view.

*OPENING OF A RUSSIAN TUMULUS.*—An interesting discovery has just been made in a tumulus at Ekaterinoslaw, in Russia. It consists of a treasure which formerly belonged to a chief of the Huns. Among the different articles is a heavy gold diadem, in which is set a cameo of amethyst of ancient Roman workmanship; also a large collar, bracelets, and drinking cups, with handles formed by animals, the whole of which are in gold of remarkable workmanship.

MASTERS AND MEN.

Sir,—Although the "discharge note" has been my, I shall be glad to say a few words in reply to your correspondent, "A Joiner." This latter designates the complaints of the masters, as expressed by the chairman of the Builders' Association, as "a farrago of nonsense," and he talks about the dictation of operatives as "mere hosh." I shall be happy to bear that the workmen in a "A Joiner's" locality, know better than belongs to their position, and have the good sense to allow the masters to use their own discretion in the management of their business; and if the masters in that favoured locality, and probably in many others, enjoy this privilege, it is too patent to be denied, in the ordinary way "A Joiner" does it, that dictation by the workmen does take place to a great extent in most of the large towns. I, therefore, conclude that "A Joiner" has not travelled far, or he has, he must have wilfully shut his eyes. Let "A Joiner" read the letter of J. Radford, who, judging from a previous letter, is no particular friend of the masters. The letter appeared in the *Birmingham Daily Post*, of the 19th ult., in which there are references to dictation of the workmen, which are something more than "hosh." If "A Joiner" has not wilfully shut his eyes, he would, even in the *Builder*, have seen recorded some instances of presumptuous dictation; but I fear that "A Joiner" has those exaggerated views of workmen's rights, that he cannot see that he is claiming more than is reasonable, and therefore cannot understand what dictation is. If so, I will just ask him to consider what he would expect if he were in the position of a master: the masters generally wish no more, nor, perhaps, so much as he would claim. I shall be glad to find that workmen generally improve their minds by the acquisition of valuable information. Only let them use it fairly and honestly, or it will be like the education of dishonest men, doing greater mischief in proportion to the amount of knowledge possessed; and let me say that the workman who can best serve his master is the educated one. Such a one can serve his master and himself too, and as opportunity offers, raise himself to a higher position without injury to his master; but, in order to do this, the workmen must shake off the chains of slavery which the trade unions would bind upon them, in forbidding their trying to better themselves by piecwork, over-time, &c. The workmen do themselves no good by harbouring a jealous fear lest the masters should get a shilling too much out of their labour; that man will generally succeed best who is willing, faithful, and trusting, and, when his time comes, will make the best master.

Whatever "A Joiner" may say to the contrary, and by whatever choice epithets he may term the statements to the contrary, it is too true that the workmen have by their unions usurped a power in interfering with the rights of the masters, who have hitherto and too long delayed to make efforts by union among themselves to check the monster evil. I am therefore glad that masters generally now see the necessity of union: experience will soon dictate the best mode of meeting such cases as may arise. I do sincerely hope that the workmen will agree to a set of rules which shall prevent any further dispute, and put the masters in such a position that they may always know what wages they have to pay.

A. B. C.

Several correspondents urge the appointment of a committee of masters and men to arbitrate, as a proposition now before the trade. One, "W. C. Gascoyne, Builder," writes,—"I feel sure, from my own experience, that great good would result by trying to settle differences by reason instead of force. I must think that if the workmen saw themselves properly represented by their fellows, and any questions affecting them fairly discussed, with the usual amount of common sense which they possess, they would, on the other hand, allow in all fairness a full discussion and an impartial hearing of any question also affecting the employers. One great fact must be admitted, that is, that in a commercial point of view, the labour is as valuable as the capital which is paid for it; therefore, I think, if both are fairly represented at this conference, there could be no cause of complaint. I feel sure that if both parties were brought together in this way both would have better faith in each other, for both are equally dependent on each other. For example, the workmen would be then represented by a body of sober, sensible

men, who would listen to reason; instead of, as now, in many cases where a complaint exists, some one or two who can talk well, and do not mind mounting a platform, carrying them away and often compelling them to strike; and, the more agitation there is in many cases, the better it answers their purpose,—forgetting the principle which is involved. Now this I wish most sincerely to see done away with, and am prepared to do all in my power to assist; and I shall be happy, if this plan is thought the right one, to co-operate with any one, and shall be most happy to hear the views of any one on the subject. I may say that, amongst the men in my employ, who number upwards of one hundred and forty, that I have spoken to upon this plan, they seem all to approve of it."

THE BUILDING TRADES MOVEMENT.

In consequence of the public announcement that the masters had renounced the "discharge note," the operatives' secretary wrote to the masters' secretary, asking for an interview between deputations from both bodies; and, that interview being granted, the meeting took place. The interview was of nearly two hours' duration, and matters were discussed in a friendly spirit on both sides. In reply to the men, the masters gave an assurance that the "note" had been unconditionally withdrawn. After a lengthy conversation, the following conclusions were arrived at:—That the masters shall meet by themselves, to agree upon such rules for the regulation of the trade as they may deem suitable; and that the men shall meet and agree upon such rules as they may deem suitable; that early in the following week an equal number of masters and men, appointed by their respective bodies, shall meet to discuss these rules; that in case of dispute each side shall choose a referee, and that the referees so chosen shall choose an umpire whose decision shall be final; and, lastly, that the rules so agreed upon between the representatives of the masters and the representatives of the men shall be binding upon the whole trade, both masters and operatives. It seemed to be generally agreed upon that all previously existing rules were now null and void, awaiting remodelling at the hands of the forthcoming conference.

At a meeting of delegates from the various carpenters' societies and shops in London, it has been resolved:—"That, in the opinion of this meeting, it would be advisable to convene a conference of the whole of the building trades throughout the country as early as possible, for the adoption of a code of rules for regulating the trade, and the appointment of a committee to lay those rules before the representatives of the masters' associations for mutual discussion, and with the object of having all future disputes settled by arbitration."

A meeting of the delegates of the different branches of the building trades has also been held at Nottingham, to confer with the masters for the purpose of adjusting the difference in dispute between the master and operative builders, and to decide upon the trade rules. At this meeting, Mr. Slim suggested that if on any question there was an equal number of votes for and against, that particular subject should be left for arbitration. Mr. Ellis observed, that any decision that might be arrived at that evening would not be final, as it would have to be submitted to the different societies before it could be binding upon them. A long conversation then ensued, in which the delegates took part, as to the reason that the men were still out on strike. Mr. Hiekin (operative) said it was undoubtedly because the secretary did not say in his note that the shops were now open for the men to return to work as before the disagreement. At the conclusion of a lengthy discussion, the following resolution was proposed by Mr. Ellis (master), and seconded by Mr. Hiekin (operative), and adopted unanimously:—

"That we, as delegates, recommend to our societies to adopt a court of arbitration, consisting of one operative and one master from each branch of the building trade; and that we communicate the same to Mr. Wheeler (the masters' secretary); and, if accepted, that an equal number of employers and employed revise their rules if they require it. Should any dispute arise, the arbitration court to settle the same. And, further, that each town shall have its own delegates, and settle its own questions in its own court of arbitration."

This resolution was agreed upon unanimously. At a similar meeting in Coventry the following resolution was unanimously agreed to:—

"That the masters and men connected with the building trades of Coventry in public meeting assembled

respectively and mutually agree to the following resolutions:—

1. That they will respectively appoint delegates to frame the rules under which each of the building trades of Coventry shall be carried on, the rules for each trade being framed by the masters and delegates of that trade.
2. That those delegates shall appoint a chairman, who shall have the casting vote.
3. That the masters on their part and the operatives on their part respectively and mutually promise to abide by and carry out all rules which may be agreed to by the delegates or decided by the casting vote of the chairman.
4. That the following persons be appointed delegates for the purposes above mentioned:—

A list of delegates followed. It was then suggested that the men should at once resume work; but, as some one demurred to this, it was decided that the men would consider the question, and give the masters an early answer.

While the whole of England has been ringing with the protests of the operatives against the employers in the Midland district in seeking to enforce the "discharge note" system; and the cry of "Down with Dictation" became so strong and unmanly that the employers wisely determined to abandon their intention of enforcing the note; we regret to find that a portion of the operatives have already taken such an ill-advised and childish step as to dictate to the Liverpool masters, that after the expiration of another six months they shall use no bricks made by steam power! The following is a copy of a circular sent to the employers:—"To Master Builders, Contractors, and Others.—Upon consideration we, the undersigned hereby give you notice that there will be no more bricks used made by steam power on and after the 22nd July, 1865, as the brickmakers of Birkenhead and its vicinity can supply you with as good an article, if not superior, to the ones now made by steam power, with the exception of white and blue fire-bricks. By order of the Committee of Management of the Amalgamated Bricklayers, Bricklayers' Labourers, Brickmakers and Plasterers." Here we have proof that no experience is of any avail in the removal of stupid errors such as that which would have prevented this country from becoming "the workshop of the world,"—which it never could have been but for the unrestricted extension of steam-power. When the cotton manufacture was in its infancy, all the foolish old women in the country railed against the use of steam in spinning and weaving because it would lead to the substitution of machinery for hand-labour, whereas it has provided labour and livings for hundreds of thousands; and of late, from war in America, thousands have been starving from the unavoidable suspension of steam-power. The foolish and impracticable dictum of the Liverpool bricklayers is just a reproduction of the absurdity which characterised the cotton operatives themselves, when they struggled against the introduction of the steam-loom, and of the folly of stage-coach drivers who opposed the construction of railways. The amalgamated bricklayers, bricklayers' labourers, and brickmakers and plasterers are grievously mistaken if they imagine that their dictation will prevent the manufacture of bricks by steam; and in this struggle with the employers they must not count on the support of the press and the sympathy of the public.

At the last ordinary meeting of the Liverpool Architectural and Archeological Society, Mr. Wylie drew attention to the notice. He said it was important that they should at once protest most decidedly against such dictation, because the time had arrived when machine-made bricks, both moulded and plain, would be far more extensively used than they had ever yet been. They should not lose sight of the fact, that attempts were formerly made to put down machinery in all its branches of manufacture. He could quote a number of instances in which, instead of machinery having been a disadvantage to skilled labour, it had been of the greatest advantage; and he believed that without machinery we could not in the present day carry on such immense operations in trade and commerce in this country as we did: therefore, the attempt of those individuals to put down machinery in the making of bricks appeared to him to be one of the most suicidal steps in which they could be engaged. He thought that, as a society of professional men, they should immediately protest against the adoption or reception of such obsolete ideas. The dictation, if allowed, would prove very serious, and would affect a great number of buildings which were now in course of erection. He characterised the conduct of the men as most absurd.

With regard to a notice sent in to the Wigan masters of a demand of 10 per cent. increase of wages by the Wigan bricklayers, a member of

the largest firm of employers in the town—Messrs. Foulgh & Son—calls upon the trade to "set their faces against the annual nuisance of notice for a never-ending increase of wages, which the men will find eventually innoxious to themselves as well as the trade, as people will be driven to invest in more lucrative forms than in building."

## MARSEILLES.

MARSEILLES, keeping pace with modern improvements, has opened a magnificent *Rue Impériale*, a colossal *préfecture*, a magnificent *palais de justice*, a museum which promises to be a wonder, and has organized a company of docks and warehouses worthy of the principal port in the Mediterranean. It appears, however, that the celebrated corporation of porters or *portefaix* of Marseilles, who for centuries have had the privilege of the carriage and storage of merchandize on the principal quays, looked upon this institution of the docks with no small jealousy. The docks (described on another page) offered to commerce the advantages of celerity, security, commodiousness, and economy, which the system of portorage could not give. Hence, a war broke out between the Corporation and the Dock Company, the former being called anti-progressionists, and the latter monopolists. The dock proprietors offered work to the porters, which some, forgoing the freedom of the corporation which they had possessed, accepted. These were at once deprived of all rights to municipal succour in case of old age or present infirmity, and the excitement became so great that the town garrison was obliged to be reinforced. It is plain that the Dock Company can have only a moral monopoly, such as railways now possess with regard to mail coaches; and it is still more certain that, if the inhabitants of Marseilles do not, by the proper extension of docks, keep pace with the demands of modern commerce, merchants will find it their interest to discharge their cargoes at some other port, such as Genoa or Trieste.

## LIVERPOOL.

The new Municipal Offices, Dale-street.—This building is now far advanced towards completion. The style is Grecian, of the Corinthian order, and the building will have a north frontage of 222 ft. to Dale-street, which will be the principal front; while it will run back to the distance of 195 ft. in Crosshall-street and Sir Thomas's-buildings. The basement floor will contain four suites of rooms, in addition to several other apartments for storage, gas-metre, lumber-room, &c. This story will have four separate entrances from the south front, and there will be an entrance east and west from Crosshall-street and Sir Thomas's-buildings respectively. This floor will be lighted by windows on each side of the building. The north front to Dale-street will be the principal front of the building. The external walls are all of Minera stone, brought from Berwig quarries, near Wrexham. The principal entrance will be in the centre, and there will be a portico and six columns—three on each side of the doorway—with Corinthian capitals. Over the entrance will be cut in large letters, "*Deus Nobis hæc Otia fecit*," and immediately above a double-arched window, which will give relief to the appearance of the front. Above this will rise a circular tower, in which a large clock will be fixed. The elevation of this tower, including the spire, will be 140 ft., while the main portion of the building to the eaves will be 62 ft. high. All the offices for public business, at the Town-hall, at Cornwallis-street, at Hotham-street, &c., will be on the ground-floor in this building. Although the exterior walls are of stone, a small portion of the south front is of patent red brick, and will not have the advantage of such elaborations in architectural design as have been expended on the front to Dale-street. The windows all round the building will have polished granite pillars on each side, and the various entrances will be in strict keeping with the design. The walls, both inner and outer, will be from 2 ft. to 4 ft. thick, in addition to the columns, and in some places they will be 4 ft. 10 in. thick. Mr. Weightman, the borough surveyor, is the architect; and the contractors for the mason-work are Messrs. John Parker & Son; for the brickwork, Messrs. Holme & Nicol; for the joiners' work, Messrs. Haigh & Co.; and the clerk of the works is Mr. J. Crierie,

under whose superintendence the Public Library was built.

New Wesleyan Schools in Toxteth Park.—The foundation-stone of new day and Sunday schools in connexion with the Stanhope-street Wesleyan Chapel, has been laid in Windsor-street, Toxteth Park. The principal entrance will be from Windsor-street, and a prominent part of the elevation is to consist of a tower about 70 ft. high. In this tower is to be the principal staircase, and there will also be a large room, the roof of which is to be of ornamented timber, stained and varnished. All the stairs will be of stone, very wide, and free from angle leads. The size of the infant-school is to be 42 ft. by 30 ft., and of the infant class-room, 22 ft. by 18 ft. The girls' school and class-room will be of the same dimensions, both having attached to them cloak-rooms, 15 ft. by 10 ft. The boys' school will be considerably larger than the others, the size being 65 ft. by 33 ft. and the class-room 24 ft. by 18 ft. There will also be lavatories and other arrangements in connexion with each school. Behind the buildings there is to be an extensive covered playground, which will be divided, for the use of the boys and girls respectively. The walls are to consist of red brick, with coloured bands and white stone dressings. The boys' school is to be on the first floor. The amount of the contract is 3,000*l.*, exclusive of the fittings, which are to be of pitch pine; but including the fittings and the cost of the land, it is estimated that the total expenditure will be about 5,200*l.*, of which about 5,000*l.* have been already collected. Mr. C. O. Ellison, of Liverpool, is the architect; and Mr. J. Martin, the builder.

Fatal Accident by Fall of a Wall in Liverpool.—The County Palatine Loan and Discount Company are erecting a building at the corner of School-lane and Peter's-lane, Liverpool, just opposite the large block of buildings now erecting by Mr. Edward Willmer, under the direction of Mr. T. Mellard Reade, architect, and Mr. Joseph Greenwood, of Hulton, clerk of the works. For some time past excavations have been in progress for the formation of cellars underneath this building and a part of those occupied by Mr. Allsop, and it became necessary to "under-pin" the north gable end of Mr. Allsop's wall to the extent of 15 ft. deep. During the progress of this operation on Monday before last, this wall gave way and buried one poor fellow in the ruins. The man was got out after three hours, but was found dead. At the inquest the jury found that the deceased had been "accidentally killed," and accompanied their verdict with a presentment expressive of admiration of the praiseworthy manner in which a police-officer had "discharged even more than his duties."

## PROVINCIAL NEWS.

East Coves (Isle of Wight).—A new mansion has just been completed at Spring-hill, for Mr. W. G. Shedden. It is in the Early English style, the external facing being of yellow malms, from East Coves Park estate, with Bath stone dressings. The architect was Mr. T. W. Burrell, Fareham. Messrs. T. & J. Dashwood, of Ryde, were the builders. The cost was about 8,000*l.*

Hanley (Staffordshire).—A "Hanley Hotel Company (Limited)" has been formed for the purpose of meeting the present inadequate hotel accommodation in the capital of the Staffordshire Potteries. The directors have selected an eligible site known as the Bank House Property, and have entered into a contract for the purchase of it. The property is opposite the junction of Pall-mall, Cheapside, and Albion-street, and is situate in one of the most convenient parts of Hanley. The proposed capital is 20,000*l.*, in 4,000 shares of 5*l.* each.

Hexham.—The proposed Hexham Town-hall and Corn-exchange building scheme has at length been exchanged. The tenders for the different works have been selected by the directors, as follows:—Mr. T. Bulman, Hexham, mason work, 2,940*l.*; Mr. E. Herdman, Hexham, joiner work, 1,758*l.*; Mr. H. Burn, Hexham, slating, 230*l.*; Mr. Ellis, Hexham, painting and glazing, 300*l.*; Mr. Holme, Carlisle, plastering, 316*l.*; Mr. Stafford, Newcastle, iron work, 315*l.*; Messrs. Walker & Son, Newcastle, iron work, 315*l.* It is expected that the foundation stone will be laid by Mr. Beaumont, M.P. The buildings will be in the new street, extending from the Market-place to Henocotes, and will be situate about midway between each terminus, on the side opposite the Abbey.

## CHURCH-BUILDING NEWS.

Rumham (Norfolk).—A feature has recently been added to the parish church of this village. The tower has long presented an unfinished appearance, owing to the want of parapet or pinnacles, which have now been erected at a cost of about 200*l.* The new work is of stone, and consists of a moulded cornice having carved gargoyles with parapet above, and finished with stepped and moulded coping. The parapet is ornamented with sunk quatrefoils and trefoil-headed panels, which are filled in with cut flints. Crossed keys and crossed swords (the emblems of St. Peter and St. Paul, to whom the church is dedicated), are also introduced in panels of flint and stone. At the angles are pinnacles rising to a height of about 14 ft. from the cornice, and having carved crockets and finials. The works have been executed by Mr. J. Stanley, of Yarmouth, from the designs and under the superintendence of Mr. J. T. Bottle, of Yarmouth, who has succeeded to the architectural practice of Mr. A. W. Morant.

Icklingham (Suffolk).—The Church of St. James, Icklingham, which has from time to time suffered the most wanton mutilation and defacement, is now being restored at the sole expense of Mr. C. E. Gibbs, of Icklingham Hall. The brick parapets which surmounted the nave and aisle walls have been removed; the chancel is to be re-roofed and re-seated, and the floor raised to its original level; the body of the church is to be repaired and re-seated; the window tracery, which was nearly all cut out and destroyed, will be restored in accordance with the original design; and the various piscinas, niches, &c., formerly walled up, have been opened and repaired. The works are being carried out by Mr. Jackaman, of Bury St. Edmund's, from the designs of Messrs. Bacon & Bell, of London.

Bideford (Devon).—The church of Bideford was consecrated on the 12th of January. The original church, deformed by galleries and tasteless additions, being also ruinous, was pulled down in 1862, plans for a new edifice having been prepared by Mr. Ashworth, of Exeter. The new edifice attached to the old tower consists of nave, chancel, aisles, and chancel aisles, an organ-chamber appropriated as a corporation-aisle, vestry, and two porches. The internal dimensions are 113 ft. 6 in. by 71 ft. The Perpendicular style has been adopted, following the features of the old church. The accommodation is for about 1,150 persons. The walls are of local stone, with Forest of Dean stone quoins, and Bath stone arcades and dressing. Very little of the old work could be re-used. The roofs are of red pine. The stone and wood carving was done by Mr. Seymour, of Taunton. The rebuilding has been wholly carried out by Mr. White, of Bideford. There is a stained window by Mr. Wales in the tower, and two by Horwood in the south chancel aisle. A warming apparatus, by Messrs. Haden & Son, has been constructed in the vaults. The outlay is about 4,500*l.*, including a restoration of the tower, not yet complete.

## GRINDING MONEY.

## WANDSWORTH POLICE COURT.

HEAVY ARSTIN, foreman to a builder carrying on works at Battersea, was summoned by Charles Legg, a carpenter, for a quarter of a day's wages, allowed in the trade, for grinding tools.

The defendant pleaded that he was not liable to pay the amount claimed.

The complainant stated, that he had been working at the rate of 5*s.* per day, the week ending at one o'clock on Saturday. At half-past twelve o'clock, on the 14th inst., his defendant gave him notice that he should not require his services any longer. He, however, continued on until one o'clock, when he was paid, minus the quarter of day allowed in the trade for grinding tools.

The defendant gave a different complexion to the case. He employed the complainant at 5*s.* for ten hours per week, with the privilege of leaving off at one o'clock on Saturday. He paid him up to half-past five o'clock, although he left off work at one o'clock, he contending that it was not compulsory only in cases in which the men were paid at the rate of 7*s.* per hour. He also said the 7*s.* per hour system had swept away the wages allowed for sharpening tools.

In reply to the magistrate, the defendant said that the money for grinding tools ought not to be given when Saturday afternoons were allowed. He believed it was not the practice in the trade. He never heard of such a custom in his life. He would swear that he had worked in the neighbourhood in which he worked, and he said the complainant's saw was not properly sharpened when he commenced working for him.

The complainant said it was the custom in the trade when the men were discharged to be paid a quarter of a day for sharpening their tools.

Mr. Ingham dismissed the summons on the evidence given by the defendant. He also said, that if the complainant had a right to claim for grinding-money, he must go to work with sharp tools, as he could not have the privilege both ways.

**Books Received.**

... to Lord Palmerston on the Employment of our Labour and Capital at Home. By GEORGE WESTON WHITE. London: Cornish, High Holborn. 1865.

The immense drain of capital from this country for foreign loans, amounting to hundreds of millions, is a subject both of apprehension and of regret; and the obvious remedy would be the introduction of reproductive works to develop our internal resources, instead of allowing foreigners to do this for other countries with our capital. A single measure could be so well calculated to assist in developing our material resources as the opening up of the country by cheap railways; and this is one of the chief suggestions urged by Mr. White in the pamphlet under notice. He insists especially on Ireland as requiring such assistance, and asks,—“Would it not be sound policy to devote a portion of the revenues of Ireland for such purposes, as has been done in India, but in a modified form,—say, for example, by giving a guarantee, for only twenty years, of 5 per cent. on 5,000l. per mile of such railways as were deemed of national importance as a commercial and military point of view?” A guarantee of 250,000l. per annum, being 5 per cent. interest on a capital of five millions, would ensure the execution of 1,000 miles of railway,—a outlay which might be extended over a period of five years.

Ireland, as an integral portion of the British Empire, cannot remain depressed and undeveloped without proving a continued source of weakness to England; and there seems to be no more obvious or hopeful way of removing this source of weakness than by first of all opening up the country by cheap lines of railway, and then, perhaps, by carrying out an extensive system of bog and other drainage of the soil. In the reclamation of wastes there is a vast field of operations awaiting the advent of capital towards the reproductive development of Ireland.

Amongst other measures which would confer incalculable benefit on Ireland would be the occasional residence of some member of the Royal Family in the country,—the Prince of Wales, perhaps, as Lord Lieutenant. It is to be regretted that no Royal residence exists in Ireland; a grant ought to be made by Parliament for the purpose, as suggested in the *Times* by Mr. Hankey.

Another great want in Ireland is industrial knowledge and industrial education; whilst there is still a superabundance of unskilled labour, notwithstanding the removal of so much even of that to foreign countries as well as to their own colonies, there is as yet comparatively little skilled labour. Industrial knowledge makes all the difference between the poverty and weakness of Ireland and the rich and flourishing condition of England.

In trying the opening up of Ireland by railways, Mr. White says,—

“Having witnessed the extraordinary results produced in India, in France, in Spain, and other parts of the globe, by the introduction of railways, I am convinced that there is no single measure which could be devised which would produce such important benefits to Ireland, as the opening up of the country by a system of cheap railways and tramways, constructed with the utmost economy, and specially adapted for agricultural traffic; and until this be done, I fear all attempts at developing the fisheries and mineral wealth of the country, and reclaiming the waste lands, will, in a pecuniary and commercial point of view, prove a failure; cheap transit being a *sine quâ non*.”

Mr. White's pamphlet is a highly important one.

**VARIORUM.**

“Naval Armour: dedicated to Lord Palmerston.” By James Chambers. London: Mitchell, Charing-cross. The author of this pamphlet is the inventor of the Chalmers target, in favour of which a good deal has been said in the public press within the last two or three years. As in so many other instances, Mr. Chalmers complains of the really stupid proceedings of the Admiralty. He quotes the strange and startling dictum of their “Controller,” that “relative resistance to shot has no bearing on the question” of naval armour.

“If Britannia,” says Mr. Chalmers, “were prepared to lay down her proud sceptre, and bury her power and glory beneath the waves she has ruled so long, she could not desire undertakers better qualified than the present

Controller and Chief Constructor of the Navy. Nor could she find fitter *shrouds and coffins* than the thin-sided and partially-armoured ships which the admiralty has prepared for her. To carry out the stanza, My Lords, who seem willing to follow wherever their officials may lead, would make most respectable *pull-beavers*; whilst the Government and Parliament could attend as *chief mourners*, deploring the sad fate they seem unable to avert. Whatever part in the humiliating pageant may be assigned to Britain's humber sons, I, for one, will be no *wite*. Let him chant a funeral dirge who may, my song shall be “Rule Britannia.”

**Miscellaneous.**

**THE TUNNEL UNDER THE SEVERN.**—We learn that this project, so far as the coming session is concerned, is abandoned, there not being sufficient funds provided to meet the requisite deposit, estimated at 6,000l.

**LONDON FIRE-ENGINE ESTABLISHMENT.**—Captain Shaw's “Report to the General Committee” of this establishment contains some useful observations and suggestions, and will require to be returned to.

**THE LOCAL GOVERNMENT ACT.**—At Guisborough, a meeting has been held, at which it has been unanimously resolved to adopt the Act for the township. The number of members to form the Local Board of Health will be twelve.

**THE STRAND MUSIC-HALL COMPANY.**—Three petitions have been presented in Chancery for the winding up of this company. All the amount paid on calls, together with 35,050l. borrowed on bonds, had been expended on the hall and the business. The company was unable to pay its debts, amounting to about 45,000l. One of the petitioners was of opinion that if the Music-hall were sold as a going concern, the assets would not amount to more than 20,100l. The sheriff took possession of the hall on the 14th January, and the provisional liquidator had let the hall at 65l. a week.

**DISCOVERY IN WELLS CATHEDRAL.**—The dean and chapter having determined to introduce gas into the choir of the cathedral for the use of the clergy and vicars choral, the workmen, under the personal superintendence of Mr. Kelway, in making an opening under the stalls on the south side of the choir, came upon a thick, massive slab of freestone, which was found to cover a stone coffin of ponderous size and weight, and of the shape in which they were usually made at an early period,—viz., wide at the head, tapering off narrower to the feet, with square corners, but without the modern widening at the shoulders. In the side or edge of the coffin, on the left side, and near the head, was found a small plate of lead, inserted in the stone, rudely engraved in the characters of the period, with the following inscription:—

“*Hi Jacet Wilhelmus de Buttona secundus, Bathoniensis et Wellensis Episcopus, Sepultus XII. die Decembris Anno Domini M.CCLXXIII.*”

The tomb is not opposite the bishop's grave, but several feet to the east of it.

**WORKING-CLASS DWELLINGS IN LEEDS.**—The mayor of Leeds (Mr. Luccock) some months ago offered a prize of 5l. for the best essay on the dwellings of the working classes in the borough. Mr. W. B. Denison, Mr. T. Dawson, and Mr. J. Taylor were selected as the adjudicators, and they have awarded the prize to the essay by Mr. James Hole, the author of “Light, More Light,” and the secretary of the Yorkshire Union of Mechanics' Institutes. The writer has entered into an examination of the character of the dwellings of the working classes in Leeds, and adduced ample evidence that the mass of these dwellings are of so deficient a nature and encompassed with evils that materially increase the mortality of the town, and produce great social evils. The following is a recapitulation of the measures which he believes will remedy the evils he points out:—1. The extension of the Common Lodging-house Act. 2. The vigorous enforcement of the powers already possessed by the Corporation and the Board of Guardians for the prevention of nuisances, &c. 3. Applying the Local Government Act, and also obtaining powers to regulate the laying out of streets, public improvements, &c. 4. The establishment of societies to assist in the erection of dwellings on sanitary principles; and 5. The erection of additional lodging-houses in different localities.

Beyond these, by the influence of temperance and education, they might hope also to assist in checking these evils.

**CLIFTON SUSPENSION BRIDGE.**—The bridge has been opened for carriage traffic. It is reported that there is no perceptible oscillation in the roadway.

**RADCLIFFE INFIRMARY, OXFORD.**—The building committee appointed to carry out the erection of the accident ward, &c., at the Radcliffe Infirmary, which are now completed, have issued a financial statement, from which it appears that the total amount of receipts was 7,113l. The expenditure includes sums “paid for various contracts for building the new accident ward, out-patients' hall, medical officers' receiving-rooms, including warming apparatus, fittings, furniture, advertising, printing, and architect's commission, 6,628l. 11s.”

**SOUTH KENSINGTON MUSEUM.**—A large part of the collections illustrative of building materials and construction, recently exhibited in the temporary iron building at South Kensington, has been removed to the south arcades overlooking the gardens of the Royal Horticultural Society, where it will be again exhibited to the public, and the usual facilities for study and comparison afforded as soon as the necessary arrangements can be made. The part removed comprises a collection of stone for building and architectural decorations, British and foreign marbles, cements, ornamental terra-cotta, tiles, woods, &c.; together with a number of interesting models of public buildings.

**LIVERPOOL ARCHITECTURAL SOCIETY.**—At the meeting on the 25th ult., Mr. Joseph Boulton, in the chair, read a letter from Mr. Ellison, in which that gentleman, after explaining that, being unable to attend, he was compelled to do by letter what he had intended to do in person, went on to say that he must protest against the reading of a paper by Mr. Rollet until the dispute concerning the construction of the roof was settled, for he thought the society had no right to mix itself up in a question of such extensive importance; and that under the circumstances the reading of the paper, or a discussion on the subject, would add very materially to the difficulties of the case, Mr. Rollet being one of the principal parties concerned in the construction of the North Haymarket roof. The chairman observed that Mr. Rollet being—according to Mr. Ellison's statement—one of the principal parties concerned, it seemed only just and right that he should choose his own time, consistently with the convenience of the society. Mr. Rollet accordingly read the paper in question.

**BURSTING OF A KITCHEN BOILER.**—Another of these accidents has occurred,—and in the north of England, as usual. It took place on Wednesday, at the residence of Mr. Jonathan Whitehead, cotton broker, Elmsley House, West Derby. In the kitchen there was an ordinary range, a high-pressure boiler being placed immediately behind the firegrate. It was on the circulatory principle,—one pipe conveying water from the cistern into the boiler, while by another the heated water re-ascended into the cistern. The fire-place had not been used for two or three days; but a fire was lighted in the grate, and in the evening the boiler burst with a violent explosion, inflicting dreadful injuries on a woman and scalding a man. The interior of the kitchen was a perfect wreck, as well as the windows, door-frames, and walls. The dresser also took fire. There must be something wrong in the construction of kitchen boilers in the North.

**SANITARY IMPROVEMENT OF BURLEY.**—A good deal of paving and pipe-sewerage has of late been carried out at Burley, according to the report for last year by the borough surveyor, Mr. Colbran, who says, in allusion to these matters, at the close of his report,—“It is proved, from statistical returns of the registrars, that the effects of sewerage and paving are most beneficial; for in Chorlton the mortality in the undrained streets was 4 per cent.; in the drained streets 2 per cent. only;—in Rochdale, well-conditioned localities, deaths to population 1 in 43 1.10ths; ill-conditioned localities, 1 in 22 4.10ths;—in Liverpool fifteen courts badly drained contained 307 dispensary cases, while the same number, well drained, contained only 109 cases, the population of both courts being nearly equal. Similar data were obtained in several other towns; and immediately after putting the streets in proper condition a decrease of mortality ensued. If these results follow in Burley it is impossible to conceive that your committee could have expended the money more judiciously.”

**HER MAJESTY'S THEATRE.**—M. Maillart's opera, *Lara*, adapted for the English stage by Mr. Oxenford, has proved a success, and will, we have little doubt, fill the house for some time to come. The music is exceedingly agreeable throughout, and Miss Louisa Pyne both acts and sings in it admirably. A *debutante*, Miss Romer, acquits herself satisfactorily, and the general getting up is good. The plot is compounded out of Byron's two poems, "Lara" and the "Corsair." How is it, people are beginning to ask, that Mr. William Harrison himself has not yet sung in his new house?

**THE WELLINGTON CLOCK TOWER.**—The clock-tower at the foot of London Bridge, narrowing the space too greatly, is to be taken down. When its erection there was determined on, we pointed out the mistake that was contemplated, and said that its removal, when up, would be but a question of time. That time has come.

**OUR RAILWAY SYSTEM.**—The first meeting of the Department of Economy and Trade of the National Association for the Promotion of Social Science was held on Tuesday night, at their rooms, 1, Adam-street, Adelphi. Mr. Edwin Chadwick, C.E., the president of the Department, occupied the chair, and read an interesting paper on "The Economical Principles of a Reform of the Legislation and Administration for the Conveyance of Goods and Passengers by Railways." An important discussion followed.

**RAILWAYS AFFECTING THE CITY.**—Mr. William Haywood's report on the projects of the railway and other companies applying for powers to construct works within the City of London, has been published. In conclusion, Mr. Haywood says, "The total area, including public ways, scheduled within the City for the several projects reported upon is 31 acres, but of this about 18 acres are already authorized to be taken under existing Acts, leaving 13 acres which are scheduled for the first time, of which about 10½ acres is property, and 2½ acres is public way." He advises, as a preliminary step, that the court should dissent from all of them.

**THE WATER SUPPLY AND SEWERAGE OF BLAYDON.**—Mr. Jos. Gordon, city surveyor, Carlisle, has, in compliance with a request from the local Board of Health of Blaydon, reported upon the water supply and sewerage of the Blaydon district. The result of Mr. Gordon's inspection and survey estimates the cost of the proposed additional water supply at 1,931*l.*, and the sewerage works at 3,510*l.*; making a total of 5,441*l.* These figures include the cost of superintendence of construction, and all contingencies incidental to such undertakings; and Mr. Gordon has laid before the Board a detailed report of the whole works.

**ON THE PROPULSION OF TRAINS ON LINES WITH FREQUENT STATIONS.**—A paper "On the Best Mode of applying Power to propel Trains on the Metropolitan and other Railway Lines having frequent Stations and in terminal Stations," was read on the 18th of January by Mr. P. W. Barlow, F.R.S., at the Society of Arts. Mr. Barlow recommends a modification of the rope traction system with stationary power to give temporary impulse in the place of locomotives. He says:—"When the duty to be performed is that of working a line in which the stations are very close together, and the stoppages frequent, it then results that all, or nearly all, the work of the engine is expended in acquiring the travelling speed; and that, in fact, it has not ceased to accelerate its speed when it becomes necessary to shut off the steam and apply the brakes, so as to stop at the next station. In fact, the same engine which in long stages would make an average speed of 35 or 40 miles per hour, is incapable, with frequent stations, of making an average speed of 13 or 14 miles, even with a greatly reduced load. In this condition of things, which is in fact the condition of metropolitan railways, a new set of circumstances has to be met, and the question arises whether, where these circumstances exist, stationary power, when applied in a manner strictly adapted to the case, is not more economical—capable of greater speed—and in all respects more suitable to the convenience and exigencies of the traffic and locomotive power?" The present system, it appears, is wasteful of power, and expensive in working. In the discussion which followed, however, the speakers were by no means unanimous as to the advantages of Mr. Barlow's proposal.

**ACCIDENT AT KING'S-CROSS-ROAD.**—On Wednesday afternoon, shortly after one o'clock, a small building in front of St. Philip's Church, which was in course of removal, fell down, injuring a bricklayer named Thomas Seale rather severely.

**THE STAINED GLASS IN HERETORY CATHEDRAL.**—A paper on this subject, by the Rev. F. T. Havergal, was read by that gentleman at a recent *soirée* in connexion with the Herefordshire Philological, Antiquarian, and Natural History Society. After giving some account of the ancient use of stained glass, he said,—"We must now draw your attention to the second part of our subject, viz., 'The Ancient and Modern Stained Glass of our own Cathedral.' That this edifice was once gorgeously filled with stained glass there is every reason to believe. Historians of the Norman and Early English period are quite silent, but yet we may fairly infer that as the carving and paving, wall and ceiling decoration, were all very beautiful, so we may, I say, safely presume that the windows were filled with the highest efforts of art. The oldest specimen that remains with us, is to be seen on the south side of the Lady Chapel. Adjoining it is another, said to be Munich glass, formerly in St. Peter's Church, Hereford. The next specimens we possess belong to the Decorated period, two windows having been very successfully restored last year by Mr. Warrington. Mr. Havergal here quoted Rawlinson's description of the windows formerly in the cathedral (p. 140), and then noticed those in Bishop Audley's chapel and the Old College chapel. He then briefly noticed the modern windows, nineteen in all,—six by Castell in triforium of choir; one by Hardman, in east end of choir; five by Warrington (including three to Archbishop Musgrave, one to Canon Clutton, and one to Bishop Huntington); one by Clayton & Bell, and five by Gibbs. Out of 100 windows admitting light to the interior of the cathedral, Mr. Havergal remarked that at present twenty-three were filled with stained glass.

TENDERS.

For warehouse, exclusive of plumber's, glazier's, painter's, and ironfounder's works (which are 130*l.*), for Navigation Company, Hornsea, Messrs. Balamy & Hardy, architects:—

Hall & Co.	£900 0 0
Booth	810 0 0
Huddleston	898 0 0
Wallis	860 0 0
Carter	860 0 0
Morley & Co.	829 0 0
Pike & Co. (accepted)	798 0 0

For completely finishing the arcades, Nos. 5, 7, and 8, Gordon-terraces, 1, Upper Richmond-road, Putney, Messrs. Charles & Sydney Lee, architects:—

Ariss & Sons	£1,302 0 0
Pain	1,288 0 0

Accepted for building new Borough Gaol at Scarborough, Yorkshire. Mr. W. B. Stewart, architect:—

*Bricklayer, Mason, and Plasterer's Work.*

Petch	£4,889 10 0
-------	-------------

*Hardgreaves.*

Hardgreaves	£137 10 0

For completion of ten houses at Kenilch-town, for Mr. Henry Gibbon. Mr. Edward Clark, architect. Quantities supplied:—

Rowe (accepted)	£1,976 0 0
-----------------	------------

For sewer.

Rowe (accepted)	£150 0 0
-----------------	----------

For coal-office, stables, and coal-shed, and sundry works, at Messrs. Rickett & Smith's Wharf, Grove-road, Bow. Messrs. Elliott & Chamberlain, architects:—

Cannon	£1,111 0 0
Wills	1,094 0 0
Tolley, Jan.	1,029 0 0
Single	935 0 0

For additions and alterations to premises in Church-street, Haverly, for Mr. Rose, Mr. Giddon, architect:—

Ennor	£260 0 0
Salmon	490 0 0
Skinner	475 0 0
Shawin, Brothers	454 0 0

For the erection of chemical works at Hackney Marsh, for Messrs. Sturson, Mauls, & Nicholson, Mr. C. Cooper, Maidenhead. Quantities supplied:—

Dabbs	£8,490 0 0
Hack & Son	7,967 0 0
Sawyer	7,653 0 0
Henshaw (accepted)	7,328 0 0

For water tank, and girders under ditto:—

The Regent's Canal Iron Work	—
Compu	£364 0 0
Ransomes & Sims (accepted)	335 0 0

For building warehouse in London-wall, Mr. C. Lawes, architect. Quantities not supplied:—

Patrick & Son	£1,134 0 0
Brass	1,038 0 0
Dove, Brothers	1,023 0 0
Rawlin	988 0 0
Hardiman & Sandon	981 0 0
Prince	893 0 0
Cannon	848 0 0
Bostell	807 0 0
Anley	814 0 0

For building warehouse in Gun-square, Minorities, for Mr. Haynes. Mr. T. C. Clark, architect:—

Tracey	£3,987 0 0
Hack & Son	3,597 0 0
Patman & Co.	3,472 0 0
Ashley & Son	3,455 0 0
Downs	3,293 0 0
Lawrence & Son	3,172 0 0
Corder	3,133 0 0
Brass	3,136 0 0
Sharppington	3,123 0 0
Anley	2,913 0 0
Hardiman & Sandon	2,913 0 0

For an inn in the Wellington-road, St. Mary Cray, Kent, for Messrs. Fox & Sons, Farnborough. Messrs. George & Vaughan, architects:—

Townsend	£618 0 0
Francis & Son	640 0 0
Loise	618 0 0
Sales	633 0 0

For two houses and shops at Beccles, for Mr. W. E. Crowfoot, M.P. Mr. W. O. Chambers, architect:—

Rix & Brett	£827 5 9
King & Blunderfield	799 10 0
Woodroff	700 0 0

For two semi-detached villas on Kirtley Cliff, South Lowestoft, for Mr. Burk. Mr. W. O. Chambers, architect:—

Swtanum	£1,017 0 0
---------	------------

For a house and shop at Beccles, for Mr. Garsham Mr. W. O. Chambers, architect:—

Rix & Brett	£316 18 4
King & Blunderfield	275 10 0

For alterations to and enlargement of St. Mark's parsonage-house, Kennington, Mr. Ewan Christian, architect. Quantities supplied by Mr. T. W. Goodman:—

Sharppington & Cole	£1,295 0 0
Rhodes & Roberts	1,177 31 0
Marland & Son	1,103 23 0
Stimpson	1,096 38 0
Luthey, Brothers	1,081 23 10

Extra on Portland cement.

CHURCH, TURRET, and STABLE CLOCKS.

J. W. BENSON, having erected steam-power and improved machinery for clock-making, at the manufactory, Ludgate-hill, will be glad to furnish to clergymen, architects, and committees, Estimates and Specifications of every description of Horological Machine, especially cathedral and public clocks, chiming tunes on any number of bells. A descriptive pamphlet on Church Clocks post free for one stamp. Watch and Clock Maker by Warrant of Appointment to H.R.H. the Prince of Wales, and maker of the great clock for the Exhibition, 1862. 33 & 34, Ludgate-hill, E.C. Established 1740.

# The Builder.

VOL. XXIII.—No. 1149.

## Discoveries at Cyrene.\*

It is said to be England's mission to evangelize the world: it certainly seems to her mission to explore it. Year by year, her hardy and enterprising sons voluntarily relinquish the comforts of home life to do battle with suffering and death in every form and in every part of the globe, impelled by that passion which is the characteristic and inheritance of the true Anglo-Saxon stock. To

the North Pole ("Are we going up that way again?") asks Sherard Osborn and his hardy crew,—to the South,—under the torrid zone,—over the wide expanse of the Sahara,—through the pestilential swamps of the West coast,—amid the trackless forests of America, the British explorer pursues his way, risking death in many forms, and enduring the extremes of heat, cold, hunger, thirst, and fatigue, animated by the desire of imparting information to the world, and consoled in his first extremity by the thought that, whether he survive or perish, his name will be remembered by his countrymen, and counted amongst those of men who have suffered and died for them in other fields and for other causes. Nor is he deceived in his hope for sympathy. Have we not gone forth into the wilds with Livingstone, journeyed to Mecca with Burton, and accompanied Speke and Grant to the Lake Nyanza, and imagined with them that we have discovered the source of the Nile? Yes; and have suffered and conquered with them, and have enshrined their names amongst our household gods. They are the pioneers of civilization, and point out the road to commerce. But there is another class of explorers who also deserve well of their country; who labour for it in other ways; who undergo as great hardships and run as great risks, and whose labours are crowned generally with more immediate and palpable results; we mean those who explore the sites of deserted cities, and exhume the buried wonders of art. These men are the benefactors of Art, as the others are the benefactors of Commerce: and though their names are not so often in our mouths, they will last as long as the world of art exists.

The name of Lord Elgin will be associated with the marbles of the Parthenon; that of Layard with the Assyrian sculptures; that of Newton with the Babylon marbles; and, lastly, those of Smith and Porcher with the Cyrene collection, as long as the statues they have rescued from oblivion endure.

Some amongst our readers may ask what are the Cyrene marbles? Where did they come

from? How were they procured? And their ignorance is pardonable; for how are they to know anything about these valuable and interesting remains of antiquity so long as they are shut up in a shed or concealed in a cellar in the British Museum. How they were acquired and whence they came they may learn from the interesting and well-illustrated volume before us, which relates how Lieutenant (now Captain) Smith, R.E., and Lieutenant (now Commander) Porcher, R.N., being stationed at Malta, obtained leave of absence, and started, upon their own responsibility, and at their own cost, on an expedition for the purpose of exploring the cities of the Cyrenaica; and how, after meeting with success in their researches, they were assisted by her Majesty's Government, and were enabled to obtain no less than 148 pieces of sculpture,—some of them of great value,—for our national museum.

These gentlemen were not tyres in the work of exploring: Captain Smith had co-operated with Mr. Newton in the excavations at Halicarnassus and Cnidus; and Captain Porcher had dug at Utica and Carthage with Mr. Davis; and both had no doubt imbibed that passion for exploration which a spice of danger and a certainty of adventure so greatly heighten. They also possessed the necessary qualifications for the task they undertook; which consist, in the first place, of a knowledge of the language of the country visited. Interpreters and dragomen are not always to be depended upon, as they are too apt to conceal the truth amidst the flowers of their eloquence, and to contrive that sundry coins shall stick to the measure with which they mete out justice between their masters and the natives. The next most important requisite to success in excavating is a ready perception of which are the best spots for digging in, acquired by practice and resulting from a sufficient acquaintance with architectural forms to enable a person to judge of the sites of temples and other public buildings. A third qualification, also essential, is a knowledge of the modes of working, and an acquaintance with the mechanical appliances necessary for moving large blocks of stone. Firmness and justice in dealing with the natives are also indispensable. To these qualifications may be added those of an experience in photographing and a talent for drawing. This last gift has, in the present instance, proved a great acquisition, as it has enabled Captain Porcher to give a series of views which make us quite familiar with Cyrene, and its rock-cut sepulchres, its gushing fountain, its ruined temples, and its well-wounded wadys.

The book opens with a short history of "the parts of Lybia about Cyrene." It appears that in the year 631 B.C., Battus the Stammerer, finding, we presume, that the impediment in his speech prevented his getting on in his own country, left the island of Thera, now Santorin, one of the most southern of the islands of the Archipelago, and took ship, with a goodly company of followers, for the continent of Africa. At first he took possession of an island, but eventually settled on the main land. Finding that the higher he got in that warm climate the more comfortable he found himself, he chose the edge of a plateau about 2,000 ft. above the level of the sea, and about 12 miles distant from it, as the site of the capital of his colony. Here there was a magnificent source of water, near which he built a temple, dedicating it to Apollo, whom he believed to be his patron. King Battus I. was succeeded by other kings until the year 450 B.C., when the regal form of government was exchanged for a republic, which, going the way of all other republics, fell a prey to internal strife, and became subject to the neighbouring sovereigns of Egypt, the Ptolemies, in the year 321 B.C. These monarchs rebuilt the five cities of the Pentapolis,—as the colony was then termed,—and gave them the names of

Cyrene, Apollonia, Ptolemais, Teuchira, and Hesperis. The last king of the race left the kingdom by will, in the year 95 B.C., to the Romans, who called it the province of Cyrenia. Up to the time of Trajan it prospered, but afterwards fell into decay, and was eventually conquered by Chosroes, king of Persia; and at last it fell into the hands of the Arabs in the seventh century, who have encamped upon its ruins ever since—fortunately for us and for our national Museum, for the Arabs are the best preservers of antiquities: they have no occasion for houses, as they are dwellers in tents; consequently they neither destroy the temples for building materials, nor do they burn the statues for lime, as some nations calling themselves more civilized have done. The Cyrenaica, then, offered a fine field to explorers, for it had not been ransacked like the provinces of Asia—indecid, few travellers had passed through it; those who had, had not opportunities for excavating.

Lieutenants Smith and Porcher accordingly left Malta, armed with a firman, for Benghazi, touching at Tripoli on the way, in the month of November, 1860. At Benghazi they assembled a caravan consisting of ten camels, riding-horses for themselves, and a few negro workmen, and started for Grennah, the site of Cyrene, on December 14th. Owing to the slippery state of the roads, they were ten days in reaching the spot, a distance of 150 miles from Benghazi. The last hours of their journey were occupied in the ascent to the plateau on which Cyrene is situate. The edge of the plateau—which is 70 miles or 80 miles in length, by many miles in breadth—is intersected by numerous ravines, which run through two other lower terraces, and descend to the sea, which is 12 miles to the north of the upper plateau.

Cyrene stands on the edge of this table-land, occupying two ridges and an intervening valley. Its necropolis, or city of the dead, which in all Greek cities is much more extensive than was the city of the living, occupies the whole north side of the range covering the hills from base to summit. The table-land has no trees, but the wadys are filled with the foliage of the myrtle and oleander. The fountain of Apollo rises between the two hills. "Here," writes Captain Smith, "a copious fountain of delicious water issues from a cavity in the face of the cliff, from which a small aqueduct, cut in the rock, runs along the side of the road for several miles. Close to the fountain it was formerly hollowed out into a series of troughs, so arranged that, by the overflow of each passing to the next, they were always full,—a slight indication of the attention paid by the Cyrenians to the wants of the horses for which their country was so celebrated. One can easily fancy the citizens of Cyrene halting in their evening drives at this beautiful spot to water their horses, and to enjoy the extensive view of the magnificent scenery around. On one hand is the high and rugged face of the cliff, overhanging the ravine below; on the other the steep hill of Cyrene rising from the beautiful valley of verdure at its base; while, far below, lies the varied surface of the plateau, stretching away for miles to the dark blue line of sea beyond."

The explorers took up their quarters in an empty tomb, cut in the face of the rock,—the most comfortable place of abode in a hot country, as it is cool in summer and warm in winter,—and devoted their time to an examination of the neighbouring sepulchres. These were of every form and variety of plan and elevation. Some had porticoes, others pilasters, chiefly of the Doric order; and others were decorated with polychrome, both inside and outside, or ornamented with busts and other sculpture, like that in the accompanying woodcut.\* Captain Porcher gives no less than fifteen plates of illustrations

\* "History of the recent Discoveries at Cyrene, made during an Expedition to the Cyrenaica, in 1860-61, under the Auspices of Her Majesty's Government." By Captain R. Murdoch Smith, R.E., and Commander E. A. Porcher, R.N. London: Day & Sons, 1864.

\* See p. 100.

of these tombs, many of them being plans, some of which, being of the ordinary type, might well have been omitted. Finding that all these tombs had been opened and ransacked, probably centuries ago, the explorers wisely turned their attention to the more important remains of the city itself.

On New Year's Day, 1861, they abandoned the tombs and attacked the temples. There were no less than five mounds upon the site of the city, which indicated the position of as many temples. One of these was inclosed by a peristyle wall and a massive colonnade of the Doric order. The temple itself, like all other temples in Cyrene, was also Doric, but of small dimensions. The plan of it, as well as that of the Temple of Apollo, both of which were taken by Captain Smith, were unfortunately lost. There was a cella, but no peristyle. A pronaos, with two Doric columns between two half-columns engaged, in the cella wall. It is to be regretted that the authors give no drawing of the peristyle wall and gateway. Their excavations on this site were rewarded by the "find" of a noble statue of Bacchus, perfect with the exception of the right arm.

Encouraged by the result of this essay, they next turned their attention to a mound in front of the fountain, which they rightly conjectured to be that of the Temple of Apollo. The information they give about the architecture of this temple, as well as of the one just mentioned, is extremely meagre; but we must remember that they did not go to Cyrene for the purpose of examining the architectural remains, but for the discovery of sculpture: they tell us that it was unusually long in proportion to its breadth, and that its entrance was at the east end, which, notwithstanding the receipt of Vitruvius, was the case in most Greek temples—in that of Minerva Polias, at Prieno; that of Apollo Branchido, near Miletus; and in that of Bacchus, at Teos. After some days spent in digging, the suave smile of the statue of Apollo the Luto-player greeted them from under the ground. His head was detached from his body, which was broken into no less than one hundred and twenty-one fragments. These being carefully collected, there was built up from them the magnificent statue now in, or rather outside, the British Museum.

These statues of Bacchus and Apollo were with great labour moved from their places on sledges, "foot by foot," and hurried or walled up to secure them from injury. Hitherto the expenses of the expedition had been defrayed by the explorers themselves, but now they had good grounds for applying for assistance to the Government. This they did in February, and pending the arrival of a reply, when their labourers left them for the harvest, which begins here in April, they determined to visit the other cities of the Pentapolis. Of these Ptolemais appears to be the most perfect, and the most interesting. There are slight remains of several public buildings, and the walls of the city can be traced throughout. "The great gateway, in the western wall, is still standing, and is remarkable for the excellence of its masonry. It is built of massive ashlar work, without mortar, the stones of which is laid in alternate courses of headers and stretchers, like the rustic work of the day." This gateway, of which we give an illustration,\* is built after the usual system of defence employed in Greek fortifications, being protected by a pylon on each side, as at Assos, and in some of the cities of the Peloponnese.

Soon after their return from this excursion, the ship *Assurance* arrived with letters, informing them that the trustees of the British Museum had granted 100*l.* towards defraying expenses. For an account of the ingenious method, invented by Captain Smith, for conveying the statues to the coast, and of their subsequent embarkation, we must refer our readers to the book itself. Suffice it to say, that the *Assurance* sailed for England with her valuable freight just a month after her arrival. Immediately after her departure, excavations were commenced upon the site of the largest temple of the five: though the results were not satisfactory as regards sculptures, several remarkable architectural features were brought to light. The temple was of unusually large dimensions, the cella measuring 169 ft. 6 in. by 53 ft. externally. There were eight columns at the ends and seventeen at the sides. The pronaos had two and the posticum three columns in antis. The columns were 6 ft. in diameter, and the capitals measured 9 ft.

across the abacus; they stood 14 ft. 5 in. apart, and 18 ft. from the wall of the cella. In the interior there were two ranges of small Corinthian columns, standing on pedestals, which supported the roof of the hypæthron, as at the Temple of Apollo Branchido, and the Temple of Apollo Epicurus, at Bassæ.

There is a remarkable similarity between this temple and the Parthenon. Both were peripteral, hypæthral, octastyle, and of the Doric order; both had seventeen columns on the flanks, and the dimensions were very similar; that at Cyrene, as measured by Captain Porcher, being 223.5 ft. long by 100 ft. in breadth; whilst the Parthenon was 228.7 ft. in length by 100.8 ft. in breadth.

There is no outer step to the peristyle shown in the plan, though there must of necessity have been one, if not three, and most probably one to the pronaos and one to the posticum. It would have made the plan and the plans of other temples clearer if the walls and columns had been shaded, and the dimensions figured in the places where they were taken.

Nine days after the departure of the *Assurance*, the *Scourge* arrived at the port of Cyrene, with the welcome intelligence that the trustees of the British Museum had granted an additional 500*l.* for the expedition. This sum enabled them to complete the excavation of the Temple of Apollo, and also dig up a smaller temple situated near the stadium—in plan similar to the Temple of Bacchus. This was peripteral, measuring 150 ft. by 100 ft. on the upper step of peristyle. The columns were 4 ft. 5 in. in diameter, and the cella-floor was raised two steps above that of the peristyle. No indications of the positions of the columns of the pronaos or posticum were discovered. They also excavated a small temple to the south of the temple of Bacchus, and on a similar plan to it, having in the pronaos two columns between engaged half-columns, and no peristyle. In the interior were found several pedestals for statues, and a flight of five steps, leading to a raised platform, at the west end. This temple is presumed to be that of Venus, as several statues of that goddess were found in it.

In September, H.M.S. *Melpomene* arrived, and soon afterwards the cases containing sculptures were, with the aid of the crew, taken to the beach and safely deposited on board, notwithstanding a show of opposition on the part of the Arabs. The two members of the expedition quitted the shores of Cyrene in the *Melpomene*, after a residence there of eleven months. The marbles were conveyed to Malta, where they were transferred to the *Supply*, Captain Balleston, who had formerly taken charge of the Budroum sculptures, and conveyed to England, where they were all arranged and identified by the zealous keeper of Greek and Roman antiquities at the British Museum, Mr. Newton, to whose efforts the expedition in a great measure owed its success. The best figures have been admirably photographed by Mr. Bedford. These photographs, together with thirty excellent views by Captain Porcher well rendered in lithography, and Captain Smith's spirited description, combine to form a volume interesting to the antiquary; pleasing to the man of artistic taste; and, moreover, attractive to every one who can enjoy the perusal of a well-illustrated narrative of adventure and discovery in a territory seldom before visited, and never before thoroughly explored.

Having endeavoured to give a brief outline of the mode in which the valuable collection of sculpture has been obtained for the nation through the exertions of two talented men, and at small outlay, we may now say how it is that similar expeditions are so frequently left to individual enterprise. In the survey of Jerusalem at present being carried on by Lieut. Wilson, R.E., and four sappers, Lieut. Wilson has to pay all expenses incurred in underground explorations out of his own pocket. It is true that this will not be a remunerative undertaking; still, as the results will be of the greatest interest to the whole Christian world, of which we consider England to be the head, we should surely consider the few hundreds that might be spent upon it by those who hold charge of the purse strings better laid out than the thousands that are sometimes expended in other ways; and we and posterity would say of the statesman who had the boldness to bear the responsibility of advocating it to his more economical colleagues,—He deserved well of his country. Expeditions such as that to Cyrene, to use a common word, "pay" (if the Budroum or Cyrene marbles were put up for sale in the great auction mart of nations, they

would realize much more than they cost the country); and they are not only profitable, in a commercial point of view, but they are also otherwise advantageous, by tending to extend the influence of England's name amongst the nations of those countries in which they are carried on; for the presence of a ship of war exalts our prestige amongst uncivilized people, who are naturally inclined to respect "physical force" more than anything else. The moral force, and the justice of the English character, also make their impression upon people who are accustomed to misrule; and these expeditions are also beneficial to the natives themselves, for, in addition to the idea of sterling worth impressed upon their minds, they have also the benefit of the sterling gold, which in itself is a civilizing power, left in their hands. Regular pay for regular work is the best corrective of predatory habits. Such being the advantages of these expeditions, let us hope that they may be more warmly encouraged, now especially that we have amongst the members of Government two distinguished by their taste for art, and whose successful missions in Eastern countries have made their names deservedly popular.

There are various fields for enterprise, and as the undertakings can be shown to pay, we should not be at all surprised if some day they are undertaken by "limited liability" companies. A bonus for the privilege of digging, and an offer to share the proceeds, might induce an impoverished Government to consent to the disinterment of those treasures of art which probably otherwise remain for ever useless to it.

Hundreds of fine Greek statues are known to be buried in the Olympian plain. 5,000*l.* properly expended would bring most of them to light, and amongst them possibly some of the precious materials of which the statue of the Olympian Jove himself, the *chef-d'œuvre* of Phidias, were constructed, for on account of its enormous dimensions (it was 55 ft. in height) it was probably never taken to Constantinople entire, as some historians state. There would be a fine dividend in that case. The city of Rhodes would be the means of obtaining permission to carry thence under it, and the results would no doubt well repay the outlay. These are two amongst many sites which could be mentioned where the results would most probably greatly exceed the cost of excavating, and certainly it is better that such fine works of art as the Elgin marbles, the figure of Mausolus, the Apollo of Cyrene, and the Venus of Milo, should be placed in national museums to instil a taste for the beautiful into all succeeding generations, than that they should remain for ever buried in the ground, or be destroyed by barbarian hands. What matter if they be not always appreciated as they deserve—truth and beauty are intimately allied; and we may be certain that the admiration of them will outlive all changes of taste; that however wildly the waves of fashion in art may rage around them, these dignified and graceful statues of antiquity will survive, serenely smiling at the ebbing and flowing tide at their feet, as though to say,—Ours is the domain of true beauty, and all your puny efforts to induce another belief will be for ever useless.

#### BRITISH INSTITUTION.

How pleasant it would be to find some new verbal system of expressing worn-out opinions of ever-recurring matters. For a long time past notice of current picture-exhibitions has involved little else than reiteration of the same judgments on the same evidence and comparisons with those of antecedent date; and if there were nothing much to be said of Messrs. So-and-So's then particular performances, a reference to something they had done formerly afforded agreeable opportunity for augmenting or qualifying praise, or the contrary, as the case might be.

It is but a poor compliment to pay to a present year's production to say that it reflects more favourably than other efforts latterly have done, very old impressions of bygone circumstances and memories never allowed to be displaced by something subsequently better worth the remembering; and one with as much of the latter as the sweet in it for those who dream and talk about progress, to be told they are getting on, because they show intermittent symptoms of becoming more likely that they were some fifteen or twenty years ago. There are too many of us who have lapsed into the chimerical belief that

\* See p. 100.

it is only necessary to drive on in the deeper ruts of life's road to make sure we are advancing; and would, probably, only be made conscious of even so simple a fact as of the world's being really run just at the point whence we started, and with only such cold comfort as might be derived from the consolation that there are thousands yet to be deceived no earlier than we were,—so dominant is the example of habit over any consideration of its being a right or a wrong one.

Whatever advantages the present show of pictures at the British Institution may possess above the common run of them are mainly attributable to a return of some of the assistance that used to constitute its importance when more freely bestowed, and to there being a larger number than usual of agreeably pretty little works—as distinct from the disagreeably pretty—while, perhaps, an extra display of merit in the emanations of one or two of its contributors of landscape.

But, unfortunately, to arrive at the conclusion of there being any favourable difference, it is requisite to ignore the greater proportion of its constituent items, and graciously accept that which is really good as compensation for so much that comes under the opposite extreme of denomination.

The leading attractions are Sir Edwin Landseer's portrait of a Skye-terrier, the property of Her Majesty, in which his power of hand and apprehensiveness of animal character are as marked as ever: (85) "Dear Old Boz," is evidently a likeness invested with all the extra value that contentment of art can give: a characteristic statement of a disappointment to horse and hounds that have been turned out for a run, but are prevented by frost and a fall of snow, and that there is "No Hunting" till the weather breaks (189), appears to be as lamentable a state of things to them as it doubtless is to their owners; with a third and still more valuable exponent of his mastery application of genius, "An Event in the Forest" (204), which may be classed with the best of its precursors. A stag has fallen from a precipice, apparently shot by the stalkers, dead, and out of reach and sight of its assailants: the body has attracted the hungry attention of a fox that finds his possession of the carcass is about to be contested by an eagle looming through the misty freezing atmosphere; the snow that covers in one cold shroud the broken masses of rock and all things represented but the living and the dead creatures, serves as an auxiliary for enunciating the wonderful mastery of form and colour attained by Sir Edwin. The picture is one of those epics in which he allegorises human as well as animal instincts, and inculcates a moral. Mr. Ansell has attempted a similar aim, but has been unhappy in selecting "The Death of Cæsar" (1) for apostrophe: viewed in the abstract as a matter-of-fact specimen of animal painting its claims to be considered superlative are undeniable; though his admirably-studied dogs, and the illustrious appearance of accessories, are so misapplied and incongruous that the result is a burlesque of serious drama.

Mr. Dawson's splendid panoramic representation of "London from Vauxhall" (195), helps very much to raise the character of the collection. Truthfulness has in no way been sacrificed to obtain pictorial effect; and yet, by a judicious selection of influences, he has been able honestly to impart to London as much gorgeous glow of colour as even Venice can boast of. Seldom have the exquisite beauties of a morning sky, with its delicate gradations of pure colour, unsullied as yet by the black breath of busy manufactories, met with such just appreciation, and such power to record it; and few could have rendered so faithfully, and at the same time invested with so much picturesque worth, wharfs and old outbuildings that the multitude would pass by as objects unlikely to be used with profit. In its combined excellence of verisimilitude and artistic treatment, it may compete with any cognate example. Not so much can be said of Mr. Niemann's "Hampstead Heath" (601); in spite of his forcible appeal to the eye for method of execution and immensity of canvas, it has the appearance of a small picture magnified, and its deficiency in the finer qualities of art is not to be atoned for by any amount of those more easily acquired, with such a comprehensive opportunity for their application.

Mr. W. B. Richmond has idealised his portraits of "Three Sisters" (118), by a peculiar though beautiful treatment that proves the susceptibility of the pretty costume now worn by young

ladies, especially if they be as charming as these are, to the supply of all the necessities of the painter. With the subdued richness of colour that pervades it, and the graceful attitudes of his sitters, so well supported by the appropriate landscape background, the work is acceptable as a picture with a poetic charm of its own, irrespective of its more immediate interest.

Mr. H. W. Phillips's study of an Egyptian's head, "Suleiman" (174), is conspicuous for the vigour and simplicity of his style,—a very admirable one,—and for its harmonious effect, as well as for the life-like presentation of the nation typified. It is one of the most charming works in the room; and was bought by the Council of the Art Union of London at the private view. Mr. Backer's "Brunetta" (217) and (541) "La Biondia," have the recommendations common to all of his productions: they are exceedingly pretty and most dexterously handled. "The Beauty of Valentinia" (551), by Mr. H. B. Burgess, shows an increase of power in its capital representativeness, although he labours under a disadvantage in so closely following in the wake of the inimitable Spanish Phillip. This objection is still more prominent in the works of others here less capable of sustaining a comparison.

There are very few illustrations of dramatic incident to be cited as having special claims of attention above those presented by Mr. E. C. Barnes in "Vive la Gloire" (374), wherein a wounded and tired out French veteran, in the uniform of Napoleon's cherished "Old Guard," is lying asleep near the village well, where he is discovered by a peasant-girl and child, who have come to draw water. No striking originality marks the conception of this story; it is simply an enunciation from a very old source of satire very well made; and the expression of terror, mixed with compassion, depicted in the faces of his startled discoverers, as well as the utter prostration of the poor soldier, indicate talent enough to build great expectations upon, increased by consideration of the workmanship and good feeling for colour that are evident in the skilful manipulation of its parts.

Mr. Pettit's "Out of an Engagement" (312), sight, has that in it which will induce to a knowledge of it after a more delicate examination. It may be supposed to represent a theatrical family a week or two after the last night of "the best pantomime in London," left without resources or hope for a speedy profitable investment of their humble abilities, arms, and legs. The father or grandfather, with the enthusiasm of a true artist, is keeping up his practice against the time his fiddle may be in requisition; but the two little girls, denuded of their "fairy glory," sit like little Cinderellas after twelve o'clock, huddled, all rags and wretchedness, over the few embers that remain to them yet in the grate. Their location is in keeping with their want of allocation, squalid enough to satisfy the most morbid views of common acceptance; but withal there is nothing in a bare garret significant enough of its inhabitants' professional calling, and nothing sufficiently pronounced to assist, beyond a surmise, the direct intention of the picture. However, this is much better in all respects than a second contribution (102), "The Wounded Despatch-bearer."

In academic proficiency Mr. C. Lucy's carefully-drawn and naturally-disposed figures of "The Sleeping Babes in the Wood" (358) fall short of little that might be wished for: overlooking the age of his children as not agreeing with their description in the ballad,—

"The one a fine and pretty boy,  
Not passing three years old;  
The other a girl more young than he,  
And made in beauty's mould;—"

and allowing for the "twelvemonth and a day" additional, they must be allowed to be very fine-grown, and the picture to be one of the stars of the exhibition. Mr. G. D. Leslie still clothes his romantic episodes in fifteenth-century dress. "Cherries" (395), in which their analogy with ladies' lips is the sentiment conveyed, if not a very serious, is, at least, a congenial motive to all who may envy the smart young gallant perched on the lower bows of the tree, deducting from philosophical researches the most pleasing and convincing results, as he feeds, in cherry-bob fashion, the lady of his choice, and finds that,—

"Cherries and lips do well agree,  
And 'twixt them is good harmony  
Of colour bright and sugar sweet;  
Therefore 'tis meet,  
This pleasant weather,  
That lips and cherries should come together.  
But lips than cherries are more sweet;  
What if they meet?"

But, to save space, it is necessary where mention is equally deserved, to note, when annotation is not easily possible, some others of the pictures of various merits, such as Mr. E. Crawford's satire on the legality of the law, "A Man of Straw" (3), wherein counsel is doing rather more than "nursing a witness;" "The Last Lucifer-match" (9), by Mr. J. T. Lucas; "The Coast of Normandy" (34), by Mr. D. W. Deane; "Baby's Corner" (51), by Mr. Frank Wyburd; "Innocence" (68), much more successful than "Guilt" (502), by Mr. A. F. Patten; "Travelling in Russia" (84), by Mr. A. F. De Prades, a notable painting of horses; "A Drop for Pussy" (91), by Mr. J. Morgan, the worst part of which is its title; "Composing his Love-Speech" (109), by Mr. D. Wilkie Wynfield; "Cramming for Examination" (121), and its companion, "Cudgelling the Brains" (410), by Mr. S. Anderson; "A Stitch in Time" (134), by Mr. W. Hemsley; "A Naid" (138), by Mr. W. E. Frost, A.R.A.; "Turned out of Church" (147), by Mr. Frank Holl, jun.; "The Dead Heat" (162), by M. A. Ludovici; "The Mountain Spring" (194), by Mr. W. Underhill; "Going to School" (225), by Mr. J. Clark; "Music and Dancing" (282), by Mr. D. T. White; "The Arabian Nights" (296), by Mr. L. Snythle; "The Protector" (307), by Mr. C. Rossiter; "A Dame's School" (370), by Mr. E. Davis; "Miranda" (453), by Mr. T. F. Dicksee; "Going Home" (461), by Mr. C. S. Lidderdale; "La Carriola" (489), by Mr. E. Long; "Une Matelotte" (517), by Mr. J. Haylar (447); "The Sea King's Funeral Boat" (529), by Mr. W. B. Scott; and "The Young Bohemian" (587), by Mr. T. F. Grabam, that call for more than a meagre note.

To Mr. S. B. Halle we would quietly intimate that it is a great impertinence to thrust upon the public so many repetitions of one face. At the British Institution last year, at the Royal Academy, at the Pall-mall Gallery, and now again at the British Institute, this same child's face, with nothing particular other in the original or in the pictorial treatment,—has smiled out upon us from fifteen or sixteen canvases at the very least, till one naturally passes by without waiting to see if the painter's imagination has led him to colour the table-cloth red or green.

Of the landscapes nothing further need be said than that they include performances by the Messrs. Cole, Jutsum, Stark, T. & J. Danby, Percy, Williams, A. Gilbert (see "The Black Mountain"), Harry Johnson, Montague, Oakes (a poetic work), G. Stanfield, and others as well known by a speciality. The three little marine pictures of Mr. E. W. Cooke, R.A., are quite a feature in themselves, and are sure to attract the attention of all who seek for excellence.

#### SCHOOLS OF SCIENCE AND ART.

Lord Lyttelton and Mr. Foley, M.P., on Science and Art.—At the annual soirée of the Kinver Grammar School, Lord Lyttelton said:—As one of the Royal Commission I heartily gave my assent to the introduction of science teaching in our public schools. The evidence in its favour was most conclusive. The subject very naturally attracted some attention in the house of Commons. The Government, through the Science and Art Department, is desirous of encouraging the study of elementary science, not only in our endowed schools, but in classes during the winter months for those who have left our elementary schools. I believe the department is doing a very useful work.—Mr. Foley, M.P., said the science classes which had been established at Kinver in connexion with the Government Department of Science and Art, had been most satisfactory. The introduction of science was a new feature; but, in a district like Kinver, a knowledge of chemistry must in many ways be most valuable. From a return which had been published, he found that, of all the science classes in South Staffordshire, the Kinver and Kidderminster classes had been most successful. He was not well acquainted with the plans of the Science and Art Department, but he had no doubt the address of Mr. Beckmaster would give much valuable information on this subject.—Mr. Beckmaster then addressed the meeting at considerable length. He alluded to the origin of the department, and the early votes of public money for scientific societies in Ireland, the founding of mechanics' institutes, and the educational objects which these institutes had in

view. Ho then dwelt on the value of natural science as a means of moral teaching.

*Christ Church District School of Art.*—On Wednesday evening, the 25th ult., a soirée took place of the students of the School of Art in Cannon-street-road, St. George's East, in union with the Government Schools, South Kensington, and their friends, to the number of between seventy and eighty under the presidency of the Rev. G. H. McGill, the president of the institution. The model drawings exhibited by three of the students (Misses Sprague, Grace, and Stewart) obtained notice, both for correctness of style and delicacy of finish. The first of the above ladies gained a medal at the last national competition. The room was decorated with flags and collections of drawings kindly lent by the Science and Art Department. The students have to thank the art-master (Mr. Meuzies) and the secretary (Mr. James Duke) for a very pleasant evening's entertainment. The school offers advantages to artisans and other students.

*School of Science and Art at Oldham.*—A school of Science and Art, presented to the trustees of the Oldham Lyceum by Mr. John Platt, of the firm of Platt, Brothers, & Co., machine-makers, has been opened at Oldham. The subjects to be taught in the institution will embrace pure mathematics, chemistry, building and constructive drawing of every kind, on the system pursued at South Kensington. The school-house consists of three spacious rooms, one of which is to be employed as a music-hall for singing-classes and concerts. Under these rooms is a gymnasium.

*The Nottingham School of Art.*—The first public meeting in the new School of Art has been held for the distribution of prizes. The award, which should have taken place in 1863, was postponed in consequence of the want of a suitable building. The lighting surface of the school is half the area of the ceiling, and the hanging space is limited to the height of 17 ft. 6 in. In opening the proceedings Mr. Alderman Birkin, who occupied the chair, remarked that they were at last settled, and had a permanent resting-place in a building which was one of the ornaments of the town. They hoped, also, that the influence of such a building would have a tendency to raise the character of the staple trades of Nottingham, and induce a greater love of art amongst all the varied industries of the town and neighbourhood. Great good had been done by the school; but the inhabitants would take a much greater interest in the affair now that they could see the preparations made, the accommodation afforded, and the appliances supplied, besides the assistance to be tendered by Government. With reference to the national medallion, which was amongst the prizes distributed, we may again state, for the information of those who do not already know, that the work is executed in *repoussé* by M. Vechte. A portrait of the Queen occupies the centre, and surrounding this is an allegory, which M. Vechte thus explains:—

"The principal figure at the top of the medallion is Genius, attended on his left by Justice, Truth, and Science, attributes essential to an academy of artists; and on his right by a student meditating. In the background crouches Jealousy or Ignorance, whilst Fame is proclaiming the merit of the successful student, and Time and a youthful Genius hold the shield to receive the student's name."

The medallion is awarded in the yearly national competition of the students of all the art-schools of the United Kingdom, and is the highest prize for success in art given by the Science and Art Department of the Committee of Council on Education. The examiners are,—Sir Charles L. Eastlake, P.R.A.; Daniel Maclise, R.A.; Richard Redgrave, R.A. (inspector-general for art).

At the meeting, Mr. F. Fussell, the head master, read a paper, in which he thus spoke of the working of the school:—

"In the first place, instruction is not confined within the building; instruction in art of a useful character is given by means of this school to fifteen public schools; and, according to the last report, 1,147 are being taught; 371 were selected and came up for examination; and 393 were successful, either in drawing, ornament, working a paper of problems in practical geography, or model drawing. There are besides about five other public schools that send their pupils for examination, making altogether, and exclusive of students, about 2,700 receiving instruction in drawing; 596 of these attended the examination, and 512 were successful. The students of the School of Art numbered 203 for last year, divided into fifty-seven different trades or occupations. Sixty-three of the higher-grade prizes were awarded for successful papers in free-hand, model, and mechanical drawing, geometry, and perspective; five, fourteen medals for advanced studies and designs; and four national medallions, a result that is more satisfactory than the preceding year, when the school obtained nineteen medals and one medallion, because at all times quality of work must be of more importance than quantity."

*A School of Science for Stourbridge.*—An effort is about being made to form a School of Science at Stourbridge. The manufacturers and employments in which many living around Stourbridge are engaged are intimately connected with several general branches of science, and to such the formation of a School of Science should especially commend itself. The promoters do not contemplate making it exclusively an artisans' school, but they look for its practical advantages being widely appreciated by artisans and others who have an immediate interest in the knowledge which such a school will seek to impart.

*Newcastle-upon-Tyne School of Art.*—The annual examination in connexion with this school has been held, and is said to have been the most successful since the foundation of the school in 1844. From the report presented by Mr. W. C. Way, the head master, it appears that the total number of students who had attended the school during the year 1864 had been 410, or fifteen more than the previous year; while the increase in the amount of fees paid by students was 26l. 10s. 11d. as compared with 1863.

*Shrood and Gloucester Schools of Art.*—The prizes were distributed by Mr. Gambier Parry at a meeting held last week. Mr. S. S. Dickinson presided, and his account of the school was most encouraging. Mr. Parry delivered his lecture, "The Claims of Art upon an Age of Business," and the meeting was also addressed by Mr. S. Marling, Mr. Samuel Bowly, and Dr. Paine. Three cheers were given when Mr. Parry presented the national medallion to Miss E. R. Stanton, its winner.

#### ORNAMENTED AND STAINED GLASS.\*

I PURPOSE giving an account of the different methods now used in England of ornamenting glass, and of the mode of producing stained-glass windows in ancient and modern times.

If a window space is to be filled in the cheapest manner, merely to be seen through, and as a defence from the weather, you would use common German sheet glass, which can be bought for 1d. to 4d. per square foot.

If the glass is not required to be seen through, but only to admit light, you would use either rolled plate (say 7d. per foot) or common ground glass; the latter being, from its exceedingly cold aspect, the worst thing to be used in any case.

Now, for about 6d. per foot extra, this German sheet glass may be ornamented with any simple device or geometric form, the pattern being of transparent glass, on a semi-transparent ground formed of white enamel.

This production, and some of its varieties, are termed "enamelled glass;" their manufacture gives employment, at Messrs. Chance's and Messrs. Pilkington's works, to about fifty hands, chiefly girls.

This is the manipulation: lay the sheet of glass on two strips of wood about 3 in. high, on a bench; paint over one side with white enamel, finely ground on a glass slab with a muller, and afterwards mixed with a little weak gum-water; you must not paint it as you would a door, but put on a thin coating of the enamel with a flat camel-hair brush, and, before it is dry, make it perfectly even with a broad badger-brush, using it backwards and forwards all over the sheet, at first heavily, afterwards very lightly. Now cut your pattern out of a small sheet of tinfoil or annealed copper, the same way as letter-plates for marking linen are cut, and place it on the dry coat of enamel. Then with a nail-brush remove the enamel, until the clear glass appears in the parts not covered by the plate. Continue this all over the sheet of glass. If the enamel is not easily rubbed off, there is too much gum in it; if the pattern-plate works up the ground, there is too little. Then, after removing the metal plate, put the sheet into a glass-stainer's kiln, for the purpose of fixing the enamel.

The white enamel is thus made: take one part of oxide of tin, or any other white substance not liable to change at a red heat, such as calcined bones or china clay, and mix it with three parts of a flux composed of three parts of red lead and one of sand, melted together for one hour at a white heat. The mixture, when finely ground with water, is the white enamel in common use.

The ordinary white enamel used for watch-

faces may be bought in cakes at the Whitefriars Glass Works for 2s. per lb., and answers every purpose.

The principle of engine-turning, as applied to the backs of watches, is also sometimes adapted to the cheap production of enamelled glass.

Or, a pattern may be etched out with a stick, as in etching on copper. A piece of the wood of which butchers' skewers are made, cut to a broad point, is generally used.

Another way is this: paint the pattern with common whitening and gum-water, and, when this is dry, cover the whole surface of the glass with the white enamel, mixed with turpentine. The whitening, which has in the trade the name of "never-stick," prevents the enamel from adhering. A similar process is used in calico-printing.

Patterns are supplied in large quantities by these simple processes, and are, as a rule, very good; in many of them there is a want of simplicity, and the outside appearance of the raw white of the enamel is very disagreeable.

A tint of colour, such as pink or blue, is sometimes used, instead of the white; but the greatest improvement would be making the white of an agreeable tone by the mixture of small quantities of some coloured enamel. I offer the suggestion of a ground made by coating the glass with a dark-coloured enamel, and ruling it with lines nearly close together, made with a needle-point. This would not be discernible on the outside, and would give the inside a more brilliant surface.

I have now to speak of embossing, some specimens of which are met with in most of the large shops in London, especially in public houses. It is remarkably easy of execution, and competition has brought down the price so low as to render the production of it by itself almost worthless as a trade.

Plate glass, the contract price of which is 3s. 3d. per foot, is usually selected for this enrichment. An ordinary pattern can be embossed on this for 1s. 6d. per foot; one very elaborate for 3s. 6d. This is the way to emboss. The plate of glass, carefully cleaned with whitening, is placed over the drawing, which is usually a bit of unhealthy scroll-work; and the ground of the pattern is painted with common Brunswick black, to resist the action of the acid. When this is quite dry, a hank is built round the edges of the glass. This hank may be formed of strips of glass, made water-tight at the lower edges with hot tallow and carbonate of iron, laid on with a brush. Then pour on fluoracic acid, which should be of medium strength, and let it remain for about half an hour. When the pattern is bitten in, say a sixteenth of an inch, scrape off the Brunswick black, and grind the surface of the pattern with emery and a piece of plate glass about 2 in. square. A clear pattern on a frosted ground is thus produced. If the acid is too weak, the Brunswick black will come off before the pattern is sufficiently bitten in: if too strong, the engraved surface will be very rough. If, therefore, the acid is too strong, or when it bites unevenly, keep the surface of the glass stirred with an old brush. If fluoracic acid of excessive strength is placed upon glass, corrosive action is instantaneous, and an appearance is given to the surface like that seen upon old glass by the action of the atmosphere for several centuries.

Any one with an ordinary knowledge of the use of the pencil, and with 20s. in his pocket, may set up as an artist in this pursuit. A bottle of Brunswick black, 1s.; one lb. of fluoracic acid in a gutta-percha bottle, say 3s.; with a rest for his hand, a few pencils, and a packet of emery; these form his humble stock-in-trade. The facility and cheapness of execution, and competition, have caused embossed glass to become one of the items in builders' contracts; and although it should not from that cause become an inferior production, yet I do not believe there are a score patterns in all London equal to what ornamental drawing should be. In most cases too much is attempted; an utter want of knowledge is shown; and what would become interesting through invention, is a vile compound of unmeaning scraps, cooked up without skill or taste.

A study of the ornamentation of the early Greek vases in the British Museum, and the acquirement of knowledge generally, would have great influence in correcting these feeble and inferior productions. In embossed glass, skilful linear ornament and invention may be hoped for, but nothing more. In Mr. Croce's office-doorways, Wigmore-street, are specimens of the highest character, and these are instances of its utmost capability.

\* By Mr. C. Heaton, Read at the Architectural Association.

There is also some good work in the windows of the Hero of Waterloo public-house, near Waterloo Station (Messrs. Hill, & Co., architects), but the patterns are all alike. The ceiling of the Library of Orleans House is of this kind of glass, but the effect is painfully cold, and unworthy of imitation.\*

We now come to the method of staining and colouring sheets of white glass, a process used principally for hall-lamp squares. The manufacture is almost confined to Messrs. Chance's glass-works. The yellows and dull reds are produced by a silver stain afterwards described; the blue is a semi-transparent enamel, made with the black oxide of cobalt, melted with a soft flux. Green is produced by painting one side blue, and staining the other side yellow; browns and flesh reds by the peroxide of iron mixed with a flux.

About thirty years ago, before the production of stained-glass windows was understood, some of our church windows were ornamented by this process. Reynolds's window, in New College, Oxford, is an instance. I lately examined this window, and found it in an excellent state of preservation. Not so the Van Ling windows in Christ Church, Oxford, also of this kind, painted in 1630 on squares of white glass, but now decaying in large patches.

The productions of the modern Munich school, which are but little more than transparent paintings, are largely indebted to this enamel system of painting. The Peterhouse Church, at Cambridge, with the exception of its fine old window at the east end, is full of these German transparencies. Occasions might arise when this system of glass ornamentation would be required; but it is an unskillful way of painting, and may be left to ornament cheap lamp squares without regret.

Both white work and embossing may be made good of their kind, and the effort to produce skilful specimens will fit the artist in some measure for work of higher import. One test for good ornamental work is the axiom advanced by the Marlborough House authorities, that "ornament must have some near or remote significance."

The art of glass painting,—that is to say, painting made of pieces of coloured glass united together with hands of lead, was invented in France about the middle of the twelfth century. At the beginning of the thirteenth century, it became a part of the system of the decoration of French Pointed architecture, spreading at the same time all over the north-west of Europe, wherever Northern Pointed architecture became established.

During the whole of this century there was such a rage for this decoration, that not a window was constructed without inserting stained glass, or intending to insert it.

There are some few existing specimens of twelfth-century glass. They occur at the abbey church of St. Denis, and at Poissy, in France, and in the aisles of the choir of Canterbury Cathedral; but the remains of stained glass of the thirteenth century are abundant.

In the south and south-east of Europe the system of decorating the interiors of buildings with mosaic work had been long established; and the most marked examples are the coarse work at the Cathedral of Kiev, in Russia, and the more refined paintings of St. Mark's, at Venice.

There was at first much similarity between glass painting and mosaic painting. The Byzantine mosaics (of Roman origin) were made of rough cubes of coloured opaque glass, imbedded in cement; and the earliest stained windows are believed to have been made of small pieces of translucent glass, imbedded also in cement.

There are but few remains of windows of so perishable a construction. There are some specimens in England that have been brought from the Continent, but are of uncertain date; and Mr. Burgess mentions that the Mosque of St. Sophia, at Constantinople,—a Byzantine building of the tenth century,—was so glazed, and that it is still a custom in the East to make the windows of glass and cement alone.

A great improvement on the use of cement was the method of fastening together the small pieces of translucent mosaic with leaden bands, having a groove on each side; and we have to

thank the inventor, whoever he may have been, but who lived somewhere about the twelfth century, for this mode of constructing stained windows, very many specimens of which have endured for seven centuries.

The construction of a stained window by means of glass and leaden bands only, must have been a very tedious work; and, in time, means were discovered of greatly accelerating the process, by making the glass in larger pieces, and by the addition of enamel painting.

Take, for instance, the head of a saint: this, before the introduction of enamel painting, would have been made up of different coloured glasses,—one colour for the hair, another for the beard, and white glass for the eyes; the lines of the eyebrows, ears, nose, &c., would have been expressed by the lines of the leaden bands, which also served to unite the different pieces of glass.

But, after enamel paintings had been invented, the process would have been this: a piece of glass as large as the head would be shaped to the required size. The features would then be painted with opaque enamel, and afterwards the glass would be exposed to a full red heat to cause the enamel to adhere.

The composition of this enamel paint is in glass painting a very important matter. The ancient enamel is in many instances perfect to this day, and occasionally has preserved from decay the glass itself; while in many modern windows, after a few years, it altogether disappears. There are many stained windows, some of them of great repute, executed within the last ten years, that have required nearly as much restoration from this cause as windows of the thirteenth and fourteenth century.

Enamel is composed of a mixture of metallic oxide, and a flux: this flux answers the same purpose as equal varnish in decorative painting; it effects the adhesion of the colour to the surface. In the decorative paintings of the Houses of Parliament, a mixture of copal varnish and turpentine was used, and I think it the best material for the purpose. In glass painting, a flux is required that shall melt at a lower temperature than the glass itself, and that shall not in course of time decay by the absorption of moisture.

Borate of soda, potash, soda, or salt, all deliquescent materials, are often used for glass-painters' colour; and they all, sooner or later, disintegrate through absorption of moisture.

A colour that you may trust is composed of red lead, sand, and oxide of iron. Melt for two hours, at a white heat, three parts of red lead and one part of white sand, and pour it into water; then pound it fine, and mix about four parts of it with one of oxide of iron (Indian red) or burnt umber, and a little manganese; grind it very fine with a muller on a glass slab, and paint the glass with it, using either a little loaf sugar and water, or turpentine mixed with old turpentine that has become thick.

Potash and soda, you are aware, are both used in conjunction with silica in the manufacture of glass; the silica and the alkali are mixed in such proportion as to neutralize any further action of the alkali. Not so in a flux composed of potash or soda. To obtain the requisite low point of fusion, the alkali must be used in excess, and, not being neutral, it very soon becomes hygroscopic. The cause of the decay of some of the ancient glass was its having been mixed with too great a proportion of alkali, which in the course of centuries has absorbed moisture enough to work the mischief.

At the earliest time in the history of glass-painting the pre-existing mosaics appear not only to have suggested the invention of stained windows, but to have been the mine whence the painters drew some of their materials. There is a striking passage bearing on this point in the treatise of Theophilus, a translation of which you will find in Winston's "Hints on Glass-staining." Theophilus was a learned and pious monk, who wrote in Greek several treatises, but when, and at what time, no one seems certainly to know; but, from his perfect knowledge of stained-glass windows, he most probably lived about the thirteenth century.

"There are found in the ancient buildings of the Pagans in Mosaic work, different kinds of glass, viz., white, black, green, yellow, sapphire, red, purple; and the glass is not transparent, but dense like marble. They are, as it were, small square stones from which are made works inlaid in gold, silver, and copper. There are also found various little vessels of the same colours, which the French, who are skilful in this manufacture,

collect: they fuse the sapphire in their furnaces, adding to it a little clear and white glass, and they make tables of sapphire, which are precious and useful in windows. They make tables of purple and green in like manner."

The supply of coloured glass by the Pagan mosaics would not have gone very far in supplying the demand for the great manufacture of thirteenth century windows. The French, there is reason to suppose, were quite able to make all the coloured glass they wanted, and to supply the wants of others even beyond the seas.

In the seventh century they were noted for their glass-work. At the end of that century Bishop Wilford brought glass-makers from France to glaze the windows of Hexham Church, and also those of the cathedral of York. The materials necessary for the construction of a thirteenth-century window were, a flat table, the size of the window, to work upon: on this the design of the window was drawn, and most likely coloured; great care was taken in arranging their colours. Then, small sheets of glass, of about seven colours, were obtained. You will not find many more colours in any early window, and these sheets were made out of cylinders of glass split open and flattened. They were thicker than our window-glass, very uneven, and more like horn than glass.

Out of these sheets were cut to shape each separate item of the window: the heads, hands, and feet were cut out of flesh-glass, the tunic, say, out of green, the girdle brown, the legs red, and shoes blue, perhaps. When these pieces were laid down on the drawing they fitted almost close together, and would look very much like a dissected puzzle that children play with; only that the lines of junction went round the hand instead of across it; but if the hand or dress were larger than the sheets of glass they did not care much where the joints ran, excepting in large faces, when they would make lines of junction round the eyes, nose, mouth, beard, hair, &c. Each piece of glass was brought to shape with a red-hot iron and a grozing-iron. If you lay a red-hot poker on the edge of a piece of window-glass, you will soon hear and see a slight crack in it; now move on your hot iron, keeping it on the glass, and the crack will follow until you may bring it round to the place it started from. The cracks that sometimes occur in our own plate-glass windows, and which would eventually run across the square, are led round with a hot iron in a small circle, and rendered harmless. By these means the men of the thirteenth century fashioned their thousands of bits of vitreous horn in making windows. It was long before the use of the diamond in cutting glass was discovered. If the pieces were not truly fashioned with the hot iron, the workmen clipped away pieces from the edge with a piece of iron with a square notch in it. This was the *grozing-iron*.

Then followed the process of copying on the glass, with the dark-colour enamel, the features, hair, drapery lines, &c., and in all cases using a little what you may, by a stretch of imagination, call shadow, but which was only a thin film of the tracing colour, used in a very conventional manner, to assist the traced lines in giving expression to the faces and drapery. The pieces of glass painted with enamel were then placed on iron trays, over which had been sifted dry ashes, to prevent the glass sticking to the iron, and put into a close earthenware box, around which the fire played until the whole was red hot. Then the fire was withdrawn, and the box and its contents were allowed to cool gradually for the purpose of annealing the glass. The pieces were then placed in their former position on the drawing, and the workman put a hand of lead round each piece. The bands of lead were cast in a mould, and had a groove on each side, into which the glass fitted.

Each joint, and wherever one lead touched another, was soldered together on both sides of the glass; and the window was completed by rubbing into the interstices some cement, to keep out the wind and rain; oil and whitening, possibly.

The completed window was then fixed in its place; and, if of moderate dimensions, had simply iron saddle-bars set into the stonework on each side, and to these the window was tied with strong strips of lead, soldered to the lead-work of the window.

If the window was large, an iron frame, an inch or two in thickness, was wrought to the leading lines of the design, and to this the window was tied, in a similar manner to the saddle-bars.

This was the construction of a thirteenth-

\* There are manufactured in the glass-works sheets of white glass, veneered with thin coatings of red and blue. These coatings are easily removed with fluoracic acid, and thus are produced the white patterns on red or blue grounds which border the windows of our newly-built stucco villas.

century window, and, with some few modifications, it is the construction of the windows of the present day.

These old windows presented several excellences. Firstly, of material; because the thick maven glass was the cause of what Ruskin calls "palpitation of colour," a rich jewelry effect which cannot be produced by a thin material. Secondly, excellence of workmanship, because the painting was well and artistically done; it also presented great individuality, makeshift painting being a rare exception. Thirdly, excellence of construction. The division of the glass into small pieces tended to subdue the glare which stained glass, however thick, has in some degree. It also very materially strengthened the fabric, and it has been the cause of so many specimens being left to this day in such good condition. The wrought-iron frame not only gave strong leading lines to the design, but was a most workmanly way of construction. Fourthly, excellence of colour; because, with not more than about half-a-dozen colours, they were well coloured, never gaudy, but always rich. Of a series of windows, in one green, perhaps, was made to predominate; in another, blue, and so on. Just so were managed the windows in the clerestory of Sherburne Minster, by Clayton & Bell, some years ago. Fifthly, excellence of design. This, with the rare management of colour in the thirteenth-century windows, gives them their greatest value. The design is always original, and full of invention and feeling, and always suited to the place it occupies. There was no particular law as to the introduction of canopies, or medallions, or ornamental work. In the latter, colour was more considered than form, which was always very severe and conventional.

But about the representation of the human figure, there has been the greatest diversity of opinion. I adhere to the opinion that has often been expressed, that the figure-drawing in the thirteenth century was of equal value with the sculptures and wall decorations of the same period; that the artist did not see the necessity of representing the human figure in any other way than as symbolical representations: as such they tell their stories well, and in the simplest manner, and they always show the qualities most valued in all other sacred illustrations, invention, feeling, and colour.

Ruskin, in his "Stones of Venice," has explained in a few words what I feel greatly at a loss to express.

"It did not take five centuries to find out the appearance of natural objects; but it took five centuries to make people care about representing them. An artist of the twelfth century did not desire to represent nature. His work was symbolical and ornamental. So long as it was intelligible and lovely, he had no care to make it like nature; as, for instance, when an old painter represented the glory round a saint's head by a burnished plate of pure gold, he had no intention of imitating an effect of light; he meant to tell the spectator that the figure so decorated was a saint, and to produce splendour of effect by the golden circle. It was no matter to him what light was like. So soon as it entered into his intention to represent the appearance of light, he was no longer in discovering the natural facts necessary for his purpose."\*

#### THE PROGRESS OF ARCHITECTURE IN THE NORTH.

NORTHERN ARCHITECTURAL ASSOCIATION.

The annual meeting of this Association was held in the Old Castle, Newcastle,—Mr. F. R. Wilson, of Alnwick, vice-president, in the chair. The secretary (Mr. Thomas Oliver) read the annual report, which said,—

"Your committee have renewed satisfaction in congratulating the Association on its increasing importance, and the number of its members and associates. We have had enrolled during the past year on our books one honorary member, thirty-one members, and nine Associates, showing an increase in our number of one member. We have, however, to lament the great loss the Association has sustained in the death of its venerable president, who, from its first establishment, has from year to year occupied the president's chair, for which his age, position, and experience so well qualified him; and who, whilst his health permitted, took the liveliest interest in all the active proceedings connected with this society."

"The financial position of the Association continues in a satisfactory state, the total expenditure being £34.12s., and the receipts £41.4s. 7d., thus leaving a balance of 12s. 7d. in the hands of the treasurer."

The voting for president, which office was rendered vacant by the death of the late Mr. Dobson, was then proceeded with, the result of which was that Mr. John Green was elected.

The chairman then read an excellent paper on "The History of Architecture in the Counties of

Northumberland and Durham and the Town of Newcastle-upon-Tyne, during the last six years," from which we take a few passages:—

*The Prosperity of the North.*—The impetus enjoyed lately by the architectural profession is due, of course, to the commercial and manufacturing prosperity of the North. This has called towns, ports, and bathing-places into existence along the north-east coast, where formerly there were but fishing villages. A few years ago, what were the Hartlepoons, Middlesbrough, Jarro, Filey, Saltburn, Scarborough, Tynemouth, and Blyth, compared to their present importance. The vitality is nowhere more apparent than in Newcastle. The merchant whose representatives were content in former generations to live in chares, and subsequently in grim and prim streets, now build themselves residences in more salubrious sites. Doubtless the attention paid to the voice of sanitary science, the spread of conviction concerning the importance of plenty of fresh air, light, and pure water, has had its weight in bringing about this result; but it is wrong not to ascribe to the commercial and manufacturing activity of the North, Newcastle would still boast the syrtan walks decked with woodbine and wild roses Mr. Dobson could recall, and its merchants be unpossessed of the princely means that enable them to line the banks of the Tyne with mansions that would not ill become the shores of the Arno or of the Tiber. Some of these new mansions, we know, are more than residences—they are storehouses of art treasure, from which the finest collection of modern art in the kingdom could be reinforced. The additions to the town-hall, under Mr. Johnson, are further evidences of well-doing; the merchants' offices are changing character, as witness the sumptuous piles upon the Quayside; and the open streets, partaking of the general enrichment, can boast of the sculpturesque Stephenson memorial.

*Alnwick Castle and Wallington.*—Any statement of the progress and prospects of architecture in the North would be incomplete unless it included mention of the splendid works which I had the honour of starting and of directing for five years at Alnwick Castle, and on which Signor Bulletti, now of Newcastle reputation, was also engaged, under my superintendance. But I do not propose to do more now than allude to them in contrast to those still gradually growing under the hand of the artist at Wallington Hall. Utterly apart as these works may appear at first sight, a second will show that there is a peculiar affinity between them. The Duke of Northumberland has remodelled his ancient castle, to embellish it, by the hands of Italian artists, with Raffaelesque decorations, with a single introduction of a Northumbrian subject. Sir Walter Trevelyan has reared a *cortile*, with surrounding *loggie*, to decorate them by native aid, with subjects that are purely Northumbrian. There are many persons who would prefer to have seen this order of things reversed, who would rather that the rendezvous of Border chivalry had been blazoned with pictures displaying Northumbrian deeds, and would deem the palazzo at Wallington more fit receptacle for Cinque-cento decorations. But I would hesitate before I made any comparison that would cause any one to look otherwise than admiringly both at the letter and spirit of the work and taste at Wallington. The plan of this mansion, when placed in Mr. Dobson's hands, and under the superintendance of Mr. Johnston Hogg, was that of a quadrangle encircling an open court; although originally, I think, it must have consisted only of three sides of a square, like other country-houses built at the same time, with the entrance, which was unfurnished with lobby or ante-room, opening into the middle room in the front of the house. The chief feature of the new work is the arcaded saloon, into which the open court in the centre of the house has been converted. This is a light, lofty hall, about 35 ft. square, and 36 ft. 4 in. high, measuring to the top of the coved ceiling. As the means to effect this end, the internal walls of the house were removed, laying bare the grand staircase and corridors on both stories that served as communications, and a series of arches on two tiers were built in their places, open to the *cortile*, like those in the famous Raffaele *loggia* in the Vatican. Of the two galleries thus formed, the upper one is protected by a graceful balustrade between the piers, the design for which, I believe, came from the pencil of Mr. Ruskin. All the pilasters are to be decorated with different groups of natural flowers, ferns, and forest trees. In the centre of each of the eighteen spandrels in the lower tier are placed

medallions of Northumbrian celebrities, beginning with the builder of the great Roman wall, and ending with Robert Stephenson. And I may add that a group, already finished of wheat, oats, and barley, and one of the plasterers, is the work of the same hand that gave the sketch for the balustrade above it; and that others have been painted by various friendly and skillful hands. The *cortile* is covered by a novel ceiling of the form Italians call a *schifo*. Besides being coved, it is divided by the beams into panels, in the centre of which are large hemispherical glass lights, specially cast in one piece by Messrs. Swinburne; and these being globular on the outside, are never obscured by rain or snow. They also possess the advantage of giving an equable shadowless light as long as day lasts, lighting up the glowing colours within more successfully than by lateral fenestration. The sculptor and painter are still engaged upon work that will further add to the richness of the general effect. Mr. W. B. Scott has not yet finished his series of pictures portraying the incidents of Chevy Chase; and Mr. Wainwright, of Alnwick, is preparing a group in marble which will represent the press made in civilization since the deeds were enacted that are depicted on the walls. On the ground floor, now nearly completed, between the piers on the north and south sides, are Mr. Scott's famous pictures, in which the history of the county is chronologically set forth. The Roman *loggie* are painted with pictures, allegorical figures, flowers, animals, and ornaments, in masses of entanglement, beautiful certainly in colour and form, but of no living interest: in this scheme Northumbrian history is depicted, embodying Northumbrian men and women drawn from the life: the forms and foliage are drawn from the life; and the implements and weapons of antique and Medieval life, are faithfully copied from local relics once in actual use, lent from private sources for this purpose. It seems to me that this *cortile*, thus rising under the creative genius of its owner and his gifted lady,—so studded with much that modern Northumbrians hold dear as relating to their fathers, and so identified with the present in containing the portraits of eminent local men, and so associated with remembrances of many cultivated minds, the fulness of whose skill has been lavished upon it,—will have an intense and special interest for all time. With a nice propriety the portrait of Dr. Charlton is introduced into the picture in which the Apostle of the North is represented endeavouring to quell the threatening outbreak among his ancestors and their rivals in Rothbury Church. The fine head of St. Cuthbert is a portrait of the Rev. George C. Abbes; and one of the ancient Romans engaged in building the great wall is a likeness of Dr. Bruce. In a word, I would that an art-patron in every county would follow the example set at Wallington.

*Architects and Architecture.*—I must now congratulate this Association upon the prospects of architecture in the North. The corporation of Newcastle, one of the strongest strongholds against sanitary reform, has capitulated. Several extensive works are about to be put in hand. The lightning of the Lancashire triulations will set new influences to bear. The further enlargement of our local industries will create new sources of power. When Mr. Dobson came into the field, and found no other architect in the county, we may be sure that architecture was at a very low ebb. If a building was wanted, a builder was employed to design and erect it. But now, to the great advantage of the public, if a palace, or a house, or a shop or shop-front, or offices, or a farm, or a pitman's cottage, is wanted, an architect is instructed, who sets builder, joiner, slater, plasterer, and painter to work, in a much better fashion, and with a much more satisfactory result, than if they had no guide. But society is by no means so well regulated in this respect, yet as I hope we shall all live to see it. We have only to look at Jarro, as an instance of the consequence of building too quickly, irrespective of a digested plan, and of inhabiting these quickly-raised fabrics too soon. The large shipbuilding trade suddenly engrafed on to this old Saxon seat of learning and piety has certainly wrought a marvel of disorder. I do not envy the new Board of Health their task; nor can I see any present prospect of creating order out of the chaos of mud-holes, hall-stairs, pits, ruts, the ground-levels of the rows of houses on one side of a street higher than those on the other, and brickfields on which bricks are being made and houses built, that mark that Balaeclavian site.

\* To be continued.

THE PROFESSORSHIP OF ARCHITECTURE,  
LONDON UNIVERSITY.

We understand that Professor Donaldson has sent in his resignation as Professor of Architecture in London University. After energetically and ably discharging the important duties of the office for twenty-three years, the esteemed professor doubtless feels that he may now, fairly, retire, and afford an opening for some younger member of the profession. The professor will doubtless be willing to give for a time some assistance to his successor.

"COLSTON'S HOUSE," BRISTOL.

STRONG efforts are rightly being made to induce the Town Council of Bristol not to choose for the proposed assize courts the site of the present Guildhall, and the ground in the rear, which would necessitate the destruction of a very interesting ancient house, called,—rightly or wrongly, it is no matter,—"Colston's House." The Bristol Society of Architects have exerted themselves in the matter, and the council of the Institute of British Architects have memorialised the town council in favour of its preservation. At a meeting of the Architectural Museum Committee, on Tuesday last, it was resolved that the president should address a letter to the Town Council to the same effect.

Respectively of the desirability of saving an ancient monument, a landmark in the history of Bristol, the site is not a good one. We have reason to believe that an opinion in favour of the great superiority of the centre of Queen-square is gaining ground amongst the members of the council.

SUBSIDENCE OF THE HERBERT  
HOSPITAL, WOOLWICH.

THE new Herbert Hospital, now nearly completed, on Kidbrook Common, near Woolwich, having shown alarming symptoms of subsidence, an inquiry was instituted, and has been going on for some days. The committee consists of Capt. D. Galton, Under-Secretary of State for War; Col. J. S. Hawkins, commanding Royal Engineer at Woolwich; Capt. W. Newsome, Royal Engineers, divisional commanding officer; Mr. Menzies, Surveyor to the War Department; Mr. Ware and Mr. Tait, clerks of the works; and Mr. G. Myers, the building contractor. The committee have resolved on the necessity of recommending that the eastern pavilion and other portions of the building should be partially reconstructed, and that other measures should be taken to remedy as far as possible defects at the base of the building, many portions of which are tottering and unsafe, in consequence of the yielding of the soil. The cause of this is said to be, that the drainage was laid down below instead of above the layer of concrete and rubble forming the artificial foundation. The occurrence, for which, it is stated, the contractor is in no degree responsible, is exceedingly unfortunate, as the structure, in its present state, is said to have cost the Government upwards of 300,000. The pavilion has been needled up, with a view of under-pinning and forming a more solid foundation without delay.

The choice of the site has always been wondered at by those who were acquainted with its boggy character. If we remember rightly, we printed some objecting letters when the place was first suggested.

SCULPTURE AND THE ROYAL  
HORTICULTURAL SOCIETY.

THE Council of the Society have announced the arrangements under which they are willing to receive sculpture on or before the 15th day of April. They say *inter alia*,—"Out of the exhibition of 1865 the Council will make purchases to the value of 500*l.*, provided that new and original works of sufficient merit are exhibited under the conditions hereafter stated. As a general rule it is desirable that all works should be finished works in plaster. But works in marble, bronze, terra-cotta, and other materials than plaster may be sent; the price of a separate plaster copy must be stated. The Society especially desires that all works sent in should be distinctly labelled with the name of the subject, and the artist's name and address, together with the price at which copies may be sold to the public,

in marble, bronze, terra-cotta, and plaster. When a plaster model is purchased by the Council, they desire to be informed at what price the artist will supply another copy in marble, or bronze, or terra-cotta, or any other material. The copyright of making and disposing of other copies in marble, bronze, terra-cotta, &c., will remain with the artist. . . . Artists of all nations are invited to send works."

We fear that the misunderstanding between the Council and the Sculptors' Institute still exists, chiefly, if we are rightly informed, because of the supposed desire of the Council to take the reproduction of a model that might be purchased out of the hands of the author of it. The present conditions do not seem to point absolutely to such a desire. We shall be glad to find these prove satisfactory to sculptors. It is very desirable that means should be taken to popularize sculpture amongst us, and it certainly does seem to us that it ought not to be difficult for sculptors and the Council of the Horticultural Society to work usefully together with that end in view.

THE HUMAN BREATH AND THE  
MICROSCOPE.

By means of what is called the pneumascopo the human breath, or rather the crystals deposited by the breath, are shown on the screen at the Polytechnic, and it is made curiously evident that these crystals differ very strikingly according to the individual. In one case they take a dagger or cross form, in another they give a series of dotted lines, and so forth. Whether this may be regulated by the saliva rather than the breath has yet to be settled, with various other similar questions. At present, in fact, no deduction of any value can be made; but the discovery seems to open a fresh field for inquiry, and many lead to important results.

THE BATH FORUM HOUSE  
COMPETITION.

MORE dissatisfaction and complaints! If architects, with their eyes open, will spend their time in these speculations, they may as well make up their minds to hold their tongues when the "toes" goes against them, for no good seems to come of the constant railing that now ensues. Competitors trust implicitly in committees and corporations until the selection is made, taking the chance of the result being in their favour. The moment the decision has been pronounced against them, they point out with sharp pens and loud voices the incompetence, if not dishonesty, of the tribunal they had voluntarily submitted themselves to.

The weak place in the selection of No. 1 design for the Bath Forum House, as the new hotel there is foolishly to be called, is this,—that Mr. C. E. Davies, the successful competitor, is the architect of the corporation who required designs, and, in that capacity, prepared the instructions issued to the other architects who proposed to compete. No architect should place himself in such a position as this. If his design be selected, and even be obviously better than any of the others (as it may well be, seeing that he must know the views and wishes of the employers better than outsiders could do), the popular belief will nevertheless be that the decision was unfair,—that in examining the designs, the man, rather than the merit, had been considered. We have good reason for believing, however, that in the present instance that was not the case.

SOUTH KENSINGTON HOTEL.

In this fashionable and healthy locality a new hotel has been opened on a plan which is likely to suit the occasions of families visiting town for a lengthened *sejour*, as well as the tastes of single or more limited parties. Six fine mansions in Queen's Gate-terrace are by adaptation connected by corridors from end to end, having three portals of entrance: these are so arranged as to be divisible into larger or smaller suites, all furnished in a good style and taste, some rooms being of noble proportions, and all ventilated and lighted in a fashion that leaves little to desire.

There are billiard-rooms, coffee and smoking rooms, baths, and every other resource that may be needed by persons who visit London for a season or for a limited time; and the arrange-

ments of the kitchen include the best modern adaptations of stoves.

The peculiar characteristic of this hotel is, that families can live as in a private house, and enjoy the advantages which community only can insure, in the use of a perfect kitchen, and the discipline of a complete staff of waiters and attendants, at comparatively moderate charges. The great influx of residents into London, which increases on all sides, renders the establishment of large hotels a necessity of the time; for, as the numbers of sojourners increase, so also do temporary *voyageurs*; and the improved style of grand hotels in other countries makes it a necessity that the London system should advance also. Higher than Belgravia, and ranging with the Park, the widest open expanse of the western metropolis, this fine district, lately a suburb, but now an integral section, will soon be connected both by railway and by a direct leading route with Westminster; all which improvements will, when carried out, render the South Kensington Hotel an advantage to the public at large.

FALL OF ARCHED FLOOR, CHARTERED  
GAS COMPANY'S WORKS, WESTMIN-  
STER.

A FRIGHTFUL accident occurred last Saturday morning at the works of the Chartered Gas Company, Horseferry-road, Westminster. The ground-floor of one of the buildings was used by the workmen as a refreshment-room. It is called "the men's lobby," and is a large room. The ceiling was formed of brick arches, springing from iron girders supported by pillars. Just before twelve o'clock a noise was heard, and down went three of the arches, running the whole width of the building,—covering an area, judging from a glance, of, perhaps, 50 ft. by 30 ft. Four men who were below were much crushed, but, strange to say, not at once killed. In a few minutes there would have been a crowd of men there, the majority of whom must have perished. Whether a girder, or the front wall, serving as abutment, yielded, we do not know. The wall is bulged and cracked,—looks, in fact, very unsafe.

The most careful inquiry should be insisted on in this and all similar cases.

MESSRS. VICKERS & COMPANY'S NEW  
DISTILLERY, VICTORIA STREET, WEST-  
MINSTER.

IN our present number we give an illustration of Messrs. Vickers's new distillery, which is in course of erection in Victoria-street, Westminster. The building stands upon a large area of land, having a frontage in Victoria-street of 200 ft. and a depth of 140 ft., with frontages facing Phillips-street and the Horseferry-road. On the ground-floor (speaking as if the building were finished) are British and foreign warehouses, distillery, large counting-house, offices, waiting-halls, stables, and waggon-shed, with a dwelling-house at the north-east angle of the building. The entire basement is converted into commodious cellars.

The frontage facing Victoria-street and the return end in the Horseferry-road is faced with white Suffolk bricks: all the other frontages are faced with picked stocks with the horizontal bands, and the arches of arcades of coloured bricks. The porch-windows and portions of parapet, string-courses, and area-wall are of Combe Down stone. The columns and panels of the porch are of polished red Aberdeen granite, with foliated caps and moulded bases of stone. The main cornice and the outer arches and labels of the windows are of Portland cement.

The interior walls of the counting-house have recessed arcades, with columns of polished Devonshire marble, with foliated caps and moulded bases of Bath stone. The ceiling is divided into recessed, moulded, and enriched coffer. The height of the counting-house comprises two floors, with a light ornamental gallery all round to serve as communication for the offices on the first floor to the different warehouses.

The whole of the buildings are now being erected by Mr. William Dowds, builder, from the designs and under the superintendence of Messrs. William J. Mayhew & Calder, architects, Charing-cross. The machinery, plant, and engines will be erected under the superintendence of Mr. F. J. Bramwell, C.E. Mr. Chinnock is the clerk of the works.

## CYRENE AND ITS NEIGHBOURHOOD.

*Gateway in the Western Wall of Ptolemais.*

*A Tomb embellished with Figures in the Northern Necropolis of Cyrene.*

[See p. 13, ante.]

MESSERS. VICKERS & COMPANY'S NEW DISTILLERY VICTORIA STREET WESTMINSTER

## SANTARY MATTERS.

*The Sanitary Condition of Leeds.*—A meeting has been held at Leeds on its sanitary condition. Mr. W. B. Denison presided, and the audience included the mayor and a considerable number of the most influential inhabitants of the borough. The causes of the high rate of mortality in the town were discussed at great length, and many suggestions were offered with the object of bringing about a more satisfactory state of things. Resolutions were also adopted calling the attention of the local authorities and the inhabitants generally to the fact that the official inspection of nuisances is not only inadequate, but that the powers possessed by the corporation are not sufficient to enable that body to deal efficiently with the various evils affecting the public health, and calling upon the town council to appoint a body of nuisance inspectors equal to the requirements of the borough, and to go to Parliament for an Act to include all the powers that may be necessary to place Leeds on a satisfactory footing as regards the health of its inhabitants. A memorial embodying these views was adopted for presentation to the town council; and an association was formed to collect information bearing upon the sanitary state of the borough, and to decide what steps ought to be taken to promote an improvement of the public health. Another topic intended for discussion by the meeting, viz., the erection of larger and more suitable dwellings for the humbler classes,—was, in consequence of the prolonged discussion, postponed to a future occasion.

*Fever in Waterford.*—The fever hospital is every day crowding with new patients, principally from the town and district of Mullinavat. So unexpected has been the increase, that the workhouse master had to apply for twenty new blankets, in addition to his present stock, to meet the emergency. The disease presents the features of one of the most malignant types of fever.

*The Mortality of the Principal Towns in the Kingdom.*—The deaths for the past week in ten of the largest in the kingdom were 3,469. The births were 3,643. The average rate of mortality was 33 in 1,000, which is nearly double the average mean rate (17 in 1,000) in healthy localities. It is remarkable, however, that, of the ten, London is the healthiest of all, except Salford and Leeds, which give a return of 29 in 1,000, while London gives 30 in 1,000. The palm in the "bad eminence" of mortality must be assigned to Liverpool, which gives 12 in 1,000; but Manchester is not far behind, which gives 40, or Dublin, which gives 39.

## THE SEWAGE QUESTION.

The examiner of private bills has reported that the Metropolitan Sewage and Essex Reclamation Company have not complied with the standing orders of the House of Commons, inasmuch as they have neglected to deposit plans of four miles of their culvert.

The promoters of this bill will thus have to petition the Standing Orders Committee to set aside the standing orders in their favour, and allow them to proceed with their bill; and there appears to be some chance of the opponents of the Essex scheme endeavouring to get the bill thrown out on this ground.

The inhabitants of Woolwich have had a public meeting to consider the question of the utilization of the metropolitan sewage and the reduction of local taxation. There was a very numerous attendance in the Town-hall, and resolutions were carried against the Essex scheme, and not much in favour of the Metropolitan Board for "hot-traying" the rat-payers, but thanking the City Corporation for opposing the Essex scheme, and agreeing to a petition to parliament against that scheme, and for a committee of inquiry.

The sewage question seems to have become the great question of the day everywhere throughout the country. At the Society of Arts, Adelphi, a paper "On London Sewage from the Agricultural Point of View" was read last week by Mr. John C. Morton. Towards the close of it Mr. Morton said:—

"Although I have not been able to overtake, within the allotted time, all the grounds on which an opinion must be formed, yet the conclusion to which I believe that the agriculturist is led after a study of the subject is, that grass as the produce and ordinary irrigation as the method—both as involving a minimum of labour—are the proper agents, by which the conversion, which we all desire, of London sewage into London milk will most probably be obtained.

Another principal conclusion is, that the profitable conversion of the enormous addition to the grass growth of South Essex, which will follow the use of London sewage, can be expected only through a great and therefore necessarily a gradual extension of the London milk trade.

Lastly, as a help out of this—one of the main difficulties which threaten the immediate profitability of any scheme for using London sewage—I hope that experiments may be instituted as to the possibility of artificial hay making. I have made no reference to the nuisance which may be expected from that agricultural use of this sewage that experience elsewhere recommends. I believe that the efficacy of the sewage as a manure will be dependent, to some extent, on its being already in a putrifying state; and no doubt a certain nuisance will be created. But if any alarmist here, ready charged with a denunciation of these plans on this account, be about to frighten us all with accounts either of putrid miasma and resultant fevers, or of new parasitic enemies, which through rotten sewage, rank and filthy grass, unhealthy cows and unwholesome milk, are thus to find their home in our bodies, breeding there disease and death, I hope that he and all of us will bear in mind that 400 acres of land, treated more wastefully and filthily than any of the London schemes propose, have been for a century and more under the very noses of the Edinburgh people; who have, moreover, been fed for generations on the milk of the cows which have consumed this sewage grass. If any evils of the kind alleged are in the least to be expected, they must long ago have shown themselves in the death rate of so large a town; which, however, I believe, stands as low as that of any in the country."

In the discussion which followed, Lord Robert Montagu, Mr. Walker (of Rugby), and Mr. H. Weller took part; and Mr. Webber said that, having been resident in Manchester for thirteen years previous to 1856, and his business (that of a cheese factor) having brought him into communication with farmers, he had seen the most astonishing results from the utilization of sewage. He might mention one case in particular within his own knowledge, in which the area of grass land was barely sufficient for the maintenance of seventeen cows, the average yield of which was 2½ cwt. of cheese per annum, and the same area of land was, by the application of sewage, made capable of supporting forty-seven cows, the average yield of which was 3½ cwt. of cheese per annum each. This was sufficient, he thought, to show the great fertilizing property of the sewage. Notwithstanding the great practical knowledge of Mr. Morton on this subject, there were some conclusions which that gentleman had drawn with which he (Mr. Webber) could not concur. He thought, however, that Essex, which might be said to have just been recovered from water, was not the best place for such an experiment as that about to be tried, and that a preferable district was that of Surrey, where they would find a dry parched soil, much better suited for the application of the sewage, which would convert that which was now almost an arid sand into good fertile soil. He believed that to take the sewage into Essex would be a failure, and the result of that failure would be to set aside, for centuries, perhaps, any further attempts to give an agricultural value to this product.

With reference to Mr. Morton's allusions to parasitic enemies, &c., we may here observe that he alludes to a letter addressed to the English public by Dr. Spencer Cobbold, the well-known investigator of parasitic worms, in which he cautions the public against employing sewage matter as manure. By the present system, Dr. Cobbold thinks that billions of eggs of entozoa (tape worms, &c.) are annually swept away into the ocean; but if the accumulation of our sewers be spread over the country, all the conditions favourable to the development of these ova, he thinks, will be promoted: the larvæ will find their way into snails and vegetables, and into our cattle; and entozootic diseases will, from the extent to which they will range, constitute one of the greatest plagues that have ever been inflicted upon this nation.

Entomology and kindred pursuits have heretofore been rather despised than otherwise by students of a higher order of science; but as a branch of sensational science they seem to be coming out with a vengeance. Mr. Morton's remarks as to the utilization of sewage for generations at Edinburgh ought to show how dangerously false such sensational speculations may be; and as regards the question between the land-snails and the cattle on the one hand, and the sea-snails and the fishes on the other, we would suggest that the sea is quite as likely to introduce the unwelcome "gnests" into our interiors as the land. If any question of a like order more especially merits attention, we should think it is whether human food produced by help of human excreta can be wholesome; but even that question has surely been settled by the market-garden produce of town suburbs.

At Edinburgh, Mr. Charles Cowan, of Valleyfield, paper manufacturer, has been reading

a paper to the Royal Scottish Society of Arts, of which he is the president, on the Sewage of Towns. So satisfied is he with the Craighinty irrigation and its results that he proposes to extend it largely in other neighbourhoods of Edinburgh. There are hundreds of acres of sand, he remarks, on the shores of the Firth of Forth, to the east of the town of Portobello, left dry at low water, which, when embanked and reclaimed, would be well fitted to receive the sewage water; and there is a considerable extent of links at or near Musselburgh, which would give as large a result as that from Craighinty. As rat-payers, he adds, citizens have a deep interest in the solution of this question. If even 10,000l. per annum could be obtained by a sale of a portion of the sewage-water, it would be justly hailed by the citizens as a great success, and would lighten sensibly the Edinburgh police rates.

A second portion of his subject related to the soapy water used by the paper-makers, and what ought to be done with it; but we need not enter into this subject, which he proposes as a problem to the Society of which he is president.

The superintendent of the scavenging and night-soil department of the City of Manchester, Mr. John Wallworth, has addressed a letter to the Lamp and Scavenging Committee on the subject of town sewage. Very naturally Mr. Wallworth thinks, like the shoemaker, that "there is nothing like leather." He looks with an evil eye on water-closets, if not too upon drains and sewers, and goes in for ash-pits. The night-soil has all been nefariously abstracted from the asphalt, and what remains in these has become quite unfit for agricultural use; and what is to be done with it shortly it is hard to say; whereas with the old material hack again amongst it, it would make as fine a compost as ever for the use of the farmer.

Our municipal authorities and our rat-payers are everywhere ruminating on the great question of the day. At Slough, just now, preparations are being made for a trial of the sewage-utilization system. The engineer, Mr. Curley, has reported to the local Government Board on the subject, and his report has been approved of. He says there are not many places so well situated for utilizing sewage as Slough. He proposes works to cost 5,300l. to begin with. Much discussion is going on at Bournemouth on the question of drainage and the disposal of the sewage. Of the existing houses there, it is said, more than one-third are still without drainage, except into cesspools. The Dublin people are astray on the same subject. A highly influential and numerous attended meeting of the inhabitants of Clontarf and the adjoining districts has been held for the purpose of taking measures to oppose the Bill about being introduced into Parliament for utilizing the sewage of the city. This they intend doing on the ground that the plan proposed would prove injurious to the health and comfort of the residents along the shores of Clontarf, Sutton, Baldoyle, &c. In fact, the question is one which is getting so universal in its interest, that it is literally impossible to give any record of what is everywhere being done; and we can only thus now and then pass lightly over a few of the most salient points in the news of the week relating to this all-important subject, as we now do.

## OUR HOMES AND THEIR ORNAMENTS.

On the 16th ult., Mr. Davidson, head master of the Chester School of Art, gave a lecture under this heading, at the Handbridge Reading-room. After sketching a theory of the early history of building, from Cain downwards, he spoke of what was being done at the present time. "Let but the architect," said he, "feel the responsibility of his noble profession; let him be conscious that it is his glorious privilege to write a page in the history of the human family, more lasting by far than that of a Coldsmith or a Macanlay; that by his work generations yet unborn judge of the habits and spirit of this period, as we do of the people long since passed away!" (2) But even this is not the whole of the responsibility of the architect. It is his task to contribute, not only his assistance to the future, but he has the comfort, the convenience, the health, the morality—nay, the very lives of his fellow-creatures in his hands. It is to the noble spirit of our architects of the present day that we owe our widened streets and our well-ventilated dwellings. They have torn down the rookeries in which the workmen and the poor were huddled together in misery and suffoca-

and have raised commodious and healthy  
for the labouring classes; and these improve-  
ments alone will ever remain as a noble contrast to  
period when all recorded of what was done for  
workmen who built the Pyramids was that  
immense amount of money was spent on  
shes, onions, and garlic. But we must edu-  
cate our workmen,—we must teach them that a  
ledge of science and art will enable them to  
take the work entrusted to their care with  
ster skill. Let us prove to them, the more  
understand of the construction, the better  
they carry out the design. Let us improve  
homes, and place in each that greatest of  
ornaments—the word of God; let us ameliorate  
their position, and give them healthy recrea-  
tion; then their spirit will be in their occupation,  
it will become a labour of love.

#### PRODUCTION OF NATURAL FORMS IN ART AND MANUFACTURE.

The lectures which Mr. Waterhouse Haw-  
kins delivering on this subject, at the Society  
arts, he has endeavoured to show that the  
nation of the hand, with regard to art, con-  
sists to be in excess of that of the mind. To  
achieve to any degree of fame in the higher  
classes of art, the artist must possess some  
feeling; but as there were those who could  
speak good English without being his-  
torians or poets, so there were artists possessing  
a certain amount of good sense, which, when it  
acquired good taste by education, could be  
more real service to manufacturers than the  
most ideal powers when not submitted to a  
regulated mind. But the artist who was  
endeavouring to aid manufacturers must obtain some  
knowledge of the process and materials by which  
works were to be multiplied. In the fourth  
lecture, on the 23rd ult., he called their attention  
to metal work. The various metals—iron, brass,  
copper, and the precious metals—were so con-  
stantly used in the every-day necessities of life,  
from the cottage to the palace, and in our  
shops and other public buildings, that there  
was a vast demand for the combination of art  
with these materials. Mr. Hawkins sketched out  
black canvas several instances of defective  
work in metal work, pointing out the paucity  
of invention which induced our artists to become  
imitators. He censured the incessant use  
of reproductions of flowers in every material—  
in paper, leather, gutta-percha, porcelain, and iron.  
He also showed how unfit feathers, dowers, and  
flowers were to form part of the decorations of  
iron gates; and even when water-lilies were  
used very appropriately into a design for a  
fountain, he remarked that had the  
artist exercised his thinking faculties he would  
have placed these flowers at the top of a high  
column supported by tree branches, in total violation  
of their natural position, which was floating  
on the surface of the water. The lecturer  
proved the necessity for a knowledge of  
the process of casting to those who design  
models for reproduction in metal, by demon-  
strating the difficulties which were often thrown  
in the way of the moulder by the inattention of  
the artist to the requirements of the process. If  
the designer had merely learnt to draw, and not  
to model, he would find great difficulty in adapt-  
ing his designs so as to avoid "undercuts,"  
and render it necessary to divide the mould,  
increasing the labour and adding to the ex-  
pense without necessarily enhancing the beauty  
of the work. During the lecture the observa-  
tions on metal casting were illustrated by a work-  
man who was making a sand-mould from the  
shells of an arch. The process of the lecturer  
rendered intelligible by his outlines on the black-  
board. At the lecture on Monday, January  
10th, metal was poured into the mould, to con-  
firm the demonstration of the process of metal  
casting.

THE HALIFAX ARCHITECTS AND BUILDERS AND  
CORPORATION.—On Wednesday, the 1st, a de-  
cision from a meeting of architects, builders,  
surveyors, and others, waited upon the Halifax  
Council to express their dissatisfaction  
with a number of the new building-by-laws and  
other clauses in the Corporation Bill to be laid  
before Parliament. It was urged by the de-  
puty that the by-laws, &c., in question were  
arbitrary, oppressive, prejudicial to the rights  
of property, and would increase 25 per cent. the  
cost of new erections. The various objections  
were referred to the improvement committee.

#### THE ARCHITECTURAL MUSEUM.

A course of lectures will commence early in  
March. The inaugural lecture will be given by  
the president, Mr. Beresford Hope, on "The  
People's Share in Art," when the prizes to  
art-workmen will be presented. Papers on  
the following subjects will continue the course:  
—On "Ancient Christian Towns in Central  
Syria, recently discovered by Count M. de  
Vogué," by the Rev. George Williams, B.D.;  
on "Ornamentation as a Hand-maid to Archi-  
tecture," by the Rev. Canon Rock, D.D.; on  
"Bells," by the Rev. J. H. Spry, M.A.; on  
"The Precinct of a Gothic Minister," by  
the Rev. Mackenzie E. C. Walcott, M.A.; and  
on "Female Proficiency in Architecture and the  
other Arts," by Mr. F. T. Palgrave.

#### RESTORATION OF TUAM CATHEDRAL.

The Vicar of Tuam, the Rev. C. H. Seymour,  
has forwarded to us a copy of Mr. Thos. N.  
Deane's report, with a view to direct attention  
to an appeal for aid in our advertising columns.  
The architect says,—"I cannot but feel regret  
that it is found necessary, from want of funds,  
to restrain the rapid progress of the work. It  
has now arrived at a point that it is not desirable  
to stop at; and I should most strongly urge  
that a great effort should be made to roof the  
building."

"Surely," writes Mr. Seymour, "the princely  
example of Mr. Guinness in Ireland, and of Miss  
Burdett Coutts, and a host of others, in England,  
should stimulate some of the rich and prosperous  
children of our Church to give us the help we  
so much need. God dispose them so to do."

#### SAINT MARGARET'S CHURCH, LEICESTER.

Two stained glass windows, by Mr. A. Gibbs,  
have recently been placed in the west end of the  
north and south aisles of this church, a bequest  
of the late Mr. Highton, of Leicester. The  
tracery, which is of an elaborate character, by  
Mr. Scott, in Bath stone, has displaced an  
abortion of the Batty Langley style, by a Mr.  
Furnage, some sixty years ago an architect of  
the town. The decayed ashlar surrounding has  
all been cut out and replaced with Attleborough  
stone, and the copings and parapets have been  
taken off and restored. The north-west buttress,  
which underwent some few years ago a very  
indifferent restoration, has been taken wholly  
down and rebuilt to harmonize with the other  
parts of the work. The masonry has been exe-  
cuted by Mr. Joseph Yates, of Saint George's,  
Leicester. The south porch, which is a good  
specimen of the perpendicular style, with a fan-  
groined vaulted roof, now in the last stage of  
decay, is to be restored by Mr. Yates, under the  
superintendence of the same architect.

#### THE OPERA-HOUSE IN THE HAY- MARKET.—THE "QUEEN'S THEATRE."

In our remarks last week on the destruction  
of theatres by fire, we said by the merest slip of  
the pen that the first Opera-house built in the  
Haymarket, and burnt down in 1789, was by  
Novosielski, instead of Vanbrugh. Novosielski,  
as every one knows, built its successor, the pre-  
sent house. Nash & Repton, however, altered  
and enlarged the original building in 1819. A  
correspondent on the subject (J. H. Barn) writes  
as follows:—

The first opera-house in the Haymarket was  
built shortly after the accession of Queen Anne,  
by Sir John Vanbrugh, and named, in compli-  
ment to her, the Queen's Theatre. It was de-  
stroyed by fire in 1789, as you say, and I have  
a large highly-finished drawing of the ruins, by  
William Copon, then scene-painter at the Circus,  
subsequently the Surrey Theatre. Distinguished  
by his architectural excellence as a scene-painter,  
he highly prized this drawing; and those who  
remember his drawing-room, at his residence,  
No. 3, Church-street, Westminster, will recollect  
it, richly framed and pendant on one of the  
doors.

Novosielski rebuilt the Opera-house with so  
much skill, that it is still second to no theatre  
for its superiority as to sound. He also built  
the King's Concert-room, for the performance of  
ancient music, in Tottenham-street, Totten-

court-road; and its acoustic merits were then  
generally the theme of praise, till the King's  
mental derangement served to repress these  
attractions at Court. The concerts were discon-  
tinued, and the Pic Nic, under the conduct of  
Colonel Greville, established there their Amateur  
Private Theatricals; but the bewitcheries of  
these high-born aspirants for historic fame  
were dispersed by the patentees of the Theatres  
Royal, aided by the strong arm of the law.  
Falling wholly into disuse, a pawnbroker, named  
Paul, to gratify his wife's humour of reigning  
supreme, as the Melpomene of the hour, con-  
structed these rooms into a regular theatre; but  
the lady failed to achieve all she expected, and  
disappeared. Under Beverley, it opened as the  
Regency Theatre; and under Chapman & Mel-  
rose, as "The Theatre in Tottenham-street," till  
Mr. Macfarren, father of the now able musician,  
fancied much might here be effected in estab-  
lishing an English Opera. Chapman & Mel-  
rose were displaced; and a new name, that of  
"The Queen's Theatre," was adopted on the sug-  
gestion of the writer, simply because it lacked  
a name, and the Italian Opera was designated  
"The King's Theatre." Now, Miss Mario Wilton  
announces the Queen's Theatre, in Tottenham-  
street, will be opened by her, at Easter, under the  
appellation of "The Prince of Wales's Theatre,"  
unwisely, as it seems to me. Macfarren failed  
there, after having produced, in a praiseworthy  
manner, Handel's "Acis and Galatea;" "Tact;"  
"The French Spy," with Madame Celeste Elliott,  
disguised as the Arab boy, which ran fifty nights;  
and other well-represented pieces. The walls of  
the Queen's Theatre are those which Novosielski  
raised.

#### THE FALL OF SCHOOL FLOOR, WESTMINSTER.

At the adjourned inquest on the sufferers by  
this accident, held on the 6th inst., amongst other  
evidence, Mr. George Vulliamy said that he was  
architect to the Board of Works, and had in-  
spected the school. The witness then read a  
report which he had drawn up for the Board.  
The chief points of the document were to the  
effect that the building was generally well con-  
structed. The beams of the floor were of suf-  
ficient size. The one that gave way was 20 ft.  
in span, 13 in. by 13 in., and supported joists  
tenoned into it. Such a beam should have  
borne a breaking-weight of 40 tons. The weight  
on the floor, when the accident happened, was  
about 7 or 8 tons, and as the next beam (which  
was cracked) partly supported that weight, the  
broken beam gave way at a strain of 4 tons. It  
should have supported 10 tons with safety. But  
it was American or yellow pine, quite dry, short  
in the grain, and brittle. It had a longitudinal  
fracture 5 ft. long. Baltic timber was the only  
timber that should have been used in such a  
position. The timber produced, he believed, was  
yellow pine. In his opinion such timber should  
not be used to bear any weight or in any floor-  
ing. It was only fit for joiners' work. Builders  
might use such timber, but an architect would  
specify that Baltic timber should be used in the  
flooring of such a school-house. Baltic timber  
had fibre, and gave way always with a great crash.  
The American timber had little or no fibre or  
turbentine. For dwelling-houses, 1½ cwt. per  
superficial foot was the amount which floors  
were constructed to sustain. In a building like  
the school the strength should bear 1½ cwt., and  
in a factory the floor should sustain 2 cwt. or  
2½ cwt. There was no doubt that the pushing  
and standing on tiptoes to see the prizes,  
exposed the beam to the greater stress. But if  
the beam had been of Baltic timber, it would  
have been strong enough to bear the pressure  
put on it. The next beam had cracks in it, and  
it would have come down if there had been a  
little greater pressure. The dimensions of the  
beams, 13 in. by 12½ in., were quite large enough  
if the proper Baltic timber had been used.

By Mr. New: Witness had calculated for adult  
weight—140 lb. He ought, perhaps, to have  
allowed 150 lb. to each person. By the Building  
Act all schools, &c., were to be inspected by the  
district surveyor, who was to decide what was  
necessary for the safety of the public, and in  
case of a disagreement between him and the  
architect or builder, the matter should be  
referred to the Board of Works.

Mr. New read the specification for the build-  
ing, which stated that "no American pine must  
be used, but that all joists, &c., should be of  
Baltic timber."

The Coroner: You attribute the break-down

entirely to the nature of the timber used for the beams?

Witness: Yes, entirely to that cause.

A Juror: Was it not the surveyor's business to see to the description of the timber used?

Witness said that he could hardly state. He was not lawyer enough to decide what was the construction to be put on the words of the Act as to the "manner" of building an edifice.

Mr. George Smith, South-street, Grosvenor-square, said that he was the builder.

The Coroner said that he was bound to tell Mr. Smith, as he was the contractor for the building, that he need not give any evidence that might criminate himself.

Witness said that he had nothing to evade. Mr. Foxhall—since dead—was the architect of the building. Witness had not either the specification or the drawings. In the copy of specifications put in, the timber was specified "Dantzic, Riga, or Memel." That was a very usual provision in such specifications. He had no doubt that his contract would include that provision. By some inadvertence the beams in question were at first put in of a smaller scantling, and he desired them to be taken out. They were taken out, and the present ones were put in in their place. He mentioned this to show, that when his attention was directed to anything wrong, he had the matter set right. Therefore, it was not likely that he would put in American pine, which would be quite as bad as too small scantling. The timber produced was, he had no doubt, Baltic timber; but it had been artificially seasoned, apparently by the gas underneath it. He could produce evidence as to his general way of carrying out his business. He had never used American timber for such work; besides it cost more than Baltic timber. He would undertake to say that the American timber he had bought for twenty years past for joiners' work cost more than Baltic timber would have cost.

By the Jury: He had no doubt that the part of a beam produced was either Memel or Riga timber. It was proper wood to put into such a building.

Mr. Richard Gill, Stanley-road, Hackney, said that he was foreman at the building during the erection. He had not a shadow of a doubt that the timber was Baltic. But he had seen cases in which Baltic timber, having been long in dock, had become very dry. There was a stove nearly under the beam, and it struck witness that it might have had the effect of drying the beam.

The inquiry was adjourned until (this) Friday.

We have little doubt but that the beam is of Baltic timber; probably Dantzic; but it has been curiously acted on.

#### NEW BOILER REGULATIONS IN FRANCE.

A MINISTERIAL decree has been issued in France relative to steam-boilers. The following is a *resumé* of the chief instructions issued:—

Every boiler, whether new or old, before it is delivered by the constructor, repairer, or seller, is to undergo a proof under the direction of Mining or Ponts et Chaussées engineers. This proof consists in submitting the boiler to a pressure, double of what it is not to exceed when working, for all boilers of a working pressure between half a kilogramme and 6 kilogrammes per square centimètre (7½ lb. and 85½ lb. per square inch) exclusively. The surcharge of proof for pressures under these limits is to be constant and equal to half a kilogramme per square centimètre; for pressures higher than the superior limit the surcharge is to be 6 kilogrammes per square centimètre. The proof is to be made by hydraulic pressure kept up as long as is necessary for the examination of all parts of the boiler. If the proof be satisfactory, a stamp indicating in kilogrammes per square centimètre the effective pressure that the steam should not exceed, is to be affixed to the boiler in such a manner as to be visible after it has been put in place. Two safety-valves are to be provided for each boiler, to be weighted so as to allow the steam to escape before, or at least as soon as, the pressure arrives at the quantity marked on the stamp, placed in view of the fireman, showing the pressure of steam in the boiler. All boilers are to have apparatus of sufficient and effective power for supplying water to them.

No steam-boiler, to be employed in a building, is to be established without a declaration being made to the prefect of the department. Certain boilers are to be established only outside a house or workshop having an upper story where

workmen are in regular employment. No boiler of the first class is to be placed at a less distance than 3 mètres (9 ft. 10½ in.) from a neighbour's habitation. All furnaces of boilers, of whatever class they be, are to consume their own smoke. Six months' delay is accorded to manufacturers to whom no notice was given at the time of authorisation, to execute these last dispositions. The boilers of portable engines are to be submitted to the same proofs, and furnished with the same safety-apparatus, as boilers established in a fixed place; so also are locomotive engines.

#### "DIRECT COMMUNICATION BETWEEN LONDON AND CALCUTTA, BY LAND, IN A FORTNIGHT."

My son has drawn my notice to the letter of Mr. Sankey, in your impression of the 21st ult., under the above heading, in which occurs the following passage:—"But the scope of this article is to draw attention to a subject which I was the first to bring under public notice, namely, *direct railway communication with India.*" My son, jealous that I should not lose what reputation belongs to the origination and promulgation of so grand an idea, suggests that I should not let the above passage in Mr. Sankey's letter pass quite without notice, and hence this letter to you, for which I respectfully ask insertion in your next number.

I have been since the year 1835 intimately connected with railways in all parts of Great Britain and Ireland; I have also had remitted to me important statistical and other investigations in respect to railways in Algeria, Canada, the United States of North America, and Denmark.

About twenty-three years ago I became personally acquainted with the late indefatigable Lieutenant Waghorn, the originator of what is called "the overland route to India." This always struck me as somewhat of a misnomer, and, at the time I mention, induced the thought suddenly to cross my brain of the practicability of constructing a railway direct from Calais, by way of Constantinople, Turkey in Asia, Persia, and Afghanistan, to Calcutta, thus having a really "overland" route, which, at the time, I said might be traversed by express trains in six days. In a few months after I added to my original scheme "an extension to Canton."

At first I was so overwhelmed by the vastness of the scheme as scarcely to dare to mention it except to a very few personal friends, who, of course, set me down as a very dreamer. In 1843, however, I commenced to elaborate the first outline of my brain, and in the geographical statistics I was aided by Dr. Black and another friend, both of whom I believe are now living.

At this time our great railway mania set in, and I was for several years largely engaged, for Parliamentary purposes, on projected lines all over Great Britain and Ireland, and in course of my travels on these duties I made known my great scheme to numerous engineers and others, officially engaged in railway affairs, many of whom are now dead, but still many living. Suffice it to name two of the latter,—Mr. John Collier, C.E., and Mr. Edwin Clark.

To have an unbroken chain of communication from Calais to Calcutta, by the route I have mentioned, I found at least one great physical difficulty to be overcome, namely, the passage of the Bosphorus. This I proposed to effect, for reasons which I need not now state, a little to the north of Constantinople, at the site of the Castles of Europe and Asia. In the year 1846 I mentioned this to Mr. Edwin Clark, who was then actively engaged in the construction of the Britannia Bridge over the Menai Straits, and I and some members of my family well remember his reply, to the effect that I might rest satisfied on that head, for his experience in the great work on which he was engaged enabled him to say that a bridge across the Bosphorus was quite practicable.

Since 1842 I have taken every fitting opportunity of mentioning the project, especially to parties who, I believed, might, in one way or another, aid it. At the outbreak of the Crimean war I had the pleasure of making the acquaintance of General Chesney, under whose command the exploration of the valley of the Euphrates was conducted, by order of Government, more than thirty years since, and to whose Blue Book I am much indebted for valuable information. To this officer I gave an outline of my plan, and we have had several conversations about it since.

Again, when crossing the plains of Algeria, in 1858-9, I laid it before M. Engeno Caillaux, Ingénieur des Ponts et Chaussées, who expressed much interest in it.

But, sir, the best epitome of the history of this subject is, I believe, to be found in an octavo volume (published by W. H. Allen & Co., in 1857), from the pen of Mr. W. P. Andrew, the chairman of the Scinde Railway, and the early and indefatigable promoter of railways in India generally. To all who take an interest in this great project the following passages, from page 5 of that work, will be acceptable. Mr. Andrews himself extracts them from an author unknown to me, whom he calls "a recent and able writer":—

"In this country, ever since the first exploration of the Valley of the Euphrates, by General Chesney, the advantages of such a route to railway or steam communication has not ceased to press itself upon all thoughtful and intelligent minds. Indian railways, which were brought to the notice of Lord Fitzgerald, the president of the Board of Control in 1842, seem, however, to have been the basis of legitimate projects of overland routes, as contrasted with mere visionary schemes.

The first edition of Mr. W. P. Andrew's work 'Indian Railways, as connected with the Power and Stability of the British Empire in the East, the Development of its Resources, and the Civilization of its People, with an Analysis of the Projects now claiming Public Confidence,' and his Railways in India, was the first great step which finally led to the project of establishing a communication between the railways of India and those of Europe. The line of Rajmahal, and by the valley of the Ganges, in Bengal, which was originally recommended by Mr. Andrews, was, it is true, for a time suspended by the Mirzapore direct project of Mr. R. M. Stephenson; but it, the Rajmahal line, was that which was ultimately adopted by the authorities, and Mr. R. M. Stephenson was ordered to carry it out. Mr. Andrews's energy was, however, only thrown thereby into a new and more important channel, and he was enabled to carry out a favourite project of a Scinde railway, from whence has arisen the still more recent scheme of a connexion between that railway, the Valley of the Euphrates, and the Mediterranean.

Not that there were any want of projectors at home. Mr. William Pary, of the Seville Iron Works, in Dublin, elaborated a scheme of a Calais, Constantinople, and Calcutta Railway, in 1812; and this was afterwards, in 1845, prolonged to Peking, under the designation of 'The Atlas Railway.' Mr. Alexander F. Campbell 'proposed a Railway from England to India' to the Honourable Board of Directors of the East India Company, in letters and maps, of the 6th September, 1843, 25th March, 1845, and 25th April, 1845; and in 1851 Mr. James Wylie published a map, with the railways laid down as proposed by Mr. Campbell, viz., from Oxford, and Vienna, Belgrade, Constantinople, across Asia Minor to Aleppo, and along the Valley of the Euphrates, skirting the seaboard of Persia, and Belochistan to Kurrachee, and thence to Calcutta.

And now, sir, although, so far as I am aware, the paragraph above extracted in which my name occurs is the earliest in type in which I am mentioned in connexion with this great project, it will be evident from what I have herein stated, that I by no means hid my candle under a bushel. The first publication I ever saw or heard of on the subject was in 1845 or 1846, in the shape of a small pamphlet by Mr. Baldwin of Nan-y-Glo, in South Wales, which I regret I have not now at hand.

In Mr. Sankey's letter, which has called forth this, I perceive great earnestness, and I shall be happy to join with him and any others who have made the subject a study, in a vigorous attempt to complete the intervening links in the vast chain of direct railway communication between London and Calcutta and Canton. When I first thought on this subject there was not a single mile of railway constructed on the continents of Europe or Asia. Now we have lines stretching to not a great distance from Constantinople on the European side; from Calcutta to the north of India on the other. I believe that Sir R. M. Stephenson is now engaged on a projected line between Calcutta and Canton. I know that lines through Asia Minor have been surveyed, and I have reason to think that the Shah of Persia is desirous of having them extended through his dominions. Surely by a judicious and concentrated effort we may achieve the grand project in its integrity.

WILLIAM PARY.

Datchet Lodge, Windsor, 25th Jan., 1865.

#### METROPOLITAN BOARD OF WORKS REPORT.

THE Report of the Metropolitan Board of Works, pursuant to Act, 18th & 19th Vict., c. 120, s. 200, for 1864, has been printed. It includes, besides the chief report by the clerk of the Board, Mr. Pollard, also the report of the engineer, Mr. Bazalgette, as to the Main Drainage and Embankment works, and that of Mr. Vulliamy, the Board's superintending architect, as to metropolitan improvements. The chief report refers to what has been done, in course of the past year, as to the main and local drainage; deodorization of the river; Thames pollution;

which had been indicated as the area of the proposed institution, the number of pauper idiots alone was nearly 2,000, while the number of idiots not indigent was great in proportion to their superior position. The central committee in Lancaster had in their eye an eligible site for an asylum, embracing about 40 acres of land near the town of Lancaster. The committee had already received subscriptions to the amount of 9,000*l.*, including 2,000*l.*, a grant, the residue of the Ripley fund. The mayor then read out a list of subscriptions from Liverpool gentlemen,—non-subscribers to the original fund,—amounting to upwards of 4,000*l.* The proceedings terminated with the appointment of a local committee.

#### LIVERPOOL.

*Sanitary Matters.*—The prevalence of fever, and the mortality of the town, formed a subject of conversation in the Health Committee last week. Mr. McGowen stated that the deaths from zymotic diseases in the previous week were 72 above the average,—in that week, 33; from typhus, 65 above the average in the former week, 55 in the latter week; and from small-pox, 18 above the average in the former, and 28 in the latter. The chairman observed that he had seen in the *Times* that the Registrar-General reported that the mortality in Liverpool was 41 in the 1,000. Dr. Trench, the local medical officer of health, said he supplied the data to the Registrar-General, who must have made his own calculations. He did not think that in the borough last year, as far as he could see, the mortality was as high as 36 in the 1,000. There were, however, periods at the beginning of last year when he was quite convinced it was above 41; but during the summer there had been a falling off in the number of deaths. The average for the year was the proper average; the average for the week really meant nothing.—The authorities are taking measures to diminish overcrowding in the dwellings of the poor; but, with the system of sub-letting to deal with, they appear to be at a loss how best to effect the object in view.

*The Fever Epidemic at Liverpool.*—A report on this subject by Dr. Buchanan has been printed. In his summary as to causation he says:—To sum up the present section of the subject,—the reason why typhus is always present in Liverpool may be defined. Destitution, dirt, and intemperance, with overcrowding and bad ventilation of streets and houses, are the conditions that keep up the disease steadily from year to year. The reasons why typhus has become epidemic are not so clear. The only positive conditions that have been ascertained appear to be these—slight but steady increase in overcrowding, some increase of immigration and of distress at the end of 1861, some increase of vagrancy, and with these some influence in each annual season. But these causes are not sufficient to account for the epidemic. The actual mortality from the fever he reports is not great, being only about 6 per cent. of the attacks in home cases, and 14 or 15 per cent. in the worst or hospital cases. The Irish have suffered most severely. We must here remark, as to causation, that the probable increase and prevalence of fever was predicted in the *Builder* so soon as the last summer began to show itself as an unusually dry one. This also occurred on a previous occasion; and, *vice versa*, an unusually wet summer ushered in an unusually healthy winter a few years since. Typhoid fevers are well known to be produced by foul drains and sewer emanations; and though typhus is more generally attributable to foul air from overcrowding and close apartments, it must at least be greatly aggravated by the typhoid cause, where there are foul drains added to overcrowding.

*New Four-wheeled Cabs.*—A Liverpool "Reader" of the *Builder* says,—“We have four-wheeled cabs in Liverpool with the fronts all glass, same as the sides, and the driver sits behind, same as a hansom. These cabs are very superior, and, in fact, look more like a private brougham than a public conveyance. Of course, being public vehicles, the fares are the same as others.” He thinks ladies may prefer these to the two-wheeled hansom cabs; but why should gentlemen prefer being pitched head foremost out of a cab, as we have seen both passenger and cabman, from the stumbling of a hansom cab horse? Besides, the hansom cabs are inconvenient and draughty, as well as unsafe. A four-wheeler, with the cabman behind, is certainly an im-

provement on the hansom in respect to both safety and convenience. It was some such cab we suggested the desirability of having, as an improvement on the present forms of cab.

#### CHURCH-BUILDING NEWS.

*Culford Heath (Suffolk).*—A church, capable of accommodating from 200 to 300 persons, has been consecrated at Culford Heath, by the Bishop of Ely. The architect was Mr. A. W. Blomfield. The style of the church is Early Pointed. It consists of a nave and chancel, forming a single chamber of uniform dimensions, and a small vestry on the north side, which is only partially separated from the body of the church by the organ. The exterior is of flint rubble, with stone dressings, and bands of cut flint and stone. Under the east window a band of stone-work is inlaid with quatrefoils of cut flint and coloured tiles, and a slight inlaying of tiles also adorns the two buttresses at this end. The roof is high-pitched, and a bell-turret of ornamental timber-work rises from it immediately over the commencement of the chancel. The windows in the nave are three in number, on each side, each of two lights, with circular tracery above: those in the chancel are lancets, with trefoil heads. The east window consists of three trefoil-headed lancets, the middle being higher than the rest, each surmounted by a trefoil-shaved light, the space between the under sides of the upper lights and the tops of the lancet-windows being pierced with small triangular-shaped openings, filled with coloured glass. At the west end a simple lean-to porch of timber-work is surmounted by a rose-window of simple design. Every window is filled with stained glass. The subjects of the east window and the chancel-window are “The Agony in the Garden,” “The Last Supper,” “The Crucifixion,” “Our Lord with the Two Disciples at Emmaus,” “The Ministry of Christ,” and “The Descent of the Spirit.” The windows in the nave illustrate the life of St. Peter, to whom the church is dedicated, the different subjects being in shaded outlines of a pale brown on a white ground, after the manner of Retseh and other German artists. The rest of each window is filled in with pattern-work on a green ground. The glass is all from the workshops of Messrs. Lavers & Barrand. The heads of the three lights of the east window are supported by columns of Purbeck marble, standing clear, with carved bands and capitals, and of equal height, the head of the centre light being silted. An inlaying of coloured marbles is also introduced in the vousoirs of the arch which surmounts the whole, and relieves the blank space above the window. The church is paved with tiles by Godwin, of Lugwardine. A barrel organ, by Corps, of Norwich, has its pipes illuminated, and forms a screen for the inclosing of the vestry. The benches are of oak, by Mr. Petch, of Culford; and the whole of the construction has been executed by the builders and workmen connected with the Culford estate. The church has been erected by the Rev. E. R. Benyon, lord of the manor.

*Leyton (Essex).*—The new church of All Saints here is cruciform in plan, and consists of nave, 80 ft. 4 in. by 27 ft. 6 in.; chancel, 27 ft. by 20 ft.; transept, 64 ft. by 19 ft. 9 in.; vestry on the south side of chancel; south porch and organ-chamber on north side of chancel, and archways to north transept and chancel. Over the south transept gable is a bell-turret with buttresses, brick arch and moulded and carved saddle-stone with wrought-iron cross. The height of nave to ridge is 49 ft. The style adopted is Middle Pointed Gothic. The nave is divided into three bays. In the centre bay, south side, is an open porch, with shafts of Lizard Serpentine marble, moulded bases, carved caps of the rose and lily, and moulded stone archivolts. The relieving arch is in coloured bricks rubbed and gauged. The other bays are filled in with three-light windows with tracery, the rear arches being in white brick. At the west end is a porch with arches, &c., formed in coloured bricks, and over it a rose window, 14 ft. in diameter, filled in with tracery, the cusplings representing a crown of thorns. Each transept is lighted by a three-light window of lofty proportions in the gable, with traciced heads. The chancel has a large five-light window, with tracery in the head, and two single-light windows in the side, also with traciced heads. The east window is filled in with rich stained glass by Messrs. Clayton & Bell, and is erected as a memorial to three members of the family of

the donor, Mr. G. C. Capper, of Leyton. The rose window and the small chancel window are glazed with cathedral and other windows with plain glass. The walls internally are faced with malm brick, with red and white brick bands, &c. The chancel and transept arches are formed of similar materials, the inner ring of the chancel arch being supported on carved stone corbels. The roofs are open, boarded, and stained and varnished. The seats have oak, &c., bench-ends; those to chancel, moulded, and with carved finials. The reredos was presented by Mr. W. Evans, of Walthamstow, and is painted on canvas. The chancel is paved with Minton's tiles, and nave and transept gangways with blue and red Staffordshire arranged in devices, and the porches with York. The nave and transepts are lighted by four coronas, and the chancel with two ornate brass standards. The church will seat 560 persons, and the whole of the works have been executed by Mr. Ennor, of London, for the amount of the contract, 2,147*l.* The architect was Mr. W. Wigginton, also of London.

*Leighton Buzzard (Beds).*—At a recent meeting of the committee appointed to carry out the arrangements in connexion with the erection of a new church at North End, Leighton Buzzard, it was unanimously agreed that an architect be advertised for to erect a church, at the cost of 2,500*l.*, to hold 500 persons. Designs to be sent in to the committee.

*Watford.*—The rapid increase of the population around the district church at New Town, Watford, since its erection in 1857, made it necessary that the church should be considerably enlarged. It was, therefore, determined to erect a south aisle, which would not only meet the want for additional accommodation, but add to the uniformity of the church, which is a Gothic building of the Early Decorated style. The plans of Mr. Talbot Bury, of London, were adopted, by which 200 additional sittings would be provided, besides 50 seats for the school children. The contract of Mr. G. Allen, of Watford, builder, was accepted, and the work has been completed at a cost of about 1,200*l.*, and the new aisle has been opened.

*Bloxham (Oxon).*—Plans for the restoration of the parish church have been prepared by Mr. Street, architect, and a statement calling for subscriptions has been issued by the parish authorities. The cost will be about 5,000*l.*, of which 2,825*l.* can now be reckoned on, including materials.

*Southampton.*—A new church is about to be built at St. Denys', Southampton, near Netley Abbey railway station, on the South-Western line; this will make the tenth church built in Southampton and its immediate neighbourhood within the last quarter of a century.

*Hales Owen (Worcestershire).*—The church bells have been restored. The first bell was cracked in the celebration of one of the numerous decisions of the Law Courts in the great case of Small v. Atwood. The inhabitants thought that the winning party ought to have presented the church with a new bell. The harmony of the peal was completely destroyed, about six years since, by the cracking of the bell in a peculiar way on Shrove Tuesday. The loss of the bells has been felt to be a great grievance by many of the parishioners, and the result has been a ready response to an appeal issued by the rector and churchwardens. The bells, to supply the place of those which had been rendered useless, have been cast by Messrs. Warner, of London, and the whole peal of eight bells has been heard again in Hales Owen.

*Durham-down.*—The parish church of St. John the Evangelist, Durham-down, built about twenty-five years ago, has been enlarged by the addition of transepts and by the extension of the chancel, on the north side of which has been placed an organ-chamber, and on the south side a vestry. The appearance of the interior of the church has otherwise been improved. The flat ceiling has been removed, showing the timber of the roof, and the church has been reserated throughout, the high pews being replaced by open benches. The seats have also been rearranged, and the convenience of a centre aisle, as well as of two side aisles, has been afforded. The floors are of Minton's tiles, the aisles and transepts of the plain black and red, while at the altar encanestic tiles have been so used as to represent emblems of the four Evangelists, two on either side of the *Agnus Dei*. The chancel has been fitted up with stalls and a choir. A new heating apparatus has been provided, and

font has been received. The organ has been moved from the south gallery to the chamber provided for it in the chancel. By the enlargements accommodation will be found for 250 additional persons. The architect employed was (Gabriel); the mason, Mr. Case; the carpenter, Mr. Williams; and the painter and glazier, Mr. Perkins. The gas-fittings were supplied by Messrs. Halo & Sons. The enlargement has been carried out in harmony with the other portions of the Perpendicular building. The entire cost of the work has been between 2,000, and 3,000.

**Barton-on-Irwell (Lancashire).**—Sir Humphrey Trafford, bart., is about to erect, at a cost of £20,000, a parish church at Barton-on-Irwell, to replace the building now used for that purpose.

**Books Received.**

*Marshes of South Italy: A few Words bearing upon Land Speculation and Cotton Growing in Italy*.—Malaria and Brigandage. By J. BAILEY DENTON, C.E. London: Chapman & Hall. 1865.

There are many lands on the face of the earth entitled to be called a Paradise, both morally and physically speaking, surely the very centre of moral power for nearly two thousand years ago this centre the seat of true Christianity ought to be that blissful region. With a mild climate, and an intelligent people, an ancient and powerful origin, and with superabundance of the priestly element, their brigandage nor malaria ought to exist in this favoured land. Yet these are still, as they have from time immemorial been, the great parts of it which have been most fully and exclusively under priest-ridden rule. Their fruits very shall know them." The present state of *Christian Italy* in these vital respects, instead of being an advance upon an times, is a shameful retrogression.

Mr. Bailey Denton, in drawing the attention of English capitalists to this subject at the present moment, has done good service to Italy as well as England. Now that English capital is extensively engaged in Italian projects, it is to be clearly understood that an Englishman buying land in the marshes of South Italy has two enemies to contend with, which will not only be his living on the scene of his speculation—malaria and brigands,—the latter being likely to deprive him of his money as the result of his life.

There are and there in the low lands—where natural causes rendered the owner independent of his neighbours, and science and mechanical power—may be observed in successful cultivation. In other places may be those efforts at improvement, such as the straightening and canalisation of river courses, where they were once confined; the cutting of open drains where the water that stagnates beneath a natural discharge, spring where the rivers are charged with the detritus of the hills, long beneficially carried out under the Government of "Canals," but nowhere is there to be seen an instance of the draining of the marshes them, in which recourse has been had either to mechanical means to lift and eject, or to under-drainage, to dissipate the water that stagnates beneath the surface. In fact, *has any valid attempt been made to drain the lowlands of Italy.* On the contrary, not only no pains have been taken to keep pace with the growing needs of the world, but from the time when the marshes made the Campagna of Rome productive, and the Pontine Marshes habitable; when Lily, Dionysius, and others showed that disease and poverty were consequences of deficient drainage; it appears that the spirit of industrial enterprise has declined in Italy, the industry and intelligence which made the low lands productive of grain have given place to indigence and crime, the natural causes of waste and disease.

It is known that the marshy lakes now existing on the coast, between Manfredonia and Barletta, were once salt lakes and harbours, the banks of which were the sites of Siponto and Salapia, and other flourishing and important towns, the ruins of which are lost in the vegetation of the existing marshes. Some efforts to reclaim the marshes have, nevertheless, been made in several places. Peter of Toledo, in 1592, and Count di Lemus, in 1610, succeeded by Domenico Fontana, partially improved the marshes of the Prince of Sogliano, in 1610, which made an attempt on the great plain of Fondi, which was made by Ferdinand IV., who also undertook the reclamation of the Diarno. The present state of these marshes is the unsatisfactory result of these efforts.

It is reflecting on the superior engineering sagacity of man, as evidenced by their works of drainage and supply, their sewers, and their aqueducts, the production of the plain strikes an English agriculturalist with amazement.

Mr. Denton's object is not to deter English capitalists from aiding in the regeneration of Italy, but, on the contrary, to show what must be done to that very end. Until the Italian Government give the requisite powers and incentives, no radical improvement can be made in the marshes, nor can British capital be made

remunerative, however impulsively it may be subscribed. The value of drainage, thorough and systematic, has yet to be learnt in Italy.

**VARIORUM.**

The *Quarterly Review* for January contains an appreciative paper on William Blake, illustrated from his works.—The leading paper in the *Gentleman's Magazine* for February is one on Aix-la-Chapelle, illustrated, in a letter from Mr. J. H. Parker, who went there for the benefit of his health,—we hope successfully.—The *Social Science Review* for February contains papers on Needlewomen, Punishment for Crimes, Children's Employment Commission, and other similar subjects.—The second issue of the *Englishman's Magazine* (February number) contains a variety of interesting matter, some of it of a semi-religious nature. One paper is on Town Churches, by Mr. G. E. Street, architect.—"Handbook and Appendix of Stations and Sidings." This is a convenient and useful alphabetical arrangement of names of places where there are railway stations and sidings throughout the country. It has been prepared by Mr. H. Oliver and Mr. J. Bockett, of the railway clearing-house. It is published by Smith & Ebbs, Tower-hill, London.

"City Sewers Commission Report on London Railways." Mr. Haywood has reported to the committee upon Improvements on the various railway projects affecting the City, in the new session of Parliament; and the report has been printed. Mr. Haywood states that the total area scheduled within the City for the several projects reported upon is about 33 acres, but of this about 18 acres are already authorised to be taken under existing Acts, leaving 15 acres scheduled for the first time, including 2½ acres of public way. For the present, the reporter says, "it seems absolutely needful that the commissioners should dissent from the whole of them."—"Laxton's Builders' Price-book for 1865" is the forty-fifth edition, and is too well known to need notice. The present issue contains the whole of the "Metropolitan Building Act," and Notes of Cases and Decisions thereon. It is necessary to mention that in this price-book the charge for bricklayer per day (as for mason) is put down at 6s. 6d., labourer at 4s.; while in Mr. Burnell's, as mentioned recently, 6s. 8d. is allowed for one and 4s. 2d. for the other. This is a serious discrepancy, and should be reconciled.—The *Art-Student* for February is an interesting number, though the illustrations are scarcely up to the mark.—Amongst the illustrations of the new number of "London Society" are two very good ones. Some of the writing, too, is above its average.

**Miscellaneous.**

**BOLTON TOWN-HALL COMPETITION.**—According to a correspondent, the authors of the six selected sets of designs, named by us in our last, are Mr. Hill, Leeds; Mr. Turner, Belfast; Mr. Brodrick, Leeds; Mr. Lynn, Belfast; Mr. McCurdy, Dublin; and Mr. Woodhouse, Bolton.

**THE WIMBLETON PARK.**—A crowded public meeting of the inhabitants of Putney (Colonel North, M.P., in the chair) has passed unanimous resolutions against Earl Spencer's Wimbleton Park Bill. It is rumoured that the Office of Woods and Forests, in a strongly-reasoned paper, have expressed disapproval of it. Lord Spencer will not, however, give up the enclosure; and "on that and other points" of his "scheme" would "prefer leaving the decision in the hands of Parliament."

**THE SUFFERERS BY THE SURREY FIRE.**—The members of the Stock Exchange, as usual with them on such occasions, have come forward most liberally. Mr. Henry Hill, F.S.A. and Mr. W. N. Budge have collected there, up to the present time, 2351. 4s., of which they have paid to the committee 200l. They have further made special donations to Mr. Rowella, the clown; Mr. Beckingham, the pantaloon; and Mr. Vivian, the sprito, for the great and efficient services they rendered in saving life and attempting to prevent the spread of the conflagration; and whatever balance may be left will be handed over to the committee, should no other case deserving special notice come to their knowledge. We shall be glad if this mention of thoughtful liberality in one quarter should lead others to follow the example.

**HOUSES OF PARLIAMENT.**—Dr. Percy has been appointed by the First Commissioner of Works to succeed Sir Goldsworthy Gurney in the management of the warming and ventilation of the Houses of Parliament.

**AN ARBITRATION CASE.**—The builder of St. John's Church, Tannton, claimed 1,000l. more from the founder, the Rev. F. J. Smith, than the architect said he was entitled to. The case was referred to Mr. Cotterell, of Bath, and he has awarded Mr. Davis 750l., the Rev. Mr. Smith to pay all the costs of the proceeding.

**BRADFORD WATERWORKS.**—On Friday, Mr. Bateman, C.E., made an inspection of Doe Park Reservoir, and we are informed that the result seemed satisfactory, and calculated, when embodied in a report, as it will be in a few days, to allay any fears which may have existed with regard to the insecurity of the reservoir. The *Bradford Observer* says, the Mayor of Bradford, Mr. Ferrand, M.P., and other gentlemen representing the Bradford Waterworks Committee and the millowners in the district, were present during Mr. Bateman's examination.

**LONDON AND COUNTY BANKING COMPANY.**—At the annual meeting, held on the 2nd inst., the directors reported that, after payment of all charges, interest to customers, making provision for bad and doubtful debts, and presenting a gratuity to each officer, the net profits amount to 126,431l. 17s. 4d., which, with 21,726l. 16s. 2d. brought forward from last account, produces the sum of 148,158l. 13s. 6d. for appropriation. The payment of the usual dividend of 6 per cent. for the half-year was declared, together with a bonus of 12 per cent., making 18 per cent. for the six months: these payments will absorb 129,529l. 1s. 3d., and leave 18,629l. 12s. 3d. to be carried forward to profit and loss now account.

**INDUSTRIAL EXHIBITIONS IN THE PROVINCES.**—An exhibition of works of art and industry has been opened in Lancaster by the mayor, in presence of a large assemblage of the inhabitants. The Assembly-Rooms were chosen for the exhibition, but large temporary buildings had to be added. The title of the exhibition is comprehensive: it is "The Lancaster Exhibition of Works of Art and Industry, Floriculture, Manufactures, Specimens of Natural History, Dioramic and Panoramic Scenery, &c.," and is consequently of a most varied character.—A public meeting has been held at Hanley to promote an industrial exhibition for North Staffordshire. Appropriate resolutions were unanimously passed.

**RESTORATION OF CHICHESTER CATHEDRAL.**—The large assembly-room of the Town-hall has been filled with an influential assemblage to receive a report from Mr. Scott, the architect of the works, and to consider the present state and future prospects of the undertaking. The Earl of Chichester, lord-lieutenant of the county, presided, and the Duke of Richmond, the Bishops of Chichester and Oxford, Lord Henry Gordon Lennox, Mr. J. Abel Smith, and numerous other M.P.s were present. The architect in his report says,—"My suggestion is, that, after the connecting portions are carried up as far as the base of the clerestory (the height to which they are at present ordered), the next step should be to carry up the spire as high as the present scaffolding will be available; that is to say, about 40 ft., which, roughly speaking, will probably involve about one-half of its cost. . . . If we assume 9,000l. as the amount up to the commencement of Mr. Bealand's contract; 37,000l. as the amount of that contract, with a margin for contingencies; and 4,000l. as, roughly, the amount which may come due to the architects and clerk of the works for the same period, we have the sum of 50,000l. as against the sum of 38,000l., which may be taken as representing your paid and promised subscriptions, leaving a deficit of 12,000l. to complete the actual necessary work. In my first report, however, I mentioned that there would be some outlay necessary on other parts of the structure, which have been shaken, or otherwise damaged, by the fall of the tower. This is most especially the case with the north transept, which is in a very shaly state, and demands very considerable reparation, not only for its own safety, but for that of the structure generally. I would, therefore, advise that the amount aimed at should be 15,000l." Appropriate resolutions were unanimously passed, approving of the report, &c.; and a sum of 6,416l. was promised and collected towards the sum required to complete the restorations.

INDIA.—The Locknow Exhibition was opened on the 24th December. All the capital for the Great Exhibition in Bombay has been subscribed, and all the shares have been taken up.

A CRISTAL PALACE AND EXHIBITION AT OPORTO.—An exhibition is to be held this year at Oporto. A building, mainly composed of glass, will be erected on the eminence of Torre de Marca, near the town; and it is proposed to open the exhibition on the 21st of August.

BURNING OF THE SMITHSONIAN INSTITUTE AT WASHINGTON.—On the 24th ult., a fire broke out in the Smithsonian Institute building at Washington, in the loft above the picture gallery, between the ceiling and the roof, caused, it is believed, by a defective flue. The loss is very serious. The top of the principal tower and several of the battlements fell.

BURSTING OF A TUNNEL.—A canal, which runs over a tunnel of the Great Western Railway, between the Scho and Hockley stations, near Birmingham, burst through the roof, and the water, escaping from the mouth of the tunnel nearest to Birmingham, flooded the railway station and the adjacent low grounds. An immense amount of damage has been done, and railway communication along the line will be stopped for some days. No life was lost.

TELEGRAPHIC.—The directors of the Electric and International Telegraph Company report that the progressive advance in the revenue of the company has continued, with slight interruption, during the six months just completed. The net profit for the half-year is 54,076l., against 50,568l. in the corresponding period of 1863. The directors again recommend a dividend of 4 per cent. for the half-year on the stock and shares of the company. This will leave a balance of 14,831l. to be added to the trust fund, which will then amount to 54,672l.

ALBERT BELLS FUND, ADELAIDE.—The committee had a meeting on the 18th ult., when the secretary reported the amount in the National Bank to the credit of the fund 223,4s. 10d., and the total amount of subscriptions of the few lists that had come in, 472, 10s. 4d. It was resolved that the mayor and town clerk be authorised to order the bells of Messrs. Warner & Sons (London), as before directed, so soon as the sum of 500l. is placed to the credit of the fund with the Bank. The collectors were urged to collect the sums at an early date, to enable the mayor to send the order for the bells, if possible, by the next mail.

"METROPOLITAN DISTRICT RAILWAY."—This is the title of a new undertaking introduced by an influential board of direction. The object is to complete the "inner circle" of the metropolitan lines of railway lately authorized by Parliament, by means of the line to be formed between the City and the West-End of London via the Thames Embankment. Ultimately the line will extend from Trinity-square, Tower-hill, to Kensington, thus completing the "inner circle." There will be eleven stations upon the line. The capital required is 3,600,000l., of which the first issue will be 2,000,000l., divided into provisional scrip certificates to bearer of 100l. each, and interest at the rate of 6 per cent. per annum will be allowed on the fully paid-up capital during construction. The direction includes the names of the Earl of Devon; Lord Naas, M.P.; the Hon. F. Lygon, M.P.; Mr. C. Gilpin, M.P.; Sir H. Drummond Wolff, K.C., M.G.; and others.

RESTORATION OF SALISBURY CATHEDRAL.—At a meeting of the Restoration Committee, held last Thursday, the Dean of Salisbury reported the progress which has been made in the preliminary works recommended by Mr. Gilbert Scott, before commencing operations in the tower. The foundations of the building have been underpinned, the basement moulding restored, and the drainage completed. Eight of the flying buttresses have had to be entirely rebuilt, while the others have been repaired. The only portion, in fact, of these preliminary works remaining unfinished are the lead covering of the roof and the restoration of the marble shafts, capitals, and bases. These were originally of Purbeck marble, but Mr. Scott has recommended the substitution of Devonshire marble, as being equal in colour to the former, more durable, and less costly. Mr. Scott explained the principles on which he proposes to deal with the most vital part of the whole work, viz., the strengthening of the tower and spire. He said he hoped shortly to submit detailed plans and specifications for the work.

FALL OF A NEW BUILDING AT BREWOOD.—The roofs of two dwelling-houses, just erected in School-lane, Brewood, but not completed, have given way, a great portion of the materials falling upon an adjoining locksmith's shop, breaking in the roof of that also. An old man was nearly harried beneath the ruins. He was speedily extricated, but was found to be severely injured. The cause of the accident appears to have been the slender nature of the materials which supported the roof, and the weight of snow upon it.

DUNFERMLINE PALACE.—The question of the ownership of the ancient and historic Palace of Dunfermline has been decided in the First Division of the Scottish Court of Session. Mr. Hunt, of Pittencrief, claimed the ownership, as against the Crown; but his claim was declared invalid by an interlocutor pronounced by Lord Mackenzie, in 1863, which found that, "the said royal palace, or ruins thereof, belonged to Her Majesty and her royal successors, and were a part of the patrimony and property of the Crown." The judgment of Lord Mackenzie, however, has just been reversed by the first division of the Court of Session.

ILLUMINATED CHARTER ROLL OF WATERFORD, TEMP. RICHARD II.—Amongst the monuments of Waterford, is preserved an ancient illuminated roll, of great interest and beauty, comprising all the early charters and grants to the City of Waterford, from the time of Henry II. to Richard II., including Edward III. when young, and again at an advanced age: a full-length portrait of each king, whose charter is given, adorns the margin. These portraits vary from 3 in. to 9 in. in length, some in armour, and some in robes of state. It deserves to be rescued from obvious danger, by the publication of fac-similes of all the illuminations, and this it has been determined to do as soon as 400 subscribers are obtained. It will be edited by the Rev. James Graves.

TENDERS.

For the second portion of Messrs. Woodall & Son's carriage factory, in Orchard-street and Granville-place, Portman-square. Mr. R. L. Rounnie, architect. Quantities supplied by Messrs. Welch & Atkinson 0 0

TO CORRESPONDENTS.

Several letters in type are unavoidably postponed. "OUR DOMESTIC FIREPLACES"—Seven letters have been received from stove-makers and gas-fitters who have used certain stoves, and will have attention. We cannot find space for testimonials. Provincial Architect (works for the Architectural Exhibition must be sent not later than April 30th)—C. R. (such piece for the distribution of water on the occurrence of fire are not unknown in manufactories) or, at any rate, have been often suggested)—H. H. (there is a school of art in Cannon-street road, St. George's in the East)—F. W. W. S. (write to the editor of the Engineer)—C. K. (next week)—R. A. (will to the editor of the Engineer)—D. E. F.—A. Joiner—R. L. B.—J. H.—C. B.—C. A. W.—C. J. E.—A. I.—A. T.—F. W. W.—F. R. W.—W. F. E.—W. B.—Wernough—An Old Traveller—W. G. E.—F. D.—T. W.—H. S.—B. R. G.—J. H.—M.—W. P. G.—A. K.—F. C.—F. D.—F. M.—D.—An Old Master. The Builder's Fire—J. T. Jun.—G. M. We are compelled to decline pointing out books and giving addresses. All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender; not necessarily for publication.

NOW READY.

THE TWENTY-SECOND VOLUME OF "THE BUILDER" (1864), neatly bound in green cloth, price TWENTY-ONE SHILLINGS.

CLOTH CASES, price TWO SHILLINGS and NINEPENCE (it is necessary, when ordering these, to state whether the Advertisements are, or are not, to be included in the Volume).

A COLOURED TITLE-PAGE GRATIS.

SUBSCRIBERS' VOLUMES will be bound, on being sent to the Office, at a cost of Four Shillings each.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

The Publishers cannot be responsible for ORIGINAL TESTIMONIALS left at the Office in reply to Advertisements, and strongly recommends that COPIES ONLY should be sent.

VOL. XXIII.—No. 1150.

Roman Antiquities  
and  
Modern Antiquaries  
in Chester.

The last monthly meeting of the Chester Architectural and Archaeological Society, the Rev. Canon Blomfield in the chair, Dr. Brushfield read a second paper on the Roman antiquities recently discovered in Bridge street, Chester. Our readers may remember that a year or so ago Mr. Tite, M.P.,

visiting through Chester, saw these remarkable remains, including the lower portions of two ranges of columns *in situ*; and not finding that any one was investigating the matter, thought very desirable that antiquaries generally should hear something about it, so took a great deal of pains to get measurements and drawings; and in January of last year laid these drawings before the Society of Antiquaries, and read a paper, wherein he ventured on a suggestion or two as to the probable purpose of the columns and the buildings.\* The columns, one on each side in number, occur within an archway, right and left of which, ranging with the columns, are remains of Roman buildings, including a hypocaust: and Mr. Tite suggested that the building was a bathing establishment, and that the columns formed porticoes; or that they were the remains of a temple, or of a shrine or statues. Inclining strongly to the latter theory, he made a supposed restoration, filling in the columns at each end between the ranges, and supplying entablature and pediments, influenced to a certain extent by the temple discovered at Bath, and illustrated by Sir Robert Smirke. Evidence of the existence of a *cella*, nor any remains of an entablature, have been discovered in Chester. Dr. Brushfield, in his first lecture, fully reported in our pages at the time, without any spice,† said Mr. Tite's paper was "full of inaccuracies both with regard to facts and conclusions," and promised to look further into the matter on his second address. This he did on the occasion to which we are referring, in a similar manner of discourtesy. There was no evidence at all, he said, of columns at the ends between the two columns; he had looked for evidence of these, and others had searched, and had found none, and, therefore, there never had been any columns, and it could not have been a temple. He cannot point out that some of the side columns were absent, and that where they had stood, they were founded on the rock, there were, equally, evidences, although it was quite certain that columns had been there. He gave various other reasons against the opinion of the remains having formed a temple,—some of them good as against the idea of a temple built strictly on the site that have been laid down as Roman rules, though not as against an exceptional shrine or temple for statuary, or for a covered walk for the frequenters of the baths,—if baths there were.

As to this setting forth of differences of opinion and objection could be taken: quite the reverse.

It might be urged as probable, that the columns formed a portico, or covered walk, in front of each range of buildings, the central space between the columns being open. Out of such discussions we get truth, or the nearest approach to it that may be reached. What we do object to, and do protest against, in the interest of science and good feeling, is the manner in which this was done, and for which it seems really difficult to account. Moreover, the rev. chairman did not improve matters; for, at the close of the lecture, he said that, since the first observations made by Dr. Brushfield had been circulated, Mr. Tite—

"Had seen reason to change his opinions. In fact, he had now come round to the views of Dr. Brushfield on the subject. He had written him (the chairman), a long letter in respect to the matter, and it would be only fair—in order to give Mr. Tite an opportunity of repentance and recovering his character—that he should read it. They would then see that Mr. Tite had come to the same views as Dr. Brushfield."

Such a statement seems to us, after reading the letter in the *Chester Chronicle*,—where, with the report of the discussion, it is printed,—quite extraordinary and indefensible. In the letter,—a very courteous one,—Mr. Tite states what led him to give some account of the remains (not knowing that others had been at work); the pains he had taken to obtain, at some cost, correct drawings of what remained; and his consequent belief in his "facts;" and thus goes on to—

"But I shall be really obliged if any inaccuracies can still be pointed out, because I will take care that it shall be announced as well as rectified in the 'Archæologia.' As to my opinion on the uses of these buildings, it is shortly this—that they were public baths, occupying two sides of an open court; that in the centre of this court was placed a small temple or shrine, supported by columns and roofed, but otherwise quite open, for I could find no trace of any cells; though most probably as at Bath (under circumstances nearly similar) there was a statue of a local god or goddess, or perhaps of some deified emperor, or the reigning emperor placed in the centre."

This portico would also furnish shelter for the visitors to the baths. The proportions and place of the opposite ranges of columns allowed of four columns at each end. At Bath there was space for six, as ascertained by the pitch of the pediment, parts of which were found, but in that case, as at Chester, the foundations of the end columns were not discovered."

There is not one word about changing his opinion, whether right or wrong, still less of "repentance." At the close, the Chairman said, "from what they had heard they could only come to the conclusion that Mr. Tite was wrong and Dr. Brushfield was right." To what extent Dr. Brushfield was right, however, except the Chairman meant, in his saying that the first inquirer was wrong, is not yet very clear. To knock down is much easier than to construct. As to the appropriation of the buildings, this is what the report of his paper says:—

"Were the remains those of a private dwelling or of a public building? We might be tolerably certain that they were those of a public edifice, gathering this from the apparently large size of the original structure. Assuming the original building to have been a public one, was it a bathing establishment? In Chester we have what is called a Roman bath, but beyond the remains of a hypocaust there is nothing whatever about it in itself to prove that it belonged to a bath at all. But did the remains in Bridge-street possess any of the attributes of a Roman bath? They did not possess a single feature by which they could be considered as such. The hypocausts, considered simply as such, proved nothing. On carefully reviewing the whole of the facts he was much inclined to the belief that they formed a portion of a Roman public bath."

Somewhat of a *non sequitur* as it reads: but so far in accordance with Mr. Tite. He ultimately comes "to the conclusion that this building, or perhaps range of buildings, comprised the public baths and *basilica* of the Roman *Deva*, with probably shops and stores." We are not called on to say this suggestion is erroneous; but quite the reverse, we rather incline to it; but at present there is not sufficient evidence to confirm the belief: it would be necessary to assume very much more than Mr. Tite asks for his shrine theory. Dr. Brushfield has evidently got this notion as to the union of baths and *basilica* from Mr. Thomas Wright's papers on Uriconium at Wroxeter, and points to the assumed conjunction of these buildings in the discovered remains of that city.

It is curious, by the way, to note how opinions

grow and get to be received, and we have an amusing instance at hand in these very Wroxeter remains. When the conductor of this journal first urged on Mr. Wright that what were then considered three long parallel apartments were in fact a *basilica*,—the inner dividing walls being the continuous foundations of the columns forming it into central compartment and aisles,—the opinion was pook-pooked and declared to be altogether groundless. Very soon after, however, we find it adopted, as well by our esteemed friend Mr. Wright, in his paper read at Oxford, as by others; and the building is now spoken of as the *basilica* without comment or doubt, and is pointed to, as in this case, as ground for a theory elsewhere.

Let us add briefly that the columns, in Chester, are about 2 ft. 4 in. in diameter, and that the intercolumniation varies slightly, the width from centre of column to centre ranging from 11 ft. to 12 ft. 4 in.: 11 ft. 8 in., however, may be taken as the general distance; the two extreme deviations, 12 ft. 4 in. and 11 ft., occurring together, and being perhaps intended to meet some special requirement. The cross width from centre of column to centre of column may be called 38 ft., and the width from the centre of column on one side to the parallel wall of Roman work which remains is as nearly half this dimension as may be. It is worth while noting as a coincidence, if nothing more, that the width and proportions of the three divisions of the *basilica* at Uriconium, if we may depend on some rough dimensions taken when the remains were first exposed, are very nearly the same as these dimensions from Chester; and so they are, too, in the *basilica* in Pompeii.

Antiquaries, especially those who are interested in Roman England, are greatly indebted to Mr. Tite, be his theory right or wrong, for bringing these most important remains to the notice of the general public; and, as it seems to us, an apology is due from Chester, not more to him than to all who desire to have such matters discussed with courtesy and candour. To the real question we may hope to return hereafter with more complete data to work on.

## NOVELTY IN INVENTION.

At last the Patent Commission, which has been sitting ever since 1862, have published their report. We think that its perusal will show that Lord Stanley, Mr. Fairbairn, Mr. Hindmarsh, and the other members have not missed their time. The different questions involved in patent law are so many and varied, that a brief notice would scarcely do justice to any one of them. We think, however, that the second recommendation of the Commissioners shows a proper appreciation of the main question. We allude to that of the novelty of an invention. "They are unable to recommend a preliminary investigation into the wants of an invention for which a patent is claimed, but they advise that a careful inquiry be instituted, under the direction of the law officers of the Crown, as to whether there has been any previous documentary publication of the invention, either by grant of letters patent or otherwise; and, if such publication have taken place, that the patent be refused. No evidence other than such documentary evidence should be admissible, and the reasons for the refusal to grant the patent should be certified by the law officers: an appeal from their decision should lie to the Lord Chancellor." Now, we consider that the whole success of the amended law will turn upon the way in which this question of novelty will be handled; and we hope that this point will be duly considered in the New Patent Law Amendment Act, which we hope to see passed this session.

If any political capital could be made out of discussions on the rights of inventors and the progress of invention, there is little doubt that the question of patents would have been long ago settled in Parliament. Even as it is, however, there is every probability that the matter will be debated during this year's session. A few of these results of the Commission have oozed out

\* See our vol. xxiii. p. 60.  
† See p. 241, vol. xxiii.

amidst the regions of Chancery-lane, but compelled by the information that all the commissioners could not come to an agreement. When we remember that the majority of the Commission consists of lawyers, we do not wonder at this. As we have said, we believe that the whole success of legislation with regard to patents depends on one question,—that of novelty. If this be properly settled, the question may never be reopened; if not, these laws will have to be continually altered and re-altered till they crystallize into a form which takes this question thoroughly into account.

If the *Times*, as a patent abolitionist, only knew it, there is a line of advocacy which it could adopt as to patent rights, with a much better brief in its hand, and with a much greater chance of success in greatly diminishing the number of patents, and the abuses resulting from their mere number; but, unfortunately, its thunderbolts are for once badly aimed,—it hits out wildly,—and is totally unconscious of a certain crevice in the armour of what it strives to slur over as an abuse. The sages of Printing House-square take only one side of the question; but it need scarcely be said that this question has several sides, as in patents are involved great interest of money and influence; and, whenever great interests are involved in any matter, we may be pretty certain that some will differ, and that there will be a fight about them. At least three distinct interests are involved in the existence of patents,—in patent right or no patent right:—1st, that of the true inventor; 2nd, that of the buyer or user of the invention,—of the public, in fact; 3rd, that of the classes of patent agents, patent solicitors, and patent barristers.

The unimpassioned observer will naturally side with the true producer of the age. The interest of the inventor simply consists in getting protection for his invention as quickly, as cheaply, and as safely, as possible. In truth, the real inventor would be greatly benefited if patents were only given for perfectly sound inventions; as, while patents can be given for improved buttons or crinolines, without even a regard whether there be any novelty about these "inventions," that invention which is the fruit of deep scientific research, carried out with practical ingenuity, must be always nominally, and often actually, depreciated. The interests of patent agents, patent solicitors, patent barristers, and of the class that undoubtedly exists in this country, and in France and in Belgium, where the same system of indiscriminate patenting is in operation,—the class of fishers in the troubled waters of the present patent law,—naturally consist in increasing the number of patents and patentees as much as possible, with the resulting pleasant patent cases, with their still pleasanter crops of fees. The interest of the manufacturer lies also in encouraging true invention, and except in so far as the interest of buyer and seller, of employer and employed, often differ in detail, his interests are identical with those of the inventor. It is true that if patents were abolished to-morrow, this would be a temporary gain to manufacturers or others using other people's inventions in their work. They would be able to fall *main basse* on things for which they have now to pay,—but within a few years the resulting stagnation would more than balance this temporary gain. Upon this point, however, opinions also seem to differ, and we find the *Times*, the present Oxford professor of Political Economy, M. Michel Chevalier, and several other scientific men and distinguished civil engineers, such as Sir W. G. Armstrong, Mr. J. Scott Russell, the late Mr. Brunel the younger, and also the late Mr. J. Meadows Rendel, in opposition to patent rights. These particular doctrines of the two political economists we have mentioned are, we suppose, partly the results of mistaken notions about free trade, and are also due to the more subtle feeling of antagonism between the man of pure and the man of applied science,—between the man who discovers a principle and only gets fame for the discovery, and the man who, perhaps, afterwards practically applies the very same principle, and gets both fame and wealth. The opposition of true civil engineers proceeds from less dignified, though, perhaps, equally unconscious motives. A civil engineer generally works up the ideas of mechanical engineers. He applies machines, details, and new apparatus and means to a great *tout ensemble*. Undoubtedly it is to the interest of all mechanical and civil engineers, of true inventors, and of the public, that only sound patents should be delivered on application. The

true inventor would find his sound patent really risen in value; the manufacturer, or civil engineer, would not—for the mere sake of a quiet life, and from dislike of litigation—have as now to pay for an invention which is merely an invention in name. As to the interests of the middlemen, such as patent agents, solicitors, and barristers, such interests are of a merely parasitic kind, and a simplification and improvement of the patent law ought to reduce the number of patent agents, while a simplification and improvement of patent litigation ought to reduce the number of the patent solicitors and barristers. These classes feed upon the public and the inventor, and they batten upon both. And substantially, these classes are more powerfully represented than any other, in the press and in the British Parliament. Their voices are heard louder and oftener, both at home and abroad. While, on the one hand, we have many public admirers of patent right *per se*, and a few advocates of the total abolition of patent right, we have few advocating the interests of the true inventor.

Now, we consider that the true interests of the public and of inventors are only to be found in a practical yet strict carrying out of the stipulations as to the novelty of any invention that it is intended to patent. The discussion of this particular point of novelty has been very carefully avoided\* by the different ingenious and eloquent gentlemen, more or less interested in the multiplication of patents and patent cases, who have, within a recent date, enlightened us on patent law. Wisely have they instructed us, but not too well. The business of these "*cibum quantumque ex mendacis captantes*,"† is too good to perform the "happy despatch." For to submit patents to a strict test of novelty would considerably diminish the annual crop of patents. To this it may perhaps be replied, that in America, where patents undergo a preliminary examination, the annual number is about the same as with us. But then, it must be remembered, that mechanical invention in the States is much more active than with us, and that the dearth of labour there greatly encourages inventions intended to meet or less superfluous labour. Here, in England, the law courts require absolute novelty in an invention; but the Patent Commissioners give a patent to any one who will ask for it, and it is probable that an enterprising experimentalist could, if he so chose, re-patent all the patents granted from the time of James I. And yet a British patent is not merely invalid if the invention has been previously patented, but also if it has been described in even a foreign book existing in our British public libraries. The mere importation of a foreign work into this country, containing a description of an invention, would not of itself be sufficient to defeat a subsequent patent for it, unless the work was actually sold and published to the public here, from the date of the patent. If, however, a single copy of a foreign work is deposited in the British Museum Library, or in any other place, to which the public can resort for information, any subsequent patent is invalidated.‡ A British patent is also invalid at the expiration of the same patent in any foreign country. §

Then comes the question whether the application of what is old to a new purpose is patentable. Many decisions in courts of law are against this; and the same perplexity on this head exists in America. "The records of the [Washington] office show that hundreds of patents have been granted in defiance" of the decision against patenting a new application of an old thing; "while an examination of the rejected department will bring to light as many

applications which have been refused with reference to these decisions."

Now, when we consider that civilized man, with all his wants and aspirations, has been forced to face with the eternal and never-changing forces of nature for at least three thousand years, it is not surprising that so much has been discovered, but rather that so much is still to be discovered. In this consideration do we find an explanation of the fact, that almost all our most important inventions—such as gunpowder, printing, and others,—are mere re-discoveries of Chinese inventions. When we further remember that human doings have been tolerably well recorded from the first dawn of civilization, and that the completeness of our means of recording facts has, stage by stage, reached its present limit, when, a fact, once published, can never be absolutely lost, we again have cause to wonder that any really new thing can be still discovered. New combinations will, of course, be always made; but we should say, for instance, that very many more new mechanical movements are not to be invented. Adding up all the patent specifications in the world, we find that there are, in all, about 200,000. Some of these are, of course, repetitions (from the same thing being patented in different countries); but taking say 150,000 patents in all, we must remember that according to our law, and according to the patent laws of most foreign countries, patents for the same thing date from their first existence in any country.

But then, again, as we have seen, specifications are not the only tests of novelty. There are numberless English, French, and German works in our public libraries, full of the most ingenious mechanical arrangements. Take, for instance, the famous French work, "*Recueil des Machines approuvées par l'Académie*," and some of the supposed greatest novelties of the day will be found therein. Some curious revelations have been published within recent dates as to the supposed novelty of a great number of noted patents. To add one more instance:—Uchatius's process for making steel, which excited much attention a few years ago, will be found described in the late Mr. Mushel's papers on "Iron and Steel" (1840) as having been tried at the Cyfartha Works in 1780. The steam-hammer introduced and patented by Mr. Nasmyth, after being specified by Watt, and also more completely described by Davenport, is a well-known instance. It must also be remembered that the only set of patents in any country which is indexed is that of our own; that very few of the French patents have been published in the official "*Descriptions des Machines et Procédés pour lesquels des Brevets d'Invention ont été pris*;" that the American patents are described in a very meagre way, and according to systems which must, not many years ago, have been changed according to the fancies of every fresh commissioner; that the Belgian publication is a mere catalogue, the same being the case with the Italian patents; while the German and Russian patents cannot be said to be even catalogued. As to the different scientific and technical works published in different countries, for, in many instances, nearly a century, no complete general index yet exists. The Royal Society have only two or three indexes of their Transactions. There is a collected index of the first thirty-one volumes of the *Comptes Rendus*. The *Philosophical Magazine* has a few separate indexes. The most useful work in its way for a search as to the validity of a patent is, "*Schubarth's Repertorium der Zechnischer Literatur*," to which Mr. B. Woodcroft has adapted his indexes. Another useful work of the kind has been published in Germany, under the title of "*Phillips's Sachregister*;" but it only refers to some eight German technical periodicals. The Patent Office, however, under the superintendence of Mr. Woodcroft, began some time ago a complete general index of all the English and foreign scientific periodicals. This had been laid aside through the mischievous obstructiveness of Mr. Edmunds, the former clerk of the Commissioners, but we are happy to say that the recent resignation of this gentleman has put a stop to the power for evil he exerted so long at the Patent Office Library, and we may, therefore, hope that the publication of this most necessary work may be no longer delayed. Another most useful work now in abeyance, though its continuation is most greatly desired by the public, is Mr. Woodcroft's "*Abridgments of Specifications*."

\* The Report of the Commissioner of Patents for 1863, Washington, 1864.

There is nothing which is more absolutely required in the Patent Office, and yet, in the face of the enormous surplus,—in the face of princely sums paid to the law officers of the Crown by inventors,—the continuation of these works indefinitely delayed. After what we have said, one can wonder at our distinct assertion that invalidating of at least 60 per cent. of existing patents, through want of novelty, is a question of the time devoted to the search. An examination of almost every disputed patent in our courts of law, will show that the work is mostly based on a question of novelty. An important patent is worth attacking. The loss of less importance often exacts the same black-mail. Upon this question of novelty, there has been no improvement in our existing law. There has been division in the camp of the legal Commission, but we think we have good grounds for believing that the question of novelty is common ground for even such *extrême* partisans as these enthusiastic inventors who wish to see infringement a felony, and that sanguine party aiming at total abolition. There are many points of view from which this question may be considered. A full appreciation of the legal difficulties of making the thorough check, which is at present next to impossible, would seem to point to some law of limitation as novelty. But, in the meantime we most certainly want a happy medium between the reckless system of indiscriminate patenting which exists in England, and the Prussian system, which consists in a patent law of despotic temper, tempered by bribery.

#### THE GENTLEMAN'S HOUSE.\*

In the third Part of his volume, Mr. Kerr considers questions of the site of the house and grounds: to some of which, as he says, "the architect and his client must give diligent attention from the beginning;" whilst others must be kept in view by the architect specially as belonging to his vocation.

The first question necessarily is the approval of the City; the second the choice of a Site; thirdly comes the whole question of the arrangement of the Grounds and the site."

And we were able to give a detailed abstract of the second Part of the work,—wherein the ground most to be desired, of each living-room office, in the general plan, is pointed out—it would have been seen how important the first two of these questions to the realization of those arrangements which are deemed best. We need not be disposed to think that, valuable as is the scheme of Mr. Kerr's treatise, the subject might have gained by a division of the questions of locality and site in the first half of the book.

In the choice of locality, there are to be considered, Climate, Shelter, Aspect, Ventilation, Water Supply, Drainage, Salubrity, Landscaping, Gardening, and Local Considerations; and of these is the subject of a separate chapter. First, according to our author, may be said to be of four chief varieties; warm and cold, and either case dry or moist." With one moist atmosphere, he says, there may be apprehended malaria, with the other malaria. An example of cold may be ameliorated by the shelter of a hill; whilst excess of warmth may be tempered by shade. The summit of a hill may be exposed; but low localities are damp and stagnant; "there is a medium, and the rule is to be to prefer within the limits of that medium an elevated site." As to shelter, it is ample if, for instance, the land slope towards the aspect of bleak winds, northward or eastward; and in some cases, wood south-westward valuable. On the sea-coast, especially the shelter must be had if possible. On the other aspect, he says:—

"When an estate slopes very rapidly to the North it is usually so much the less presented to the influence of the rays; the course of the sun is so much lowered and cooled; the latitude is practically so much more North. On the other hand, there is a great inclination towards the South, the amount of heat is so much increased, the course of the sun heightened and lengthened, and the shade made in a manner more South. The chief effect of the land is as regards evaporation from the soil. The slope will be the more moist as an advantage in dry countries, and the same as a disadvantage in wet weather; coldly will be the case in winter, but the more so in summer. The declivity must be very considerable before any great difference is to be perceived; but it is sufficient that if the climate of the locality at large be too warm, a more Northward aspect will so far overcome it, and if too cold, a more Southward aspect; if moist, the South side of a hill is so far the best, and if too dry the North. In any quarter, again, where the

East wind is particularly unwholesome, we should for obvious reasons prefer a Westward inclination."

The question has to be viewed, not merely as to the house, but as to the grounds and gardens.

As to ventilation, or the sufficient circulation of air on an estate, it is mainly remarked that it is generally a question of shelter and level.

Nature of the soil has to be considered both as regards the farming and gardening value,—including the capabilities for the growth of timber,—and the capabilities of drainage and of economic construction of a foundation. The effects, alike, of wet weather and heat, upon clay soils have to be borne in mind.

Water may be available in various forms of supply; but in the country a well is generally required. Our author regards the well as of "these several kinds—the surface-well, the common suction-well, the deep-well, the Artesian-well, and the Artesian-fountain." He says:—

"When the superficial strata are gravel and sand, it is not unusual to find good water without going deeper, and it will also have the advantage of being of soil quality."

We should be inclined to add, here, a special recommendation that the source, or intake of the service-pipe, should not be near the house, where pollution would be likely to ensue; moreover, at a distance, the source should be carefully watched. Considering the risk, in any district of increasing population, or one where there are likely to be manufactories, we would say, preference should be given to the deep-well; although Mr. Kerr, not unreasonably, regards a depth greater than that for which a suction-pump will suffice, and at the same time where the water will not rise as in the Artesian-well, as inconvenient. He admits that there are these risks attendant upon surface-wells, that "after much rain the water may become cloudy, and that in seasons of drought it may entirely disappear." He distinguishes the "Artesian-well" from the "Artesian-fountain," as, the latter, "the only 'Artesian-well' of scientific writers," and the former the case where the depth of boring and the pressure are just what will provide for a rise of water "to a level at which digging may conveniently meet" the water.

As to drainage, it may be remarked, merely, that that of the land is part of the present question, whilst that of the drainage of the immediate site of the house is referred to in the following section.

Concerning salubrity, all the points previously treated bear upon it: or it may "be very simply defined to consist in the possession of good air and good water;" but the author does not omit to note that there may be nuisances from manufactories, to interfere with it, or unwholesome exhalations from "pools, marshes, or autumnal woods."

Landscaping-gardening as an object, should, like the other points, be considered from the first, in the choice of an estate. Irregularity of surface conducing to the picturesque, which has taken the place of the perfectly symmetrical disposition of gardens supposed to be served by a dead level, will be desired. Shelter northward and eastward, and a broad panorama towards the other points of the compass will be desired. The landscape-gardener will hope to find the general position of the estate "upon a somewhat Southward slope, or if not, inclining Westward rather than Eastward." Or he will consider how to supply the needed shelter by plantation.

"If the estate be on a Northward inclination, unless it be a very slight one indeed, he will see reason for much anxiety; if it be actually on the North side of an exposed hill, the case is desperate."

And further, as to the picturesque, besides groups of trees, and larger clumps which he may cut up into groups, or a running stream whence "there will rise up before his fancy those pleasant pictures of lake and brook and fishpond, cascade, waterfall, dripping well, and grotto, which make even a ditch, if it be but well filled with clear water, a treasure to the skillful artist."—

"If we will not object to broken ground, rocks, wild knolls, a gravel-pit even; quite the contrary,—he will convert everything of the sort into dashing bits of art. But what he will not like is such a thing as a congeries of square flat ploughed fields, bounded by trim hedge-rows,—every stick of timber cut away for the ventilation of dry crops,—every little excrescence pared off, and every rough place made smooth,—not a weed to be seen upon the land it may be, and not an inch of opportunity lost for making two blades of grass to grow where but one grew before—but, nevertheless, with all its complect material plenty, to the artistic eye a barren desolation—a vacant clock-face, with a single feature upon which the ingenuity of art can hang a smile."

The "Local Considerations" are such as facility of communication with a railway, or with a town, and others, such as the society of the

neighbourhood, and "not to speak of legal points as to the existence of those indisputably good fences which all the world over make good neighbours."

Locality being decided upon, there comes the Choice of Site for the house itself. Or, rather, it is impossible to pronounce perfect satisfaction "with any general situation for the establishment at large, without having ascertained definitely that it offers an eligible spot" for what is to be the "centre and heart of all." Many a fine estate possesses at the best but an inferior Site for building; and many a charming spot for a house is destroyed in value by the disadvantageous circumstances which surround it. Much of what has been said of the choice of locality for the estate, will again apply; but there are other "principles and illustrations" bearing "upon the House alone." Our author treats these in separate chapters, as Prospect and Aspect, Adjuncts of the House, Sanitary Provisions, and, lastly, Position in the Landscape, and Artificial Site.

He says that the first idea in looking for a site, is to get prospect, but that "the matter is not by any means settled" by the selection of high ground: there is the rival question of Aspect. Having in the former part of his work "had occasion to point out how intimately considerations of aspect affect the comfort and convenience of almost every room," he would now apply the principles generalized.

"Aspect first, prospect second; this is the rule, and exceptions only prove its importance. Prospect being charming, aspect never thought of; this is too often the practice, and no remedy is of any avail."

Having in the previous Part, found that in nearly every instance of a dwelling-room, a South-East aspect was the most desirable, he necessarily considers it plain that a Southward and Eastward landscape is the first thing to be looked for.

"If the only wide and pleasing view were towards the Northward,—say a sea-view,—with the whole Southward sweep hemmed in by wood or buildings or occupied by flat, square, farming fields, or sand-banks and back-water, or peat-bog, or what not,—then it would certainly be very doubtful whether any possible ingenuity could accomplish a compromise, whereby to save the Drawing-room from the desperate alternative of having either a sunless exposure or a desolate view. But if, with the north, as the preferable prospect, the South should be nevertheless in any reasonable degree acceptable, the course is clear,—give to the Drawing-room Front the inferior view with the favourable aspect, and make available the pleasant landscape, which is so unfortunately situated, by opening it to the Dining-room and some others. Or, even more, by some careful trick of plan give to the Bed-room, the Morning-room, perhaps the Drawing-room itself, one of these supplementary windows we have often spoken of, and let the charms of aspect and prospect be combined."

The author's object is to point out the principle that if the landscape towards the South be unfavourable, the evil must be accepted, without change of the direction of the front,—or only moderating the evil by ingenuity of the architect's own, or by that of the landscape artist. He concludes:—

"Accordingly, as has before been hinted, the best possible site is that by which from a slight eminence on the Southward side of a hill you look upon the whole expanse of Southward country beneath, lying on to the North, together with the shelter, the view also of higher ground; whereas, the worst possible site is that where you find yourself on the Northward side of the same hill with the genial warmth of sunshine and the wide exposure of the landscape alike shut out by the summit, and the exposure and cheerlessness of a Northern aspect together super-added. A good standard disposition under the most favourable auspices will be this:—South-East the Drawing-room, Front, North-West that of the Dining-room, and North-East the Offices, the South-West being left for any compensation required by necessities of plan. The Entrance may then be either North-West or South-West; or by moving the Offices to the North angle it may be obtained on the North-East, or on the East angle. The South-East as master of aspect is best for the Entrance, as almost all else; but to place it on the Drawing-room Front is not to be suggested."

In the chapter on Adjuncts of the House, the author treats of the artistic connexion of the house with the ground, and of the "want of foothold" often noticeable,—a want which we have ourselves repeatedly spoken of, and perhaps as often in referring to buildings in London, and to public statues, as to houses in the country.

The adjuncts to which Mr. Kerr gives particular attention are those of a terrace-walk for the drawing-room facade, the lady's parterre of flowers, and the space for the access of carriages,—this last inclusive, or not, of a regular curvaceous count. A good site involves a considerable space of nearly level ground; and the chief purpose of the chapter is to show that whenever the site is irregular in surface, it is a point for inquiry whether there is a sufficient area for the house, offices, and the immediate adjuncts, all on one level. For, throughout the volume, Mr. Kerr dis-

\* See pp. 2 & 53, ante.

countenances offices in a basement, unless when they are unavoidable, as in town-houses; though his book contains at least one good plan of a country-house, Messrs. Banks and Barry's Bylaugh Hall, Norfolk (from our pages), where the kitchen is in the basement; and it has also a plan, showing the offices as modernized of Latham Hall, Lancashire, where the kitchen, of the basement, was merely moved from the main building to a new position. His objection originates partly in the going up and down stairs, and partly in the supposed difficulty of intercepting "kitchen-odours." Are these inconveniences essential to basement offices? The great distance of the kitchen, in large houses on the other principle of plan, should have some weight attached to it. The fact that the most important town-houses have their kitchens in the basement, is not unimportant in the question; and there are persons who prefer to occupy rooms which are raised one story above ground: in fact, sanitary arguments have been put forth to show there should be such a preference.

Passing over the remainder of the section, we come to the section which treats of the Arrangement of Grounds and Adjuncts. It opens with a short but interesting chapter on Style in Landscape-Gardening, wherein it is shown that there is here as elsewhere, the contrast between Classic and Picturesque. The Italian and English styles of landscape art; the connexion between the English style and the Gothic revival, and between the Italian style and Palladianism; the features and rival merits of the two manners, the origination of the doctrine of the Picturesque, the taste for ruins and baronial architecture, and other subjects are touched upon. Mr. Kerr remarks that although a diversity of principle similar to that which exists between the Classic and Gothic in architecture, results in the fact of two corresponding styles in "the art of landscape," there is this one difference, that although the Classic style in gardening is, as in architecture, historically Italian, the picturesque style is not, as in architecture, Mediaeval, but modern, in fact English. The principles of this latter style are analogous to those of Mediaeval design. He adds,—

"Still the rise of this new style was in no way dependent upon the process of Gothic revivalism; on the contrary, as a singular and most interesting fact, it was by means of the introduction of the new principles of landscape-art that the architectural revival itself first acquired standing-ground. In a word, if we say that the origination of the 'natural' style of landscape-gardening in England gave rise to the revival of Gothic architecture and Gothic art at large in Europe, this is practically very nearly correct,—as we shall see."

The characteristics of the Italian or Classic manner may be said to turn upon what our author calls "the staidness of symmetry";—

"The centre line of the House becomes that axis of the Garden in front and of the Garden in the rear, the basis of a plan all geometrical and all in perfect balance."

The English or Picturesque style is altogether different from first to last."

Each style may be misused; wearisome monotony may be produced in one, and eccentricity instead of the true picturesque in the other;—

"but it is equally true that some of the efforts of the old school, although now out of fashion, are of an imposing grandeur, which will never cease to attract admiration, and that on the other hand the charm of the new style, if fashion were to change to-morrow, is a thing that no considerations of deficient staidness could ever set aside."

He says that—

"The question how far the two styles of landscape-gardening are respectively to be identified with the two corresponding styles of architectural design takes three forms:—namely, first as regards historical connexion; secondly, as regards artistic connexion theoretically; thirdly, as regards practical adaptation."

The English manner of landscape-gardening was introduced through the influence of writers who, dissatisfied with the generally prevailing classicism, discovered in a certain sense the Picturesque. It came to be argued that ruins were useful as elements in a landscape: then, Baronial architecture was patronized by the picturesque school; and Gothic architecture as a whole, followed.

As to a connexion of an artistic kind, between the English style of landscape-gardening and Mediaeval design, and between the Italian style and Classic design, there is this only to a certain extent. The present custom of landscape-gardeners, is to adopt the symmetrical for the immediate adjuncts of the house; but for the more remote arrangements, the English style is exclusively employed.

Under the general heading, Arrangement of Grounds, come the heads, Carriage Approach, Entrance Court, Terrace, Lawn, Flower Gardens; Kitchen Garden and Orchard, Greenhouses, &c.;

Conservatories, &c., and Ornamental Grounds. Mr. Kerr distinguishes two varieties of the domestic Terrace, saying that "the distinction involved may be considered a question of style." One terrace is "a promenade along any facade of the house, enclosed in front by a dwarf-wall or balustrade, and elevated to the level of the Principal Story, some feet above the surrounding surface." The other species is similar, as to height, and as to its use as a promenade: but it has no balustrade; or it has at most, a stone curb, whilst it is united to the lawn by a grass-slope. What appears mainly to constitute the terrace is the broad straight walk.

Part IV. of the volume, "Notes on Architectural Style" is an inquiry into the present state of a question which somehow is raised in the majority of cases, even where the architect's client expresses himself as in want merely of "a plain, substantial, comfortable Gentleman's House." We regard Mr. Kerr's exposition of the subject as masterly: nevertheless we are not inclined to accept his description of the client's astonishment at having the question "what style" put to him. It is perfectly true that the architect will now-a-days expect a choice,—we have evidence of this in the letters sent to committees, by architects who write for "instructions," but, as we have heretofore said, one of the first thoughts of any one of the public requiring a house to be built, is what style he will have it. Or rather, we might have said, the latter individual commences with a prejudice for or against a particular style; the prejudice against, being founded upon his observation of particular houses as having had their convenience interfered with through their decorative features. But such interference is solely the result of settling out on the line of imitation, and not on that of such use of the precedent as alone is art. Mr. Kerr, however, could not be far wrong; and he may be nearly right as to the existing practice, when, representing the architect as pressing for a decision, he makes the latter explain that "all" the styles are "comfortable." But an error, which he does not point out, is in architect specifying by name, styles as open to selection: for, it is perfectly clear, that the moment a selection in that way is made, the test of ability will be the reference to the old style, and that the necessity for pleasing his client will act unfavourably upon the architect's exercise of his invention. This, happily, has begun to be not so much the case in domestic architecture as it is in ecclesiastical; but the effect is apparent notwithstanding. The omission by architects of the Mediaeval school,—who once reproduced merely,—of features which are the most characteristic of the original Mediaeval architecture, is a move in the right direction, whatever the merit of the actual productions. It is because we think Mr. Kerr's exposition of the requirements of the Gentleman's House will help in a similar direction,—to wit, that of art-architectural,—that we attach to the book a value other and additional to that which will be perceived by many, and beyond what even the author has cared to claim. We must insist, however, on that which we have been repeatedly at pains to show in these pages, that whilst the pursuit of novelty has its dangers, and has lately done considerable harm, a work of art in architecture must and ought to be a thing for the description of which the customary designations of styles, and language generally, will be insufficient. The ascription of the name must come after the formation of the style: the art cannot be fitted to the name,—failure must be the consequence of effort so inconsistent with what constitutes art.

Mr. Kerr gives an accurate explanation of what is meant by "Style." He says, the answer to a question why the different styles should be recognised, is "to be found in the unprecedented degree to which the English public has lately become imbued" "with the character of virtinism," and that the consequence of this state of things is that the question before referred to, has to be asked.

His object, however, in this portion of the volume, is to show what are the chief accepted varieties of style in domestic architecture, and to give such explanations as may enable the reader "to discern the points of contradistinction, of course historically, but practically much more form." He gives ten sketches in pairs, one simple form of exterior plan being adopted in the whole. The plates represent the Elizabethan manner of the sixteenth century, and the Palladian of the seventeenth and eighteenth; the "Elizabethan of nineteenth century adaptation,"

and "the cotemporary Rural-Italian," the recently introduced Palladian Italian, and "the corresponding style now used by the French,"—(in the latter illustration he is not exactly accurate, as in his basement and porch; moreover, it is difficult to say what is the prevailing style of French villa-architecture,—so great is the variety;) the somewhat continental "Renaissance" wherein the roof is an important feature, and "an equivalent form of the Mediaeval type, likewise a new fashion" and lastly, or supplementarily, the ordinary Cottage style, of the every-day English villa, and "the Scotch style (of the Elizabethan period), which has spread over Scotland and the North of England from the head-quarters of Edinburgh." In the subsequent chapters, he examines each style of the series under the considerations of "Situation, Scale of Building, Materials, Comparative Cost, Comparative Importance, Ornamental Character, The Use of Style Internally, and Influence upon the Interior Plan." Of the purely Classical type in the series, are the Palladian, the Palladian-Italian, and the French examples; whilst of the purely picturesque are the Elizabethan, both ancient and modern, the Mediaeval, and the Scotch examples; "whilst the Rural-Italian is obviously Classical rendered picturesque, the new Renaissance the same, and the Cottage style, within narrow limits, still the same."

Taking a preliminary and general view of the list of considerations, he commences with situation. He observes (following out what he had remarked under Landscape-Gardening), it may be said "that Picturesque architecture suits best a picturesque site, and Classic the reverse." Now, this is a common mode of reasoning; but is it correct? We do not claim to decide the whole matter; but we would urge that it should be pondered over; for, in our opinion there hangs upon the decision, not merely a question such as that taken up by Mr. Kerr at the moment, but the whole question of art-architectural. We may, at least, venture to assert (and this also is a point which we do not advance here for the first time), that all architecture gains its chief expression by contrast with the works of nature. We do not except even street-architecture; and when we have at different times referred to the smoke-miasma, we have not failed to include the obscuration of the sky and clouds amongst the causes of a deficient perception of such good work of art as may have been designed. Far from the Classic manner being suited best to sites the reverse of picturesque, we hold the fact to be proven by the examples, that the manner,—and by reason of the contrast and the regularity,—is suited best to the sites that are picturesque. What is to be said of the Parthenon on its rocky site, or of the Temple at Tivoli, and what of Blenheim, Castle Howard, and Chatsworth? The view of any one of these English palatial residences,—bosomed in woods, whilst foot-holding the ground with the constructed features of spreading base, and foreground of terraces,—whilst the mid-distance presents objects of minor architectural importance,—can never fade from the memory of a true architect, or from; what is just now of more importance to our argument, that of any one of the public.

As to Scale, our author considers the Classic manner as "at least the more imposing for the largest masses." With reference to materials, "the less finished their character, the greater the inducement to adopt picturesque treatment." Cost is not properly a question of style at all. The most important consideration is that of Interior Plan. To the author's previous treatment of that question, we have given attention. In the chapters descriptive of the plates, there is a happy discrimination between the new Elizabethan and the old, the latter having no intentional irregularity, whilst the former will make a distinction between gables even which are generally the same on plan. In the chapter on the Rural Italian style, there are some useful remarks under the head *the use of Style Internally*, touching the question,—not neglected by us, but which has received far too little attention generally,—whether a novelty, as in joiners' work or furniture, is likely to be accepted, with a view to the accordance of interior with exterior. Without saying that we adopt every word of Mr. Kerr's, let us read what he says on the result of an "attempt to introduce style—say some presently fashionable form of Continental Mediaevalism"—into English joiners' work.

"There are scores of instances to be referred to. The pleasing refinement of our little mouldings round the panels, is superseded by clumsy stopped-chamfers; perhaps the most successful is superseded by the matched and beaded boarding which has so long been identified

and "the cotemporary Rural-Italian," the recently introduced Palladian Italian, and "the corresponding style now used by the French,"—(in the latter illustration he is not exactly accurate, as in his basement and porch; moreover, it is difficult to say what is the prevailing style of French villa-architecture,—so great is the variety;) the somewhat continental "Renaissance" wherein the roof is an important feature, and "an equivalent form of the Mediaeval type, likewise a new fashion" and lastly, or supplementarily, the ordinary Cottage style, of the every-day English villa, and "the Scotch style (of the Elizabethan period), which has spread over Scotland and the North of England from the head-quarters of Edinburgh." In the subsequent chapters, he examines each style of the series under the considerations of "Situation, Scale of Building, Materials, Comparative Cost, Comparative Importance, Ornamental Character, The Use of Style Internally, and Influence upon the Interior Plan." Of the purely Classical type in the series, are the Palladian, the Palladian-Italian, and the French examples; whilst of the purely picturesque are the Elizabethan, both ancient and modern, the Mediaeval, and the Scotch examples; "whilst the Rural-Italian is obviously Classical rendered picturesque, the new Renaissance the same, and the Cottage style, within narrow limits, still the same."

Taking a preliminary and general view of the list of considerations, he commences with situation. He observes (following out what he had remarked under Landscape-Gardening), it may be said "that Picturesque architecture suits best a picturesque site, and Classic the reverse." Now, this is a common mode of reasoning; but is it correct? We do not claim to decide the whole matter; but we would urge that it should be pondered over; for, in our opinion there hangs upon the decision, not merely a question such as that taken up by Mr. Kerr at the moment, but the whole question of art-architectural. We may, at least, venture to assert (and this also is a point which we do not advance here for the first time), that all architecture gains its chief expression by contrast with the works of nature. We do not except even street-architecture; and when we have at different times referred to the smoke-miasma, we have not failed to include the obscuration of the sky and clouds amongst the causes of a deficient perception of such good work of art as may have been designed. Far from the Classic manner being suited best to sites the reverse of picturesque, we hold the fact to be proven by the examples, that the manner,—and by reason of the contrast and the regularity,—is suited best to the sites that are picturesque. What is to be said of the Parthenon on its rocky site, or of the Temple at Tivoli, and what of Blenheim, Castle Howard, and Chatsworth? The view of any one of these English palatial residences,—bosomed in woods, whilst foot-holding the ground with the constructed features of spreading base, and foreground of terraces,—whilst the mid-distance presents objects of minor architectural importance,—can never fade from the memory of a true architect, or from; what is just now of more importance to our argument, that of any one of the public.

As to Scale, our author considers the Classic manner as "at least the more imposing for the largest masses." With reference to materials, "the less finished their character, the greater the inducement to adopt picturesque treatment." Cost is not properly a question of style at all. The most important consideration is that of Interior Plan. To the author's previous treatment of that question, we have given attention. In the chapters descriptive of the plates, there is a happy discrimination between the new Elizabethan and the old, the latter having no intentional irregularity, whilst the former will make a distinction between gables even which are generally the same on plan. In the chapter on the Rural Italian style, there are some useful remarks under the head *the use of Style Internally*, touching the question,—not neglected by us, but which has received far too little attention generally,—whether a novelty, as in joiners' work or furniture, is likely to be accepted, with a view to the accordance of interior with exterior. Without saying that we adopt every word of Mr. Kerr's, let us read what he says on the result of an "attempt to introduce style—say some presently fashionable form of Continental Mediaevalism"—into English joiners' work.

"There are scores of instances to be referred to. The pleasing refinement of our little mouldings round the panels, is superseded by clumsy stopped-chamfers; perhaps the most successful is superseded by the matched and beaded boarding which has so long been identified

with the stalls of Stables; the neat simple, serviceable architraves become heavy, odd splay; it is not unlikely that the very form of the doorway must be amended—an open porch, as at a three-cornered flat arch, in defiance of the principle of workmanship involved; it is a mercy if the hinges and lock escape from an appeal to the dicta of authenticity; and lastly, the graining (one of the most charming species of ornamentation ever contrived in the world) is judged to be deceptive in fact and non-authentic in history; so that we must be content with the varnish alone,—with a stain underneath, to make the common deal resemble the oak we cannot afford. It is plain that not one English gentleman out of a hundred will submit to this; and we are at last happily free from all difficulty of the kind in respect of the style of design. In Italy, for the details of our favourite doors and windows, and all the rest, are exactly the details of that style. Our so-called Italian is, in reality, the veridical English style of modern house-building.”

Mr. Kerr returns to this line of argument in his chapter on the “Medieval or Gothic Style.” We may observe that before coming to that, he says in a chapter on the style which he calls “English Renaissance, that the term Renaissance” may be understood to indicate the modern adaptation of Classicism (primarily Italian) received, wherever it may happen to be, through a “French channel.” Now, this use of the term may exist; but it is erroneous; just as is that which he uses for the “some writers” who “call the entire ‘European School of modern Italian architecture’ by the term; a practice which our author correctly says ‘is likely to mislead.’ The term English Renaissance can be correctly made to apply to no other styles than the old Elizabethan, together with the Jacobean; French Renaissance to none but such as those of Francis I. and Henry II.,—or perhaps including the work of the time of Henry IV.; and Italian Renaissance to none later than the Quattrocento, or style of the fifteenth century,—of the early part of that century more especially. The use of the term Cinque-Cento for the architecture of the period just referred to, by many writers, instead of that of the commencement of the sixteenth century, is equally mistaken. Whatever the difficulty of finding a term, or the objection to a synonym, we should never use a term that is erroneous, or one already applied to something else. The designation we have usually adopted for that manner which is the subject of Mr. Kerr’s Chapter, is Franco-Italian, or French-Italian; but we are by no means wedded to it; whilst we repeat, every manner that can be exactly fitted with a name, will usually have a station rather than art as its characteristic.

In the Chapter on the “Medieval or Gothic Style,” our author alludes to three facts:—

“First, the practice of Gothic architecture in ecclesiastical building is passing (like all other things) through a succession of mere fashions; secondly, there is arising a claim to universal dominion for Mediævalism, and destruction for all else, which is arrogant and transcendental; thirdly, a new style has been growing up, an incredible worship of the Ugly.”

The point at which he considers the question of style has arrived in his dealing with it, may be stated thus:—the doctrine that there are a certain number of styles equally eligible, is not to be accepted aesthetically; though certain styles will be demanded,—since the paymaster will be patternmaster.

The characteristics of the Gothic, “as at present applied to domestic building in England,” he says, “are more abstract and grammatical than imitative.” They are derived from many sources. But they are such as the following:—

“Intentional irregularity of plan; intentional variety in height; general verticality of features; then a compromise of this primary verticality to meet a recent innovation of bands of varied colour; the use of turrets as a part of the verticality; the essential use of the pointed arch for the same reason; then the modification of this principle by the introduction of various flat arches and pinnacles (which are more convenient internally); the special use of roof-crests, and other ornamental iron-work, such as finials and railings; the conspicuous display of all the use of mullions in the windows as sparingly as possible; the repetition of crockets and pinnacles as painted with feebleness of purpose; the very sparing use of buttresses; the application of continental pierced parapets; the use of rough stone and brick in the horizontal variety of colour already alluded to, and so on; with other courses throughout the whole the acceptance of Gothic detail.”

He concludes with his ordinary series of questions. As to *Situation*, he considers that the site if not picturesque, should be capable of being made so; and as to *Scale of Building*, that there is only this difficulty, than any very large domestic edifice is apt to be pronounced a college or convent, or an asylum,—whilst even a Gothic parsonage is open to the question why the Elizabethan should be superseded; that *Materials* and *Cost* are no impediments; that for *Importance*, there is a disadvantage, as a bonae in the Gothic manner looks smaller than it is, and also cheaper; and that as to *Ornamental Character*, the style can serve the “advocate of mere muscular ugliness,” or it can display grace in every de-

tail. The next question, however, that “of the use of *Interior Style*,” he observes, is “especially important with regard to Gothic.” The “archæological connoisseurs” he says, “cannot get the public to agree” to the proposition “that the forms and constructive data of the middle ages are perfectly suitable to our wants.” The old systems of carpentry and joinery are obsolete and superseded.

“Consequently, if any practical builder, or architect, not an archæologist, will pursue this principle on constructive ground into the details of form and arrangement which constitute the ordinary style of our interiors, it will be found that our woodwork and plaster-work, our doors, windows, fireplaces, partitions, and staircases, with our chimney-pieces, plaster cornices, glazing, painting, graining, and paper-hanging, and even our chairs, tables, sideboards, carpets, and other multifarious furniture, are a system which has grown up gradually year by year, which belongs rightfully to the time, and cannot be interfered with except in defiance of natural laws.”

Bare stone or brick walls, exposed joisting, unpainted woodwork, stoveless fireplaces, vaulted passages, boarded ceilings, darkness, nakedness, ugliness, public opinion in England will pronounce to be simply preposterous in theory, and unprofitable in practice.”

To the view taken in the first portion of the extract, we have occasionally drawn attention, and with illustrations quoted even from the Palace of Westminster.

As to the influence of external Gothic forms upon *Interior Plans*, Mr. Kerr’s tone is one of perfect satisfaction, as might be supposed from what we have already said of previous parts of his work.

We refrain from particulars of his chapters on “the Cottage Style” and “the Scotch Baronial Style,” and of his “Concluding Remarks.” These last are generally to the effect that the “historical and geographical variety of style” for our domestic architecture is confined in two classes of styles.

Part V., devoted to the subjects of Accommodation and Cost, gives modes of estimating. The first chapter lacks the perspicuity that characterizes the volume generally. The author states two questions as to be dealt with, namely, the progressive degrees of accommodation, and the relation of accommodation to cost; whilst he alludes to a third subject of inquiry, the proportion that outlay upon a new house should bear to the owner’s income. Another preliminary question entered upon, is that of the provision to be made for servants; and this he illustrates by a tabulated statement.

The modes of estimating mentioned are four,—1, By bill of quantities of materials; 2, By cube-measurement; 3, By superficial area; and 4, By number of rooms. He gives the preference to the last of these, for his purpose,—but of course not omitting to state that, for an accurate estimate, the bill of quantities is not to be dispensed with. We may here mention that there is a chapter headed “Supplementary Expenses,” which, if extensively read, would probably prevent much misunderstanding between architects and their clients on the subject of “extras.”

Taking as the standard “an ordinary model of plan of whatever class,” and assuming a locality near London, he starts from data per foot cube, which he puts thus:—

	Per cubic foot.
“For the Main Building or Family Department.....	8d. to 15d.
“For the Attached Offices or Servants’ Department.....	6d. to 10d.
“For Stables and Farm-offices.....	4d. to 8d.”

These prices, he explains, leave Fixtures, Drainage and Water-supply, Garden, Artificial, Foundation, Decoration, and other “supplementary expenses” not allowed for.

Proceeding upon the data, he ascertains the prices per square, and constructs a table, or “Estimator’s Ready Reckoner,” wherein, after the column “Total Outlay Required,” there are under “The Family Department,” columns headed “Price per Cubic Foot,” “Average Height of Rooms,” “Price per Superficial Square,” “Corresponding Number of Squares,” “Cost at the Prices Given,” “Number of Rooms to correspond,” and “Average Price per Room,” and under the “Servants’ Department,” columns similarly headed,—the final column of the whole table being headed “Total Outlay Resulting,” and showing the same figures as the first column, or within a pound or two. In the following chapters are given tabulated statements of the accommodation of each example of house, or from one of the value of 1,250l. to one of 40,000l.,—stables and farm-offices being the subject of a distinct chapter. Thus, the price per square for the family rooms of the 1,250l. house being stated as 40s., and the price for the Servants’ Rooms of the same, as 28s., it is found

that the first department may have thirteen rooms, at 68s. per room, and a total area of 2,230 sq. ft.; and the other department, the same number of rooms at 28s. per room, and a total area of 1,290 sq. ft.—the sizes of the separate rooms being given in detail. Adding to the product 892l., of 2,230 sq. ft. at 40s. per square, 361l., which is the product of 1,290 sq. ft. at 28s. per square, the sum is 1,253l. for the house; only, to that must be added the cost of fences, fixtures, architect, and so forth,—besides, as a matter of prudence, 10 per cent. on cost of the house, for extra.

Respecting the concluding Part of the volume, or Appendix, giving numerous plans and critical notes upon them, we need not limit to what we have said. We may mention, however, a set of plans belonging to a design for a London house by the author, wherein much skill is shown. We doubt, however, if the diminished size of the front room, in the ground story, be not too dear a price to pay for the central position of the entrance to the house. One feature in Mr. Kerr’s arrangement is the provision of open areas for light in the middle of the length, on plan, of the party-wall, or the line of division of the two properties. This arrangement, universal in Paris (and in America), has been quoted by certain speakers and writers, as evidencing a want of consideration by the French, for requirements of ventilation; though when the shaft is not glazed over, it permits of ventilation, as it also affords light, to parts of the plan which could otherwise receive neither. Whether in the case of two different houses, windows opposite to, and at very short distance from, one another, as they are often in Paris, would be objectionable in London, as on the score of fire, may deserve consideration: Mr. Kerr’s plans are not completed by an indication of the arrangement, in this matter, of the house adjoining.

We may also observe that the English student, taking his view of the subject of French plan from Mr. Kerr’s book, must give the utmost importance to the distinction which the author drew in his first page, between the English and the French habits of life. It is not that the love of home-comfort is confined to this side the Channel; but the French plans, even of mere *appartements*, recognize that entertainments and receptions are of some importance to the cultivation of social and friendly relations. It may be that nothing would compensate for the deprivation of domestic comfort; but looking through the whole work of M. César Daly, from which our author has taken one illustration, we do not see that such deprivation would be the case. There is, however, in the small houses in France, a tendency towards an arrangement *en suite*, found only in the English houses of the present day which possess *state-rooms*. From the French point of view, the English are *une nation égoïste*; and we are inclined to think that the home-keeping of the latter, and the want of appreciation of the social intercourse which is least costly, to some extent justify the designation. The habits of life of each nation are capable of improving those of the other; and in like case, we believe, are the respective arrangements of plan.

Perhaps the portion of Mr. Kerr’s work to which we have done least justice, is that which relates to the kitchen; though we have alluded to the description of the fittings as in great detail. We have been assured by a provincial architect, that a perusal of this portion of the volume, by one of his clients, has eased his labours considerably; for, the client had seen what items would be required there as well as in the offices generally, and readily assented to their being included in the specification; so that they will not swell the amount of extras, which the architect of a building is commonly held to have created by his omissions. But the whole volume, in fact, is a *catalogue raisonné*, or specification, of items to be provided in plan, as well as a definition of principles, and a guide in that logical process of which planning consists. That portions of the work, those which we have indicated as already the most useful, could be improved by the suggestions of architects, is possible; and we may venture to say that all assistance that can be rendered, will be duly valued by Mr. Kerr. As the book is, and with whatever the features of it concerning which we have expressed doubt or difference of opinion, we regard it as a most valuable contribution to the literature of our profession. Already in this edition, it is a work of great importance to students; and, we venture to prophesy, it will become a text-book for those who are more advanced. And, if its demonstration of “How to Plan English

Residences" be taken to relate to only such planning as is concerned with the provision for ordinary wants in a place of habitation, or as at most is not inimical to art, instead of to relate also to external and internal decorative effect,—from the first inception, as skilful planning should,—it will through that demonstration alone, facilitate the labours of the architect, and in other respects directly aid in the production of a superior character of art in "the Gentleman's House," as in buildings for habitation of each and every class.

ALGERNON, DUKE OF NORTHUMBERLAND, K.G.,  
IN CONNEXION WITH ART.

In the early dawn, on Sunday morning last, as the snow was falling falteringly on Alnwick Castle, and strewing deep silence in its courts and in the streets of the town without, Algernon Percy, fourth Duke of Northumberland, departed this life. One of England's mightiest nobles,—with a lineage authenticated through dim centuries, till it is found springing from Charlemagne, and through him from Caroloman, major demus to Clotharius, king of France,—various duties devolved upon him; but it is not our province to describe the several phases of his life: our limits confine us to an indication of his influence upon architecture and the arts generally. Born in 1732, the late duke lived through grand eras in our history, serving his country as a midshipman whilst *la grande armée* was parading Europe, and as an admiral in the years that the third Napoleon has ruled France, while he has seen evolutions as startling in the world of art and letters.

Early in the present century the subject of our notice, then Lord Prudhoe, devoted himself to the study of Egyptian antiquities on the banks of the Nile; and, as the readers of Sir Gardner Wilkinson's works on Ancient Egypt may remember, made several interesting discoveries. So popular did this branch of archeology become under his auspices and those of his collaborators, that a museum of antiquities that was without a mummy or sarcophagus was considered as devoid of interest as a garden without peas or cereals raised from seed found on Egyptian tombs. One of the towers on the line of circumvallation of Alnwick Castle contains the valuable collection of ancient Egyptian relics amassed by him at this time, and these it was ever his pleasure to show to guests. Subsequently the traces left by the ancient Romans of their occupation of this country had an especial interest for him. In 1852, the Archaeological Institute held their annual meeting at Newcastle-upon-Tyne, when His Grace received a large number of the members at Alnwick Castle. For this occasion he ordered a complete investigation to be made of the station of Breconium, which was accordingly excavated and surveyed, and made the subject of a communication to the society by Dr. Bruce. The duke also assisted with his own purse the publication of the work on the Roman Wall, by the same hand, copiously illustrated by Mr. Mossman; and a further work on Roman Remains is approaching completion, by his liberal aid and staunch encouragement. He caused, too, a survey of the Roman wall and roads in Northumberland to be made by Mr. H. Maclachlan, whom he afterwards deputed to make a chart of the county, showing the numerous British camps, and consequent points of occupation by our pre-historic predecessors—a task not yet completed. The late Mr. Archer, as we recently mentioned, enjoyed a permanent commission to draw other antiquities in the county. The duke had few Medieval predilections. As in an antique *borso* restored by modern skill, there is a great gap in the periods of art with which his memory will be associated. Familiar with the household gods of the Egyptians, when Joseph presided over Pharaoh's house, and with the evidences the Roman emperors left of their dominion in our isle, his mind spanned the long interval to delight in modern knowledge and progress. This break is apparent in his disregard of the Medieval associations of Alnwick Castle, and in his wide patronage of classic art generally. But the authorization of the handsome quarto, printed for private distribution, illustrating the architecture of Alnwick, Prudhoe, and Warkworth Castles, by Jewett, Le Keux, and Delamotte, is a departure from these preferences; and the elaboration of the slight papers read by the Rev. C. H. Hartshorne at the meeting of the Archaeological Institute

referred to above, into a portly volume, "On the Military and Feudal Architecture of Northumberland," full of illustrations, showing the peculiarities of Northumbrian castles and peels, all at the cost of his Grace, is another exception. These two volumes, aiming at fulness of detail in a few edifices rather than at generalities concerning many, stand apart as the most ample authority upon castellated architecture yet issued. As an instance of his perception of the obligations of his station as Border chief, and of his acquiescence in their necessities, rather than as a specimen of his literary sympathies, we may add that the duke incurred a large outlay, about six years ago, on the publication of a gorgeous edition of the poems of Robert Story, a Northumbrian peasant.

Soon after his accession to the dukedom, the duke proposed to put one of his principal seats into the sumptuous and artistic condition befitting the residence of a noble of his rank. To this end he commissioned three architects to prepare him three designs, showing the extent of the capabilities of the seats assigned to each to reach the elegance and fitness required. He apportioned Sion House to Mr. Decimus Burton, Northumberland House to Sir Charles Barry, and Alnwick Castle to Mr. Salvin. He ultimately selected Alnwick Castle, the seat which is most completely identified with the Percy race, as the scene of his proposed building operations. His grandfather, about a century before, had made the same selection when he created first Duke of Northumberland. The letters of Horace Walpole make frequent allusion to the progress of the works at Alnwick, which fulfilled many of the conditions observed by his own taste at Strawberry Hill. When the work then executed was pulled down in 1854, with all its intricate plaster mouldings, fan-traceries, and lac-like vagaries, from among the *debris*, there spoke two voices, from among the *debris* first, a piece of parchment was found, corked up in a bottle, on which the master-masons had written the exaggerated statement that they had "built this castle;" and, by-and-by, when the restorers moved a marble sarcophagus placed in the chapel to the memory of the wife of the first duke, there lay mouldering there a bundle of old love-letters written by the duchess to her husband; her diary too, some silver coins, silver medals struck in commemoration of the restoration of the castle, with views of it upon them, and some intaglio portraits of the duke and duchess. It was considered a difficult question how these decorations should be replaced. Professor Donaldson related in a paper read to the Institute of Architects the various considerations that arose, and how the duke's long stay in Rome made him at last decide in favour of Italian embellishments, for which the Commandatore Canina furnished him with designs moulded upon existing works of the Cinque-cento period. As the works proceeded, the advice of the late Professor Cockerell and of Professor Donaldson was obtained. How the Commandatore despatched a small staff of efficient artists, Montiroli, architect, Mantovani, painter, and Bulicetti, sculptor in wood, to Alnwick; how he ultimately journeyed to look upon this work of transplantation himself, and died on his road home, we have already told. But we may add, as an instance of the duke's kindly interest in those of his fellow men associated with him in any undertaking, that he arranged that the Italian architect, Montiroli, should see our national sights in the provinces as well as in the metropolis, such as the manufactories and architectural lions of Edinburgh, Newcastle, Birmingham, Manchester, and Liverpool; and, in reverse, sent the resident architect, Mr. F. R. Wilson, to Rome, that he might have the advantage of seeing, *in situ*, the art reproduced under his care. The workmen, numbering some hundreds, were the frequent objects of his thought. On each anniversary of the day on which the duchess laid the foundation-stone of the Prudhoe keep tower they were all invited, with the other workers employed on the estate, to a banquet. When the number of men upon the works was at the highest point nearly eight hundred mustered on these occasions.

The duke also introduced Italian art at Sion House, and at his seat of Stanwick, in Yorkshire. Where practicable, as in the carving at Alnwick Castle, he employed native workmen to work out the Italian designs; but such work as mosaics, statuary, and friezes, was executed in Rome, and conveyed to its destination ready for fixing. He further evinced his Italian art sympathies by the purchase of the Camuccini

gallery. For the pictures of Northumbrian incidents depicted upon the coved ceiling of the ante-chamber leading to the new state apartments, at Alnwick Castle, he employed a German artist, Herr Gotzenberg.

Besides the architects mentioned as consulted by the duke when contemplating the enrichment of one of his seats, he employed Mr. Deason and Mr. Green to a large extent in the numerous works constantly progressing at his cost, as well as maintained, among the officers of his estate, a resident clerk of works, whose business was to keep all farm-buildings in repair. It will be fresh in the remembrance of our readers that the duke laid the foundations of five new churches, and was subsequently present at the consecration of them, only a short time ago, all of which, with their parsonages, were indebted to his means; and the parish church of Alnwick has just been restored also at his cost. He has improved the cottages on his Northumbrian estates to an extent that may be estimated at the expenditure incurred which is said to have been 100,000*l.* Many and many a village may be seen with a crescent painted on every door, indicating that it is ducal property. When the late duke came into possession most of these consisted of picturesque but ruinous cottages such as that in which Burns was born, composed of four low walls, a door, a window a third of the size of the door, and a thatched roof spanning all. It is now difficult to point to one of these: they have been superseded by new, substantial buildings, with as large an amount of the picturesque element in them as those displaced, mostly built from designs by Mr. Deason; the only drawback being that they occupy the precise sites of the former cottages with the same rears of soaked soil from piggeries.

The partial restoration of Warkworth Castle is another architectural work carried out by the late duke. This, with the restoration of Warkworth Church, to the accomplishment of which he was a liberal subscriber, has been described in these pages.

In sanitary matters the late duke lent his aid to ascertain whether it was possible to utilize the liquid sewage of Alnwick upon the grass lands around. The works constructed for this purpose were made at his cost and on his land; but owing to some mismanagement the experiment has not proved so successful as it should have done. His Grace placed Alnwick Castle in the hands of Mr. R. Rawlinson for sanitary revision, thus adding his testimony to the importance of such a precaution. The subdivision of sanitary science in which the ills of overcrowding are combated had not, however, been brought under his notice.

There are two indications of the large number of people living upon the duke's Northumbrian estate that may be quoted. On the day of the great annual fair in July, on the eve of which watch and ward are still kept against incursions of the Scots, it is the custom of all the tenants alike and willing to do so to ride into one of the courtyards of the castle and there be regaled, and thence to proceed to the market-cross in procession, headed by the duke's piper, also on horseback, wrapped in a Northumbrian plaid, with the Percy badge (a silver crescent) on his arm and in his cap, playing "Chevy chase" on his pipes as he rides, and there proclaim the fair. This cavalcade of hearty, broad-shouldered Northumbrian farmers rarely consists of less than seventy or eighty men. The other test is that of the Percy Volunteer Artillery Corps, which musters more than 500 athletes.

Large hearted and liberal handed, the late duke, while managing his vast income with discretion, loved to do things handsomely. He liked every kind of work executed in the best possible manner; not stinting the cost of such excellence; but always requiring an estimate; and was displeased if it was exceeded. When his brother, the third duke, died, about 600*l.* were raised in subscriptions to erect a public monument to his memory. At this stage the proposal was placed in his hands to carry into effect. He commissioned Mr. Dyce to make a design for a stained glass window, to be placed in the east end of the church which it was one of the last acts of his brother to build. He then sent the cartoon to Munich, where it was executed for a sum far exceeding the subscriptions, not tolerating the restrictions which penny enforces on art. Mr. Dyce received 500*l.* for the design; and the glass, with its guards and carriage, cost 1,139*l.* 5*s.* From his earliest days, when as a midshipman he handed his superior officer a cheque upon his father for

1,000l. for a charitable purpose, to his latter days, when he founded a Sailors' Home at Shields, and sent the sick sailors in the *Dead-nought* some thousands of bottles of choice wines, he exhibited the same sea-faring generosity, the same quiescent grandeur of temperament. He was deeply interested in every contrivance for the saving of human life; and, whether it was a request to assist an inventor to bring out a plan by which sash-windows could be easily turned upon a pivot, so that there was no danger incurred by standing on sills to clean them; or to promote life-saving operations upon a larger scale by presiding over and helping the Life-boat Institution, he ever lent his willing aid to every scheme.

A full-length portrait of the duke, in his robes, was painted by Grant. A choice medallion was executed of his Grace, as well as one of the duchess, during his stay in Rome. And Northumberland House possesses a portrait of him seated in the bay-dey of youth.

The burial-place of the Percy family is in the Chapel of St. Nicholas, Westminster Abbey. Thither will be conveyed the remains of the late representative of the most noble race of Percy, earls and dukes of Northumberland, whose shield displays the quarterings of eight hundred and ninety-two alliances.

EXPERIMENTS ON THE STRENGTH OF TIMBER.

The following particulars of experiments were carefully made by competent persons. At the present moment they have an additional value and interest:—

No. 1.—A piece of pitch-pine timber, 13 ft. bearings, 11 in. square.

Weight.	Deflexion.
3 tons .....	25
5 " .....	39
7 " .....	6
9 " .....	78
10 " .....	91

Permanent set .09 after weight was removed.  
No. 2.—As No. 1.

Weight.	Deflexion.
3 tons .....	19
5 " .....	33
7 " .....	45
9 " .....	58
10 " .....	67 Set .06

These pieces (Nos. 1 and 2) were quite dry, rather shaly, but nearly free from knots. Being found sufficiently strong for the purposes intended, the experiment was not carried further.

No. 3.—A piece of Baltic timber of good quality, 20 ft. bearings, 12½ in. deep, 12½ in. in breadth.

Weight.	Deflexion.
2½ tons .....	5
5 " .....	106
7½ " .....	137
10 " .....	2
12½ " .....	237
15 " .....	312 Set .37

No. 4.—The weight applied a second time to the same beam.

Weight.	Deflexion.
2½ tons .....	75
5 " .....	138
7½ " .....	187
10 " .....	262
12½ " .....	337

The beam upon this trial would not sustain a greater weight than 14 tons, and would have broken with that weight, had it been continued.

No. 5.—A piece of Danzig timber, the quality very superior, 19 ft. 4 in. bearings, 14½ in. deep, 14½ in. in breadth.

Weight.	Deflexion.
2½ tons .....	22
5 " .....	45
7½ " .....	74
10 " .....	107
11 " .....	12
11 tons 12 cwt. ...	13

The permanent set, after the above weight had been removed, was hardly perceptible.

No. 6. A piece of Memel timber, rather coarse and knotty, 19 ft. 4 in. bearings, 13½ in. square.

Weight.	Deflexion.
2½ tons .....	72
5 " .....	136
7½ " .....	213
10 " .....	305
11 " .....	37

This beam would not sustain a greater weight than 11 tons. 12 cwt., and would have broken

had the weight been continued upon it, but the permanent set, after the weight was removed, did not much exceed 1.8th of an inch.

No. 7.—A wood beam, 20 ft. long, 10½ in. deep, 6 in. broad, made of two 3 in. yellow planks, bolted together.

Weight.	Deflexion.
12 cwt. ....	35
20 " .....	71
32 " .....	1:105
40 " .....	1:37
52 " .....	1:75

A truss of iron was afterwards applied, the beam deflected nearly 6 in. without breaking.

The weight was in all cases applied to the centre of the beams by hydraulic pressure, and the deflexion given is in inches, and decimal parts of an inch.

ART IN BIRMINGHAM.

The New Permanent Art Gallery, in Birmingham, opens to the public with an exhibition of 500 pictures, on Thursday, February 23rd. By the regulations of this Society, no works are admissible but when forwarded by the artist, who has the option of exchanging them at pleasure, and to whom is remitted, on the day of sale, the price of the work, which, at the time of purchase, can be removed by the buyer. Many well-known names will be found in the list of exhibitors. The price of admission will be 6d. on Thursdays and Fridays; 2d. on other days.

THE SANITARY CONDITION OF WHITEHAVEN.

SCARCELY eighteen months have elapsed since Whitehaven was visited by an epidemic fever which ravaged the whole town, carried off numbers of its inhabitants, and for a considerable time caused it to be shunned by strangers as a place that could only be visited under the greatest risk. The authorities of the place, a corporation called "The Trustees," to whose neglect the visitation was altogether attributable, were momentarily roused to a sense of duty; sanitary measures were hastily adopted with instantaneous effect; and it was understood that such steps would be taken as would prevent the recurrence of the disease. A thorough system of sewerage was promised, the disgraceful arrangements which the absence of all drainage forced upon the residents having been one of the principal causes of the epidemic; and it was fondly hoped that within a brief period Whitehaven would enjoy some of the benefits of cleanliness. But when the immediate danger had passed, it appears they relapsed into their old state of indifference,—the sewerage was forgotten, and the town was suffered to return to its former dirty condition. The consequence is precisely what might have been expected. At a recent meeting of the Whitehaven Board of Guardians, according to our authority, the *Carlisle Journal*, Mr. John Hodgson has made some startling disclosures as to the sanitary state of the town. Within the last four months there have been fourteen fatal cases of small-pox and twenty-three of fever—ten of these fatal cases having occurred in one street, and within the space of a hundred yards. "I may tell you," said Mr. Hodgson, "that we have 193 inhabited cellars in the town, only twenty-two of which satisfy the requirements of the Local Government Act." The "trustees" still remain inactive. Not a single trench has been made for a sewer, not a by-law published, not an office provided nor a clerk appointed, as by the Act of Parliament. Of all the misances which afflict this town we are of opinion that its "trustees" are the greatest, and ought to be got rid of. Should the Home Secretary send down another inspector, as we hear it rumoured he is likely to do, he will very probably recommend the establishment of a separate and independent Board, distinct altogether from the trustees, in order to carry out without further delay the provisions of the Local Government Act. As the present Board is not elected according to the intentions of the Act, Government will, no doubt, consider this an additional reason why a further official inquiry into the state of the town should be made.

INFIRMARY FOR PRESTON.—Nearly 6,000l. have been subscribed towards establishing an infirmary for Preston and its vicinity.

PICTURES AND DRAWINGS BY THE LATE DAVID ROBERTS, R.A.

THE Architectural Galleries in Conduit-street now contain 873 paintings and drawings, chiefly the latter, by David Roberts, hitherto unexhibited, and a charming and instructive exhibition it is. Not water-colours, but spirits-and-water colours, might most of these admirable productions be truthfully termed, so vigorous, sparkling, and effective are they, and that too, with the slightest possible expenditure of means. Recollect his early life spent in scene-painting; that he produced about 200 pictures, now scattered over the kingdom; that his Spanish sketches, recently sold, and many others, are not here,—and what a monument we have of genius, perseverance, and industry united. His first picture sent to the Scottish Academy, and rejected, was afterwards sold by him for 30s., and never paid for: for the last picture he painted he might have had just what sum he chose to name in half-a-dozen quarters. It is noted as a coincidence and not uninteresting that the first scenes he painted for Elliston when he came to London and was engaged at Drury Lane, were "Old St. Paul's," and "St. Paul's as it is," and that the latter was the subject of the last picture he painted on, one of his remarkable series of views on the Thames mostly executed for Mr. Charles Lucas. Two of the volumes of his extraordinary journal, in which he kept pen-and-ink sketches of all his pictures, and the prices paid for them, increase the interest of the present exhibition. It is to such an extent an architectural exhibition, offering to students hints and lessons of the greatest value, that some of the more active members of the Architectural Exhibition, *par excellence*, were actually discussing at the private view the desirability of arranging to keep it open by-and-by free to all members of the profession, in lieu of the accustomed annual collection.

POMPEII.\*

I NOW come to the more interesting portion of my subject, the arrangement of plan, the architecture, and decoration of the private houses. I say more interesting, because, whilst in Greece, Italy, and elsewhere, we have abundant remains, in all states of preservation, of the public monuments and temples built by the ancients, in Pompeii and Herculaneum alone are we able to trace out their domestic dwellings; and, although various descriptions of them have been handed down to us by the Classic authors, still there were many points which remained mysteries till the discoveries of these two cities cleared them up.

The mode of life of the ancient Romans was not very different from that of the present inhabitants of the south of Italy. They rose early, and the greater part of the day was spent in the open air. A slight repast of bread and fruit was taken on getting up; the business of the day was then transacted till noon, when they had lunch, or what we should call "dîner à la fourchette" (only they had no forks). After lunch came a stroll down to the Forum, where all the public meetings were held, the news heard, and the courts attended to hear the trials. Then those religiously disposed might pay their devotions, either to Jupiter, Isis, Venus, or any other deity to whose worship they specially dedicated themselves. If spectacles were being held, they might go to the amphitheatre or the theatre; and, finally, taking a bath (the most important operation of the day), home to dinner or supper, after which no further business was transacted.

The Pompeian houses seem all to have been arranged on a similar plan, the size and number of the apartments varying according to the rank and means of the owner, and to local circumstances. They consisted generally of two floors only, ground and first floor. The latter, occupied by slaves and servants, was low, of little importance, and extended over a portion of the house only. There is but little architecture in the exterior of the houses, as it was invariably occupied by shops, the light being admitted to the rooms from courts in the interior. This may probably have been for the sake of privacy and protection, glass windows being a very great rarity in Pompeii, and also because a shop, sheltered spot, open to the air, in a hot climate, is the greatest luxury one can have. The shops

\* By Mr. R. P. Spiers. See p. 84, ante.

were small. Some had rooms at the back; some had staircases evidently leading to an upper floor, and others communicated with the mansion or house behind. In the latter case the shop was kept by a slave (termed "dispensator") belonging to the owner of the mansion, who thus disposed of the surplus products of his farms and lands. The shops all opened to the street, as they do at the present day in the south of Italy and Sicily, and they were closed at night partly by means of wooden shutters sliding in grooves cut in the stone, and partly by a door swinging on a pivot, the whole fastened together probably by a bar of iron or wood. The grooves in which these shutters were placed are still visible in all the shop-fronts, as also the pivots in their sockets on which the door turned. In many of the shops, particularly those destined for the sale of liquors, counters of masonry, with jars fixed in them, still remain. They have their faces toward the street decorated with small slabs of marble of irregular shape, set in cement and polished.

The names of the different owners were written over the shops in red paint, and some of them had signs of their occupations in has reliefs of terra cotta, many of which are found now. Thus a goat indicated a milk-shop or dairy; two men carrying an amphora, a wine-shop; the phallus, a seller of amulets and love-charms; a man whipping a boy hoisted on another's back, a schoolmaster; and so on. It is difficult, of course, to find out what was sold in the greater number of the shops, their contents having perished or else been removed to the Museum at Naples. The bakers' shops are easily distinguished by their mills and ovens: these latter are similar to our own.

The mills are very curious, and consist of two stones; the lower a cone, with rounded top, somewhat of the form of an egg, with a base or pedestal, and groove cut in it to catch the flour in its descent; the upper stone, in shape like a dice-horn, fits over the lower: in order to lessen the friction, a pivot is let into the upper part of the lower stone and a corresponding socket fixed in the narrow part of the upper stone, four holes being bored in it (parallel to the pivot) to let the corn pass through. The narrow part of the upper stone was hooped outside with iron, and holes cut in it into which wooden bars were inserted to turn it round; this being done sometimes by men, sometimes by asses. The corn was placed in the hollow portion of the upper stone, passed gradually through the boles in the iron socket, was ground between the surfaces of the stones, and finally fell into the groove round the base. Several loaves of bread were found in the different ovens; they are flat, about 2 in. deep and 8 in. diameter, and sometimes have had their form given to them by a mould.

The houses of the higher classes are divided into two parts, in accordance with the domestic customs of the Romans and their double life; the first being public, the second private. The public part comprised the vestibule, or prothyrum, atrium, alae, fauces, and tablinum; the private, the peristyle, cubicula, triclinia, pinacotheca, bibliotheca, exedra, &c. The vestibule or prothyrum was a long narrow passage, about 6 ft. wide, which led between the shops on either side to the atrium or hall; sometimes, though rarely at Pompeii, a small porter's lodge was provided on one side of the vestibule. The atrium was the largest room in the public part of the house, and it was here that the owner received his clients or supporters: in the smaller houses of those who were clients themselves, and therefore waited on others, this atrium served as the common resort of the family. It was a large apartment, roofed over, with an opening in the centre called compluvium, towards which the roof sloped to throw off the rain-water into a shallow marble basin on the floor, called impluvium. Of these atria there were five kinds—

1. The Tuscanicum, or Tuscan atrium, the oldest, and most commonly found in Pompeii. The roof was supported by four beams crossing at right angles, the included space forming the compluvium.
2. The tetrastyle, or four-pillared atrium, similar to the last, except that the beams of the roof were carried by columns, one at each corner of the compluvium.
3. The Corinthian atrium had a greater number of columns round the impluvium, which was in consequence larger.
4. Atrium displuviatum, had its roof inclined the opposite way, so that the rain was thrown off towards the outside.
5. Atrium testudinatum, which was roofed

over entirely, without any compluvium or impluvium: this kind existed only in the poorer houses.

Of course none of the roofs exist now in Pompeii; all have perished. Such restorations as one sees of them, therefore, are made from descriptions by various authors, and from representations in painting found on the walls. The roof round the compluvium was edged with ornamental tiles called antefixe, and at the corners lions' or dogs' heads, to carry the rain-water, and throw it into the impluvium. The open space was sometimes shaded by a veil, to diffuse the light and moderate the height. On the side of the impluvium, facing the entrance vestibule, was generally a small marble table, and in front of it a figure in bronze or marble, holding a vase or a flower, from which water poured into the impluvium, this figure carried on a pedestal or foot.

The floor was paved in mosaic, or ornamented by small squares of marble set in cement, at regular distances apart. Round this atrium were several rooms.

1. Alae, or wings; small recesses for conversation.
2. Cubicula, or sleeping apartments, generally set apart for visitors, or for the male portion of the family.
3. Tablinum; a large room, facing the vestibule, always opening into the atrium, and sometimes into the peristyle beyond, without any wall or separation.

Curtains were probably drawn across this room on either side: at Herculaneum have been found some iron rods, to which such curtains might probably have been suspended; this room contained the family archives, statues, pictures, &c. On one side of this tablinum was a small passage called fauces, which admitted of transit to the private portion of the house without crossing the tablinum. In the private portion of the house were,—

1. The peristyle, which resembled the atrium in plan, but was larger, and always surrounded by a colonnade, the centre space open to the sky, with flowers, shrubs, and fountains in it.
2. Cubicula, or bedchambers: these were very small and inconvenient, entirely out of keeping with our modern notions; but as the Romans spent all day in the open air, they only required sufficient room for a bed to sleep in, their ablutions being performed either at the public baths or in private ones, attached to all the larger houses.
3. Triclinium, or dining-room,—the name being derived from the three couches which encompassed the central table on three sides, leaving the fourth open to the attendants. The size of the rooms and their number, of course, depended on the wealth of the proprietor. They did not give, however, very large dinner parties, or, when doing so on special occasions, used the atrium, the impluvium being boarded over. At their feasts the guests lay with the upper part of the body reclined against the left arm, the head a little raised, and the back supported by cushions; they used knives and spoons, but picked up their food generally with the fingers of their right hand. If ladies were admitted, they generally sat on the couches. Their meals seemed to be somewhat similar to the French repasts now-a-days, beginning with the promulsio or stimulants to the appetite; then courses of meat, fish, flesh, and fowl, and finally dessert. The wine was kept in large amphora, or jars, in earthenware, about 2 ft. 6 in. high, of which many are found now in Pompeii. The jars were inscribed with the name of the consuls in office at the time of the vintage from which the wine was made.

*Æci*, or halls, were large apartments, richly decorated, sometimes looking out on gardens; they constituted the ladies' drawing-room.

*Pinacotheca*, or picture-gallery, for each picture, of which, however, there were very few.

*Bibliotheca*, or library,—a small room, very little space being required for the papyri, or rolls of manuscript, which were taken and read in the—

*Exedra*,—a room generally used for study or conversation.

*Lararium* was the chamber devoted to the Lares, or household gods.

*Xystus*, or garden, only found in the larger houses.

In some of the larger mansions, a special portion of the house was set apart for the female branch of the family, and termed the *venerem*. The kitchens were very small, the cooking being done by charcoal fires, as it is now in some parts of France and Italy.

The upper floor of the house, I have said, was occupied by slaves; there was also sometimes a

solarium, or terrace, adorned with flowers and shrubs, with trellis work, where probably the evening meals were taken in the summer months. These apartments constituted therefore the various requirements of a Pompeian house. I will now take one or two examples of the more important in Pompeii, in order to note their general arrangement or peculiarities.

The house of Pansa is one of the largest and most interesting in Pompeii. Its exterior is occupied on three sides by shops, one of which communicated with the house, and therefore may suppose was kept for the sale of the produce of Pansa's estate. Another shop (from the mills and oven) belonged to a baker. There were also three separate small houses attached to it. The principal entrance is decorated with two pilasters on either side of the doorway; the vestibule is paved with mosaic; thence follow the atrium, two alae, six cubicula, tablinum, fauces, peristyle, ornamented with sixteen Ionic columns, painted red one-third up, the rest fluted; four cubicula or sleeping chambers, two triclinia, a splendid æcus or hall facing the garden—this latter half the size of the mansion,—a servants' hall, and kitchen. In this latter was a curious painting, representing a sacrifice to the Lares, who are persecuted by two serpents near an altar; representations of different animals and fish are also painted round. Serpents were looked upon with great reverence, and were considered as creatures of good omen; they were of a harmless character, and thoroughly domesticated, the ladies putting them round their necks, like a boa, in hot weather. They became at last almost a nuisance, like cats, from their large increase in numbers, no one daring to kill them.

The house of the tragic poet, though small, is especially remarkable for its paintings: in the vestibule was the celebrated mosaic, of the "Cave canem," copied in the Pompeian court of the Crystal Palace. In the triclinium was the celebrated fresco of Leda presenting to her husband Castor, Pollux, and Helen, as new-horn birds in a nest. The peristyle is terminated by a wall, on which was painted a view of an imaginary garden. The house of the Centaur, or of Castor and Pollux, is of considerable size, and consists of two distinct houses, separated by a peristyle common to both. This house has an atrium of the third variety, with twelve Corinthian columns round it. In it were found two highly decorated chests, lined and bound with iron, which still contained a few silver and gold coins that had escaped the attention of some individuals, who returned and made excavations after the eruption. They were unfortunate enough to miscalculate their distance, and arrived in the yard by the side of the atrium, so that they had to penetrate the wall and the bulk of the chest before they could arrive at the treasure it contained. In the house of Sallust, on one side of the vestibule, is a large shop for the sale of liquors, which opens on to it; on the other side a large hall, an unusual feature. This house has also a venerem, a kind of harem, set apart for the female portion of the establishment. The house of the coloured capitals has a second peristyle, surrounded by a long range of twenty-four columns. Two other plans of newly excavated houses which I have sketched are curious, one called the house of Sircium. The irregularity of its peristyle is the chief feature about it: from each of the columns also projects a small bronze water-pipe, forming with the fountain and waterfall in the marble tank, a pretty system of ornamental waterworks. The other plan is of a small house, known as that of the "grand balcony": the upper part of the house, viz.—first floor—projects forward over the street, and is carried by wooden brackets or cantilevers. The first-floor rooms here are very richly decorated. There is one other house of importance I have not yet described, "the Villa of Diomedes." It is one of the most extensive private houses, and more especially interesting as a suburban villa or residence. The house is built on the side of a hill, so that there are as many as four different levels,—first and ground floor, basement, and cellars. It is one of the few houses in Pompeii which has a porch in front. There is no atrium: you enter the peristyle from the prothyrum; round it are triclinia, several cubicula or bedrooms, one of them elliptical in plan, with an alcove; a complete set of private baths, with court and portico, apoclyterium, frigidarium, &c. Also a room in which a large collection of robes were found; a gallery lighted by windows, looking out on terraces; library and reading-room. Stairs lead to the apartments beneath, which seem

to have been used by the family; they were situato on the basement floor, and looked out on the garden at the back of the house. They are, perhaps, the only apartments in Pompeii in which the ceilings remain; they are vaulted and painted with fancy arabesque decorations. Large terraces surround the garden, under which are shady porticoes,—most delightful retreats in summer. In the centre of the garden was a piscina or fishpond, with jets d'eau, and a kind of arbour with columns, on which probably were trellis work and vines. Under the portico, and lighted by loopholes at the level of the ground, are galleries, probably used as cellars, from the large collection of amphore discovered there. No less than seventeen skeletons were found in this cellar, chiefly of females, who had taken refuge there during the fall of ashes over the city, whilst the men had taken to flight. Two of the skeletons were children whose blond hair and texture of dress were still apparent. By the garden-gate were found two skeletons, one presumed to be the master of the house, with a collection of coins near him, and the key of the gate in his hand; the other probably a slave, beside whom were found several silver vases.

#### Architecture and Decoration.

Nearly the whole of the architecture of Pompeii betrays a strong Greek feeling in its mouldings and ornament; and although, under the domination of the Romans, their architecture was gradually introduced, especially in the size and form of the public monuments and temples, still a certain refinement and beauty existing in them induces us to believe that, even if not by Greek artists, they were not executed by Roman artists. Whilst the sections of the carved Roman mouldings were always portions of a circle, those at Pompeii seem to have been traced by hand, or approach more to the curves of concave sections; and yet, notwithstanding the resemblance in feeling to Grecian work, the results are so different that one is at a loss to account for it. To take the Doric column, for instance, which, in the latter period of Greek supremacy, reached a proportion of only 6½ diameters, here in Pompeii it falls to 8 or 9 diameters without any apparent transition. It is true that in the latter city they supported light weights, such as terraces constructed of wood only; in all other particulars the Pompeian Doric column fulfils the conditions of beauty in the Greek order, having no base mouldings, a simple capital, and ornamented with twenty flutings.

Again, the width of the volutes of the best Greek Ionic caps is equal to 1½ the lower diameter of the column, whilst in the Pompeian they are only 1¼. The Pompeian Ionic cap has also another peculiarity in the difference of the form of the echinus moulding. Now the Grecian echinus is narrow and deep in form, like an egg with its shell around, and what is usually called the tongue more like the head of a lance. In the Roman examples the egg is broader, the lower portion semicircular, the shell more spread out, and the tongue between takes the form of the barb of an arrow.

In the Pompeian echinus, however, the egg is extremely small, and the shell has an ogee form; the tongue is similar, but wider than the Greek.

The capital of the Corinthian order, like that of the Ionic, is smaller in proportion to the column, than either the Grecian or Roman varieties; its leaves resemble more those of the cabbage than the acanthus; and, as if to return to the original natural type from which it probably was copied, the volutes or spirals resemble more the natural tendrils of a plant, than the conventional form of them in the Greek and Roman caps. The temple capital, and it has been copied in this country in the Bank of England, designed by Sir John Soane.

There are no relics of the Classic period more interesting than the terra-cotta ornaments which are found in such abundance, and which give us an insight into the architectural decoration of the domestic and less monumental buildings. It has often been a matter of some inquiry whether this perfection of detail, these subtle proportions of the Parthenon and other buildings, only but lately discovered, and which we can scarcely now lay down by mathematical rules of the greatest complication, but which with them was instinctive and the result of highly-trained minds and eyes,—whether the smaller buildings were designed and carried out with the same care; and I think that amongst other proofs these terra-cotta relics show us that they were not; for, although they show artistic feeling and

taste in the highest degree, they are comparatively clumsy and rudely made; and I cannot help thinking, that now we have arrived at such mechanical perfection in the manufacture of these articles in terra-cotta and brick, a careful study of some of the old Pompeian and Roman work to be found in the British Museum and elsewhere will greatly assist the architect in finding out the secret of their artistic beauty and effect, in order to instil a similar feeling into our modern work with a clear distinction of that kind of ornament which is best represented in the material. Time will not permit me now to enter into further details about the architecture, as I have yet a word to say on the mosaics and fresco painting.

Of the mosaics I shall say but little: those of Pompeii generally consisted of black frets on a white ground, or white on a black ground; sometimes they were executed in colour, as in those found in the Villa of Diomedes. The formation of pictures in mosaic was originated by the Greeks, who arrived at extraordinary perfection in their manufacture; they are works of enormous labour and expense. Rougher and coarser kinds of mosaic are also to be found in Pompeii; one kind forming an ornamental covering for columns in the place of stucco and paint: a second kind consisted of irregular-shaped pieces of marble and stone, stuck in cement, and not smoothed down to an even surface, with shellwork. The great fountain is a good example of it, which latter is more remarkable for its singularity than good taste.

The fresco-painting of Pompeii is very interesting to us, having but little acquaintance with that kind of work. The Pompeian fresco-painter used some kind of resin, which he mixed with the colours in order to give them tenacity and render the imparts of their tints glutinous: wax was placed afterwards on the painting, to fix the colours and brighten their tone. The plaster consisted of seven parts of sand and four of marble dust, each successive coat being formed of thinner and finer stuff than the last. The several coats were laid one upon the other without allowing any one to dry. The painter then commenced by tracing with a graver or style the principal lines for ground tints. He then indicated with the same graver the figures of arabesque, and proceeded to fill them in with colour, the wall being still moist. As, however, the work proceeded, the wall would naturally be drying, and hence the amalgamation with the surface would be less complete. You will understand from this description of the system employed in painting, that the putting on of the colours had to be done with great celerity, that there was no time for study of composition or effect; in consequence, their painting must be looked upon as decorative rather than finished drawings or paintings. Of course, they had the power of cutting out the plaster in any part, and forming it again, but this was rarely done.

From careful observations of the different frescoes from Pompeii and Herculaneum, I was able to perceive that there existed two or three different styles, which might, in fact, be expected from the changes of people to which the town has been subjected: hence the Etruscans, or Cumæans, and the Greeks, naturally must each have brought in their special styles; and, in later date, the Romans. To draw a clear and definite line of distinction, however, would be very difficult with so few illustrations as I have here. Without regard to style, however, I might class the paintings in three divisions:—

1st and highest. The pictorial representation of groups of figure, which I would call the ideal based on nature.

2nd. The representation of natural foliage, plants, &c. the real based on nature.

3rd. The representation of imaginary perspectives of imaginary architectural feature, the ideal based on conventionalities, fantasies, and conceits.

The first is certainly the most important because it gives us a glimpse of what the ancient Greek paintings may have been; for, judging the Grecian sculpture and architecture in comparison with the Pompeian, we may draw our conclusions as to what the Greek paintings were in comparison with those found at Pompeii; and the paintings of Greece may be fairly supposed to have been superior to the paintings of Pompeii as the Grecian sculpture and architecture surpasses the Pompeian. The Pompeian paintings, therefore, are extremely interesting to us in that light; they rank, however, themselves as paintings of the highest class. I have, I am sorry to say, but few illustrations of them here;

I must refer you to the works of Sir W. Gell and Professor Donaldson, and also to the Pompeian Court of the Crystal Palace, in proof of what I say.

The composition of the figures, the elegance of their movements, and power of drawing, are most remarkable, especially when we take into consideration the hasty manner in which it was necessary they should be executed. The paintings under the second head are curious, as contradicting the assertions often made, that the ancients never copied nature directly, always resorting to some conventional treatment of it. Nothing can exceed the beauty and simplicity with which the natural foliage of trees and shrubs is depicted: whilst our modern artists would occupy whole hours in the painting of an apple, for instance, the Pompeian, in as few minutes, produced the same with at all events sufficient indication and power to last eighteen centuries. This kind of decoration was generally employed at the further end of the peristyle, where it was supposed to represent a garden beyond. I may mention, that near Rome, at the "Prima Porta," has been discovered a chamber painted in this style. I was fortunate enough to get access to it when in Rome last year, and was astonished at the brilliancy of the colours and wonderful execution.

To the third class of paintings I looked forward with considerable interest and curiosity, in the hopes of being able to discover in these architectural perspectives traces of a style of architecture in which metal would form the chief material; but I am sorry to say that I could discover little in it but what might have been the composition of imaginative minds; and my chief reason for disbelief in it is that it contains all those details such as architraves, friezes, with triglyphs and cornice, which belong to stone architecture, and are quite unfitted for the true use of iron. So that even supposing these compositions of attenuated columns, &c. were copies of the terraces which existed on the tops of the houses; we have nothing to learn from them more than we could do ourselves, and it is the archaeologist rather than the architect who would feel interest in them. However, be they what they may, it is impossible not to admire their wonderful execution, and the grandeur and apparent size they give to the apartments whose walls they occupy.

And now a few words on the general system of decoration. The walls appear to have been divided into three parts in height, the lowest about 3 ft. high, constituting, as it were, a dado; the second (according to the height of the room) some 9 ft. or 12 ft. above the dado; and the third up to the ceiling. The lowest was the darkest in tone, the second intermediate, and the uppermost the lightest of all, generally white: sometimes there were only two divisions.

Hence, if the dado were black, the middle portion would be red or yellow, and above white. If the dado was red, the middle portion would be yellow or blue; and if the dado was yellow all the rest of the wall would be white. The object of this was probably that the lower portions of the wall were the most likely to be soiled, and therefore the darker they were in tone the better; which may also account for the singular idea of painting the lower portions of the columns red or yellow. The colours I have given are, of course, only the grounds on which were painted various designs.

Panels or compartments were always executed in simple and unmixed colours, such as red, yellow, blue, &c. Sometimes the panels were of the same colour; sometimes varying, or relieved by borders or a white background with architectural perspectives. Nearly always the centre of the panels is occupied by single figures or groups in pale colour on the dark background, or in small frames or medallions. The number of accessory ornaments which accompanied these decorations were composed of an infinity of garlands, borders, frames, standards, panels, friezes, and other details of which it is difficult to understand the meaning, except that, esthetically speaking, they are pretty.

Towards the latter days of Pompeii, the rage for colour seems to have taken such possession of the people and their artists that they sacrificed form to it in every possible way: hence we find the beautiful mouldings of the earlier ages covered with stucco and painted, with as many broad surfaces as possible for the display of colour; and the simple and elegant columns, originally Doric, of the temples and porticoes made to lose all their elegance and beauty, being converted into pseudo-Corinthian by the addition of

THE ROYAL HOSPITAL FOR INCURABLES, WEST HILL, PUTNEY HEATH.

*Mr. W. P. Griffith, Architect.*

numerous coats of stucco, and then painted. Another kind of decoration is that whose origin was probably derived from the third class of paintings before alluded to. It consists in the representation in stucco relief of these architectural perspectives, and was employed in places where the rain or moisture would affect paintings: it was formed whilst the stucco was wet, partially with the plasterer's trowel, partly with moulds.

In conclusion, I think there is a great deal to be learnt from the plan of the private houses in Pompeii; for although our climate is very different, there are still certain principles which it would be well to bear in mind, such as the simplicity of their arrangements and the beautiful perspectives they give. I am not sure if in our country mansions and villas those peristyles and courts could not be well introduced, covered with glass if you will, and in the centre of them fountains and shrubs. The plans and details of the public baths are extremely interesting, because it happens that they are being introduced into England at the present time.

Our institutions, religious and civil, of course would clash somewhat with the public monuments and temples; but we cannot help, however, looking with envious eyes on those grand forums and public places, so necessary to health in a large metropolis, and affording so great an opportunity for improving the tastes of the people by the display of national monuments of a high class.

With respect to the fresco paintings,—perhaps the most interesting portion of my subject,—I may as well say that, on strict reasoning, I cannot advocate all Pompeian work as based on a healthy and true principle. Whenever reason, however, enters into the question, it is very difficult to lay down any laws. The doctors themselves do not agree; for whilst one, on strict scientific principles, advocates diaper patterns, another cries out for common sense, and suggests "as a truthful idea the painting of lovely children jumping through vine-leaves."

The Pompeian decoration certainly arrives at great perfection in the objects its artists probably had in view, viz., that of pleasing the eye with elegance of form and beauty of colour. If we can satisfy these demands, it matters little the means by which we arrive at it. I can only recommend, therefore, to architectural

students a careful study of the principles on which such perfect harmony and contrast of colour are obtained in the fresco-paintings of Pompeii: their own hearts will dictate to them the best means of displaying it.

#### THE ROYAL HOSPITAL FOR INCURABLES.

A PERMANENT home for this institution has been obtained on the crown of West Hill, adjacent to Putney Heath. The freehold estate was purchased for 18,000*l.*, and consisted of a mansion, known as Melrose Hall, and 24 acres of park land. The mansion was erected by Mr. Gibson, of Hackney, for Mr. John Anthony Rucker, who died in 1804, leaving the residence to his nephew; and in 1824 it was purchased by the Marquis of Stafford, since which time it has been occupied by several noble families; and in 1862 it formed the temporary home of his Highness the late Viceroys of Egypt.

This building, with its fine hall 35 ft. 8 in. by 29 ft. 6 in., has been retained as the centre of the new hospital; and the addition of a north wing, the first stone of which was laid on the 11th of May last year, is just completed. Although the old mansion was a substantial building, still, beyond a cement pediment and a porch, it had no external architectural features: the windows were simply openings, and 2 ft. below the ceilings. An architectural character has now been imparted to it by raising the windows and adding architraves, pediments, &c. The east, or garden front, remains to be similarly treated.

The new wing is about 100 ft. long by 63 ft. in width, and comprises a basement; ground story, 15 ft. 6 in. high; one-pair story and two-pair story, with a Portland stone staircase; lift for infirm patients, and diet and coal lifts. The corridors are 10 ft. wide, and are formed with rubbed Yorkshire stone slabs, 5 in. thick, on cast-iron girders, each stone being in one length. The north front of the new wing faces the Kingston-road, and consists of a rustic basement, supporting four three-quarter Ionic columns surmounted with an entablature and a pediment, the entablature being continued along lateral or wing additions. The building is faced with white Suffolk bricks, and all the architectural

portions are of Portland stone. The whole of the site of the building has been covered with concrete, to avoid damp.

The contractor for the building was Mr. William Bird, of Kensington; the warming has been done by Mr. Perkins; the kitchen arrangements were put up by Messrs. Benham & Sons; the gas-fittings by Mr. Biggs; the arrangements for ventilation were by Mr. Watson; the fire-proof doors by Messrs. Lawrence; and the oak fences by Mr. Beale. When completed, the building will accommodate 300 inmates; and every comfort and amusement has been provided, including libraries, bowling-greens, &c. A small farm is in course of formation, with cow-houses, dairy, and so forth.

The cost, up to the present period, has been about 11,000*l.* The works have been carried out from the designs and under the superintendance of Mr. W. P. Griffith, architect.

#### BOMBAY CATHEDRAL.

This building, which it is proposed to restore, or rather recast, is the oldest Christian church in India, and as such it has associations connected with it which would render many loth to destroy the structure entirely. It is, however, but ill adapted to the exigencies of the climate or to its purpose as a cathedral church, and it has accordingly been determined to enclose the old building with a kind of cloister, and raise a lofty roof over its present ceiling, enlarge the chancel, and in fact modify the structure very greatly, while yet preserving its main internal features.

The illustration which we give shows the building as proposed to be restored, as it will appear when seen from the north-east.

A fountain, from the designs of Mr. Scott, R.A., is proposed to be erected opposite the western door; but the designs for the general work are by Mr. James Trubshawe, architect, Bombay. Should they be carried out in the liberal and complete spirit in which they have been conceived, they will transform Bombay Cathedral into a building worthy the great and thriving city, to which at present it can hardly be said to be an ornament.

Recently, we gave a view of the new font which was sent out to the cathedral from this country.

ROYAL ARCHITECTURAL INSTITUTE

PHILIPSON DEL.

1865

### THE UTILIZATION OF SEWAGE QUESTION.

The main points of progress (if we may so call it), since our last notes were written, relate to the report of the Coal, Corn, and Finance Committee of the Corporation of London to the Court of Common Council on this subject; and to a continuation of the discussion at the Society of Arts on Mr. Morton's paper, already spoken of.

The City Committee state that—

"Having maturely considered the report of Baron Liebig, the greatest known authority upon agricultural chemistry, they are of opinion that the scheme of the Messrs. Hope & Napier, if it could be carried out, would be a glaring violation of the laws of agricultural science, from which the least possible increase to our home supplies of food would be obtained, as well as the smallest return to the ratepayers of the metropolis for their property.

In conclusion, the committee are of opinion that it is for the interest of the nation that a searching investigation into the system of economic sewage utilization should be instituted by Parliament before any steps are taken for the utilization of the sewage of London or of any other town, and that the interest of the ratepayers of the metropolis demands that the plan of Messrs. Hope & Napier should be strenuously opposed."

The report has since been adopted by the whole corporation.

In speaking of Baron Liebig's letter to the Lord Mayor, which was laid before the committee, the report says:—

"The committee find that Baron Liebig's analysis of the various fertilizing matters found in sewage and in Peruvian guano, have led him to the conclusion that in 828 tons of the London sewage, taking the total ammonia amount at 246,000,000 lbs., there is as much ammonia as in 1 ton of Peruvian guano; and estimating the value of the ammonia, phosphoric acid, and potash found in a ton of guano to be worth 7*l.* 1*s.*, he is of opinion that the fertilizing matter contained in 1 ton of sewage is worth 1*s.* 4*d.*, and the annual amount of the metropolis sewage is worth 2,040,715*l.* He, however, further states,—"If the ammonia be reckoned at the price that the farmer pays at present for it in Peruvian guano, the ton of sewer water would be worth something more than the double of that price." This would give 4,081,430*l.* as the annual value of the metropolis sewage—a sum somewhat larger than that arrived at by the committee, basing this estimate on the analysis of Messrs. Hoffman & Witt, and the present retail price of Peruvian guano, which price must necessarily rise that of every other manure." The committee further find that Baron Liebig points attention to the power of soils to abstract from sewage the fertilizing matters therein contained, but that of all soils pure sand possesses this power in the smallest degree; and with reference to the dilution of the sewage he states:—"A series of experiments with artificial sewer water proved that a dilution with water as great as that of the sewage of the metropolis in no wise diminishes the absorbing effect of the soil. I found, moreover, last summer, by experiments regarding the growth of plants, that a soil completely saturated with manuring matter did not, as might be supposed, further the development of the plants' growth, for to many, on the contrary, it was prejudicial." The committee also find that Baron Liebig conclusively proves the fitness of sewage as a manure suitable for arable land and general farming purposes, and emphatically points attention to the error of the continually applying one description of manure to land."

As regards the value of sewage, we scarcely think that it has been kept so clearly in view as it ought to be that value is relative, and that the true value of a thing is what it will sell for at the moment. Sewage may contain certain quantities of chemical ingredients which, were they in the form of guano, and as available for immediate use on the land, would be of a certain value; and in time to come that value may be realized even in the sewage form; but is the metropolitan sewage as a whole, and under present circumstances, of the value indicated? Charqui, or jerked beef, could its sale be depended on in this and other countries to a sufficient extent at 3*d.* per lb., might be regarded on the South American prairies as being of the value of say 1*d.* per lb., and in future time it may come to be of that value, but at present it is not so; it is simply worthless. Better therefore to regard it as not of one-tenth that value and sell it at this till it gets into extensive use, when its value will rise accordingly. In arguments as to the value of sewage there may thus be serious fallacies which may greatly interfere with the disposal of sewage as a positive nuisance, which at present must be got rid of at any price, and even though at a premium for taking it away. This is not merely a commercial question in short, but a sanitary one,—and primarily, indeed, a sanitary one, only secondarily commercial.

The discussion on Mr. Morton's paper was continued last week, at the Society of Arts, by Professor Voelcker, Mr. R. Rawlinson, Mr. Mechi, Mr. Edwin Chadwick, C.B. (the chairman), and other gentlemen; and several letters on the subject were afterwards received, from Mr. J. Bailey Denton, Mr. Walker of Rugby, and Mr. John Bethell. Into this lengthened discussion we cannot enter; but we may select a few points from the remarks of one or two of those who took part in it.

Mr. Rawlinson said he had only a few minutes ago heard it intimated, by so high an authority as Mr. Alderman Mechi, that there was a probable advantage to arise to the metropolis in applying its sewage to large areas for agricultural purposes in small dressings. He could only say that, at the present moment, all the knowledge he possessed, and all the experience that had come to him, were in a precisely contrary direction; and he also held that, if large sums of money were raised by a company, and if the large works planned were attempted for the application of the sewage of the metropolis over hundreds of thousands of acres, he thought that it would only result in bankruptcy. To carry sewage over large areas necessarily involved two things,—very expensive lifting power, and very expensive permanent plant below the surface for the so-called distribution. Where the application of sewage had been a success, he found that it was in cases where it had been applied in large dressings, in the simplest possible manner, over comparatively small areas, with no price paid for it, and with very simple apparatus. In Edinburgh there was a very limited area, about 400 acres, receiving the refuse of considerable portion of the city, which came down without any cost, without any fettering conditions as to how, when, or in what way it should be used. The greatest possible results were thus produced from the land so treated; but in the town of Leith, clear-headed, calculating Scotsmen were going to expend 66,000*l.* in severing the Leith district; and, in the face of a rental of 35*l.* an acre on the opposite side of the city, they were spending this large amount of money to carry the pipes on to the sea, that the sewage might there be discharged. If any one thought they were wrong in this, and would like to take the sewage and make use of it, he (Mr. Rawlinson) would be happy to place him in communication with the corporation, who would be only too happy to let him have the sewage for nothing. Surely there was something in this, in spite of what Alderman Mechi had said about the necessity of taking the sewage back to the land.

Mr. Stuart Barker said he had applied sewage on a farm by means of a hose and tap, and scarcely any beneficial results had followed, but he afterwards cut an open drain, and the result was immediately perceptible in the increased quality and crop of grass. If they were to commence the work again, there was no doubt that some improvement might be made; but it must be recollected that the sewage of London was now at Barking, and that it could not be brought back, but must be dealt with under existing circumstances. If it was not allowed to go into the river as at present proposed, then it must be carried farther down the river.

The Chairman said that when he was in Paris some time ago, he had the honour to speak to the Emperor on the subject, when he submitted that his Majesty's officers ought to conduct for themselves trial works for dealing with the sewage of Paris: they did so, and impartial persons would acknowledge that these trials were the best that had been made: they were conducted by Professor Moll, of the Conservatoire des Arts-et-Métiers, assisted by Mons. Mille, ingénieur-en-chef of Paris. These gentlemen, with others, came over to this country, and examined for themselves the chief works, at Watford, Leicester, and Rugby, the liquidated manure firms, and the Edinburgh irrigated meadows. They decided against the application of sewage by the method of submersion, and adopted in preference the method by steam and Pipe distribution.

Mr. Bailey Denton, in his postscript, draws attention to the necessity of regarding the water economy of the country in dealing with the sewage of towns. In allusion to the scheme of Messrs. Hope & Napier, he says:—

"Some years back I investigated the Essex Marshes, and am enabled to state that at least nine-tenths of their extent must be under-drained before they can be profitably laid out for irrigation; and, it may add, as a fact capable of proof, that to irrigate the marshes of any low-lying valley is to increase its unhealthiness, though that may be greatly mitigated by under-drainage. I do not by stress upon the increased evil of irrigating with sewage instead of water, as it must be manifest to every one that manna, which is due to the deleterious matter evolved with water under the influence of the atmosphere, is more likely to arise from the putrid matter of the London sewers than from the clearer waters which are generally used for irrigation. At this time I am engaged in ascertaining the connection of water meadows in a well-known valley into dry meadows, because they are found unhealthy; and it seems the reverse of discretion to make the wet meadows in the metropolitan valley still more wet by irrigation, and apply sewage for the purpose, when the neighbourhood is already known to be subject to fever and ague."

### TELESCOPIC RAIN-TUBE AND TRAPS.

How frequently is the architect annoyed and disappointed at seeing a building, upon which he has bestowed considerable thought and attention, disfigured by the overflowing of the rain-water pipes.

If he has been mindful to prevent noisome smells escaping up the pipes by trapping them, he finds the traps stopped, and knows by experience that the carelessness of workmen or the neglect of servants renders useless the clever contrivances that have been adopted, and he feels the want of a ready and simple means for remedying such defects; being aware that they so annoy his client as to make him overlook considerable merit and services rendered.

Besides experiencing this, it has been brought home to me, in a forcible manner by seeing wet making its way through the walls of the drawing-room of my own house, in which I thought I had omitted none of the most approved appliances. The usual remedies were applied, viz.:—the builder was sent for, who, with the aid of workmen, a truck, and a lofty ladder, discerned that the rain-water pipe was partially stopped, and my gardener upon digging down found the trap wholly so. In time this was remedied, and the annoyance forgotten, but will doubtless be revived when the bill comes in.

It occurred to me, after a little thought, to make a short length of the lower part of the pipe, sufficiently large to slide as a telescope tube, and to be suspended upon two additional nails, shown in the drawing; so that any one could readily remove any obstruction, and then lower it down again.

Now as to the trap. This is of brown stone-ware; fixed a few inches below the surface of the ground, and into it is placed the lowest short length of pipe, the upper part resting upon two hooks; and when the telescopic length is raised as before described, this part can then be lifted off the hooks and out of the trap, which can then be cleaned out with the band, and the pipe can be replaced.

JOHN TAYLOR, JUN.

### EDINBURGH.

EDINBURGH is said to be beautiful, not on account of, but in spite of, its architecture. If that be the case, it behoves the inhabitants to keep a watchful eye on contemplated alterations and additions of its buildings, that they be such as to add to, and not detract from, that peculiar charm given to it by nature. Fortunately the manufactures are few, and their accompaniment of tall chimneys, with the usual concomitant of smoke, is seldom met with, although the grim monsters have thrust their snouts aloft in some places where they would have been better absent.

When the Government, several years ago, purchased the old Theatre Royal and Shakespeare-square, as a site for a new post-office, a vigilant look-out was kept lest the erection should be unworthy of the site, which is one of the best in the city. The design was prepared by Mr. Matheson, of Her Majesty's Office of Works, and met with general approval; and the building is now nearly completed, so far as the stone-work is concerned, and an opinion can now be formed of it as a *fait accompli*. Upon the whole, it may be looked upon as a successful effort, and worthy of ranking with the works of Adams & Elliot, which it adjoins; but it appears to us that the details have been timidly dealt with: the projections are too small, and the recesses not deep enough; the consequence being a paucity of light and shade, and an effect of monotony which would not have been the case with bolder handling. The style is Italian, and the dimensions are 140 ft. on the north and south elevations, and 180 ft. on the west. All the elevations, excepting that to the east, are visible from the street, and are treated architecturally. The façade is of two stories in the centre, and an additional story is added at the north-east and north-west angles, and along the whole of the south elevation: the centre two-storied parts are slightly recessed. The main entrance is in the centre of the north front, towards Prince's-street. It consists of a loggia, which is ornamented with Ionic pilasters, with wreaths hanging from the volutes, and is approached by three arched openings, supported on panted piers. The whole ground floor is restricted, and has arched windows; the second floor has square-headed windows, decorated with pediments; and single Corinthian columns are placed be-

TELESCOPIC RAIN-WATER TUBES.

between the windows of the centre part, and coupled columns at the pavilioned angles and along the south front. The attic third story consists of arched and moulded windows, with pilasters between, and is crowned by a balustrade, which feature is placed in front of the windows of the second and third stories. The sloping nature of the ground exposes the basement to the south, where there is no roadway; it is lighted with square-headed windows, having large key-stones. Mr. George Roberts is the contractor for the whole work; and the expense will be about 80,000*l*.

The sensational mania has spread from our literature to our architecture: an example of this is to be seen in Grove-street, the work of Mr. Frederick Pilkington. In a given space the architect seems to have striven to produce every variety of window: the pointed arch, round arch, elliptical arch, and horse-shoe arch, are in juxtaposition,—the whole being decorated with a profusion of carving of natural foliage: repose for the eye there is none, and an uneasy effect is produced upon the spectator. It is with considerable regret that we make these observations, as a step in this direction was much needed to relieve the dreary monotony of the west-end architecture; but Mr. Pilkington has outrun prudence. With less effort after novelty, and more attention to elegance of proportion and harmony of effect, Mr. Pilkington may yet do something more worthy of commendation.

Building operations have been very active at the west end during the last season, and Fresh Pond has been opened at East and West Coats and at the Dean. None of the buildings deserve notice as architectural works: the same bad, tame, and uninteresting fronts as form the general mass of the streets of the new town are

again repeated, the only attempt at variety being that oriel windows are added to those at the Dean and at West Coats; but in each case a design, being once made, is repeated along the entire line, and the effect is even worse than where the walls were left flat. Surely a little wholesome variety would not cost the designers much trouble (it could easily be done without adding to the expense), although it would require a little thought, and employ a larger portion of the draughtsman's time; and no one deserving of the name of artist would grudge this for the sake of the result.

#### ART AND CONSTRUCTION IN PARLIAMENT.

*The new Law Courts.*—The Attorney-General has asked and got leave to introduce his bill into the House of Commons for the concentration of the courts of law. He stated that the present bill was entirely free from the objections taken to the bill of 1861. The estimates were now proved, which they were not at that time, and there was now no fear that the public should be called upon to make good any deficiency. The 200,000*l*. to be provided by the public would be covered by the value of the buildings and the sites to be vacated by the present courts, and the additional 400,000*l*. required would involve only a payment of 16,000*l*. a year in addition to the fees of suitors at present paid. Sir H. Wiloughby, who first spoke on the question, said he had no objection to the improvement proposed, but the finance connected with it did not inspire him with much confidence. The cost, — 1,500,000*l*.—was sure to come out of the public

purse, and it would be better to face that certainty at once, or else dismiss the project. Indeed the expense would more likely amount to 2,000,000*l*. or 2,500,000*l*. Mr. Cowper then asked and obtained leave to introduce his bill to enable the Board of Works to acquire the site for the projected law courts. On another occasion Mr. Walter asked the First Commissioner of Works whether he would lay upon the table of the House a return showing the number of houses at present standing on the site of the new law courts, to which Mr. Cowper agreed.

*Fires at Theatres, &c.*—In reply to Mr. H. Lewis, Sir G. Grey said there was no intention at present to introduce a bill requiring that the plans of theatres and all places of public resort—for it could not be confined merely to places of amusement—should be submitted to a Government architect before those places were built; but the subject to which the question referred, namely, the construction of those buildings so as to provide security against fire, and for the safety of the public in the event of fire, was one, no doubt, of very great importance, and deserved serious and careful consideration.

*The Metropolitan Streets and Bridges.*—Sir William Fraser announced that on an early day he would call attention in the House of Commons to the condition of the streets of the metropolis as regards lighting, paving, cleansing, and traffic.—Mr. Locke asked the First Commissioner of Works whether it was intended to remove the obstructions erected along the centre of the carriage road over Westminster Bridge; and why heavy vehicles were now not allowed to pass along the tramways, for the convenience of which it was said they were constructed; and why light vehicles were now compelled to pass along these tramways contrary to the original

arrangement. Mr. Cowper said that the present arrangement was part of the original design, but it was one of which he never approved. In July last he requested Mr. Page to prepare a plan for the removal of the tramways from the centre to the side of the bridge. Tramways, in accordance with that plan, would be laid down in about a month.

**Protection of Rivers, and Sewage of Towns.**—Lord R. Montagu obtained leave to bring in Bills to amend and better to administer the laws for the protection of waters in rivers and streams in England, and for facilitating the more useful application of town sewage in Great Britain and Ireland.—Sir G. Grey, while giving his ready assent to the introduction of these Bills, said that he doubted whether they were yet in possession of sufficiently full and accurate information to enable them to legislate effectively on the subject, and he took that to be the opinion of the noble lord himself, from the fact of his giving notice for a committee of inquiry.

**The Main Drainage.**—Viscount Enfield asked the hon. member for Bath (Mr. Tite), as a member of the Metropolitan Board of Works, the progress made in the main drainage of the metropolitan district, and when the same would probably be completed.—Mr. Tite said the main drainage was very nearly completed, both on the north and south sides of the Thames. The whole would come into operation by the 29th of March, with the exception of the Low-level Sower, which was connected with the Thames Embankment. The total cost would be about 4,000,000l. **Dublin International Exhibition (1865).**—Sir R. Peel obtained leave to introduce a Bill for the protection of inventions and designs exhibited at the Dublin International Exhibition for 1865.

#### COMPETITIONS.

**Middlesex' New Exchange.**—A meeting of the directors of the new Exchange was held on Tuesday, the 7th inst., when the various designs for the new building which had been submitted for examination were discussed. After deliberation the prizes were awarded thus:—1. "Apropos" (Mr. Swan, architect, Newcastle); 2. "Erimus" (Mr. W. H. Blessley, architect, Middlesbrough); 3. "Happy New Year" (Messrs. O'Donoghue and Grundy, architects, London and Glasgow). The design of "Cleveland Nota Bene" was considered by the directors to be in every way the best, but in consequence of the name of the architect having transpired it was not eligible for a premium. It is not improbable, nevertheless, that it may be selected for execution.

**Christ Church Schools, Battersea.**—In a limited competition for these schools for 600 children, Mr. E. C. Robins was the successful competitor; and the works are to be proceeded with immediately.

**Bolton Town Hall.**—The town council have confirmed the award of Professor Donaldson. The names of the selected six given in our last are correct. The first three, Mr. W. Hill, Mr. Thomas Turner, and Mr. Brodrick, will receive the first, second, and third premiums in that order.

#### MASTERS AND MEN.

The arrangement between the Midland master builders and their workmen is proceeding in a friendly and hopeful manner towards a final settlement. A joint meeting of masters and men took place at Birmingham on the 10th inst. in the Town-hall, under the presidency of the mayor, in order "to elect delegates to attend the conference for drawing up rules for the future government of the trade."

The Chairman explained that the delegates would be formed into a committee, whose duty it should be to draw up a code of rules for the future regulation of the trade so far as concerned the relations of employers and men. It was intended either that the chairman of the committee should be asked to act as umpire in all disputes on which the committee could not agree, or that the delegates appointed by the masters should appoint one referee; that the delegates appointed by the operatives should appoint another referee; and that if they could not agree they should appoint an umpire, whose decision should be final and binding upon all parties. These were matters of detail which the committee would have to settle for themselves. In this way it was hoped that the dif-

ferences existing in the building trades might be settled in a manner honourable to both parties, and that the recurrence of strikes or similar difficulties for the future would be prevented. In conclusion he moved the first resolution, viz., "That it is desirable to appoint delegates from the masters and operatives with power to settle all trade regulations." The resolution was carried almost unanimously.

The Chairman then said it was proposed that an equal number of delegates should be appointed from the masters and from the carpenters, and from the masters and the joiners, and so on in continuation from the masters and each trade. He then called upon Mr. Bruton to name the delegates from the carpenters.

The following were appointed delegates unanimously:—Messrs. John Price, William Burgess, William Sayers, Walter Jones, Joseph Allen, and James Bruton.

The Chairman then called on the master builders to appoint their delegates to meet the carpenters. The following delegates on the part of the masters were then chosen to meet the delegates from the carpenters:—Messrs. Joseph Hardwick, J. Cresswell, William Webb, William Briggs, Charles Jones, and David Murray.

In response to a call of the mayor, Mr. Hunter, secretary to the bricklayers, stated they proposed sending six delegates to the conference. The following were appointed unanimously:—Messrs. James Lucas, J. Priest, James Stacey, John Hunter, Peter Davis, and Joe Freeman. The following were appointed on behalf of the master builders, to meet the deputation from the bricklayers:—Messrs. Hardwick, William Parker, Pritchard, Thomas Barnsley, W. Briggs, and William Webb.

Mr. Blakemore said the plasterers proposed sending three members to the conference, viz., Messrs. J. Doyle, Henry Hudson, and Charles Blakemore. These were approved.—Messrs. Hardwick, Graham, and Bassett (of the firm of Holmes & Bassett) were appointed delegates on behalf of the master builders to meet the plasterers.

Mr. Carroll, for the labourers, said they proposed sending six men to represent their interests. The following were accordingly appointed:—Messrs. Thomas Kane, Patrick Carr, Thomas Connolly, Thomas Norry, Patrick Carney, and William Carroll. The following master builders were appointed to meet the labourers: Messrs. Hardwick, E. Barnsley, Benjamin Smith, William Blower, Joseph Jeffrey, and J. Wilson.

A resolution, "That the employers and operatives severally agree to conform to and carry out all rules which shall be agreed to by the delegates, or decided by the casting vote of the chairman or umpire," was then unanimously carried.

The Board of Arbitration at Coventry have met several times, and, we hear, have come to a very satisfactory arrangement. The mayor presided over the meetings, but was not called upon to give a casting vote in a single instance. The masters have already agreed to give the men a considerably increased rate of wages.

The navvies and labourers engaged by Mr. Adamson, the contractor for the new reservoirs for supplying Hartlepool with soft water, have struck in consequence of a change in the mode of paying their wages. Hitherto they have received them fortnightly, but henceforth they are to be paid monthly, to which the men demur, and some of them have taken out summonses for the recovery of that which is due.

A general meeting of the operative plasterers of Newcastle, who had been on strike for the last thirteen weeks, was held on Saturday night. The cause of dissatisfaction is a reduction, proposed by five of the masters, of 2s. per week for the winter quarter. The men work the same hours all the year round, namely, ten hours per day. They state that they would have submitted to the reduction if the masters had proportionately reduced the hours, so as to start at seven and give over work at five during these months. Three of the masters having sent for their men to start work on Monday morning, it was resolved that no men go to work until a proper agreement be come to as regards wages and hours of labour, namely, 27s. a week for nine months; 2s. for winter quarter; ten hours a day for summer; seven a.m. to five p.m. in winter.

We understand that after several meetings of the master builders of Carlisle, a unanimous resolution has been come to "to pay the masons and bricklayers by the hour on and after the 1st of March."

#### THE FALL OF SCHOOL FLOOR, WESTMINSTER.

The inquest was resumed on the 10th, when evidence was given on the part of Mr. George Smith, the builder, that the timber was Baltic. The beam had been sawn in two, and was before the jury. In course of the evidence,

Mr. Thomas Piper, a builder for twenty-three years, and at present a surveyor, said the timber on the table was Baltic timber. Attributed the accident to the imperfect construction of the building. These beams, 13 in. by 13 in., were calculated to bear 40 tons; but in the present case the joists were tenoned into the beams, and thus the latter were reduced in strength to such a degree that they could only bear 16 tons breaking weight. In answer to the coroner, the witness said that he wished to qualify the expression "imperfect construction." If the building were regarded simply as a school, the construction was sound enough, but not for a public building. 12 in. by 6 in. would carry some 16 tons. If the room were filled with adults, and then were in agitation, the weight would be about 16 tons.

Coroner: But the whole weight of the audience was not on this beam?

Witness said that he calculated that when one of the beams yielded, the weight thrown on the beam which broke amounted to some 16 tons?

Mr. New: Do you not know that the Act of Parliament expressly says that schools shall be built as "public buildings"?

Witness said that he did not consider that every public building should be made strong enough for any possible purpose to which it might be put. A school-room was not like a town-hall, intended for the meeting of masses of people.

Mr. Vulliamy was recalled, and said now that he had seen the timber cut through, he was disposed to think the timber might be Baltic.

Mr. James Howell, district surveyor of Westminster, said that Mr. Fosdall was a man of considerable ability. He (witness) met him at the schools several times, and was perfectly satisfied with the scantling of the timber. It was quite clear that the broken piece had lost all tenacity. Had it been proper timber it would have borne all the weight upon it. He treated this as a public building. Beams are usually 10 ft. apart, whereas these were only 8 ft. apart.

Mr. Rhodo Hawkins, architect of the Committee of Privy Council on Education, said that the plans and specification were submitted at his office, and he approved of them. Upon his report, Government made a grant of 1,000l. It was no part of his duty to inspect the buildings when in progress. These beams, if intact, would bear 40 tons if distributed, or 20 tons if placed upon the centre.

The Coroner said that the evidence taken only rendered the duty of the jury a more anxious one. Here was a building purposely constructed by the clergy regardless of expense, so as to get a substantial structure; yet by some means it happened that through a defect the floor gave way, two persons were killed, and ninety injured. If it had turned out that the builder or any one else had purposely used an inferior timber to save money, the offence would be criminal; but the evidence negatived that supposition. The fact remained that timber was sold and bought as the best Baltic timber, which proved to be altogether unsound. It seemed very desirable that some test should be resorted to in order to ascertain the quality of the timber used in buildings; otherwise there was no security that any public or private building might not give way suddenly. The present inquiry would, no doubt, direct public attention to the question of the safety of buildings, for the catastrophe which had taken place had created a general feeling of consternation.

The jury returned a verdict of "Accidental Death."

#### UNCONSCIOUS VENTILATORS.

I NOTICE in your description of the designs for the London Meat Market, the sentence, "In the basement ventilation may be difficult." But does not the footway of a place resorted to by thousands offer a very easy means for supplying a fan? I am no mechanic, but I imagine that a number of persons passing over a floor may unconsciously set and keep at work wheels sufficient to disturb cold or foul air, so as to equalize the atmosphere. It has always appeared to me a mistake in ventilation to make it perceptible.

J. C.

LONDON HOUSES IN WHICH REMARKABLE MEN HAVE LIVED.

In course of the very extensive alterations, not to say improvements, which are now going on in London, many a house made famous by its having been once inhabited by some one or other of England's worthies, will be known no more. Some, like the house of Milton, in Barbican, and that wherein poor "Goldie" lodged, in Green Abour-court, have been swept away by the railway, and their very sites lost. Others, if not actually demolished, will be most difficult of identification, in consequence of the alteration of the names of streets and numbering of houses, now going on under the direction of the Metropolitan Board of Works. The Board, I think, should, and perhaps do, keep a record for public reference of the changes which each house undergoes in this way; and the Society of Antiquaries, or some other body which takes an interest in such matters, should record, and from time to time make public in some work, any change affecting the identity of houses which have a public and historical interest.

Can any of your readers say if anything of this kind is being done? WILL PARK.

THE STRIKE AGAINST A MANCHESTER ARCHITECT.

Sir,—I have reason to think that some of your readers have regarded the strike of the Manchester bricksetters against myself with interest, and that they will be glad to know that the difficulty has now come to an end.

Last Wednesday, at a meeting of the Manchester Union Bricksetters, convened by placard, it was resolved, by a large majority, to "open" to the members of the Union all works under my superintendance in the neighbourhood of Manchester. The new county goal, however, was excepted, because between the contractor for this building and the bricksetters there is still a question at issue.

The cessation of the strike is the voluntary act of the bricksetters themselves. No concession was made to them, for the simple reason that there was nothing to concede. No circumstance has occurred to afford any special reason why the position the bricksetters had assumed should at this particular time be abandoned.

No pressuro which they could not easily have withstood has been brought to bear upon them. The only influences from without which have been at work, so far as I know, have been a little pamphlet, in which I endeavoured, by a narrative of the strike, to show the men that their hostility could not be justified; and the expression of public opinion which that narrative has called forth.

I think, therefore, that the bricksetters have themselves virtually admitted that their determination to enter upon this strike was a mistake. And here lies the moral of the story. I point it out with no other purpose than that it may show the committees of trade-unions how desirable it is,—for the sake of their dignity, if for nothing else,—that similar mistakes should be avoided in future.

ALFRED WATERHOUSE.

THE DIMENSIONS OF LARGE CHURCHES.

My catalogue of large churches, published last Christmas, has brought me information of some more, as I hoped it would. Some of my correspondents request that I will not publish them merely as an appendix, but an entirely new list, so that they may cut it out and keep it. I accordingly do so, and take the opportunity of correcting some figures in the former list by others from better authority.

I do not repeat the explanations which I gave before, but I notice an accidental mistake in writing Patrington among the churches with double transepts, instead of those with east and west aisles to their transepts. It is too small to appear in the list.

I now give the heights of the vaults or ceilings, and of the single or principal towers and spires of each church where I have been able to ascertain them. And I distinguish the spires by S before them, and the central steeples by C after them.

As Llandaff Cathedral is being restored, I restore it to its old dimensions. The most important additions are the two churches at Lynn

and one at Spalding. St. Nicholas's Chapel at Lynn has as many bays as King's, and nearly the same total width; and it had a tower, which is gone. St. Margaret's has two towers, and had a central lantern too. That town in former times, and not so long ago, seems to have distinguished itself by a destructiveness hardly exceeded by the great cathedral-destroyer, Wyatt. Wimborne Minster, I think, is the only church with a complete central and a single west tower, both surviving.

I find it necessary to say that I mean to express no opinion as to the architectural importance of any church by its place in the list. They must be put in some order, and, on the whole, that of the area seems the best. I just repeat that all the measures (except of course the steeples) are internal, and in feet.

THE RESTORATION OF STOWMARKET CHURCH.—On removing the gallery on the north side, the old carved oak screen of the Tyrrell Chapel was fully exposed to view. Part of the panelling has been ruthlessly removed in years gone by, by some persons who could have had no taste for the beautiful. We believe that, in the specification for the restoration, no provision is made for the preservation of this piece of antiquity. It is to be hoped that it may be restored and preserved.

ARCHITECTURAL ASSOCIATION.

The usual meeting of the members of the Association was held on Friday evening (the 3rd inst.), at the House, in Conduit-street. The chair was occupied by Mr. R. W. Heaton.

The following new members were elected.—John James, Esq., 11, Upper Cheyne-row, Chelsea; Thomas Smith, 3, Church-street, Stoke Newington; and John Heaton, Esq., Office of Director of Works, Admiralty, Somerset House.

Mr. Mathews, hon. secretary, drew the attention of the meeting to the fact that an advertisement had recently appeared, offering the magnificent sum of £10, for the best design for a manufactory. Contrary to his expectation, designs to the number of between thirty and forty had been sent in, and were exhibited at Messrs. Lett's, where he had inspected them. Many of them were very good indeed; others were bad, as might be expected. Now, he considered that the members of the Association, as a matter of principle, ought to be on their guard against being tempted into such a trap as that. If it were encouraged the effect would be, that a builder had only to advertise for designs, and for a paltry sum he could supply himself, and throw the profession altogether overboard. They would be standing in their own light if, in violation of the principle on which they ought to act, they enabled a builder to execute works without reference to an architect.

The Chairman agreed with the secretary, that the matter to which he had drawn their attention was one of considerable importance. If this move on the part of builders was not practically resisted, by the members of the Association taking no notice whatever of such invitations, contractors in want of an idea had only to advertise for designs, and for a paltry sum he could supply himself, and throw the profession altogether overboard. They would be standing in their own light if, in violation of the principle on which they ought to act, they enabled a builder to execute works without reference to an architect.

The Chairman congratulated the meeting upon the privilege they had enjoyed in having had so practical a lesson. He considered that stained glass windows were in hand, and looked after as well as designed by the artist, and until it was it would not have fair play.

The Chairman referred to the stained-glass windows of the Cathedral and Museum of Rouen, as specimens worthy of study, on account of the harmony of colours which they exhibited. It was worthy of inquiry whether quarried glass afforded as good protection from the weather as large sheets. By some it was held that it did not. It was, however, in its favour, that if the glass were broken, it was more easily repaired; whereas if the large sheet was broken, the whole window should be replaced. He believed that quarried glass, if well and strongly put together, would be as much weather proof as glass in large sheets.

After some observations from Mr. Harris, on the necessity of observing a proper proportion between the size of the window and the height of the figures upon it,

Mr. Ridge, hon. secretary, said that the effect of some of the stained-glass windows of the present time was simply rich and fine, but he held that they did not accord with the principles which ought to guide and direct them in the matter. Stained glass should be at once essentially rich, and fitted to transmit the light, and in some cases purpose should have as little shadow as possible. The glass should be fitted for the frame in which it was to be placed, and for the position which it was intended to occupy in subject and treatment. It was, he thought, a great mistake to be straining after fine paintings on glass. Glass was not the proper vehicle for fine paintings—canvas was. The reason that quarries were liked was, that the windows was, that they broke up the light, and prevented a flood of sunshine falling upon the congregation. He hoped, however, and believed that some other method of breaking the light would be discovered, and that large sheets of glass would come to be universally adopted.

A member said, it seemed to be considered that stained glass was altogether Gothic, and its suitability to any other kind of architecture was to be ignored. He, however, said, that architecture went out of fashion—and from some recent specimens, such as the Strand Music Hall, it was not improbable that the public would one day or other get sick of it—what was then to become of stained glass? How would the gentlemen who laid down such stringent rules for their guidance, be affected by the change, and how would the change affect the art? He could not agree with the view that there was not high art in painting on glass as well as in painting on canvas.

Mr. Harris observed, that he had not meant to imply that low art in painting upon canvas was high art in painting upon glass. There was, he admitted, high art in both, but they were altogether different things. In reference to what had been predicted as to the probable decline of Gothic, he had only to say, that if Classic architecture came to be adopted, stained glass could, he thought, be suited to it. At present, however, it was difficult to pursue the theory.

Mr. Bassill would ask those who desired the pictures upon glass, what was to become of the end which windows were meant to answer, if their ideas were carried out. The light should be as little blocked out by shadow as possible, and therefore the pictures were out of the question. They could not have perspective, or canopies, or stained glass. The material, namely, glass, and the object in view, namely, the admission of light, shows very clearly borne in mind. Wall painting and window painting were two different and distinct things, and it was not possible, even if it were desirable, to treat the wall and the window alike. He was an advocate for the use of a large number of colours and tints. The man who could not handle six or seven effectively, would make a mess of it if he tried his hand at twenty or thirty. The paper which had been read was a valuable one, and he conveyed his thanks to its author was entitled to their thanks, and would accordingly propose a motion to that effect.

Mr. Lewis seconded the motion, which was unanimously adopted. Mr. Heaton, in acknowledging the compliment, expressed his opinion, that stained glass was capable of the highest art, but it was a different art from that of ordinary paintings. Shadow was sometimes used to subdue the light, but there were other means of abating it, namely, by the use of heavier colours. For himself he

was altogether opposed to the former method, viz., shadow. The material was too beautiful to be so covered up. As to Classic architecture, he believed that stained glass could be designed to accord with that style as well as with the Gothic.

### METROPOLITAN BOARD OF WORKS.

MR. FURNESS'S CONTRACT.

At last week's ordinary meeting, Mr. Bazalgette called the attention of the Board, in a letter, to a claim of £5,772, for extras, by Mr. Furness, the contractor for the Northern Outfall Sewer. Mr. Bazalgette stated, on account of the public misunderstanding as to certain points, he was anxious that the Board should appoint some engineer of high reputation to investigate and certify as to the justice of Mr. Furness's claim, and that the fee for such investigation, to the extent of a hundred guineas, be deducted from his own salary, as engineer to the Board. Mr. Furness's consent, he added, would be requisite to the special appointment of such an engineer. Mr. Westerton stated, that he and Mr. Beale, who had brought with others, and had satisfied themselves there was a misunderstanding on the subject. As an instance, it was stated that puddling-clay had not been put down over the saving of several thousand pounds to the contractor; but they found, that although no clay had been put down, the crown of the sewer had been laid with the much more costly concrete, as a road might be made over it, for which clay would have been the worst material possible. This concrete was, of course, on the crown of the sewer. Mr. Freeman, on behalf of the Main Drainage Committee, thanked Mr. Westerton for the straightforward and many statements he had made in removing the misunderstanding from the public mind on the subject. It was then referred to the Main Drainage Committee.

### CADGING ARCHITECTS.

DEAR MR. EDITOR.—In a weekly penny paper the following advertisement appears—  
“Mr. R. E. Architect, would esteem it a favour if those members of the Clergy and Churchwardens who contemplate rebuilding or restoring their Churches, Schools, &c., would assist him to submit drawings of the proposed works, for which no charge will be made unless such drawings are adopted, and the works executed accordingly.  
Architects often feel insulted, and justly too, by the miserable conditions and premiums offered to them in the case of competitions; but I little thought things had come to such a pass as this, that they should resort to advertising after the example of a Tottenham-court-road upholsterer, who calls for special attention from those about to marry;” or as in the case of smoke doctors, who advertise “no cure, no pay.” M. R. I. B. A.

### “OUR DOMESTIC FIREPLACES.”

Sir,—Under this title there appeared in the *Builder* a notice of a work by Mr. Edwards, which contains very erroneous statements with reference to my stove.  
I had no opportunity of contradicting these except by writing a work in answer; but this would not find its way into the hands of all the readers of the work in question. I had, therefore, no course but to remain silent; but now that some quotations from this work appear in the *Builder*, I am, in justice to myself, bound to request you to give a positive contradiction to the truth of what is quoted, viz., in the one, the holes intended to divide the grate, and to pass off by separate channels to the chamber under the fire-bar, and there to unite in an ascending flue into the chimney; in the other, the heated products are carried down a single flue behind the grate, and are then intended to divide and pass by two ascending flues into the chimney.  
If Mr. Edwards can show that I have ever had manufactured stoves with two ascending flues, as he first states, or a flue behind the grate, as he secondly states, I will pay to any charitable institution Mr. Edwards may name, one hundred pounds.  
I adopt this course, as I have neither time nor inclination for controversy, and if Mr. Edwards does not avail himself of this offer, it will be considered that he finds he is mistaken; and I trust it will be a lesson to him to be more careful for the future how he makes statements that are so damaging from their want of truth.  
JOHN TAYLOR, Jun.

•• We may add that we have received a letter from Mr. Frederick Marshall, containing some strong expressions in favour of the stove.

### OUR FIELD WALKS.

Who shall decide when doctors disagree with each other? Yet much less when they disagree with themselves? In the course of last month was argued in a court of law, the case of the right of way, in the once beautiful walk between London and Highgate, commemorated in “Hone's Every-Day Book” under the name of Hagshub Lane.  
Vice-Chancellor Sir J. Stuart, while avoiding a direct decision as to whether the public right had ceased, stated that at one time it was said by a very learned judge, Mr. Justice Holroyd, that if there was once a public right of way, it could only be extinguished by Act of Parliament, but that learned judge subsequently altered his opinion.  
Mr. Editor, may we not well say, with his Dickens, “A Black House”?—“Fog everywhere. Equally for the protection of the public, and for settling the opinions of the judges learned in the law, do we not urgently require to an Act of Parliament, short, decisive, and declaratory, to be passed,—something as follows:—“Every thoroughfare to which a public right was unquestioned and unquestionable in the first year of the nineteenth century shall remain so in perpetuity, unless expressly abrogated by Parliament.” This is the more necessary, because the process of doing away with a thoroughfare is so apt to be an insidious one, like a secret disease in the human body, to which the doctor is not called in until too late.  
GEORGE MACKENZIE.

### PREVENTION OF FIRE.

Sir,—In the interesting article in the *Builder*, Feb. 4, on the important question of fire extinction and prevention, you quote from Mr. Bate's paper, read before the British Association, in 1861, his concluding remark,—“If once the flames had obtained a hold, it was utterly impossible to extinguish them;” and again, “It is no small thing to see some anti-combustible solution.” &c. For years the public have had the option of having timber rendered unburnable by a simple and inexpensive process, which also preserves the wood from decay and the attack of insects. This process, known as burningizing, was introduced some twenty years ago, and fully tested by competent Government authority, and most favourably reported on. Surely the system is not defunct. No doubt, some of your readers and contributors know all about this, and will enlighten a Naval Captain, who seeks protection from

### ACTION THROUGH WRONG “QUANTITIES.”

SCHEVZER V. PACE.

THIS was an action in Court of Common Pleas (Westminster), to recover 190*l.* on a builder's contract. The defendant, it appeared, had obtained an allotment of land at Twickenham, on which he wanted to build a house, and he employed Mr. Pace as the architect, to draw the plans and specifications. The plaintiff entered into a contract with the defendant to build the house, but before doing so he saw Mr. Pace, the architect, who called upon him and offered to take out the “quantities,” for which the plaintiff paid Mr. Pace 13*l.* On these quantities the plaintiff entered into a contract with the defendant to build the house for 440*l.* On proceeding with the work the plaintiff afterwards found that the quantities were under-estimated to the amount of 190*l.*, and, treating Mr. Pace as the defendant's agent in that matter, he now sought to recover this sum from the defendant.

Mr. Chambers submitted that there was no case to go to the jury. Pace, the architect, was not acting as the defendant's agent in measuring out quantities, but simply as any other architect might have done employed by the plaintiff, who paid him for his work. He referred to the case of “Shorliff v. Hare,” tried before Mr. Justice Blackburn, and reported in the *Builder*, in which the defendant in a similar case was held not liable. His Lordship (Byles), was of opinion that the plaintiff ought to be estopped, and paid the defendant's architect to make out the quantities, and the architect had made a slip when he estimated a nozzle, giving leave to the plaintiff to move to enter the verdict for him, if his judgment should be wrong.

### EXTRAS BY ARBITRATION.

WE have already briefly mentioned the result in the following case, but the matter is sufficiently interesting to call for fuller particulars.

The Rev. F. J. Smith, of Taunton, having determined on building a new church, to be dedicated to St. John, at the above place, and at his sole cost, employed Mr. F. G. Scott as the architect, who prepared the plans and specifications for the work. Mr. Henry Davis, builder, also of Taunton, having been employed by Mr. Smith on several occasions, the plans and specification were placed in his hands in August, 1855, to estimate the cost of the work. This he did, and sent Mr. Smith a tender amounting to 6,92*l.*, which was accepted, Mr. Scott stating that it was a moderate one. No other person took any notice of the plan, and the parties having a great deal of confidence in each other, the usual formalities and precautions in transacting such business were neglected between them. The church went on to completion, and was consecrated in 1857. The completion of the work Mr. Scott sent a clerk to take an account of and measure off the extra works. Mr. Davis and Mr. Smith afterwards met at Mr. Scott's office, and went through the account, and then use the differences between them. There were several matters in dispute; but the two principal ones were,—First, as to the relative value of Hamdon Hill stone and Lydeard sandstone; secondly, value of Lydeard sandstone was intended by the drawings and specification to be used. The specification stated, “All the dressings to be of Box ground and Hamdon Hill stone, in the proportion of two of Box to one of Hamdon;” and this was the only clause relating to the dressings, no mention being made of Lydeard sandstone in the specification. When Mr. Scott supplied the working drawings, they represented a considerably larger proportion of Hamdon stone than Box, and Lydeard sandstone was introduced in considerable quantities. Mr. Scott held, that 18, 64, per foot cube was a sufficient price for the Hamdon stone used, above the value of Box intended, and that the Lydeard sandstone was intended to be used, and would not recognize it as an extra. Mr. Davis charged 2*l.* 3*d.* per foot cube for the Hamdon stone used more than the value of the Lydeard stone. The difference between them was therefore very considerable. Mr. Davis claimed about 190*l.* as a penalty for the non-completion of the work by the time stipulated in the contract. Mr. Scott, to support his views, relied on some of the detail contract drawings, in which the name of the stone was not put, but only “White stone.” Mr. Davis, on the other hand, stated that he believed the penell-mark referred to Box stone and Hamdon stone only, in accordance with the specification, and that he did not intend to use any other stone; he estimated, also, that as Hamdon stone and Box were oolites, and that the Lydeard sandstone would require to be rubbed with water and sand to bring it to the same face as the Box and Hamdon, the specification being silent as to sanding any stone was a further argument in his favour. Mr. Davis thereupon brought an action against Mr. Smith to recover the amount of his account, who contended, that as the contract stated, “The decision of the architect shall be conclusive on every question which may arise in respect of the drawings, specification, conditions, and agreements,” that Mr. Davis could gain no redress, and must abide by such decision. The action, however, went on, when Mr. Smith paid 18*l.* into court; but on the 17th of trial, at Mr. Smith's request, the action was adjourned to August last, consented to leave to arbitration all matters in dispute between them, each party to pay his own costs incurred in the action up

to that time. The arbitrators were two gentlemen of Taunton, who chose as their umpire Mr. Cotterell, of Bath. The hearing occupied several days, many builders and surveyors being examined on both sides, when the arbitrators, being unable to agree, left the whole case in the hands of the umpire, who awarded that the sum of 567*l.* 18*s.* he paid to Mr. Davis over and above the sum of 18*l.* paid into court, and that Mr. Smith do pay all the costs of the said arbitration, and incident thereto.

### SUB-CONTRACTORS AND JOURNEYMEN.

CLEBURNWELL COUNTY COURT.—NOON V. HENSHAW.

THIS was an action brought by a journeyman carpenter, to recover one week's wages actually earned. Mr. West appeared for defendant, who is a builder and contractor. Plaintiff said, that a short time ago he heard of work at a building being erected for a printing-house, in the Farrington-road. He applied at the works, and saw a man named Collins, who represented himself as Mr. Henshaw's foreman. Collins set plaintiff on, and he continued at work. Collins told plaintiff what work he was to do, and on Saturday paid him the wages. Upon a certain day he applied at the pay-place, and then found that there was no Mr. Collins to pay him. Plaintiff then applied to Mr. Henshaw, who said he was not doing anything to do with the work, as Collins was a sub-contractor, and not his foreman at all. He added that he had given Collins no orders to set men on.

A witness was called, and deposed that he also had been set on by Collins, who represented himself to be the foreman.

Cross-examined: I have not yet brought an action, as I am waiting to see the result of this. There are a good many of us waiting for the result.

Mr. West: If your Honour decides this case against the masters, it will be a serious matter to do with the defendant, and he will prove that he had nothing to do with putting on these men. I have here a contract between Collins and the defendant.

The Judge read it, and said that perhaps Collins was a sub-contractor under that; but then he drew money for the express purpose of paying wages, and that put him in the light of a foreman between defendant and the men.

Defendant said he did not employ the men, and that Collins was a sub-contractor, and had drawn 14*l.* more than was due to him.

Judge: I confess I am rather surprised at the defence set up, as I am sure all the great builders have journey-men set on in the same way as was the plaintiff. I do not wish to give judgment in this case, as I think it would look better if a settlement were come to without my judgment. I will adjourn the case, so that you may have time, Mr. Henshaw, to settle with the men. But does not your Honour think it would be better for me to subpoena Collins?

Judge: No. I think it would be graceful on the part of defendant to settle the matter.

[What would be “graceful” has nothing to do with the matter. It is a simple question of right or wrong. Was Collins a sub-contractor?]

### GAS.

THE Metropolitan Gas companies are reducing their prices generally.

The City, Chartered, and Great Central Gas Companies, which now supply the citizens of London with gas, have addressed communications to the City Commissioners of Sewers, stating that they will, at Christmas next, reduce their price to 4*s.* per 1,000 cubic feet.

The Commercial Gaslight and Coke Company, Stepney, have also issued a notice to their consumers in the eastern part of the metropolis, that from and after the 31st of March next, the price of their gas will be reduced from 4*s.* 5*d.* to 4*s.* 4*d.* per 1,000 cubic feet.

The Phoenix Gaslight and Coke company, lighting a great part of the south and south-east of London, have also issued a notice to their consumers, that from and after the 31st of March next the price of their gas will be reduced to 4*s.* in the town and to 4*s.* 3*d.* in the country part of their district.

The directors of the Equitable Gas Light Company, which supplies gas in the vicinity of Charing-cross and South Belgravia, have given notice that on the 1st of July next the price of their gas will be reduced from 4*s.* 6*d.* to 4*s.* per 1,000 feet.

The metropolitan gas companies have quite as much reason to improve their gas as to cheapen it. As it is, however, the public may as well have cheap and bad gas as dear and bad; and they ought not to be satisfied, therefore, with the proposed reductions.

Steps are being taken to form a new gas company, to be called the Kent Gas Consumers Company, for the benefit, especially, of Lee, Blackheath, Lewisham, and the vicinity. The nominal capital is 100,000*l.* in 10,000 shares of 10*l.* each, the first issue being 25,000*l.* The company propose to supply fittings and maintain them in good repair, charging a rental of 7*d.* per annum on the amount so expended. The maximum charge for gas will be 4*s.* 2*d.*, and they propose to reserve power to pay a

dividend of 1 per cent. over and above 10 per cent. for every reduction of 2d. per 1,000 cubic feet from 4s. 2d. they may make. At the Plymouth or Nottingham prices for gas they would therefore be entitled to share dividends of something like 17 or 18 per cent. per annum.

The Tonbridge Wells Gas Company announce a reduction of price from 5s. 5d. to 5s., and the Canterbury a reduction to 4s. 6d. The Whitstable Company have reduced their price from 8s. 8d. to 5s. 10d. but the consumers are not satisfied. The Sutton Gas Company have made a reduction for the last quarter from 7s. to 6s. 6d.; the Shepton Mallet Company from 7s. to 6s.; and the Newcastle-under-Lyme Company announce a reduction from 4s. 6d. to 4s.: last year this company reduced their price from 5s. to 4s. 6d.: notwithstanding these successive reductions, they have just declared a dividend at the rate of 10 per cent. for the last half-year, and have to erect a new gasometer to meet their still increasing business.

The Penrith Gas Company have agreed to charge 3s. 9d. to private consumers, and 2l. per lamp per annum from the highways committee of the local Board. The Worcester Gas company have declared a dividend at the rate of 10 per cent. per annum for the last half-year. The Chester United Gas company have declared their usual dividend of 10 per cent. on ordinary stock, and 7 per cent. on preference stock, with the arrears of dividend for 1861, amounting to 13s. 1d. per cent. The Longton Gas company have announced a reduction in their price from 4s. to 3s. 8d., with discount of 5 per cent. for prompt payment.

The Chelmsford Gas Company have resolved to reduce the price of their gas to the consumers generally at Michaelmas next, from 5s. 5d. to 5s., with a discount of 5d. for cash payments, making the net charge 4s. 7d.

The Warwick Gas company have resolved to reduce their gas 6d. per 1,000 ft. for the current year. This has brought the price down to 5s., and for speedy payments another 6d. per 1,000 is allowed.

The Crowle Gas and Coko Company have agreed to reduce the price of their gas. The chairman announced a dividend of 10 per cent., and the reserve fund exceeds that of former years.

The corporation of Stockport have given notice of a reduction of 6d. per 1,000 ft., after the 1st of July next. The price then will be 3s. 6d. per 1,000 ft., both within and beyond the borough boundary, with discounts, by which their large consumers will be supplied at 3s. per 1,000 ft. Their gas is manufactured entirely from the best Wigan canal, and is of twenty-four candles' illuminating power.

The Croft and Hurworth Gas Company (Darlington), have declared a dividend of 8 per cent., with a surplus for reserve fund.

The city of Hong Kong has been lighted with gas; but it is a mistake to state, as has been done, that this is the first use of gas in China. The Chinese have long used natural jets of gas in some parts, conducting it through bamboo cane pipes to their houses.

#### CANALS AND RESERVOIRS.

**Bursting of a Canal in Birmingham.**—A flood of a very serious nature has occurred through the bursting of an arm of the Birmingham Old Canal, which has done considerable damage to the Great Western Railway, between Hockley and Soho, and flooded an immense area of ground partially traversed by streets in the neighbourhood of Lodge-road, Hockley-place, and Icknield-street. Between Hockley and Soho stations (Great Western Company) the line of rails passes under a tunnel about 100 yards long, belonging to the Birmingham Canal; and it is through some portion of this tunnel that the water has burst. This part of the canal is not used for ordinary traffic.

**Bursting of a Reservoir.**—A large body of water, contained in the reservoir, situate between the two lines of railway, at Bishbury, near Wolverhampton, recently burst through the embankment, and deluged a considerable portion of the surrounding country, sweeping off immense numbers of cattle and sheep from the adjacent fields for a great distance. The accident is attributed to the great accumulation of water from the late thaw and subsequent heavy rains.

**The Doe Park Reservoir.**—We have received the following from Bradford:—Mr. Bateman's

report on the condition of Doe Park reservoir has been received, but, although the report in detail is satisfactory, yet it concludes, we understand, with the expression of a doubt as to the security of the reservoir. Mr. Bateman states that there is a loss—partly from a spring and partly from leakage—of 200,000 gallons per day; and, while there need be no apprehension of danger so long as the embankment remains unremoved, and there is an absence of colouring matter, yet the embankment and reservoir ought to be very narrowly watched, and steps, of course taken, if any appearance of colouring matter appear in the leakage. The reservoir, therefore, is not in a perfectly satisfactory condition.

#### Books Received.

*Metropolitan Board of Works: Report of the Main Drainage Committee on the Evidence given before a Committee of the House of Commons on the Sewage of the Metropolis and on Statements in the Vestries, &c.*

The Main Drainage Committee report that the evidence they were called upon by their Board to examine was given in a "reckless manner," and that the charges are of a "baseless nature." At the close of the report, they say:—

"Your Committee, in conclusion, would strongly urge on your Honourable Board the propriety of now closing the controversy. Your Committee have felt the importance of fully replying to all the allegations made under cover of a Parliamentary inquiry, and have, therefore, in obedience to your reference, minutely investigated the several charges, and collected the body of documentary evidence contained in the Appendix, which, in the opinion of your Committee, completely and satisfactorily refutes the accusations against your Board and its Engineer. But your Committee feel, upon a review of the character, objects, and associations of the witnesses examined before the Parliamentary Committee, and the course which has been pursued in other places, by other persons, that further action on your part would in no way conduce to the public service, and would occupy, needlessly, the time and energies which ought to be devoted to the practical duties of your Honourable Board."

As regards the source whence the Board contemplated getting the material for the embankment, which is spoken of in this report in connexion with Mr. Ridley's tender, the committee state that Mr. Ridley himself calculated on not only obtaining the material from the land, but on being paid for its deposit; that although the Board, on 11th November, 1864, resolved that land material was the best, but that for deepening the river a portion should be taken from it, the Thames Conservators have not threatened any legal proceedings for not taking it all from the river.

Under the head of books received, and in this connexion, we may here note that "Mr. Ridley's Testimonials" have been printed.

*Priory Church of St. Mary and St. Baise, Boxgrove, Sussex.* By LACY W. RIDGE. 1861. Day & Son, Gato-street, London.

BOXGROVE PRIORY CHURCH, a transitional church of the eleventh and twelfth centuries, has many points of interest, and repays study. Some particulars of the building were given in our pages recently, when Mr. Lacy Ridge read a paper on the subject to the Architectural Association. A medal was given to him by the Institute of British Architects for a set of measured drawings of the church, and he has done well in now rendering them generally accessible by means of lithography. They do not pretend to be more than working drawings.

#### Miscellaneous.

**ALARMING OCCURRENCE IN A CIRCUS AT LIVERPOOL.**—In Crousett's Circus, Crosshall-street, Liverpool, while the performance was proceeding, those sitting under the gallery were alarmed by a loud cracking noise, which was immediately followed by the front of the gallery falling out, and its occupants being precipitated below. A scene of indescribable confusion followed. To make matters worse, some of the gas-piping got disconnected, and the gas blazed up, which led some to think that the building was on fire. Several children who were precipitated from the gallery were seriously hurt. The building is not very substantial, and it is said there were fewer people in the gallery than usual. Erections of this description should be supervised.

**BOSSERT'S COMBINED ALBUM AND MUSICAL BOX.**—The specification of this invention, just filed by Mr. Henry, the patent agent, Fleet-street, describes an album (especially for photographs) combined with a musical box, in such manner that on opening the book-cover the music will begin playing, and continue to play until the book be closed, or otherwise.

**THEATRE BUILDING.**—With reference to suggestions that have been offered, not now for the first time, that arrangements should be made so that the auditorium and the stage might be separated in the event of a fire, Messrs. Clark & Co., of Gato-street, ask us to repeat (what they have said elsewhere) that they have recently fitted up the New Theatre Royal, Glasgow (which was previously destroyed by fire), with their steel fire-proof revolving shutters to the proscenium, carpenters' shops, and property-rooms, and at the present time they are negotiating with other provincial managers for these fire-proof curtains, which shut off the audience from the stage.

**WANTED, A DESIGN!**—The Lords of the Committee of Council on Education desire to obtain a design for the decoration of one of the large lunettes at the north end of the south court of the Kensington Museum. The subject is to be an illustration (life size) of workmanship in any decorative art or manufacture. Three artists will be invited to make a suitable design, for which the Department will pay 50l. for each. In addition to the artists to be named, assistants of any country not specially invited can compete if they think fit to do so. And two sums of 50l. and 25l. will be paid respectively to the two artists not named by the Department whose designs are chosen. The design ultimately adopted by the Department will be enlarged by students for execution in mosaic, life size; and the artist whose design is chosen for execution will be required to superintend the enlargement of the work and approve it, for which he will receive a further payment of 50l.

**BOSTON HARBOUR TRUST: BILL FOR SURVEY.**—At a recent meeting of this trust, a notice "to order payment of Mr. Hawshaw's bill for survey and report on the state and condition of the Haven and outfall" was considered. The clerk read the particulars of the bill, the total amount of which was 210l. Mr. Ald. Wren designated the bill as most exorbitant, and said that nearly the whole of the report would be found word for word published in Morton's "Compendium for 1862." They had to pay 210l., therefore, for what they could obtain at home for 6l. Mr. Morton asked,—"Was any survey really made?" The clerk said, "Yes; we were walking all day beside the river." Mr. Morton: "But that's no survey, professionally considered."—Mr. Briggs moved that, as the proposer and seconder of the engagement of Mr. Hawshaw were not present, the bill stand over till another meeting. This was agreed to.

**PUDDLING BY MACHINERY.**—Amongst the papers set down to be read at the annual meeting of the Institution of Mechanical Engineers in Birmingham, on the 26th ult., was one upon "machine puddling," by Mr. Menclaus. The author of the paper was accompanied by the manager of the Dowlais Company, who have the use of the patent. Mr. Menclaus had in the room a bloom of iron in the condition in which it left the furnace, and which weighed 5 cwt. As it lay upon the floor it looked like a huge iron egg, and near to it were specimens of the same iron in a finished state. There were also diagrams, not only of the furnace in question, but also of the various descriptions of furnaces which contemplated the stirrings of the molten iron in the ordinary puddling furnace with a "rabble" or paddler's tool moved by machinery, so as to imitate manual labour. Mr. Menclaus said that he had thoroughly satisfied himself of the practical value of the invention; and the Dowlais Company were then engaged in laying down works, in which eight of those rotating furnaces could be kept in operation in the production of an unexceptionable quality of finished iron. The quality of the bloom and of the iron in the finished state, which had been rolled from other blooms made in the furnace, was pronounced excellent. Every such furnace as that now used at the Dowlais Works can easily produce 60 tons of iron a week. It is said that by the use of the rotary furnace the expense of production will be diminished, as compared with the cost of iron made by hand labour, at the same time that the quality is improved.

**HELP FOR FALLEN HORSES.**—When a horse in shafts falls down, he nearly always falls with some or all of his legs under one of the shafts, and his body over the other, and there is the greatest difficulty in getting him up again, in many cases the weight of the loaded cart being thrust forward, and pinning the horse to the ground. If the shafts, however, were fastened by bolts and pins to the cart, they could easily be removed, and the cart drawn back by a few bystanders, who could easily preserve its equilibrium, and then the horse could immediately get up.

**SCARBOROUGH CO-OPERATIVE, INDUSTRIAL, AND PROVIDENT SOCIETY.**—The members of this society (working men) are now erecting new premises in North-street, opposite to the Pantheon, from plans furnished by Messrs. J. & D. Petch, architects. The premises will comprise cellarage, shop with three plate-glass windows, warehouse, show-rooms, office, committee-room, reading-room, library, store for the flour department, coal store, and other necessary conveniences; the contracts for which have been accepted by Messrs. B. Smith & Son, for brick, stone, and plaster work; Mr. W. Jowsey, joiner's work; Mr. James Hardgrave, slating; Mr. W. Waters, ironwork; and Mr. W. Prince, plumbing, glazing, &c.

**OPENING OF A MODEL LODGING-HOUSE IN WARE.**—A model lodging-house, erected in Kibb's-lane, Ware, under the direction of the Hertford Building Company, has been publicly opened. Kibb's-lane is a narrow thoroughfare running out of the New-road, near its termination in High-street. It is described by the *Herts Mercury* as probably the poorest and most object-looking lane in the town. The Lodging-house stands upon the site of nine poor cottages, which were pulled down for the purposes of its erection. The premises are entered through a gate, which opens from the lane into a tolerably wide space in front of the house, fenced off from the public way by a railing. The porch is slightly ornamental, and gives a somewhat cheerful aspect to the building, which is properly plain. Some dissatisfaction is rightly expressed as to the lowness of the ceiling of the dormitories, and as to two double-bedded divisions. Ventilation, however, has been attended to.

**THE NORTH HAYMARKET ROOF, LIVERPOOL.**—The Markets Committee last week presented to the Council several reports and resolutions on this subject, including reports of Mr. Alfred Waterhouse, architect, and Mr. Robson, with plans and estimates for a roof, combining iron and wood in its construction, with an estimate of cost; also tenders for the completion of the roof according to the original specification, and recommendation that the construction of the roof be proceeded with in accordance with the terms of that specification, and under the direction of the architect and surveyor; and that the tender of Messrs. Burroughs & Son, for the construction thereof, at the sum of 3,720*l.* be accepted. The committee had passed a resolution exonerating Mr. Rollet from any blame or irregularity in the matter of the late accident. The confirmation of the proceedings was agreed to after disposal of an amendment disapproving of the recommendation of the Markets Committee, which was moved by Mr. Gladstone, and seconded by Mr. Pictou, but rejected by a majority of 50 to 10.

**ANOTHER NOVELTY IN CABS AND OTHER CARRIAGES.**—“A Patent Carriage Company, Limited,” has been formed at Birmingham, for the purpose of bringing into use sundry novel improvements. The framework is of angle-iron, welded. By using this several inches of space are saved, and added to the accommodation. The panels, which in ordinary cabs are of wood, in these new ones are of papier maché. The paper resembles leather, but is stiffer and very tough. Every part of a cab usually of wood, indeed, is in this instance made of paper. The springs are beneath the body, which brings the wheels 5 in. nearer than in the ordinary vehicle, and yet also gives additional room in the width. The window runs along the roof on the inside, and draws down like a sash; and there is a sash door, which may be pushed down, and coils itself below the body of the vehicle. The ventilation is also improved. One style of Hansom has a top which slides down, and thus an open carriage is provided. The cost of vehicles is said to be considerably reduced by the new mode of construction.

**TELEGRAPHIC.**—At the eighth ordinary general meeting of the Atlantic Telegraph Company, the directors, in their report, which was adopted, stated, that at present the new form of cable showed every probability of fully answering the expectations formed of it. The Hon. Mr. J. S. Wortley, the chairman of the company, observed that at present 1,120 miles of cable had been fully completed, and tested foot by foot—in fact, tested more than was necessary. It was proposed to lay the cable in the fine weather, between May and July, and by the end of that month it was hoped that the great enterprise would be successfully accomplished. The half-yearly meeting of the Electric and International Telegraph Company has been held, and a dividend of 4 per cent. for the half-year unanimously agreed to.

**A GOOD RECTOR NOT NECESSARILY A GOOD CHAIRMAN.**—The restoration of the parish church of Warrington has led to some slight unpleasantness between the Rev. W. Quckett, the rector, and his parishioners. It would seem that rector, and his management the expense incurred was more than 10,000*l.*, or double the estimated cost, and on a fresh appeal for the completion of the tower and spire the subscribers “struck,” until Colonel Wilson-Patten, M.P., came forward and gave his guarantee that no money should be expended until the entire sum required for the contract was raised, so that the subscribers should know how much was required. Upon this a sum little short of 4,500*l.* was speedily subscribed, and on Monday week it was stated that the contract could be carried out for about 4,500*l.*; upon which a building committee was formed, of which Mr. R. Assheton Cross was nominated chairman, the rector holding the second place only. Upon this Mr. Quckett remonstrated, as it showed a want of confidence in him. Colonel Patten replied that, while collecting the subscriptions, he had met with no one who had expressed the least want of respect for their rector, but nearly all had expressed a great want of confidence in his judgment in conducting building operations; and he was bound to say that, as a subscriber to the fund, he felt not the slightest confidence in him in the matter. Other laymen having expressed similar opinions, the committee were unanimously elected as proposed.

**RAILWAY MATTERS.**—The London, Chatham, and Dover Company have arranged for “workmen's trains” between Victoria and Ldgate stations as on the Underground. The fares will be 1*s.* for once going to and fro each week day. A pneumatic railway is projected at Scarborough to connect the north and south sands.—The Birkenhead Commissioners have petitioned Parliament in favour of the bill for connecting the Liverpool and Birkenhead railways by a tunnel below the River Mersey.—A tunnel at Newmarket has partially fallen in. The cause of the accident was an unusual flow of water from the Warren-hill, occasioned by sudden thaw, partially washing away the earth from the abutments, and so greatly affecting the condition of the brickwork that between 50 ft. and 60 ft. of the wall gave way.—The Goring station of the Great Western Railway, between the Didcot and Reading junctions, has been destroyed by fire.—The Bickley Tunnel on the South-Eastern Railway has been completed. The tunnel forms a portion of a new route to be opened up between London and Dover and the south coast, and which will shorten the present distance by the South-Eastern lines between London and Dover, St. Leonards, Hastings, Folkestone, and the Continent, by thirteen miles. The new line leaves the Lewisham Junction of the North Kent and Mid Kent Railways, and runs in an almost perfect straight line to the present Tunbridge Station of the South-Eastern, passing on its way through Bickley, Chislehurst, and Sevenoaks. The tunnel at its greatest depth is about 40 ft. below the surface, and in others it is not more than 4 ft. or 5 ft., and might, therefore, have been much more conveniently made in open cutting through Sundryidge Park, to which, however, the owner, Mr. Samuel Scott, very naturally objected. The tunnel is egg-shaped, is built of unusual strength, and is 964 yards long.—The first brick of the great tunnel of the Midland Railway intended to pass under Hampstead, and to form a portion of the Midland extension line into London has been laid. The tunnel will be 1,800 yards in length, and at its greatest depth will be 35 yards below the surface. The first brick was laid at a spot in Barham Park, near the Hampstead-road.

**ST. MARY'S CHURCH, HORNSEY-RISE.**—The east window of this church has been erected in a commemorative of the late Mr. William Halse. It is a central light is a figure of our Lord. He stands in the act of benediction, with the globe, surmounted by the cross, in his left hand. In the triplets, on either side of the Saviour, are represented the four evangelists, with St. Mary and St. Elizabeth. The upper range of subjects comprises incidents in our Lord's life, selected from the petitions in the Litany, and arranged in the following manner:—The Annunciation, the Nativity, the Baptism, the Crucifixion, the Burial, the Resurrection, and the Ascension. The lower range of subjects exhibits incidents from Old Testament history, suggestive as types or parallels of those in the upper series. They read as follow:—The Announcement of Isaac's Birth by the Three Angels, the Birth of Isaac, the Passage of the Red Sea, the Sacrifice of Isaac, the Casting of Joseph into the Pit, the Raising of the Widow's Son, and the Translation of Elijah. The centre wheel above displays five groups of Apostles on the Day of Pentecost, with a dove in the midst; the smaller wheels contain figures of adoring angels. The window was designed and executed by Messrs. Lavers & Barrand, of London.

**THE ROUND TOWERS OF IRELAND.**—An interesting paper (the subject matter of which had been communicated by Mr. Caleb Palmer) was read in the lecture-room of the Dublin Athenaeum the other evening, by Mr. J. D. Darling, on the subject of “The Round Towers of Ireland.” The paper combated many of the opinions of Dr. Petrie, Walsh, and other writers on this much debated subject; and, in endeavouring to throw light on the origin of the mysterious round towers of Ireland, the lecturer stated that he would rely on sacred and profane history and tradition in support of his ideas. His theory was that the worship of Baal, as it had existed in the East, had been introduced into Ireland by the Phœnician colonists, and that these towers had been erected in connexion with the adoration of that false god. He endeavoured to show that temples erected for the service of Baal corresponded, in their essential particulars, with the round towers at present existing in Ireland. The lecturer then referred to numerous historical works to prove that the Phœnicians, who worshipped Baal and various heavenly bodies, colonised Ireland, introduced their religion into this country, and erected these round towers.

TENDERS.

For the erection of three houses and shops, Kennington-road, for Mr. W. Davis. Mr. H. Jarvis, architect.—

NOW READY.

The TWENTY-SECOND VOLUME of "THE BUILDER" (1864), neatly bound in green cloth, price TWENTY-ONE SHILLINGS.

CLOTH CASES, price TWO SHILLINGS and NINEPENCE (if necessary, when ordering these, to state whether the Advertisements are, or are not, to be included in the Volume).

A COLOURED TITLE-PAGE GRATIS.

SUBSCRIBERS' VOLUMES will be bound, on being sent to the Office, at a cost of Four Shillings each.

NOTE.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

The Publisher cannot be responsible for ORIGINAL TESTIMONIALS left at the Office in reply to Advertisements, and strongly recommends that COPIES only should be sent.

Advertisements cannot be received for the current week's issue later than FIVE o'clock, p.m., on Thursday.

ADVERTISEMENTS.

TO ARCHITECTS, ARCH-ENGINEERS, & ANTIQUARIANS.—Messrs. COX & WYMAN, Printers of "The Builder," having had great experience in the production of every variety of Work relating to Architecture, Topography, and the Fine Arts, their Establishment affords superior facilities for the execution of the above description of PRINTING, whether illustrated or otherwise, in the best possible manner, and at moderate prices.—COX & WYMAN, Printers and Classical Painters, 74, 75, Great Queen-street, London, W.C.

TO ENGINEERS, MILLWRIGHTS, &c.—The Committee of Visitors of the Devon County Lunatic Asylum are ready to receive TENDERS for PROVIDING, FIXING, and SETTING TO WORK, at the Asylum at Axminster, a SET of BREASTING PUMPS, together with shafts and belts, and the Irons, &c. The drawings and specifications of which may be obtained on application to the Engineer, Mr. J. H. B. Drake, at the Asylum, Axminster, or before MONDAY, the 6th day of MARCH next. The Committee do not oblige themselves to accept the lowest or any Tender.

BOMFORD LOCAL BOARD OF HEALTH.—The above Board will, at their Meeting on the 20th day of MARCH, at 8 o'clock, in the Town Hall, Bomford, receive TENDERS for REPAIRING and MAKING GOOD (where necessary) with 3-inch York Slabs, the present PAVEMENT with their drains, &c. Tenders to be delivered to me on or before MONDAY, the 6th day of MARCH next. The Committee do not oblige themselves to accept the lowest or any Tender.

TO BUILDERS.—TENDERS are required for the ERECTION of a COTTAGE RESIDENCE, at Ongar Hill, Addiscombe, Surrey. The drawings and specifications of which may be obtained on application to Mr. H. WALKER, Architect and Surveyor, Ham Lane Wick, Middlesex, to whom the Tenders are to be delivered, on or before FRIDAY, the 3rd day of MARCH, 1865, at 5 o'clock in the evening. The lowest or any Tender will not be accepted.

PARISH of St. MARY ABBOTT'S, Kensington, in the County of Middlesex.—PAYING CONTRACT.—The Works, Buildings, and Sanitary Committees of the Vestry of the Parish aforesaid will meet at the Vestry Hall, Kensington, on FRIDAY, the 3rd day of MARCH, 1865, at SEVEN o'clock in the evening, to receive TENDERS for the SUPPLY of 200 CASES of PAVING, Granite, Kerf, Chained, and Dressed Granite, and other Contractor, &c.; also for Re-laying Old Kerf, Paving, and Channels, for One Year from 1st April, 1865. The form of Tender may be obtained, together with all particulars, on application to the Vestry's Surveyor, Mr. JAMES BROADBENT, at his Office, Vestry Hall, aforesaid. Tenders to be sealed and endorsed "Tender for Masons' and Paviers' Work," and to be delivered at my Office on or before FRIDAY, the 3rd day of MARCH, 1865, at 5 o'clock in the evening. No Tender will be received unless made upon one of the said printed forms, but any Tender may be accepted the lowest or any Tender. The Contractor or Contractors to enter into a written contract, and to pay the expense thereof by order.

PARISH of St. MARY ABBOTT'S, Kensington, in the County of Middlesex.—TO IRONFOUNDERS The Works, Buildings, and Sanitary Committees of the Vestry of the Parish aforesaid will meet at the Vestry Hall, Kensington, on FRIDAY, the 3rd day of MARCH, 1865, at SEVEN o'clock in the evening, to receive TENDERS for the SUPPLY of 200 CASES of LANTERN IRONS, 14 inch TINS LANTERN, UPRIGHT SERVICES, BENCH, REDUCING SOCKETS, and COCKS, to be delivered at the Vestry's depot, Penobscok road, Kensington, within three months after the acceptance of the Tender. The form of Tender, together with all particulars, may be obtained on application to the Surveyor, Mr. JAMES BROADBENT, at his Office, Vestry Hall, aforesaid. Tenders to be sealed and endorsed "Tender for Lamp Columns," and to be delivered at my Office on or before FOUR o'clock in the afternoon of FRIDAY, the 3rd day of MARCH, 1865, at 5 o'clock in the evening. No Tender will be received unless made upon one of the said printed forms. The Vestry do not bind themselves to accept the lowest or any Tender.

PARISH of St. MARY ABBOTT'S, Kensington, in the County of Middlesex.—TO GAS-FITTERS and OTHERS.—The Works, Buildings, and Sanitary Committees of the Vestry of the Parish aforesaid will meet at the Vestry Hall, Kensington, on FRIDAY, the 3rd day of MARCH, 1865, at SEVEN o'clock in the evening, to receive TENDERS for the SUPPLY of 200 CASES of LANTERN IRONS, 14 inch TINS LANTERN, UPRIGHT SERVICES, BENCH, REDUCING SOCKETS, and COCKS, to be delivered at the Vestry's depot, Penobscok road, Kensington, within three months after the acceptance of the Tender. The form of Tender, together with all particulars, may be obtained on application to the Surveyor, Mr. JAMES BROADBENT, at his Office, Vestry Hall, aforesaid. Tenders to be sealed and endorsed "Tender for Lanterns," and to be delivered at my Office on or before FOUR o'clock in the afternoon of FRIDAY, the 3rd day of MARCH, 1865, at 5 o'clock in the evening. No Tender will be received unless made upon one of the said printed forms. The Vestry do not bind themselves to accept the lowest or any Tender.

TO BUILDERS.—TENDERS are required for BUILDING the FOUNDATIONS, &c., of a large HOUSE, at Oroydon.—Plans and specifications may be seen on the 15th and 16th inst. at the Office of the MILNERS, 10, Pall-mall, W.C. No pledges in law to accept the lowest or any Tender.

BUILDERS willing to TENDER for the ERECTION of a DETACHED VILLA at East Endbury, are requested to communicate by letter to Mr. W. F. GOSLING, Architect, 72, High-street, UNION-TOWN.

TSWICKUNION.—TO BUILDERS.—Persons desirous of CONTRACTING for the ERECTION of ONE or MORE LANE HOUSES, and other WORKS, at the above Union House, may see the plans and specifications at my Office, 10, Pall-mall, W.C. Tenders to be delivered to me on or before FRIDAY, the 3rd day of MARCH, 1865, at 5 o'clock in the evening. No Tender will be accepted unless made upon one of the said printed forms. The Vestry do not bind themselves to accept the lowest or any Tender.

MIDLAND RAILWAY.—TENDER for the REPAIRING and MAKING GOOD of the WORKS required in MAKING certain ADDITIONS and ALTERATIONS to the GOODS WAREHOUSE, at the Bristol Station, the drawings and specifications of which may be obtained on application to the Engineer's Office, Gloucester Station, on and after THURSDAY, the 2nd inst. The Board of Directors will proceed to open and consider the same at their meeting, on FRIDAY, the 3rd inst. The lowest or any Tender will be accepted.

TO CONTRACTORS.—TENDERS are invited to be sent in by Builders, Contractors, and others, for a CHURCH about to be erected at Brixton, near Brixton, and specifications may be inspected at the Mechanics' Institute, on or after MONDAY, the 20th inst. The Contractors will be required to find securities for the full completion of their Contract. The Committee do not bind themselves to accept the lowest or any Tender. All Tenders must be sealed and sent to the Secretary, the Rev. J. H. Hardy, Marke, near Brixton, on or before the 20th MARCH. Quantities are not specified.

NOTICE.—The convenient RESIDENCES advertised below deserve the particular attention of persons with limited means, as they combine the advantages of a Moderate Rent with the liberal Education afforded by the Free Grammar School of St. Olave and St. John, and for which the Children of Residents in these Houses would be eligible.—St. John's, Harold's-down.—Convenient BUILDERS' YARD, SHOPS, HOUSES, and PREMISES TO BE LET BY TENDER, by the Governor of St. Olave's Free Grammar School, Southwark, on 7 o'clock on Monday, the 20th inst. from Lady day next ensuing; that is to say, all that compact Building, Free, Dwelling houses, and Premises, situate and being No. 1, on the west side of Queen-street; all those Tenements situate and being No. 3, on the west side of Queen-street; and Nos. 1, 3, 5, and 4, on the south side of Queen-street; also all those Two Warehouses and Premises, situate and being at the south-east corner of Great-street and Cove alley; also all that commanding Corner Shop No. 22, 24, 26, 28, and 30, on the north side of Freshford-street; also all very convenient Dwelling house and Premises, situate and being No. 53, on the south side of Queen Elizabeth-street; and those Dwelling houses, situate and being Nos. 13, 14, and 15, on the west side of Parish-street. The leases for which Tenders are required, being of long duration from Lady-day next, all of which are situate in the parish of St. John, Harold's-down, in the county of Surrey, together with the appurtenances thereto, respectively, being in full and complete repair, and in a good state of cultivation. The particular and conditions, plans of the premises, and specifications of the works and repairs required, may be seen at the Office of Mr. HENRY STOKES, the Surveyor, No. 6, Duke-street, Southwark, between the hours of TEN and FOUR o'clock any Sunday excepted; and Tenders, in writing only, are to be delivered at the Office of Mr. R. MINSHULL JONES, No. 100, Toodleys, by Southwark, by or before BREADBENT'S clock on MONDAY, MARCH 2nd, 1865, immediately after which a Court of Governors will be held at the School, for the purpose of taking the same into consideration, and where persons making such Tenders may be present punctually at ONE O'CLOCK of the same day; but the Governors do not bind themselves to accept the highest or any other offer.

A TREATISE ON SMOKY CHIMNEYS: their CAUSE and PREVENTION. By FREDERICK EDWARDS, Esq., F.R.S., F.R.S.E., &c. &c. A treatise upon the causes, and the means of preventing, the smoke arising from chimneys, and the means of rendering them more efficient. A new and improved method of constructing chimneys, and the means of preventing the smoke arising from them, and the means of rendering them more efficient. A new and improved method of constructing chimneys, and the means of preventing the smoke arising from them, and the means of rendering them more efficient.

OUR DOMESTIC FIRE-PLACES: a Treatise on the Economical Use of Fuel and the Prevention of Smoke. By FREDERICK EDWARDS, Esq., F.R.S., F.R.S.E., &c. &c. On the strength of the apparatus, of every man to his trade, we may imagine should be a more complete power to give us information about these things than a well-ordered practical man, who has manufactured thousands of them, and made an examination of all the respective merits in a life-long study? But he so extremely admitted that, as in love and war, all sorts of stratagems are fair in trade, that the public are apt to eye with reserve any production of this kind, and to distrust their own ears, and to regard it as an oblique or disguised advertisement. It would, however, gratify the application of this opinion, to Mr. Edwards's work on "Our Domestic Fire-places," which, although it may answer the purpose of an ordinary trade book, belongs to a higher order of things. This Mr. Edwards's work is not only a treatise on a class of practical subjects, but it is a treatise on a class of practical subjects, and it is a treatise on a class of practical subjects.

A SERIES OF TECHNICAL VOCABULARIES IN HIGH LANGUAGES, comprising the leading terms in the following constructive branches: CIVIL and MECHANICAL ARCHITECTURE. Price 2s. CIVIL ENGINEERING and STEAM-ENGINEERING. Price 2s. CIVIL ENGINEERING and STEAM-ENGINEERING. Price 2s. CIVIL ENGINEERING and STEAM-ENGINEERING. Price 2s.

A NEW MONTHLY SCIENTIFIC JOURNAL. Messrs. CASSELL, PETER, & GALPIN beg to announce that they will publish, on the 1st of MARCH, NINEPENCE ONE of a NEW MONTHLY First-class SERIAL, to be entitled

THE SCIENTIFIC REVIEW and JOURNAL OF THE INVENTORS' INSTITUTE.—The main objects of the "Scientific Review" will be to record fully and faithfully, from month to month, the progress of Science both at home and abroad, to point out the bearing of recent discoveries on those previously made, and to keep their practical utility most steadily in view.

Among the boundless variety of subjects which will find a place in its pages every branch of production, every department of scientific research, having a practical tendency, will be duly noticed. The "Scientific Review" and Journal of the Inventors' Institute will also form a medium of intercommunication between scientific men throughout the world; and an opportunity will be afforded them of canvassing the merits of rival inventions, and of pointing out the merits of the one over the other.

Each number will generally contain one or more reviews of scientific descriptions of new or improved machines, processes, and apparatus, with illustrations when considered especially important; an scientific topics of current interest; a résumé of the progress of manufactures and practical science; and a list of the latest inventions, together with the names of the inventors, and the names of the persons to whom they have been assigned.

Subscribers desirous of receiving copies each month at their residence, will secure their delivery post free by remitting a year's subscription of 7s. to the Publishers. All communications intended for the Editors to be addressed as follows:—The Editors of "The Scientific Review." Messrs. Cassell, Peter, & Galpin, Esq. Ball's Square Yard, London, E.C. The Ball's Square Yard, London, E.C.

N.B.—Advertisements in the First Number must be sent to the Office of "The Scientific Review," Ball's Square Yard, Ludgate-hill, on or before the 20th of February.

# The Builder.

VOL. XXIII.—No. 1151.

Restorations in Northern Italy: Verona.

N Maffei's "Verona Illustrata" (published 1732), a first-class work in Italian archæologic literature, we find the statement that, "while some hundred books have been dedicated to the subject of Roman antiquities at Verona, not one has hitherto given any report of the Christian antiquities, not less valuable in that city; nor has any writer yet even thought of publishing a separate account of those latter." Great has been the change in the direction of Italy's antiquarian studios since these words were penned, thanks to impulses given principally by savans at Rome and Florence; but we are not aware that a local theme so rich as that referred to has yet been turned to account with adequate abilities in the language.

The first visit to Verona is a memorable event to the tourist imbued with love or reverence for the genius of the Christian Middle Ages; and under the present circumstances of this country, the reflective observer must find an additional source of interest in the comparison between those provinces now ruled by national and constitutional government—the States of United Italy,—and those still under the absolute power of the stranger. Austria seems in this land like a conqueror on the march, eager to extend his lines and outposts on every side, to make the most of a temporary position, and under all too strong a necessity of exciting force to have time for thinking about such subordinate interests as the attainment of confidence or popularity. Yet this, like other comparisons, admits of exception, and may be applied in the general way, whilst at the same time one is ready to be just towards traits of more magnanimous policy, in the interests of public works and monuments, which the German ruler has occasionally exhibited in his occupation of Italy's fairest regions. The liberal furtherance of the complicated works at Milan Cathedral, whilst that city was under his sway, may class together with the restorations begun about a year ago, at the splendid mausolea of the Scaligers, among claims to gratitude on the part of Austria in Italy. But, oh! the difference! the evidences of languishing decay and stagnant incertness in the aspects of those cities where the stranger still holds invidious dominion, contrasted with the life of life, the signs unmistakable of progress on every side, where the authority of a native king is established!

Entering Verona by night, an impression of the grandiose is received from its vastness and situation, the unusual length and massive buildings of its streets; but, by daylight, one soon perceives how superficial is the semblance of prosperity, how mournfully apparent are the marks of decay. Wonderful indeed is the wealth of this place in scattered Medieval fragments, and details of architecture so richly characterized! One observes at almost every step some ogee arch or Gothic window with colonnettes and mouldings, some fine cor-

niche work or pointed canopy over a devotional picture, all in the warm red local marble; but these treasures are gems thrown away amidst mouldiness and neglect, and there seems reason to fear that a much longer continuance of the actual conditions in this subject city may result in the total decay, even to annihilation, of much that now contributes to invest her with such interest. The Corso and some streets lined with shops are thronged; the picturesque Piazza dell' Erba, surrounded by grand but dilapidated Medieval architecture, and lined with stalls and rich profusion of fruits, vegetables, and flowers, is in the morning hours one of the most animated as well as striking scenes of its description imaginable; while quarters more remote from the thronged centres remind us of half-deserted convents, or haunts of hopeless poverty—suburbs like wretched villages, inhabited by woe-begone tenants, whose cottages are in the state of incipient ruin. A prevailing depression seems to weigh down the life of the entire population, indicated in the longing, aimless air of passengers in the streets, the half-shabby, half-showy style of establishments, as well as of men and women, excepting only the ever-present and dashing wearers of white uniform, whether officers or privates, alike recognizable as "masters of all they survey," and (with other characteristics) the devout attendants at churches, where females wear the graceful black veil of Spanish origin. That gloomily imposing specimen of military architecture (rebuilt, as it now stands, in 1350), known as the Castel Vecchio, whose enormous brick towers dominate over the broad river and over the majestic battlemented old bridge that here spans the Adige, rises like a stern symbol of the isolated and baleful sway beneath which Verona lies prostrate; and one statistical fact (we have mentioned it before), is sufficiently telling for comment on the blight and desolation now overshadowing her, that amid a population of 75,000, not fewer than 30,000 is the numeric force of Austria within her walls! Entering the grand old cathedral (founded 1187, the actual vaulting of the year 1402, many details removed by Sanmichele in 1534), we were sorry to see its chancel-arches encumbered with crimson draperies, for some approaching festival of the Madonna—a theatrical decoration offensively discordant. Quite out of keeping, too, is the style in which its choir and tribunes have been altered by the modern works, among other achievements of which was the removal of the tomb of Pope Lucius III., who held a council in this church, died at Verona, and was buried in the same building, his monument placed before the high altar, whence it was taken to be deposited underground. Nothing could be more venerably characteristic than this cathedral's façade and portal, with the double piles of enclostering pilasters, the quaint relief statues of prophets holding scrolls, the harbaric wild beasts, preying upon feebler quadrupeds (symbols of orthodox triumph over heresy), and the grim figures of Roland and Oliver, in complete armour, with large diamond-shaped shields; these curious details, happily uninjured and untouched by modern hands, though the upper part has suffered from wretched repairs in brickwork, its marble cornice-lines left interrupted by the decay, restorers have not attempted to make up for by replacing what is lost. S. Stefano, the former cathedral, of the eleventh century, a small and now subordinate church, near the river, with simple gable-headed façade and octagonal tower, the exterior plain and quaint, the interior cold and gloomy, has been in part modernized with the usual bad taste.

The most remarkable church of Verona, S. Zenone, so unique and awe-striking in its dreamy grandeur, was founded by Pepin in the eighth century, rebuilt 1138-1178, the actual sculptured gates being of the year 1178, and the choir of the thirteenth century. This edifice is like an

expression of olden Catholicism in all its aspects—darker as well as brighter; and if we sought anything correspondent in the analogies of literature, we might fix on some chapter in the "Golden Legend." An ascendant mysticism, a solemn harmony, attained through complex and bizarre varieties, so impress as perfectly to overpower the mind. And yet here, too, are drawbacks in the evidences of cold neglect and neglected decay, of pultry taste and degrading superstitions. Such a spectacle as the seated statue of S. Zeno, in red marble, absolutely barbaric as to execution, with a fishing-rod with which hangs a silver fish in his clumsy hand, a money plate in front, and benches for kneeling in a circle around, shocks and insults the religious feeling excited by that noble architecture in its twilight solemnity. The frescoes of the fourteenth and fifteenth centuries once covering the walls along both aisles, are now effaced, save in a few instances; and we were told that, besides those left to fade away by natural process through exposure and damp, others had been deliberately destroyed. A "Crucifixion" of the school of Giotto, with miniature kneeling figures of Can Signorio della Scala and his confessor, a Dominican friar, is an interesting picture fortunately preserved. We again see S. Zeno fishing (of course symbolically), on one panel among the very curious bronze sculptures covering the great doors, pointed out by the custode as of the ninth century; the rest of these interesting bronze reliefs (subjects from the Old Testament) being by two artists of the twelfth century, Guglielmo and Niccolò da Figarola. An adjacent cloister of the Benedictine Abbey, whose monks used to serve this church,—one of the finest examples of similar construction in Italy,—has been converted into a magazine for military stores or provisions; and we could only enjoy a brief glimpse of its half-concealed arcades, beautiful (as even under such disadvantage could be perceived) in their still perfect details, with round arches resting on coupled columns. Near these rises an old square tower of bricks, lofty and picturesquely dismal, the sole other remnant of that monastery, said to have been once the palace of King Pepin, whose more extensive buildings were taken down, by the proprietor unfortunately possessed of them, in 1812.\* The custode of S. Zenone, a man superior to the average calibre of his class, who loves and appreciates his charge with enthusiasm, talked of Ruskin and the interest taken by him in this celebrated church, leading us to understand that the critic had been on terms of sympathizing friendliness with this honest and loquacious employé. Others of the grand old churches at Verona, S. Anastasia, S. Fermo, S. Bernardino, retain their leading features uninjured and their characteristics of ancient dignity; though wherever renovation has been accomplished, it is at once perceived that the restoring taste here was against just principles not less than in Rome or Naples. Renaissance (in the modern sense) appeared rather early in the fifteenth century at Verona, and was first due to the architect Rivio, followed later, with the same principles, by Falconetto and Fra Giocondo; finally, by the more distinguished Sanmichele, born in this city (1484), where the church of S. Giorgio (a kind of miniature St. Peter's) is deemed his masterpiece.

In a quaint little piazza before the small church of S. Maria Antica (consecrated by Pope Alexander III. in 1177) stand within a square of iron railings those celebrated monuments of the Scaligeri, approaching which our disappointment was great, though it soon gave way to a sense of approval at seeing the finest of those tombs, that of Can Signorio, almost concealed by scaf-

\* Maffei mentions an epigraph as extant in these cloisters, with record of the formation of the first cemetery for the monks under an abbot in the eleventh century; and another, recording the restoration of the cloister arcades by another abbot, A.D. 1123.

folding raised for repairs, its majestic *ensemble* being thus withdrawn from appreciation, though details might still be examined, as we could pass within that modern framework in order to observe and admire. How necessary such works as those now in progress are is especially evident in this monument, and in the equestrian figure at its apex, one arm of which is wanting. We need not attempt to describe again those well-known and magnificent examples of Medieval art that so admirably combine grace with solemnity, delicate lightness with elaborate richness, whilst sculpture and architecture are in such perfect accord, that, as in the marriage of words with sweet music, the mind cannot sever one from the other. We gave some particulars in our papers "Coming Along" last year, when we urged on the authorities the necessity for reparation and careful support. The most ancient is a simple sarcophagus, containing the body of Mastino I., elected perpetual "Captain of the People," who was assassinated to avenge the honour of a young lady, A.D. 1272; the latest in date, that above-mentioned of Can Signorio, deceased, 1375, and last of this dynasty in power at Verona, whose ambition it was to surpass all his ancestors in the splendour of the tomb, for erecting and adorning which he spent in his lifetime 10,000 *forins* of gold, the artist being named in the epigraph, Boninus de Campilono, of the diocese of Milan. We may conjecture, in that vanity directed to posthumous honours, an expiatory feeling sprung from remorse in the mind of this guilt-stained potentate, the murderer of his own brother, Can Grande II., whose humbler tomb, a sarcophagus without inscription, stands on the pavement near, and who fell by fratricidal treason, the author of that crime being then only nineteen years old (1359). Three other sarcophagi, distinguished only by the sculptured crest, without epitaphs, are associated with the monumental group, but are to be removed from their actual places in order to be henceforth located according to succession of date. Bonino, the artist of that most splendid work, is considered by Italian critics to partake more of the German style than that native to Italy, and most in credit at his period,—an age when, as strikingly manifest in his case, almost all architects were (in the words of Cicognara), "at the same time sculptors, without exposing the merits of one art to conflict with the sacrifices of another." That writer and Maffei give the names of eight sculptors who had attained eminence at Verona *previously* to the epoch, in the thirteenth century, generally assigned as that of the revival of Christian art; the most noted among these, Brioletto, being conspicuous so early as the eleventh century, and most renowned for his extant masterpiece, the "Wheel of Fortune," in a circular window at the S. Zeonno Church. No Italian city, in fact, possessed so many artists of name as did Verona within that elsewhere darkest period between the Longobardic kings and the Scaliger dominion, which commenced in the person of Mastino I., elected to dictatorial supremacy in 1261,—the date corresponding to that at which Niccolò di Pisa had just attained the zenith of his fame by his admirable sculptures on the pulpit of the baptistery in his native city.

The monument of Mastino II., father of Can Signorio, deceased 1351, is almost on a par in beauty of conception and finish, though not indeed evincing an art epoch quite so advanced as that of his son; and this former being unencumbered, we could observe its conditions, happily not such as to require any material repair.

#### DRAWING FOR ARTIZANS.

In consequence of some observations made by us not long ago as to the actual money value to an artizan of a knowledge of drawing, we have received within the last month a larger number of letters than usual, from masons, carpenters, and others, asking what steps they should take to acquire this power. "I hope," said one, representing several, "you will excuse the liberty I take in writing you. In the first place, you must know, I am a mason by trade, but, unfortunately, totally unacquainted with mechanical drawing, and I have been obliged to refuse two or three offers as foreman that I might have accepted had I been acquainted with lines." "I must tell you, I went once to a night-school, for a week or two, and, by the way they commenced to teach me, I saw it would be wasting my time and money, so I left. Copying houses on such a small scale that you had to put

your eyes nearly on the paper to see all the lines, and by gas-light, with a mason's heavy hand, was not the right work for a person that had never done anything of the sort before." Some asked for the name of a good school, others to be directed to an easy book, and a few complained that the course pursued in some of the schools in connexion with the Department of Art was not, in their opinion, suited to their wants.

To several of these correspondents we have written privately, giving such suggestions in their particular cases as seemed calculated to be serviceable. To continue doing this, however, is out of the question, and we would here reply to two or three inquirers, that the best thing they can do, is to go to the Central Schools at South Kensington, and learn for themselves the course that is there pursued. An artizan class, we understand, has been formed there, meeting in the evening, and involving a payment either of 2s. or 3s. a month, according to the number of evenings in the week they desire to work. The class is already well attended, and the head master of the schools, Mr. Burchett, is so anxious that this should prove really useful to artizans, that if any of them who are in earnest will go to the school on a Monday, Wednesday, or Friday evening, about half-past seven o'clock, information will be readily afforded them, so that they may make up their minds as to entering or not. We shall be glad if we induce some, at any rate, of the younger men to avail themselves of the advantages here offered. They will find, too, in another part of the establishment an art-library of great extent and comprehensiveness, from which, when further advanced, they may obtain any amount of assistance in their studies by a merely nominal payment. Those who live at a distance should apply to the school of design in their neighbourhood, the West London School, for example, in the Portland-road, at any of which we have no doubt the masters will willingly listen to and consider any suggestions that may be made as to improvements in the course of study, with reference to their wants and opportunities.

Let us, however, say at once, that skill in drawing, especially if not sought till late in life, is not to be acquired by merely wishing to possess it. It must be worked for; the effort must be persevered in: but it is work that will become a pleasure; an effort that will bring its own reward. There are plenty of people who would willingly acquire knowledge or skill; but when they find that there is no royal road to its acquisition,—that it is not to be had without the labour of study,—at once give in and excuse their own want of application and perseverance, by complaining of want of opportunity.

We assert, as we have before asserted, that opportunities are not wanting to any one who will resolve to use them.

To some who say they are far from a school, and want to acquire skill in line-drawing at home at such odd hours as they can command, we would suggest the purchase of odd sheets of Laxton's "Examples of Building Construction" as copies. These are drawn to a large scale, and are very clear. An "Elementary Treatise on Orthographic Projection," by W. S. Binns, published by Messrs. Longman, in Cleig's School Series, may be had for a shilling, and will show them how to draw in plan, elevation, and section, geometrical forms which are continually before their eyes; while, as an introduction to free-hand drawing, Mr. Walter Smith's "Examples for First Practice" can be obtained for a shilling at Messrs. Chapman & Hall's, Piccadilly, and are well adapted for self-instruction. The same "School master, Mr. W. Smith, has published a "School of Art Practical Geometry" for a shilling, which will be found very useful. Some time back, we may mention too, we gave some practical hints on the self-teaching of drawing. We said then, as we say now,—go at it with a will. Do not be discouraged by a little difficulty at first; make your own opportunities; work and learn; and rest assured that whether it advance you in this world or not,—and the chances are that it will advance you,—you will never have reason to regret the effort.

PUGIN TRAVELLING STUDENTSHIP.—The first election for the Pugin Travelling Studentship has been decided in favour of Mr. J. Tavorner Perry, of Sloane-street.

\* 19, Arundel-street, Strand.

#### ARCHITECTURAL NOTES IN FRANCE.

NOYON.—LAON.\*

PERHAPS in commencing my paper I may be allowed to enter very briefly into a few general remarks on the church architecture of France. In the great architectural revival in the twelfth and thirteenth centuries, church architecture was divided into five grand divisions—cathedral, monastic, conventual, collegiate, and parochial. Until the end of the twelfth century the cathedrals of France did not begin to assume those vast dimensions which are so grandly exemplified in Beauvais, Noyon, Laon, and Rheims; until this time the internal disputes of the different communities were against that great combination of strength between the ecclesiastic and civil bodies, which at the end of the twelfth century started that noble competition amongst so many cities in France, as to which should erect the grandest and most splendid building. It was about this time that the priests made common cause with monarchy against the remnants of the old feudal system; and the result of that alliance was the raising of those magnificent cathedrals at Laon, Rheims, Noyon, Chartres, Amiens, and Beauvais, which as far surpassed in grandeur the old monasteries and abbeys as they themselves surpassed the smaller churches.

From the time when Philip Augustus came to the throne of France, in the latter end of the twelfth century, until the death of Charles V., in 1380, there seemed to be a grand rivalry in cathedral and church building: priests and laymen united against the Church became the mutual stand-point of all parties. In this brief century and a half, France became covered, as it were, with buildings, which at this day are the wonder and admiration of us all: in these two generations flourished hosts of artists of all kinds, whose works live still as everlasting monuments of their great power and genius.

At the same period, too, were built many of the old regal and episcopal palaces which still exist in nearly every cathedral town.

These palaces were added to from time to time as the wealth and possessions of their owners increased, and in them were held their courts and various local parliaments; for which purposes, as well as for the gathering together of the vassals, and for giving large banquets and other entertainments, was the great hall, which in all these early palaces, whether regal or ecclesiastical, forms one of the principal features. In addition to the hall, were the chapel and the apartments of the lord or bishop, and offices thereto; chambers for the treasure and archives and other valuable documents; rooms for the retainers of the house, and also guard-rooms and dungeons; and generally also guard-rooms and dungeons; a strongly fortified gateway or keep.

The Royal Palace was the palace *par excellence*, and often the other palaces took the title of the noblemen who possessed them, as that of the Comtes de Beauvais.

The episcopal palaces were always situate close to the cathedrals, and generally also immediately contiguous to the walls of the city, so as to contribute to the defence thereof if necessary, and for the purpose, as will be noticed at Laon, they were originally fortified. These palaces probably often determined the position of the cathedrals. M. Guizot, in his history of France, tells us that formerly the bishops were the natural lords of the towns, and that they governed the people, being their magistrates within and their protectors without.

The palace was often connected by a gallery or cloister with the cathedral, by which the bishop and his friends entered.

It is well for the art student to note the various developments of the different parts of the ecclesiastical edifices of the Middle Ages; the different forms of the buttresses and windows, and the gradual refining, so to speak, of the mouldings; for by them one can see the expanding, as it were, of the thoughts and feelings of the early builders: the variety of design, in some of the parts is most curious and interesting. The earliest types of buttresses that I have seen are those in the church of St. Remi, at Rheims, which are circular on plan, and probably date from the end of the tenth, or beginning of the eleventh, century. The next form seemed to be those which, while being square on plan, had but a very small projection in comparison with their height, and which often ran square

\* By Mr. Edis. From a paper read at the Architectural Association, as elsewhere mentioned.

up into the cornice, without slope or moulding of any kind, as in the transepts of the small church at Rots, near Caen; or sometimes diminishing on the face and sides, about two-thirds of the way up, with very small spays, and the top spay being sometimes finished with a small piece of carving or rude sculpture. It is also well to note how carefully these old architects always sought to design their buttresses, not only to be strong as counter thrusts, but to appear so, and to show clearly what they were intended for.

In the church of St. Martin, at Laon, which is about the date of the middle of the twelfth century, the buttresses are very massive, and brought well out from the faces of the walls, so as to give an appearance of extreme strength; the slopes are long, and are finished at the bases with heavy projecting mouldings, being in reality part of the string courses returned.

Towards the middle of the thirteenth century, the buttresses were made to project much further; and about this time, too, they began to be decorated either with niches for statues, or with columns at the angles, and with crocketed pinnacles as terminations running up above the cornice. The later ones are all kinds of shapes, the bases being square; the next stage perhaps also square; and then the plan would be reversed and the face would be angular; and at the junction between the square and the angular faces there would perhaps be small pinnacles. The weathering tables of these later buttresses were also much deeper, and the mouldings much coarser.

As regards the windows, until the end of the eleventh century the windows of the churches were rarely filled with glass of any kind, but had gratings of either wood, stone, or iron, some of which were made to open and shut; but in general they were, I believe, built into the spayed sides. The very early windows were always small, and with the external angles spayed off to a less degree than the internal ones, to admit of free egress of light and air; but soon the discovery of stained glass compelled the enlargement of the window-spaces; and from this time they began to assume all the varieties of form and size which the mind of man could invent, from the simple lancet, with plain trefoil head, to the magnificent rose windows, such as those at Laon and Rheims; until later the architects seemed to wreath their masonry like garlands, and to form it into endless graceful designs of flowing tracery.

The walk from Ourcamp to Noyon is along a straight dreary road, amid long rows of weid-looking poplar trees, and is by no means a pleasant one, for the road is, for the most part, paved with stones, and very hilly; and the traveller will be right glad when at last the chimneys of Noyon come in sight, and he is able, after perhaps a long day's march, to rest himself after his labours at the little inn or hotel which faces the south front of the cathedral.

In Murray's Handbook of France you are told that the cathedral at Noyon "is of interest to the antiquary and the architect;" and a short paragraph tells you that "it is a fine Romanesque edifice, begun in the twelfth and completed early in the thirteenth century;" and informs you, also, that "it presents an interesting example of the transition of the Round to the Pointed style;" and in about a dozen short lines does the writer dispose of what is undoubtedly one of the first and purest of all French cathedrals: essentially religious in its character, and beautiful in its charming simplicity of outline and detail, this cathedral furnishes enough for study and examination for a whole fortnight's holiday, and one, too, which will amply repay the architectural student who will quietly settle down in the comfortable little inn close at hand, and make up his mind for a week or fortnight's sketching and study. In 1130, the town of Noyon and its cathedral were destroyed by fire. The bishop of that date had almost entirely exhausted his means in building the neighbouring abbey of Ourcamp, and was unable to restore the cathedral. His successor commenced that imposing edifice which now remains; a building which is almost entirely abandoned the old Basilica form.

The plan of the cathedral is cruciform, the transepts and choir having circular ends, and the latter having also five circular eastern chapels, and four square north and south chapels, two on each side. It may be, perhaps, that the essentially religious character of the plan, and the absence of any approach to the old Basilica, or, if I may so call it, civil form, is owing to its having been

commenced before the grand revival movement set in; a revival in which the clergy and the laity joined hands, and became as one. The two grand square western towers were commenced after the building of the choir and transepts, but were never completed; and although the simple low pyramidal timber roofs, with the quaint spirelets at each angle, are exceedingly picturesque, the building seems to want the spires,—which no doubt were intended to have crowned the towers,—and the effect which their grand skyline would have given. The plan of the vaulting is similar to that at Laon, that is to say, hexa-part; the mouldings of the vaulting-ribs are very simple and beautiful, and those to the choir are ornamented with small rosettes, which give an exquisitely charming appearance. On the north side of the nave is a chapter-house of later date, and part of the old cloister still remains. The arch mouldings of the windows of the chapter-house next the cloisters on the east side are very richly carved with foliage. The porch, which extends across the whole of the west front of the cathedral, is all open, with a pierced arcade or balustrading running along the whole top; this is probably a century later than the rest of the building, and although beautiful in its way, does not add to the simple magnificence of the *tot ensemble*.

The doorway in the east end of the south transept is a charming little bit of Romanesque work; it has a projecting pediment, with a pointed harvel vault, resting on exquisitely-carved capitals.

The next town that I propose to draw your attention to is Laon. I know of no town which impresses at first sight the beholder more than this, situated as it is on the summit of a lofty and almost isolated hill on the borders of the vast valley of Champagne, with the roads winding round and round till they gradually enter through and pass behind the old fortified walls; the picturesquely wooded slopes of the hill, and the whole crowned at its summit by the magnificent cathedral, gives an appearance of strength and grandeur that I have never seen equalled. If you choose to walk from the station, which is in the lower town at the foot of the hill, there is a short cut up a series of steps cut out of the hill, from the top of which you have a most magnificent view of the surrounding country. The walk round the walls beneath the old and new fortifications gives you many charming views over the vine-clad plain below; and, looking up at the masses of ancient masonry which mingle with the natural fortification of the rock itself, the place seems as though it would be almost impregnable to an enemy. It was here that Napoleon, in 1814, first fought and lost a battle with the allied army under Blucher.

One of the old gates, the Porte d'Arden, still remains, but is now little more than a picturesque ruin, with its low-pointed entrance-arch and guard chamber over, and the two quaint circular turrets which flank the gateway right and left.

Laon was another of those towns which, like other wealthy towns in France, was at one time perpetually engaged in feudal strife; but from the time when Philip Augustus, in 1191, allowed or confirmed their corporation rights, for which they had been fighting, these worthy burghers joined heart and soul with the priesthood in vying with the other large towns in building a cathedral which should surpass in grandeur and magnificence anything that had been before; and as Laon was one of the most democratic of all French cities at that time, it would seem that a sort of concession was made, so as to design a building which should be capable of purposes both civil and religious, for M. Mariou, in his archaeological history of this cathedral, tells us, that at times most extraordinary scenes of buffoonery were enacted therein, and suggests that it was probable that the wily bishops and priests, with whom the good people of Laon had for more than a century been perpetually wrangling, thought, by giving in a little at first, and by not insisting all at once upon having a building entirely for religious purposes, that they contrived thus to gain the means and assistance, without which it would have been entirely impossible to carry out their grand scheme.

It will be noticed that the plan of the cathedral gives the appearance of an immense hall or basilica with aisles.

The choir is finished square, and the transepts are very shallow, being literally, if we except the two flanking towers and porches between

them, only the length of two bays of the nave or body of the church; and, with the exception of the two small square chapels on the north and south sides of the choir next the transepts, there are none, whereas at Noyon the whole of the choir is surrounded by chapels; but Noyon was built probably forty or fifty years before Laon, when the priest rule was stronger, and could therefore, as it were, throw more religious element into its plan.

Murray, in his guide-book, gives the date of the present cathedral as 1114; but this is evidently wrong,—at least the architecture of the present building is certainly not twelfth century work, and M. Marion tells us that it was probably commenced after the peace of 1191; the old cathedral having been damaged, and in great part destroyed during the disturbances of the preceding three-quarters of a century. In the original cathedral the apse was circular, and had circular chapels, somewhat similar to those at Noyon, as has been ascertained without doubt by the discovery of the old foundations, by M. Beswilwald, the architect.

The present edifice is probably of the early part of the thirteenth century. There is a charming unity throughout the whole building, as if it had been carried out at once and without any lapse of time intervening between any portion of it, as is the case in so many of the Continental churches. The view down the nave and choir from the west entrance looking east is grand in the extreme; its immense length, over 400 ft., giving a marvellous perspective vista. The cathedral is peculiar, as having a double triforium, making it four stories in height. The top triforium consists of a long arcade, opening into a narrow gallery behind the clerestory windows are quite plain, and sufficiently wide to fill up the spaces between the vaulting. The vaulting shafts are small and clustered, and finish with bases on the top of the abaci of the columns of the nave arcade. The main columns of the nave arcade, which carry the clustered shafts, which take the transverse vaulting ribs, are much larger than the alternate columns, and have five small detached shafts upon their faces, one at each angle of the square, and one in the centre on the faces next the nave. The alternate columns are circular, with octagon bases. The seven towers, when first erected, must have formed a grand and imposing sight. M. Viollet-le-Duc says, they were originally surmounted with spires, which are now destroyed. The large central tower has now a plain wooden roof, hipped all ways to a point. The arrangement of the buttresses to the top stage of this tower is very good. The western towers, as well as the parts of those at the four angles of the transepts which remain, are all open, the windows not being filled with glass, and the effect of the immense open lancets, and the open angle buttresses or turrets, seen from a distance, is very impressive; but to my mind I cannot think them so charming as the two western towers of Noyon Cathedral, which in their very simplicity and squareness seem so beautiful and noble.

There is one thing in Laon Cathedral which every one who first sees it will marvel at,—I mean the immense figures of horses and oxen which stand staring out into space from the recesses of the open angle buttresses of the northwest tower, which seem anything but religious or beautiful, and certainly out of place so high above ground. It seems as though these strong, hardy, and enterprising people of Laon meant to do something that should outvie their neighbours, and carried up these said animals and then caged them, and they, in their very fright at being in so celestial a region, had fossilized.

In early days certain birds and beasts had symbolic qualities, such as the lion, the symbol of force and courage; the pelican, of charity; and the basilisk and the dragon, of the devil.

The battlements of the cathedrals of Notre Dame, at Paris and Rheims, are surmounted with enormous elephants and other fantastic figures, either of beasts or birds, which stand like grim sentinels watching over the buildings they adorn; and perhaps these Laon burghers put up these immense horses and oxen as symbols of their faithfulness and docility. At all events, these masses of stone, which were doubtless constructionally necessary, have had life and character given to them by the sculptor.

One thing these sturdy builders did not do as well as the rest of their work in this cathedral at least: they scamped the concrete, or forgot it altogether; for the two western towers had fair to fall altogether, and cracked from the summit almost to the base, so much so that a great part

of them has been obliged to be taken down and rebuilt; as also a part of the west end of the nave; and the patchy appearance which the restoration of those parts in which the new stones have had to replace the old is anything but agreeable to the eye. There are three enormous rose windows in this cathedral, one in the east end of the choir, and one in each transept. That in the north transept is a singularly beautiful one, and is filled up with a series of smaller roses.

The one in the east end of the choir is more to be wondered at for its size than admired for its beauty. There is a curious old thirteenth century figure bearing a sun-dial on the wall at the east end of the old covered cloisters adjoining the south transept, an angel, the size of life, standing on a carved corbel about 14 ft. from the ground, and, with wings crossed, carries the dial. The figure is much mutilated, and the old dial has been destroyed. The present one is supported in front of the figure by iron brackets fixed into the wall, the arms of the figure which carried the original one having been broken off. The cloisters are exceedingly beautiful, the arcades being divided into two by low single shafts, from which spring pointed arches. The space above, and between the vaulting, is filled up, and pierced with plain circular openings with quatrefoil tracery therein; and around these inner circles or openings are a row of small plain holes, about 6 in. in diameter, moulded on the edges. The vaulting ribs spring from a cluster of low shafts, alternately octagon and circular, the octagon ones being of marble. In the south transept there is a very fine old font, the bowl of which is black marble, resting on a circular stone shaft and base.

The only other church in Laon is that of St. Martin, at the east end of the town,—a twelfth-century building very similar in detail to the cathedral, but with much coarser detail. The west facade is a very good specimen of fourteenth-century work.

The only other building that offers much interest to the architectural student is the old Bishop's Palace which adjoins the cathedral on the north side.

The present episcopal palace, now used as the Palace of Justice, was rebuilt after the fire, which, in the beginning of the twelfth century, destroyed the old palace as well as the greater part of the old cathedral. The sketch which I have taken is from the old wall of the town, and represents the ancient grand hall: this is ascribed to Bishop Garnier in 1245. This view presents a long facade running parallel to the old wall, and is one of the most interesting parts of the building, but sadly mutilated. The three picturesque circular turrets which are corbelled out from the wall-face with exquisitely moulded corbels, into which the flat square buttresses of the ground store run up, and help to carry the superstructure, had originally pointed or spirelet roofs, but these, as well as the battlements, which ran along the whole front, have long since been destroyed. Between these turrets are beautifully moulded pointed windows arranged in groups of three, each of which shows traces of having been filled up with mullions and tracery, so as to form two lights somewhat similar to the windows in the sacristy of Ronen Cathedral. The ground or lower story is almost plain, and of great strength, pierced only by a few small narrow-pointed windows, and gives the idea that the building was originally used, or intended to be used, as a means of defence. This would also seem to be implied by the battlements, which, as I have before stated, originally finished the top of the walls.

I notice in a sketch that M. Viollet-le-Duc has of this building, taken from about the same point as my own, that he has made the windows in the east end of the great hall pointed, similar to the others; whereas, in the present building, these windows, which certainly have every appearance of being part of the original structure, the mouldings being very similar, as well as the other details, are square-headed. The heads are beautifully moulded; the same moulding returns part of the way down the jambs, the lower portion of which, as well as the mullions, are formed of small clustered shafts, with delicately carved caps and moulded bases. The heads which fill up the angles under the moulded springer stones or corbels of the circular turrets, are very curious, and the whole of this building is most interesting. The cloister on the south side, immediately facing the cathedral, has a very good arcade, with large circular columns and deep flatly-carved capitals, these latter being for the most part in three tiers of stories, with a band of flat leaf foliage running round

each. Above this cloister was probably a gallery, which served as a promenade from the great hall, while the front of the building is admirably situate for defence in case of need.

#### GENERAL EXHIBITION OF WATER-COLOUR DRAWINGS.

EGYPTIAN HALL, PICCADILLY.

THE collection of drawings to be seen now at the Egyptian Hall is only part of the proof that the establishment of a gallery devoted exclusively to water-colour as distinguished from oil paintings, was indeed a requirement of very many artists; for, with the great space at their disposal, the Committee of Selection were ultimately obliged to reject a large number of acceptable works. The promoters of the exhibition have reason for congratulating themselves on the success of their inceptive experiment; and the present result of it will probably be to astonish those who have hitherto imagined that the two Water-colour Societies, and such opportunities as other institutions may have been able to offer for the purpose, had been nearly sufficient to represent the extent and prevalence of the art.

Although the established societies have in a great measure absorbed the *élite* of the profession,—those who are universally acknowledged to be its ablest exponents,—water-colour painting may be considered the vernacular of British artists generally, and unrestricted by any necessity for becoming a member of, or sharing the abilities attached to, a set,—for here no obligation of the kind is involved. It may be supposed that this beginning is but the promise of something even hotter hereafter, and that many well-known contributors to other exhibitions who do not confine themselves to one medium, may adopt water-colour occasionally, or be induced to practise it more frequently than they yet have done.

Landscape and marine subjects claim the most attention as usual, or even more than is usually the case, for there is little else to divide it; the figure drawings and composed incidents are too few and far between to break the monotony, evenly good as it is. But in this abstract world of its numerous constituent items exists attraction enough for any but those who look for leading instances to cause it, or deprecate the overwhelming ascendancy of one department over the other.

In the serenity of such production, Mr. S. Solomon's Bacchanalian youth, "Antinous Dionysiacus" (239), is very conspicuous, though it is hard to understand why the upper part of the figure should be so very beautiful, admiring recollections of the antique, whilst the legs and lower half of the drawing are so inferior in every respect to it. There is no such drawback to his "Hebrew Woman carrying an Offering to Jerusalem" (175), which emulates the most admirable characteristics of the old masters; and, with another charming study of a head, "Glanco" (369), shares such qualities as few modern painters could endow them with. Of similar excellence are Miss Solomon's "Hypatia" (221), and "A Study" (262).

There is much to commend in M. Jose Tapiro's group of Italian peasants (32), "Ite domum venit Hesperus," which, though disagreeably black in colour, looks real and animated; and in Mr. J. A. Pasquier's more brilliant "Escort" (87); while Mr. G. H. Thomas's "Girl in chaise of a Butterfly" (210) is charming in its way, and Mr. Poynter's "Legend of the Fan" (364), and his "Young Lady catching Gold Fish" (376), if not charming in theirs, are very forcibly drawn and elaborated; but, with Mr. Cave Thomas's "Students of Padua" (462), and Mr. Walter Field's pretty "Water-lilies" (517), are not significant enough to contend with the greater strength of the landscape delineators. Nor, on the other side, is there as much claim for prominent position as would establish a right of precedence; for some of the most satisfactory examples make but a modest appeal in regard to size or striking effect, whilst the more immediately attractive in some cases are the least likely to occupy the attention very long. There would, indeed, be some difficulty in specifying particular works to account for the interest that belongs to a total of more than 300 assistants; and yet we do but justice in epitomising them as a most encouraging and laudable evidence of the correctness of the views of the promoters of the undertaking.

#### THE MANCHESTER ART-WORKMEN'S INDUSTRIAL EXHIBITION.

THIS exhibition was opened on Monday with a very numerous assemblage of friends of the movement, and Sir John Kay Shuttleworth made an interesting and valuable address.

The first suggestion to hold such an exhibition was made by the grainers and decorators of Manchester, and they applied to the Council of the Royal Institution for permission to hold the exhibition in that building. The council at once gave the use of their large and well-lighted picture-galleries gratuitously, desiring to promote any spontaneous movement of this kind in the direction of art production. As the rooms are capable of displaying a considerable number of objects, the original intention of the promoters was enlarged, and they have requested friends to lend their drawings, models, photographs, and other works of the class so as to give additional interest to the collection. The Council of the Institution have also placed the collection of sculpture and paintings at the disposal of the committee of the present exhibition. This collection contains some of the finest works of Etty, Flaxman, Chantrey, and some good specimens of the old and modern masters.

The grainers and decorators, who were the first promoters, are also the chief exhibitors, and some of the specimens of graining and imitations of inlaid marble are excellent specimens of manipulative skill. Some of the best works of this class are by Mr. W. Sutherland, the secretary to the exhibition, embracing a large number of panels in imitation of various woods and marbles, &c.; also some arabesques of good design. Two doors (324 and 325 in the catalogue), by James Bean, W. Beverley, and J. Aspinwall, in the employ of Best, Brothers, of Rochdale, and another door (86), by R. Pollett, in the employ of Mr. Robertson, Manchester, are admirably executed works; and a panel (85) by the latter artist, is an exceedingly beautiful specimen, not only of excellence of skill, but also of design of a high order. Messrs. Greig, Dow, Lomas, Welsh, Robertson, Simmons & Son, also exhibit some good works in graining and decorative painting, and H. Graham contributes some very excellent specimens of polishing. Some carved flowers and fruit, by W. Green, and some wood carvings by J. Barker, of birds, are executed with great taste and skill. A statuette, carved from a block of hard india-rubber, by P. Bohanna, is quite a work of art, and has the effect of bronze.

Some good specimens of parquetry and encaustic tiles are contributed by Mr. Oakden; and some panels and capitals in carton-pierre, of considerable merit, by J. W. Hindshaw.

An interesting collection of marbles is exhibited by Messrs. Patteson, Latham, Macdonald, Greig, Gregory, and Sutherland. There are also specimens of ecclesiastical decorations, Medieval metal work, impressed bricks; a large number of very pretty models of villas and other buildings by Mr. Thwaites; and a remarkably good model of a triple window at Sir Benjamin Heywood's Bank, by W. Palmer.

Many of the objects exhibited have been executed in leisure hours, which might otherwise have been less profitably employed.

Besides those specially named there are many other works of merit which it is impossible for us to notice; but a glance is sufficient to show that there is, within a radius of twenty-five miles from Manchester, a large amount of talent in works of the character above referred to, and there is ample encouragement to those who have come forward to promote, and who have so satisfactorily opened, this exhibition, to repeat the experiment in future years, when no doubt a wider interest will be felt in its success among the art-workmen of the district.

THE CONCENTRATION OF COURTS OF JUSTICE BILL.—RETURNS.—In the House of Lords last week, the Earl of Longford said he wished to call attention to the return of the houses to be removed and the persons who would be displaced. The return only gave the owners and lessees and omitted all notice of the lodgers. He should like to know how many of the working classes would be removed out of their houses. The Lord Chancellor said, he would direct further inquiries to be made relative to the whole of the persons who would be displaced, and obtain an accurate return. The Earl of Shaftesbury said the return was not in accordance with the standing order of the House. It was a perfect mockery.

"THE COLLECTANEA ANTIQUA,"—  
ARCHEOLOGY OF HORTICULTURE,  
AND RECENT ANTIQUARIAN DIS-  
COVERIES.

The sixth volume of Mr. C. Roach Smith's "Collectanea Antiqua," as far as it is published, fully maintains the high character of its predecessors as a contribution to our archaeological literature. Part the Second, now just issued, not only from the variety of its contents, but from the extensive researches displayed therein respecting the subjects discussed, yields a more than usual interest. The article entitled the "Archæology of Horticulture" is brought to a close, and our indifference in these later times to the culture of the vine in England, Wales, and Ireland, as an out-door plant, is fairly rebuked by the overwhelming evidence the author produces of its successful growth, and the extensive manufacture of its produce into wine, within almost a century of our own times.

The Romans, we are informed, under licence from their emperors, extensively cultivated the vine in Britain and elsewhere, especially when Probus had removed the narrow-minded restrictions imposed by Diocletian. There is no doubt but that this people cultivated the "*genus feras*" in their gardens, and beside their villas, in England; and the fig-trees still shadowing the old walls at Reculver, in Kent, ignoring, as we do, the absurd legend which attributes their first cultivation to Julius Cæsar, are most probably the product of some parent trees introduced by the Roman system of horticulture. Sir Robert Atkyn's suggestion that "*vineæ*" meant nothing more than apple orchards, and that the only native vine ever made in England, was cider and perry, seems now completely refuted. Much documentary evidence has been introduced by Mr. Roach Smith from Sir Henry Ellis's "Introduction to Domesday," of entries in that record relating to vineyards, and the amount of their produce.

To the numerous examples therein given, we add another, which has reference to the manor of Chislet, in Kent, once in the possession of the great Monastery of Saint Austin, at Canterbury, and which is set down in Domesday Book as producing annually "*tres arpeni vineæ*." The descriptive paper on Babylon, the old Cairo of Egypt, is a contribution from Mr. Fairholt. This, with the editor's articles on "Roman Leadens Seals," "The Villa at Carisbrook," the "Coins of Caranians," and "Remains of Roman Potteries on the Medway," will well repay the attention of the general reader, as well as that of the antiquary.

The field, however, of recent Anglo-Saxon discoveries in Kent, Cambridgeshire, and in other parts of England, opens up a series of interesting inquiries; and in this part of his "Collectanea," Mr. C. Roach Smith has given us, for the first time, a description of many rare and curious relics now added to our archaeological stores. The Saxon remains not very long since brought to light at Faversham, and in the possession of Mr. Gibbs, have lent increased interest to similar discoveries, and some of the most interesting of these relics have been engraved in the present work.

Golden pendants, caruncles, some of large size set in gold and silver, highly elaborated fibule, mostly of the circular type, ornamented with garnets, lapis lazuli, ivory, and mother-of-pearl, and quaintly incised on their gold-washed surfaces, have lately been found in various localities, together with numerous necklaces of beads of various materials, colours, and devices. Some of these ornaments exhibit considerable skill in their manufacture, and the various rare and beautiful vessels of glass which have lately been discovered have attested, if not a higher civilization than has generally been attributed to the northern nations, a complete mastery of the most delicate manipulation in their production and ornaments. A series of papers are contributed in respect to these and similar objects, and Mr. Roach Smith gives, Plate 31, Fig. 6, an engraving of an iron implement found in a cemetery near Orwell, in Cambridgeshire, the exact use of which the editor confesses himself at a loss to define.

In the absence of the object itself, however, correctly it may have been drawn, it is somewhat hazardous to throw out a suggestion as to the purpose for which it was made; still I think when I assert that this implement was constructed for the purpose of grasping the head of the pieces of metal which complete the structure of those mysterious objects called "clinch-bolts,"

I am not far from a correct solution of its application. With such an implement, the Anglo-Saxon mechanic might hold the square iron rivet, whilst he clinched it with a blow of his hammer on the bolt.

The upper part of the implement might be first used to hold the bolt itself, especially if it were worked, when in a beated state, from the forge. The object itself would thus be a sort of pincers or bolder. This opportunity may be taken to say a few words relative to the clinch-bolts themselves, especially as Mr. C. Roach Smith rightly throws some doubt over the idea that they belonged in any way to the warriors' shields, more especially to those found in this country.

In a grave at Sarr, more than seventy of these objects were found. They lay pretty nearly in equal numbers on each side of the interment. Wood adhered to their entire length between the nut at each end. The heads of the bolts were in most cases strained one way; many, both ways, outwardly, as if they had riveted together their planks of wood, which, when stretched apart, had warped the heads of the bolts out of a parallel. There were, however, no decisive proofs of the existence of these planks, under the supposition that the body had been inserted between them. If so, all remains of this sort of coffin had disappeared.

The opinion that I have arrived at is, that these clinch-bolts were the rivets of two sides of a stretcher, upon which the corpse had been carried to the grave, and either accidentally or designedly left behind, when the earth was thrown in. In most cases I found about eight or ten clinch-bolts on each side of the skeleton. Each bolt would represent a cross piece of wood, perhaps a thin latten, which connected the rods or shafts of the stretcher, and kept them apart; and upon this bed the corpse was borne to the grave. Traces of such cross-pieces might easily have disappeared, when the only evidence that ever remained of the wood of the more solid arms was the small portion preserved, in immediate connexion with the bolts. In some cases, two cross-pieces would suffice, the other rivets, connecting a mattress of lincu, or canvas cloth, stretched out between them.

As the cemeteries of the Anglo-Saxon population were always at some distance from their settlements, and not unfrequently on a wide down or upland, a contrivance like the one suggested must have been used to convey the corpse to the grave. A few of the hodies might have been borne in cars, perhaps those of the rich and influential; but even then, these stretchers would be required for the last offices of interment. The stretcher might in most cases be taken back for future uses, especially where economy was necessary, or when in a shallow grave the corpse could be lowered down by hand, with little difficulty.

In a paper contributed by Mr. Wylie to the "Archæologia," vol. xxvi. part 1, an account is given of the interments of the Alemanni, at Oberflacht, in Suabia. In some instances, given, the dead were deposited on a species of wooden bedstead, or "death couch," which had also a galled roof over it. The stretchers alluded to would form somewhat analogous "death couches," especially if blocks or bars of wood at each end raised them but a few inches above the floor of the grave.

In more than one of the graves at Sarr I distinctly noticed the evidences of transverse bars or blocks of wood, beneath the head and feet of the skeleton.

Many small rectangular rivets, about 1 in. or 1½ in. long, were also found, sometimes with and sometimes without clinch-holts. I am inclined to think these were in some way connected with the contrivance here suggested, the more especially if canvas have been partially used for the bed of the bier.

A brief notice of a "Medical Seal set with an Ancient Gem," concludes part ii. of the "Collectanea Antiqua." The previous paper was on "Remains of Roman Potteries on the Banks of the Medway." The extent of these works appears to have been very considerable. Remains of the red polished ware, commonly called Samian, have been found at Upchurch and Haislow, and what has been discovered has by most antiquaries been considered to have been imported, and to have been used by the potters and their families, or the population they drew around them.

Great quantities, however, of this red ware have for many years been dredged up from the Pan Shoal, nearly opposite Reculver. A vessel

approaching the British shores, laden with this manufacture, is generally supposed to have been wrecked on this bank. Some ingenious arguments, however, may be adduced to show that this shoal was the site of submerged potteries, probably a continuance of the land remaining from Warden Point, in Sheppy, the inroads of the sea on the north-eastern coast of Kent having been constant since the earliest historic period. J. BRENT, JUN., F.S.A.

## CONTINENTAL NEWS.

*Cologne.*—On the 1st of April of last year the works were resumed upon the Northern Tower of the Dom, after remaining untouched for a long time. From that date to the end of the year 21 ft. in height were added, so that the tower at present reaches up to 63 (Dhenish) feet. The walls are here 20 ft. thick, and about 4,000 cubic feet of stone are necessary for every foot in height, which costs nearly 4,500 dollars, or 675l. This enormous thickness will not be reduced until the work is up the third stage of the tower. Great efforts have recently been made to rid the surrounding neighbourhood of a number of old and ugly houses which entirely mar the sight of the splendid pile. The "Colonia" Insurance Company and the Cologne-Minden Railway Company have just set a good example in this respect: they have given up two very large houses immediately under the shadow of the Dom as a free gift to the city, on condition that the site be left free and unencumbered in perpetuity. The corporation is now negotiating for the purchase of some five or six more houses equally "in the way," and when these too shall have been pulled down, no cathedral in Europe will have a grander or more open space around it. In the mean time internal decoration has not been neglected. Freiherr von Waldbot. Bornheim, the representative of one of the oldest noble families on the Rhine, has appealed to the aristocracy of Rhenish Prussia and Westphalia to fill in the remaining windows of the transepts and nave with stained glass; and in answer to this appeal seven windows have lately been filled in at a cost of 210l. per window.

*Vienna.*—In the Sternegasse there is an old nunnery which has been used for years as a police-station. Here a very ancient underground chapel has been discovered; it is circular on plan, having an altar in a niche. On examination the altar was found to stand over a vault from which a coffin had evidently been removed. Subsequent research has elicited that Eleonore, wife of the Emperor Ferdinand II, was buried here, but removed to the cathedral of St. Stephen in 1782, when the sisterhood dispersed. Frescoes cover the walls, and there are several statues of the Virgin, Joseph, &c. Mr. Joseph Lipert, architect, of this city, has just been intrusted with the restoration of the Cathedral Church of Presburg, where for centuries the Kings of Hungary were crowned. The choir, with its chapels, will be restored first; the walls will be painted and picked out in colour, and the windows, nine in number, will receive some very rich stained glass.

*Wartburg.*—Even the most hurried traveller, rushing on to Leipzig after crossing the Rhine, must have noticed Eisenach, at the entrance to the Thuringian Forest, with the Wartburg towering above. It was at Eisenach where Martin Luther begged his bread from door to door, singing carols and ballads; it was, whilst hidden in the Wartburg in after years, where he translated the Bible, that he threw the inkstand at the devil! But it was long before this, in the days of the Minnesingers, that Lohengrin and Wolfram von Eschenbach competed for the laurel-wreath. Since the extension of the old castle, in the twelfth century, little or nothing was done until three years ago, since which time the work of restoration has been steadily progressing. The fine old hall, with its round-arched windows,—the identical place where the competitive trials of the skill of the Troubadours were held,—is now thoroughly restored; and the walls under the windows, which are high up, have been covered with frescoes by artists from Dresden and Dusseldorf. The subjects represent a variety of incidents of Mediaeval local interest. From the top of a barbican at the angle of the hall, one of the most lovely views over the Thuringian Forest is gained. In crossing the yard in order to reach the cell of Luther, we pass the heargarden; and there, sure enough, a live hearth is kept to this very day. The lower part of the house once occupied by Luther was, until lately,

a small restaurant. This has now been removed to a building especially raised for that purpose, and thus the old house will be once more worthy of the memory of the great man who lived there under the protection of the Comte Palatine. The chamber occupied by the Reformer is *in statu quo* to this day,—table, bed, and all, even the ink-spot on the wall.

#### FROM FRANCE.

**Names of Boulevards.**—A sweeping change has taken place, by an order of the Prefect of the Seine, in the nomenclature of many of the Paris boulevards. In the twelfth arrondissement the boulevards De la Rapée, Charenton, and Saint Mandé are to be absorbed by the extensions of those of Bercy, Reuilly, and Picpus. Between the twentieth and eleventh arrondissements the boulevards Montreuil, Fontarabie, and Des Trois Couronnes are all to be under the denomination of the boulevards De Charonne and Belleville; also the boulevard Montmartre will absorb the names of boulevards d'Amantiers and d'Aulny; and so throughout a long list. The rage for change may go too far.

**Lime Bricks.**—At Lyons, on the left bank of the Rhone, are the several brick and lime kilns of La Guillotière, Saint Fond, Charpenne, and Vaulx-en-Velin, where bricks called those of "Les Rivières" are made of a sandy clay containing thirty-one to thirty-two per cent. of carbamate of lime finely disseminated through the mass. These bricks have, as the ancient Lyonnese buildings testify, considerable durability: that this should be the case is extraordinary when the amount of lime is taken into consideration; but the process, as explained by the *Annales de la Société des Sciences Industrielles de Lyon*, by which the bricks are hardened, fully accounts for this durability. This consists in drawing the bricks from the kiln as soon as they are burned, and before they are quite cooled, and throwing water over them by sprinkling. They harden and set immediately as soon as wetted, whereas if left to cool alone they would crumble to powder. The calcined lime has absorbed the water, and the brick has become one of cement.

**Vicinal Railways.**—Several projects of vicinal railways have been lately surveyed in France. In the department of the Somme two lines are proposed bifurcating at Frévent; one is to run to Doullens and Aumiens, and another to Abbeville by Auxi-le-Château and Saint Riquier; a third branch is to start from Hesdin to Crotoy, passing through Crécy and Rue. Surveys for several other lines have been authorized by the Minister of Public Works.

**The Sun a Motive Power.**—M. Mouchot having called the attention of the Academy of Science to the effects of confined air heated by the sun as a motive power, Captain Deliancourt, commandant of the garrison of Salda, in Algeria, writes to the *Science pour Tous*, saying that he invented and set to work a solar pump in 1860. It consisted of a box hermetically sealed, with the exception of two pipes,—one leading down a well, and fitted with a valve opening upwards; and another, with a valve leading outwards, through which the water flowed whenever it was required. A thin sheet of metal blackened surmounted the solar pump. When the air in the reservoirs became heated and rarefaction took place, the air escaped freely by the second pipe. On cold supervening contraction of the air took place, and the water rose in the first tube from the well into the chamber. This was expelled by the second pipe on application of heat again, and so on alternately.

#### THE PARIS CIRCULAR RAILWAY.

In our number for the 31st of December last, p. 950, we described the works of the Paris Circular Railway, from the Quai de Javill to the Route de Chatillon, the portion not yet commenced. The remaining section, from the Route de Chatillon as far as the bridge over the Seine at Bercy, is in hand, and will complete the circle of this great work. Between the Route de Chatillon and the Avenue d'Orleans, the line is in cutting, passing under the latter by a bridge, 290 ft. 6 in. span, which will carry the station building, with a frontage of 65 ft. 7 in. The sides of this cutting are faced with retaining walls, in mosaic masonry, carefully pointed, with considerable batter, and supported by counterforts. In some places these walls pass through ancient quarries, and it is necessary to build up piers from the

solid to support them. On each side of these subterranean works of consolidation, a gallery of inspection, a metre wide, has been provided for the service of the quarries.\* Beyond the Avenue d'Orleans the line continues in cutting as far as the *Chemin Vert*, at a depth of 36 ft. In this cutting a loop-line branches off to the Sceaux Railway, just before the commencement of the Montrouge Tunnel, at the *Chemin Vert*. This tunnel, the longest on the circular railway, is 987½ yards long, and is carried under the heights of Montsouris, sometimes on solid ground, but oftener over chasms, requiring vast substructures. It passes at a level of 69 ft. under the Sceaux Railway, beyond which it ends, and a cutting, in curve, 52½ ft. deep, succeeds, over which the Arcueil aqueduct is carried by a light series of arches.† The Valley of the Bièvre is next passed by a long embankment, extending to beyond the Rue de Bel-Air, under which are two semicircular arches, one for the *Chemin de la Poterne-des-Penpliers*, together with the lowest branch of the Bièvre stream, and the other for the east branch. Beyond this valley an excavation cuts through the ancient hamlet of Bel-Air, and over which two bridges, 29 ft. 6 in. span, carry the Rues de Bel-Air and du Moulin-de-la-Pointe. Further on, the line passes under the Route d'Italie, 147 ft. 8 in. wide, by a bridge 12 ft. 8 in. span. Here will be the Maison-Blanche Station, the platforms being arranged between the Routes d'Italie and de Choisy-le-Roi. The Route d'Ivry passes over the cutting by a bridge, the superstructure of which is 36 ft. over the rails. Beyond the Butte des Moulins, the ground descending rapidly towards the Seine, a considerable embankment follows the cutting, and the Boulevard de Vitry is crossed by a girder-bridge, of which the abutments have been terminated. Farther on, the line crosses over the Orleans Railway, by a bridge, 147 ft. 8 in. span. From this point to the Pont Neuf, or compound bridge, on which it crosses the Seine to join the northern half-circle, the line is supported on heavy retaining-walls of considerable height.

#### THE MANAGEMENT OF SEWAGE.†

The system for the management and utilization of sewage recommended in Mr. Menzies's work, he states, has been to him a matter of long and serious study. It comprises details applicable to cottages, dwelling-houses, public buildings, and towns; with suggestions relative to the arterial drainage of the country, and the water supply of rivers. Mr. Menzies is deputy surveyor of Windsor Forest and Park; and has made many experiments during fifteen years that the Crown property at Windsor has been under his care; and during the last few years of the Prince Consort's life Mr. Menzies had frequent opportunities of hearing the Prince express his views on this subject, to which His Royal Highness had given earnest attention. Readers of the *Builder* will recollect what was said in our pages as to the Prince's plan of sewage filtration by an upward process. Mr. Menzies's system comprises this process as the best possible mode of preparing the sewage, either of towns or of private establishments, for use upon the land, both as a liquid and as a solid, or compost.

The author seeks to show that, when properly carried out, the conveying of sewage by suspension in water is the cleanest and probably the cheapest for the occupants of buildings, and the most beneficial for utilization in the country; that all the portions of houses set aside for closets and foul water should be on the cold or north side; that the families should live on the warmest side; that from a sanitary point of view both these arrangements are best; that there is no better filtering or mixing medium than house-ashes, which are always abundant in the neighbourhood of human dwellings; that the

\* On the 4th and 8th ult., a general visit, under the direction of M. Lesmélery, mining engineer, in the service of the department of the Seine, to the Catacombs took place. Many strangers, admitted by ticket, accompanied the authorities. The rendezvous was in the courtyard of the octroi building, near the ancient Barrière d'Enfer, at 2.30 p.m., when the company, provided with lights, descended. They emerged, after a visit of rather more than an hour to this ancient bone-house, at the staircase of La Tombe-Issoire, near the route d'Orleans.

† This conduit was constructed under the Emperor Julien, to supply the Thermes palace, but was destroyed during the Norman invasion. It was rebuilt in the reign of Henri IV.

‡ "A Treatise on the Sanitary Management and Utilization of Sewage." By William Menzies. Illustrated. London: Longman & Co. 1865.

filtering process, which simplifies the application of the liquid overflow, separates the solid matter, which can so much more easily be removed into the interior of the country, where the want of manure is every day more felt; while the filtered liquid, which is much less portable, can be applied more beneficially near the towns; that there is no better purpose to which this liquid can be applied than growing grass and vegetables, and that these are the most desirable crops to obtain; that the kind of grass grown with this liquid is best adapted for milk-cows, which again are so valuable near a town; that the exclusion of the rainwater from the sewage-drains is healthful for the towns and essential to the perfect utilization of the sewage in the fields; and also that, as many of our towns now draw great part of their water-supply from the rivers, the rainwater of the lands lying in the upper portions of those rivers should be allowed to pass into the stream unpolluted by a mixture of what is not only noxious but very injurious to health.

Mr. Menzies, for various reasons, strenuously advises the separation of the rain-fall from the sewage, both in towns and in separate establishments; and he believes that if the plans he is advocating are studied and carried out from the beginning in the case of any town or large building, this separation of the rain-water from the sewage will be the most economical, because, at a short distance from a house, rainwater may be discharged into an open ditch or water-course of any kind; whereas, if it be mixed with the sewage, the whole must be conducted to a greater distance from the house in larger pipes than would be required for the sewage alone, and consequently at greater expense.

Flushing of the drains, as he observes, is essential, as the water used for the ordinary purposes of water-closets is not sufficient thoroughly to sweep out everything that is in the pipes. Ventilation of the drains is elaborately considered in his book with reference to rain-water pipes, closet apparatus, house-windows, &c. The water-closet system is preferred by him to earth-closets, iron pans, &c.

The author's reasons for making upward filtration a feature in his system may give in his own words:—

"The sewage of any building, unmix'd with rain or surface-water, having been conducted away from the house in the manner I have described, the next step is to deal with it; and here we must note some of its peculiarities.

For the first three days after sewage is deposited in water, the solid parts are lighter than water, and float on the surface apparently in their original state. After that time they gradually dissolve, a considerable part of their ingredients becoming embodied in the water, and the residue falling to the bottom, where it remains about a fortnight; after which period a portion of what has sunk rises again, having formed some new combination, and floats in the shape of a very pasty substance. This double action has presented no ordinary difficulty, and made all deposit-tanks quite useless. It is essential to deal both with the solid and liquid parts during that fortnight, little need be said about cesspools, as they are universally acknowledged to be highly dangerous, and should on sanitary grounds be done away with at once."

It is not prudent to attempt to reduce the sewage to a pulpy mass by agitators, as this involves machinery and risk of nuisance, and some of the ingredients I have mentioned cannot be broken up.

The solid parts of sewage in dry weather, if allowed to discharge into a river, will float along and be little changed in their character after being conveyed three miles in a running stream which has a smooth bottom, and travelling at the rate of two or three miles an hour. This is important in a legal aspect, as bearing on the subject of nuisances.

The advisable method, therefore, is to pass the sewage through filters or straining tanks acting upon the upward or ascending system; so that when, after the third day, the solid parts fall to the bottom, they may get in below something which will prevent them from rising the second time. No filtration acting by a downward or side process will be so successful, because the very action of filtering clogs the pores through which the liquid has to pass. In the upward process, however, we have two forces acting in opposite directions,—namely, the solid matter descending under the power of gravitation, and by the force of the current; the liquid ascending through the beds to the level of the incoming pipe. The construction of these filters requires much consideration of details.

Every engineer adhering to the principle of upward filtration must work out the remainder for himself. It is also essential that the filter should be watertight.

To the Prince Consort belongs the entire merit of first perceiving the principle of upward filtration, and designing such a tank as would continue to act, and before he pointed it out made many attempts at filtering sewage-matter, but all had failed. In the spring of 1853 the Prince Consort sketched in my note-book the only plan upon which he was satisfied these tanks would remain efficient; and much subsequent experience has proved that he was right, and had opened the way for a great public benefit, for nothing satisfactory can be done without them. The first was built at Bourne about eight or ten years ago. Since then they have been much improved, and five or six are now in regular operation, not one of which has failed.

The general expense of one for a family, such as I have shown, would be from 12l. to 15l., according to the loca-

ity. I would here also remark that unless the rain and surface water are kept apart from the sewage, filtration is in most cases impracticable. For large towns it is absolutely so.

Mr. Mensies is of opinion that the course to be followed in regard to the disposal of sewage is no longer a matter of doubt or discussion;—that the time has come to go to work in earnest;—and that the whole of this subject, not less than the Smoke-prevention Bill, the Chemical Nuisance Bill, and many others of a similar class, deserves to be dealt with not as a local but as a great national question.

#### THE BUILDING TRADES.

It is to be hoped the Midland arrangement between the masters and the men will ere long extend to other districts throughout the country. Meantime, disputes are still going on, as at Leeds, Sheffield, Bristol, and elsewhere. At Leeds, a meeting of the operative joiners and carpenters has been held, in consequence of the West Riding Association of Master Builders having refused the terms proposed by the men, namely, an advance in the wages from 5½d. to 6d. an hour, 56 hours to constitute a week's work; and an alteration in one of the present rules, by which men working out of doors would be enabled to reach the pay-table on Saturday at twelve o'clock, and on other days at half-past five. The meeting resolved that both society and non-society men should co-operate to negotiate uncompromisingly with the employers. At Sheffield, a numerously attended meeting of operative joiners has been held, to determine what steps should be taken to secure an advance of wages. After considerable discussion, it was unanimously resolved to ask for an advance of 3s. per week during the summer months, and 1s. during winter, the latter period to begin with November and end with February. It was also resolved to forward copies of the resolutions to the employers, and to express the willingness of the operatives to confer with them on the subject at any convenient time. Last year a similar movement was made, which resulted in a strike. A similar movement is likely to be made by the journeyman painters. At Bristol, the demand of a rise in wages from 5½d. to 6d. an hour has been renewed by the carpenters and joiners, and a strike threatened if the terms be not agreed to by the 6th of March.

We are glad, however, to learn that the desire for arbitration between masters and men is extending. On the 22nd, a meeting of the Stourbridge and district branch of the General Builders' Association, met the operatives of each branch of the building trade, at the lecture-room of the Mechanics' and Working Men's Institute. The chair was taken by Mr. William Akroyd. The object of the meeting, as set forth by advertisement, was to appoint delegates from masters and operatives of the district, in equal numbers, who shall meet together at an early day, to endeavour to come to an agreement to settle all local trade disputes by local arbitration, instead of unhappy and disastrous strikes, and to discuss and arrange local rules for the better guidance of masters and men.

The Chairman having opened the meeting, it was resolved,—

"That arbitration is the best mode of settling disputes between masters and men."

For the carpenters there were appointed Messrs. Thomas Preece & Shirley Hall, and for the Masters, Messrs. Joseph Chapman & J. W. Hfe.

Mr. Pagett said the bricklayers, for the present, declined to take any part in the proposed court. For the bricklayers' labourers, Martin McAleale and Patrick Calligan were appointed by the operatives, and Messrs. C. Harris & William Brettle on behalf of the employers. For the painters and plumbers, Messrs J. Allsop, sen., and Mr. Clare were appointed for employers, and Messrs. Joseph Rutter & R. Meredith for the men.

The Chairman said that the formal business was nearly over, and he must remind them that the persons they had appointed they must regard as a ministry, and abide by the decisions given, and they might be assured that good would result. He trusted that a good feeling would spring up and continue, and that all would work for the public good. He thought before separating they should agree to a general rule, and he had drawn one, which he trusted they would sign in their unanimous accord. To the following was then put and carried:—

"All trade disputes shall be settled by an arbitration court, composed of delegates appointed by masters and

men in equal numbers, with a chairman not engaged in the building trade, whose vote on any question in which the vote of the delegates shall be even, shall be final.

Sir,—The statement respecting the plasterers' strike in Newcastle is not correct. The masters referred to asked their men to accept the same wages and work the same hours as in previous winters, which they refused to do. No new conditions whatever were attempted to be imposed, and they were offered summer wages again in twelve weeks. The advance takes place on Monday next, and as their resolution not to go to work, &c., has been wisely rescinded, the strike will then be at an end.

W. B. WILKINSON & Co.

#### THE NUMBERING OF HOUSES IN LONDON.

In reply to "An Antiquary," who lately addressed to us some queries respecting the numbering of London houses (vol. 23, p. 69), a correspondent, J. H., reminds us that Mr. Cunningham, in his Handbook, fixes the date at which houses were first numbered in London as June, 1764, and mentions Burlington-street as the first, and Lincoln's-inn-fields as the second place where numbering was introduced. This, however, is scarcely correct, because, in Hutton's "New View of London," 1708, it is pointed out, when speaking of Prescot-street, Goodman's Fields, that, "instead of signs, the houses there are distinguished by numbers, as the staircases in the Inns of Court and Chancery." J. H. mentions the following advertisement in the Spectator, April 29, 1718:—"In George-street, in York-buildings, in the Strand, the third house on the right hand, No. 3 being over the door," &c.

#### MANCHESTER ASSIZE COURTS.

The great hall in the new Manchester Assize Courts, represented by the accompanying engraving, is a remarkably fine apartment, similar in character to Westminster Hall, though much less in size. Its length, from north to south, is 100 ft.; its breadth, 48½ ft.; and its height, 75 ft. to the apex of the roof. The flooring is formed of tiles, stone, and marble, well designed by the architect. The hall is lighted at each end by a large window. That on the north has seven lights, is 32 ft. high and 18 ft. wide; that on the south side has six lights, and is 30 ft. by 16 ft. The heads of the windows are filled with rich tracery. Both windows are filled with stained glass. The north window contains in the centre light a colossal figure, representing King John holding in his hand the great charter; the other compartments have also reference to the same great era in English history, and the window has at the bottom these words, extracted from the Charter:—"To none will we sell, to none will we deny, to none will we delay, right or justice." The south window contains the arms of England, Ireland, and Scotland, the Duchy of Lancaster, and the several towns in the Salford hundred. Below the north window is a spacious recess, used as a book-stall, a telegraph office, and as a station for messengers. Three handsome moulded and pointed doorways, with richly-traceried heads, situate exactly opposite the doorways from the portico, lead to a vestibule giving access to the judges' retiring-rooms. The arched entrance to this vestibule is flanked by passages, also arched, leading to the tower and to the civil and criminal courts. The passages are lighted by three windows filled with stained glass, representing some mysteries in heraldry. On the right and left of the west or main entrance are staircases, communicating with the grand jury-room, the barristers' refreshment-room; and at the ends of the western side of the hall there are communications with the refreshment-room in the basement.

The roof of the hall is of open timber work, of massive construction, and high pitched. It rises from wooden wall-brackets, the feet of which rest on stone-moulded corbels, springing from the wall in boldly-relieved carved foliage. The spandrels of these wall-brackets are filled in with plate-pierced tracery, of geometrical design. Grotesques are carved on the projecting ends of the brackets, from which hang coronae of rich design. The timbers of the roof have been decorated successfully in colours, by Mr. Crace, of London.

The wall-brackets, already mentioned, support lattice timber trusses, 16½ ft. in depth, running the whole length of the hall on each side; these trusses again carrying principals of the ordinary king-post-truss kind, which support the upper part of the roof.

Mr. Waterhouse, we may remind our readers, is the architect of the building; and when his design was selected for execution, we gave an

exterior view of the proposed buildings and plans. In carrying out the designs, the arrangements have been somewhat altered, and we have thought it desirable to give plans of the building as it now stands. Admission to the Courts, it will be seen, can be obtained from the Great Hall, by a direct entrance or by the corridors which run round them. The Crown Court is on the right, or at the south end, and the Nisi Prius Court to the left, or the north end. The courts are similar in size and in their general arrangements. The walls are panelled with oak to a certain height. Each court is 59 ft. by 45 ft., and lofty. The Crown Court is lighted by single lancet windows, with cusped heads, divided by piers and shafts of lime stone. The Nisi Prius Court is lighted by eight triplet lights, with traceried heads. The ceilings are of oak, and nearly flat. The benches are under canopies, and in the wall over the canopies are niches for statuary. The judges, as they sit in their respective courts, are *dos-à-dos*. Between the two courts is a consulting-room for the judges. We have pointed out, however, by references, the appropriation of all the apartments. To go from one court to the other, the judges pass under a grained vestibule, the piers of which support the tower. In each court, directly opposite the judge's bench, is a gallery for ladies. That in the Crown Court is in six bays, and the arcade is supported by coupled granite shafts, 8 in. in diameter. The arcade in the Nisi Prius Court is of five arches, supported on granite pillars, 16 in. in diameter, having sculptured capitals.

The Sheriff's Court is on the south side of the hall, opposite the Criminal Court, from which it is only separated by a corridor. It is much smaller than the other courts, being only 4 ft. by 26 ft. The walls are surmounted by a string course and cornice, between which, and forming the frieze, are encaustic tiles. This court is lighted from the roof, which is of open timbers, and supported on moulded stone corbels.

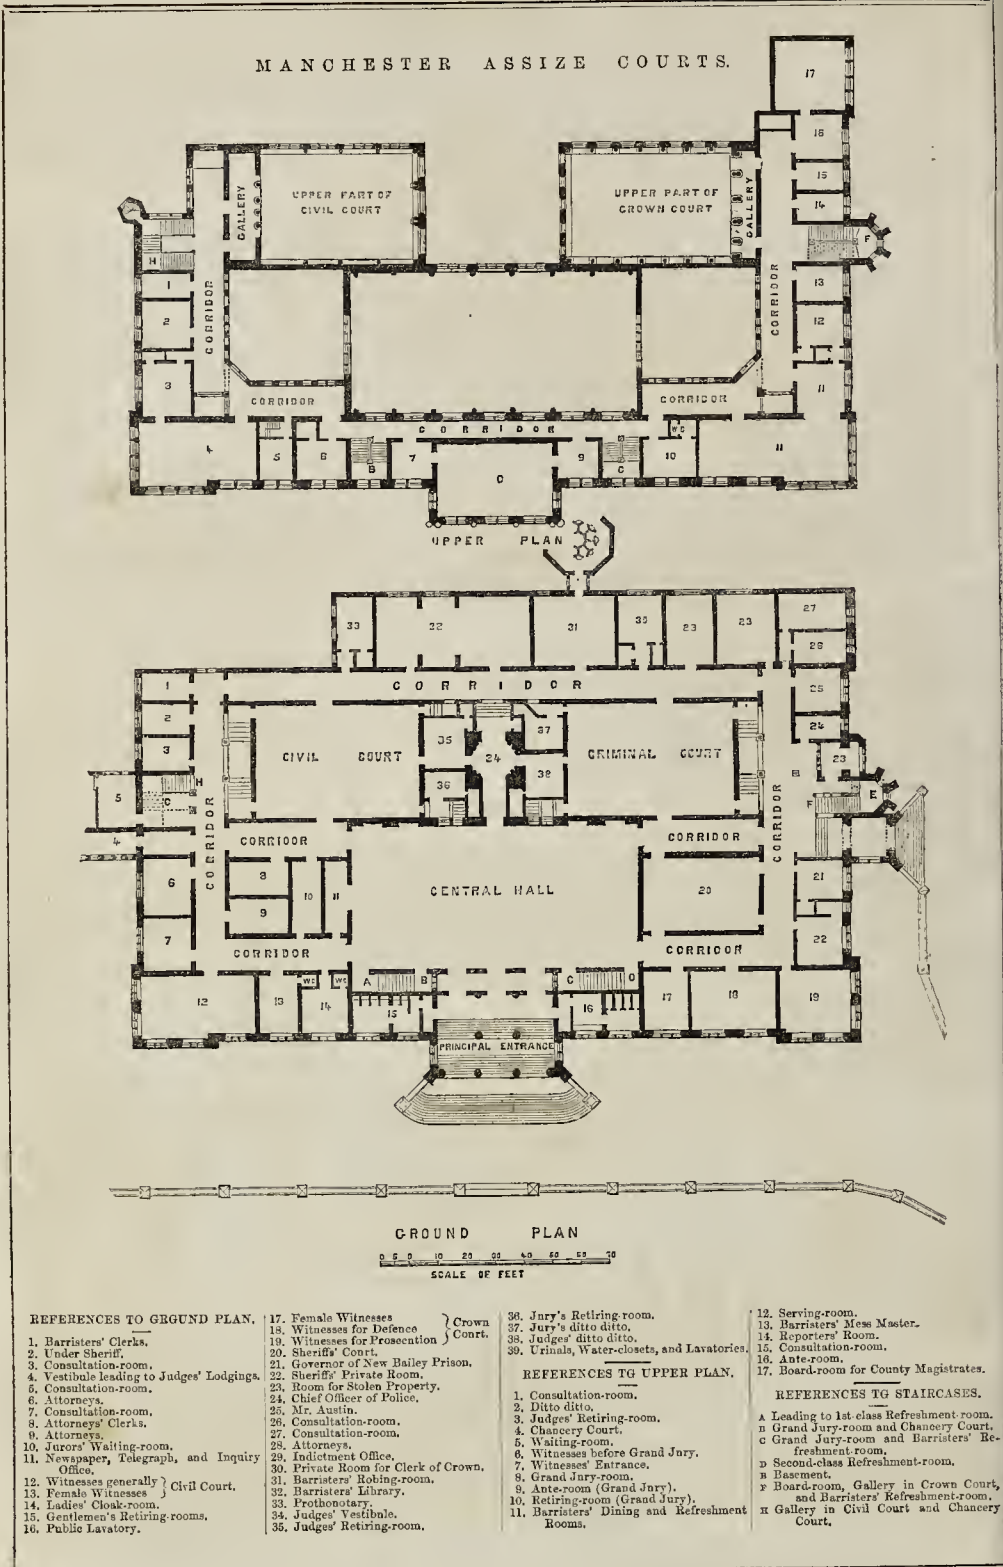

The arrangements of the courts have been found remarkably satisfactory in actual use.

Our engravings give also two views of the "Judges' Lodgings," placed between the north side of the courts and Colham-street, the principal front being towards Great Ducie-street. This building covers an area of 92 ft. by 90 ft., and is three stories high in front, and four at the back. The architecture is in keeping with that of the courts, and the ornamentation is also on a similar scale of elegance. Between the two buildings is a screened wall, in which is a massive entrance gateway. In the panel over this gateway is to be placed a bas-relief, representing the pageant of Solomon. There is a corridor of communication with the courts, lighted from the courtyard by eight beautiful lancet windows. The interior arrangements of the lodgings are handsome. From the courtyard there is an entrance through a vestibule to a spacious hall, in which is a stone screen in four bays at the bottom of the main staircase. The shafts of the screen are of serpentine marble, and the capitals and spandrels are splendidly carved. The staircase is wide, is constructed of pitch pine and a pierced balustrade of geometrical design. The dining, drawing, and breakfast rooms are on the first floor, where are also the offices of the house-keeper and butler, and the judges' associates. The drawing-room is a splendid apartment, 40 ft. by 20 ft., and has an oriel window, and a three-light traceried window, both looking towards Great Ducie-street. The dining-room is 35 ft. by 20 ft., the ceiling being of timber beams on carved stone corbels.

We may add, as all concerned may be proud of having been connected with this work, that the contractor for the foundations was Mr. R. Neill; for the superstructure, Mr. Bramall; statuary, Mr. Woolner; decorative ironwork by Messrs. Skidmore & Co., Coventry; stained glass, by Edmondson & Son; Heaton, Butler, & Bayne; and Lavers & Barrard; tiles were supplied by T. Oakden, Manchester; wood carving, by Banks; stone carving, by Herr Imhoff, O'Shea, Whelan, and Green; ventilating and heating, by Messrs. Haden & Son, Trowbridge; asphaltum, by Walters; the clerk of the works was Mr. Littler. The materials used in the building are, for the exterior, Darley Dale stone and grey Dalbeattie granite; for the interior, Yorkshire stone, magnesian limestone, Stoney stone, grey freestone from the Forest of Dean, and red granite (for columns) from Peterhead.\*

\* We may use this opportunity to mention that Mr. Heywood (Deansgate, Manchester) has published a very clear and sensible little "Handbook to the Assize Courts," by Mr. Pockwell.

## ARCHITECTURAL SCULPTURE AND THE PRIZE SCHEME.

Knowing that your pages are always open to any subject which may have for its aim the advancement of art—even in its most humble capacity—I am led to venture a few remarks upon the recent distribution of prizes to art-workmen by the council of the Architectural Museum.

It is impossible to over-estimate the amount of good diffused among art-workmen generally by these annual exhibitions: not only do they excite a spirit of healthy rivalry for excellence among the whole body, but they tend, more than any other influence could do, to bring our studies into their proper channel. And in these days, when so much is produced, and so much of that production is spurious and vile, we surely cannot be too thankful to those who generously point out the way by which we may achieve a pure and wholesome feeling for that which is pure and truthful in art.

But while these advantages are offered to almost every grade, I am somewhat puzzled to discover why the architectural sculptor should be expelled from the catalogue of good things. The engraver, the wood carver, the chaser, the enameller on silver or copper, are thought worthy to be taken under the protecting patronage of the council, while the architectural sculptor is left entirely "out in the cold"—who, though last to be considered, is certainly not the least important of those enumerated above. In fact, his importance is constantly admitted, and his efficiency constantly questioned by all those most intimately connected with him. Then, since both are confessed, why are we expelled from the good guidance of the council of the Architectural Museum? It cannot be that we are already sufficiently advanced in our art to proceed without farther instruction; for we have only to look round to see at a glance that in many most essential points we are most lamentably deficient. No one can deny that there is for the most part a meanness and a barrenness of thought about many of our works that require a thorough reformation. We have certainly picked up in a vagabond sort of way a few wandering ideas of the uses of conventional forms in ornament; and these are applied alike to the church and the theatre, the shop façade and the nobleman's villa, but how often do we look in vain for the slightest indication of the feeling of symbolism that should adapt the work to its purpose? On the contrary, if we glance at the works of the Medival sculptors we find them actually teeming with life and illustration; as legible to read as a story-book,—telling their tale and pointing to its moral. Animals, birds, and incidents in human life, are used in conjunction with good ornament to impress upon the beholder the feelings most natural to their locality. Everything seems studied for its place, and nothing is found out of place. And who can tell how much good feeling and morality the silent eloquence of these old sculptures may have taught the many generations who have gazed upon them?

But these arguments are not new. They have been urged over and over again by every architect who thinks seriously upon the matter; and some have even gone so far as to say, while lamenting over our shortcomings, that they dare not trust us with the free use of animals and the human figure in our carvings, lest we should make a hotch of their whole work; which the sagacious argument reminds one forcibly of the cautious old lady who forbade her sons entering the water until they had learned to swim.

Knowing these things, and feeling with many others the unpleasantness of our deficiency, I wish humbly to suggest that we should be allowed, in common with the other branches of art-industry, to partake of the privileges offered by the council; and I think the sequel will prove that architectural sculptors, as a body, will not be found in the rear of their brother competitors. Our work is certainly of sufficient importance to be considered, and I trust that consideration will be given. If we look at the matter in a broad light, I think we shall find that our position and cultivation should be the first thought of every one who wishes to see our countrymen hear themselves with credit in comparison with their neighbours; for, in the majority of cases, our work is not hidden from view. It is out in the broad highway,—open to the criticism of every cosmopolitan who may visit our land; it meets him at every turn,—in the hall of public amusement and the temple of public worship; he can

criticise it freely as he passes along the streets, and thereby form the standard of his opinion of the competency or incompetency of the whole art-students of England.

Perhaps some may think I wish to claim for ourselves too high a place; but I state a simple fact when I say that ours is the most public of all decorative arts; and that, is, therefore, the most potent reason why we should have every means of instruction thrown open to us. The wood-carver, the gem engraver, the enameller and silver-chaser, may produce most skillful and beautiful works; but, for the most part, they are no sooner executed than they are lost to view,—hurried to that "bonne from which no traveller returns," a private collection. Of them it may be truly said,—

"Full many a gem of pure ray serene,  
Our deep unfathom'd country masons bear,  
And many a flower is carried to hide unseen,  
And waste its beauty on an easy-chair."

But I fear I am trespassing too much upon your valuable space; and, in conclusion, I humbly venture to hope that we may yet fall into the good graces of those who so generously offer their patronage and aid to others, and trust that we may not see another competition for prizes at South Kensington that shall leave out architectural sculpture as an "unconsidered trifle."

R—DD—S.

\* Prizes were offered for stone-carving by the Society of Arts recently; but the response was small.—Ed.

## ORNAMENTED AND STAINED GLASS.\*

The stained windows of the Decorated or Second-Pointed churches retain in some measure the mosaic character of those of the thirteenth century; but, as there is a tendency in all manufactures to economize labour, so it was in the fourteenth century. The glass was used in much larger pieces, and was not quite so thick as before; and, in the early part of the century, the invention of staining white glass, yellow very much simplified the manipulation, and gave an unmistakable character of its own to the productions of the fourteenth century, which gradually partook more of the character of translucent paintings than of mosaics.

I am not aware of any account of the first introduction of yellow stain. It produced a most striking result, and was easy of application, and it has been freely used to the present day. It appears that if silver, or any combination of silver, is in contact with glass, and exposed to a full red heat, the silver enters the minute pores of the surface, changing the white glass to yellow, and blue glass to green; the surface of the glass being, to all appearance, unaltered. We do not know how the ancients applied the silver, but the fact that silver would stain glass being known, many ways of applying it would suggest themselves.

The union of stained glass with architecture has always been most close; the alterations in the one have been accompanied by alterations in the other. The greater freedom of design and approach to naturalism in the sculptures and wall decorations of the fourteenth century may also be traced in the stained glass of that period.

There is no finer example of Second-Pointed glass than that in the chapel of Merton College, Oxford. A range of subjects under short canopies are placed upon white glass, on which is traced the most exquisite linear ornament; and this range of highly-coloured subjects is carried entirely round the building, forming a glorious string-course of jewelry.

During the period of Third-Pointed architecture, stained windows were still retained as the most necessary enrichment. A new style of design, however, more in character with the alteration in the style of architecture, was introduced. The mosaic system of construction, and the rich colouring of the two preceding centuries, was laid aside, to be reproduced in our own day. The system of firing and leading the glass was of course retained; but the whole effort of the fifteenth century artists was to produce a sily effect of colouring. There was an excessive proportion of white glass in all their windows, and the use of yellow stain on white glass was the principal aim of their colourists. We must do them the justice to say that the manipulation was most painstaking, amounting in many instances, especially in the early part of the century, to microscopic care. There is a fine

and well-coloured Third-Pointed window in the Beauchamp Chapel, Warwick, but it is an exceptional work. It was in this, the fifteenth century, that Gothic architecture, after living in strength for ten centuries, began its decline, and towards the commencement of the sixteenth century altogether disappeared; and stained glass, as a decorative art, shared, like a faithful servant, its decline of fortune.

In the sixteenth century there arose in Germany a new style of glass-painting, named by Winston the Cinque-cento style, from the introduction of Italian or Renaissance feeling into the ornamental parts of the windows. The Italians, although loving colour, always preferred it of the opaque sort, mosaics and frescoes, and rarely, if ever, filled their windows with stained glass. They, however, set the fashion to the world, in the sixteenth century, of Faldian architecture; and their ornamentation materially influenced the designs of northern windows. The church of Sainte Jacques, at Liège, and the chapel of the Miraculous Sacrament at Brussels, contain the most marked and best-known painted windows of foreign sixteenth century work. They both seem to be the work of the same hands, the ornamental work, at least, bearing the same detestable character. The windows of King's College, Cambridge, are the best English productions of the sixteenth century; and those in the apse of Lichfield Cathedral, the east windows of St. George's, Hanover-square, and of Fairford Church, Gloucestershire, are the best known foreign works in England. However good in drawing, and however skillful in manipulation the works of the sixteenth century may be, there is but little, if any, consistency between them and the architecture, which was treated as a mere framework for their exhibition.

The productions of the seventeenth and part of the eighteenth century were clumsy attempts at picture-making, and are not worth speaking of. The dawn of the revival of the art of glass-painting in England was about 1750. Sir Joshua Reynolds's window in New College, Oxford, painted by Jarvis, of York, in 1780, is the type of eighteenth century work: it is painted with semi-transparent enamel, on squares of white glass. There is a little yellow stain, but no coloured glass, if I remember rightly. For nearly seventy years this attempt at transparent picture-making prevailed; the introduction of raw pot metal blue, and a little ruby glass, being an occasional improvement.

Ruby glass in 1820 was so prized that in some shops it was wrapped up in flannel for careful keeping; it can now be bought for 1s. a foot.

The introduction of stained-glass windows similar in character to those of the thirteenth and fourteenth century is due to Pugin, who stirred up the few glass-painters who, previous to this time, were engaged in the production of coloured windows for staircases, lull-lamps, and, as an occasional higher flight, a church window. He gave commissions for windows to each of them in turn, but eventually induced Mr. Hardman, of Birmingham, then a metal-worker, to establish a business of glass-painting in connexion with his metal-works. I need scarcely add that from small beginnings a most extensive business has for a long time been carried on there.

It is due to Pugin's memory to state, that his great energy and liberal dealing are now frequently spoken of among the surviving glass-painters of his time. Mr. Willement was engaged upon the same pursuit at the same period, but his works were principally heraldic.

The manufacture of stained windows, as now practised, resembles that of the fourteenth more than of the thirteenth century; but it has been greatly facilitated by the use of the diamond for cutting the glass, and by the use of iron kilns in place of those of clay.

This is the history of the production of a modern stained window, and it will apply to ninety cases out of a hundred. The person who wants one usually goes about as he would for a tomb-stone, and for a similar purpose. The best advice is obtained as to where it can be had, or he has seen some window that has met his fancy, and he goes to the place where similar work can be supplied. In course of time a coloured drawing on a small scale is made, embodying his ideas; if approved, and the order given, the glass-painter commences his work. Instead of a board the size of the window, used by the ancient glass-painters (large sheets of paper not then being invented), a full-sized drawing is made on thick paper: this is called a cartoon. A length of common glazed lining-

\* See p. 98, ante.

muslin, the same as ladies' dresses are lined with, is laid all over it, and the outside shapes of the hands, head, feet, drapery-lines, &c. are marked on it in black ink; each of the shapes thus marked out represents a separate piece of glass, which with the diamond are cut out of sheets of coloured glass, coloured all through when the glass itself was made, not stained afterwards. There is only one stain, and that is yellow. There are 140 different tints of colour now made to select from, instead of six or eight, as in the thirteenth century. The pieces of glass are then fitted together on the lining-muslin, and the features and lines of the drapery are then painted on the glass with opaque enamel.

There are now made large sheets of thick white glass, and on these the pieces of coloured glass forming the picture are fastened, by dropping from a pallet-knife a few drops of melted bees-wax and resin round each. The painting in progress can then be held up to the light, and alterations made if necessary. In this state the shadowing is done: it is not really shadowing, as understood in ordinary painting, for coloured glass is too beautiful a material to be obscured with shadow, but consists in toning down the too prominent parts and giving value to others. For instance, if the hair of the head, expressed by lines traced in the glass, has not sufficient force, a film of enamel colour, either grey or brown, is painted all over it; and force is given to drapery folds, which are expressed by strong black lines only, by indicating their form in a similar manner.

This so-called "shadow" is always found in old work: I believe it to be necessary to new work in good work it never materially interferes with the flatness of the painting, or the transparency of the glass. It may be done by stippling; or, by smearing over the surface a coat of enamel, and removing what is not wanted with a hard brush: it is really immaterial which method is used, each artist having his own favourite method. Shadowing is a necessary evil, and its excessive use has been one of the faults of modern work. After the glass is shadowed, it is broken down, and placed piece by piece upon beds of dry whiting on iron plates; then put in an iron kiln. There is no mystery in these kilns: they are simply iron boxes, around which play the flames of a fire beneath; a slab of fire-clay being interposed to prevent the direct action of the fire upon the bottom of the kiln.

The object is to obtain a regular and high degree of heat, and to prevent the entrance of the carburetted hydrogen from the fire, which would reduce the oxide of lead in the flux to a metallic state, and so cause its disintegration. These kilns are usually made much too short; a good size is 4 ft. long, 14 in. wide, and 14 in. high, open in front. It will admit six or seven iron plates, resting on ledges at the sides. The work is fixed in the best that can be obtained; the bricks set close together, and grouted with fire-clay.

The pieces of glass, when properly fired and annealed, are put back, piece by piece, in their places to the muslin, stretched on a flat bench. The painter joins the pieces together with leaden bands, string grooves on each side, as the ancients did; but the modern lead, instead of being cast in a mould, like the clumsy stuff formerly used, is forced through dies to the exact gauge required. The work is then soldered, and, when cemented, and fixed in its place, is preserved from injury by iron wire guards: copper guards are more pleasing, more costly, and liable to be stolen.

There can be no objection to *memorial windows*, at the present custom of placing the works of different artists in the same church, without regard to architectural fitness, is an evil. Fancy the feelings of an architect, who, after the completion of his carefully-studied work, finds it considered merely as a frame for independent paintings on glass. I think it would conduce to the better ornamentation of the interior, if the decoration of a church, a scheme of the whole of its painted windows were drawn out, and no departure from that scheme allowed.

The whole should be, if possible, the work of one artist, whose style was thought to be the most suitable. Many schemes for a series of windows in a church may be thought of. Take, for instance, the Power, Wisdom, and Goodness of God, which was Dr. Backland's mission in his *Edgewater Treatise*; the Doctrine of Atonement; the Te Deum; Illustrations of the three dispensations, the Patriarchal, the Mosaic, and the Christian; the Ministry of Angels; the Acts of Mercy; the Parables; the Beatitudes; or, the Sacraments; all afford grand series of subjects,

which would be of far greater interest than an ill-considered mixture of subjects from various sources.

There is some probability that the two systems of decoration, stained glass and mosaic work, will, in England, become general; they have never, that I am aware of, been united to any great extent in the same building. It has been contended that the use of one does away with the necessity of the other. Chevreul takes this view, giving as instances, St. Peter's at Rome of coloured walls, and Cologne Cathedral of coloured windows. The free use at the Wolsey Chapel, Windsor, of mosaics and stained glass, will, when the work is completed, set this point at rest. I fear that the gold-ground mosaics, which already suffer from the glaring gilding of the principals, will be further damaged in effect by the contrast of the stained glass.

The Exhibition of 1851 was a landmark in the history of glass-painting, as of most other industrial productions. The works of Hardman, and the French windows of Lussow, Gerente, Capronier, and others, took the conceit out of most English glass-painters. Then commenced a demand for a natural representation of the human figure, instead of the *symbolical* treatment of the thirteenth century; also, for sheets of glass of similar texture to the old; this has been responded to by Messrs. Powell, of Whitefriars, and Messrs. Bartley, of Sunderland. There is still a want of circular ruby like that of the thirteenth century, and at a reasonable price; but this is likely to be supplied by Dr. Salvati, of Venice.

The short-comings of the English glass-painters were abruptly redeemed in the Exhibition of 1862. No French work came up to either Clayton's glorious St. Cecilia, or Jones's glass for Waltham Abbey. The efforts of the French artists consisted of close imitations of ancient glass, or of semi-transparent paintings. Their attempts in the former were as a Chinaman's would be. You may remember a work of Coffetier, a reproduction of old glass; the subject was a Virgin and Child. The sinking of the surface of the glass below the traced lines, the effect of great age, was produced by the use of fluoric acid. This is on a par with the representation of decayed teeth in Raskin's Renaissance lion. The French artists have not yet given that attention to material that has been an Englishman's care. The productions of Gerente are about the best of the modern French school, and his works have been fashionable in England; but compare his great staining window in Christ Church, Oxford, with the one in honour of the founder, a portion of which was in the Exhibition of 1862. In Harrow School chapel there are a most instructive series of windows by Gerente, Wailes, and Clayton & Bell: the advance in the art shown by the works of the last firm is unmistakable. The new Gothic Church of Sainte Clothilde, in Paris, is filled with the best efforts of the modern French school of glass and wall painting, and in both there is an entire absence of Gothic feeling; for, although the figures are well drawn, they appear more like coloured German prints, than what figures in stained glass should be.

The exportation of painted windows should be to France, not of French work to England, for the English school of glass-painting is as much in advance of the French school as the illustrations of our own *Punch* are superior to those of their *Charivari*. It is customary to produce stained-glass windows, or painted glass (the terms are synonymous), by the square foot. The best English work varies from 30s. to 40s. per foot. The pretty picture glass of the Munich school is rarely supplied under 5s. per foot. That price was paid for the glass in Peterhouse Chapel, Cambridge. The new window that embellishes the east end of the church in Star-street, Paddington, cost 6s. each square foot; and the cartoons were afterwards bought for a very high price, said to be 500l.

The plainest glazed work has shared in the improvement of the higher branches. Quarries, formed by horizontal and perpendicular lines, and of many tints of white glass, mixed, or German circles, each about 4 in. diameter, and glazed together, frequently take the place of the old 6 in. by 4 in. quarry of billions cathedral glass. At the building of the University Union, at Oxford, the glazing with German circles was absurdly objected to, as looking like frog-spawn, or bottle bottoms. The upper parts of the Oxford Museum have since been glazed in this way; and when the sun shines on them, they are as bright and beautiful as clusters of diamonds.

A clever modification of circular glazing has been introduced by Mr. Norman Shaw, architect. It is the use of the centres of crown tables of glass, usually called "bull's eyes." They are of the most trifling value, and answer the purpose of the expensive German circles. It is an improvement partially to stain a few of them.

It is a step in the *wrong* direction to use the sheets of rolled glass in which imitation lead lines are produced by indentations. The ancients were compelled to lead together their small pieces of glass; and the needless imitation of this has always a cheap-and-nasty appearance.

The press has hitherto taken but little part in educating the public in the knowledge of glass painting. An occasional honest and learned criticism on completed windows would prevent, in great measure, the selection of the trumpery works that sometimes disgrace our churches.

CLEMENT HEATON.

#### THE RELATION OF THE PUBLIC TO ARCHITECTURE.

SIR.—The architect is often met by many of his clients who may object to the style or to certain features of a design, saying that they are "going to pay for its execution, and, therefore, they can have what they like; and that, although they do not know how to design for themselves, they fancy they know what is in correct taste;" and, indeed, ninety-nine persons out of a hundred will declare that they know a good design when they see it.

Now, although it may be urged that architecture is an art which ought to appeal to the mind of every one, and that all ought to know when a design looks *well* or *neat* (to use a meaningless term frequently applied to the style of a building); and further it is urged that all have a right to judge and correct a design produced for them, because it was produced for them, it should be borne in mind that a house is not like a painting, to be shut up in a room and only gazed at and admired by those who pay their shillings to see the productions of their favourite painter; but is visible by all, and all fancy they have a right to criticise it. It will be found on examination that this right is maintained on two erroneous grounds, namely, a false estimate of their own competency to give an opinion, and a wrong conception of the art of designing,—which grounds we shall proceed to examine.

It is often assumed that architecture is an inferior kind of art, because its main object is of a utilitarian nature, and, as such, is brought in contact with every one in daily life; and, therefore, on account of a familiarity with its externals, it is thought it may be the more easily judged of.

This is a mistake. Architecture, like all other arts, can only be criticised by what is termed a *connoisseur*,—a person who happily rarely met with in architecture, chiefly owing, no doubt, to the self-conceit arising from the notions just described extensively prevailing. None can plead ignorance of the general principles of design on account of the difficulty of obtaining a knowledge of them, as the articles published in this paper from time to time, if not sufficient to enable them to attain an entire mastery of the rules of the art, will at least cause them considerably to modify their views. It is admitted, however, that the supposed competency of every one to judge of the merits and demerits of a design, and the assurance with which this competency is asserted, arises from the preconceived and vague notions of design which each has imbibed through the medium of the eye, without any mental guidance or reflection. The buildings which the eye has been accustomed to look at for years become fixed in the mind, and should any new ones exhibit a change in any parts or ruling forms, they are stigmatized as being in bad taste. No pains are taken to assign any motives resting on the principles of art-criticism to support the opinion; for the criticism is instinctively suggested by his badly-educated eye. When such instinct is deeply rooted, there will be a struggle ere the eye is convinced of what the mind, by arguments, may be made to assent to.

It has been said that the eye only sees what the mind sees. Now, applying this theory to architecture, there are many proportions and beauties of form which escape the ordinary observer, and which many buildings will not enable such a one to discover, unless he has made a comparison of them with his mental

vision also. Since it has now been made apparent that the ordinary observer cannot distinguish which is true and correct taste, and that no instinct will guide him in this art as in other arts (because the mind, rather than the feelings, is appealed to), how many, then, must be the bad forms and ugly shapes which he must register on his brain, having along the streets of a great city?

Again and others have told us that "the eye should never be suffered to dwell for a moment on a bad form," for, as we find it is far easier to fall into a bad habit than to get out of it, so the impression of a bad form once left with us is not easily eradicated. The erroneous views entertained by the public,—or rather, that portion of the public who think themselves competent to criticise designs,—seem to be that each modern design is only a composition of parts taken from old buildings,—in short, that architects' offices are little better than furniture manufactories.

Now, if copying the details and parts of buildings alone were certain to secure a good design, all designs made by putting together such parts would be equally meritorious. This, we know, is not the case. There is a great inequality amongst buildings in point of merit which even the ordinary observer will note. It requires more than a bare application of the principles to produce a good design: it requires a correct eye to determine the proportions of the various parts, and a kind of mechanical perception of the suitability of each part to perform the task allotted to it.

Again, supposing the views entertained by the public relative to design be correct, the best examples from the best buildings would, when associated, produce a building which ought to equal if not surpass those from which they are taken. This is not the case, because it is found that it requires talent to select examples which, in a modern building, will be in good taste. Supposing the copying from old buildings to be the true principle of design, a building made up of the best parts of other buildings, although it may not equal them, ought not at least to produce a bad effect; and yet how many outrages on bad taste are there which, doubtless, please the public, because they meet within them familiar forms, but such fail to please the connoisseur because they want some leading idea to bind the whole harmoniously together. Such ill-composed buildings can only be compared to the incoherent expression of a madman, who, although he may employ the choicest language, may fail to make himself understood, because he does not know what he wishes to express.

To those who deny the architect any art beyond that of putting together cribbed pieces of design, we would say the really most ill-designed buildings which appear to have been put together by one who could not possess the ingenuity of placing a child's puzzle, show by their eccentricities that there is a ruling genius which has affected the whole design. It is not so much by the absence of any law as by the existence of some eccentric law (if it may so be termed), that it is shown there must be a law regulating even the composition of a design. Is then, it may be asked, architecture to be an exclusive art, on which only an initiated few are to pronounce an opinion? No; the influence of true architecture will ever be felt by all, but only the initiated will fully appreciate it, and be qualified to judge of its merits.

The charms of a really beautiful building will not be lessened when the self-conceit is not flattered, and the agreeable feelings of superior knowledge sustained by the dictation of the ignorant to the professional man, who, it is falsely imagined, is paid to sacrifice every true principle of design in pandering to an uneducated and often vicious taste. H. J.

#### ACTION FOR WRONG QUANTITIES.

Sir,—The notice in your paper of the 18th instant of a trial which took place a few days before, in which we were plaintiffs, does not rightly state our case. We in no wise employed Mr. Faice, but unfortunately were one of five builders to whom he sent lithographed bills of quantities, asking for a tender. We made a tender, "as per quantities furnished," which was accepted; but they introduced so very false that we only went on with the work upon receiving a letter from him as Mr. Pask's architect, acknowledging the quantities were short, and promising that, at completion, the whole matter should be set right. As nothing was offered, we were advised to proceed by action against the man who was in enjoyment of the proceeds of the error. The Judge who tried the case thought the mooted point of agency so important, that he reserved it for the consideration of the Judges, still giving us leave to move for a new trial, should the decision be against us. SCRIVENER & WHITE.

#### COMPETITIONS.

**Proposed Schools for Leicester Workhouse.**—The committee appointed to consider the plans sent in by the different architects for the approval of the Board, met on Thursday in last week, to examine the same. The designs are eight in number. The following are the mottoes and estimates:—S—, 4,300l.; Prudentia, 6,189l.; Experimental, 6,191l.; Shield, 7,000l.; Experience, 7,137l.; Leicester, 7,150l.; Sigma, 8,550l.; and Non Quam, 9,000l. The designs selected by the committee for the final decision of the Board are Prudentia, Experimental, and Shield.

**Penalton Town Hall.**—The Penalton Finance and Town Hall Committee invited six architects of Manchester to furnish them with designs for their proposed new town-hall, and at their meeting, on Monday evening last, it was decided to adopt the Italian design furnished by Mr. Alfred Darbyshire, and the works are to proceed forthwith, under his superintendence. The estimated cost is 9,000l. The committee also give to each of the unsuccessful competitors the sum of 20l., towards defraying the cost of preparing their designs.

**Exchange, Middlesborough.**—The author of the design marked "Cleveland Nota Bene" is Mr. C. J. Adams, and the works are to be carried out under his superintendence. Instead of O'Donoghue & Grundy in our last amongst successful competitors, read Grundy & O'Donoghue.

#### "COMPETITIONS AND THE 'ALLIANCE'"

TAKING it for granted that the object of the circular issued by the "Architectural Alliance" is, as far as possible, honesty in architectural competitions, I would wish to offer some remarks upon two of the suggestions as to the drawings that should be submitted. The sections and elevations should be either in outline, or shading to be used, except flat shades in the windows. "The perspective drawings should be either in outline, or etched in black or brown ink, or shaded with Indian ink or sepia; no colour to be used."

Now the first rule virtually says, "You may show colour, but not form," as a geometrical elevation, without shading, unless the building consists of a flat facade, cannot give any idea (excepting to an architect) of the actual form; and the second says, "You may show form, but not colour." I must confess that I cannot see the reason for this, unless it is to guard committees being captivated by smart or meretricious drawings; but I put it to any architectural artist, whether he cannot, or whether he can, draw in sepia, or even with etching, produce an equally, if not more meretricious drawing, than he could do in colour. I fancy no architect would confess to designing a building without reference to materials or colour; and I would preclude him from honestly representing his design as it would appear if executed, is, I think, not only unjust to him, but would deprive committees of the only means of judging of the actual effect of the proposed building, or leave them the difficult process of combining, in a sort of mental camera, the colour of the elevation with the form and denounced accidental shadows, and other tricks that are resorted to to disguise, instead of illustrating, form; or had warned committees against blank windows, which, even in some of our important public buildings, and especially in stone balconies, only available to adventurous cats; or had suggested that in warehouses and insurance offices, as a rule, are not appropriate architectural features, or that they would have done good service, not only to conscientious members of the profession, but likewise to those seeking their services. They may say that in recommending that in all works involving an outlay of 2,000l. and upwards, the matter should be referred to one or two architects," they would guard committees against being misled by either meretricious drawings or inappropriate ornament; but "quis credidit ipsos credulos?" When we find architects putting highly elaborate cornices where they can only be seen by a man lying on his back, we naturally feel some want of confidence even in such a precaution.

There is one matter in which a strong protest should be entered by the profession, or the Alliance on their behalf, and that is, the limited time given in many important competitions. I need, I am sure, only refer to the competition for the Museum of Natural History, the time given for which was, if I remember rightly, hardly a couple of months. Unless an architect was satisfied to take the black plan, prepared by Mr. Hunt from suggestions by Professor Owen, as the basis of his design, it was utterly impossible, excepting a permanent national institution, to give the subject sufficient consideration and to have the drawings prepared, unless to one who fortunately possessed quick powers of study and design, and a powerful staff to carry them out. When we compare, in that as well as other instances, the hurry in procuring designs with the delay in taking any practical steps to carry them out, we cannot but wonder at the little importance that seems to be given to the intellectual ingredient in competitions; as I will not imagine that, in contemplating the erection of a building which is intended for a permanent national institution, any set of men could be influenced by other than the desire to obtain the best possible design. W.

**A NEW FRENCH MUSICAL INVENTION.**—The "light fantastic too" may now trip along to its own peculiar music, in the form of musical pumps, a pair of which, or at least of musical boots, has been exhibited to the Emperor. The pressure of the foot itself in dancing or walking evolves the music to which the foot keeps time!

#### HER MAJESTY'S LETTER TO THE RAILWAY DIRECTORS.

It is greatly to be desired that the Queen's letter to the railway boards, combined with the heavy amount of compensation for damage by accidents, which the past year must have exacted from many of them, may have the effect of removing the official blindness which appears to have universally affected them, and for which their preponderating influence in the House forbids us to hope for any compulsory cure. It would appear that the directors always proceed on the grounds that they are administering the funds of the shareholders with the view of a dividend, the convenience of the public being but a secondary consideration. Would it not be more satisfactory if they would try the plan of considering that they are administering the funds of the travelling public contributed in the shape of fares, and that their first duty is to return a *quid pro quo* in the shape of convenient and safe means of transit. If they can also manage to pay a dividend to the shareholders so much the better for them; but always the public first, the shareholders afterwards.

A consideration of the circumstances attending the many accidents which have occurred within the last few years will, I think, entitle any one, without presumptuously trenching on the functions of engineers or traffic manager, to arrive at the conclusion that there are only some three or four fundamental errors to which almost all such accidents may be traced, and, with all humility, I take these to be:—

1. Ill-placed economy in the matter of signalmen, pointsmen, and porters.

2. Want of sufficient traction-power to cope with the greatest amount of work that can be any accumulation of traffic be thrown upon the engine.

3. Total disregard in the time-tables of the agreement of nominal time required for the performance of a journey and the time actually occupied.

The reports of the engineers into the causes of the greater portion of the accidents referred to, testify to the fact that, either through overwork, or deficiency in intelligence or nerve, the signalmen have failed just at that critical time when perfect acquaintance with their duties, and ability to perform them, were required. Surely, the saving effected by setting some half-instructed porter, remunerated at the rate of from 18s. to 25s. a week, for twelve or fourteen hours' work a day, to perform a duty in which the greatest care and intelligence, and activity of observation, are required, must be more than balanced by the large amount of damages which must have been incurred through such accidents as that in the Clayton Tunnel, and that on the Ascot Cup day. Perhaps, however, the greatest blot on the system is the want of punctuality in the time of the trains.

A daily traveller for twenty years past, from a much frequented station, I know numbers of passengers who always, as the saying is, run it close. They know that the train seldom or never keeps its time, and they prefer the chance of being occasionally late, to the nuisance of having to wait from five to ten, or twenty minutes, on an exposed platform. The system induces a looseness of punctuality in passengers, guards, and porters all alike. It is ludicrous to contrast the starting of a train from the London termini, with the porter, bell in hand, waiting for the stroke of the clock, ready to cut off your nose in the gate if you are a moment behind, with the arrival of the same conveyance, more or less in arrears at all the stations on the line.

Suppose, for an experiment, this plan were tried:—Let the train start as now at the appointed time, and let there be an engine to draw its full complement of luggage, accompanied by an unusually large number of old women of either sex, who are somewhat slow at comprehending the little details of getting their tickets, finding their money, and knowing exactly by what class they mean to travel,—if by such a state of affairs the train loses two, three, or five minutes at the station, it may make up for the delay by the time it arrives at the next station, and let the time be such as it may not be unreasonable or dangerous to expect to be kept. It is perfectly certain that to the majority of travellers it would be far more satisfactory to expend a considerably larger percentage of time on every journey, knowing that the time named would be kept to a minute, than to have the present total want of faith in any time-table, making it quite impossible, where it

is necessary to go from one railway to another, to count with any confidence on reaching the station at the proper time.

If such a reform of the system were carried out, it may be fairly expected that a large increase of traffic would be produced, of what may be termed a voluntary kind, such as excursion and holiday trips, on which occasions the most serious accidents have happened; and this, with the amount saved by avoiding the destruction of life and limb, not to mention the rolling stock of the company, would go very far to compensate for the increased cost of officers and of engine power; but whether it do so or not is not the question which interests the public at large; the railways monopolise the traffic, and the companies should be compelled to do the work with punctuality and safety.

AN OLD TRAVELLER.

KNIGHTSBRIDGE BARRACKS.

SIR,—Various reports are in circulation respecting this magnificent position; some that the present building is to be abated, and that new and more appropriate quarters are to be erected for the Guards; again, that the barracks are to be transferred thence to another place; and, lastly, that the site is to be sold!

Surely so great a spoliation of Hyde Park, the glory of London, cannot be meditated for a moment; there are already intrusions enough upon this fair expanse.

Whatever may be the intention, it is devoutly to be wished that the noblest caseway of the West-end, if it is to be overshadowed in the narrowest part, just opposite the barracks, may be widened by at least 15 ft., so as to give it a more direct and equable aspect. On all sides improvements of the parks have been carried out by the Chief Commissioner, and none with greater effect, than by the enlargement of the natural roads, by withdrawing the boundary railings; for both park and roadway appear to be expanded by the change—as, for instance, in Whitechapel.

The abatement of the barracks, and addition of the site to the park, would be the greatest improvement, and the most estimable concession to public convenience and taste. If this, however, be impracticable, let us hope that the strip required from the area to enlarge this leading thoroughfare may be spared from a plot of 200 ft. in length, which has latitude enough remaining for the construction of a barrack and dining-hall larger and more capacious and healthy than the present antiquated caserne; and to build a range of mansions or a lofty barrack here would be sacrilege.

Q.

PLAIN-TILING.

SIR,—I was much surprised to see your correspondent, who signs himself "Practice," recommending the bedding and jointing of tiles, especially bedding them at the bottom end of the tile. It is quite clear that tiles so bedded must be very liable to render the roof damp, as any water that got in at the top of the tile, either by percolation or flaws in the tiles, must be blocked up by the mortar at the bottom of the tile; and, independently of the water which falls on the outside of the roof, there is always a considerable quantity of damp in the inside of the tile, which condenses and hangs in beads on the underside of the tile, especially in damp weather. These beads increase in size, they are attracted into the other, and run down in small streams on the underside of the tile, until they come in contact with the mortar at the bottom of the tile, which prevents the water running out at the end of the tile, and copying itself outside on the tile underneath, which would be the case if the bottom of the tiles were open and clear; and this water, blocked up, must of necessity drop off on the little ceilings below. Indeed, I have known eaves roofs so tiled in where they have been ordered to spread a layer of sawdust on the top of the ceiling to absorb the damp which fell from the roof and stained the ceiling underneath. Your correspondent complains of the London bricklayers not being careful in filling the cross joints with mortar, in that they say all the mischief. But the mischief is, that mortar should be in the cross joints at all; for were carefully the cross joints are filled and bedded together with mortar, it is impossible to get them water-tight, as the continued action and shrinkage of the roof, and the deflection of

the laths when they become tender, will always break up the cross joints and let the wet in, which is very likely to spread through, as the beds of mortar prevent it running off with the same facility as though they were all clear. The system proposed by your correspondent is as old as Ben Jonson, but has become obsolete years ago.

HENRY PRICE.

I REMEMBER, quite well, a church in Sussex that underwent certain repairs—new ridding, as it is commonly called by bricklayers, that is, the tile-work taken off, the roof straightened, relathed, and tiled. The tiles were laid in mortar; and, when finished, I may venture to say, the wet came in in a hundred places. The architect was astonished, the bricklayer more so. One said the gage was too long; another said the pitch was too flat; but how could that be, when the roof had not been altered any more than made straight? The bricklayer was then ordered to get a thin instrument, and thoroughly clean out every cross-joint, which, when done, had the desired effect.

My experience tells me, the best way to do plain-tiling is to use good heart-look laths, cleft as straight as possible secured by tenter-hooks at the bottom edge, and flat-head from the pins; bed the first two courses in mortar, then cover the roof with damaged hay or soft turley-straw, then place a sufficient number of tiles regularly over to do the roof. The use of the hay is to give the bricklayers greater facility to make the tiles lie more even at the bottom end. As the tiles often vary in length from the pin-holes as much as 1/4 in., the bricklayers, in that case, can take a small quantity of the hay, and place it under the pin, making the tile lie straight with the tile already laid. Should there be a straight tile come next a hollow one, it can be made level, or nearly so, with the hay. My impression is, that is the only advantage in using hay. There should then be a list of haired mortar carefully pointed along each course of tiles at the heads, the underside of roof, to prevent snow or wet dripping up. The pointing is not required along or at the lath.

HOW HOUSES ARE BURNT.

In the enclosed rough sketch of an actual appearance after a fire, in a new house in a rising seaport town, is worth anything to open the eyes of Insurance Offices, and of the tenants of new houses, please to insert it in your journal. Here the joists of the first-floor run into the chimney and close under the grate, only sunk out for the thickness of the 1-in. slate hearth. The joiner plugs into the lathwork flue, without hesitation, for his skirtings and angle heads. Now, all this is so easily obviated if the officers would insist upon trimmer arches and the use of cement, instead of wood to the skirtings around the chimney breasts, that I wonder how they suffer such a barefaced premium to fraudulent firing for one moment longer. "If we will not take the risk other officers will," is the reply of the officials; but I cannot help thinking the public have considerable interest in this matter, and for that reason I trouble you with this letter. In this particular case the builder professes himself to be "proud of doing his work well." He is not a slop builder,—borrows money from the office, which also insures. Two years, and the house is aight. Would any sane man insure the house for a week? The thing is made to burn.

A COUNTRY SURVEYOR.

\* \* \* The letter is sufficiently explanatory of a constantly recurring state of things without the sketch. The Denery, at Windsor Castle, was nearly burnt down on the 17th, through the presence of joists under the hearthstone, and which became ignited.

CASES UNDER METROPOLIS LOCAL MANAGEMENT ACT.

RATE FOR PAVING.

At the Clerkenwell Police Court, Mr. Henry Bickerton, as the representative of owners in the same position as himself, in the Seven Sisters-road, was summoned before Mr. D'Eyncourt to answer the following complaint made by the vestry of the parish of St. Mary, Islington:—

"For that you, being the occupier of the house numbered 2, in Mutton-place, which said house abuts on and forms part of the said Seven Sisters-road, the footway of which has been flagged by the vestry of the said parish of St. Mary, Islington, pursuant to the provisions of the 18th section of a certain Act of Parliament of the 25th of Victoria, c. 102, and also being within the jurisdiction of the said vestry, have not paid to the said vestry the sum of 18s. 7d., being the proportion of the estimated expense as determined by the surveyor for the time being of the said vestry, to be paid by you for providing and laying flagging in the said street called Seven Sisters-road, and which said footpath the said vestry deemed it necessary and expedient should be flagged."

Mr. D'Eyncourt decided that there has been no such repair as would make the occupiers liable under section 7 of the second Act.

Mr. D'Eyncourt's judgment will be found in full in the Morning Advertiser of Friday, the 17th instant, should any of our readers desire to refer to it.

NEW EXCHANGE, HULL.

The first stone of the new exchange was laid on the 15th inst., by Mr. T. W. Flint, chairman of the Hull Exchange Company, in the presence of the mayor and sheriff of Hull, and a numerous assemblage of merchants and other leading inhabitants. The site is at the corner of Lowgate and Howlley-lane, in which stood, in the fourteenth century, Suffolk Palace and its dependencies, the residence of the De la Poles, a name imperishably connected with the town of Hull. The building will be in the Italian style, three stories in height, exclusive of basement, the elevations towards the streets being principally of Hare Hill stone. It will comprise an exchange-hall, 70 ft. by 40 ft., with an arched ceiling; stations for three telegraph companies; several suites of offices, refreshment-rooms, vaults, &c. The architect is Mr. W. Botterill, of Hull, and the contractor, Mr. R. Weatherley, of York, whose contract is 6,560l. Mr. W. Lewis is clerk of the works.

BRITISH ARCHÆOLOGICAL ASSOCIATION.

At the meeting on January 25th, Mr. G. Vere Irving, V.P., in the chair, Mr. Powell exhibited two finely-sculptured marble busts of Jupiter and Cleopatra, recently obtained from Pompeii. Mr. Edward Roberts, F.S.A., exhibited a part of a wooden window-frame from Framingham Church, entrusted to his care by the Rev. Mr. Mannissy, of Diss. It is of Early Norman date, circular, about 10 in. diameter, with perforations round the edges for lacing. Mr. Roberts accompanied the exhibition with remarks upon the earliest lattice-windows referred to in the Old Testament, and the continuance to this day of similar lattices in the East, and to the modes of carving and lacing windows prior to the introduction of glass. Mr. Augustus Goldsmith, F.S.A., exhibited a bronze miniature figure of a Caryatide, found at Herculanum. It is in the form of a semi-nude dancing-girl, with legs crossed, and in elegant pose.

Mr. Charles Faulner, F.S.A., exhibited rubbings of two diminutive coffin-lids, found upon digging a grave last summer in Deddington Church, Oxon, measuring only 20½ in. by 1 ft., and 4½ in. in thickness. They are of local marble, sculptured, and represent a floriated cross. The edge of one is also sculptured. They belong to the end of the thirteenth or beginning of the fourteenth century. Mr. Carmichael said he had met with one 4½ ft. in length, by 1 ft. 3 in. Mr. Planché suspected they were memorials of children.

Dr. John Harker, of Lancaster, forwarded drawings and a paper, on the discovery of a number of British funeral urns. Lord Boston forwarded some elegant card-purses belonging to the reign of the Stuarts. Mr. Cuming read some notes on purses, in continuation of a previous communication printed in the Journal.

WIDTH OF STREETS UNDER THE LOCAL MANAGEMENT ACT.

Our attention has been called to a plaint instituted by the Metropolitan Board of Works against Mr. Cox, of Chelsea, builder, respecting some houses lately erected by him in a place called Hob-lane, in that locality, and heard before Mr. Arnold, at the Westminster Police-court, on the 2nd of February, and finally adjudicated upon on the 9th instant.

Mr. Raymond represented the Board, and Mr. Day attended for Mr. Cox.

After having heard counsel at considerable length, Mr. Arnold pronounced judgment in favour of Mr. Cox; and as the nature of the summons is fully set forth in it, an extract from the judgment is all that it will be necessary to refer to:—

"The summons in this case recites a by-law, which was made under the provisions of the first Metropolitan Local Management Act, and also the 88th section of the Metropolitan Local Management Amendment Act, and alleges that Mr. Cox has received notice of its existence, and notwithstanding it forbade his erecting certain buildings in a road of a less width than 40 ft., as prescribed by the Act of Parliament, that he had done so on the southern and eastern side of Hob-lane, Chelsea, which was within the limits of the Act relied on. On the part of the complainant, Mr. Pollard, a preliminary objection, but not pressed by Mr. Day, had been taken, that the proceedings ought to have been instituted within six months, and, if really any offence had been committed, the objection must have prevailed, irrespective of the wishes of either party, as my jurisdiction as a magistrate would have been at an end.

Mr. Raymond having, however, contended that, putting aside the statutory period of six months, there is a penalty in the case of a continuing offence, and this imposes upon me the necessity of stating my opinion, differing as it does from that of Mr. Selts, with whom I have communicated, and by whom the original summons was issued.

The question, then, is, what is the offence complained of? In the words of the summons, that the defendant had erected certain buildings, whereby a certain road had been formed and laid out for building as a street for carriage traffic. The first question is, when was the building erected? It is admitted it was commenced on the 12th of May last, and on the 11th, two days afterwards, the district surveyor examined it, and the complaint was not made until the 30th of December.

If the commencement of the foundation was to be taken as the erection of the wall, the alleged offence was discovered six months ago. I could not interfere, but I am of opinion that the wall or building cannot be said to be erected till completed. If the wall was completed before the 30th of June, I should be reluctantly compelled to hold that the complaint comes too late. Mr. Cox, against his own interest, has admitted that it was finished on the 12th of November, which brings it within the six months.

The facts of the case, I think, are these. There is an existing road called Hob-lane, used at present for carriage traffic, which is not of the width required by the statute. Over this road the defendant has no rights, except those he holds in common with other subjects. The land on one side of this road does not belong to him, but a large piece on the other side has become his by purchase, though not bought from the owner of the road or the land on the other side.

On the piece of land he has purchased, he has built houses and laid out streets in conformity with the by-law relating to new streets. The backs of one of these rows of houses abut on Hob-lane. He has brought the outer walls of the backs at the rear of these houses so close to the boundary wall of Hob-lane, as not to leave a width of 40 ft. between those walls and the boundary wall on the other side of the lane, namely, the wall of Cremorne Gardens.

Two questions arise on this state of things: first, whether the existing road called Hob-lane has been formed or laid out for building as a street for the purposes of carriage traffic by the defendant. I am of opinion that it has not, that he has not in any way interfered with the existing road, and had, in fact, no right or power to do so. This, of course, is decisive, as far as my jurisdiction is concerned.

Mr. Day, his counsel, said that the parish had acted with bad faith to him. This Mr. Cropton denies, saying it was a question between Mr. Cox and the Vestry.

The Board and Vestry are so mixed up together that it is difficult to distinguish between the two.

Mr. Cox has done all that he was required to do. There was a strip of land reserved for the Vestry of Chelsea, with a right to purchase it within twelve months. Mr. Cox was allowed to run up his buildings, the Vestry not having chosen to purchase it. Mr. Cox is proceeded against.

I certainly do not think that the Board were justified in turning round on Mr. Cox, and, if I were to grant a case for the Queen's Bench, which the Board has called for, it would be a very strong ingredient in it.

I must give Mr. Cox his costs."

This terminated the proceedings.

#### PROVINCIAL NEWS.

**Brighton.**—From the surveyor's report on the projected new Music Hall, we find that the leading feature of the design submitted is the large hall, the dimensions of which are,—length, including the orchestra, 138 ft.; ditto, measured from the front of the orchestra to the south wall, 104 ft.; width, 71 ft.; height, 50 ft. It will seat 2,420 people. The large room at the Town-hall is 84 ft. long, by 36 ft. wide, by 31 ft. high; and the Music-room at the Pavilion is about 58 ft. by 40 ft. The question of considering this report, and also another for a room with offices, to "be used by the School of Design, or for similar purposes," 49 ft. by 33 ft., and 20 ft. high, was deferred.

**Maidenhead (Berks).**—In this town, of late years, many villas have been built, which have been quickly occupied, and the erection of many more is about to be commenced. The rapidly-increasing population has caused several of our public buildings to be insufficient for the wants of the town, and the town-hall is amongst the number. The town council, seeing this, at their last council meeting, appointed a committee for enlarging or in some way adding to the present building; and there is a probability that a lecture-hall and a corn exchange will be built, and an extensive hotel also erected.

**Hantage (Berks).**—The new corn exchange here has been inaugurated. The building was originally intended to have been erected on the site of the present town-hall, and designs were supplied by the architect for that purpose, but ultimately it was decided to change the site to that of the old Red Lion. Only part of the scheme has been carried out. The building at present erected comprehends the exchange-room and rooms for the residence of a clerk at the south end. The exchange is 80 ft. long, 31 ft. 6 in. wide, and 24 ft. high. Internally, the walls are composed of red and white bricks, with plaster panels. From the piers spring plaster ribs, occurring every 12 ft., and between these ribs is a ground-glass ceiling. Encaustic tiles also relieve the monotony of the red and white brick walls. It is hoped that at some

future period the frontage towards the town-hall will be taken down, and some other building substituted. The cost of the building was about 1,400l., and the site 900l. Mr. Dover, of Oxford, was the builder, and the architect was Mr. Wheeler, of London.

**Bradwell-on-Sea (Essex).**—The parish church of St. Thomas has been re-opened for divine service, after a partial restoration. In the nave new windows of Bath stone have been inserted of decorative character. The old square high pews have been replaced by low seats of oak. The pavement throughout is of tiles. The sacra-ment table is of Bath stone, and the altar is of alabaster on each of the faces, and a pillar of green Irish marble at the angles. It is supported by a block of red serpentine. The carving was executed by Mr. Earr, of Lambeth. The font is also of Caen stone. The chancel has been almost rebuilt, and is fitted up with oak stalls, ornamented with poppy-heads. The work in the nave was executed by Mr. Saunders, of Maldon.

#### CHURCH-BUILDING NEWS.

**Winford (near Bristol).**—The foundation-stone of a new church (to be dedicated to St. Katharine) has been laid by Miss Katharine Alethea Hardman, at Broadfield Down, in the parish of Winford. The church will be built of local limestone, with Bath stone dressings, &c., and will consist of a nave, apsidal chancel, porch, and vestry. All the seats will be free. The site has been given by the lord of the manor.

**Ridwell (South Wales).**—Mr. Owen Bowen, secretary to the Carmarthen and Cardigan Railway Company, has presented to the parish church a brass turret clock, showing the hours on two dials 5 ft. in diameter, striking the hours on a bell of 12 cwt.; and the quarters on 2 bells, 8 cwt. and 5 cwt. respectively. Mr. Benson, of London, was the maker.

**Tarporley (Cheshire).**—The partial restoration of, and erection of an additional chapel to, the church are approaching completion. The restorations comprise the redressing of all the windows and the tracery in the north chapel, and the erection of an additional window and new doorway or approach thereto. A new timbered open roof has also been constructed, as well as a new arch to the north aisle. The new chapel is named the Monumental North Chapel. The Ardern Chapel was recently restored by Lord Binning, who is largely contributing to the present restoration of the church. The architect is Mr. John S. Crowther, of Manchester, and the general contractor for the works, Mr. R. Beckett, of Hartford. The contractor for the masonry is Mr. J. Holland, and the clerk of the works, Mr. G. Holland. A new tower or steeple to the church is contemplated, but the restoration is to be completed in four years, and three of these have already elapsed.

**Horninglow.**—The foundation stone of St. John's Church was laid on St. John's Day. The building is in the Geometrical style, and consists of a nave 70 ft. 3 in. long, and 21 ft. wide; north and south aisles, each 10 ft. wide; a chancel, 28 ft. 6 in. long, and 18 ft. 9 in. wide, with vestry and organ-chamber on the north side. The tower will occupy the western bay of south aisle, and will be surmounted by a spire, the top of which will be about 120 ft. above the ground level. The church will be divided into bays by five arches and columns between the nave and aisles, and will be lighted by a large west window and windows in the sides and end of aisles. The caps to piers and the keys to arches will be carved. The chancel arch will be moulded and carved, supported by marble corbel shafts. At the east end a five-light window will throw light into the chancel. The church will have two entrances—one at the west end, another on the south side of the tower. The walls will be built of bricks, faced with Coxcomb stone, and the windows, doors, arches, and ornamental work will be executed in Bath stone, with blue York and red Mansfield stone in bands and arches. The roofs will be open timbered, plastered between the rafters, and ornamental ridge cresting. Sitting accommodation is provided for 386 adults, and 72 children. Mr. E. Holmes, of Birmingham, is the architect, and Messrs. Lilley & Elliott, of Ashby-de-la-Zouch, are the builders.

**Manchester.**—St. Alban's Church, Waterloo-road, long closed in consequence of bindrances and difficulties, has now been opened under

license from the Bishop of Manchester. The church has been erected solely by voluntary donations. The seats will all be free. The building, up to the present time, has cost upwards of 7,500l. The edifice is designed in the Early Geometrical Pointed style. The tower at present is only carried up to the level of the ringing-rooms, and is temporarily roofed in. When finished together with its spire, the entire structure will rise to the height of 255 ft. The nave is seated with open seats of simple character, and the aisle with chairs. The church is warmed on the hot-water principle, and lighted by gas coronas suspended from the roofs. The whole of the roofs are of open timber framing of simple character. The architect is Mr. Crowther, of this city; and the contractors are Messrs. Ellis & Hinchcliffe, for masons' and brick work, and Mr. Foggett for the remaining works. Mr. Skidmore, of Coventry, supplied the gas-fittings and chancel screen, and Mr. Walker the heating apparatus. The church will accommodate 800 on the ground-floor.

**Kegworth.**—At a cost of about 1,900l., and under the management of Mr. Mitchell, of Sheffield, architect, the church here has been restored.

**Sheffield.**—The subject of church extension in Sheffield has been practically dealt with by a numerous and influential meeting, over which the Archbishop of York presided. The scheme is to erect, within five years from this period seven additional churches within the town of Sheffield. To effect this object it is proposed to raise a sum of 31,200l., the subscription to which will be spread over the like period of five years. At a preliminary meeting, a sum of 3,800l. was promised. Mr. John Brown has given 5,000l. for the erection of a church in Brightside, near to his works; the Church-Building Aid Society gives 4,000l.; and at the meeting upwards of 3,000l. more were promised; so that about 16,000l. have already been subscribed for the work.

#### RAILWAY MATTERS.

**Railway Reform.**—Now that the vigorous mind of Mr. Edwin Chadwick, C.B., is at work on this great question, the hope which we lost, after years of pioneering endeavours in the *Builder*, revives, in full force, that something will at last be done to clear the country of a multitude of railway abuses and defects. Mr. Chadwick's "Address on Railway Reform," delivered before the Social Science Association, has been printed (1, Adam-street, Adelphi). In this address, agreeing with such men as Robert Stephenson and the best authorities on railway interests, that railway management by directors elected from shareholders has been fully tried and found inefficient, Mr. Chadwick proposes a unity of management, with reduced rates, throughout the whole country, somewhat on the principle of the Post-office department, for the joint interests of shareholders and the public; and he maintains that foreign countries are far ahead of us in respect to railway management, in which especially we, above all other nations, ought to be foremost. We are glad to observe that the Chancellor of the Exchequer, in reply to Mr. Roebuck, states that Government intend to advise the appointment of a Royal Commission to inquire into the costs of railway conveyance and the charges made for it on the public.

**Proportion of Railways to Population.**—The amount of railway accommodation, in proportion to population, in various countries affords some curious subjects for speculation. We might have reasonably expected that England and Wales, with their rich mineral resources, their manufacturing skill and mercantile enterprise, would have taken the lead in the matter of railway accommodation, but the official returns do not show this to be the case. According to the *Railway News*, Scotland, whose sons are to be met with on almost every green spot on the earth's surface, seems to retain a spirited remnant of her population at home, seeing that she has for her 3,062,294 inhabitants above 2,000 miles of railway, or about 660 miles for every million persons. England and Wales, with above 20,000,000 inhabitants, have about 8,600 miles of railway, or about 430 miles to the million. Ireland, with nearly six millions inhabitants, has about 1,750 miles of railway, or nearly 290 miles per million. Next in their order among European countries as regards railway accommodation are Switzerland, Belgium, Sax-

ony, Prussia, and France, which have just about half the extent of miles of railways open that England has per million inhabitants of the respective countries.

**Miscellaneous.**—The traffic receipts of railways in the United Kingdom amounted, for the week ending the 11th of February, on 11,796 miles, to 571,400l.; and for the corresponding week of last year, on 11,460 miles, to 542,082l.; showing an increase of 336 miles, and of 29,318l. in the receipts.—The directors of the London and North-Western Railway Company have resolved to recommend to the proprietors a dividend for the past half-year at the rate of 7 per cent. per annum, carrying forward a balance of 25,542l.—At the half-yearly meeting of the London and Blackwall Company, the proposal to lease the line for 999 years to the Great Eastern Railway Company, at 4½ per cent. per annum, was carried by a large majority.—The dividend proposed by the directors of the Caledonian Railway is at the rate of 7½ per cent. per annum. The dividend for the corresponding half of 1863, was at the rate of 6½ per cent. per annum.—Upwards of a twelve-month since Mr. Rouch Smith wrote a pamphlet, proposing, among other means, to give the poorer classes cheaper fruit, the planting of Government waste lands, and the banks or sides of railways with apple-trees. Mr. Smith, it seems, circulated his pamphlet extensively in France, where it excited much attention, and to good effect, for at the present moment the planting of railways with apple-trees is going on extensively.

**GAS.**

A PUBLIC MEETING of ratepayers and gas consumers of St. Pancras has taken place in the Vestry-hall, at Camden-town, for the purpose of considering the question of the supply of gas, and to take measures to secure a reduction in its price. Statements were made condemning the attempt of the Imperial Gas Company to introduce a Bill in the present session to increase their capital, so as to prevent the consumers having the benefit of a reduction under the provisions of the Metropolis Gas Act, so soon as a certain percentage on the existing capital was obtained, and which was now nearly, if not quite arrived at, by the Imperial Company. A resolution calling upon that company to reduce their price to 2s. 9d. per 1,000 ft. was adopted, and it was resolved to petition Parliament against their Bill for increase of capital, and also for the abolition of the Gas Act, which, by allowing the districting, gave the gas companies of the metropolis a complete monopoly.

The supply of gas is a monopoly, not only in the metropolis, but in most parts of the country. A new company now and then starts up and obtains an Act, but the new directors have to choose between war to the knife and a quiet 10 per cent.; and it is easy to see how the matter ends. The Legislature allows the gas companies to divide 10 per cent. When they have done that, it allows them to look back and see whether, in any one or more years during the last six years they have divided less than 10 per cent.: if so, they may apply the surplus to making up that deficiency. When every shareholder has received 10 per cent. on everything, the surplus is to go in reducing the charge per cubic foot to the consumers. But Parliament has taken no security for the economical administration and expenditure of the companies. They are obliged to publish their accounts, certainly; but, if they disclosed ten times as much extravagance and maladministration as they do, there is no machinery for obliging them to keep down expenditure, and do justice to the consumers. The consequence is that gas a great deal better than is got could be made, even in London, for less than 3s. per 1,000 ft., at a saving of 800,000l. a year. It is said that 1,000 ft. of the Cannel gas supplied at a much cheaper rate in Manchester and Liverpool will burn as long, and give about as much light, as 2,000 ft. of the wretched coal gas charged in London at 4s. 6d. per 1,000 ft.

The gas movement is exciting considerable attention at Gravesend. The consumers are now paying 5s. per 1,000 ft., and when it is considered that the company get their coals cheaper there than in many other towns, and that gas-ter is sold at 3d. per gallon, and coke at 14s. per chaldron on delivery from the gas-works, it is clear that the price ought to be greatly reduced. A deputation is to wait upon the directors of the Gravesend Company; and, if they refuse to reduce their price, a public

meeting will be immediately held by the gas consumers of the town.

The directors of the Sandwich Gas Company have just issued a notice, stating that on and after the 1st of April next the price of their gas will be reduced to 6s. per 1,000 ft.; and that there will also be a further reduction of 6d. per quarter for the hire of meters.

A fearful and fatal explosion of gas has occurred at Liverpool. A warehouseman named Bowen, in order to discover whether a strong smell of gas or foul air coming from a sewer in the adjacent yard arose from escape of the gas supplying the warehouse, went with a lamp to the yard, and applied it to the iron plate covering the entrance of the sewer. An explosion took place, and an immense sheet of flame shot up to the height of 15 ft. or 16 ft., and lasted for a few seconds. The iron plate or covering was blown into fragments, one of which struck Mr. Bowen on the back part of the head, inflicting a fatal wound. Several other persons were also injured. The pavement was blown for a distance of 60 or 70 yards, the boulders composing it being scattered about in all directions. It is a singular and scarcely credible circumstance, in connexion with this accident, that Mr. Bowen not only lectured on chemistry, in his leisure evenings, but had made arrangements to deliver a lecture on gas, with illustrative experiments, at Birkenhead, the same evening! His conduct was just about as sensible as if a dealer in gunpowder were to thrust a red-hot poker into a barrel to see whether it contained gunpowder.

A company has been introduced by gentlemen intimately connected with Brazil, called the "Rio de Janeiro Gas Company," for the purpose of acquiring two concessions for lighting that capital with gas. These concessions, which grant a monopoly until 1879, have been worked by a Brazilian company, which is said to have realised good profits. In 1863 the net profit was 64,500l., and in 1861, 65,000l. It is proposed to purchase the privilege for the remainder of the term, with all the works and contracts; and for this purpose subscriptions are invited for the capital required, which is 600,000l., divided into 30,000 shares of 20l. each, all to be paid up by the end of June.

**Books Received.**

"BENEFICENCE in Disease" is the title under which Mr. Joseph Toynbee publishes (through Churchill), his introductory address, delivered at the opening of the St. Mary's Hospital Medical School. In opposition to Sir John Forbes, who states the object of disease to be to arrest or destroy life, Mr. Toynbee holds that disease is for the most part a reparative process, implying some antecedent injury, and works out his view in a way calculated to induce useful thought. Even without at once accepting Mr. Toynbee's theory, we would urge that disease is not to be regarded as a scourge from the Creator, but is a result of man's ignorance, or inattention to the Creator's laws.—The Grammar of French Grammars, by Dr. V. de Fivas. Lockwood & Co. The twenty-fifth edition of this work, just now published, is before us. We commend the book sufficiently when we say that we are not surprised. It is concise and precise; and two valuable qualities in a grammar.—A paper on Agricultural Fairs and Markets, by Mr. Fyfe, in the journal of the "Bath and West of England Society for the encouragement of Agriculture," has some observations on the want of space in new Corn Exchanges for the exhibition of proper samples, which architects may usefully bear in mind. The complaint against dealing on pocket samples, dried by being carried about the person, is becoming general.—"The Past, Present, and Future Almanac," published by Day & Son, London, consists of two tables, neatly mounted for the pocket, by means of which the day of the week for any date in any month of any year, and the date for any day in any month of any year, may be found without any trouble. It is a very clever and useful arrangement.—Amongst the reading-books that have reached us comes "Nelly Nowlan" (Nelson & Sons), a story by Mrs. S. C. Hall, illustrated, but not quite so well as it deserves to be, though one of the engravings, "Nelly and the Blind Girl," has considerable merit. Nelly Nowlan is a brave little Irish girl, with good common sense, and a better education than those about her, who comes to get

service in England, rather than make a marriage at home she *thinks* she shall not like. Her opinions on what she sees (the rights-of-woman women do not escape) and the adventures she meets with make up the book. It is a vigorous and amusing story, and, like everything Mrs. Hall writes, cannot be read without advantage.

**Miscellanea.**

LIVERPOOL ARCHITECTURAL AND ARCHEOLOGICAL SOCIETY.—An entertainment was given on the 17th, by the Liverpool Architectural and Archaeological Society, in aid of the funds of the Architects' Benevolent Society, at the Philharmonic Hall, Liverpool, and is described as a great success. Drawings and models were displayed, and dancing closed the evening.

NORTHAMPTONSHIRE ARCHITECTURAL SOCIETY. THE annual meeting of the Northamptonshire Architectural Society was held in the Lecture-hall, Gold-street, on Monday, the 13th, Mr. H. Thornton in the chair. The report read by the hon. secretary described the progress made with various churches in the county. From the treasurer's statement, it appeared that the gross receipts for the year, September 29th, 1863, to September 22nd, 1864, including Mr. Botfield's legacy of 10l., amounted to 106l. 1s. 10d. The gross payments amounted to 78l. 11s. 6d., leaving a balance in hand of 27l. 10s. 4d.

"OUR DOMESTIC FIRE-PLACES."—We have received a letter from Mr. Edwards, in reply to Mr. Taylor's challenge in our last number, stating that his information was derived from copies of Mr. Taylor's specifications, rather than from observations in buildings where the grates have been erected; and that he "could not distinguish between Mr. Taylor's announced schemes and his practice." On submitting this statement to Mr. Taylor, that gentleman asserts that "it is not correct," and says,—“Mr. Edwards has given as false a description of the hook of my patent as he has of the construction and working of my grates.” The challenge is therefore unanswered, and the public must draw their own inferences. Here the inquiry must end with us: we cannot carry the correspondence further.

SOUTH LONDON WORKING CLASSES EXHIBITION. The attendance at the Lambeth Baths has been very satisfactory, notwithstanding the cruel weather to which we have been subjected. We contemplated giving a notice of the principal objects exhibited; but, going through the collection again, came to the conclusion it was not desirable. We have specially marked the cases of some of the potters (pottery belongs to the district), such as W. Parsons (53); Hopkinson, sen. and jun. (54 and 125); and R. Edge (99); J. Mahey, modeller (74); E. James, mason (29); J. G. Rose, house painter (66), for some pictures; C. Burgess, wood-carver (153); W. Mynott, bricklayer; inlaid tables (266); W. Kennedy, plasterer, a mirror frame (545); Lovett, some small iron hinges (639); and a few others. There is very much that, although interesting under the circumstances, showing indeed great cleverness under difficulties, is awfully bad, and not calculated to raise public taste.

LONDON ASSOCIATION OF FOREMEN ENGINEERS. The twelfth anniversary dinner of this association was celebrated at the Bridge House Hotel, London Bridge, on Saturday evening last, the 18th inst. The society, which was founded in 1852 with the object of supplying the want of co-operation that had long existed among foremen of the engineering trade, and affording them an opportunity of friendly intercourse, intellectual cultivation, and physical good, comprises amongst its members not only working foremen, but many of the principal master engineers of London; and its success and practical usefulness were satisfactorily evidenced by the fact that, on the present occasion, the assembly numbered upwards of 250 gentlemen connected with the trade. Mr. John Penn occupied the chair, and Mr. Wm. Naylor the vice-chair. Mr. Newton, in responding to "Prosperity to the Association," adverted to the practical excellence of the mechanical and scientific subjects discussed by the association, and expressed his belief that, in the future, the institution, so valuable in diffusing scientific information throughout the profession, would become one of the greatest associations of its kind in the world. The contributions amounted to 500l.

**CARLISE CASTLE.**—The Secretary for War "has determined upon retaining the Castle in the hands of the Department, and not letting any portion of it, as originally contemplated."

**GUY FAWKES REDIVIVUS.**—Mr. A. Gordon, C.E., has published a letter written to the Hon. Mr. Gwyer, in which he states that there are twenty steam-boilers under the floor of the Houses of Parliament, many of them working at high pressure, and some of them not tested for ten or twelve years. Unless matters are carefully managed he anticipates a Guy Fawkes explosion.

**SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.**—This society held its second *convention* of the season, at the Architectural Gallery, in Conduit-street, on the 16th instant, amidst a collection of pictures and drawings by the late David Roberts, R.A., of which we have already spoken. The proceedings of the evening, as is usual at these *réunions*, included a performance of miscellaneous music.

**METROPOLITAN BOARD OF WORKS.**—The Main Drainage committee reported in support of Mr. Bazalgette's proposition to refer the examination of Mr. Furness's claim for extras to an independent engineer. This view was not, however, taken by the Board. After a long discussion, it was resolved, by a majority of twenty-three to five, that the matter should be left in Mr. Bazalgette's hands, and it was expressly understood that this was to be a vote of confidence in him.

**THE NEW HOTEL AT FALMOUTH.**—This new building is nearly completed, so far as relates to the portion which it is intended at present to build. The plans were drawn for a central block with two lengthy wings; but the centre building and western wing are not yet to be constructed. It is the eastern wing which is almost finished. As already constructed, the hotel is 244 ft. in length by about 90 ft. in height, and the main body of the building is 48 ft. in width.

**SCIENCE OF SEAMANSHIP.**—The Astronomer Royal is to deliver a course of three lectures on "Magnetical Errors, Compensations, and Corrections, with special reference to Iron Ships and their Compasses," at the South Kensington Museum, on the Thursdays in March, in connexion with the Royal School of Naval Architecture. Though single lectures may have been given previously, this is probably the first *course* of lectures on this important subject which has been delivered in the country, and should have the attention of those who are interested in the matter.

**THE BRITISH LAND COMPANY, LIMITED.**—The ninth annual report states that the sales for the year have amounted to 142,335l. 3s. 6d. The annual statement shows a balance of profit in favour of the company of 26,339l., and out of this sum the directors recommend a dividend of 10 per cent., and a bonus of 5 per cent., free of income-tax, which will amount to 16,656l., leaving 9,683l. to be carried forward. The amount of capital paid up has been increased from 100,000l. to 120,000l., by the issue of 10,000 new shares, on which 2l. per share have been paid.

**THE OLD WORKHOUSE SITE, OXFORD.**—This site, which consists of 5½ acres, was sold by the guardians to the late Mr. Ambrose Smith for the sum of 8,000l. Subsequently negotiations were opened with some of the leading Roman Catholics, who conceived the idea of erecting a college on the site, which is well adapted for a public building. It was accordingly bought by Dr. Newman for 8,400l., but the proposal encountered so much opposition from some leading Roman Catholics that the design was abandoned, and negotiations were then opened with the University, who have resolved on becoming the purchasers for 9,000l.

**THE ENGINEER AND RAILWAY VOLUNTEER STAFF CORES.**—The following appointments have lately been by the War Office:—To be Lieutenant-Colonels, —George Parker Bidder, C.E.; John Hawkshaw, C.E.; John Robinson McClean, C.E.; John Fowler, C.E.; Charles Hutton Gregory, C.E.; Joseph Cubitt, C.E.; Thomas Elliot Harrison, C.E.; George Willoughby Hemans, C.E.; George Robert Stephenson, C.E.; Charles Vignoles, C.E.; William Henry Barlow, C.E.; Charles Manby, C.E.; James Allport, William Cawkwell, Seymour Clarke, Cornelius Wiles Eborall, James Stewart Forbes, James Grierson, George Hawkins, Robert Moseley, and Archibald Scott.

**FALL OF MARSDEN ROCK.**—A favourite and well-known marine summer resort of Newcastle and Gateshead people, called Marsden Rock, lately gave way, and fell through the dwelling beneath it, smashing every article of furniture within reach. Upwards of five tons of rock fell. All the members of the resident family were fortunately in a small kitchen at the side of the house and escaped injury.

**THE WATER SUPPLY AT ROTHERHAM.**—AWARD OF THE ARBITRATORS.—The circumstances which led to arbitration will be remembered. The guardians of Sir George Sitwell claimed 20,000l. as compensation, and the Board offered 1,000l. They therefore refused to negotiate. After hearing the whole of the evidence adduced, the arbitrators—Mr. T. Hawksley, C.E., and Mr. C. E. Cawley, C.E.—took time to consider their award. They were unable to agree upon the amount that should be paid, and the matter was therefore left in the hands of the umpire, Major Blackburn, C.E., of Oldham. His decision was received on Tuesday night. The total sum he awards to Sir George is 1,104l. 5s. 3d., or 18,897l. 14s. 9d. less than the sum claimed. As the Board have to pay about 100l. more than they offered, the costs of the arbitration, amounting to 174l. 11s. 1d., fall upon them.

**THE EARLY ENGLISH GATEWAY, SMITHFIELD.** A correspondent wishes, very properly, to call attention to the old entrance-gate to St. Bartholomew's-chose from Smithfield. This specimen of the Early English style has been for many years, in a great measure, concealed by an adjoining house.—One side of the gate being, in fact, snugly inclosed in a tailor's shop, whilst the top part of the gate, sculptured with its characteristic mouldings, serves as a support to the flooring of the tailor's bed-chamber. The tailor's and the three adjoining houses have now bills stuck upon the walls, announcing that the whole property will be sold by auction in March, the Early English entrance-gate perhaps included. It is the opinion of some persons that the gate is the property of the city of London: if so, it is to be hoped that it will be cared for. However that may be, it would seem desirable to say a word in time in order that measures may be taken to preserve and repair the old gateway.

**SCHOOLS OF ART.**—A correspondence has recently passed between Mr. Beresford Hope, as chairman of a committee of officers and masters of schools of art, on the one hand, and the Committee of the Privy Council on Education on the other, relative to the various recommendations of the Committee of the House of Commons of last session on art schools. In Mr. Hope's letter, the points on which his constituents concur and do not concur are stated with some detail; and on the part of the Committee of the Privy Council careful consideration is promised. Their lords, however, say that they cannot return to payment of masters by certificate.—A preliminary meeting has been held with the view of establishing, by subscriptions and donations, a School of Art in Oxford. The mayor presided, and there was a numerous attendance of members of the University and city. Appropriate resolutions were passed, and a provisional committee appointed.

**OPENING OF A NEW TEMPERANCE HOTEL IN MANCHESTER.**—The Trevelyan Temperance Hotel, situate in Corporation-street, has been opened. The total cost of the building, including furniture, is 17,000l. The ground-floor contains the restaurant and café, 46 ft. by 26 ft., and 18 ft. high, lighted by eight large windows, and with a separate entrance at the corner of the building independent of the hotel. It is heated by steam from the basement. A gallery at the end of the room affords an arrangement for an orchestra. A serving-room, with hoist from basement, immediately adjoins the restaurant. A large commercial-room is provided on the left-hand side of the entrance; and beyond this, on the same side, are offices for the manager. This floor also contains a lofty smoke-room, a tea-room, lavatory, closets, &c. The first-floor consists of the coffee-room, ladies' coffee-room, billiard-room, private sitting-rooms, bath-room, &c. All the other floors are appropriated to bedrooms with bath-rooms, &c., on each story. The principal staircase is of stone, and all the corridors have stone floors carried on brick arches, to render them as nearly fire-proof as practicable. The design, selected by competition, was by Messrs. Clegg & Knowles, architects, under whose superintendence the works have been carried out.

**A NEW BUILDING SPECULATION.**—The Regents Park Estate and Pantechnicon Company, with a capital of 200,000l., in 20,000 shares of 10l. each, only one-half of which are to be issued in the first instance, propose to purchase the site, buildings, and contents of the Colosseum, to erect a terrace of houses fronting the park, and a Pantechnicon for general storage at the rear in Albany-street. The plans are said to have the sanction of the Treasury and the Woods and Forests.

**DECORATIONS IN ELY CATHEDRAL.**—Readers will have observed the statement that the paintings on the ceiling of the nave of Ely Cathedral commenced in 1558, by Mr. Le Strange, of Norfolk, are now completed. It will be remembered Le Strange only lived to finish one half the work, which was commenced in 1558, his death taking place in 1562. He painted the six bays at the west end, and at his death the work was committed to Mr. T. G. Parry, of Gloucester, who has now completed the six easternmost bays. The twelve bays of nave are painted with a series of sacred subjects from the west to the east, commencing at the west end, with the Creation of Adam, and ending with Our Lord in Glory, in the bay nearest the Octagon. We shall shortly give a view of the whole piece of work from east to west, with a detailed account of the various subjects that make up the general design.

**PATENT RIGHTS AND INDUSTRIAL EXHIBITIONS.** A paper was lately read by Mr. Webster, C.C., F.R.S., at the Society of Arts, "On the Claims to Protection of Inventors and Authors of Designs first published at Industrial Exhibitions," in which he urged that provisional protection, free of charge, ought to be accorded to new inventions and designs exhibited in industrial exhibitions. Mr. Campin coincided in Mr. Webster's views, and directed attention to the fact that if, as had been the case, some of the exhibitors produced original paintings, drawings, or photographs, they had under the Art Copyright Act, protection for forty-two years for a fee of one shilling; whereas, if they turned their attention to mechanical or chemical pursuits, and originated any novelties in those departments, they would have to take out patents, and pay 25l., 50l., and 100l. He considered that the poor inventor would only be ensnared unless the Patent Law were amended, as well as provisional protection given.

**TENDERS.**

For sundry alterations and additions to the Guildhall Coffee-house, for the Guildhall Tavern Company, Limited.  
Mr. W. Sabine, architect:—

Mansfield and Son	.....	£12,180 0 0
Ferry and Jackson	.....	12,173 0 0
Brown & Robinson	.....	11,950 0 0
G. Myers & Son	.....	11,763 0 0
Brass	.....	11,753 0 0
Hill & Kiddle	.....	11,724 0 0
Ashby & Sons	.....	11,681 0 0
King & Sons	.....	11,216 0 0

For building a new house at Maidenhead, for Mr. Wm. Nicholson. Mr. Charles Cooper, architect:—

Lamb	.....	£571 12 0
Ferry and Jackson	.....	365 4 10
Cooper	.....	559 15 0
Silver & Son (accepted)	.....	559 0 0

For erecting the Railway Inn, Baldock, for Messrs. Simpson, Baldock. Messrs. Nash & Son, architects:—

Twelve-trees	.....	£487 0 0
Warren	.....	460 0 0
David	.....	458 10 0
Williamson	.....	447 9 0
Lunn	.....	437 0 0

# The Builder.

VOL. XXIII.—No. 1152.

Farm Homesteads of England.

WITHIN the time during which the *Builder* has been running its course, a great change has been made in England in respect of the arrangement and design of farm buildings. A parcel of scattered hovels, wasteful of labour, wasteful of life, and of course, therefore, wasteful of money, have given place, in most quarters, to buildings more or less well arranged, united, and suitable. The fact has been recognised that a farm is a manufactory, and that, to carry it on successfully and economically, there must be proper buildings and appliances. Moreover, it has been seen that in this direction, as in others, taste is not costly; in fact, that

"Taste, never idly working, saves expense."

We might take some credit to ourselves for contributing to bring about this improved state of opinion, designers and constructors of farm buildings on several occasions having avowed the influence exercised by observations in our pages, much as more recently the designers of hospitals have been doing. There is a large field yet open for improvement, and in some cases where the desire existed, want of knowledge,—want of proper advice,—has led to wasteful expenditure. It was a good thought, therefore, on the part of Mr. Bailey Denton, to collect a number of plans by various hands adapted to farms for different purposes, feeding, breeding, and dairying.\* We have on more than one occasion mentioned his work with commendation, but our readers will thank us for making more completely known to them its contents and worth. Mr. Denton has given twenty-four specimens of homesteads, the plans being accompanied with descriptive matter not only concerning the buildings, but also the farms upon which they are situated, and the mode of husbandry to which they apply. They embrace covered homesteads, and homesteads distinguished by special accommodation for the rearing and feeding of all descriptions of stock; and it is claimed that care has been taken to select examples from farms of various sizes as well as from those characteristic of different localities, in order that persons concerned may study precedents analogous to their particular requirements.

There are also views of existing farmhouses, plans and elevations of labourers' cottages, and various illustrations of roofs, doors, and windows; details of cow-house arrangements, sections, and so on. Concise descriptions are given of the various homesteads as they follow one another; the Flemish Farm, Windsor, designed by Mr.

Turnbull; Thorney Farm, Cambridge, by Mr. R. Mein; Buckden new Farm, Lincolnshire, by Mr. E. Smith; Postland Farm, Lincolnshire, by Mr. E. Browning; Northbrook Farm, Oxfordshire, by Mr. W. Wilkinson; Haines-bill Farm, Berkshire, by Mr. F. Chancellor; Netherhampton Farm, Wiltshire, by Mr. Robson; Uphampton Farm, Shobden, by Mr. Alexander Milne; Tattenhall Hall Farm, Cheshire, Mr. George Jackson; Long-leat Home Farm, Wiltshire; and so on. The designer of the last one, Mr. W. Wilkinson, says in a letter,—

"I consider farm homesteads, with well-arranged covered yards, possess many advantages over those with ordinary open yards. In the first place, the manure is made and kept without being prejudicially exposed to the atmosphere, nor to the rain, which is known to deteriorate its properties; next, the manure becomes in a fit state to be removed direct to the land when it is required; again, the saving of labour in the removal of the dung, from the various buildings which abut upon the yard, the cleanly appearance of the roads round the buildings, the non-requirement of underground drainage and manure-

tanks, and the comfortable lodging the yards afford to all stock, are points which are much worthy of consideration."

No doubt of it. The great point in such an arrangement is to ensure good and even ventilation.

Several specimen arrangements of farm machinery are given, and form a valuable chapter. This is a matter to which attention will be more and more directed. We see in the increased application of steam power to agriculture the great means by which produce will be increased, and the condition of the agricultural labourer raised. The present position of the thousands horn into "that state of life" is not creditable to the age.

In speaking of farmhouses and the evil effect of putting small houses upon small farms, Mr. Denton lays down the rule that "No farm should be so small that it cannot support a house above the pretensions of a bailiff's cottage." It is

Plans of Farm Houses.

\* The Farm Homesteads of England. A Collection of Plans of English Homesteads, to illustrate the Accommodation required under various Modes of Husbandry. Edited by J. Bailey Denton, C.E. London: Chapman & Hall.

found better for both owners and tenants, as well as for the community at large, that where the tenure of land has been in small holdings two or more should be thrown into one good farm; and one of the criteria is the test prescribed, namely, the capability of maintaining a farmhouse of the proper character.

In order more clearly to express his meaning, the editor has appended the following data of house-accommodation for farms of different size and character, illustrated by existing examples:

I. For a farm of 200 acres of dairy or mixed husbandry. The farmhouse should contain the following accommodation:—

*Ground-floor, basement, and attached Out-buildings.*—One or twositting or "living" rooms (in the latter case the second room will be used for an office); kitchen; back kitchen or scullery; pantry; larder; cellarage; and apple-chamber; dairy, and dairy offices; wood and coal houses; ash-pit and privy: and on the *upper or chamber floor*, five bedrooms.

Plan No. 1 represents a farmhouse which may be taken as a specimen of this class. It was erected by the editor for Viscount Palmerston, at Toothill Farm, near Romsey.

II. For a farm of 500 acres, of tillage or mixed husbandry:—

*Ground Floor, Basement, and attached Out-buildings.*—Parlour; a "living" room; store-room; kitchen; back kitchen or scullery; dairy offices; larder; cellarage; and apple chamber; ash-pit, and privy. On the *Upper or Chamber Floor*.—Six bed-rooms of larger size, to include one spare room; linen closet; and water-closet.

The specimen of this class of farmhouse (2) was designed by Mr. John Hawkins, of Hitchin, for Mr. Dashwood, at Little Almshose, near Hitchin, Herts.

III. For a farm of a thousand acres, of tillage or mixed husbandry.

*Ground Floor, Basement, and attached Out-buildings.*—Parlour, sitting-room, and office; store-room; china closet and water-closet; kitchen; back kitchen or scullery; pantry and larder; cellarage; and apple chamber; dairy offices; brew-house, hakehouse, wood and coal-houses, ash-pit, and privy. *Chamber Floor.*—Seven bed-rooms of superior character, including two spare rooms, one dressing-room; a linen closet, and water-closet.

An example of this class of farmhouse (3) is given in the following plan, representing a house near Wisbeach, erected by Mr. John Beasley, for Lord Overstone.

Of the *architecture* of the farmhouses given we cannot say much in praise.

Mr. Denton sets himself to combat the belief that a labourer's cottage of five rooms,—that is, with three bedrooms, and with the necessary living-rooms and out-buildings,—can be erected for such sums as have been named by competing architects in submitting designs; and he has done well in removing misconception on the subject. After giving the results of various inquiries on it, he says,—

"Reduced to figures, we shall find that three-bed-room cottages will cost from 130*l.* to 150*l.* each; those with two bedrooms, from 90*l.* to 130*l.* each; and those with one bed-room only, from 70*l.* to 100*l.* The mean return required to repay principal and interest in thirty years may be taken at 5*l.* a year for the first, 6*l.* 12*s.* for the second, and 5*l.* for the last description of cottage."

The asserted cost may be here a little overstated, but not much; and it must be remembered that, in some localities and under particular circumstances, savings may be effected. Admit, however, Mr. Denton's figures, and we still assert, as doubtless he would, that proper cottages must be provided for the labourers. If unintermitting labour in the cultivation of the land for six days out of the seven will not provide for the workman a abelter where his health and decency can be maintained, the sooner the workman applies his labour in a more productive field, or walks off to a country where the land will maintain him, the better for the human race. There is reason to hope that the inquiries which are now being made may result in such changes in the law of settlement and rating, such remission of taxation under certain circumstances, such cheapening in the cost of building, and other steps, as may admit of the provision of proper homes for the labouring classes in place of the unsanitary dog-holes that now disgrace too many parts of the country, destructive alike of health and morality.

The digest with which Mr. Denton's hook is concluded is "a concise description of the principles recognised in the construction and arrangement of approved farm-buildings," and

will be found valuable. Early in it he gives numerous facts and opinions touching the value or otherwise of the covered yard system. His practical deductions from these are, that science and practice point, 1st, to increased shelter for stock; 2nd, to the better preservation of manure; 3rd, to a better appreciation of straw as an element of food; and 4th, and consequently, to the designing of new homesteads in such a manner as to admit of part, if not the whole, being covered when circumstances render it expedient. A study of the plans given shows that the nearer the homestead approaches the form of a square the better will it admit of this optional adaptation. The reasons for this are specially obvious in tillage and mixed farms, inasmuch as the straw barn is always a central building, and the food-preparing arrangements are necessarily connected with it; and the more compactly the stock can be placed in connexion with them, the less costly will be the structure itself, and the greater the saving in manual labour.

From the rules which he finds most generally recognised we may condense the following:—

The whole of the homestead should be within range of the master's eye, and as few outlets or backways as possible should be allowed for the egress of idlers.

In open-yard arrangements, all the higher buildings should, if practicable, occupy the north side or back range, in order that they may afford the greatest amount of protection from the cold winds. This rule coincides with the plan of having the granary and food-preparing chambers in a line with the thrashing-larn, as they, being double-floored buildings, admit of a considerable range of high buildings in one line. The range of buildings thus connected should be of one uniform width. The outside width must vary according to the materials used; but the best width, measured from the internal walls, is 24 ft.

All animals thrive in the presence of sun and light in winter: stock-yards should consequently have a southern aspect. In stalled buildings and boxes for fattening, a means of regulating the admission of light in summer should be retained, as the fly ceases to irritate stock when light is excluded, and repose is best secured by a modified light resembling twilight.

All lateral single-storied buildings should, if possible, be made of one breadth, say 20 ft., outside measurement (brickwork). The advantage of a uniform width is found to consist in the capability of conversion from one purpose to another, as necessity for alteration or extension arises.

The windows of the stable should have an eastern aspect, and the stables themselves should be as cheerful as possible. They should, moreover, be adjacent to the cart and implement sheds. Food should not be stored in lofts over stock, standing in closed stalls or boxes, as the heat and effluvia are pernicious to it.

All buildings should be spouted, and the water from the roofs should be conveyed to an underground tank, near the motive power by which it will be raised for use.

All yards, except sheep-yards, should be "dished," and the drainage therefrom conveyed to a tank, from which it may be pumped over and mixed with the burnt earth and other refuse collected under a compost shed built for the purpose, whenever it would be unprofitable to convey it direct to the land in its liquid form.

The materials used should not only secure durability to the buildings, but should also be of suitable strength; and the superior skill of an architect will be shown in the selection of materials to secure these objects with the best effect.

We may not, however, now carry the matter further, and must content ourselves with recommending such of our readers as are interested in, or desire to be interested in, the planning, construction, or use of farm-buildings, to obtain for themselves Mr. Denton's book. To architects we say, there is still much to be done in the way of improvement in this direction: why not help to do it?

EXHIBITION OF PORTRAIT MINIATURES.—It is proposed to open, at South Kensington, in June next, as complete an exhibition as possible of the works of the miniature painters of the present and the three previous centuries, both in this and in other countries. A committee of connoisseurs is to be invited to assist in the formation of the exhibition.

## ARCHITECTURAL REVERIES.

### THE FLORAL DECORATIONS OF CHURCHES.

Few, with any love for art, and who feel an interest in our church architecture, can have failed to remark the gradually increasing skill which has been displayed during the last eight or ten years in the Christmas and Easter decoration of churches. It has indeed become so remarkable, that a visit on the last occasion to some of the metropolitan churches in which such decorations have been made a well-studied feature of the great annual festival could not fail to prove bigbly instructive to a student of any branch of decorative art. The effects attempted and the results achieved have been in many cases so bold, and at the same time so successful, that one feels irresistibly tempted to follow to its source the custom of architectural decoration, and endeavour to trace its possible influence on the general public taste in art, and even on the eventual formation, or modification, of some of the integral features of the permanent architecture.

The decoration of public buildings on festival occasions with flowers, fruit, foliage, and draperies, is as old as the art of architecture itself. Indeed, some of the best defined features of many different styles of architecture have arisen out of, or been suggested by, the temporary ornamentation of religious and other public buildings on the occasion of great national festivals. The supports of the excavated temples of Egypt were at first simply reserved masses, vast and rugged. These rude columns, as successive generations of workmen became more and more skilful at their work, were made smoother and more symmetrical; but the first palm-leaves or lotus flowers that formed their capitals were not sculptured ones,—not the result of the intuitive taste and graceful design of the rock-cutter. The first wreaths of palm and lotus at the tops of those massive columnar supports were leaves freshly plucked from neighbouring palm-trees, or flowering flowers snatched from the waters of the Nile; and when at last it occurred to some bolder and more tasteful artisan to carve more permanent flowers while hewing out his column from the solid rock, he did not deem his sculpture complete until he had, by the aid of suitable pigments, imparted to his leaves and flowers of stone their natural colours. This was possibly the first step in polychrome architecture; and there is the more inducement to suppose that this was really the case, inasmuch as there was a natural reason for the use of certain colours; while, a merely arbitrary application of red, blue, or green can scarcely be imagined to have been the first step in that direction. The date-palm and the lotus were both sacred plants among the early Egyptians; the palm-tree was, indeed, of vast importance to the population; the fruit was the staple food of a large portion of the people, and the leaves and wood were made to serve many important purposes. This tree formed, in fact, a leading feature in Egyptian daily life, and its habits and forms of growth were consequently so well and generally known that they were made the basis of many of those symbolic signs used by the priests, which preceded the use of writing, as we now understand that term. For instance, it was well known that a full-grown tree generally put forth twelve new leaves in the course of the year,—and a palm-leaf was therefore used to signify a year in the hieroglyphic system of writing. The lotus-flower had many mystic significations, on account of its growing on the surface of the water, which caused it to become a striking feature in both Indian and Egyptian mythology, while from its seed a kind of bread was made, which formed almost the only food of a portion of the population; so that we may easily account for the use of the leaves, flowers, and fruits of these plants in forming the festoons, garlands, and other decorations of the columns and entrances of the public temples; and we may conceive that, being also associated with the religious faith of the nation, it would eventually occur to the temple-builders to make such ornaments permanent in the forms of carved stone, as soon as they had acquired sufficient skill to do so.

If we turn from the bold antiquity of Egyptian temple-work to the somewhat more recent architecture of Greece, we shall still find the same influence at work. Those festal decorations of Grecian temples which arose out of the performance of sacrificial offerings were eventually reproduced in stone by those sculptor-architects,

who first felt themselves equal to the task; and in this way the gilded horns of sacrificed rams, which were attached to the highest part of the rind columns, as a natural and at the same time ornamental record of the sacrifice, came in due time to be considered as essential additions to the column; and in erecting new ones, marble horns were at once supplied by the sculptor, and so originated the graceful Ionic capital. In other cases the skulls of sacrificed bulls were, in like manner, affixed to the beam, or fascia, immediately supported by the columns, as a convenient position for their display; in which situation, when richly gilt, they form a striking and appropriate ornament. On special festivals, when the temples were decorated with flowers, the golden horns would naturally present themselves as inviting the suspension of garlands, or of intermediate festoons of woven flowers (like the "gold and silver hooks" of the columns which we read of in the Mosaic account of the building of the Tabernacle), and the appropriate combination, presenting images of material existence and its decay, forming, as it were, symbols, both of the opening and of the end of life, was afterwards reproduced in the more enduring marble, as we see it on the Roman tomb of Cecilia Metella, on the Appian Way, the remains of which are still so beautiful, and in some parts so sharp and perfect, and so purely white, that one might fancy them freshly left by the hand of their sculptor.

That the symbol of plants is closely interwoven with the architectural and other decorations of Greece and other early nations, may, indeed, be easily proved from many existing monuments. For instance, on the south coast of Sicily, a band of Greek colonists founded a city on a beautiful spot rendered fertile by the course of the small river Selinus, so named from the abundance of wild pansies which grew along its borders, and which the Greeks called *Σελίνος*, a name which was appropriately given to the new city. This herb was probably made sacred to the tutelary nymph of the stream, and was doubtless offered up in the probationary sacrifices which were periodically made. That the herb was considered a sacred symbol we know from its being adopted as the badge or seal with which the State stamped its coinage, on specimens of which, preserved in our numismatic cabinets, we find a very excellent, though roughly executed, representation of the leaf of this plant. The plant itself was, no doubt, used in the periodical decoration of the temples, and became eventually a sculptured ornament in friezes and other architectural features, of which no remains now exist. The same might be said of the silphium, a beautiful and valuable plant which forms the device of the coins of Cyrene, an African colony of the Spartans. The plant had been made sacred, from some peculiar association, to the founder of the colony, and naturally became a leading feature in the decorative sculpture of the place. But the most remarkable example of decorative foliage first used as a temporary ornament, and afterwards becoming a permanent architectural feature, is that of the acanthus plant, which, by successful artistic treatment in its transmission to marble, became the exquisite Corinthian capital. The precise associations which first led to the use of the picturesque leaves of this plant as a temple decoration, are now unknown, and their place has been supplied by a graceful fable, with which, however, rigid archaeologists have necessarily very little sympathy.

In Jewish architecture, the symbol of plants also formed an essential feature, as we learn from the description of the building of the Tabernacle, in the Pentateuch, in which both the embroidery and sculpture of such emblems are commanded. These emblems had, no doubt, been first used simply in their natural forms; but having become closely associated with certain religious observances, were incorporated in the prominent decorations of the patriarchal temple. It is thus that we read of the bell-flowers and pomegranates being used as the chief features of ornamental bordering in the priestly garments; and we may imagine that similar objects were made to form part of the ornamentation of the "hangings" of the gate of the court, which were of "needle-work of blue and purple and scarlet and fawn-tinted linen;" as also for the "curtains" of the court that were suspended to the "silver hooks" of the pillars of Shittim wood, which fitted into sockets of brass. At the corners of the altar, made of Shittim wood, and plated with brass, were "horns," just as we see them in Roman altars that are still perfect, the sculptured horns

taking the place of the real horns of the sacrificed rams, just as on the columns of Greek temples, when under the artistic chisel of the Hellenic sculptor, they were moulded into the beautiful device which we know as the Ionic capital. In the Temple of Solomon, the first permanent Jewish temple, constructed in part of real masonry, many of the ornamental details of the tabernacle appear to have been scrupulously followed and reproduced, while the more solid nature of the building naturally suggested many new features. For instance, we read of solid brass columns of 18 cubits in height, which were cast by Hiram the widow's son, a man of Tyre, "well filled with wisdom and understanding and cunning in all kinds of work in brass." To surmount these columns, Hiram cast two bowls, or capitals, which were 5 cubits high, being a third of the height of the column itself. These bowls were covered with a net-work decoration, also of brass, which appears to have been separately made, and was ornamented with four hundred pomegranate flowers, or fruits; "and upon the top of the pillars was lily work, so was the work of the pillars finished."

The pomegranates, and bell-flowers, and lilies of the early decorations had become, as we find, a solid part of the building. The sculptured cone of the cedar, in consequence, perhaps, of the cedars of Lebanon having formed the leading material in the construction of the temple, also formed a principal feature in Jewish ornament. It had originally played its part only in its natural state, as in some festivals it continued to do to the end of Jewish nationality. For instance, we learn from Josephus, in his "Antiquities of the Jews," that on the Feast of the Tabernacle, an ornamental bunch or bouquet of flowers and branches, called *Leulab*, was carried by the priests in their procession to the temple. This *Leulab* is represented on the coins of Barcochbas, issued during the revolt in the reign of Hadrian, and appears to consist of foliage and cones of the cedar, mingled with flowers, possibly pomegranate-flowers.\* In fragments of decorative sculpture, discovered near the tombs of the Jewish kings by recent travellers, the cedar-cone and pomegranate-flower are frequently found playing a very ornamental part in the floral patterns wrought by the chisel of the ancient Judaean sculptors.

In the Gothic architecture of Medieval Europe, similar adaptations of natural decorations to sculptured ornamentation may be traced. This kind of application and distribution of imitations of natural foliage in Gothic architecture may, however, be distinctly traced to Roman models, as when we find the ivy-leaf, the vine-leaf, or the rose forming the foliage of Gothic capitals of Christian churches, in which position its arrangement is precisely founded on that of the acanthus in the Corinthian capital, though it must be observed that its treatment may be said to be entirely original, and springing from the peculiar artistic spirit of the age. The occasional decorative devices of these Christian temples on the numerous festivals observed in the early Church were also founded on those of Pagan origin, and had positively been first used to symbolize Hellenic or Druidic myths; and in this way the garlands and wreaths, votive offerings to Pagan deities, and the mystic virtues symbolized by the mistletoe, or the holly, were transferred from the Pagan temple or the Druidic forest cave to the Gothic aisles of the Christian church, and were purified and sanctified by the new purposes to which they were assigned. As the marble columns and gilded vaultings of numberless Pagan temples were consecrated to the use of a purer faith, so, in a similar manner, were their permanent decorations; and this, in fact, is a sufficient answer to those who would abolish the Christmas decorations of our churches, because, forsooth, such decorations were of Pagan origin. It would seem that we might as well destroy our Christian temples themselves, because similar temples, archaeologically speaking, were undoubtedly the invention of Pagan priests. However this may be, it appears pretty certain that the advocates of decoration in honour of the great annual festival of our Church have prevailed over their adversaries in an overwhelming majority of cases, and all real discussion appears now to concentrate itself on the question how such decorations can be rendered most effective and most appropriate.

\* Some numismatists assign these coins to Simon Maccabaeus himself.

Only very few years ago nearly all our national attempts at church decoration were of the roughest kind. Sprigs of holly were stuck about at hazard, according to the inspiration of the clerk or pew-openers, and with no more artistic meaning than the Christmas sprigs which are stuck into the fat joints that form the leading features of our festal display of butcher's meat, or as we see the holly and mistletoe stuck up about kitchens by John and the cook, with a big bunch containing the requisite mistletoe suspended in the middle of the ceiling, or, in default of a hook at that desirable spot, from the upper part of the door-frame. In other kinds of festal decorations, our attempts were not much more felicitous. At that period, a time still very recent, our occasional trips to the Continent revealed to us an entirely different state of things. We found there that decorations on the occasion of national festivities were made quite a seriously artistic matter, of which the governments themselves often assumed the immediate direction, calling to their aid the greatest artists of the time, who felt in such opportunities a wonderful field for the exercise of theories of taste on a large scale. In this manner the taste of the artist class was expanded, and healthily trained to breadth of effect and vast continuity of design, in which an infinite number of judicious combinations resolved themselves into long vistas of ornament—vast avenues of design, which received value and impressiveness from the repeated occurrence of the same forms at fixed distances, producing by mere reiteration an impression of grandeur and spaciousness, which no ingenuity of device could realize within a confined space. In devices composed either of greenery, of draperies, or of night illuminations, the special forms of existing edifices or of existing lines of trees were skilfully made the basis of the general design, and in this way the unartistic spottiness and isolated patch-work of an inferior system, or rather that arising from the non-existence of any system at all, was successfully avoided. As examples of this kind of well-considered festal decoration, that of the Fête de St. Louis, at Paris, may be mentioned, at the time when, in the reign of Louis Philippe, vast butts of wine were placed at equal distances between the trees of the Champs Elysees, surmounted by flags and other decorations along the whole line of that noble avenue, till the furthestmost butts and flags became mere coloured specks in the distance, the effect produced being of that grandly continuous character which has, even in works on a smaller scale, an artistic value that nothing else can supply. The entirely architectural character of continental illuminations never failed to rouse the admiration of the artistic tourist at a time when we had not yet attained our present perfection in that class of festal demonstration, and a tourist of that class never fails to recall them to mind when discussing such subjects. The sudden and simultaneous illumination of the entire dome of St. Peter's at Rome at the hour of twilight of Easter Monday might be named as a splendid example of this kind of illumination. The draperies of the balconies of the Corso on the last day of the Carnival may be cited as another illustration of continental taste in such matters; but, in regard to draperies, it cannot fail to strike the critical observer that those used in the Italian churches on the great festivals, or during the performance of especial *funziones*, are often in the worst possible taste. On these occasions the interesting architecture of the finest Medieval churches of Italy may be seen entirely covered with gaudy strips of scarlet or purple cloth, made still more gaudy with stripes of yellow worsted, in vulgar imitation of gold lace. The custom is doubtless founded on antique practices, when the pagan temples were similarly clothed on solemn occasions, when even the public statues were clothed with real draperies above the folds of their robes of bronze or marble,—just as at the present day the statues of the Virgin Mary are similarly attired on *fete days*,—a special and often very various and extensive wardrobe being kept for this purpose. The church hangings above referred to are also of a permanent character, all fitted to their special columns, pilasters, &c., with complete tie-strings, loops, hooks and eyes, &c.

One can scarcely conceive that such vulgar trappings should be made to conceal on festive occasions the rich and various marbles, the matchless sculptures, inlayings, mosaics, paintings, and other decorations of the pilasters of St. Peter's, the works of the greatest artists of the greatest artistic age of Italy; yet, inconceivable as it may appear, such is the case, and

nearly the whole of the beauties of the superb interior of St. Peter's disappear under the vulgar and monotonous trappings of red and yellow that are then made to cover its marvels of art. We may imagine that in the analogous decorations of Greek temples upon which these dressings founded that a better taste prevailed, and that the decorations were made to aid, and not to conceal, the more permanent beauties of the building. Something worth exhibiting was no doubt shown on such occasions, as sometimes we see even in modern Rome, when, as an exception to the vulgar dressings of scarlet and yellow, the magnificent tapestries designed by Raffaele, and wrought in the celebrated looms of Arras are suspended round the piazza San Pietro on the festival known as that of the *Corpus Domini*, which unfortunately occurs in the summer, when few, if any, foreign travellers are in Rome. In decorations of greenery, especially on the occasion of festivals occurring in the winter, the southern nations of Europe have never been so profuse or so successful as those of the north, because, most of the plants being evergreen in those climates, green foliage has not the attraction that it has with us, where most of our native trees are deciduous, and present but bare branches during the winter season; thus rendering our few evergreens doubly valuable both as garden favourites and as offering an attractive means of decoration at a time when green leaves are a rarity.

From the earliest Christian times, the holly, the yew, and other native evergreens have been used in church decoration at Christmas, the holly being an especial favourite on account of its bright scarlet berries, with which its branches are often very profusely covered, and its crisp, bright leaves bright as though they had just received a coat of brilliant varnish. The use made of these means of decoration was, however, till within the last few years, of a very rude character, and exhibited no attempt at artistic arrangement,—especially in the disposition of the decorations in such a way as to be in accordance with the architectural style of the building, and in unison with its principal lines and leading ornamental features. Our more frequent intercourse with the Continent has, however, given us some useful hints in this respect, and vast progress has been made; inasmuch that our church dressing, with native evergreens, during the present season, may challenge comparison with any kind of occasional decoration that artistic ingenuity has ever devised. The ornamentation of some of the churches in the Tybrinnian, Belgrovanian, and Westborough districts, has been undertaken this season, as on some previous ones, by well-organized committees of ladies, assisted by the advice of artistic friends, either professional or amateur, and the results have been in many instances quite admirable. The trace of female fingers in the graceful and delicate borderings composed of leaves and berries may everywhere be noticed; and the judgment with which such borderings have been adapted to the architectural moulding of the buildings is not less worthy of praise. The pointed arches springing from the columns of the aisles and nave, and which are generally bare of decorative sculpture, have had its absence supplied by natural foliage, with a grace and propriety that a designer of architectural ornament might envy. The famous dog-tooth ornament has been far outdone in effectiveness by borderings of crimped laurel leaves, held in their symmetrically projecting forms by cunning and invisible needlework. While other borders, entirely new in character, composed of alternate leaf and berry work, have been introduced in hollow mouldings in various positions with very charming effect. Corbels of real foliage have been devised at the springing of arches, where no sculptured corbel existed, and, not only supplied its place, but provided an ornament more fresh and beautiful in character than any mechanical reproduction of Mediceval stone-work could possibly be.

The decoration of a pulpit, in one of the Bayswater churches, is brought to our recollection as we are attempting to describe these graceful works, which struck us as peculiarly elegant and successful. Not one inch of its sculpture is concealed, and not the slightest portion of any really salient and important feature interfered with; and, in fact, the general richness and absolute beauty of the work have been most materially aided. The bare bevil of a plain projecting moulding below the eye has been so successfully enriched with a device composed of projecting masses of holly-berries, sym-

metrically surrounded by leaves of the same plant,—the device repeating itself at intervals, after breaks filled with a rich pattern formed of sprigs of yew,—that the best of our carvers might envy the design and execution of that charming border, while panellings and tracery of suitable character have been made to enrich the bare parts of the work with equal success. This piece of successful decoration was put to a severe test in being shown to the architect who designed the pulpit; and his verdict was delivered as follows: "If I could have had that laurel border actually executed in green Galway marble, that ivy tracery in malachite, that holly in verd antique, and the berries in rosso-antico, with the white snow-berries in transparent alabaster, I might have called my work the finest piece of pulpit sculpture that was ever executed in any country."

The reading-desk in the same church has also been adorned with equal success. It is of deep brown oak, and consequently the dark foliage of the common holly would not have told out against it; but the variegated variety has been substituted, and by its means all the fine outlines which were entirely without carved ornament have been enriched with such judicious effect that at the first glance a spectator might fancy that the decoration was produced by delicate sculpture in various coloured woods, of which the structure might be composed. It will look sadly hard and shorn of its charms when these fragile and soon-fading Christmas decorations are removed.

The fonts have formed favorite features for decoration in all the churches, and their detached position and generally picturesque form lend themselves very readily to this kind of adornment. In some cases, especially in a church in Birmingham, visited for the express purpose of examining its Christmas decorations, the system of ornamentation we have been attempting to describe has been very successfully applied to the windows. The windows in question are without stained glass, and the tracery, though good in style, is of extreme simplicity; but both painting and a rich subordinate tracery have been supplied by means of gracefully-disposed runners of ivy. The ivy selected for the purpose is entirely confined to those young shoots from the ground that cling closely to a wall or paling, with the leaves spreading out flatly to right and left, in symmetrical succession. These long pliable shoots are tastefully conducted over certain portions of the glass, here forming tracery close and lace-like, and there leaving broad open spaces in striking contrast, the whole arrangement producing the effect of a combination of tracery and painting intermingling, which, while of purely Gothic character, has yet a freshness of style and a piquant originality that no slavish reproduction of the artistic devices of a long-past age could ever produce, however skilfully rendered. And this remark brings us to the main gist of the present article,—the advantage that may be artistically gained by the study of decorations of this kind when really managed with taste and discrimination. It is quite evident that a whole series of borderings, bosses, corbels, spandrel ornaments, tracery, and other features appropriate to the enrichments of our modern church architecture, might be struck out from a study of these mere bints, if the student were both willing and able to learn. We should thus impart a new character, and one entirely coincident with the spirit of the age, to our modern churches; and while preserving the noble traditional forms upon which their main lines and features are based, give to architectural compositions of that class an entirely original freshness, much more in accordance with our artistic dignity than the mere reproduction of established forms. The honest and vigorous carrying out of such a plan in devising new decorations, would culminate in the gradual production of a new phase of Gothic, as distinct from any former style as Early English from Tudor, and yet as pure and orthodox in art as either of those styles or any other phase of our national church architecture.

It was by a closely analogous course that the cinquecentisti of Italy made the style of the Renaissance (so distinct and beautiful in itself) to grow out of the Italian Gothic of the fourteenth century. Ghiberti's sculptured bordering on the architrave of the doors of the famous Florentine baptistery is, in fact, a close copy of a temporary decoration of flowers and fruits artificially connected by knotted hands, just as such decorations were applied to the doors of public buildings at festive seasons; and the re-

sult of Ghiberti's experiment, which suddenly transformed Gothic decoration into a new phase of ornamental design, resulted in producing an entrance to the celebrated baptistery which made the greatest artist of that day exclaim that the doors of Ghiberti were worthy to be doors of Paradise.

HAMILTON PLACE, PICCADILLY,  
LONDON.

EVER-GROWING Tybrinnia is naturally impatient to get to still-increasing Belgravia without passing and encountering the straits and terrors of the Park-lane end of Piccadilly. The life of the great Duke of Wellington was more than once endangered at the Gloucester House corner of Park-lane; the poet of the "Pleasures of Memory" who enjoyed his daily walks in and about the Green Park and Piccadilly, dreaded the same terrible crossing, with its cross-fire of carriages, cabs, heavy waggons, and hutchers' carts. It is now worse than it was when, compelled by my daily occupation, I shot the crossing with a ready step. What "shooting the bridge" in a boat at Old London Bridge was to our forefathers, shooting the Park-lane crossing of Piccadilly is to their great grandchildren of the year 1865.

The Hon. William Cowper has a Cowper's task before him in endeavouring to satisfy the requests,—nay, demands,—that are made upon him to relieve Park-lane of some of its ceaseless traffic. Hack cabs, it is thought, might be allowed to diverge from the lane into the park at Stanhope Gate, and lessen the traffic the other way by entering Hyde Park at Hyde Park-corner, and making their exit at Stanhope Gate. But the Chief Commissioner turns a deaf ear to their arguments and entreaties, and insists on keeping the park as it is,—a private, not a public carriage thoroughfare.

It was said, sarcastically, and in some respects truly enough, by Gifford, the editor of the *Quarterly*, that Old London Bridge would not be taken down until either an alderman or a cargo of turtle were lost beneath it.

Caroline, queen of George II., spoke of shutting up St. James's Park, and converting it into a noble garden for the palace of that name. "She asked my father" (Horace Walpole used to relate) "what it would probably cost." "Only three crowns," was the reply.

What, we will ask and reply, will her Majesty Queen Victoria gain by opening to public carriages a part of Hyde Park? Our Lady the Queen will save the lives and limbs of many of her subjects, and endear herself additionally to all of them.

I have already had occasion to refer to the great Duke of Wellington, and the dangers of the Park-lane crossing, and in doing so, have had thus pleasantly prodded to recollection an anecdote of the Iron Duke truly characteristic of the man. The principal records of England were stored for security in the Norman Chapel of the great White Tower of the Tower of London, and in the vaults of the White Tower were deposited a Waterloo-sized supply of "villanous" gunpowder. We may fairly assume that no sane man with an addiction to field sports would keep his title-deeds in his gun-room; but what was the Field-marshal and Constable's reply,— "Oh, if the powder is in danger, I must see to that; you can possibly afford to lose your records, but I cannot afford to lose my powder;"—a reply at once sensible and humorous.

After this prelude and, I trust, not unpleasant digression, I shall rush into the middle of my subject.

In the House of Commons (a week but since), on the second reading of the "Piccadilly and Park-lane (New Roads) Bill,"

Sir J. Ferguson, on rising to ask for some explanation from the representatives of the Metropolitan Board of Works, said, "There were two questions which he should like to have answered. Some years ago a bill was introduced by Lord Llanover, then Chief Commissioner of Works, for this purpose, but it was abandoned in consequence of the law officers of the Crown, the present Lord Chancellor and Lord Chief Justice of England, having given their opinion that its provisions would violate the rights of the Crown tenants. He should like to ask the Chief Commissioner how it was that this measure was better worthy of support than that which was then abandoned. It was true that since that time Parliament had sanctioned an interference with the rights of Crown lessees in the case of the

Thames Embankment, but in that instance great concessions of land were in return made to the Crown tenants; and, even if that had not been the case, it could hardly have been argued that because the rights of such persons had been interfered with in one case they were ever afterwards to be entirely disregarded. He should further like to know why the Chief Commissioner of Works had since last year changed his mind upon this subject. In a letter, dated July 2, 1864, and addressed to the Metropolitan Board, the right hon. gentleman objected to the transformation of Hamilton-place into a thoroughfare on the ground that it was not wide enough to accommodate the traffic which it was intended to carry through it, and that the alteration would be an expensive and uneconomical measure. He should like to know whether Hamilton-place had grown wider since last year, or why the right hon. gentleman had changed his mind?

Our only M.P. architect (and he is always in his place when architecture is asked about, and up to the question before the House) spoke, in the course of his remarks, as follows:—

Mr. Tito did not wish to enter into a discussion of estimates, which he admitted were matters of considerable uncertainty, but he appealed to the plain sense of the House whether it was not obvious that the alteration of Hamilton-place, with its six houses on one side and two [?] on the other, must be a cheaper operation than the destruction of Gloucester House and others behind it. Four plans had been suggested for meeting the evil which the Bill sought to remedy. One was that the Chief Commissioner of Works should, with the authority of the Crown, permit carriages to pass through the park, but that the right hon. gentleman had refused, and, he thought, properly refused, to permit. The second was the extension of South Audley-street into Piccadilly. But if any one looked at the map he would see that the line of South Audley-street directly impinged upon Gloucester House, and, therefore, such an alteration could not be made at a cost of less than 300,000*l.* or 400,000*l.* besides which, the northern entrance to Audley-street was a quarter of a mile from the Edgware-road, the direct access to the Paddington Station, from which came the great bulk of the traffic which now crowded Park-lane. On these and other grounds, therefore, the Metropolitan Board abandoned the idea of prolonging South Audley-street. There remained, then, two plans, one for the opening up of Hamilton-place, and the other for the widening of the south end of Park-lane. It was true that Hamilton-place was narrow at the upper end, but by the purchase and rebuilding of two houses it might be enlarged without great expense; while, according to the estimates which had been made, the widening of Park-lane would involve a sacrifice of at least 100,000*l.* of public money.

Mr. Cowper, with his hearty Hertfordshire air, was heard in reply. Park-lane was the only direct thoroughfare which lay between the north and south of the district which extended from Church-lane, Kensington, on the west, to Berkeley-street on the east. The traffic which passed through it was to a great extent that of two great railways, which was forced through a passage not more than 18 ft. wide, so that one or two heavily-laden vans were sufficient to block it up completely, while it was exceedingly difficult for three ordinary vehicles to proceed along in a parallel line. Now, his opinion was, that the best course to adopt with a view to remedy that state of things, was to widen Park-lane; but the Metropolitan Board, who seemed to have only lately awakened to a sense of their duty in the matter, were of opinion that the enlargement of the southern end would involve a larger expenditure than they ought to undertake. He himself thought the Board were rather too timid in this matter; but the majority having decided against the adoption of the plan which he had just mentioned, the alternative lay between doing nothing at all and accepting the proposal contained in the Bill under discussion. He would not oppose the introduction or second reading of the Bill.

After others had spoken, the Bill was read a second time.

The "We are seven" houses in Hamilton-place, Piccadilly, were, when first erected, thus inhabited:—

No. 1 (west side, end of Piccadilly).—  
Dr. Smallbrooke,  
Lord Montgomery (also "Coilsfield, Ayrshire," Burns's "Ye banks and braes and streams around the Castle of Montgomery").

In 1813 this house was inhabited by Lady Catherine Tylnay Long:—

"Long may Long Tylnay Wellesley Long Pole live,"

but long she did not live here; and No. 1 is dropped by Mr. P. Boyle, "Fashionable Court and Country Guide Office, Vine-street, Piccadilly," made "for the use of Porters in the Hall, Servants, &c.," and, let me add, whose now scarce Guides of fifty or sixty years since provide very pleasant reading for lovers of the past in the present day.

This No. 1 passed to Lord Foley in 1814, and in 1818 to Lord High Chancellor Eldon, great-grandfather of the present earl, and Crown tenant of No. 1.

No. 2. The first owner I can find of No. 2 is Francis Russell, Duke of Bedford,—Charles James Fox's and Sir Richard Westmacott's Duke of Bedford. Strange—that owning so large a portion of West-end London as the Russell or Bedford family owned and owns, our ducal Russell should have his London house *not* on his own property. From Hamilton-house the Duke of Bedford of 1819 removed to No. 13, St. James's-square, still away from his own vast London property. And who was the Duke of Bedford's successor in No. 2? Why, Earl Gower, the first Marquis of Stafford and the first Duke of Sutherland. The duke died in 1833, and the dowager Duchess of Sutherland and the Countess of Sutherland in her own right retired from stately Stafford House, and passed the remainder of her London life in pleasant No. 2. This countess in her own right was, I may observe, an accomplished artist.

No. 3 was first inhabited by Boyle Earl of Cork and Orrery, from 1810 to 1816 or 1817, when Lord Foley, of Witley Court, in Worcestershire, "came into possession."

No. 4 was first inhabited by Bingham, Earl of Lucan, from whom it passed, in 1814, to the great Duke of Wellington, whose London house it was when the Battle of Waterloo was won by his fine genius for war. I wish I had been aware of this fact when compiling my "Hand-book of London." From the duke No. 4 passed to Lord Grenville; next to Mr. Labouchere, the father of Lord Tamton; next to Mr. Bevan, the banker; next to the *bibliophile*, Mr. Grenville, whose fine library, bequeathed by him to the British Museum, was well taken care of—*à classic No. 4.*

No. 5 was the residence of the Marquis and Marchioness of Conyngham. The marchioness, the influential favourite of George IV., was living here in her dowager days, when the first gentleman in Europe, and the last of the Georges, was in his grave. How different the retiring thoughts of the Dowager Marchioness, in No. 5, from those of the Dowager Duchess in No. 2.

No. 6 belonged to the Earl of Belmore, a Lowry-Cony by birth, and an earl in the Irish peerage. The Earl of Belmore, of 1865, lives in Eaton-place.

No. 7 was the residence of another Boyle, Richard Boyle, Earl of Shannon, from whom it passed to Mr. Philip John Miles, of Leigh Court, near Bristol, whose collection of pictures of the Italian school, was and is widely and deservedly famous. This same No. 7 was afterwards inhabited by the late Mr. H. A. J. Munro, of Novar, and the rooms *refitted* with another fine collection of pictures. Here were to be seen the celebrated "Madonna dei Candellabri" of Raffaele, some noble landscapes by Turner, and a View of Venice, by Bonington,—a masterpiece in every sense of the word. No *one* house, that I can call to mind, has held two private collections of pictures equally famous as were once to be seen in noisy, yet secluded, Hamilton-place, Piccadilly.

And have I not proved, I will ask, that this quiet little "place," of seven houses, through which it is now proposed to turn the traffic running to and from Tyburnia and Belgravia, is one very rich indeed in pleasant and "perhaps" undisturbed associations?

PETER CUNNINGHAM.

**COST OF THE SHEFFIELD INUNDATION COMMISSION.**—The cost of the inundation commission now sitting in Sheffield, is declared by a local paper to be at the rate of one guinea per minute, exclusive of the large sums paid by sufferers and others who are acting in opposition to the Water Company. It is estimated that the commission will, by the time it has finished its labours, have cost the company 50,000*l.*

ON THE MUNICIPAL ORGANISATION OF PARIS, PARTICULARLY WITH REGARD TO THE PUBLIC WORKS.

On this subject Mr. G. R. Bunnell read a paper at the Society of Arts, on the 22nd ult., Mr. W. Hawes in the chair, giving some valuable particulars of the present system under which such remarkable changes in Paris have been effected. It will be found in full in "the Journal" of the society. Mr. Bunnell, while admiring the results, thinks the system would prove eminently a failure if applied in our own country. Towards the close of the paper, the writer says:—"But it remains for us to ascertain how the prefect manages to provide funds for the total change that he is effecting in the plan of Paris, and in the improvements there carrying out under his energetic management. In the first place, the revenues of the town are of themselves very large, and they have been pledged long since to meet such of the expenses as are authorised by the government; and in the second place, the city of Paris has entered upon the abuse of its credit, by the creation of a species of floating debt, that I think will end in bankruptcy. The yearly receipts of the town of Paris are (or were last year) 155,590,040 francs, or 6,223,600*l.* nearly, which are raised from a population of not more than 1,667,841; and this, it must be understood, only represents the sums that the inhabitants pay for their local taxation, for the government taxes, that are levied directly from the payer, are quoted at the sum of 33,411,718 francs, or the additional sum of about 1,335,468*l.* This sum of about six millions and a quarter would amount to an annual payment of about 3*l.* 15s. per head of the population, and it cannot be a matter of surprise that the expense of living in Paris is becoming rapidly unbearable. The incidence of the taxation is no doubt disguised by reason of its indirectness, but this only makes it more heavily felt by those who do consume the articles taxed. A man pays in Paris according to his consumption, not according to his means; and thus the rich man escapes contributing to the state. The poor man is forced to pay more in proportion than his neighbour. Of course Englishmen have nothing to do with the manner in which the French may levy the revenue that they may require, but it is right to call attention to the radical unfairness of the system, when so many people here are clamouring for the introduction of a similar one amongst ourselves. As it is, however, the rate of local taxation may be taken at nearly 50 per cent. on the rental of the inhabitants of Paris, including, however, all the relief of the poor, the expenses of the hospitals, the schools, &c., which with us are left to the care and charity of private individuals.

But it is to the creation of a description of municipal floating debt that the most impartial people look with the greatest dread. The city of Paris, even now, has a funded debt that gives rise to the payment of 13,428,746 francs, to defray the interest, and 10,314,892 francs, for sinking fund, or nearly a million a year is thus absorbed out of the 6½ millions raised by the town. This is not all, however. The prefect has been allowed to issue obligations in the name of the city, and for the *Caisse des Travaux de Paris*, to the extent of 80 millions of francs, or for 3,400,000*l.*; and, if reports are to be credited, so far from his being contented with that enormous sum, he has extended it to the amount of 98 millions of francs (or 1,500,000*l.* nearly), in the case of the works undertaken in the Boulevard Magenta. It is precisely the danger of this abuse of the credit of the town that is to be feared, and it is in this respect that the absence of anything like a controlling power in the municipal council of Paris is to be deplored. As the members of this body are all of them merely government nominees, and hold their places only as long as they vote the budget that is presented to them, the council municipal of Paris becomes nothing more nor less than a body chosen to give a semblance of legality to the proceedings of the prefect; it is utterly powerless to resist or to oppose any measure that he may have determined. Hitherto there has been no such result as was to be expected from this ignoble parody on municipal government, and Paris has gained in healthiness, in beauty, in convenience; in fact, in everything that tends to make life valuable in large towns. The administration of the city funds is confided to a series of officers, who conduct their business with singular skill and attention to the public interests, though it must be confessed that they have allowed the spirit of

red-tapeism, in the conduct of it, to gain the ascendancy; but these officers are not empowered to resist the will of the prefect if he should venture to step beyond the limits of his duty. They are only to discharge their functions; they have no deliberative voice, and they must carry into effect the orders that they receive from higher powers than their own. There is no kind of check upon the fancies or the caprices of the prefect of Paris, in fact, and it cannot therefore be a matter of surprise that he should have been misled in many cases, and should have made the mistake of confounding straight streets with good lines of communication, and broad boulevards with efficient means of ventilation. I fear that much of what has been lately executed in Paris, especially in the neighbourhood of the Madeleine and the Parc Monceau, is liable to this reproach; and certainly it would have been long before the town would have been thus modified, if the conseil municipal had been freely chosen, or if it had correctly represented the wishes of the inhabitants. There is, moreover, this danger about the course that our neighbours have entered upon, that they have created a fictitious demand for labour of the highest and most dangerous class, which they must go on employing; and thus the necessity of always continuing the works at the expense of the town is a constant source of pre-occupation to them. The true remedy to this state of things, to the danger of the gradual increase of the debt of the city, and the creation of the fictitious demand for labour, would be, in my opinion, to restore to the municipal council some sort of control over the money of which they are supposed to regulate the application.

In the course of the discussion that followed, Sir Thomas Phillips, Q.C., said, in looking at the vast improvements that had been carried out in Paris, there was one subject which had been greatly neglected, and that was the effect of these improvements upon the great masses of the working people. In making a new street, large numbers of the working classes were displaced, without any means being taken to provide them with dwellings elsewhere. He knew that the inconveniences in this respect were very great in London at the present time. He had had occasion to sit for some of the local judges, and many occasions occurred of applications for warrants for the ejection of tenants from their habitations, which he was bound to grant; but no one could witness the extent of suffering occasioned by the inability of the poor man to provide himself with another lodging, without feeling that a great evil had been created by turning these people out of their dwellings—bad as these often were, and wanting in all proper sanitary arrangements—without any provision being made for their accommodation elsewhere. With regard to the great works executed in Paris, Mr. Emmell had spoken of their great architectural beauty, but there were differences of opinion on this point. Many people, like himself, might regret that the picturesque features of the city, and the old historic associations connected with it, had been swept away.

Mr. Lavanchy thought the impression conveyed in the paper was that the prefect was the leading, if not the sole, authority in all those matters of public improvement involving so large an expenditure of money. He was quite sure that an error of that kind had not been intentionally made; but the fact was, that any great public work of the nature described must be accepted and approved by at least three separate bodies or commissioners prior to its being laid before the Conseil d'Etat; and if approved by that body, it was finally submitted to the Emperor; and, if sanctioned by his Majesty, was referred back to the prefect to be carried into execution. With regard to the cost of many of these great improvements, it was well known that this was not borne exclusively by the municipality. The sites having been purchased by the prefect, they were re-sold by tender to companies or individuals, by whom they were disposed of to the different parties who built upon them. He thought it was much to be regretted that some such plan as this was not adopted by the Board of Works in regard to the public improvements in London.

Mr. Beloe regretted to hear that the water supply of Paris was at present only on a limited scale; but that regret was modified by the statement that an augmented supply might shortly be expected. The water supply of Liverpool and Manchester was happily of the most ample and satisfactory kind, and had been carried out

by the municipalities of those towns irrespective of the cost to the public. He regretted that the endeavours made by the Government some eight years ago to effect an arrangement with the water companies of London, by which, under the Board of Works, a general supply of water to London could have been obtained, had been defeated.

Mr. Dalton defended at some length the Board of Works. With respect to the great improvements carried out in Paris they had been told that a taxation of 3*l.* 15*s.* per head of the population had been the result; whereas the whole rates in respect of the main drainage and improvements of London did not amount to more than 9*d.* in the pound on the local assessment, or about 10*s.* per head of the population. The Board was asked to make larger public improvements. Where was the money to come from? Would the inhabitants like to submit to octroi duties, as they did in Paris? There was an outcry the moment an increase of the rates was spoken of. With respect to the Vestry, which was said to have been elected solely by the publicans of the parish, that arose entirely from the other parishioners not taking the trouble to look after their own affairs. It had been urged that the Board of Works ought to decide upon a comprehensive and definite plan of public improvements, but he might state that the Board had plans already before them involving an outlay of not less than 26,000,000*l.* The present generation were called upon to bear the burden of the neglect of their forefathers. London had grown to a great extent without the thoroughfares being commensurately increased.

The chairman, in closing the discussion, argued that the health of the poorer classes was cared for in a higher degree in London than in Paris. Whatever might be the beauty of Paris, it was obtained by a heavy burden of taxation—enormously greater than in London—so great as to excite our surprise that it could be borne by the people. Although, however, the cost was enormous, the indirect return obtained by making Paris the centre of attraction for all the world ought not to be lost sight of. Then the question came, could we so heartily London as to make it a greater centre of attraction than Paris, and whether an equal expenditure in London would produce results equal to those of Paris? They must look to the matter of climate in the first place. London was subject to changes of climate and weather which were unknown in Paris. In the latter city the winter was cold, but dry and clear; in summer the heat was greater, but there were fewer wet days. In the matter of the cleanliness of the streets, the continuance of fine dry weather, both in summer and winter, was a great element. Then, again, there were questions involved as to the difference in the habits of the people. Would our population consent to be concentrated in flats, as was the case in Paris, with scarcely a house occupied by an independent family? Could the habits of the people be so altered as to forego that domestic isolation which was so characteristic of the English? While we continued to have separate dwellings, London must necessarily be spread over a very large district, and its roads and drains must be of such great extent, compared with Paris, that the difficulties were increased in proportion.

#### ROYAL HORTICULTURAL SOCIETY.

VARIOUS extra prizes are offered, including several gold medals, with reference to the Saturday weekly shows, and money prizes by the president. A late vice-president offers special prizes,—gold medal, or 10*l.* 10*s.*; large silver medal, or 7*l.* 7*s.*; small silver medal, or 3*l.* 8*s.*, for the most tastefully decorated dinner, or table. Beautiful arrangement of the fruit, flowers, and china will be the test of merit in this exhibition; valuable fruit, or flowers, or china, are therefore not required. Each table is to be laid as if for a dinner, "à la Russe," of ten persons.

Another special set of prizes is to be offered for Window or House Gardening by the working classes, and an exhibition of flowers so grown is to be held. The financial position, so far as we can deduce from the accounts submitted at the last general meeting, held on the 14th, is not quite so satisfactory as we should desire, and makes us a little nervous for the future. The revenue account for the year 1864 shows a balance due to treasurer (overpaid, therefore, we presume), of 2,784*l.*, and liabilities to the amount of 3,546*l.* We shall be glad if our deduction be wrong.

#### ST. PATRICK'S CATHEDRAL, DUBLIN.

THIS building, now completely restored, for the building is now presented to the city of Dublin in a state of grandeur in which it never before existed. It was a labour of love. The work, commenced with the original intention of spending about 80,000*l.*, is not left unfinished, although nearly twice that amount was found necessary. A knotty problem has been solved, and though critics will discover some irregularities of detail at which to level a shaft, all honour is due to the taste of the beneficent gentleman who has saved this truly national monument for the admiration of generations yet to come. Around this old fane hangs an interesting history, stretching back to the middle of the fifth century of the Christian era.

Although it is called a restoration, the term does not properly express what has been done; for the building is now presented to the city of Dublin in a state of grandeur in which it never before existed. It was a labour of love. The work, commenced with the original intention of spending about 80,000*l.*, is not left unfinished, although nearly twice that amount was found necessary. A knotty problem has been solved, and though critics will discover some irregularities of detail at which to level a shaft, all honour is due to the taste of the beneficent gentleman who has saved this truly national monument for the admiration of generations yet to come. Around this old fane hangs an interesting history, stretching back to the middle of the fifth century of the Christian era.

Founded in or about A.D. 1100, by Archbishop Comyn, first of the Norman Archbishops of Dublin, it occupies the site of a former structure, one of those small and unpretending churches, which, scattered so numerously through Ireland, have almost justified its name as the "Isle of Saints." This original edifice was raised in commemoration of the national saint, who had given his name and blessing to a well which exists close by, and has shewn now this renovation. The church erected by Comyn was burnt in 1362, and rebuilt, in 1364, by Archbishop Minot, with the addition of a tower, but having no spire.

Portions of these venerable relics of antiquity are preserved in the walls. There is a vaulted chamber at the extremity of the south aisle, which is assumed, with some reason, to be a part of the early church. In it are the three oldest monuments in the church;—one of them, an effigy of Comyn, cut in granite, and characteristic of the period; another, considerably mutilated, supposed to be that of De Sandford, an immediate successor of Comyn; the third is in a better state of preservation, and a perfectly legible Latin inscription gives the name of Michael Tregray and the grounds of the prelate's hope.

St. Patrick's not only did duty as a house of worship, but for many years sheltered the chief seat of learning in Ireland; for a university, originally projected by Comyn, terminated its existence only in the time of Henry VIII. This building has been by turns a church and a court, a barrack and a hall of council. It has suffered from time to time from revolutionary wars. Soldiers of the Commonwealth took up their quarters in it; and here hinged the loyal veterans of James II. until the cause of their master was irretrievably lost. Here are memories, too, of the unfortunate Strafford, Boyle, Earl of Cork, &c. Through its aisles once marched in triumph the couping William of Orange; and later still, in connexion with it we have the names of Jeremy Taylor, Fuller, Swift, Berkeley, with others too numerous to mention.

Through all these years, with their various changes in taste or fashion, it must be expected that continued and repeated repairs resulted in partial mutilation of the building as it had passed from the care of Minot. Then it was, in all probability, a fair specimen of the Early English period. Some of the details are now in a good state of preservation: from these Mr. Guinness has taken his cue; and, in replacing many of the innovations of the Perpendicular and Decorated Gothic periods which had crept in, he has endeavoured to reproduce the building in a form such as may have been the aim and design of Archbishop Minot, or his architect. For instance, the windows above the magnificent western entrance, which had been displaced for a five-light Perpendicular window, are restored to their original character—three single lights, with banded shafts, in harmony with the triforium, of which there is here a fine example.

No doubt, some of the flying buttresses and pinnacles which surround the eastern end of the Cathedral belong not to the fourteenth century; they are later additions. In their removal Mr. Guinness would not have been justified.

The materials used, too, at different periods, have varied. In one part was the old moulding, Caen stone, now replaced by the hard and durable Tullamore limestone, in tint a very

light blue; in another a red sandstone formed the window dressings.

A spire of granite was erected (we had almost said perpetrated), in 1750, in accordance with the will of Bishop Stearne, once dean of the cathedral, who bequeathed the sum of 1,000*l.* for the purpose.

This, surmounted as it was by a huge stone ball of more than a ton weight, had a most ungraceful appearance. The summit was blown down in the great storm of 1839, and the trunk remained in that forlorn condition until Mr. Guinness formed a point to it, and surmounted it with a handsome gilt cross, 7 ft. in height. The elevation of the span is 103 ft., and Minot's steeple measures 123 ft. from its parapet to the ground, making in all a total of 226 ft. The tower stands at the north-west angle of the cathedral, and has a fine old spiral staircase in its massive walls, and is provided with a peal of eight bells, which have always been celebrated for their volume and purity of tone. Some of them are marked with interesting inscriptions. Two of the bells had been rendered defective. These were given to Mr. John Murphy, of Thomas-street, Dublin, to recast. This arduous and critical trial of splicing has been attended with complete success. Two new bells have been added to supplement the peal. In this tower also is a turret clock, manufactured by Mr. Benson, of Ludgate-hill, and a magnificent specimen of artistic ingenuity and perfect workmanship: its cost will be about 1,000*l.* It possesses the novelty of being a chime-clock: it will play four tunes, simple and well marked: these, selected and arranged by Dr. Stewart, the present organist and musical director of the choir, will be played at intervals by day and night. The tunes are,—*"Adeste Fideles,"* at 3 a.m. and p.m.; at noon and midnight, *"Martyrdom,"* at 6 a.m. and p.m., *"Roussseau's Dream,"* at 9 a.m. and p.m., *"The Sicilian Mariner's Hymn."* In all cases these will be repeated twice, with an interval of one bar between the parts. The dials of the clock, two in number, are 8 ft. in diameter.

It is to be regretted that this cathedral lies in a district of the city of Dublin low in level, both physical and social. For the remedy of the former a vast deal has been done; and from the restoration of the building itself may probably be drawn the remedy of the latter. Under the cathedral flows an old tributary stream of the river Liffey; this is called the Foddlie; and it is to the repeated overflows of the stream after heavy floods that the hastening of decay is attributed. It was at one time an uncommon occurrence that the floor of the building should be several feet under water.

Mr. Guinness saw that one of the first steps to be taken in preventing the destruction of the church, was to effect a thorough drainage of the ground upon which it stood; accordingly he commenced by removing the floor. Large drainage-pipes were laid, the soil was thoroughly dried, and a layer of rubble deposited, over this a stratum of shingle, completely impervious to moisture. The floor was lowered 2 ft., and is now reached by a flight of steps down from the street-level, its original position, as marked by the bases to the nave-piers.

These works have been performed by Mr. Murphy, contractor without (and we are forced to say more's the pity) the superintendence of an architect.

Of the new stained-glass windows,—of which some have been contributed by Wailes, of Newcastle; Clayton & Bell, Ballantine, Barff,—their painted windows,—and a few by local artists,—some are memorial windows; much room remains, however, to commemorate worthies yet to come. We hope to see in one portion of the building, ere long, a mark of recognition of the splendid gift which the Irish metropolis has received at the hands of an illustrious citizen, in the form of either a magnificent window, or a statue, for which there is plenty of room. The building already contains some good specimens of sculpture, and these by hands not unknown to fame; we may mention that of Capt. Boyd. Shortly we may hope to see here an effigy of the late Archbishop Whately, by the same artist. Another commemorative project is at present being agitated, namely, the opening of a new street, to be called Guinness-street, from St. Stephen's Green, where is a residence of Mr. Guinness, to the cathedral, for which would be necessary the demolition of the most filthy purlieus of the city. By this, for which a company is in process of formation, two good objects would therefore be obtained.

The stalls of the Knights of St. Patrick, an order instituted in 1783, and who are here installed, have been entirely renewed. Above the canopies are placed the helmets and swords, the latter having sheaths of crimson velvet and gilded hilts; the upholstery is of Utrecht velvet. In the stalls are the armorial bearings, and high above, from the sills of the triforium, hang the twenty-three banners of the knights in their legitimate brilliant hues.

The pulpit, altar-screen, the bishop's seats, and other details are executed in Caen stone,—having Irish marbles introduced as shafts,—and reflect credit on Mr. Lane, architectural sculptor. The pulpit is erected as a memorial to the late Dean Pakenham.

The new organ was built for this cathedral by Messrs. Bevington & Sons, of London, and is fixed behind the stalls on the north side of the choir. The instrument shows two faces; one over the key-board, filling an arch in the choir with gilt diapason pipes; the other, looking west, into the north transept, containing the large 16-ft. pedal diapason. The organist is well placed for hearing the choir; great mechanical skill was exercised to accomplish what has been done. About 300 of the old pipes have been used again, including those of the stops by Renatus Harris, making up the total of 2,750 pipes. The tone is powerful without harshness. An interesting story belongs to the old organ, a portion of which is worked up in the new. It is said to have been presented by the Duke of Ormonde, who captured it at the siege of Vigo.

The gas-fittings were supplied by Mr. Mooney. The heating adopted is by means of argand stoves consuming gas. These are so constructed that there is no disagreeable effluvia whatever; and twelve of these stoves are sufficient to warm the cathedral.

It is expected that many good changes will follow the example set by Mr. Guinness, who has given quite a new impetus to the improvement of the city.

#### THE DISPOSAL OF SEWAGE QUESTION.

BARON LIEBIG is evidently deeply interested in this question. Not satisfied with what he had already written to the Lord Mayor of London and others on the subject, he has since addressed to his lordship another very long letter, specially decrying Messrs. Napier & Hope's scheme, and with as strong an animus as if he intended being himself a competitor for the disposal of the metropolitan sewage could the City Corporation only succeed in undoing what the Metropolitan Board of Works have already done.

The Baron's tone is not pleasant, however chimerical he may conceive Messrs. Napier & Hope's scheme to be. And, besides, he takes a one-sided and false view of that scheme, as,—though merely sanitary reformers, and no special advocates of any agricultural scheme in the midst of the present Babel of views,—will easily show. But first as to the Baron's objections:—

"If London was situate on a hill, the Maplin Sands forming the slope of that hill ending in a plain bound by the sea; if, furthermore, the Maplin Sands, instead of being perfectly pure sand, as is stated, consisted in their upper part of foam and clay, like the Edinburgh meadows, we should then be justified in concluding that those slopes would be converted by means of the sewage of the metropolis into fertile meadows, the rental of which, varying with the character of the soil, would be from 20*l.* to 30*l.*, while a small portion of them would bring 40*l.*, and the sandy meadows near the shore, when covered with a black deposit, half an inch in thickness, would then acquire a worth of 22*l.* an acre."

But,—

"It is in vain to think of transforming the Maplin Sands into a fertile soil producing luxuriant vegetation; as, in order to do so, more than two millions of tons of clay would be necessary to form the requisite superficial 1 in. in thickness."

In short,—

"The project of Messrs. Napier & Hope is one of the most curious. It is in the fullest sense of the word baseless, for the land to be experimented on does not as yet exist, being covered at high-water by the sea. All the calculations, therefore, as to crops, returns, and percentage of capital, are absolutely fabulous. It appears to me like a soap-bubble, glistening with bright colours, but inside hollow and empty. There is not the slightest doubt that every penny expended in that frivolous undertaking would irrevocably be lost."

The carrying out of this scheme would not only be a squandering of an enormous amount of money, but before long would also be looked on as a national calamity."

Let us hasten to explain that this "national calamity" does not seem to have anything to do with sanitary evils. The question Baron Liebig here views exclusively as an agricultural one; and accordingly, in alluding to national calamity,

he immediately expatiates on the lessons of history to which he long since called attention.

The disposal of the metropolitan sewage on the Maplin Sands, then, would be mere waste of valuable material, since the Maplin Sands are pure and mere sand, and can never be converted into meadows by any quantity of sewage wasted on them for any length of time. Therefore Messrs. Napier & Hope's scheme is baseless, fabulous, frivolous, calamitous, hollow, and empty like a soap-bubble.

But Messrs. Napier & Hope's scheme is something more than the conversion of Maplin Sands into meadows. It is the conversion of either meadows or arable land into tenfold greater fruitfulness, as the sewage goes along the whole length of Essex,—a district with comparatively few residents,—to disembogue its surplus waste (even if that should turn out to be mere waste) into the Maplin Sands and the ocean. And is not this Baron Liebig's own very view of what *ought* to be done with the metropolitan sewage? Or does he contemplate the formation of some great inland lake of sewage, to be retained till farmers can be induced to use the whole of it, leaving none at all to be otherwise disposed of? Is it not clear to the commonest sense, that for some years to come an ocean outfall, directly or indirectly, that will not contaminate any river, *must* be provided for the surplus of the perpetual stream of metropolitan sewage? And if Messrs. Hope & Napier cannot make it pay by supplying the Essex farmers, how is Baron Liebig or anybody else able to do so by supplying *Belfordshire* or *Middlesex*, or any other farmers? And even though they could, still, must they not find an ocean exit, whether with Maplin Sands or not with Maplin Sands as the saw-*all*? If the Maplin Sands be made of such material as can never be converted into meadows by sewage, that is Messrs. Napier & Hope's look-out; and we do not see how even the Metropolitan Board could *better* themselves even in a pecuniary (far less a sanitary) sense, by turning their sewage river inland, always taking it for granted that they have made as good a bargain with Messrs. Napier & Hope for the supply of the Essex farmers as they were likely to be able to do with any one else (providing for the requisite surplus exit) who meant to supply the farmers of any other county. If the Board have *not* made a close enough bargain with Messrs. Napier & Hope for this purpose, that is another question, but it does not affect the feasibility of their scheme as a *whole*, either agriculturally or sanitarily; and that scheme appears to us to comprise all that Baron Liebig himself seems to be fighting for, although he either does not see it, or affects not to see it. Moreover, time presses, in a sanitary sense, and the re-opening of the whole subject is likely to lead to great delay and serious evils, with probably little of either agricultural or pecuniary advantage, either to town or country.

The value of town-sewage to the farmer has been brought before the notice of the Royal Agricultural Society of England by Mr. Lawes (Baron Liebig's special opponent on some points in this country, by the way), whose views were supported by most of the speakers who took part in the discussion which followed upon the reading of his brief paper. As far as experience in this country furnishes data for forming an opinion on the subject, it would appear to be decidedly opposed to the statement of Baron Liebig, that "the full value of sewage and its separate constituents can only be got at when it is employed on arable land." Mr. Lawes remarked that "the parties whose opinions may be regarded as having some weight have almost all declared that the (practical) difficulties attending the application of sewage to arable land are so great, that grass land is the only land to which it can profitably be applied."

The Bill prepared and brought into the House of Commons by Lord Robert Montagu, Sir Fitzroy Kelly, Mr. Ferrand, and Mr. Hibbert, for facilitating the more useful application of town sewage in Great Britain and Ireland, has been printed. It proposes, amongst its other provisions, to give power to local sewer authorities to acquire waste lands, sandbanks, and other lands improvable by the application of sewage under the Lands Clauses Act, on a provisional order granted by the Secretary of State, and confirmed by Parliament. Power is also given to local sewer authorities to contract with landholders for the application of sewage to their lands,—the term of such contract in no case to exceed ten years; and landholders may form associations to take such concessions of sewage.

The corporation of London have presented their petition to the House of Commons, and copies of the same, together with Baron Liebig's report on the utilization of the metropolitan sewage, and the second report of the corporation, have been forwarded to each member of both Houses of Parliament. The petitioners pray that before appointing a private Bill committee to inquire into the Metropolitan Sewage and Essex Reclamation Bill, the House will appoint a select committee to take into consideration the best mode of utilising the sewage of the metropolis and other towns of the kingdom, and to inquire into all the plans for dealing with the sewage, and specially to report upon each of such plans for the information of the country, with a view to secure for the ratepayer the greatest amount of profit from the utilisation of this property.

The Metropolitan Sewage and Essex Reclamation Bill has been read a second time, and been referred to a select committee of ten, as proposed by Mr. Ayrton. And very rightly, too.

#### THE O'CONNELL MONUMENT COMPETITION, DUBLIN.

In response to the advertisement for designs for a monument to O'Connell numerous designs have been sent in. These form a collection of the usual kind,—the good and the bad intermixed,—and we might almost say, in studying some of them, that the chief impression made on the observer is as to the widely different views which are entertained of the essential properties and character of a national monument, as it is proposed this should be considered.

They are now exhibited in the City Hall, Dublin. The models, of which there are eight, are conspicuously placed in the magnificent hall of this building. Around, on screens, are arranged the drawings, made to almost every conceivable scale; contributed chiefly by Irish, but, happily, not entirely neglected by English artists of good reputation. Of the latter, however incongruous the design may seem, when considering the purpose of the structure, we cannot speak in two high terms of one specimen of Decorated English Gothic, with an infinite variety of detail, twisted and moulded through innumerable permutations. It is the work of Mr. Cibbs, of Oxford.

On another screen is an admirable specimen, exquisitely drawn and coloured, of a classical temple, containing and sheltering a colossal statue. At the four sides, apparently from tastefully-designed fountains, gush copious streams of the refreshing water, probably from the Vartry, so long promised to the city. Attached to this is the name of Mr. Heffer, Liverpool.

The majority of the designs are architectural, but in most there is a fair sprinkling of sculpture, such combination being seemingly acknowledged as the most legitimate treatment of a monument.

Amongst the sculptors from whom designs might have been expected, we find MacDowell and Foley conspicuous by their absence. It is not, however, to be inferred from this that mediocrity reigns. Although it may be said of the architectural compositions here exhibited that they are comparative failures, those only being suitable which are beyond the means at the disposal of the committee, it must in justice be said of some, if not all of the models exhibited, that they would form groups creditable as such to the British nation, while their authors will guarantee their execution for the sum named. If the more successful of these should have been suggested by the acknowledged success of the Nelson monument in Liverpool, no one should blame the authors.

Amongst these, foremost are the designs of "Derrynane," James Farrell, Joseph Farrell, Thomas Farrell, John Farrell, and John Cahill, all of whom have already won distinction; the first perhaps not so much a sculptor as an architect, his design is admired for its symmetry and grouping.

The works of Mr. Thomas Farrell are not unknown, and in this instance he has proved true to the reputation which he has framed for himself. His panel for the Wellington Testimonial in the Phoenix Park has before now been noticed in terms of praise; and of his recent statue of Capt. Boyd, in St. Patrick's Cathedral, it has justly been expressed by one who has visited the principal cities in Europe, including Rome, that he "has seen few statues to equal, but none to surpass it."

Mr. James Farrell is known as the author of that extensively pirated work, "La Colombe Retrouvée;" also of the group, "The Orphans," exhibited in the London Exhibition of 1851. The Society of Arts in New York now possess an original model named "The Hunter;" also from his studio.

Mr. Cahill submits a design, in which sculpture and architecture appear to be well balanced; but it is questionable whether so much as he proposes could be executed for anything like the amount named in the conditions. Moreover, the sculpture would require much thought yet properly to express the ideas—suitable enough—of the author.

#### LEADING THOROUGHFARES OF THE WEST.

FROM the programme of improvements as passed by Parliament last week, some ray of hope is held forth that not only the public buildings of this city will be suitable to its population and great commercial wealth, but that its boulevards and grand thoroughfares may sustain comparison with those of Paris.

The River Embankment—the most effective of all our modernizations—will necessitate several traverse lines of communication; and the Law Courts occupying the *juste milieu* between Town and City, and situate in the blocked-up space between our two greatest leading thoroughfares Holborn and the Strand, will also impose the necessity of wide and intercommunicating streets.

Concurrent with these two innovations of marvellous embellishment, a small beginning is made in the amendment of our ways by the continuation of Park-lane, in direction to Piccadilly, which it is to enter at right angles. This is truly an improvement, long needed and demanded, although some opposition was made, and diversity of opinion exhibited, as respects the two latter projects; the sanction of the Legislature was deliberately given as to the best and most feasible measures, which in the initiative give assurance of better things to come.

To widen the tortuous end of Park-lane, as suggested by others, would be a work of time and of heavy expense; whereas the continuation in a straight line by Hamilton-place is complete by only cutting open a road from Holford House (the old lane remaining the same), in aid of the new issue into Piccadilly.

It is by no means necessary to abate the porticoes nor to arch over the areas of Hamilton-place mansions, for the roadway is 37 ft. wide at the narrowest part, and 42 ft. wide from area to area, at the entrance to Piccadilly; when, however, it was recommended to substitute for this great leading duct from *Edgware-road* to *Grosvenor-place*, a less direct line by *Andley-street*, which would debouche into Piccadilly at Cambridge House (actually impinging upon it), the enormous cost of the buildings to be demolished could hardly have been considered; besides that the delay of carrying out such wholesale demolition must have extended from session to session; and at same time the width of *Andley-street* in some parts is no greater than that of *Clarges-street*. For a main arterial duct this last street would be wholly inadequate, its mean width being only 32 ft. from area to area, the average width of the Park-lane gorge being only 24 ft. from house to house!

It is quite clear that openings and clearances through Mayfair are much needed for the wide ranges of modern West London, which have been spraddled since this was the only aristocratic quarter *circa* Hyde Park; but for commercial and passenger traffic, what is really needed is a direct thoroughfare between the widest and most densely populated quarters of the metropolis: the existing zigzags, mazy though they be, are as yet sufficient for retired residents, and the carriages of their guests and visitors; therefore the delay of carrying out rather to be left in the management of the Berkeley and Sutton estates, which share the wide district between them; to disturb their slumber is needless.

On the Grosvenor estate, the most extensive of all the system of management is very different. A clearance has been made of several streets, and Grosvenor-place has been extended in a straight line to the Victoria Hotel; this whole district being now laid out with direct routes leading to the Palace and to Westminster, by Victoria-street, an open space being reserved for plantation, and the projected buildings

planned by the architect in a style to correspond with Belgravia, so as to form a suitable connecting link with the Westminster improvements. Again, on this estate, between *Andley-street* and *Park-lane*, a range of noble mansions in *Holford-street* has been removed, to make way for improvements on a grand scale, to make way for the seeming sacrifice of large rentals, when carried out, as in this instance, with skill and judgment, are sure to pay in increased returns, and the interests of owners and occupiers are both served; but this can happen only on large estates. The great obstruction to improvements in the ancient portions of the metropolis, is the minute and interminable subdivision of property and of interests; therefore, the only plea for the opening of any strait or barrier is public convenience and imperious necessity; and the power and action of the corporation, and of Parliament, the only resource and authority. So it is that the City has stood so long disfigured by obstructions to traffic, and lots so palpable as *Middle-row*, *Holborn*; the gorge of *Chancery-lane*; *Temple Bar*; the sealed thoroughfare north of *St. Paul's*, indignantly blocked only by the ecclesiastical and *ironical* fence; as well as by numberless other barriers in the busiest quarters of trade, which, if managed as in the estates referred to, would be promptly amended, and made to return a doubled rental to the owner, and at the same time to facilitate traffic and trade for the whole community.

It is the province of the Chief Commissioner, as of the *Édile* of old, to have regard for public interests in this respect; and most certainly much is due to Sir B. Hall (*Lord Llanover*) for his commencement in improving our leading public thoroughfares. The opening and railing in of *Piccadilly*, and the removal of the old *Ranger's House* (*Lady Gordon*) were due to him. The Hon. Mr. Cowper has meritoriously followed in his steps, and has opened *Bird-cage Walk*,—and planted the park borders. To every passenger along *Piccadilly* the removal of the old wall and gateway with its stages, and the floral embellishment of the borders, are a solace. But, as the teeming city has since extended a mile and a-half to *Kensington*, there are still fouler blots to erase. The unsightly and ill-placed barracks at *Knightsbridge* stand now in the way, and stop all improvement in this the most healthy, fashionable, and picturesque portion of the *fin de siècle*, which ought to be the noblest boulevard of West London. A narrow strip of 1,200 ft. in length is covered by stables and an ill-constructed and unhealthy barrack. Being in a densely-peopled quarter, it is the worst for troops; whilst the position, elevated, open, and fashionable, is most valuable for the aristocracy. Six public-houses and music-halls, built close to it, exclude first-class mansions, and depreciate the whole *vicinage*. Surely a site distant two or even three miles from the *Horse Guards* would not be too far for cavalry, as we find that *Chelsea* and *Kensington* suit the infantry for quarters. Such a removal would be beneficial to the troops and a boon to the public.

QUODAM.

#### MODERN LONDON BURGLARS.

OF late, robberies of valuable goods have been so frequent in the metropolis, that it has become a question to be put to architects and builders whether it be not possible to construct business premises not only *fire-proof*, but also *thief-proof*. These robberies, which have astonished the merchants and traders of London, show in a marked degree the ability and activity of the thieves, and the adroitness and cunning so remarkable in the system of receiving and getting rid of valuable goods. At the same time, the want of sufficient preventive and detective cunning on the part of the police shows some fault in a specially organized, and calls loudly for a speedy remedy.

The planning of all the more recent great robberies shows a remarkable similarity, which would lead persons to believe that the mischief has been done by one daring and dangerous gang. But bowever this may be, when we consider the concentration of the police in the City, it is difficult to imagine how the plunder of many thousands of pounds value can be carried off without question through the streets in the night time, unless it be that the heavy footsteps of the police in the silent streets give but too sufficient warning to the thieves. Besides the police who are visible, however, there is also a considerable staff of detective police who are always on duty.

In one instance, the robbery was effected by means of a side passage, on a Saturday night or on Sunday, into the premises of a watch-maker and jeweller. The house above the shop was used as offices, which, as well as the shop, appear to have been left unoccupied from the Saturday till the Monday morning; so that the cracksmen were left without interruption to break through walls and panels, and into safes and other strong places. In this case, as it has been in others, there was a strong light in the shop during both night and day; and in the shutters were loopholes through which the police could look into the shop and discover intruders or any disturbance of the arrangements of the property.

In another instance, access was obtained into an adjoining cellar, through the wall of which a hole was cut in a most scientific manner into the adjoining vault, in which was the safe of a hullion and jewel dealer, the chief part of whose stock was taken away, and, so far as we know, nothing has since been heard of it. In connexion with this robbery, it is to be noted that there were not only persons living on the premises, but also a watchful little dog; yet no alarm was given, and the policeman on the beat heard no disturbance on the night of the robbery.

In the Strand, in another case, three men engaged the top room of a lodging-house, from which they made their way to the outside of the roof; and after proceeding a short distance, they opened a mode of admission into the premises of a watchmaker, where they collected a quantity of valuable property, returned with the booty to the lodging-house, and left with it in a carpet-bag between three and four o'clock in the morning.

Another extensive robbery was successfully effected in the premises of Mr. Walker, at the corner of Sun-court, Cornhill. The upper part of this house was occupied as offices; and into one of these, which was rented by Sir John Crossley, the thieves entered, and there they took about 20l. from an old-fashioned safe. Afterwards an attempt seems to have been made to force the sides of Mr. Walker's shop, but this was so thickly plated with iron that the burglars were foiled. They next seem to have made their way into an apartment below the shop, and drilled the ceiling and upper flooring with numerous holes very close together around a space large enough to admit the body of a man. This being done, the piece of flooring was knocked upwards by a sharp blow, and then with case watches and jewelry were seized and carried away, the value of which is said to be between 5,000l. and 6,000l. In this case there were lights in the shop, and the opportunity for police inspection through the holes in the shutters; and yet no discovery of the burglary was made until some of Mr. Walker's people went to business on Monday morning. Three if not more persons seem to have been engaged in this work.

Such events as these following in such rapid succession have caused much uneasiness, and prove that more is needed than there is in use at present to protect property from the hurglar's skill; and when we find that walls with iron plates have offered successful resistance, it becomes a question whether, if the floor or ceiling had been so protected, safety would not have been ensured. A due regard to safety is not only needful in connexion with shops, but it is also requisite in connexion with chambers in banks in which treasure to an immense extent is laid away. The loss of the bullion, &c., in the Bank of England would be a national disaster, and an audacious attempt by tunnelling was at one time made to effect such a robbery.

Some years ago, as we remember, a gentleman who went to a north of England town to manage a branch of the Bank of England there, was in constant fear that thieves would tunnel from the sewers or elsewhere into the underground chamber in which the treasure was kept; and this fear was not altogether groundless. It may be worth while to inquire if there be no risk in this way in our quarters.

At night, the Bank of England is carefully guarded, not only by certain officials of the Bank, but also by a detachment of soldiers; and in most other banks there are clerks and other responsible persons who sleep on the premises. It might be worth consideration if the same precaution should not be taken in other places where a large amount of valuable property is kept. Several persons having charge in this way would prevent collisions, and also deter offenders. In many provincial towns, alarm-bells have been used to a considerable extent in warehouses, manufactories, &c. Why

should not this plan be brought more extensively into practice? Wires laid properly, and communicating with a powerful alarm-bell, which would continue ringing for a considerable time, would often save property. But, above all, we need increased vigilance on the part of the police; for through the trust which is reposed in them, the public are liable to be more lax than they should be in their precautions.

Instances of the careless way in which gold is sent from the jewellers of Clerkenwell to the flattening-mills constantly occur. Boys are entrusted in the winter nights with gold worth 100l., and even more; and there is such a perfect system of receiving, that matters of this kind may be bought and paid for at a small rate, without question, and in a few hours the melting-pot will have effectually rendered the material unrecognizable. Surely, with all our police appliances, the present arrangements of the receivers should be prevented, and then we should have a large diminution of crimes of this description.

People are inquiring, How is it that such daring deeds are effected under the very eyes of the police? During a number of years we have had opportunities, in various ways, of marking the working of both the City and the metropolitan police, and we cannot agree with some of the speakers at the ward meeting that they are a set of ignorant bores; for, before admission can be obtained into the force, the men have to show that they have received a fair amount of education. Their character must also bear careful inquiry; but we believe, as many others do, that the police have, during the last few years, deteriorated; and the cause of this is evident; for, in various directions, there has been increased demand for labour, and the wages of several trades have materially increased, while the sum paid to the police has remained stationary. The amount of salary of the greater part of the force is certainly not sufficient for the proper support of those who have families; and, when we consider the large trust and confidence placed in the police, it is of importance that they should be properly paid. There can be no doubt, too, that, in many parts of the metropolis, the numbers of the police are insufficient for useful service. In the Caledonian-road, which has now become a bustling and important thoroughfare, robberies are of frequent occurrence. Other instances might be mentioned. Enough, however, has been shown to prove that the present system of police requires consideration and improvement; and, in case any inquiry should be made, the detective police should not be overlooked, nor the advantages or disadvantages of the system of rewards, without which it is not easy to get them actively to work.

#### BEAUTY IN COMMON THINGS.

ARCHITECTURAL INSTITUTE OF SCOTLAND.

At the last meeting, Mr. Jas. Gowans read a paper on "Beauty in Common Things," urging, at starting, that beauty in shape or form must rest on true geometric principles. He agreed with those who maintain that both the Greeks and the Christians determined the plans of their buildings by geometric figures, and went on to say,—Much has been done to increase the comfort of the lower classes of this country, and no doubt the interior of a house is of the first consequence; but, while this is so, the exterior should be designed so as to have true shape, however plain and unpretending it may be; for it is quite possible to develop beauty in the cottage of the poor as well as in the mansion of the rich. Ugliness, which stands in the same relation to beauty in the material world as beauty does to goodness in the spiritual world, does a great deal more than merely offend the eye. It has its effect in lowering the moral tone of those whose senses are habituated to it. Beauty, again, being akin to goodness, has the opposite effect,—that is, of reforming and elevating the moral sense of those who are constantly under its influence. Having said so much as to the exterior of our buildings, I wish now to notice how the same principles which give grace to the exterior should be carried to the interior, not only in determining the exact proportions of the rooms, but also in producing the furnishings, so that each and all may harmonize, and produce that unity of effect without which nothing can be perfect. How often do we find that, while some portion of the furnishings may be all that the

eye could wish, the feeling, on the whole, is marred by some incongruous article designed without reference to any law either in shape or colour. How diverse, for instance, are the articles which are brought to our table; and how few of them partake of those simple lines which not only please the eye, but are so well adapted to the uses for which they are required. Why should our tea-kettles, teapots, and the commonest articles that we use, not be designed upon those fixed laws which I have already so often referred to? If the silversmith, founder, and potter, who produce those articles were trained upon a system, instead of leaving them to use their intuitive perception of what was either ugly or beautiful, we should have articles which would not only give pleasure to those who use them, but would, besides, influence the taste in judging what was perfect or imperfect—whether in those things which man made with his own hands, or in Nature herself. I am aware that since the London Exhibition of 1851 there is a very marked difference in the shape of the articles to which I refer; but this desire in the public for that which is simple and shapely in itself is not matured so rapidly as it should be, from the fact that in our schools of design no such laws as I hold by are laid down for the primary instruction of pupils. Nothing, in my opinion, can be more simple than the use of those lines for beginners; and if the article goes no further than the mere skeleton of the figure there will be true shape, and a pleasing proportion. And if the skeleton requires to be clothed over, the elaboration should flow from the same lines, which will always give a harmony and repose to the finished design. Our exhibitions, agricultural meetings, flower shows, and such like, are all tending in the same direction; and although the severe geometric test which I have laid down is not brought forward in a distinctive way, you will find that the judges at those meetings always give the prize to that which is the most perfect in geometric form and colour. Mr. Gowans concluded by showing that the same principles applied to colour.

Professor Blackie said there were one or two points on which he differed from Mr. Gowans. He thought Greek architecture had nothing whatever to do with religion, except in the outer decoration of it,—namely, in the sculptural decoration. Then he thought Roman architecture, again, had nothing to do with Roman religion, but was merely the natural tendency of the human mind to improve. The same remark applied to Christian architecture. No doubt, Christianity mounted to heaven, and so it was natural that in their architecture they should desire to bring things up to the highest degree of perfection. He could not see that architecture had anything to do with religion one way or another. He could not understand at all how that because the Greeks worshipped an unknown God they should take the circle as the base of all architecture. He should like to understand the connexion between the circle and the unknown God.

Mr. J. D. Peddie said, that geometric principles had much to do with material beauty of all kinds thereof could be no doubt whatever; and, especially in the art of the architect, it was impossible for any man to deny the importance of the observance of geometric principles. But he had not been able to understand to what extent those who upheld similar theories to those Mr. Gowans had proposed, considered the beauty of architectural works to depend upon the observance of geometric principles—whether they maintained that this was a condition of the beauty of architectural works, or whether they meant that if a man was merely sitting down like a machine and working by geometric rules he could thereby produce a great architectural work. He was very much inclined to doubt this doctrine altogether. He believed geometric principles had very much to do with architectural beauty. They probably had as much to do with beauty of architecture as the laws of harmony had with music; but as no man by merely observing the laws of harmony could produce a great musical composition, so no man could produce a great architectural work merely by observing geometric rules.

ARCHÆOLOGICAL DISCOVERY AT COLCHESTER. Some workmen, while employed in the garden of Mr. Robert Hall's fruit-er, Colchester, have discovered within and near the Roman wall on Balkerne-hill, a fine specimen of Roman tessellated pavement, the most elaborate and ornamental in design of any yet found in this town.

INNS OF COURT HOTEL. FRONT IN LINCOLN'S INN FIELDS.  
MESSRS. LOCKWOOD & MAWSON, ARCHITECTS.

THE ARCHITECTURAL ASSOCIATION.

The usual meeting of members was held on Friday evening, the 17th ult., at the house in Conduit-street.

The chair was occupied by the president (Mr. Christian).

Mr. William Downal, of 15, Tavistock-square; Mr. Andrew Murray, of 4, Alfred-place, Islington; Mr. William Frederick Potter, of 29, Elmore-place, Lower-road, Islington; and Mr. Gilbert R. Redgrave, of 18, Hyde Park Gate, South Kensington, were elected members of the Association.

Mr. Blasbill proposed, and Mr. R. P. Spiers seconded, a vote of thanks to the Royal Institute of British Architects for opening the voluntary examination class lectures to the members of the Architectural Association.

Mr. Blasbill expressed his regret that there were no examinations this year, and that the few gentlemen who had presented themselves would consequently be disappointed.

The vote was unanimously accorded. Mr. R. W. Edis then read a paper entitled "Architectural Notes from Bouvais to Rheims," including sketches of Noyon, Laon, and the towns and villages along the route, part of which we have printed.

At the conclusion Mr. Ridge observed that architectural travellers often lost a treat by not carefully examining the pretty little buildings so frequently to be found along the high roads of France, and which in their design and arrangement were so widely different from those observed in England.

Mr. R. P. Spiers observed, that of Rheims Cathedral especially, the portion round the choir had an extremely fine effect. There was, however, one feature in the cathedrals of France which he had noticed, and that was, that the length was not so great compared with the width. It had always struck him, on entering Westminster Abbey, that much of the effect of so grand a structure was lost in consequence of the building being so narrow in comparison with the great height from the floor to the pitch of the roof. With regard to the cathedral at St. Etienne, he thought it bore evidence of having been patched up in a remarkable manner. The Town Hall at Rheims was extremely well planned, and there was an old aisle in it which was especially curious and worthy of notice. When, in 1861, he visited the place, he saw some interesting mosaics which had been recently discovered, and which it was proposed to deposit in a museum about to be formed. Referring to the portion of the paper read by Mr. Edis, which treated of Christian iconography, Mr. Spiers observed, that he believed the nimbus was of very early (Pagan) origin; and as an illustration, he mentioned that a statue of Diana had been excavated at Pompeii, which had the ornament or emblem so frequently found in the works of the early Christian period.

Mr. Blasbill said he quite approved of the plan adopted by Mr. Edis, in his expedition of examining the village churches of France. The practice was, he thought, much to be commended, as students of architecture were too much addicted to studying and copying cathedrals only. It was more profitable for them, as young architects, to visit the churches, and to become thoroughly conversant with them, than to occupy so large a period of their time in cathedral research, as few of them would ever have the chance of building a cathedral, although he hoped that he himself might have that privilege before he died. With respect to the advice which was every now and then given to students, not to study foreign works, all he could say was, that he thought such advice would generally be traced either to amateurs or to architects who had never themselves designed anything good. He moved a vote of thanks to Mr. Edis for his very interesting paper.

Mr. John Hayward defended the Puritans from the charge of iconoclasm, which had been preferred against them by Mr. Edis, and also by Mr. Spiers, and contended that they ought to be judged, not according to our views of art or of toleration, but with relation to the feeling of the age in which they lived. The object which they had in view was not so much to destroy objects of high art, as to prevent what they imagined to be idolatry.

The Chairman spoke in favour of visiting the small churches of France, and deprecated the idea that they were not to study French architecture.

Mr. Edis, in acknowledging the vote of thanks,

referred to the so-called "restorations" now going on so vigorously in France, and observed that there were no greater iconoclasts than the French sculptors, who would chip off the most delicate foliage, or the most elaborate and beautiful ornament, if it happened to be a little cracked.

COMPETITIONS.

*Belfast.*—In a recent limited competition for a Wesleyan college, proposed to be erected at Belfast, four architects, distinguished for their success in public buildings, were invited to compete; these were,—Mr. Jones, Dublin; Mr. Hill, Leeds; Messrs. Lanyon, Lynn, & Lanyon, Belfast; and Mr. Fogarty, Dublin. After considerable examination the committee selected the design No. 2, submitted by Mr. Fogarty, as that best suited for their purpose. He has accordingly been instructed to prepare the working drawings. The cost, as at present arranged, is not to exceed 10,000l. It may be well to mention that the committee presented the unsuccessful firms each with 40l., as some compensation for their trouble in the preparation of designs.

BRITISH ARCHAEOLOGICAL ASSOCIATION.

At the meeting held February 22nd, Mr. G. Godwin, V.P., in the chair, a letter from the treasurer, Mr. Pettigrew, accompanying some presents to the library, made by the late Duke of Northumberland, laid upon the table, was read by the chairman, lamenting the decease of a nobleman so distinguished and beloved. His Grace had given his assistance to the next congress of the Association, at Durham, in the month of August. Mr. Pettigrew concluded his letter in the following terms:—"In his Grace's decease, science has lost an ardent student, antiquities and the arts a most enlightened cultivator, letters and literature in general a zealous friend and supporter; but in that which more especially regards the moral individual and his perpetual exercises as the friend of the poor and needy, it were difficult to employ terms sufficiently cogent to express what we must all so sensibly feel." The chairman from his own knowledge described several services rendered to archaeology by this most excellent man.

Mr. Wilton Rex communicated a paper, "On the Customs and Privileges belonging to the Town of Glensford, in Suffolk, with the Antiquities of the same," which was read by Mr. Levien, and gave rise to an interesting conversation. Mr. J. T. Irvine sent drawings of remains in the churches of Bradford-on-Avon and Ashton Steeple. The former were very curious, representing some ancient pieces of stone built into the church, and singularly sculptured, presenting interlaced strap works in panels, with a chequered or diaper design, resembling the arrangement of some early tessellated pavements. There was likewise half a recumbent figure of a lady in the costume of Edward I., or beginning of Edward II., coloured.

Mr. George Vere Irving read a paper "On the Swords of Andrea Ferrara," illustrating his subject by many examples and rubbings, with varied characteristics.

Mr. Halliwell exhibited a beautiful seal of the Guild of Holy Cross at Stratford-on-Avon, which he had never met with before. It is very elegant, and belongs to the fifteenth century.

A paper on the finding of a large collection of Saxon coins at Ipswich, by Mr. Francis, was read.

BRADFORD WATER-SUPPLY.

THE DOE PARK RESERVOIR.

An important inquiry has been held at Bradford respecting the security of one of the reservoirs connected with the waterworks of that town, and as attention has been frequently called to this reservoir by Mr. Ferrand, M.P., in the House of Commons (in consequence of whose complaints Mr. Rawlinson, C.E., was sent down by Government), and much uneasiness occasioned to the inhabitants in the valley below when the reservoir has been filled for testing purposes, the following account will no doubt be read with interest.

The Doe Park Reservoir is one of three reservoirs which have been constructed for the purpose of compensating millowners for water which the Corporation of Bradford has ab-

stracted from the tributaries of the rivers Wharfe and Aire. These reservoirs together have an area of about 160 acres. The expense of making these three reservoirs has, however, secured to the people of Bradford valuable drainage grounds amounting to above 10,000 acres, the water from which is said to be remarkably pure and soft. The reservoirs for collecting the waters from these districts cover about 150 acres, and the conduits for bringing the same to the town are upwards of thirty miles in length, and include about five miles of tunnelling.

These important works have cost above half a million, and have been carried out by Mr. Leather and Mr. Dooke, civil engineers, Leeds. Mr. Cott, C.E., of Bradford, is now in charge of the works, and acting as waterworks manager in addition to his duties as borough surveyor.

On applying to the magistrates for certificate of completion, Mr. Bateman, who has made a special examination for the Bradford Waterworks Committee read an elaborate report, in conclusion of which he said:—

"On the whole, therefore, although I cannot pronounce the reservoir to be in a perfectly satisfactory state, I believe the embankment to be secure, and the work free from danger, the provision for passing the flood waters sufficient, the arrangements for discharging the water well designed and executed, and the reservoir capable of holding the quantity of water required by the 61st section of the Bradford Waterworks Act, 1854.

I consider it, however, necessary that there should be a resident watchman, and that the quantity and character of a leakage and all the circumstances of the reservoir and works should be narrowly and carefully observed and recorded. Any change which indicates waste or danger should be immediately attended to; but so long as the leakage remains stationary in quantity and free from colour or matter in suspension, and the embankment retains its proper shape, I believe it is far better to leave the work alone than to endeavour to reduce the leakage by any method which would disturb the grounds."

The magistrates agreed, after consideration, to adjourn the decision of the question until the 18th April next.

ROMAN ANTIQUITIES AND MODERN ANTIQUARIES OF CHESTER.

ALTHOUGH the following communication reports some of the particulars already given in our pages we might lay ourselves open to the charge of unfairness if we did not print the whole of it.

My attention has been directed to the number of the *Builder* for February 18, containing a leader headed "Roman Antiquities and Modern Antiquaries in Chester," commenting upon a newspaper account of two lectures which I recently delivered in Chester upon some Roman remains discovered within the limits of the city in June, 1863, the same subject having been brought under the notice of the Society of Antiquaries in a paper read by Mr. Tito in January, 1864; and I rely upon your sense of justice to afford me an opportunity of making a few remarks upon it.

The only portion of your comments of which I have personally to complain, is that in which I am accused of a want of courtesy to Mr. Tito,—a statement that I read with considerable surprise, as nothing could have been farther from my wish; nor can I or my friends discover any passage in either of my lectures which could possibly be with common fairness distorted into such an accusation. I certainly ventured to state that Mr. Tito's paper was "full of inaccuracies," and that in it he had committed grave archaeological errors; adding, that the sooner such errors were rectified the better for archaeology, as in the most recent work of any importance on Roman remains ("Notices of Roman Bath," by the Rev. W. H. Scarth), the Chester discoveries were compared with those at Bath, a comparison that was certainly not warranted by the facts. In so doing, however, I do not for a moment consider that I passed the bounds of fair criticism, and had Mr. Tito reason to complain in similar terms of inaccuracies, &c., in my paper, I should certainly not have attributed his adverse criticism to a want of courtesy on his part.

Whatever may be Mr. Tito's present opinion as to the character of the Chester remains, does not affect the question. I had to deal solely with his original opinions and statements, as they appeared in the report of his paper in *The Gentleman's Magazine* for March, 1864, and which Mr. Scarth also quotes in the work just referred to, the correctness of which he had an opportunity of verifying as he had read Mr. Tito's original paper at Bath. From this report I extract the following:—

"On further examining these excavations, Mr.

Tite found the distinct remains of a small temple or shrine. This temple originally consisted of twenty-four Corinthian columns, four at each end and eight on each side. Of these, ten remain in their places—that is, there were ten bases and considerable portions of the shafts. Other fragments of the shafts and portions of the capitals were found in the rubbish, and the foundations of the twenty-four were to be recognised," and further, that the first base discovered rested "on a square block of red sandstone standing on the maiden rock."

These are not simply opinions or suggestions advanced by Mr. Tite, but they are, to quote the words in his letter read before the Chester Archaeological Society, "incontestable" facts; and yet, however the quotation may be defended, it is "full of inaccuracies." In the first place, the blocks under the bases did not rest on the maiden rock, but had a thin bed of stone concrete beneath them, the same plan having been adopted under the foundations of all the walls also. Secondly, nine bases only were discovered, all of which were *in situ*, with one exception in the northern range, which had been evidently pushed out of position during the erection of some modern buildings. Thirdly, the sites of two rows of pillars, ten in each range, were to be recognised even where the bases were absent; and so far I coincide with Mr. Tite, between whose original statement and that to which you allude in the first column of your leader there is a marked discrepancy; but of the original existence of any in the intervals between the ends of the rows (answering to the front and back porticoes of a temple) there was not the faintest trace; the ground at those points was on the same level as that occupied by the terminal pillars, and it was the general opinion of architects and archaeologists who visited the site, that, apart from other reasons which I mentioned in my lecture, pillars had never been erected there. Fourthly, there is the distinct assertion that the remains were "those of a small temple or shrine."

Mainly based upon these pseudo facts, Mr. Tite exhibited before the Society of Antiquaries a drawing of "a beautiful restoration of the whole building, with its baths, palestra, gardens, &c., a restoration of the temple or shrine, &c." Now I must and do maintain that he was not warranted in exhibiting such a drawing, based, as it was, upon imperfect and insufficient data. Of the main building, neither its length nor breadth could be ascertained, nor could the dimensions of even one room be determined, as a Medialval wall, parallel to the external one of the original Roman structure, and belonging to the adjoining property, intersected the whole range. As for the "palestra, gardens, &c.," it is hardly probable that they would be attached to the temple of a simple military colony, like Chester, whilst they were absent at important places like Pompeii. When Sir William Gell made a drawing of the restoration of the Temple of Fortune at Pompeii, ample data were furnished him for this purpose from amongst the fragments found within the ruins; and the same may be said of that of the restoration of the Temple of Minerva at Bath, in the great work of Lysons; whilst at Chester, beyond the existence of two rows of pillars, there was literally no evidence whatever in support of Mr. Tite's statement.

Moreover, in his comparison of the Bath temple with the supposed one at Chester, he states the former to have been hexastyle, whilst the latter was tetrastyle, forgetting the Roman practice that "where the end portico was tetrastyle, there were never any columns at the sides, except false ones" (*vide* Smith's Dictionary of Greek, &c. Antiquities—art. Templum). This was one of several reasons I mentioned at my lecture as being fatal to Mr. Tite's theory; and I further added that although a Roman architect in *Deva* might not have carried out all the ordinary rules of temple construction, yet it is scarcely probable that he would have deliberately violated the whole of them.

With reference to the paragraph to which you take exception as being a *non sequitur*, I may remark that the newspaper abridgment of my paper is at that part imperfect. After having explained the attributes of a Roman bath as shown by the discoveries at Caerwent, I pointed out that the Chester remains possessed none of the essential characteristics of a bathing establishment, beyond the presence of a range of hypocausts; but, considering that they assimilated so closely in character to those first uncovered at Wroxeter, that they were evidently those of a public building, and that they formed

only a small portion of the original structure, &c., I was inclined to the belief that they formed a portion of the remains of public baths; but to this I subsequently added, that the "absolute proof must wait until future excavations expose more of the southern portions of the building." Of the conjoint erection of baths and basilicæ we have not only the evidence of the Wroxeter example, but also the records of others at Ribchester and Lancaster.

However distasteful it may be to Mr. Tite to find his statements questioned, I attribute the errors in his paper to the circumstance of his visit to Chester having been of a hurried character, and that it did not afford him sufficient time to make an accurate personal inspection of the remains (I am assured by the gentleman who accompanied him to them that his visit did not extend to one entire hour). However much he may have been assisted by the two visits of his clerk, it does not alter the fact that his lecture, like his own visit, bore the marks of great precipitancy; so much so, that at the very time he was reading his paper before the Society of Antiquaries (January, 1864), the excavations were not completed; in fact, unless he materially enlarges his original paper, it will, I believe, be found that he has omitted to mention many of the important features connected with these remains.

Not one of the members of our local Archaeological Society, many of whom visited the site several times weekly during the progress of the excavations, and who are as competent as Mr. Tite to judge of the character, &c., of the buildings, coincide with him in his opinion; and considering the many opportunities they had of studying them, I leave it to your readers to judge whether he or they are the more likely to be correct. One other comment on Mr. Tite's paper and I have done. In the *Gentleman's Magazine* report of it are these words:—"This was the state of things when these remains were fortunately seen by Mr. Tite;" and, "that his paper was received with much satisfaction, and it was considered fortunate that so complete an account of remains so interesting had been thus accidentally preserved." Now, no stranger could possibly read these extracts without at once coming to the conclusion that if a local Archaeological Society existed at all, it must have seriously neglected its duty in allowing such remains to be left undescribed and unrecorded; whereas, from the very onset the members of the Society had done all in their power to ensure a correct description being brought under the notice of one of the Society's meetings, and of subsequent publication in their journal: they therefore, with good reason, have to complain of a want of courtesy on the part of Mr. Tite, in permitting such a reflection to be thrown upon them. It is true that in his letter read before the Chester Society, he stated, "Though I made every inquiry I could not find any one who was collecting any particulars as to the remains themselves, except my friend, Mr. Peacock, to whom I was referred;" but this only proves that his inquiries must have been of a most meagre description. Mr. Peacock (the gentleman he mentions), as well as Mr. Hodgkinson, the architect of the site, both knew that I was at work collecting materials for a paper on the subject, and they each rendered me most valuable assistance. Further than this, the Marquis of Westminster, the owner of the ground, had given directions that every facility should be afforded me for the purpose. And on June 23, 1863, the day following the discovery of the hypocaust, it was officially announced at a meeting of our Society, that I had promised to watch the progress of the excavations, and to bring under the notice of the Society a report of all the remains that were uncovered,—a statement which appeared in the local journals of July 1st, 1863, and which was known to the majority of the members of the Society.

In conclusion, I must again disclaim any want of courtesy on my part towards Mr. Tite, notwithstanding his injustice to our local archaeological society; and with reference to the important Roman remains which have formed the subject of his paper, as well as of mine, my sole desire has been to place the facts fairly and without prejudice before the antiquarian world.

T. N. BRUSHFIELD, M.D.

\* \* \* What we complained of was the tone of the paper read and the remarks made, and we see no reason whatever to alter our opinion. Mr. Tite found in Chester certain very curious remains, so far as he knew unrecorded. He

took great pains to measure and describe all that was to be seen. As soon as he learnt that others had done so also, he sent a courteous note, stating his regret that he had inadvertently interfered with a duty undertaken by others, but unknown to him. Mr. Tite, of course, is not responsible for the opinions and conclusions of the *Gentleman's Magazine*, which, after all, seem to have been the main provocative. Why such an amount of anger should have been shown because of a well-meant and kindly effort, followed by a most courteous and reasonable explanation, must still remain a modern "Chester mystery," though no Miracle.

#### WORKHOUSE AND HOSPITAL NURSES.

DURING the late protracted investigation by Mr. Farnall, Poor-law Board Inspector, in connexion with the death of a man in the Holborn Union, that gentleman expressed an opinion respecting workhouse nurses exactly similar to that which we have on several occasions given.

Mr. Farnall said,—“I object to pauper nurses in workhouses; but I am not a guardian of the Holborn Union. We have in the metropolis a great number of paid nurses, and I believe that the ratepayers benefit by it, because the paid nurses get rid of the sick cases sooner than the pauper nurses.”\*

As regards the case of the man whose death has led to this inquiry, we will only say that he was, according to the account of his friends, a man of large and robust frame, and was admitted into the Holborn Union suffering from rheumatic fever; and it is clear that, owing either to want of care or knowledge on the part of the nurse, bed-sores were allowed to form on the man's body, so that his condition seems to have been shocking. Eventually he was removed by his friends, and soon after died,—it is said, chiefly in consequence of the want of proper care and attention. In this instance the head nurse herself seems to have been unqualified to attend to a large number of persons, many of them seriously sick; and it also appeared that one of the male night-assistants had not been appointed in consequence of any indications of his fitness, but because of his not being able to sleep in the night-time. Even with the most vigilant care on the part of the medical attendants and masters of workhouses, if the nurses are unfit there will fall to be justice done to the sick poor; and the custom of placing paupers to fill important posts in those large establishments is most objectionable; as is also the practice of appointing such inmates to teach and exercise guidance over large numbers of young children.

There is a custom which, under present arrangements, causes hardship to the most destitute. In cases of sickness, in some of the workhouses, friends are allowed to visit the patients and take with them tea, sugar, and other little matters, which, by contrast with pauper fare, may be considered luxuries. Presents of money are also made to the sick, by what almost amounts to the same thing, to the sick, by those who have the means, and in these cases the patients are likely to meet with a little extra kindness and care; but those who have no friends are, in far too many instances, on this very account, left in misery and neglect.

We have heard complaints of a similar kind in connexion with porters and nurses of more than one of the metropolitan hospitals—a point which requires investigation, not only as regards in-door but out-door patients.

#### THE DEATH-RATE OF PARIS.

A REPORT, drawn up by M. Deville in the name of the inspectors of the verification of deaths in Paris gives the following account of the mortality in that capital during twenty-four years, from 1840 to 1863.

As far as can be judged from documents furnished by different historians, the annual mortality in Paris about the beginning of the last century was 1 in 28. Fifty years later an improvement took place to 1 in 30, and in 1836 there was only 1 death to 38 inhabitants. The year 1840 was an inexplicable exception to this gradual decrease in the death-rate, which rose

\* It seems that the cost of attendance upon the sick in the thirty-nine metropolitan workhouses amounts to a little over 10,000*l.*—a small sum when the large number of the inmates of the workhouses in the metropolitan district is taken into consideration.

in that year to 1 in 33. In 1841, from which date the commission has been able to obtain absolutely authenticated documents, the mortality was 1 in 26. Five years later, viz., in 1846, at the period of the quinquennial census, it declined to 1 in 37. In 1851 it improved to 1 in 38, and in 1856 to 1 in 39. The above rates are for ancient Paris, the population having been increased by the addition of the suburbs in 1860, the period of the annexation. Yet, with all this increase, the census of 1861 giving for Paris 1,696,141 inhabitants, the mortality was only 1 in 39. During the years 1862 and 1863 the decrease progressed steadily, 1 in 40 being recorded for each year. Thus in twenty-four years (from 1840 to 1863) four inhabitants were gained. The Commission attributes, and with some reason too, this amelioration to the vast public works carried on throughout Paris, by which each individual enjoys more space, more air, and more plantations; to the immense surface drainage through the new sewers; to the unremitting exertions of the Commission on unhealthy lodgings; to the better installation and organisation of the hospitals; to improvements in the management of barracks; lastly, to the greater prosperity of the labouring classes, who are better cared for, better clad, and better fed.

#### EXCESSIVE DEATH-RATE OF MANCHESTER AND LIVERPOOL.

In a recent number of the *Builder* attention was directed to the serious excess of the death-rates of these important towns. The deaths in Liverpool are given at 42 in 1,000; the mortality of London 30 in 1,000; so that the deaths in Liverpool are 12 in 1,000 more than occur in the metropolis. In Manchester the deaths are 40 in 1,000, or 10 in each 1,000 more than London. The deaths in certain healthy neighbourhoods are but 17 in 1,000; so that Liverpool is in excess 25 in each 1,000, and Manchester 23 in each 1,000. This waste of human life is monstrous, and ought to lead to the greatest care on the part of the health officers; for it is to be noticed that the death-rates of both Manchester and Liverpool have greatly increased since some illustrated papers were published in these pages descriptive of the first-named city. At that time the death-rate of Manchester was about 33 in the 1,000, and that of Liverpool about 35 in the 1,000.

At the time of our visit to Manchester on that occasion we pointed attention to the excess of deaths, and objected to the system of ash-pits and cesspools, which, to the astonishment of many, receive so much favour from certain members of the corporation. There can, however, be no doubt that this practice is the cause of much sickness and death. The cellar dwellings, many of which have been allowed to remain in use with certain modifications, are another source of mischief, as are the small dwelling-houses which are without thorough ventilation, and which in many instances are built back to back. But besides these proximate causes of preventible disease, we referred in the notes mentioned to risk which there was of the pressure of the cotton famine driving the people to overcrowding, and by this means leading to the outbreak of fever and other disorders which arise from this cause; and there is no doubt that this has been the case in both those places. In Liverpool this has been caused, to a more considerable extent than in Manchester, by the removal of dwellings which had been occupied by the poorer classes. We hope, however, that the state of the health of these towns will be carefully inquired into, and that the intelligent and energetic men of Manchester and Liverpool may enter into a contest, for the purpose of endeavouring to reduce to the greatest extent the death-rates of their respective localities.

#### SCHOOLS OF ART.

*The Ipswich School.*—The usual annual exhibition of the works of the students of this School, has been held at the new Assembly-room, Northgate-street. The exhibition contains a large proportion of oil and water colour works, and chalk drawings, and is reported to be creditable to the students, and to the master, Mr. W. T. Griffiths.

*The Southampton School.*—The distribution of medals and prizes in this School, has been deferred. The total number of students under

instruction in the School of Art, has been 145, and in public and private schools, 1,300. There is an increase of 283 since last year. There are to be distributed 1 national medalion, 7 medals, 20 prizes, and 31 certificates, besides 110 prizes to children of poor schools, and 55 honorary certificates to students of private schools in the lower grade, besides the local prizes. Suitable accommodation for the School is urgently requisite.

#### PROPOSED STATE ASSISTANCE TO ART-SCHOOLS.

HAVE you seen the code of rules for State assistance to art-schools, proposed by the Department of Art, to meet the Select Committee's recommendations? If so, you have seen the greatest injustice (proposed to be done) that ever was inflicted on a body of respectable men. Art-masters are, as a body, a hard-working set of men, and not over-well paid. It was a source of alarm to many when a large part of their income was proposed to be taken away, though an equivalent was offered by the Department of Art. I never was frightened myself at the loss of certificate allowance, because I saw a disposition to give an equivalent. But this last minute not only abolishes the equivalent, but ignores the art-masters' certificates, placing them entirely on a par with those held by national school-masters for teaching drawing in national schools, and offers precisely the same assistance to holders of second or elementary-grade certificates as to third grade or art-masters' certificates. Any intelligent schoolboy could take, and often has taken, the second-grade certificate, in a few months' occasional study; and this is the standard of art knowledge which in future will only be required in candidates for masterships of art-schools!

The scale of payments also is such that only a very slight portion of the enormous grant for art-education will ever find its way into the provinces; and allowances to provincial schools for art-pupil teachers are to be abolished, so that the master of a school of art which has three or four class-rooms will find himself entirely without assistance. The direct opposition to the Select Committee's decrees will, I hope, prevent this proposition from passing Parliament.

The art-masters in the provinces have studied for years, at great expense to themselves, and some cost to the country, and the inevitable consequence of this minute will be either to drive them away entirely from the public service or turn them into bad public servants. A premium is positively held out to them to prevent the spread of art knowledge, because every person taught and becoming possessed of the elementary certificate may at once become a rival teacher, as well paid by the State as the art-master who has studied and worked for years.

This is especially the case among school-masters, when there ought to be held out the greatest inducement to teach them.

A MASTER.

#### OVERFLOW-PIPES TO THE RAIN-WATER HEADS.

The sketch in your recent number of "Telescope Rain-water Pipes" shows a very great improvement, as it gives an opportunity for unobstructing the pipe; and I beg to suggest that all rain-water heads should have an overflow-pipe in front, as is often found in the old lead heads: the difference in the east would be but trifling, and the advantage very great.

How often do we see the fronts of houses spoiled, and the brickwork damaged, from this cause; and also the paper in the rooms.

The overflow-pipe would get rid of another difficulty, for it is well known that the heads are often fixed to fall backwards as they are drawn close to the brickwork by the pipe-nails, and the overflow is backwards when the head is stopped.

Allow me to point out another great evil in fixing cast-iron rain-water pipes and heads without painting the inside of the sockets,—the water lodges, rusts the pipe, and, after a time, the socket is cracked. I have often found an overflow at the joint from this cause when the pipe is stopped, and been obliged to put new pipes, this evil arising from a little carelessness in not painting the sockets.

I hope the manufacturers of rain-water heads will take the hint I have now given, as other hints given in the *Builder* have been taken.

OCTAVIUS.

#### HEALTH IN SHROPSHIRE.

The rate of mortality is fearful in many parts of Shropshire. In Madeley parish, containing about 3,000 inhabitants, there were, from Oct. 1 to Dec. 31, 1864, inclusive, 94 deaths, and only 87 births. A great number of these deaths were from small-pox, others from bronchial and inflammatory diseases. A mortality so excessive is attributed to the malaria arising from the River Severn; and no doubt that evil exists.

A great cause, however, will be found in the deficiency of drainage, and the want of airy, well-ventilated dwellings for the poorer classes, most of whom live in wretched hovels (for which they pay exorbitant rents), without cellars, paved with porous tiles or bricks upon damp clay, without drains, and, what is worse, often without good water, as the country is all coal and iron.

Another large village, two miles from Madeley, and fourteen from Shrewsbury, with the pretentious name of Dawley Magna, is worse, if possible, than its neighbour. It is a large colliery district, and may be truly called "a Black Country."

The churchyard is about 4 ft. above the road; and as the cemetery is very old, perhaps this is an accumulation of "mortal coils." A portion of this bank has been excavated, and in the churchyard a school, of brick, has been built, the back, with the utmost contempt for drainage, abutting against the mould of "some mute inglorious Milton or Cromwell, guiltless of his country's blood." The result was more than the hardy little colliers could stand; and sickness and mortality were so great that the school had to be abandoned, and now stands, with its broken windows (although not above a dozen years since it was built), a melancholy memento of want of foresight. The Sunday scholars are accommodated in a room in the "Church Wickets," through the kindness of the landlady, who, though "a publican," we may venture to say is no great sinner.

JANUS.

#### FALL OF A NEW SUGAR REFINERY AT LEITH.

A CALAMITOUS occurrence has taken place at Leith in the fall of a large new sugar refinery, belonging to the Leith Sugar Refining Company, which was in progress of building near Redraes, on the Bonnington-road, near Edinburgh. At least four lives have been lost, several persons severely injured, and a valuable property almost entirely destroyed.

The refinery was built in two divisions—one a building four stories high, the other and larger one, of eight stories. It was in the last-mentioned building that the accident took place, and which was 82 ft. long by 44 ft. broad. It consisted of eight flats—the lowest of which was 11 ft.—and the others 9 ft., from floor to ceiling. The total height of the building must, therefore, have been between 80 ft. and 90 ft. The building was constructed entirely of iron and brick, so as to be completely fireproof. The floors rested on a series of brick arches, which it was intended should be paved with flags. A row of six iron columns ran through the entire length of the building from north to south, which supported iron beams running across the breadth of the building, from which the arches of the different floors were sprung.

The roof of the building was a large tank for receiving water, which was 4 ft. deep, and was made of ½-inch iron plates. The tank, which must have been of immense weight, rested equally on the outer walls and on the iron columns. Unfortunately, however, the foundations appear to have been insufficient for the very heavy superstructure; so says the  *Scotsman*. The foundations on which the pillars rested were stone piers, each surmounted by a block of free-stone, 4 ft. square, in which the iron part of the column was sunk, and fixed by iron clamps. The failure of one of these blocks of stone is supposed to have been the immediate cause of the accident.

The architects of the refinery are Messrs. Blake & Barclay, engineers, Greenock; contractors for the brickwork, Messrs. Allan & Mann, Glasgow; for the machinery, Messrs. Blako & Barclay; for the iron beams and columning, &c., Messrs. Cowden & Brodie, Paisley. All the parties engaged were considered men of good reputation in their respective departments.

### ARCHITECTURAL SCULPTURE AND THE PRIZE SCHEME.

UNDER the above title you printed in your last number a letter, suggesting that the council of the Architectural Museum should include architectural sculpture in their prize schemes, and inferring that stone carvers have been lost sight of. This has not been the case, for on several occasions prizes for works in stone have been offered. The response, however, has never been up to our expectations, and we have put down the inconvenience of working at home in such a material as stone as the probable cause of failure. When our council consider the question of prizes for next year, it may be disposed to renew their offers for stone-carving.

JOSEPH CLARKE, Hon. Sec.

### BUILDERS AND ARCHITECTS.

SIR,—The article that appeared in your publication of February 11, under the above heading, has been to me a source of some amusement.

"Measure and Value" says,—"Perhaps I can explain my meaning in the shortest way by showing what led me first to keep out architects. I do not wish to blame him for so doing, as it must be apparent to any one with common sense that it would be to his interest to do so. Having no one to control his movements, he would, of course, be in a position to make the matter agreeable to his own wishes. Under the circumstances, may it not be fairly presumed that he would make the opportunity beneficial to himself?"

"Measure and Value" goes on to observe that architects, as a rule, advise their clients that builders, as a class, are a set of rogues, and that it is highly dangerous to have any dealings with them except under the protection of one of themselves. Surely architects would not make those grave assertions without just cause? "Measure and Value," by his own showing, has been very successful, having, as he assures us, acquired a competency, while time out of ten that commenced when he did have gone to the bad. As he is so much to the good without supervision, let us hope he has in all cases been ever mindful of his clients' interests. Architects, he says, must not expect any good feeling from builders while they continue to do so and so. I would venture to suggest that architects would not wish or expect any, as it would, in my opinion profit them nothing. It would appear to me that architects are employed to look after their clients' interests, and not to study whether they have the good feeling of builders towards them. "Measure and Value" further says, in any other business a tradesman who is known to turn out good work is patronised; not so in our trade, where architects have their way. This, I presume, should read, where architects have not their way, as it must be apparent to the most unobservant that architects are employed for the sole purpose of seeing that the works are well and effectually performed. "Measure and Value" also says, "I advise all honest builders never to let an architect get between them and their customer, if they can help it." Were I a builder, I doubt not I should enter into his views. The reason, of course, is obvious. A COMPTONIAN OBSERVER.

\*\* Of course, when we printed the letter referred to, we had no intention of seriously discussing whether or not it is desirable to employ an architect. Our reason for inserting it was stated at the time.

### COMPENSATION CASES.

#### BIRMINGHAM V. THE SOUTH-EASTERN RAILWAY COMPANY (CITY TERMINUS).

THE jury was summoned in this case (Lord Mayor's Court) to assess the amount of compensation to be paid to the claimant in respect of certain freehold property in Dowgate-hill and Turnwheel-lane, Cannon-street.

Mr. Bovill, in opening the case for the claimant, stated the property in question consisted of a spacious and recently-erected pile of buildings, known as Dowgate-hill Chambers, and a house and premises in the rear, 5, Turnwheel-lane, known as Stebbing's Billiard-rooms. The Dowgate-hill Chambers were the freehold of the claimant; the premises, No. 5, Turnwheel-lane, were subject to a lease, of which five years were unexpired, at the close of which it would have become the freehold of the claimant. The counsel then went through the various terms of the claim, which, he said, amounted in round figures to 36,000*l.* The company had offered 24,000*l.*, which the claimant refused to accept.

Witnesses having been called in support of the claimant's case.

Mr. Lloyd, on behalf of the company, repudiated the figures given them by the claimant's witnesses, and called a large number of surveyors, who valued the compensation at 20,233*l.* to 22,027*l.*

The jury, after a short absence, awarded the claimant 30,500*l.*

#### WOOD V. THE CHARING-CROSS RAILWAY COMPANY.

An inquiry was held on the 28th February, at the Surrey Sessions House, before Mr. Gresham, the High Bailiff of Southwark, to assess the compensation for Nos. 89 and 90, Redcross-street, and Robson's yard, in the rear.

Mr. Lloyd, with Mr. Mellor, appeared for the company; and Mr. Bovill, Q.C., with Mr. Butler, for the claimant.

The property was held under a lease for three lives, on the Bishop of Winchester's estate, known as Winchester Park, leased to the Messrs. Pott. The principal contest was as to the value of the yard after the expiration of Robson's underlease in 1872, the witnesses for the plaintiff placing it at from 180*l.* to 250*l.* per annum, and those for

the company from 120*l.* to 130*l.* Another disputed item was a percentage on the value for the right to enfranchise, which the claimant put at one-third of the dry value, and the company at six. The claimant's witnesses, Messrs. Edward Roberts, Edward Habershon, Thomas Green, and Henry Rice, varied in their valuations from 2,023*l.* to 2,253*l.*; for the company, Mr. H. A. Hunt was called to lessen the value of the right of enfranchisement, and Messrs. C. Lee, F. J. Clark, J. Shaw, F. Vigers, F. Murrill, and W. Snook, for the valuations, which were from 904*l.* to 1,624*l.* The jury, after considering for nearly an hour, returned a verdict of 1,750*l.*

We understand that there has been a great deal of litigation in the matter, and this issue was directed by the Master of the Rolls, the costs being held over until a jury had determined whether the formal offer of 1,400*l.* was or was not sufficient.

### PREVALENCE OF FIRES.

THE prevalence of fires at present is even greater than usual. The last of any note, as we write, is that which has completely destroyed the well-known Saville House, on the north side of Leicester-square. This was the result of the foolish act we last week commented on,—using a light to discover if gas was escaping. Another great fire has destroyed Messrs. Defries's premises in Shoreditch. The large fire which recently occurred near the London Docks, and other fires, have followed each other of late in London with startling rapidity.

The new Hulme town-hall was on fire recently from a flue connected with the heating apparatus igniting some of the woodwork. Fortunately the fire was discovered early, and the means provided within the hall itself proved sufficient for its extinction before much damage was done to the building.

Soon after the opening of a court hall, at the Ducal Palace, Brunswick, a fire broke out, and the whole building, except the left wing, has been burnt down. A bronze chariot, which formed the principal ornament of the façade, was melted by the heat.

In reading again the article on fire extinction in the *Builder*, of the 4th ult., I am struck with the remark made relative to the use of steam instead of water for the purpose of extinguishing fire. Having repeatedly in my long service in steam-ships seen the furnace fires put out in an instant by a jet of steam from a plug in the boiler, I can quite believe that our steam fire-engines would be much more serviceable as steam-generating annihilators than as mere pumps. You justly say that flame is the most dangerous constituent, rising and setting fire as it rises.

SAFETY.

ALLOW me to reply to the "Naval Captain's" inquiry as to the mode of rendering wood inflammable for ships' decks and sides. Sir W. Burnet's principle (as carried out by Lieut. Jackson, R.N.) secured this object, but has not been adopted as it deserved; probably it will be when beyond the patentee's hands, by being run out. I beg to state I submitted my idea of rendering a ship fire-proof (from accident or warfare, such as red-hot shot or shell), and laid it before the Admiralty, as the *Times* had stated "A man would be immortalized who could keep a ship secure against destruction by fire." I have proved "it can be effected" by applying the timber floors, or sides, or ceilings, in an *end grain series of panels*, which nothing will set fire to, as wood so placed only chars and forms a sooty face, whereas the timber floors and sides of *face or side grain* are capable of being fired immediately by flame, or hot bar, shot, or shell.

W. AUSTIN.

### SANITARY MATTERS.

UNDER the title of "Threatened Absorption of the Thames," a contemporary says.—The Bill now before Parliament for incorporating the Cheltenham and Gloucestershire Company, if carried, will prove most serious to Oxford, Reading, and all the other towns on the banks of the Thames. The company propose to supply the towns of Cheltenham, Charlton-Kings, Cirencester, Cricklade, and other places, by pumping the water from the Cerney springs, which now supply the river Thames. Such a measure, if carried out, will diminish the water of that noble river a million of gallons per day. This announcement, which was made by the vice-chancellor at the recent meeting of the local board of health, caused some little consternation in the city of Oxford, and will, doubtless, throughout the valley of the Thames. The Oxford board of health have resolved to petition Parliament against the

scheme.—At the Bristol Council House, an agent for premises in Jarman's-court, Horsefair, has been summoned for suffering houses to be overcrowded in that court in such a manner as to be injurious to health. There were forty-eight inhabitants in four small houses, and only two closets in common. The fever had prevailed in the court, which was the only infected place in the neighbourhood. The defendant was fined 10*s.* and costs, or a distress to be levied on his goods; in default of sufficient distress, seven days' imprisonment. Another person was summoned for a similar offence in Foxhall-court, St. James's. The magistrates ordered the houses to be closed until they were rendered fit for human habitation.—The prevalence of fever in Glasgow was considered at the last fortnightly meeting of the Police Board. From the minutes of the sanitary committee, it appeared that during the last fortnight there had been 427 cases of fever reported as against 367 cases during the previous fortnight. This was the greatest number of fever cases which the medical officer had yet reported to the board, thus showing that fever was still on the increase. Means were being taken to prevent the overcrowding of dwelling-houses, and Mr. Carrick (master of works) was instructed to proceed with his plans for the erection of a temporary fever hospital on the north side of Parliamentary-road.

### PROVINCIAL NEWS.

*Basingstoke*.—The Corn Exchange building has been opened. The building is at the corner of Wote-street and the lesser market, in close proximity to the old corn-market and the town-hall. The edifice is in the Italian style, and is faced with Bath stone and yellow bricks. The principal entrance is from Wote-street. There is a basement and a ground floor, the former being intended to be used as corn and other stores. On the ground floor is the large Corn Exchange room, 50 ft. long, 57 ft. wide, and 33 ft. high to the skylight. It is surrounded by iron columns supporting an ornamental iron roof, and skylight. A gallery is constructed over the principal entrance, which can be used for musicians, and other purposes. The lighting is provided by side windows, as well as the skylight, and the ventilation has been arranged by means of forty-two side-swing windows. The hall is lighted at night by two large gas coronas, and about a dozen pendant globe lamps around the sides. This portion of the work was done by Mr. Soper. The iron columns are of a chocolate colour, chased with scrollwork, tinted green and amber. The wrought-iron principals supporting the roof are of a similar shade, relieved with lighter lines. The architects were Messrs. Salter & Wyatt, of London; and the builders, Messrs. H. and R. Holland & Hanman, also of London.

*Wolverhampton*.—It is proposed to erect a new town-hall, sessions house, and police barracks in Wolverhampton. The borough surveyor has been instructed to report on the probable expense of erecting certain of the proposed new buildings.

*Selly*.—The opening of a new armoury and drill-shed at Selly, constructed for the use of the 38th West York Rifle Volunteers, has been celebrated with rejoicings. The armoury occupies a prominent position at the bottom of Brook-street, close to the railway, but several hundred yards from the station. The premises consist chiefly of a large central hall, which has been designed as a drill-room; and adjoining it are two prominent wings, one of which is fitted up as rooms and offices for the use of the Selly corps, while the other is devoted to the use of the sergeant who takes charge of the building. The central portion of the building is one story in height, while the wings are subdivided into two stories. The dimensions of the drill-room are,—length, 80 ft.; width, 40 ft.; and height, 23 ft. At one extremity is a staircase and balcony, for the use of those who may desire to witness the evolutions of the corps. In the interior the walls of the drill-room are uncovered, but the sameness of the tiers of brick of which it is built is diversified by rows of white. Externally the building consists of a central gable, which forms a transept to the drill-room, with Gothic arched windows; and there are two gables to the wings at the ends. The whole structure is faced with red brick, with bands and cornices of white brick, and the gables are finished with iron finials at the foot and apex. The interior of the building is chiefly

lighted by the large windows in the centre gable. All the rooms set apart for the use of the corps are lighted with gas, while the drill-room is illuminated by three large star pendants.

**Hereford.**—An ornamental drinking-fountain is to be erected in St. Peter's-square, at the cost of certain citizens, and on a plan approved by the City council, and carried out to the satisfaction of the City surveyor.

**Llanelli.**—The local Board of Health, having secured about 25 acres of land to be laid out to the best advantage as a public park, determined to consult Sir Joseph Paxton, M.P., and that gentleman has recommended Mr. Barron, of Sketty, to be employed by the Board in laying out and planting the ground.

**Burton-upon-Trent.**—A company is about to be formed, called "The Burton-on-Trent Building Company (Limited)," the objects of which are mainly to provide for the erection of houses in and near the town of Burton, suitable for the requirements of the labouring population.

**Wiltinton.**—The foundation-stone of a new hospital for the Chorlton Poor-Law Union, has been laid at Wiltinton. It will cost, with the furniture, nearly 20,000*l.* and is intended to accommodate 500 inmates.

**Sheffield.**—The Cutlers' Company have at length resolved to carry out the long talked of enlargement of the Cutlers' Hall. The plan approved of proposes to leave the ground-floor, meeting-room, entrance-hall, assembly-room, vestibule, and dining-hall without any alteration; to enlarge the grand staircase; to build a new dining-hall, 100 ft. by 50 ft., with galleries, offices, &c.; the room to be entered from the present dining-hall on the right by a lobby, 18 ft. 6 in. by 15 ft., with other entrances for waiters, &c., giving also a second room on the ground-floor, 85 ft. by 50 ft. The architects are Messrs. Flockton & Abbot. They estimate the whole to cost, including decoration, 5,000*l.*

**Darlington.**—The Society of Friends at Darlington, in order to celebrate the Prince of Wales's marriage in a way more congenial to their own feelings than that generally adopted throughout the land in March, 1863, set about to raise funds for establishing an accident and fever hospital, which has long been much wanted. Mr. John Ross was the architect employed, and he has erected, under the direction of Mr. John Pease (upon the land of that gentleman in Russell-street) and others associated with him in committee, a building capable either of further extension in case of need, or of conversion into dwelling-houses should failure ensue. The cost of the building, exclusive of land, the fittings, &c., has been 1,649*l.* 17*s.*

**South Shields.**—A meeting of the shareholders of the proposed New Theatre Company has been held, and a memorandum of association, together with the articles, were laid before the meeting and adopted. It is expected that the company will shortly be duly registered, and in a position to take preliminary steps for the purchase of the ground and the erection of the building. The proposed site is on the north of the Golden Lion Hotel, in King-street.

#### FROM SCOTLAND.

**Anderston (Glasgow).**—A new church in connexion with the Established Church of Scotland, has just been opened, at the junction of Dumbarton-road and St. Vincent-street, in the Anderston district. It is from the designs of Mr. James Salmon. The edifice stands east and west, and consists of nave and aisles, with organ-chamber behind pulpit at east end of nave. It is fitted up with galleries in the aisles, which are treated as two stories, and are continued round the west end of the nave. The nave roof is of the same pitch as the aisle roofs, both on the exterior and interior. The walls are built of freestone in broad and narrow courses of ashlar alternately, and relieved with red lands occasionally. The arches, &c., of the windows and doors are alternated by coloured stones. The cornices, door and window caps, label terminations, &c., are all carved. The roof is of timber, and decorated with gilding and stencilling in positive colours. The walls are of rough plaster, in courses corresponding with the exterior, and are broken up into geometrical and emblematic forms in red, buff, and black colours. The wall over the organ at the back is dispersed in gold on a blue-grey ground. The church is seated for upwards of 1,000 persons, exclusive of the choir-benches, and is provided with cushions and kneeling-boards. The pulpit is of large size, and

decorated with carving, containing busts of Peter, James, and John. The interior is described in its structure and decorations as being in advance of anything yet in the city, and also as being the first church in Scotland, in connexion with the Established Church, to introduce the organ. The tower, for want of funds, is at present carried no higher than the eave of the clerestory, which, till executed, mars the effect of the exterior. The whole cost, exclusive of the organ, is about 4,500*l.* The contractors were,—for mason's work, Messrs. Bruce & Kerr; Wright's work, Messrs. McIntyre & Jack; slater's work, Mr. Darrie; plumber's work, Messrs. Ingleton & Phillips; plasterer's work, Mr. Wm. Thompson; painter's work, Mr. Charles Gray. The stone carving has been executed by Mr. Earp, of London; and the carved woodwork of the interior by Messrs. Rhoddis & Grassby. The organ is from the manufactory of Messrs. Hill & Son, London. Mr. James Lamh was master of the works. The gas-fittings were by Mr. Hugh Buchanan, and the beating by Mr. John Hay.

**Dundee.**—A large stained-glass window has been added to the already considerable number of those which decorate St. Paul's Episcopal Church. The window has been given to the church by Mr. O. G. Miller. The frame is a two-light one in the west end of the north aisle. In the right-hand opening of the window, under a canopy of tabernacle-work, is a full-sized figure, after Holman Hunt, of our Lord, as "The Light of the World." Beneath this, the principal division of the window, is a smaller panel or compartment containing a representation of "Our Lord giving Sight to the Blind." In the left-hand division, and under a similar canopy as the other, is a second full-sized figure of our Lord, as "The Bread of Life." Underneath this is a representation of the "Marriage Feast of Cana." In the cinquefoil at the top is a miniature representation of the Paschal Lamb, the bordering being artistic in arrangement. The artist-manufacturer was Mr. John Scott, of Carlisle, who has already filled in several windows in this church.

**Glenгарry.**—A new church at Glenгарry has been opened for public worship. It has been built at the sole expense of Mr. Edward Ellice, of Glenгарry and Glenquoich, M.P. The new church is situate on a rising ground, a short distance to the west of the inn, on the north side of the river Garry, and close to the road from Invergarry to Skye. The edifice is built in the form of a parallelogram, 48 ft. long by 24 ft. wide, with a porch and vestry attached. The east gable is surmounted by a stone heltry, and the west by a simple cross. It is lighted by a traceried window in the east end, and by a series of triplet-pointed windows along the sides. Internally the roof is open-timbered, stained, and varnished, and is of larch, grown on the estate. The seats and pulpit are of pine, also varnished. The seats are arranged to accommodate 150 persons. Mr. Ross, of Inverness, was the architect.

#### CHURCH-BUILDING NEWS.

**Bedford.**—A vestry meeting has taken the reports of Mr. Palgrave and Mr. Street, on the subject of the restoration and enlargement of St. Paul's Church, into consideration, and has resolved to proceed with the work on these reports if the funds already subscribed can be sufficiently increased to cover the expense. Mr. Palgrave had proposed the removal of the tower and spire out of the line of the church, which, though of great length, is cut in two, as it were, by its thick piers and small arches, so that only one-half can be used in divine service, unless by two clergymen. The architect suggested that the tower should be re-erected in connexion with a new north aisle. Mr. Street was consulted, and concurred in the proposal to remove the tower, as it was in a state rendering it impossible to alter the piers and arches so as to open up the church. Mr. Street, however, stipulated that the worked stones should be used in the re-erection in such a way as to form an exact likeness of the tower as it stands. This the vestry has resolved on doing, with this modification, suggested by Mr. Palgrave, that as the tower will only be seen as behind the church, its height be raised to a certain extent, so as to be sufficiently visible.

**Wootton.**—This church, which has undergone a restoration from plans prepared by Mr. Butterfield, of London, architect, has been re-opened. The arch between the nave and the chancel and the two side arches in the chancel have been re-

built, and the whole of the pillars have been cleaned and restored. The western tower arch has been thrown open; and to do this, an old gallery, which formerly blocked up the upper portion of the arch, has been removed. The reredos has been decorated according to designs prepared by Mr. Butterfield, and the chancel roof has been similarly adorned. The old high-backed seats have given way to open oak benches. Near the centre aisle is a new font, the principal portion of which is formed of Devonshire marble, which is intermingled with Italian, French, and Irish marble. The basin is supported by a number of pillars.

**Pangbourne (Berks).**—The demolition of the church here will be commenced immediately. At a committee meeting recently held, the tender of Messrs. Reavell & Sons, of Windsor, for the erection of the new church, was unanimously adopted, the amounts being,—for the body of the church and fence walls, 2,742*l.*; tower, 860*l.*; spire, 258*l.*; as designed by Mr. Woodman, architect. The new church, which is intended to occupy as nearly as possible the site of the old, will consist of nave and north aisle, chancel and chancel aisle, south porch, and vestry at the end of chancel aisle. The tower will be at the west end of the nave, and about 70 ft. in height, surmounted by an octagonal stone spire, rising to the height of about 130 ft. The walls will be built with flint and stone; and the timber of roof, &c., will be open, stained, and varnished. The style adopted is the Early Decorated. The old bells, after undergoing extensive repair, will be re-hung in the new tower. The church will be heated by warm air, and it will provide accommodation for 413 persons. The churchyard will be inclosed with a flint and stone wall.

**Northleigh (Oxfordshire).**—The parish church has been re-opened. Besides the repair of the nave, aisle, and tower-roof, the gallery at the west end and high pews have been swept away, and low seats of deal, varnished, put in their place. The east window of the chancel, which was bricked up and hidden by an Italian altar-screen of painted deal, has been opened, and a Grecian canvas-screen of wood replaced by a stone screen. A pulpit of stone and new south porch have also been added. The whole has been completed from designs of Mr. G. E. Street, the diocesan architect. The entire cost of the chancel was defrayed by the governors of Bride-well Hospital.

**Guernsey.**—The newly-erected church of St. Stephen the Martyr, at the Rocquettes, in the parish of St. Peter-Port, has been opened. The project for erecting a church for the accommodation of that portion of the population of the town parish which is resident in the western suburb, was set on foot about seven years ago. The church, which is built of grey and redd-tinted Guernsey granite, in courses of rubble work, with Caen stone columns and dressings in the interior, consists of nave, two aisles, which run the whole length of the building, and a chancel. The eastern and western gables, and the north porch, have much architectural merit, while the whole structure has an appearance of reality and solidity which compensates for the want of ornament. The church has an open timber roof, and the aisles are divided from the nave by massive round columns of Caen stone, from which spring arches faced with the same material. Each side of the chancel is furnished with two rows of carved oak seats running longitudinally, and the body of the church is fitted with semi-open seats, which will accommodate 750 persons. The pulpit, which is of carved oak, is placed against the southern side of the chancel arch. Twelve very handsome gilt gneelers, with five jets each, are placed in the nave, six on each side. Most of the windows are to be filled with painted glass, to be supplied by Messrs. Morris & Marshall, of London; but the completion of this part of the work has been delayed by the illness of one of the artists. The Caen stone font, at the western entrance, has been presented by Mr. D. de Patron, the builder of the church. The church contains 750 sittings, of which 450 are free. The entire cost will amount to 5,000*l.* Mr. G. F. Bodley, of London, was the architect, and Mr. D. de Patron, the contractor.

**Wadsworth (near Doncaster).**—The chancel of the Church of St. Mary, Wadsworth, has been renovated and improved, under the direction of Mr. Teale, a local architect. Mr. Athron, of Doncaster, and Mr. Green, of Wadsworth, were the contractors. The principal work has been the insertion of a new chancel-arch of Roche Abbey stone, in the place of a labn and plaster

affair erected some thirty years ago. New low-stalls have taken the place of the pews in this part of the church. The floor of the chancel has been brought back to its original level. Many old features have been discovered during the progress of the work, and are left exposed, showing points of architecture of former times. The *sedilia*, *piscina*, locker, and two lancet windows are among the principal features that have been brought out. Mrs. Walker, of Wilsie House, has provided an organ, which is placed in the north of the chancel. Mr. Meacock, of Doncaster, supplied the instrument, which cost 66 guineas.

**Ebennes (Sussex).**—A subscription list has been opened for the purpose of building a new church at Ebennes, in the south-west part of the parish of Kirdford. Lord Leonfield has contributed 1,000*l.* towards this object; and Mr. Penchey, of Elnrooe, 500*l.* and the site. Other donations make with these a total of 2,000*l.*

**Mirfield.**—A public meeting of the inhabitants of Mirfield has been held "for the purpose of considering the desirableness of erecting, by voluntary subscriptions, a new parish church, more suited to the increased and increasing population of the district." A proposition affirming the desirableness of building a church by voluntary subscriptions was passed with acclamation, and a committee was formed, and a subscription-list opened. Before the proceedings closed it was stated that upwards of 5,000*l.* had been subscribed. This is exclusive of a sum of 3,000*l.*, a legacy left by a Mr. Lee, for building a tower and providing a peal of ten bells.

**Fenny Bentley (Derbyshire).**—The restoration of the Church of St. Mary Magdalene has been completed, by the re-seating of the nave to correspond with the north aisle, the addition of a stone broached octagonal spire to the tower, 55 ft. high above the parapet, and some other and minor improvements.

#### DISSENTING CHURCH-BUILDING NEWS.

**Mansfield (Notts).**—A new Wesleyan chapel has been opened in this place. The edifice occupies the same site as the old building, which has been entirely removed, and is a stone structure, the walls being pitch-faced with dressed quoins to relieve the openings. The building is of Italian character, the principal façade having an open vestibule in the centre, with its entablature supported by stone columns and pilasters, having carved capitals of conventional foliage of the Corinthian type. The two wings are flanked by rusticated pilasters the whole height of the building, terminating in carved consoles supporting the main entablature, and the cornice is surmounted by an attic or perforated balustrade, upon which are placed six vases, relieved by carved foliage. The two tiers of windows have stop chamfered jambs, archivolts, and key-stones. The seats of the chapel are of stained and varnished deal, with mahogany cappings, and the gallery pews are arranged continuously round the walls, forming an oval well in the centre, the front of the well being painted in colours (delicate lilac and green), with the panels and carved ornaments picked out with gold. The supporting columns underneath are of cast-iron, relieved by a spiral band and bronzed, and with white foliated capitals. The main ceiling is surrounded by a cornice, and has in the middle a foliated centre piece, from which is suspended a star-light or corona. The ground-floor of the chapel internally is about 56 ft. by 45 ft., and the gallery about 80 ft. by 45 ft. In the rear, on the ground story, and communicating with it, are constructed a large vestry, 24 ft. by 20 ft.; class-room, 14 ft. by 12 ft.; and minister's vestry, 12 ft. by 10 ft.; and there is another class-room, 20 ft. by 11 ft. A crowded congregation can effect ingress in the rear as well as in the front of the building. The works have been carried out by Messrs. Lamb & Stevenson, of Nottingham, the contractors in chief, assisted by Mr. Maude, of Mansfield, for the ironwork and heating apparatus; Mr. Greening for the painting, &c.; Mr. Wheeler for the glazing; Messrs. Lewis for the slating; and Mr. Smith & Mr. Rawlins for the carving. The gas-fittings have been supplied chiefly by Messrs. Thomason & Co., of Birmingham. The building has been carried out from the designs and under the superintendence of Mr. John S. Norris, of Nottingham, architect, at a total outlay (exclusive of site and value of old materials) of about 2,500*l.*

**Liverpool.**—A new Presbyterian church is to be erected in Prince's-road, from a design by Messrs.

W. & G. Andsley. It is to be a Gothic building of the Early French period, with a spire 175 ft. high, and traceried windows. The nave will be 100 ft. long, the transepts 80 ft., and sittings provided for 1,250 persons. 5,000*l.* have been raised at one effort by a Welsh congregation, in order to assist in carrying out the design.

**Huddersfield.**—The new Congregational church, Hillhouse, has been opened for divine worship. The church is situate about a mile from the centre of the town, in a rapidly increasing neighbourhood. The building is in the form of a cross, with nave, transepts, and organ recess. The front elevation is a gable, containing a five-light window, with decorated tracing, and a double doorway underneath. To the left, at the angle formed by the junction of two streets, a tower and spire rise to the height of 120 ft., and have been erected by the sons of Mr. Willans, in memory of their father. The pews are about 36 in. wide, low, with leaning backs. The galleries extend all round the church. The windows are glazed with cathedral glass, with a coloured margin. The aisles are separated from the nave by light iron columns, surmounted with foliated caps, carrying an arcade of wooden arches, which support an open hammer-beam roof. The woodwork is deal, stained dark and varnished. The lighting is by large gaseliers suspended from the roof and brackets under the galleries, and the warming by hot air. The dimensions of the church are, extreme length, 93 ft.; width of the nave, 49 feet; width at the transept, 63 ft.; and height, 43 feet. Accommodation is provided for about 950 persons, and the whole cost of the building is less than 4,000*l.* The architects were Messrs. Pritchett & Son, of Darlington.

#### STAINED GLASS.

**St. John's, Wapping.**—The chancel of the church of St. John, Wapping, has received, during the past week, two painted windows, as memorials. The subjects are—the Resurrection of our Lord, to the memory of Jane Randall; and the Ascension, to the memory of Joseph and Ann Oliver. The windows are about 10 ft. by 5 ft.; each subject filling the centre; a border surrounds them. The artist was Mr. Bell, of Bristol.

**St. Mary's, Guildford.**—The memorial window to the late rector has been finished. In the centre part of the tracery are the four Evangelists; to the right and left are St. Peter and St. Paul; and to the right and left of these are St. Thomas, John the Baptist, St. Andrew, and St. Philip. The five lower compartments have "The Nativity," "The Baptism," centre "Crucifixion," "Resurrection," and "The Ascension."

**Uppingham Church (Rutland).**—It is intended to erect a coloured glass window and a reredos in this church, to the memory of Bishop Jeremy Taylor, whose pulpit is still in use in the church.

**Carfax Church, Oxford.**—A stained-glass east window, a memorial of the late Mr. James Morrell, is being put up in this church by Messrs. O'Connor, of London.

**St. Noot's Church.**—A new stained glass east window has been placed in St. Noot's Church, by Messrs. Hardman, of Birmingham. The execution of the glass has cost 450*l.*, inclusive of the guards and fixing, the money being chiefly contributed by the congregation. The lower part of the window represents the last scene in the sufferings of the Saviour, mystically treated with angels receiving the sacred stream in golden chalices. The upper part symbolises the exaltation of the Redeemer as contrasted with His humiliation below.

**Seighford Church (Stafford).**—The old church of this parish has been recently beautified by a stained-glass window, erected at the expense of Mrs. Thompson, of Seighford Hall, as a memorial of her husband, the late vicar. The subject represented is the interview between the Angel and the three Marys at the Sepulchre on the morning of the Resurrection, and it has been executed by Mr. Gibbs, of London. The window is a single light. A canopy surmounts the group, and a geometrical border of varied design runs round the whole.

**Roman Catholic Church, Leamington (Warwickshire).**—Two more altar windows have been fixed in this building, completing the decoration of the chancel. The subject of the centre one, which is divided into two lights, is Our Saviour, surrounded by the Apostles, and giving the keys to St. Peter. Introduced into the tracery, in a large medallion, is the figure of God the Father,

in the centre of a cinquefoil, filled, as canopies, with ornamentation. The right-side window is the counterpart of that on the left, and they contain two large figures representing St. Christina and St. Williams; and in the tracery an angel bearing a crown of thorns. The windows, which were executed by Mons. T. Dury, of Warwick, were presented to the church by two ladies of Leamington.

**Leek Woolton Church (Warwickshire).**—Stained glass has recently been fixed in the new rose-window in this church with subjects representing "Eljib raising the Widow's Son," "Christ Preaching out of the Ship," "The Storm at Sea," and "Christ Raising Lazarus," and in smaller openings the family-badge, monograms, and Gothic ornament. The glass was designed and executed by Mr. W. Holland, of Warwick.

**Gloucester Cathedral.**—The east cloister of this cathedral is about to be adorned by two new stained glass windows. One will be erected to the memory of the late Dean Plumtre, the other to that of the late Dean Rice. Mr. Powell is the artist employed, and Messrs. Hardman & Co., of Birmingham, furnish the glass. The late Mrs. Wetherell intended to put in a memorial window in the north cloister to the memory of her husband, the late Ven. Archdeacon Wetherell, canon of Gloucester. The new stone-work for this window has been prepared, and it is expected that the work will be completed by the executors of the deceased lady.

**Trull Church (near Taunton).**—A memorial window has just been placed in Trull Church. The window, which is in the Perpendicular style, consists of three lights and tracery. In the centre light is represented the Resurrection, and below this "Our Lord raising the Widow's Son," in the right-hand light, "Our Lord bearing His Cross," and the "Raising of Jairus's Daughter;" and in the left, the "Entombment," and the "Raising of Lazarus." In the tracery are angels with scrolls, and others bearing the emblems of the Passion. The whole is surmounted by a crown. At the bottom of the window is the legend "I am the Resurrection and the Life;" and below this, on a brass plate, an inscription, "In memory of James Vhart, Commander, Royal Navy." The window was designed and executed by Messrs. Horwood, of Mells, near Frome.

**Window to the late Duke of Newcastle.**—A design, by Messrs. Ballantine & Son, Edinburgh, has been selected for a stained glass memorial window to the late Duke of Newcastle, to be erected in Basfield Church, near Nottingham. The design represents the Magi worshipping the Infant Saviour, symbolising the devotion of his grace to the cause of religion.

#### SCHOOL-BUILDING NEWS.

**Sleaford (Lincolnshire).**—The new day-school erected here by the Wesleyans has been opened. The building, which is of white brick, has been erected by Mr. Bennison, of Sleaford, from designs furnished by Messrs. Pattinson, of Ruskington, under whose superintendence the whole of the works have been carried out. The entrance is by a porch on the south side, and the large room, measuring 48 ft. by 30 ft., affords sufficient accommodation for the education of 200 children. The height of this room and two smaller ones at the east end of the building is 17 ft. Hot-air flues have been introduced for the purpose of heating. The cost of the building, with fittings, &c., will amount to about 1,100*l.*, of which sum nearly 950*l.* have been promised.

**Louth.**—It is probable that a scheme for rebuilding the grammar school and Bede houses here, on the site now occupied by the old school, will shortly be carried out.

**Cottenham (Cambridgeshire).**—The tenders for the erection of a new British school in this place were as follow: that of Mr. T. Piggott was accepted, with the understanding that no person from another place should be engaged upon the works:—

Christman, Haird, & Graves .....	4368 10 0
H. Haird & Leach .....	342 1 0
Leach, Ingle, & Smith .....	333 0 0
Piggott .....	329 0 0

**Bromley (Middlesex).**—An infant-school, being the first of a block of buildings, has been opened by the Bishop of London. It is used as a mission-church on Sundays, and will seat 400 adults and children. It is 70 ft. in length and 24 ft. in width, with open framed roof and boarded to under side of rafters, the whole stained and varnished. Several of the windows

are gabled, and have Bath stone dressings; there is also a quasi chancel, with wood screen and iron cresting. The entire cost was about 800*l.*, which, with the cost of the site for a church, parsonage, boys' and girls' schools, has been defrayed by the Bishop's Fund committee. Mr. G. J. Watts was the builder, and Mr. J. W. Morris the architect.

**Harpenden (Herts).**—The new Sunday and National School-rooms in this village have been opened. The style is Gothic, and the cost 600*l.* The dimensions of the school-room are 50 ft. by 20 ft.; and there is a class-room 20 ft. square. The roof is of deal, with lath and plaster between the rafters. Messrs. Slater & Carpenter were the architects, and Mr. Miskin, of St. Alban's, the builder.

**Bristol.**—The foundation-stone of the new schools in Temple parish has been laid by Mr. O. C. Lane, Master of the Society of Merchant Venturers. The school was founded by Edward Colston in the year 1711, and since that time upwards of 6,000 boys have had religious and commercial education in it. The building about to be erected will accommodate 200 boys, and the same number of girls. The architects are Messrs. Foster & Wood. The cost of the new schools, master's house, and recently purchased land, will be 2,500*l.*

**Books Received.**

*Galbraith & Houghton's Scientific Manuals: Mathematical Series: Manual of the Steam-engine.* By the Rev. Joseph A. Galbraith, M.A. London: Longman & Co., 1864.

This treatise appears to be a very good one, based on Count de Pambour's theory of the steam-engine. The author is a professor of natural and experimental philosophy, in the University of Dublin, and a Fellow of Trinity College; and for the last ten years he has given lectures in the School of Engineering at Trinity College, based on the same principles, though developed and applied somewhat differently from the mode adopted by De Pambour. The English edition of the treatise by the latter author has long been out of print, and Mr. Galbraith is desirous of placing the theory again in the hands of English engineers.

**VARIORUM.**

Admirable, Mr. Punch! Well done, John Tenniel! "Telescopic Philanthropy," for the good it is calculated to effect, shall whitewash thee of some private sins, should such befall thee. "Please 'em, ain't we black enough to be cared for?" says the neglected, attenuated, sharp-eyed London street-boy to Britannia (beautifully drawn), looking through a telescope for objects dark enough in mind and body, in all conscience, poor boys, poor refuse. For God's sake, gentlemen legislators, do something for them! If that adjuration do not strong enough for you, then for your own sake do it.—A pamphlet titled "The Agricultural Value of the Sewage of London examined in reference to Principal Schemes submitted to the Metropolitan Board of Works" has been published by Stanford, London. Although this may be regarded as a partisan publication in favour of Messrs. Hope & Napier's scheme, it seems to give a very fair statement of what can be said in its favour. An outline of Messrs. Hope & Napier's scheme is of course given, and the subject is illustrated by a map of the route and field of distribution in Essex. As to the question of value, it points out, just as we recently did, that the value of sewage is relative, and that "all comparison between the value of sewage and the value of guano is simply absurd."

"Guano is saleable the moment it arrives in port: there is a price current, and at a reduction of two or three pounds a ton on that price it would be easy to sell, even before it was landed, an additional fifty or even a hundred thousand tons. The merchant has no difficulty in storing it, neither has the farmer. If it is not required this season, it will lie in the manure-shed until next. But the value put upon sewage by certain persons (a value entirely disclaimed by agricultural chemists) depends on the chemists doing something which it is impossible to do. If the fertilizing constituents of the solid and liquid sewage of London could be taken out and dried without any expense, they would be worth a sum variously estimated at from one million and a half to three millions. But as the process is impossible, any calculation founded on this estimate is a waste of time. Before the sewage can be made worth anything, it must be conveyed to a place suited to receive it, within the reach of persons prepared to purchase manure largely diluted with water. To those who want it, sewage has a certain value; but to

those who do not want it, it is worse than valueless, because it can neither be stored nor got rid of."

The author remarks, on such questions of value, that "the time has not yet arrived, predicted by Baron Liebig, when the fertilizers of 1,000 acres can be carried in the pocket of a shooting-jacket;" and he reminds the English public that—

"It is notorious that on several points of practical agriculture this eminent professor has been egregiously wrong;—so wrong, that any farmer who had followed his advice would have inevitably been ruined. For instance, the experience of twenty years has proved that systematic drainage, originally suggested by Smith, of Deanston, and perfected by Josiah Parkes, is the greatest agricultural improvement of the age. Yet when this system was first adopted, or rather indorsed with the authority of the Royal Agricultural Society, Professor Liebig believed and asserted that the result of thorough drainage would be to impoverish and eventually render barren the soil so treated. At the same time he introduced to public notice, through Messrs. Mospratt, the eminent manufacturer, chemists of Liverpool, a patent mineral manure, which he promised should correct the effects of drainage, and enormously increase all crops. While the drainage proved a great success, the patent mineral manure proved a total failure. Still more recently Baron Liebig has authoritatively stated that the soil of England, under the modern system of high farming, is becoming impoverished and reduced to the state of barrenness which afflicted the Roman States in the latter days of the empire; but, challenged to point out a single example of this exhaustion in any parish or noted farm in England or Scotland, he has remained silent,—facts being notoriously opposed to the professor's theory."

"The Ambulatory Schoolmaster: Miss Burdett Coutts's Letter on the Extension of National Education." This tractate contains a reprint of the letter to the *Times*, in which Miss Burdett Coutts suggests a scheme for carrying education into small hamlets scattered at too great distances for children to meet in one common school. Instead of sending the children to the teacher in such cases, she proposes sending the teacher to the children, day or week about, as most suitable or convenient. The *Times* leader on the subject is appended to the reprint of the letter.—"An Abridged Text Book of British Geography." By William Inghes, F.R.G.S. Longman & Co. Mr. Inghes's "Geography of British History" is well known and appreciated, but too large and costly for some uses. This little abridgement is specially prepared to obviate that difficulty, and gives, compendiously, a large amount of information in a cheap and pleasant form.

The current number of the *Band of Hope Review* (to show the spirited manner in which this little publication is conducted) contains an engraving from a vigorous and effective drawing by Mr. Cava Thomas. It represents the brave sailor who stood to the wheel while the ship burnt, and brought her safely in, only to die himself.

**Miscellaneous.**

**ROYAL ENGLISH OPERA.**—Gounod's "Médécine Malgré Lui," with English words by Mr. C. L. Kenney, has been produced very successfully under the old title of "The Mock Doctor," and has enabled Mr. Henry Corri, who plays the chief part, to take an advanced position. The music is remarkably lively and pleasant throughout, and some of it will soon be universally popular.

**PROPOSED TESTIMONIAL TO PROFESSOR DONALDSON.**—A project is afoot, on the part of Professor Donaldson's friends and pupils, to testify their esteem for him, on the occasion of his vacating, next June, the chair in University College, London, which he has filled so zealously and conscientiously for the long term of three-and-twenty years. At present it has scarcely taken its proper shape, and we will confine ourself to the brief intimation that Mr. Chas. C. Nelson, by whom this worthy project was initiated, will gladly receive co-operation.

**PRINTERS' ORPHAN ASYLUM.**—From a printed report of a public meeting to establish a Printers' Orphan Asylum, which has been laid before us, we are glad to observe that a very successful commencement has been made towards the realization of this excellent purpose. Numerous subscriptions have already been obtained from various well-known printing establishments, the printers of the *Builder*, Messrs. Cox & Wymann, holding, we perceive, a prominent place in the list of master printers, readers, and compositors who subscribe. No attempt at present will be made to erect an asylum building: orphans will be sent to existing institutions at the cost of the orphan fund. The new institution is designed not to compete with, but rather to supplement, the other charities of the trade.

**MONT CENIS TUNNEL.**—The Turin correspondent of the *Avenir National* says: "The Mont Cenis works will probably be completed sooner than was hoped: rocks have been reached much softer than those hitherto found; and the progress may be calculated at the rate of 250 metres per month. Should no unforeseen obstacles arise the tunnel might be opened for traffic towards the close of 1868. I can guarantee the accuracy of these details, which interest the whole world."

**ECCLESIASTICAL ARCHITECTS.**—Sir: The enclosed paragraph, cut out of the *Illustrated Christian Times*, gives another instance of professional(?) practice.—H. S.

"The Rev. W. Woods said good-by to the Baptist church at Swaffham, on Monday, at a farewell meeting. After tea an address, with a purse containing thirty-five sovereigns, was presented to Mr. Woods, with many expressions of esteem. Mr. Woods has spent ten years in Norfolk, and has laboured hard and successfully both at Swaffham and in the country. In addition to his pastoral labours he has been the architect and surveyor of four capital chapels, at Diss, Dereham, Swaffham, and Yarmouth."

**OUR RAILWAYS TO BE SUPERSEDED!**—A contemporary has received a letter from Mr. W. H. James, C.E. (eldest son of the late Mr. William James, of Warwick, founder of the present railway system), stating that he has invented an improved mode of transit, whereby passengers may be conveyed 100 miles at the very small charge of one shilling each, provided there are a sufficient number of travellers; and for great distances at the rate, if desired, of 100 miles an hour and upwards, when there are no intermediate stoppages, with greater safety and much greater comfort than on the present railways; and that this improved system of transit may be brought into general use in less than one-tenth part of the time, and at less than one-tenth of the cost, of the present railway system.

**WORKS EXECUTED IN THE CITY.**—The usual annual report of Mr. Haywood, C.E., engineer and surveyor to the City of London Sewers Commission, on works executed, has been printed by authority of the Commission. From this report it appears that 230 premises were drained in 1864, in addition to 13,548 previously drained, leaving 2,223 without known drainage. Various improvements, as from setting back frontages, cutting off angles, &c., have been effected, and new ones projected. There are now thirty-three halting-places within the limits of the City, but no additional drinking-fountains have been erected, and there are still only five within the jurisdiction of the Commission. Cow-houses have been reduced from 20 to 19, and lodging-houses from 135 to 123.

**THE DUJARDIN TYPE-PRINTING TELEGRAPH.**—This improved type-printing instrument has for some time been experimentally worked by the Electric and International Telegraph Company, with favourable results, according to the *Mechanic's Magazine*. The type-wheel, says our authority, is of the ordinary form, with the type disposed around its periphery. Motion is communicated to it by means of a weight acting upon a train of wheels, and this motion is governed and made to take place, "step by step" by means of an escapement attached to what may be termed a pendulum vibrating between the poles of two electro-magnets. The type-wheel, in its motion from one letter to another, is thus independent of the electric power, and this motion would even take place by the effect of the weight, if the currents, rapidly alternating in the two electro-magnets, were interrupted. The weight and the escapement, in fact, of themselves give to the type-wheel a motion which is synchronous with that of the apparatus at the sending station, also set in motion by means of a weight, for the transmission of alternately positive and negative currents, the synchronism being merely controlled by the action of the latter. The transmitting apparatus is furnished with keys similar to those of a piano, and corresponding to the letters of the alphabet. When one of the keys is depressed, a current somewhat longer in duration than those which regulate the step-by-step movement of the type-wheel is transmitted at the exact moment of time when the latter reaches the proper position for the impression, upon a band of paper, of the corresponding letter. In the new inking apparatus the resistance offered by friction to the motion of the type-wheel is said to be greatly reduced. It is composed of a pad of velvet, the pile of which only is in contact with the type.

**THE MIDLAND BUILDING TRADE ARRANGEMENT.**—At Birmingham, a private meeting of the several delegates appointed by the members of the building trade has been held, at which, after some discussion, Mr. Thomas Lloyd was appointed as umpire. Mr. Lloyd was waited upon by a deputation from the delegates, when he accepted the office.

**NO RAILWAY COMPENSATION FOR LOSS OF BUSINESS.**—It seems that a recent decision of the Exchequer Chamber declares that compensation cannot be claimed for loss of business during the making of a railway. A number of persons who have been injuriously affected in this way by the Metropolitan Railway have formed a committee to raise funds to carry an appeal against this decision to the House of Lords.

**LEAMINGTON SURVEYORSHIP.**—The following were the selected candidates for the Local Board Surveyorship:—Mr. Joseph Niblett, London; Mr. T. D. Barry, Norwich; Mr. Archibald D. Dewney, Warrington; Mr. Edward Clavey, Derby; Mr. John Laing, London; and Mr. William Alderson, Basford. The final contest lay between Mr. Barry and Mr. Niblett. On the votes being taken, seven were recorded for Mr. Barry, and six for Mr. Niblett: Mr. Barry was therefore elected. The applications received were fifty-two in number.

**MAGNESIUM LIGHT.**—Mr. W. Stubbs writes,—There is great difficulty in keeping a continuous flame with this metal, even when fed by clock-work into a spirit-lamp flame. My remedy is to feed two thin wires at once instead of one: one always remains ignited, and burns the other when a momentary imperfection occurs.—We hear of the use of magnesium light in the chambers of the Great Pyramid; now, in consequence, seen properly for the first time. We shall hope to have it taken into the New Orange chamber, as we suggested, for a proper examination of the interior.

**GAS.**—A new gas company, by name the Commercial Gas Company of Ireland, is now in process of formation, for the city of Dublin, eventually to extend its advantages to other cities and towns of Ireland. Dublin is at present lighted by two companies, which for some time acted more or less in opposition, but a few years since seemed to come to some tacit or private understanding concerning the price and quality of the gas supplied to consumers. The new company proposes to supply light of threefold the power of the old gas, and at a price lower than that at present charged to the consumers in Dublin.

**CAMBRIDGE ARCHITECTURAL SOCIETY.**—The first meeting of the Society for the Lent Term was held on Thursday, the 16th ult., the Rev. W. J. Beaumont, in the chair. The Rev. J. H. Henderson gave an account of the Lady Chapel of Ely Cathedral, and of the restoration now in progress. He entered into detail as to its original foundation, and the speculations which had been made as to whether it had ever been intended for a Chapter-house. He explained fully all the circumstances of its formation into a parish church, and the taking down of the old church, which was simply lean-to on the north side of the cathedral; and he concluded with a very interesting account of all the difficulties which had to be encountered before the present restoration had been commenced. Considerable discussion took place with regard to the proposed arrangement of the seats, after which the meeting adjourned.

**PRINCIPAL AND CONTRACTOR.**—It has been decided, in the case of Gray v. Pullen, that where a duty is by statute imposed upon a person in respect of work which the statute authorises him to do, and he employs a contractor to do it, and, by an act of omission on the part of the contractor, a breach of the duty arises, the employer is responsible. The owner of premises within the Metropolitan Local Management Act was authorised under sect. 77 of the Act to make a drain from his house into one of the public sewers. He employed a contractor to do the work, and in the course of doing it a trench was cut across the public footway, which was afterwards insufficiently reinstated, and in consequence thereof the defendant sustained an injury. The Court of Exchequer Chamber held (reversing the judgment of the Queen's Bench) that the defendant was personally liable for the breach of duty occasioned by the negligent omission of the contractor.

**PROPOSED WORKING MEN'S CENTRAL INDUSTRIAL EXHIBITION.**—A meeting, composed chiefly of committee-men of the late North London Industrial Exhibition, has been held in St. Luke's, when the following resolution—"That a Central Working Men's Exhibition for the parishes in and around London take place, at a time and place to be determined on hereafter,"—was carried unanimously. A committee was then appointed. The proposed exhibition will take place some time during next year. The Industrial Exhibitions Bill, we may here remark, has been read a second time in the House of Commons.

**ACCIDENT IN THE WESTMINSTER-ROAD, LAMBETH.**—A firm of linendrapers had been enlarging their warehouses, and were adding to the buildings another house, adjoining. In order to carry out the designs of the architect, a heavy scaffolding had been erected in front of the four stories of the premises, and the men were actively engaged in running out the cornice at the top of the building, when the front of the wall between the two houses fell, and the whole of the scaffolding from the base to the roof of each structure parted asunder, and fell half way across the wide thoroughfare of the Westminster-road. Over 1,000l. worth of silks and satins were buried in the ruins, and over 36l. worth of plate-glass was demolished, but most fortunately and singularly, not a single person was injured. The front of the three buildings was afterwards barricaded, as three or four rooms, the staircase, and the drawing-rooms, were all in a dangerous state.

**TOMB OF JAMES III. OF SCOTLAND.**—The researches made in the grounds of Cumbankenneth Abbey during last summer by the Royal Society of Scottish Antiquaries and the magistrates of Stirling wick, says the *Scotman*, in all likelihood, cause this fine old ruin of the eleventh century to be repaired, and the tower saved from destruction. The most interesting fact in connexion with the Abbey was the discovery of the tomb of King James III. The grave was found near the spot where in old guide-books and histories it was indicated to be, and was covered with a marble slab, bearing the marks of iron hands and sockets. The whole circumstances of the discovery were laid before the Queen, who signified her wish to erect a memorial stone or cross over the remains of her royal ancestors James III. and his Queen, Margaret of Denmark. The Stirling town council at once unanimously assented to the desire of the Queen. During the excavations, several large oak trees were found in one of the foundations.

**THE COURTS OF LAW CONCENTRATION BILL.**—In the Commons, on Tuesday, Mr. Kinnaird moved "That it be an instruction to the select committee on the Courts of Justice Concentration (Site) Bill that they have power to make provision for appropriating or obtaining sites, and for the erection of lodging-houses or other suitable dwellings for the working classes proposed to be displaced by the said Bill." Mr. Cowper opposed the motion, as placing impracticable duties on the committee. A brief discussion ensued, after which an amendment was moved by Mr. Hennessy, modifying the terms of the motion; but Lord Palmerston declined to accept the amendment; and on a division it was negatived by 18 votes to 8, when, forty members not being present, the House adjourned. A correspondent of the *Times* suggests that the Carey-street site ought to be abandoned, and a site on the Thames Embankment chosen. Although there are strong points in this suggestion, and especially, too, as it would settle the question of working-class dwellings for the displaced ones, we cannot cordially adopt it. The author of the suggestion imagines that one year's further delay would be all that would take place, but this we think is more than doubtful. It might be not a few years ere everything was settled for the new site and the new design; for although the *Times* correspondent urges that no change in the plans need be made, he somewhat inconsistently points out that, while the Carey-street design requires four frontages, the Embankment design would only require one. Though not inclined to advocate this suggestion, however, something ought to be done to provide new dwellings for those displaced. And although the town railways are offering facilities for the conveyance of working people to and from the suburbs, we are quite aware that there are other difficulties in the way, such as the necessity which some workmen, such as tailors, are under to live near their employers.

**WHARFS AND WAREHOUSES AT BATTERSEA.**—Now that the Thames Embankment will sweep away no less than 2½ miles of wharfs, and almost entirely close up the water-way to many warehouses, there is an absolute necessity for new wharfs and warehouses as a substitute for the old. A new company, with this view, we observe, is being got up under the title of the West London Docks and Warehouses Company, with a capital of 500,000l., in 25,000 shares of 20l. each, one-third of which has already been subscribed, for the formation of wharfs and warehouses with river frontage at Battersea. The company is under good direction. Sir Charles Fox & Son are the engineers, and Mr. F. Vigors and Mr. F. Whitaker the surveyors and architects. The site chosen is close to the Victoria Railway Bridge, and there will be railway communication between the wharfs and all the great railways in the metropolis. A canal basin is also to be constructed.

**TENDERS.**

For erecting eight almshouses in Easton-street, Wycombe, Mr. Edward J. Payne, architect:—  
 Ashton..... £1,925 0 0  
 Reavell & Sons..... 1,185 0 0  
 Hollis..... 1,150 0 0  
 Fierce..... 1,060 0 0  
 Ward..... 875 0 0  
 Burnham..... 945 10 0  
 Spicer (accepted)..... 777 0 0

For additional stables for Messrs. E. & W. Sturge, Bridge Wharf, City-road, Mr. James Harrison, architect. Quantities supplied by Mr. Arthur W. Q. Nicoll:—  
 Brass..... £235 10 0  
 Ashby & Sons..... 470 0 0  
 Asford & Co..... 465 0 0  
 Browns & Robinson..... 465 0 0  
 Little..... 465 0 0  
 Coleman..... 465 0 0

For shop and dwelling in London-street, Norwich, for Mr. John Haat, Mr. Edward Boardman, architect:—  
 Rice..... £765 18 0  
 Hall..... 737 15 0  
 Blythe..... 728 18 0  
 Wales..... 699 0 0  
 Brown & Bailey..... 687 15 0

For forming warehouses, &c., for Mr. Pratt, on Tombland, Norwich, Mr. Edward Boardman, architect:—  
 Brown & Bailey..... £370 0 0  
 Ford..... 379 0 0  
 Rice..... 355 15 0  
 Blythe..... 333 0 0  
 Schedule of prices for remainder.

For erecting seven almshouses and twelve almshouses at the North Pole Gardens, Islington, Mr. C. Foster, architect:—

	For the seven.	For the twelve.	Total.
Ellis.....	£31 10 0	...	£96 19 0
Gadby.....	27 0 0	...	45 0 0
Davy.....	22 10 0	...	41 2 0
Grover.....	21 0 0	...	33 0 0
Hughes.....	22 5 0	...	36 0 0

For new schools at Hemel Hempstead, Herts. Mr. Joseph James, architect. Quantities not supplied:—  
 Humphreys..... £255 0 0  
 Sear..... 745 0 0  
 Monk..... 690 0 0  
 Young..... 667 0 0  
 Cheshire..... 680 0 0

For four semi-detached houses, Lordship-road, Stoke Newington, for Mr. P. Charles, Mr. Herbert Ford, architect:—

# The Builder.

VOL. XXIII.—No. 1153.

Gothic Architecture in Spain.

WE have heretofore had very little precise information concerning the monuments of Gothic architecture remaining in Spain; general notions of the size and grandeur of some of them, gathered chiefly from the drawings of David Roberts and Villamil; but little, if any, knowledge of their dates or of their architectural details. Mr. Ferguson's chapters on "Spanish Architecture," suggestive as they are, only served to show how scanty the readily-available information was; and Mr. Waring, in his book, illustrates chiefly what is known as the Plateresque

Renaissance work. Concerning the Moorish remains in Granada and elsewhere, we have complete information; but of the Gothic structures, as we have said, next to nothing for the professional or otherwise precise inquirer. Mr. Ford, in his excellent "Handbook of Spain," affords many interesting particulars, but his space is necessarily very limited, and he gives no illustrations. His references, however, to local guides and authorities have served to lessen the difficulty of Mr. Street, who has sought to supply the want to which we have pointed, and whose portly and very handsome book, the result of several journeys to the country, is now before us.\*

Viewing the interest of the subject as three-fold,—first, Artistic and Archaeological; secondly, Historical; and, lastly, Personal; he has first of all arranged the notes of his journeys in the form of one continuous tour; and then, in the concluding chapters, has attempted a general résumé of the history of architecture in Spain; and, finally, a short account of the men who, as architects and builders, have provided the materials of his work. As an appendix, he adds two catalogues,—one of dated examples of buildings, and the other of their architects,—with a few translations of documents which serve to bring before us very clearly the way in which these Mediæval buildings were carried on. He appears to have been most

assisted by a Spanish hook, the title of which may be Englished as "Notices of the Architects and Architecture of Spain, by D. Eugenio Llaguno y Amirola, edited with additions by D. Jnan Agustín Cean-Bermúdez," in four volumes, compiled about the beginning of this century, but not published until A.D. 1829.

His book consists of 527 pages, and is very fully illustrated with engravings and plans from drawings by the author. Remembering the extent to which he is engaged in the practice of his profession, it speaks loudly for his industry and power of application. The full-page engravings, some of which we are enabled to reproduce, are fifty-one in number, and of folded ground-plans there are 25. On the plans the age of the various parts is indicated by shadings to the extent of the author's light, and he has added, in most instances, much to our personal gratification, a selection of the Masons' Marks observable on the different portions. These marks, we may note, are the same in character as those we have found in many parts of the world, and in most cases, indeed, identical in form.

The pentalfa , the universal , this form , the eight-pointed star , less

common in England, though it is to be found, and many others well known prevail. Our author at starting correctly points out that travelling in Spain involves no real difficulty, and very little personal inconvenience in the way of food and lodging, especially if, when journeying in the autumn, the traveller take his advice and live occasionally on bread and grapes. In his first tour Mr. Street entered the country from Bayonne, travelled thence by Vitoria to Burgos, Palencia, Valladolid, Madrid, Alcalá, Toledo, Valencia, Barcelona, Lérida, and by Gerona to Perpignan. In the second he went again to Gerona, thence to Barcelona, Tarragona, Manresa, Lérida, Huesca, Zaragoza, Tudela, Pamplona, and so to Bayonne; and in the third and last by Bayonne to Pamplona, Tudela, Tarazona, Sigüenza, Guadalajara, Madrid, Toledo, Segovia, Avila, Salamanca, Zamora, Benavente, Leon, Astorga, Lugo, Santiago, la Coruña, and thence back by Valladolid and Burgos to San Sebastian and Bayonne.

The Cathedral of Burgos being the first described, the cathedral arrangements common in Spain are set forth:—

"The choir proper (Coro) is transferred to the nave, of which it occupies commonly the eastern half; the portion of the nave outside, or to the west of the Coro, being called the 'Trancera,' and that to the east of it the 'Entre los dos Coros,' and in most great churches the 'Crucero,' or crossing, and the transept really do the work of the nave, in the way of accommodating the people. The floor of the nave proper is, indeed, too often a useless appendage to the building, desolate, dreary, unroofed, and cold; whereas in the transepts, the services at the altar and in the choir are both seen and heard, and this accordingly is the people's place. A passage is sometimes, or perhaps I ought to say is usually, made with low iron or brass screens or railed leading from the eastern gate of the Coro to the screen in front of the altar. This is especially necessary here, as the choir proper is deep, and the people are thus kept from pressing on the clergy as they pass to and fro in the long passage from the altar to the Coro. Gates in these screens admit of the passage of the people from one transept to the other whenever the services in the Coro are not going on. The Coro is usually fitted with two rows of stalls on its north, south, and west sides, the front row having no desks before them. The only entrance is usually through the screen on the eastern side, and there are generally two organs placed on either side of the western bay of the Coro, above the stalls. In the centre of the Coro there is always one, and sometimes two or three lecterns, for the great illuminated office-books, which most of the Spanish churches seem still to preserve and use. High metal screens are placed across the nave to the east of the Coro, and across the entrance to the choir, or 'capilla mayor,' as its eastern part is called. These screens are called 'rejias.' Above the crossing of the choir and transepts there is usually an open raised lantern, called by the Spaniards the 'ciborio,' and behind the altar, at the end of the Capilla mayor, is usually a great sculptured and painted retablo or reredos. All these arrangements are generally described as if they were invariably found in all Spanish churches, as they certainly are at Burgos and many others now; and an acute and well-informed writer in the 'Ecclesiologist' suggests that their origin may perhaps be looked for in the early churches of the Asturias and Galicia, since he had looked in vain, in both Spanish and Mozarabic liturgies, for any peculiar dogma or ritual practice which would have involved arrangements so different from those common in other countries. The grounds for my opinion will appear as I describe other churches in other places; but I may here at once say that what occurred to me at Burgos was to some extent confirmed elsewhere, namely, that most of these arrangements have no very old authority or origin, but are comparatively modern innovations."

In the church of San Gill, in Burgos, there is an iron pulpit, of which a view is given. The support is of iron, resting on stone, and the staircase modern. The framework at the angles, top and bottom, is of wood, upon which the ironwork is laid. The traceries are cut out of two plates of iron, laid one over the other, and the ironwork is in part gilded. The canopy is of the same age and character, and the whole effect is described as being very rich.

The old cathedral of Salamanca, attributed to the twelfth century, has a strikingly handsome lantern at the crossing, vaulted inside, and of which we give a view.\* We can scarcely call it "a dome" (as Mr. Street is inclined to do), and outside it takes the character of a low spire, with an entasis: four great circular pinnacles built against the external angles resist the pressure of the vault. The exterior angles have lines of simple and boldly contrived crockets, and the stones with which it is covered seem all to have been cut with scallops on their lower edge. The stonework of the exterior is much decayed, but otherwise the whole work stands well and firmly. Attention is called to the admirable treatment of the gables over the windows on the cardinal sides of the dome. No doubt they answer the same purpose as the circular turrets at the angles in providing a counterpoise to the thrust of the vault, and the change from the circular lines of the angle turrets to the sharp straight lines of these gables

Fig. 3.—Barcelona. Casa Consistorial.

\* "Some Account of Gothic Architecture in Spain." By George E. Street, F.S.A. London: John Murray, 1865.

\* See p. 172.

produces an agreeable effect. So, too, the contrast between the shafted windows, with their springing lines definitely and accurately marked by sculptured capitals, and the openings in the turrets, with their continuous mouldings. The value of contrast—a treasure in the hands of the real artist—is here consciously and most artistically exhibited; and it was no mean artist who could venture to make so unparading a use of architectural ornamentation without producing any sense of surfeit on those who look at his work even with the most critical eyes.

At the beginning of the sixteenth century, it was determined to have a new cathedral, and Mr. Street gives interesting particulars of the steps that were taken as to the designing of it. In 1509, a Royal order was issued to Anton Egas, master of the works at Toledo Cathedral, to go to Salamanca to make a plan for the proposed cathedral. Egas seems to have delayed so long that it was necessary to send another order to him, and then at last, in May, 1510, he went. The same kind of command had been laid at the same time by the king on Alfonso Rodriguez, the master of the works at Seville, and after these two had considered the matter, they presented a joint plan, drawn on parchment, showing the heights and widths of the naves, the thickness of the walls, and so forth; but they were unable, they said, to agree as to the proportion of length to breadth in the Capilla mayor, and so they settled to meet in ten days at Toledo, and then to appoint a nupire. Nothing more seems to have been done by them, for in A.D. 1513 the Bishop and Chapter resolved to call together a junta of architects to make another report; and Rodriguez being dead, they summoned Anton Egas of Toledo, Juan Gil de Hontañon, Juan de Badajoz de Leon, Alonso de Covarrubias of Toledo, Juan Torner, Juan de Alava, Juan de Orozco, Rodrigo de Saravia, and Juan Campero, who all assembled in September, A.D. 1512, at Salamanca, and drew up their report. The detailed character of this report is very curious. It describes the dimensions of every part of the church, the thickness of the walls, the projection of the buttresses, and the exact position that it ought to occupy. The architects not only agreed in all their opinions, but testified to their truth by taking an oath "by God and St. Mary," saying each one, "So I swear, and amen."

What Spanish architecture owes to that of Germany is seen in many places. Sta. Maria, at Benavente, for example, with its five apses projecting from the east wall covered with semi-domes might stand for one of the Rhine churches.

San Vicente, at Avila, is a remarkable church, and exhibits sculpture which induces some natural exclamations:—

"To me the sight of such work as this is always somewhat disconcerting. For here, in the twelfth century we find men executing work which, both in design and execution, is so immeasurably in advance of anything that we ever see done now, that it seems almost vain to hope for a revival of the old spirit in our own days; vain it might be in any age to hope for better work, but more than vain in this day, if the flimsy conceit and impudent self-assertion which characterise so much modern (so-called) Gothic is still to be tolerated; for evil as has been the influence of the paralysis of art which affected England in the last century, it often seems to me that the influence of thoughtless compliance with what is popular, without the least study, the least art, or the least love for their work on the part of some of the architects who pretend to design Gothic buildings at the present day, may, without our knowing it, land us in a worse result even than that which our immediate ancestors arrived at. Here, however, at Avila, in this porch of San Vicente, let us only so delicately and beautifully, but also so solidly and so right; let us try to follow his example, knowing for certain that in this combination lies the true merit of all the best architecture—Pagan or Christian—that the world has ever seen."

The cathedral at Toledo our author finds to be an example of the pure vigorous Gothic of the thirteenth century, "equal in some respects to any of the great French churches." The first stone of it was laid in 1227. Mr. Street is disposed to think the architect (called in his Latin epitaph *Petrus Petrus*) was a Frenchman. At any rate, he had his knowledge from France. It has five aisles; is 395 ft. long, 176 ft. wide between the walls; the nave being 50 ft. in width from centre to centre of columns; and it is excelled in area only by the cathedrals of Milan and Seville.

We must pass rapidly through the book, and will take out a couple of specimens of domestic architecture. The first (Fig. 2) is the finest in Valencia, the Casa Longa, or Exchange, commenced on the 7th of November, 1182. The architect is thought to have been Pedro Compto. The main front of the Lonja is still very nearly

as he left it, a fine specimen of late Spanish pointed work. The detail is of the same kind as, but simpler than, the contemporary works at Valladolid and Burgos, and there is a less determined display of heraldic achievements; though the great doorway, and the window on either side of it which open into the great hall, and which are so curiously grouped together by means of labels and string-courses, have some coats of arms and supporters rather irregularly placed in their panels. The great parapet of the end, and the singular finish of the battlements, are worthy of note. The principal doorway leads into a fine groined hall, 130 ft. long by 75 ft. wide, divided into a quasi nave and aisles of five bays by eight columns, sculptured and spirally twisted. The portion of the building to the left of the centre is divided into three chambers in height, the upper and lower rooms being low, the central room lofty and well proportioned. The lower rooms have plain square windows. The next stage, windows of which lofty proportions, and with their square heads ornamented with a rich fringe of cusping. There are pointed discharging arches over them. The upper stage of this wing is extremely rich, the window-openings being pierced in a sort of continuous arcade, the pinnacles of which run up to and finish in the parapet. This parapet is enriched with circular medallions enclosing heads, a common Italian device, betokening here (says the author) the hand of a man whose work was verging upon that of the Renaissance school. At the back is a garden, the windows and archways opening on which are of the same age as the front.

The second is the Casa Consistorial in Barcelona (Fig. 3). This building is said to have been commenced in 1369, and finished in 1378,\* and inside the great hall an inscription bears the date 1373. The enormous arch-stones of the principal doorway are very common throughout Catalonia, and are seen indeed as far east even as Perpignan. The figure of St. Michael has metal wings; and as the little church dedicated in honour of the same archangel is just on the other side of the Casa, it seems as if there was some special connexion between the two buildings. The *patio* or quadrangle is oblong in plan, and on the first-floor the passage is open to the air, with delicate arches all round. On the east side of this passage a door opens into a noble hall, with a dais for the throne at the upper end, and doorways on each side of the dais.

Of the cathedral in Barcelona ("the Manchester of Spain"), Mr. Street gives a full description. It would seem to have been commenced in 1295, and was still in progress in 1329, the date, according to our author, of the bulk of the work. Jaime Fabra, or Fabre, appears to have been the architect,—*el Maestro*."

"In the deed which I give in the Appendix, he describes himself as 'lapicida,' citizen of Mallorca, and says that he is about to go to Barcelona, to undertake a certain work there, at the request of the King of Aragon and the bishop. This was in A.D. 1318, and it is clear, I think, from the terms of his contract, that Fabre was something more than architect, and really also the builder of this church in Palma. The term used might indeed lead us to suppose that he was a mere mason, but the request of the king and the bishop proves that he was much more than this, and is useful as showing that these titles literally translated are very apt to mislead."

The last stone of the vault was placed in September, 1448. We give a view of the interior (Fig. 4). The planning of the nave is very peculiar. It seems as though the main requirement of the founders of this church was a plentiful number of altars; for there are no less than twenty-seven distinct chapels inside the church, and twenty-two more round the cloister. The chapels in the south aisle have a row of other chapels, which open into the cloister, placed back to back with them, and the windows which light the former open into the latter, showing, when seen from the nave chapels, their glass, and when seen from the cloister chapels the dark piercings of their openings. The arrangement is not only extremely picturesque, but also an evidence of the care with which the sun was kept out of the building. The Coro here is in its old position in the two eastern bays of the nave, with the old screens around it and all its old

fittings. It is to be observed, however, that here, where the late Spanish arrangement was from the first adopted, the western entrance to the choir was preserved, and so the awkward plank which the wall of the Coro generally presents on entering is not felt. West of the Coro are two bays of nave, over the western of which rises the lower part of a rich octagonal lantern. This is carried on bold piers of square outline, which, from the very simple arrangement of the shafts of which they are composed, have the grandeur of effect so characteristic of Romanesque work. The cross arches under the lantern are lower than the groining, and on the east face the spandrel between the two is filled in with rich tracery and arcading. Arches are thrown across the angles to carry the octagonal lantern, of which the lowest stage only—which is well arcaded—is built.

The Cathedral of Tarragona, Mr. Street describes as one of the most interesting churches he has seen in Spain, affording one of the finest types, from every point of view, that it is possible to find. It unquestionably is a very noble interior.

The Cathedral of Gerona has, perhaps, the widest pointed vault in Christendom, the clear width of the nave so covered being 73 ft., with a height proportional. These Spanish churches, or rather we would say, churches in Spain, are well deserving the study Mr. Street recommends, showing what may be done by boldness of design and simplicity in detail, provided there be solidity of construction and tasteful disposition of sculptured decoration sparingly used. Sculpture in excess becomes oftentimes a needless touch to the Spanish architect of the Middle Ages. Suffice it, at present, and without accepting all its conclusions, that the book is a valuable contribution to the history of our art, and should lead many to visit the country.

#### THORVALDSEN.

The Danish sculptor, Thorvaldson, was of Icelandic origin; and in times of old, doubtless, so noble a genius, had his countrymen then been such lovers of statues as the old Greeks were, would have been declared to be a son of the Scandinavian god, Thor, only Thor was by no means so celebrated for his constructive as for his destructive genius.

The father of Thorvaldson was a poor carver of ships' heads at Copenhagen, who had great difficulty in cutting out a lion's head so as to resemble anything else than a poodle. The family had been known and respected in Iceland for no less than nine generations. The carver was sent to Copenhagen to provide for himself, when only seventeen years old, but he never rose out of poverty; and notwithstanding his son's celebrity even before the father's death, the old carver died in an asylum among cripples and other disabled poor.

The young sculptor,—whose Christian name, if he was ever christened, is actually unknown, although, being usually called Bertel, it was believed to have been Alberto, or Carlo Alberto,—was born at Copenhagen, on November 19th, 1770. In his youth he had no school education whatever, and it was not till he was thirty-five years old that he began to study the Danish grammar. His father, however, would appear to have taught him reading and writing,—at least, his autographic productions strongly resembled those of his father, but we have known many instances in which a son's handwriting was very like his father's, although not taught by him to write. Bertel Thorvaldson, while a youth, worked with his father as a carver, and was very useful to him in "developing" the poodle genius into the genus *leo*. Hence, it was with no great good-will his father allowed him to cultivate his peculiar genius for statuary in any other way than in ship-load carving. There were discriminating persons in Copenhagen, however, who induced the father, who seems really to have had more affection for his son than the son himself afterwards showed for the father, to allow Bertel to go to the Arts Academy School, which cost nothing, and for which the father had no means to pay had it cost anything. In 1781 Bertel was admitted to the first "Sketching Class," and in 1782 he was promoted to the second,—a very unusual thing, it was considered, for a boy only twelve years old to accomplish. This very talent, it was, however, which tempted his father to employ him at home as an assistant in his own carving business, so

\* *Parecrista*, Recuerdos, &c., Catalonia, l. 107.

† "The directors of the work of the new temple," says Las Furió (Diccionario histórico de los Profesores de las Bellas Artes en Mallorca, p. 55), "agreed to give to the architect, Master Jaime, eighteen sueldos a week for the whole of his life, at well when he was ill as well; and during the work, in case he should have to go on matters of business to Mallorca—his country—the Chapter bound themselves to pay him his travelling expenses and maintain him as well going as returning. They promised also to give a house rent free for him and his family, and two hundred sueldos annually for clothing for him and his children."

that the kindred pursuits of the father stood greatly in the way of the son's advancement. Bertel was still allowed to attend the Academy classes, however; and in 1786 he was removed to the Modelling School, and here, for the first time, began to study from nature and to work in that substance wherein his most famous pieces were subsequently executed. One of the academical professors, Nicholas Ahlidaard, the artist, attracted by the rare talents of his pupil, took great pains with him, and was even afterwards of much use to Thorvaldsen. When a lad of sixteen he gained the small silver medal, which was regarded as something remarkable, and induced the provost, whose brother was secretary to the Academy, to honour him with the title of "Monsieur Thorvaldsen," of which title the young artist was almost as proud as he was of the medal; and amongst all his subsequent titles and his crop of medals he never forgot the compliment of the provost.

In 1789 Thorvaldsen gained the large silver medal of the Academy for a *bas-relief* of "A Sleeping Cupid," a work which is still preserved in the Academy, and betrays, it seems, evident marks of Ahlidaard's instruction.

In 1790, Thorvaldsen first appeared before the public as a statuary at the request of a school-fellow, Nicolas Wolff, who commissioned him to model three statues representing the tutelary deities of Denmark and Norway for a triumphal arch. Thorvaldsen at the same time executed a portrait medallion of the crown princess, Maria Sophia Frederica, for whose entry into Copenhagen the arch was erected. A plaster worker, named Regal, induced the lad to sell him the portrait for a trifle, and multiplied it in plaster for sale to his own advantage.

Thorvaldsen had great reluctance to risk his examination for the small gold medal of the Academy. He tried to "keep his spirits up by pouring spirits down" while about to enter on his preliminary task of sketching "The Expulsion of Heliodorus from the Temple;" but he fairly ran away, and was brought back by one of the professors, and in less than four hours produced a sketch which met the entire approval of the examiners: the model from this gained him the gold medal on the 15th of August, 1791.

His reputation thus became widely extended, and procured for him many powerful friends and patrons. On the 14th of August, 1793, the great gold medal was awarded him for a *bas-relief* of "Peter healing the lame Man." This entitled him to a travelling stipend for three years on the Continent; and of this privilege he eventually, but somewhat reluctantly, and much against the inclination of his parents, availed himself by going to Rome. In the interval, however, he earned a competence by painting portraits, which were much sought after. He also devoted a good portion of his time in making mirror-frames with his father, and in executing vignettes for booksellers. His friend Ahlidaard also procured him employment in modelling several *bas-reliefs* and statues for the new palace at Copenhagen. His method of working was peculiar, and seems to have attracted the notice of *savans*. Instead of first modelling them, as was usual, in clay, and afterwards taking a plaster cast, he would gradually build them up from the base with stones and stucco,—a composition the more difficult to work in on account of its drying so speedily. A Swedish sculptor went to see Thorvaldsen's workmanship on this occasion, and asked how he executed such beautiful figures. "With this," replied Thorvaldsen, curtly and simply, holding up his scraper.

"Thorvaldsen is now in Rome! God be with him! He is a good fellow, but an idle dog." Such was the remark made by the captain of the vessel in which he sailed to Rome, when writing to his wife. No doubt, Thorvaldsen was in the continual habit of lounging about the decks, with his pipe in his mouth and his hands in his pockets, staring at nothing in the far-off horizon or the azure sky, which his busy brain, however, was often then, to a certainty, peopling with the numerous gods and goddesses of his laborious future; or leaning lazily over the gunwale, and down into the blue depths of the ocean, where statues swam about before his mind's eye as the fishes did before his unheeding outward vision. The wonderful list of this idle dog's sculptural works, comprising no less than 500 separate items, each item often comprising a whole group or a number of duplicates of sculptured figures, amounting in all, we should think, to not far short of a thousand distinct forms of sculpture, gives a striking com-

mentary on an idle phraso, by the use of which the world are too apt to stigmatise the habits of those sons of genius whose ways are not as their ways, and who do not jog on in the ordinary grooves of worldly wisdom.

Thorvaldsen's self-dependent consciousness of inward power, as well as his diffidence, were manifested on his arrival at Rome by the fact, that of all the numerous letters of recommendation he had brought with him he only presented one, that to his archaeological fellow-countryman Zoëga, whose influence, however, was both great and beneficial. Perhaps his natural lowness of spirits may have conduced towards his reluctance to make use of his letters of introduction. He hired a studio in Strada Babuina, previously occupied by Flaxman, but was shortly afterwards attacked by fever, and indeed to this disease he was repeatedly a martyr while in Italy. Love formed a *voluntarie* with a girl named Anna Maria Magnani, with whom he was associated the only child he ever had. Rome about this time was in a very unsettled state, and Thorvaldsen did not make much pecuniary progress. The Copenhagen Academy took the matter into consideration and voted a further stipend to him for a year after the expiry of the three years of his travelling studentship. He had forwarded several works by that time to the Academy, and he now set to work on his afterwards famous "Jason with the Golden Fleecce." He broke up his first model, however, but rapidly produced another, in clay, larger than life-size. This was in 1803. Canova was much struck with the excellence of the design, and it excited general admiration. The year, however, expired without any material improvement in the sculptor's prospects, and he prepared to return home, but on the very day of his departure a valet came into his studio, and told him that an English gentleman was waiting outside, and very much desired to see his statue of "Jason." Mr. Hope was the man, who restored hope to Thorvaldsen. He asked him to name his price for "Jason" in marble. Six hundred zecchinos, or 300*l.*, was the price. Mr. Hope at once agreed to this, remarking that the remuneration was but small for so large a work—so great a work, he might have said. He paid 300 scudi, or about 63*l.* in advance; and thus it was that Thorvaldsen's portmanteau was untrapped from the *veturino's* conveyance, and he became for many a long year a citizen of Rome. His difficulties, however, may be said to have only now begun: he had to purchase the marble for "Jason," at Carrara, and that cost 650 scudi. Other and minor orders flowed in, and the designer of "Jason" went forth, and connoisseurs hailed him as the regenerator of the long-lost antique art. It was at least eight years, nevertheless, ere he acquired anything like distinction as a sculptor. This was partly owing to repeated attacks of fever, and also partly to political causes. It is painful to find Thorvaldsen's father telling him by letter, after this, from the asylum, that Herr Ahlidaard was his only friend, and had lent him ten dollars to pay the expenses of Bertel's mother's funeral, which he had had hard work to pay back; and the poor old man adds—"God knows what my burial will be."

Oehlenschläger, the renowned tragic author, thus describes Thorvaldsen as he saw him previously to the summer of 1810, in his studio, whether he went to inspect the statue of "Jason." "As I stood absorbed in gazing at it," he says, "I became aware of the presence of a man very meanly dressed. His countenance was remarkable for the regularity and intellectual expression of its features, and for the deep blue of the eyes. He stood beside me, with his boots bespattered with clay, and regarded me with evident attention."

Commissions poured in from all quarters, and Thorvaldsen never hesitated to undertake them, reckless of the circumstance that not even his "Jason" had yet been executed; and, although no one would have now called him an idle dog, he certainly exposed himself to the charge of being an ungrateful one; for it was only after four years after Mr. Hope had given him the order for "Jason," that the statue was executed! He did make amends, however, by unexpectedly sending, along with "Jason," in 1828, a bust of one Mr. Hope's children, and another of his valuable works. Moreover, a "Jason" executed at that time was at least worth as many thousands as Mr. Hope paid hundreds for it.

It was not till 1838 that Thorvaldsen finally left Italy, and returned, greatly renowned, to his native country, where he was received as if he had indeed been a son of Thor. Forty-one years of his life were thus spent in Italy. He died in 1843, expiring suddenly while at his favourite resort, the theatre. In 1848 his remains were removed from the Frue Kirk to the museum which he had founded in Copenhagen, and which was then completed.

This outline has been gleaned from "The Life of Thorvaldsen," collected from the Danish of J. M. Thiele; by the Rev. M. R. Barnard, B.A.," just now published,\* in which those who desire to know more of him should look for it. The volume itself is but a sketch; and it seems to be a matter for regret that the author did not make greater use of the voluminous memoir of Thiele, if not even extending to a full translation; for Thorvaldsen is well enough known and rightly enough esteemed in this country to have justified such a course.

The volume is appropriately dedicated to Her Royal Highness the Princess of Wales.

#### SAVILLE HOUSE: WHY WAS IT BURNT?

THE accounts of the destruction of Saville House by fire have omitted notice of circumstances that would deserve to be remembered in any efforts to develop a system of construction less productive of danger than that which now prevails. Something has been written, in our own pages especially, concerning the system which allows each house,—or in the majority of cases,—to be as so much firewood conveniently disposed for the perfect ignition of the whole mass during a period of time to be counted by minutes. Even should the rapidity of the communication of flame be moderated by accidental circumstances, such as the absence of a great rush of air through an opened door, smoke will precede the flames, and suffocate those who might have remained some minutes longer unburnt. Though it has been shown that if quartered partitions and joisted floors were filled in solid between the timbers, the rapid spread of fire might be materially contracted, and perhaps arrested, the greater number of partitions and floors are still constructed hollow. Fire-proof plaster which have stood severe experimental tests, are, consistently with the general inattention to the whole matter, scarcely used at all; and ordinary plastering, which, well executed, is really capable of resisting fire for a moderate length of time, is so laid that it is of little service, especially where joists are weak, and fractures in the plaster have commenced. In short, each house is still built like a funeral pile, with the proper spaces and channels left for supply of air and the lapping on of flame from stick to stick, only excepting that there is an ostensible outer casing which is more or less effectual in confining the fire to one house, according to the number and arrangement of any openings in the wall, and to the vicinity of other buildings and the direction of wind. The result from the arrangement of the material quite resembles that from the housemaid's manner of laying the domestic fire when the wood has been dried, and is well laid for the crackling up quickly. The effect to sight and hearing is absolutely identical: the period elapsing from the first catching fire, to the complete inflammation, judging from what we have seen, must be the same in the two cases.

Circumstances attending the destruction of Raggett's Hotel, in Dover-street, several years ago, as then described, deserve to be recorded in the history of this subject. We cannot now turn to the newspapers; but we recollect that one of the incidents showed that the slightest hesitation in making an escape after the first intimation of an occurrence of fire, although scarcely any smoke or flame be distinguishable at the moment, involves the utmost danger. On the occasion referred to, one of the inmates of the hotel came out of his room-door, saw nothing, went back, delaying little more than an instant, and was somewhat injured in descending the stairs. It is not necessary to allude to the loss of life then, and on so many other occasions.

The value of good party walls was shown on the occasion of the destruction of Saville House; but the fire in Leicester-square should lead to consideration of the danger which there is of communication of fire from one building to another, through the existence of a feature in

\* Chapman & Hall, Piccadilly.

the arrangement of adjoining buildings, that is modern, and is becoming almost general. We have sometimes referred to disadvantages which there are sanitariously in the practice, growing with the increase in the value of ground, of building on the sites of yards and gardens. The structures, which in the majority of cases must be top-lighted, form a perfect means of communication of fire from one building to another. The fire in Leicester-square did not extend to the houses east and west of Saville House, in the front towards the square; but had the fire occurred in Messrs. Stagg & Mantle's premises, it would have been communicated to Saville House, by reason of the existence of a one-story building of the kind to which we have alluded.

But this circumstance is not the only one to which attention should be directed just now. There were other circumstances which, it may be said, might be supposed to have attended such a fire, but which required no special demonstration to convey the impression of. We have spoken of them, but only slightly. The writer of these lines happened to arrive in Leicester-square only five or six minutes after the explosion; but flames were pouring out of the windows of the second or principal floor; and in two or three minutes more, the whole interior of the story seemed as a furnace. So early was this, that little more than the ordinary crowd in the square was to be noticed. A long time seemed to elapse before the engines came; though we do not think there was unusual delay; and the Chandos-street station is not far off. When the engines got to work, the water from them seemed to vanish in spray without reaching the fire; or the streams bore about the same importance to the fire, as those from a boy's squirt would to the most glowing fire that there could be in a kitchen-grate. The exertions of the firemen may have helped to save adjacent premises; as regards Saville House, they seemed to have no effect whatever, unless one prejudicial; the fire ceased when everything combustible was burnt. Great damage, however, was done to goods in adjoining premises, by the water.

Our own impression of the extreme rapidity, and otherwise remarkable character, of the total inflammation of the principal floor, is more than confirmed by a statement, by Mr. J. E. Collins, the painter of several exhibited portraits of Miss Bateman. Mr. Collins happened to be passing at the time, on the footway next Saville House; and the window of one of the lower stories, where the explosion is said to have occurred, was blown out in front of him. He ran to the opposite side of the road, immediately turned round to see what was the matter, and saw the flames at the windows above, much as we have described their appearance only about five minutes later. His impression was that some combustible liquid, as turpentine, must have caught fire on the second floor. It seems to us that the appearance, whether due to any such cause as this last, or to combustion of gas following the explosion, — as in the case at Liverpool, taken as reported, and which we alluded to in our last number as mentioned previously, — or to a rapidity of communication of flame greater even than that which is ordinary, should even now suggest official investigation. Inquiries on fires, after having been revived, — and one of them, that on the fire of Covent Garden Theatre, having led to knowledge of possible causes of fires, — seem to have again fallen into disuse, unless where there is loss of life. We venture to assert that what was seen by ourselves, and others, previously to the arrival of the engines, at the fire in Leicester-square, deserves some further attention, at least with the object of greater care in the gas-arrangements, as in the construction, of many classes of buildings.

There is another circumstance to be noted of the fire in Leicester-square, not less important than any other that we have alluded to. Although almost immediately after the manifestation of fire in the second or principal floor of Saville House, the whole of that story was glowing and crackling like a furnace fed with wood, it was very long before the fire got to the story above. What was the construction of the flooring we are not aware; but it could scarcely have been such as that of the commoner kind of London house. We have heard several statements from persons who witnessed the fire; and each one has included surprise at what indeed was sufficient to surprise ourselves. The case affords one more piece of evidence that a floor may offer considerable resistance.

We may mention here that there is an invention, Nickson & Waddingham's "Patent

Slate Ground for Plaster," — once noticed by us in a review of the materials and manufactures at the Architectural Exhibition, — which, besides other advantages over wooden laths, has the property of fire-resistance. The secretary of the Patent Plaster Foundation Company, at Manchester, has lately written to us saying that on the evening of the 20th ult., a fire occurring in certain offices in that town, in Faulkner-street, and of which the ceiling and partitions were plastered on the slate-ground, the fire was confined to the one room, and did not touch the joists or flooring above, though a wooden beam below the ceiling was burnt to a depth of 2 in., and the whole of the partitions and fittings, and a joiner's bench and tools, were destroyed. The actual damage did not exceed thirty pounds. The offices are in a new warehouse, and had been locked up at about eight o'clock in the evening.

In conclusion: the destruction of buildings by fire should be made to result in some accurate knowledge of circumstances which cause the calamity, and of all those which induce the rapidity of a conflagration, and eventually in an improved system of construction. Unfortunately the most important data for any questions which there are, are to be gathered only at the time of outbreak of a fire, and within a very short interval after, or before the fire-brigade and persons competent to form opinions have had time to arrive.

#### THE EXHIBITION OF THE ROYAL SCOTTISH ACADEMY.

The Scottish School of Art, although of comparatively recent origin (the present is the thirty-ninth exhibition), has added some of the greatest names to the roll of British artists. Those of Wilkie, Raeburn, Dyce, Watson Gordon, Roberts, Phillip, Noel Paton, Gibson, and Calder Marshall are sufficient testimony of the truth of this statement. The tendency of this age of telegraphs and railways is to reduce peoples to an uninteresting uniformity of habit and manner; but any nation, worthy of the name, having a history of its own, and a distinct peculiarity of natural features, must, in the nature of things, evince a distinct type of character, although this may be greatly modified by change of circumstances. The shepherd of the hills will be a man of as different a stamp from the labourer of the plains, as the ploughman of the ocean from the ploughman, so long as hill and dale, land and sea exist. It is needless, therefore, for a certain class of writers, to pour ridicule upon the Scot, because he shows some peculiarities, unless, indeed, these peculiarities are deserving of blame; but, upon the broad field of art, there is room for all to roam at freedom without offence.

The peculiarities of the Scottish School of Art may be said to consist in appreciation of character and a certain bold, rough mode of treatment, combined with a rather heavy and dull tone of colouring. At the same time it must be confessed that there is a manifest improvement in the matter of coloring within the last few years; and this improvement is mainly due to the influence of one artist, Mr. John Phillip, whose "Spanish Wake" (453) is the chief attraction in the galleries. Its strong contrasts of light and shade, mirth and woe, its glorious colour, mastery drawing, and dramatic effect, produce a lasting impression upon the mind; but, as its merits were sufficiently demonstrated upon when it was exhibited in the Royal Academy last year, it is unnecessary for us further to refer to them. Before closing our preliminary remarks, we would refer to another influence at work, that tends towards and less conventional than he otherwise might be. Having studied in the northern capital, and acquired in that limited field a certain reputation, his ambition prompts him to seek a wider field of exertion; so he shifts his studio to the capital of the empire, where greater advantages are at his command, and a new impulse and direction given to his exertions. A few years ago Messrs. Faed, Petty, Orchardson, Archer, and J. and A. Burr, followed this impulse; and since then their works have been received with much favour, and commanded a more ready sale than they could have done in the provinces.

The present exhibition is in many respects above the average of former years, not only from the importance of the works exhibited by well-known artists, but from the increased power

and improvement shown by younger and less known men. The number of works exhibited exceeds by forty-seven those in the last exhibition of the Royal Academy, and we cannot undertake to go over the catalogue in detail, but will confine ourselves to a notice of the most prominent and meritorious productions.

Mr. Horatio Macculloch, has long retained the first place as a delineator of the Scottish highlands, and no one excels him in giving the general expression and feeling of the "brown heath and slaggy wood, the mountains and the flood;" but he seems not to be aware that there are other colours than brown and grey in a highland landscape. "Glencee" (125) exhibits his peculiarities in a marked manner. The mist creeping along the summits of the bold range of mountains, with their bald and rugged sides, is true to nature; but in the foreground there is no indication of living colour: all is dead brown, not a spot of green moss nor a tuft of living heather, not a blade of grass nor a solitary wild flower or stunted bush. In this region of mist there is always sufficient moisture to preserve some green spot for the eye to rest upon, even in the hottest summer. No. 669, "Local Aehray," shows a little more attention to local colour; and of having more been studied from nature; but the grass and felled trunks of trees are conventional and slovenly in execution.

"He was Faither and Mither and a' things to me" (506), is a charming little picture, by Thomas Faed, and will be remembered by visitors to the Royal Academy, and by our readers.

We cannot see much to admire in the work of Mr. Harvey, the newly-elected president (529), "A Joyful Mother of Children;" it is good neither in colour nor texture, and is decidedly faulty in drawing, as witness the awkward ungraceful position in which the girl who is being assisted into the open window is thrown: the mother is a very common-place looking dame, and her family have no special beauty to recommend them. It is in his landscapes that Mr. Harvey appears to best advantage; and the effect of sunshine in the room, and the glimpse of landscape seen through the window, are the redeeming points of the picture, which, by the way, might as well have been called portraits of Mrs. So-and-so and family.

Several specimens of the late Mr. Dyce are sent by their proprietors, none of them great works, but each exemplifying, in some degree, his peculiar merits. (155) "Study of a Head," is full of dignity, and the colour of the drapery remarkably fine, but the flesh appears leathery and the beard rather woolly. (511) "Pegwell Bay, Kent," is highly finished and carefully detailed, and the flickering evanescent light of the declining sun on the chalk cliffs truthful and evincing keen observation. (711), "The Mouth of the River Rosa, Arran," is a small carefully finished piece of landscape, without any peculiar excellence of colour or expression.

There are three specimens of the late David Roberts in the Exhibition. (419) "One of the Chapels of the Church of St. Jacques, Dieppe," is one of his earlier productions, and shows more attention to detail than he afterwards bestowed on his later works, of which (795) "San Giovanni e Paolo, Venice," is a good example. It would appear from the works of Mr. Roberts, that generalization of detail in a painting of an architectural subject produces more grandeur of effect, and less feeling of littleness, than when the detail is carefully elaborated. Many are apt to forget that the province of the painter is distinct from that of the delineator. 833 is a sketch of "Burns's Monument at the Anld Brig o' Doon," in which the landscape is merely indicated by dashes of neutral tint.

Mr. William Douglas lives in an atmosphere of romance; he is at home in old tapestried chambers, with quaint furniture, in libraries with heaps of works strewn about, and in vaulted cells where the alchemist mixes his simples and the necromancer wields his magic wand. His principal work this year is entitled "The Return of the Carrier" (546). In a Gothic chamber a hiliopoliot pursues his studies, and a young lady watches her opportunity of gaining possession of a letter, brought by a carrier pigeon, without disturbing the stillness that reigns around. The room has an appearance of genuine antiquity about it, and the drawing and texture, as in Mr. Douglas's works, are excellent.

Mr. James Drummond's works are thoroughly national in subject, and exhibit the faults as well as the merits of the Scottish school; he displays great antiquarian research in the selection

of the costumes and accessories of his pictures. The characteristics of the various historical personages are, in most instances, happily expressed; the execution is sometimes loose, and the colour and texture seldom good. (606) Queen Mary's "Last Look of Scotland," is about the worst specimen from his easel that we have seen; the figures are crowded into a small boat, to such an extent that it could not "live" in a calm sea, far less in one, as in this instance, when a brisk breeze is blowing; the boat, moreover, lies towards the wind, as it could not do with the sail filled out in the opposite direction.

Mr. Peter Graham promises to be, if he is not already, the best landscape-painter in Scotland. His landscapes are not mere transcripts of nature, but poetical productions of a high order. His "Ruins of other Times" (624), would have been better named "A Picture of Desolation." At the edge of a stagnant pool a blasted pine-forest is falling to decay; a damp, cold shroud of mist is slowly embracing in its folds the distant landscape; a solitary raven—the only inhabitant of this dreary spot—is perched upon a branch of a fallen pine, which by slow degrees has parted from the root; and a deer's skull lies partly imbedded in the marshy soil. It is easier to suggest than to produce, and still easier to find fault: in this spirit we might express an opinion that the picture would have been finer than it is had the number of pines been fewer, with one in the foreground rising sheer up to the top of the canvas.

There are some minds like milk that will only stand one skimming; and Mr. Alexander Leggatt's seems to be of this order. Last year he produced a rich bit of clotted cream, from which he derived a considerable amount of butter; this year he produces nothing but skim milk. The figure of "Palissy modelling from Nature" in his last year's work possessed considerable power of expression; and although the other figures introduced, and the accessories, were rubbish, their defects were overlooked upon the supposition that the artist had been hurried in finishing the picture; but this excuse cannot be urged in favour of what he now exhibits. Palissy again appears (755), declining to be converted to Popery, even by a king. His majesty stands in a stony attitude, intended to represent offended dignity; whilst the old potter cringes before him, and two female figures in the background look as if they were the work of the potter's art, which they can hardly be, from their position and size.

A Dutch painter, A. Mollinger, of Utrecht, sends two landscapes, (279) "Church of Village Zwoelo," and (362) "Rainy Day in latter End of Summer, hamlet Weezep." Neither of these is a subject that would have engaged the attention of any of our artists; they have better at command all around: the more credit, therefore, is due to the Hollander who has used to such good effect what he could get. The sunny calmness of the one, and the dull leaden hue of the other, are admirably represented, and the flat uninteresting landscape stretches far into the distance.

Mr. Sam Boneh works at railway speed—express time; he can execute a painting,—ay, and a good painting, too, in its way,—in a single day. Such being his impetuous mode of working, it is useless to look for high finish or much detail; doubtless his pictures would be more valuable as works of art with more attention to these particulars; but it is not in his idiosyncrasy, and we must take him as we find him. 552, "In the Trossacks," shows good colour and modelling in the hills; but the birch-trees are flat and devoid of character, the perspective of the road is defective, and the flock of sheep like so many packs of wool.

Mr. J. B. Macdonald just falls short of excellence in his "Episode in the Time of the Test Act" (686), *vide* "Old Mortality," cap. 8. Milwood, the miserly laird, is well hit off, and so is the fanatical bitterness of old Manse, and the pawky cunning of Cuddy. Bothwell is a gallant-looking trooper; but Henry Morton, the gay gallant whom Bothwell addresses as Captain Popinjay, is more like a tapster in a city tavern than a hero of romance, and it would not require the craft of the Brothers Daveport to undo his bonds. The picture is good in colour, and strong and forcible in execution.

Mr. H. Cameron's "Sunny Hours" (487) is a charming little picture, reminding us of Mulroddy in the coloring of the figures and the mode in which the landscape is brought into harmony with them.

Mr. Macdaggart confines himself to the delineation of peasant life, with an occasional essay

at portraiture. His principal picture (367) "Word from the West," which represents the reading of an emigrant's letter, a subject which has been frequently painted before, is, unlike the generality of his works, dull and heavy in colour, and deficient in imagination and sentiment. No. 387, "A Summer Afternoon," is full of sunshine, and so is (454) "The Press-gang."

Mr. McWhirter is a diligent student of nature; he has painted on the spot the snow-peaks of Norway and the sunny plains of Italy, as well as many a pleasant nook in his native land; but it is obvious that "The Exile's Garden" (317) is a creature of his own imagination,—the lily and the rose, the poppy, digitalis, and hare-bell all bloom luxuriantly together; whilst at the same time the over-ripe apples are falling from the tree. His "Temple of Vesta, Rome: Evening" (708) is charmingly treated.

In the republic of letters Scotsmen are said to excel in biography,\* and the analogy holds good as to portraiture. The late president, Sir John Watson Gordon, stood unrivalled in the delineation of character, though deficient in texture and colour. There are four of his works exhibited, the finest of which, we think, is the unfinished one of Mr. John Pender, M.P. (534).

There are two fine examples of Francis Grant, "Major-General Sir Hope Grant" (452), simple, unaffected, and manly, the colour rather chalky; and (689), "The Lady Mary Craven," full of grace and refinement.

No. 474, "Rev. Shafto Orde," and (533), "Alexander Mitchell Innes, Esq.," by Colvin Smith, are vigorous and broad in treatment. Francis Crickshank's "Portrait of Alexander Cassels, Esq., W.S." (581), has something akin in it to Sir J. Watson Gordon's famous "Provost of Peterhead."

No. 668, "Portrait of Anderson Ferguson, M.D., Inspector General of Military Hospitals," by Norman Macbeth,—a noble head finely rendered; and 424, "The Rev. James Begg, D.D., full of self-consciousness. 328, "The Earl of Dalhousie," like all Mr. Phillip's works, fine in colour and vigorous in touch.

Water-colour painting has never taken firm root in Scotland. Notwithstanding the patronage of royalty, Messrs. Macleay & Gregg have hard work of it, and it was not till he emigrated southward that Mr. Burton could get his works satisfactorily disposed of. There is an idea prevalent in the north that water-colour is evanescent, and the "canny Scot" likes to have something substantial for his money, so he goes in for what he considers more durable stuff, and invests in oil.

Last year Mr. Waller Paton entered the ranks of the small band of water-colourists, and must have met with some degree of success, as he again appears as one of their number, and, in our opinion, his works in that medium are superior to his oil paintings. He delights in purple, violet, and crimson, and sunsets are the invariable product of his brush. 41, "The Dhu Hlochian," a grand expanse of deer-forest, is, perhaps, the best work he has yet produced; it is rich in tone, yet subdued and harmonious in effect, and full of air.

Mr. G. M. Greig's "Jedburgh Abbey: Evening" (209) offers a marked contrast to Mr. Paton's, being somber and subdued in tone; and the same qualities appear in 216. Mr. Greig is a little too timid in the use of colour: a visit to the Water-colour Society's Gallery in Pall-mall East would do him no harm.

Mr. J. J. Benmatyne has several brilliant landscapes: 106, "Benvenne and Loch Achray," and 86, "Glennulas," particularly.

Mr. Horatio Macculloch's small studies are excellent in effect; and the productions of Messrs. Clarke, Stainton, W. H. Nutter, and others, deserving of more attention than time and space will allow us to bestow on them.

The sculptures consist chiefly of busts, and we shall only refer to two of them as exemplifying diametrically opposite modes of treatment. That of "The Rev. Principal Candlish," by Mr. D. O. Hill (863), represents the peculiarities of physiognomy of the reverend Principal in the most exaggerated manner, and the expression is more that of a barrister attempting to puzzle a jury than that of a divine. 864, "Bust of the Rev. Wm. Robertson, by George Macallum, has all the dignity and spirituality becoming the sacred profession. Mr. Calder Marshall's "Summer Cloud" (883) seems to float on air; the graceful undulation of the figure, the drapery wafted

about as with a gentle breeze, and the very shadows which it casts, all tend to the main object of the sculptor. Mr. Macdonald's "Bacchante" (885) is a graceful and lovely maiden, with none of the wildness and exuberance of spirits that one looks for in a follower of the god of wine. She is probably, however, meditating on joining the British League.

It seems strange, at first sight, that architecture should be the least popular of the fine arts. Works of painting and sculpture generally become the property of private individuals, and disappear from the sight of the public; but a building, once it is erected, becomes, in a manner, the property of all; and if the principles of the art were more generally understood, we should not have to complain of the want of art which is too frequently displayed by proprietors and builders; our suburban villas, instead of being, as in ninety-nine cases in a hundred they are, mere places to live in, would be a source of continual interest, each displaying some peculiarity of taste, and giving an additional charm to the landscape. Every tyro can pretend to a knowledge of iconology and prate about colour, light and shade; but to be able to appreciate an architectural design requires a knowledge of styles, and of the fitness of the parts for the service they have to perform. To acquire this knowledge requires study; and unless the critic knows the terms and technicalities of the art, he cannot make himself understood. With all their faults, competitions have done much to popularize architecture.

The Royal Scottish Academy are much more liberal in affording space and good places for designs that have any claim to be called works of art than the Royal Academy in Trafalgar-square; and local architects are beginning to take more advantage of this, and find it to their interest to do so, and in many instances bestow much care in getting up the drawings.

There are upwards of two dozen designs in the water-colour room, some of them of works of considerable importance.

Mr. David Bryce exhibits two views of the Bank of Scotland, as now being remodelled (21 and 192). No architect is better qualified than Mr. Bryce for the difficult task set before him; under his hands a great number of the mansion-houses throughout Scotland built during the latter end of the last century and the beginning of the present, in the tasteless and barren manner then prevalent, have been converted into picturesque and interesting edifices. The Bank of Scotland stands in advance of the picturesque and broken line of edifices which crown the ridge running from the Castle towards Holyrood, and present a marked contrast, in their rugged and ancient appearance, to the more regular and modern new town which they overlook. The elevation towards the south is not devoid of merit, and has been retained and used by the architect as the key-note for the additions. The north or back elevation is a hideous ill-proportioned mass, with no architectural enrichment; but as about to be altered it will form one of the most prominent and elegant additions to the architecture of the city; and from its great height, caused by the rapid fall of the ground, it will have a majestic and grand appearance. Mr. Bryce has added wings, which are thrown back as seen from the north, and project beyond the line of the south front, and has thus given breadth to, and taken away from, the flatness of both elevations. These wings are surmounted by open lanterns, roofed in with scaled domes, with sculptured eagles at the springing and a winged figure at the apex. The central dome has been raised in height, and a lantern added similar to those on the wings; between the projecting wings on the south front, which are terminated by circular-headed pinnacles, runs a screen of one story, with apartments behind. The central portion of the north elevation shows a large circular-headed pediment, supported by caryatides, and decorated with sculpture. Viewed as a whole, the design appears more like an original creation than a specimen of patch-work.

Messrs. Peddie & Kinneir's design of Kenclies House, Forfarshire (20), shows that they have a competent knowledge of the domestic Scotch style. In their additions to Lushallon House, Fifeshire (133), they introduce an infusion of the Cinque-cento along with the Scotch with happy effect; the tower is particularly deserving of notice. In the Sheriff Court House, Greenock (91), the same firm use the style practised by the late Medieval architects in Franco in the Hôtels de Ville there. The central tower in

\* *E.g.*, Boswell and Carlyle.

this design seems ever-done; and the double buttresses at the angles do not seem necessary for construction, and are certainly not elegant additions to the design.

Mr. J. A. Hamilton's "Public Offices in Leith" look better in execution than on the drawing; the old Scotch style groups pleasantly with the shipping and surrounding buildings. The Batty Langly pepper-box turrets at the angle would have been better absent.

No. 105 is an "Architectural Design in Memory of H.R.H. Prince Albert as it would be seen from Holyrood" by Mr. R. Raeburn. We hope and trust it never will be seen from Holyrood or in any other shape than its present one. It consists of a pyramid rising to the height of 120 ft. profusely gilt, and having Doric porticos on its four sides.

No. 66, "Mansion House, Grange Loan, Edinburgh," Mr. F. Pilkington. In looking at Mr. Pilkington's designs we feel disposed to admire them at first sight, but a closer inspection modifies this admiration and discloses many faults. This mansion displays considerable originality in the mode of treatment, the basement containing the kitchen offices is not, as is usually the case, either sunk below the ground-level or screened off, but stands clear, the entrance being from the side; by this means an appearance of greater altitude is obtained than in the usual mode. In the centre of the front elevation, battress-like piers are projected, upon which are superimposed the pillars of an arched balcony, which looks as if hoisted upon stilts. The angles are rounded off into the form of towers, and filled in with clusters of arched windows, not a very safe piece of construction. The "Free Church, Kelso" (161), is less open to criticism than Mr. Pilkington's former ecclesiastical designs, and is possessed of considerable beauty: the very deep recess given to the porch and window above can hardly fail to produce a good effect, but it must be obtained at the expense either of double walls or by constructing them of extraordinary thickness.

Messrs. Douglas & Stevenson send a view of the "Kelvinside Free Church, Glasgow" (226). The spire has a certain stern grandeur about it much superior to the overloaded style so frequently used; it is hardly in keeping, however, with the church to which it is attached, which is heavy and lumpish.

## WOMAN AND THE FINE ARTS.

### THE ARCHITECTURAL MUSEUM.

The session of 1865 was inaugurated by the delivery of a lecture, on Tuesday evening last, at the South Kensington Museum, by Mr. F. T. Palgrave. Subject, "Woman and the Fine Arts." Mr. Joseph Clarke presided.

The chairman said that, in consequence of a slight accident, the President of the Society, Mr. Beresford Hope, was unable to attend that evening, as it had been his intention to do, for the purpose of distributing prizes to art-workmen and delivering an address on "The People's Share in Art." He was sure they all joined with him in regretting the cause of Mr. Hope's absence. The accident was, however, he was happy to say, a slight one, and they hoped to have the pleasure and advantage of Mr. Hope's presence on the next evening of meeting. Mr. Palgrave had very kindly undertaken to deliver a lecture which he had prepared for the 21st of March.

Mr. Palgrave said he hoped to have been a listener rather than a speaker on that occasion, and he heartily joined the chairman and the meeting in regretting Mr. Hope's absence. He had, under these circumstances, to throw himself on the indulgence of the meeting, as he might have been enabled before the day originally named for the delivery of the lecture to have made it more worthy of the subject and of the meeting. The subject was, "Woman and the Fine Arts." Mr. Palgrave then proceeded with his lecture, the reading of which, and of the short poems and extracts with which it was interspersed, occupied nearly an hour and a half. The first inquiry instituted was why women had not attained the measure of success in poetry, in painting, in music, or in sculpture which had been reached by men. Contemporaries, painters, musicians, and sculptors were, for obvious reasons, excluded from consideration. Europe had passed through the first stage of civilization, in which women were slaves; and through the second stage, in which women were regarded as com-

petent only to act as housekeepers and perform works of charity. In the present day, men professed to place women on a level with themselves; but had not woman reason to maintain that man did not honestly carry out his profession? She was surrounded by the deadening influence of an atmosphere of false compliment and flattery, in which no energy could be expected to live. The qualification of excellence in the fine arts, besides physical aptitude and educational facilities, might be described as imagination and fancy on the side of intellect and the emotional feelings on the side of the heart. If it were true that these exhausted the conditions necessary for success, was it not strange that during 3000 years the success of women in the departments of art alluded to should have been so meagre? Excluding contemporaries, and looking altogether to the past, how few women had distinguished themselves as poets. Mrs. Phillip and Mrs. Hemans, who stood in the front ranks, did not soar above their contemporaries, Waller and Sonthey; in painting there was a greater paucity still; while one bar of music, written by a woman, or one statue from a woman's hand, did not exist to challenge admiration. There must be something in the nature of woman, or in her position and external circumstances, to account for this non-success. There was an educational hinderance, but he thought it was somewhat overrated. Girls of seventeen were required to cease to be students, and to become ornaments of society. The rich storehouse of antiquity was thus closed to a girl at a time when she could have entered it with advantage, and when boys have not only full liberty to explore it, but are required to do so. Even if the education of boys be interrupted, they have opportunities of resuming and completing it, which girls have not. Men and women do not, therefore, start in the race on equal terms, except, perhaps, as to music, in which the position and circumstances of the latter give them an advantage, from which, however, nothing has resulted. What song written by a woman has survived a generation—not to speak of greater works? The last thing he would think of contending for was that women should be the mere echo of men. Their work was in great part essentially different; but in that in which it was similar, why was there not nearly similar success? They were not in a position to assume that there was anything in nature to account for it. The natural bar could not be pleaded until one or two generations of women had been educated as men were—until in education, as in other things, women and men stood on a perfect equality. Until this condition of just comparison were supplied such could not be instituted. Training was nothing without the proper gifts; but it was equally true that gifts were nothing without the proper training. England in poetry, and France in painting, had recently shown examples of excellence which posterity would not soon let die.

At the conclusion of the lecture,

Mr. Gambier Parry moved a vote of thanks to the lecturer, which was subsequently carried by acclamation. Mr. Palgrave, he said, must be possessed of no little courage to have contemplated rising before a meeting consisting of ladies and gentlemen, and boldly instituting a comparison between them. That he had succeeded in the task he proposed to himself resulted from this, that he had justified the position of woman, and shown that from adverse circumstances she was unable to place herself in competition with man. He had, however, hinted that there was another poetry—the poetry of common life—in which woman shone with peculiar lustre, and through which they exercised a mild and genial influence upon the ruder race. The gentlemen present could not, from anything they had heard, go away in the slightest degree enhanced in their own opinion, or with the idea that the dearest amongst their female friends had been disparaged.

## THE ROYAL MEDAL OF ARCHITECTURE.

The Institute of Architects have resolved to recommend to Her Majesty for the Royal Gold Medal, Mr. James Pennethorne, fellow. The Council in their report named a well-known church architect; but the members in general meeting assembled thought differently, and, by a vote of 38 to 13, decided as we have stated. The recommendation of the Council in respect of the award of one of the ordinary medals was also set aside.

## HOSPITALS IN FRANCE.

The Surgical Society of Paris has published the following instructions with regard to the reconstruction of the Hôtel Dieu and hospitals in general.

1. A hospital should be situated in an open space and on a declivity. The grounds attached to the building should be of considerable extent; a superficial area of 50 square metres (538 square feet) per inmate is the minimum of the space, and which ought to be increased progressively with the number of patients.

2. The former removed a hospital is from populous neighbourhoods the purer will be its air, and no hospital should be retained in the midst of large towns but those of urgency, or for the purposes of instruction. This sanitary measure would be attended with economy, and would permit large towns like Paris to establish hospitals on open spaces of inexpensive ground.

3. In hospitals of 200 to 300 sick, it is easy to obtain good sanitary dispositions; but it is next to impossible to realise these when double the above number is exceeded. Within these numerical limits, the expenses of all sorts are pretty uniform, except in very full hospitals.

4. The elements of the atmosphere mingling always in a horizontal direction, we must, by furnishing space, guard against the effects of contact and proximity which constitute the evils of overcrowding, and which are produced from inmates to inmates, from ward to ward, and from building to building.

5. It is not only by increasing the cubical content allowed to each inmate that contagion can be effectually guarded against, but by augmenting the superficial space at present so insufficient in our civil hospitals. For the same reason it is considered undesirable to multiply the number of stories, each of these engendering a stratum of air more or less vitiated. In the rigour of salubrity, more than two stories should not be adopted.

6. It would be illusory to imagine that a large cubic current of air in the interior of the wards would compensate for want of space and exterior aération, or that an abundant artificial ventilation would make up for either of these conditions. Nothing can compensate for the insufficiency or the default of the natural circulation of air.

7. Buildings, completely isolated, with the same aspect, exposed, without any obstacle, to the rays of the sun, to the effects of rain and the action of the winds, are to be disposed of in a single line, or in parallel lines, at wide intervals of 50 to 100 metres, so as to obtain an effective separation, and a free and plentiful current of open air.

8. Small wards of fifteen to twenty beds are easily managed as far as attendance is concerned. The inmates incommode each other less; the chances of direct contagion are less also; the cleansing, &c., more rapidly performed. They ought to be preferred for ordinary service, except when special arrangements are necessary to be adopted for some classes of patients who require a larger space and separate wards.

9. The furniture of the wards ought not to hinder in the least the free circulation of air. The superintendents have the power of suppressing curtains if they think proper.

10. The wards are to be separated by landings and attendants' rooms. It would be advantageous to have one ward to receive the convalescent inmates during the day, and at meal-time, so that the common convalescent ward would be cleared out in the middle of every day and purified.

11. The periodical and regular emptying of the wards, and their being left vacant for some months, have, in the French military hospitals and in those abroad, been attended with results indicating the necessity of the general adoption of this measure in time of an epidemic.

12. All arrangements are to be made so that any refuse or substance liable to create effluvia may be rapidly destroyed or removed, either from the interior of the wards or from their neighbourhood, so as not to cause any appreciable emanation on the premises.

LUNATIC ASYLUM, COUNTY DOWN.—Mr. Francis M'Gaughey, of Omagh, has been declared the contractor for the erection of this institution, at the sum of 43,174*l.* 1*s.* 1*d.* Mr. Wilkinson is the architect.

## ENGINEERING PRIZE.

M. PERRONNET, engineer-in-chief, president of the Society of Civil Engineers, Paris, has offered a prize medal of 2,000 francs for the best treatise furnishing the results of new experiments, undertaken by the competitors, in an engineering point of view, on one or more questions comprised in the following programme:—To determine by a great number of experiments the resistance of vehicles and locomotives to traction on a railway, taking into account all the circumstances which can modify them, such as, the state of the rails, vehicles, and engines; the force and direction of the wind; the surfaces of the carriages and the length of the trains; the dimensions of the axles and the wheels; the method of attaching the carriages; the distribution of the load and construction of the engines; friction of mechanism, coupling of wheels, escape of steam and draught of chimney, gradients, curves, &c.; to determine separately the influence due to each of these above circumstances. To analyze the causes which, in curves, modify the resistance, whether for an isolated vehicle or a series of carriages, and to guide the reasoning by experience. To find by experiment a practical formula for calculating the load that a locomotive of given form and dimensions can draw, taking into consideration adherence to the rails and other important conditions. To study the circumstances which modify the production of steam per square metre of heating surface, such as—the position of the sides in relation to the fire-box, the thickness of the plates, the interspacing of the tubes, &c. To determine the resistances opposed to the passage of the steam from the boiler to the valve-box, and from this into the cylinder; to determine the difference of the pressure of the steam in the boiler and in the cylinder in different conditions. To inquire into the effects of "priming" upon these differences of pressure; to examine the causes which influence the counter-pressure; to determine the influence of draught upon the dimensions of the exhaust pipe, and the pressure and velocity of the exit of steam and the dimensions of the chimney; to examine the resistance met with by the air in its passage from the fire-box to the chimney. These *mémoires* are to be written in the French language, and all the mensurs indicated are to correspond with the units of the metric system. The Society of Civil Engineers of Paris have adopted the above programme, which can be had on application to the secretary, No. 26, Rue Buffault, Paris.

## ARTESIAN WELL, PARIS.

THE interesting work of the boring of the artesian well at the Place Hébert (eighteenth arrondissement) continues actively, in spite of the enormous difficulties met with at almost every step. The first 72 ft. of the shaft are lined with masonry; then succeeds wrought-iron "tubbing," in sections 6 ft. 7 in. in diameter, and 3 ft. 3 in. high, forced in by screw pressure. When this lining had been carried down through thirty-six beds of different strata a zone of sand was reached, mingled with such a quantity of water that it was almost in a fluid state. This dangerous sand might have been traversed by driving the tubbing with extreme precaution, had it not been for another obstacle which preceded itself. It was found that the undercurrents of water had actually driven the tube out of the perpendicular. To obviate this was impossible, so that nothing remained to be done but to remedy the defect radically by taking up the tubes altogether, and continuing the masonry lining, which afforded a better guarantee of stability. The cylinders having been removed with enormous difficulty, it was plain that the masonry could not be continued on the ordinary conditions, and that a new method must be devised. This was done as follows: after several yards had been excavated below the existing masonry, and the sides properly shored up, a strong cradle of timber, exactly fitting the circumference of the well, was lowered and held suspended by stout chains to beams over the orifice of the well. This being done, the masonry was rapidly carried up from the cradle or platform as far as the existing lining, the chains being scaled up in the work. One section being thus terminated, another space was cleared away and another circular platform laid down, by other chains, and the masonry laid upon it. By this ingenious method, the *calcaire grossier* was at last reached, and a firm footing gained, though
