These congenital malformations of the large arterial trunks, are probably due to the persistence and enlargement of fetal vessels which normally become obliterated. From the aortic bulb of the embryonal heart, which is situated under the cephalic extremity, two vessels arch backward, one on either side of the foregut, forming the first pair of vascular arches, and descend along the sides of the notochord as the primitive aortae. As the heart is gradually moved away from the head, four more pairs of vessels are succes-

sively developed, which connect the bulb with the descending trunks; making in all, five pairs of vascular arches or one for each branchial plate. Zimmerman describes an additional pair between the fourth and fifth.

The bulb, primarily a single cavity from which, through two common trunks, one on each side, blood is sent to all the arches, is divided by a septum parallel to its long axis, into two compartments; one becoming the pulmonary artery, situated anteriorly, and continuous with the fifth pair of arches, the other forming the systemic aorta, placed posteriorly, and communicating with the fourth pair, through which all the arches above receive their blood supply. Notwithstanding this separation near the heart, both pairs of arches, *i. e.*, the fourth and fifth, ultimately empty into the descending aorta which has been formed by the coalescence of the primitive aortæ.

Vascular arches. [After Quain.]

This symmetrical arrangement of the vascular system is soon destroyed by the obliteration of certain vessels. Even before the last arch is perfectly formed the connections between the first pair and the descending aortæ may be destroyed. However, the fourth and fifth arches, lying nearest the heart and soon exceeding the others in size, are the chief factors in this transformation. The vascular arches on the left side continue to increase in size and in greater part become permanent, while those on the right gradually become obliterated, except where they furnish the supply to permanent arteries.

On the left side the fourth arch becomes the arch of the aorta and, in the fetus, is constricted between the origin of the left subclavian and the junction of the ductus arteriosus, forming the isthmus, which, soon after the closure of the duct, attains the diameter of the adjacent trunk. The fifth, on this side, forms a part of the left pulmonary artery and the ductus arteriosus, which is occluded soon after birth but remains as a round cord. On the right side the

fourth arch is permanent for a short distance as the innominate and right subclavian arteries, as far as the origin of the vertebral, beyond which it diminishes in size and finally disappears. Only a small portion of the fifth persists on this side as the root of the right pulmonary artery; the distal portion becomes obliterated.

In this case, the fourth arch of the right side has not only remained patulous throughout, but has exceeded the left in size. The fourth arch of the left side has retained some of its fetal characteristics; because it was doubtless unnecessary for the isthmus to enlarge after occlusion of the ductus arteriosus, as the blood current could readily pass through the right arch.

The position of the recurrent laryngeal nerves is due to the fact that they pass to the larynx from the vagi under the fifth pair of arches, while the heart is well forward, and, as this organ assumes its position in the chest, these nerves are drawn down by the vessels and, consequently, are eventually found, on each side, looping under the lowest permanent arch.

ACROMEGALY—WITH A CASE.

Read before the Georgia, Tennessee and Alabama Tri-State Medical Society at its Seventh Annual Meeting.

BY J. R. RATHMELL, A.M., M.D.

PROFESSOR OF OBSTETRICS AND DISEASES OF CHILDREN AND CLINICAL MEDICINE, CHATTANOOGA MEDICAL COLLEGE. CHATTANOOGA, TENN.

Dr. Paul Marie of Paris, in 1886, gave to the medical world a classic description of certain rare pathologic conditions and appearances to which, though noted possibly for many years, he gave the name *Acromegaly*, thus adding to medical nomenclature a new word. This word is a combination of two Greek words, meaning enlarged extremity. But the term is elastic enough to cover more territory than just what its root words signify, so that in general, *acromegaly* may be defined as a symmetrical enlargement of the extremities and face.

Reported cases studied to the present time apparently fix five facts, *viz.*, that hereditary influences cut no figure in causation; that the disease usually appears between 12 and 30 years of age; preponderates in males; that theorists are at sea as to the causes, and that all treatment up to date is unavailing.

To account for the simultaneous and abnormal growth of the supraorbital arches, the malar eminences thick nose and lips, the protruding chin, the enlarged bony arches of the jaws, the voluminous tongue, the big spade-like hands, with sausage shaped fingers, the feet showing same changes as the hands, and toes same as fingers; to show why, as the disease progresses, the strength diminishes; there is loss of precision in and coördination of movements; for failing sight, lassitude, apathy, slowness in movements, defective memory, amnesic aphasia and other symptoms I shall not now list, is the question. It was to ascertain the central causes of these conditions that led Marie, Klebs, Virchow, Friedrich and others to make their investigations. Several of the theories contemplated the involvement of one or more of the ductless glands and glandular structures. Klebs advanced the theory that the disease was due to the persistence of the thyroid—a ductless gland. Virchow maintained that the macroscopic appearances were simply the terminal stages of conditions whose early periods were not rec-

ognized. Marie's theory claimed the disease to be of neurotic origin, and dependent upon the involvement of the pituitary body—a ductless gland—as the essential feature. Others again theorized to disprove the existing theories by stating that the pituitary body had been found enlarged without the presence of acromegaly; also the entire absence of this body had been observed and no symptoms of the disease were present; that the thyroid gland, the spleen, thymus gland and suprarenal capsules have all been diseased and yet no acromegaly existed. Others again show a close relation between this disease and cretinism, myxedema, otitis deformans. So in view of this uncertain state of things we seem to be sure of three facts, as gathered from the literature on this subject, viz.: we have a disease, a name and a description.

While I shall not be able to add anything new in the way of discovering any predisposing or exciting causes and bring forth anything new in the pathology of this disease, yet I desire to add to the list of reported cases yet one other, which not only has many of the symptoms common to the cases already reported, but also some features that, so far as I have been able to ascertain, have not been mentioned.

On Dec. 17, 1894, there came into my office a man complaining of shortness of breath that at times distressed him so much he could scarcely live. He also stated that he was so extremely weak at times that he was compelled to sit down to keep from falling; also that he had great difficulty to keep his food and drink on his stomach. So soon as he would take nourishment, the stomach ejected it like a bullet from a gun. He was born in England, of English parents, and he gave his age as 52 years, height five feet eight inches, weight 165 pounds.

I observed that he was pale, in fact the skin was extremely white, with a purplish hue to the lips. The face large and broad; brow heavy; orbital arches prominent, due to dilatation of the frontal sinuses; cheek bones prominent, due to dilatation of the maxillary sinuses; nose large; lips thickened; jaw protruding; chin large; the junction of body of jaw with inferior maxillary formed an obtuse angle; tongue broad, thick, smooth, yet slightly fissured, filling the whole mouth, making it quite difficult to articulate distinctly. The neck was short, thick, letting the head well down between the shoulders. Spinal column slightly kyphotic in the cervico-dorsal region. The muscular system was well developed, having been an iron-worker as well as a farmer, but his extreme weakness greatly annoyed him. His feet and hands were cold all the time, he said, though he had them well protected. Fire even did not warm them. Examination of the lungs revealed them to be sound, but the heart showed hypertrophy and some dilatation, with an occasional loss of a beat. The cardiac symptoms led me to suspect something wrong with the valvular arrangement, though nothing could be definitely determined. Pulse was small and feeble. The hands were very large in all their dimensions. The fingers were thickened and nails broad. The hands looked like paddles. The feet, like the hands, had grown to an abnormal size. The toes, especially the big toes, had thickened and lengthened until they were odd-looking appendages.

About fourteen years previously, he noticed a change taking place in the size of his hands, feet and face. But progress was very slow. About eight years ago his attention was called to his vomiting his food occasionally, and also to the peculiar manner in which he

did it. He was not nauseated nor sick, but would suddenly empty his stomach. He thought this dyspepsia, as it was called, was produced by the water of a certain spring from which he was drinking. He noticed that the food and water would return unchanged in character. He was treated by the profession for dyspepsia, but without good results. For some time before coming to my office he said he had suffered occasionally from difficulty of breathing, which he could not explain. He did not think he suffered from asthma. He gave no history of syphilis, alcoholism, insanity or any hereditary disease.

After trying to meet the indication for treatment with the proper remedies, he went to his home three miles in the country. Early in January, I was called to see him at his home. He was spending his time about equally between lying in bed and sitting up in a rocking-chair before the fire. His loss of strength had increased; he could keep no nourishment or drinks on his stomach, and was having at intervals great distress from the peculiar character of breathing. He had lost rapidly since I saw him. He had a good appetite, was hungry and thirsty all the time, but the stomach refused to retain anything.

I wish to call your particular attention to this refusal of the stomach to retain nourishment, and also to the abnormal rhythm in the respiratory act. The vomiting I regarded as reflex, of cerebral origin. The peculiar spasmodic breathing was of the Cheyne-Stokes variety, which indicated a disturbance of the equilibrium of the respiratory act at the breathing center. The breathing was irregular day and night until three weeks before death, when he seemed to get some better in this respect. The pause between the respiratory movements lasted ordinarily a half minute, sometimes reaching a whole minute. To compensate for this cessation, the respiratory movements, at first feeble, increased rapidly until in the succeeding thirty seconds there would be eighteen respirations, when apnea would be overcome and another rest in breathing followed. This continued day and night incessantly, whether asleep or awake. Sometimes these storms of breathing were so terrific that upon two occasions the interval of rest was so long the friends thought him dead, but he rallied and breathed again. The severest attacks of spasmodic breathing occurred at night.

As to the physical symptoms—his dulness, apathy and inability to think and articulate—these continued to increase until the end, yet at no time was he totally unconscious. He had great difficulty in finding suitable words to express his idea. This form of amnesic aphasia is not uncommon in acromegaly.

Being unable to retain food in the stomach he was nourished wholly by the rectum. Thus he was kept alive, though the waste of the system was not counteracted, by enemas of milk, eggs, wines, etc., from January 5 to March 29 following, when he died. He was nourished by enemas about thirteen weeks. His body wasted rapidly during the last of the illness, so that the abnormally large bones were made more prominent thereby.

His death was by apnea. The end came during one of the spasms of abnormal respiration.

Assisted by Dr. W. C. Townes, postmortem examination was made six hours after death. The skin was exceedingly white, but the lips and finger nails were blue. Rigor mortis had begun but had reached only a slight degree.

The circumference of the head through the occipito-mental diameter measured $27\frac{1}{2}$ inches; from the angle of the face to the symphysis, $4\frac{3}{4}$ inches; circumference of hand around the palm, $10\frac{1}{4}$ inches; width of palm, $4\frac{1}{2}$ inches.

The costo-cartilages were completely calcified so that it was necessary to saw them in two in order to open the thorax. The lungs were sound with calcified points, size of a millet-seed on the surface. The heart was hypertrophied, but no evidence of valvular disease. There was no calcareous deposit in the endocardial region. The right ventricle was filled with blood; the left partially so. Heart stopped in diastole. Postmortem and antemortem clots had formed in both ventricles. No disease of the heart was discernible. The mucous membrane of the stomach was highly congested, and enlarged blood vessels roughened its surface. This condition is most likely accounted for by the long absence of food. A small upper portion of the ileum was filled with fecal matter of considerable consistence; the lower part was filled with gas. The large intestine was normal, except an occasional enlarged gland undergoing cheesy degeneration, probably antecedent to calcification. Appendix vermiformis was normal.

An indenture on the external surface of the calvarium, posterior to the coronal suture on right side, indicated that at some time the skull had received a blow from some blunt instrument. No history, however, of an injury having been received was obtained. The internal surface of the skull was roughened by a number—a dozen or more or less—of sharp-pointed spinous projections, varying from one-sixteenth to one-eighth of an inch in length, which pressed hard upon the dura mater.

The upper surface of the hemispheres of the brain was apparently normal. The base, however, showed an imperforate and knotted condition of the posterior cerebral artery on the left side. It looked like a string of beads. The remaining portion of the surface of the base was normal, except in the region of the sella turcica, where the pituitary body was greatly enlarged. This glandular structure had grown to the dimensions of a medium-sized hen's egg. The dura mater round and about it was calcified, and it was difficult to remove the body from its attachments. The average weight of this body is from 5 to 10 grains, but this one weighed, after having lain in alcohol six months, 476 grains.

The questions that naturally arise are: Did the growth of this gland cause the peculiar enlargement of the face, hands and feet? What caused the obstinate vomiting, and what produced the Cheyne-Stokes respiration?

SEPTIC DISEASES OF THE KNEE JOINT.

Read before the Wabasha County Medical Society.

HY C. H. MAYO, M.D.

SURGEON TO ST. MARY'S HOSPITAL,
ROCHESTER, MINN.

The great size and peculiar formation of the knee joint, with its many communicating bursæ, render its destruction probable by infection, and the loss of the limb, or life itself, is of comparative frequency.

A brief review of the more important of its anatomic features will explain why sepsis is so destructive.

The strength of this largest articulation of the body is in its powerful ligaments, which unite its opposing surfaces, articulating only by contact. The bony axis

of the limb changes at the knee, the femur slanting inward from above and the tibia being vertical. The lateral ligaments of the joint have the least strength. The posterior are strong and the capsule becomes ligamentous anteriorly. The most powerful and important ligaments of the joint are the crucial. The synovial membrane extends above the patella and beneath the extensor tendon, the cul-de-sac reaching a point one inch or more above the trochlear surface of the femur. Above the synovial sac is a bursa about one inch long separating the quadriceps tendon from the femur and communicating with the joint in four out of five cases. The upper third of the ligamentum patellæ is separated from the synovial sac by a pad of fat, the lower two-thirds are in relation to the bursa interposed between it and the tubercle of the tibia. In the popliteal space interposed between the internal condyle of the femur, the inner head of the gastrocnemius and the semimembranosus is another bursa usually communicating with the knee joint. The bursa beneath the popliteus tendon always connects with the joint and usually with the tibio-fibular articulation. The posterior part of the synovial sac has other bursal pouches in the adult. The epiphyseal line of the femur is intracapsular, showing the route of infection in the complicating joint abscess, occurring in some cases of periosteal and osteomyelitic diseases, and the source of effusion in fractures involving this region.

In a consideration of septic diseases of the knee joint we are only concerned in the more simple injuries causing synovitis, when auto-infection renders them septic. The entrance of blood into the joint is of the same significance, as a slight injury may occasion a hemorrhage, which never entirely coagulates, regardless of the quantity effused, but mixes with the synovia, and its absorption is extremely slow. These cases, through delay in absorption, or improper management, may develop the simple purulent synovitis.

Acute purulent synovitis occurs in young children, as a rule, in the first few weeks of life, and has been considered a probable umbilical infection. These cases discharge early and in most cases the joint function is not permanently impaired—as shown by Krause and Volkmann. In a case of doubt concerning the character of a joint effusion the hypodermic can be used for aspiration with the same freedom as it is now used on the chest to demonstrate fluids in the pleura. The withdrawal of a small quantity of serous effusion has the same effect as is so frequently noticed in the pleura, the stimulation of absorption. In the more simple purulent collections, a large caliber hypodermic needle can be used to withdraw the contents of the joint, and then distend it with a 1 to 1000 bichlorid solution. After a massage of the joint withdraw the bichlorid solution, repeating the process with normal salt solution.

Gonorrhæal synovitis, which has been shown by Councilman and Ott to be due to auto-infection by the gonococcus, may be treated in the same manner, after a thorough trial of large doses of potassium iodid has been made without relief.

Penetrating wounds of the knee joint, including incised, punctured, lacerated and gunshot injuries, are well classed among the most dangerous of bodily injuries not proving immediately fatal. Their gravity depends solely upon the introduction of septic matter into a serous cavity at the time of injury, or during its subsequent care.

The simpler forms of lacerated and punctured wounds are the most frequent, as distinguished from the complicated cases in which the injuries to adjacent structures may be of more serious consequence than the opening of the joint. Where the wound is small and the synovial sac not visible great care must be exercised in judging of joint penetration. The free flow of synovial fluid may only indicate the opening of a bursa, or large tendon sheath; the rapid distension of the joint with blood may also come from a contusion, without joint penetration.

In cases in which the nature of the injury would indicate a possible foreign body, septic origin or contamination, the probable diagnosis must be confirmed by exploration of the wound, under strict antiseptic precautions, when, should the synovial sac be found opened, the interior of the joint should be thoroughly flushed with a 1 to 1000 bichlorid solution and drainage established, preferably by means of folded rubber tissue, and a copious dressing applied. In cases of joint injury where we can be reasonably certain of an aseptic wound, an antiseptic dressing may be applied, with rest of joint, awaiting the development of symptoms before further interference.

Should infection occur during treatment, the incision should be enlarged, antiseptic irrigation applied and freer drainage established. Synovia may flow for several days, and unless infection supervene, a perfect recovery results. In those cases in which infection occurs the result obtained will depend upon several factors, viz.: The nature and degree of infection, the freedom of drainage and the treatment applied. Infection produced by the less virulent pus-producing germs may not be clinically demonstrable for from two to seven days. The turbid effusion filled with flakes of lymph will then indicate vascularization of the synovial sac. The joint becomes red, swollen, painful and tender; a chill more or less severe indicates the commencement of infection.

Systemic toxemia is evidenced by a fever, which continues as long as the joint is distended with pus. In the less virulent infection, if a free drainage is secured, the joint structures may be maintained and a fair degree of joint function preserved, even after several weeks of discharge. Insufficient drainage, or a more virulent form of infection, may rapidly so disintegrate the joint structures that a functional result is impossible. The ligaments become softened, the cartilages necrosed and separated, the synovial membrane thickened and the extension of the purulent process into adjacent bursæ and tendon sheaths develops abscesses in the thigh and posterior tibial regions. The limb is enormously swollen and the general septic condition is very marked. Life may be saved and recovery hastened by an early amputation, otherwise death may ensue from toxemia, or after months of discharge life and limb may be saved, with a functionless joint.

In the case of streptococcus infection, the course is more rapid and death frequently occurs early, from phlebitis, gangrene or septicemia. In mild or mixed infections secondary to chronic joint disease it is possible to have a walling off of the abscess in a portion of the synovial pouch, as mentioned by Andrews, similar to like conditions in the peritoneum or pleura. Gunshot wounds of this joint require the same care as the lacerated and punctured wounds. Injuries by large missiles require exploration, and in case of serious

bone injury a partial arthrectomy may be necessary, while those made by small caliber bullets may be treated as doubtful cases until interference is demanded by the symptoms developed.

Bullets are usually sterile, but there is always danger from the particles of clothing carried in by them. In gunshot wounds of this joint, unless serious hemorrhage occur requiring control, the first consideration is the application of an antiseptic dressing. Dividing the knee-joint cavity into spaces and treating suppuration by drainage with four to six drainage tubes, as recommended by Andrews and Gerster, suffice for some cases, and may be supplemented by a tube drain through the popliteal space, as practiced by Hartley. Edmond Owen recommends the vertical incision on either side of the patella, and in some cases to connect the two incisions by cutting the patella ligament.

Frederic S. Dennis and Roswell Park report cases successfully treated by continuous irrigation or immersions in weak antiseptic fluids. The one essential feature in the treatment of the more serious forms of phlegmonous inflammation of the joint is free drainage. The transverse incision from prominence to prominence of the condyles across the front of the joint, as made for resection, presents the freer exposure for dry gauze pack of all parts of the joint, or the use of the gauze pack saturated with a solution of 5 per cent. balsam Peru in castor oil, so successfully employed by W. W. Van Arsdale in the treatment of suppurating wounds. This incision will accomplish all that an amputation can promise, with less shock and with the saving of a useful limb, and in many cases a limited degree of motion.

In three cases in which the patella was severed through its center, the two halves afforded a firm hold for passing sutures behind and closing the joint at a later period.

In the January, 1895, issue of the *Annals of Surgery*, is reported my first case treated in this manner and the successful treatment of four similar cases in the past two years, leads me to emphasize my former statements. Two of these cases have one-fourth motion. In the *Annals of Surgery*, Vol. XXII, page 503, in report of transactions of the New York Surgical Section, is the following from Dr. Arpad Gerster, which so perfectly describes the treatment, I present part of it here: "Dr. Mayo's suggestion struck him as very plausible, and he has applied it in two cases. The result had been excellent. As all know, these acute forms of joint phlegmon necessarily end in ankylosis, if, indeed, they do not cause loss of limb or life. The cartilaginous covering of the bones forming the joint is destroyed, and therefore ankylosis is inevitable. Knowing this fact, the surgeon in adopting this method of treatment frankly accepts the necessity for ankylosis. The road then becomes very clear. The treatment consists in laying the joint open by a transverse incision, extending from one condyle to the other, just as a joint is laid open for resection. Then as many more incisions are made as may be necessary, in order to open up every collection of pus or fluid in or about the joint. The capsule in all these cases is very intuuescent and swollen, and for this reason occludes all drainage tubes in a way to make retention inevitable. Then lay the joint freely open, removing or not removing tissues, as the case may be, pack and drain every recess, and treat it as an open wound. It is astonishing how rapidly the phleg-

monous process ceases, when compared with other methods of treatment. After the symptoms of active inflammation have subsided, the joint is put in proper position and ankylosis is allowed to take place."

THE IMPORTANCE OF SYSTEMATIC EXAMINATIONS OF UTERINE SCRAPINGS AND EXCISED PORTIONS OF THE CERVIX.

BY PALMER FINDLEY, M.D.

CLINICAL INSTRUCTOR OF GYNECOLOGY, NORTHWESTERN UNIVERSITY
MEDICAL SCHOOL.
CHICAGO.

This paper has for its object: 1, the emphasis of the importance of systematic examinations of uterine scrapings and excised portions as an aid to diagnosis in gynecology; 2, the presentation of a well known method of making such examinations; 3, the setting forth of its limitations; 4, the relation of the microscopic to the macroscopic appearances; 5, the relation of the microscopic findings to the clinical manifestations.

It will be the purpose of the writer to demonstrate that such systematic examinations can be made by all who have a practical knowledge of microscopy; that without such systematic examinations a malignant growth will often escape detection until clinical manifestations point to a growth too far advanced to permit of a radical removal, and that many times such an examination is the only means of making a positive early diagnosis. It is the custom of the writer to preserve for examination all products of curettage, to make a systematic microscopic examination of them, which is kept on record, and to which subsequent reference can be made. All who have followed this routine method can not fail to appreciate the importance of such examinations. Where a malignant growth has not been suspected it has been detected in its early development; on the other hand, a condition highly suspicious of malignancy has been proven innocent. In the majority of cases the microscope has only served to verify the clinical diagnosis. Not infrequently has a timely hysterectomy been performed as a direct result of the microscopic findings, and, on the contrary, where the clinical symptoms strongly indicated a hysterectomy for a malignant growth the microscopic examination contraindicated and precluded the radical and formidable operation. It is therefore evident that the greater part of the examinations will no more than verify the clinical diagnosis, yet the occasional finding of an unsuspected malignant condition, the verification of a suspicion and the disqualification of a wrong clinical diagnosis will be sufficient reward for the time and labor expended. The practice of making these examinations is becoming more general. The busy surgeon usually trusts the work to an assistant pathologist or colleague, and in most hospitals such examinations are made as a matter of routine by the resident pathologist.

The following method adopted by the writer will be presented in the belief that it will be found to be the most reliable and simple method for diagnostic purposes; it is the simple method of practical utility to the general surgeon. Where original research in the histologic and microchemic methods is desired the reader is referred to modern works on microscopy.

Because of the difficulty in obtaining sections of the mucous membrane of the corpus uteri the tissues

are best obtained by curettage; while with the cervix the mucous membrane is so closely adherent to the underlying tissues and the desired tissue is so easily excised it is preferable to remove a wedge-shaped piece of the cervix for an examination. The section should include some healthy tissue, in order to make a microscopic field of the entire pathologic condition together with some healthy tissue. Scrapings are never so satisfactory for examination as are excised pieces; the relations of the histologic elements are disturbed, the extent of the lesion can never be ascertained, and though the scrapings may show only inflammatory changes the underlying tissue may be the seat of a malignant growth.

CELLOIDIN EMBEDDING METHOD.

The scrapings and excised pieces are first cleansed of blood in cold water. They are then placed in a 4 per cent. aqueous solution formalin for twelve hours, then in 50 per cent. alcohol for twenty-four hours, next in 70 per cent. alcohol for twenty-four hours, followed by 95 per cent. alcohol for twenty-four hours, and finally hardened in absolute alcohol for twenty-four hours. The specimen may be placed directly in 50 per cent. alcohol without fixing in formalin, and if the sections are small they may be placed directly in 95 per cent. alcohol for twenty-four to forty-eight hours and then in absolute alcohol for twenty-four to forty-eight hours. After the tissue is thoroughly hardened in the alcohol solutions they are placed in a dilute solution of celloidin for twenty-four hours. If the solution is quite dilute it is not necessary to precede this step by placing them in a solution of equal parts of commercial ether and absolute alcohol for twelve to twenty-four hours, thus saving time. The next step is to place them in a thick solution of celloidin for twelve hours, then mount on cork or a block of wood in celloidin, expose the mounted specimen to the open air for a few minutes, then place in 70 per cent. alcohol for a few hours and the specimen is ready for section cutting. The most satisfactory stain is the double stain of hematoxylin and eosin. In this way about eight days are required, but the actual time spent in the work is not so great providing all necessary material is at hand. Where time is an essential factor the paraffin method may be adopted and the specimen ready in forty-eight to seventy-two hours. For serial sections the paraffin method may be used, but for ordinary usage the serious objection to its use is the necessity of an oven for the purpose of keeping the paraffin at the proper temperature. Dr. Cullen of Johns Hopkins University has presented to the profession a freezing method by which the examination can be made in fifty to sixty minutes.¹

The steps in the method are, in brief: 1, tissues cut with a freezing microtome; 2, sections fixed in a 4 per cent. formalin solution, three to five minutes; 3, 50 per cent. alcohol, three minutes; 4, absolute alcohol for one minute; 5, stain and mount. By this method it is possible in a doubtful case to determine upon further operative procedures within an hour after the exploratory curettage, and hence is of the greatest value in those exceptional cases where an immediate diagnosis is imperative, otherwise it is not satisfactory because of the hasty and imperfect preparation of the section for microscopic examination.

By way of illustrating the importance of such examinations the writer will briefly mention his

¹ For a full description of the method see Johns Hopkins Bulletin, No. 49, April, 1895.

experience of the past two months in the examination of scrapings. In all cases clinically diagnosed as chronic endometritis the microscopic examination of the scrapings verified the diagnosis. Where the diagnosis was in doubt from a clinical point of view the microscope was indispensable. The following cases occurred in the practice of Dr. E. C. Dudley of Chicago, they have been reported in detail and will here only be referred to in brief for the purpose of illustrating the value of systematic examinations of uterine scrapings in diagnosis:²

Case 1.—Was deaf, hence no history could be obtained further than that she is 40 years of age, had menstruated regularly until the last two months, during which time she has flowed almost constantly. For two weeks the flow has been increased in amount and has had an offensive odor. The patient denied the possibility of pregnancy. Dr. Dudley examined the uterus under ether and found it free of adhesions, regular in outline and about the size of a fetal head at term and of the consistency of a pregnant uterus. From the physical examination Dr. Dudley believed it to be a pregnant uterus, but decided to explore the uterine cavity because of the negative history of pregnancy and the offensive bloody discharge. Accordingly a curette was introduced, the instrument went to the handle, an incident which for the time suggested the possibility of having penetrated the uterine wall. An offensive sloughing mass was withdrawn by the curette. From the naked-eye appearances this mass was thought to be either placental tissue, sloughing fibroid or a malignant growth.

The scrapings were examined by Dr. Eisendrath, pathologist of St. Luke's Hospital, by whom chorionic villi were demonstrated. Three days later the woman was delivered of a sloughing fetal mass which bore evidence of having lain dead in the uterine cavity several weeks. In this case the history was entirely misleading and the symptoms and local condition indicated operative interference. The microscopic examination was made in a few minutes, the specimens were neither hardened nor stained. Simply a thin section of the scrapings was made with a razor and examined under a low magnifying power.

Case 2.—Mrs. B., age 45, American. Attending physician, Franklin B. Favill of Chicago. The clinical history was that of a chronic endometritis together with some loss of flesh, nausea, loss of appetite, menorrhagia which had existed for two years and in the past two months was followed by an odorless watery discharge. Dr. E. C. Dudley performed an exploratory curettage October, 1896. Profuse vegetations were removed by the sharp curette. On examination of the scrapings I found adeno-carcinoma of the corpus uteri in its early development. The diagnosis was confirmed by Dr. Arthur Edwards of Chicago and afterward by examination of the sections of the uterus. Dr. Dudley, assisted by the attending physician, Dr. Favill, Dr. William H. Rumph and the writer, removed the uterus per vagina two weeks later. Since the exploratory curettage the uterine growth was seen to have almost filled the uterine cavity and to the naked eye appeared as a soft, red villous growth confined to the endometrium. Sections of the uterine wall including the growth were examined, and the atypical glandular growth demonstrated to have extended into the underlying tissue to a considerable depth. It is hoped that a radical removal of the growth is effected. This case would undoubtedly have passed for a chronic endometritis had no microscopic examination been made.

Case 3.—Mrs. H., age 46; was undoubtedly approaching the menopause, the menses had become more and more infrequent and scant. Six months ago she began to flow profusely and frequently and six weeks later the menorrhagia was followed by a watery discharge, which had a disagreeable odor. An exploratory curettage was made by Dr. Dudley, in which he removed a submucous polypus from the corpus uteri. Upon examination of the scrapings I was able to demonstrate the presence of a round-cell sarcoma of the corpus. The round cells were mixed with a lesser number of spindle cells and a few giant cells. Notwithstanding the fact that the patient had marked symptoms of uremia from a chronic nephritis which had existed for an unknown period prior to the exploratory curettage, the urine containing a large amount of albumin,

granular casts, blood in great quantities and 200 grains of urea secreted in twenty-four hours; a vaginal hysterectomy was performed by Dr. Dudley, assisted by Dr. Franklin Favill, Dr. Peterson and the writer. Chloroform was given and the patient came out of the operation in fairly good condition. Following the operation the uremic conditions were deepened, but gradually became less marked until the fourth week after the hysterectomy, when there ensued lobar pneumonia, with suppression of urine. At the present writing the kidneys are secreting 200 grains of urea in twenty-four hours and the patient is gradually recovering from the lobar pneumonia. Examination of the extirpated uterus demonstrated a submucous polypus which had undergone sarcomatous degeneration at the base. In addition there was a double pyosalpinx and pelvic abscess, from which a culture of streptococci was made. Microscopic examination of sections of the uterine wall including the growth established the diagnosis of round-cell sarcoma, which had not penetrated far into the uterine wall.

These three cases, briefly recorded, illustrate the importance of systematic examinations of the uterine scrapings as a means of diagnosis in gynecology.

1617 Indiana Avenue.

THE ABDOMINAL TYPE OF RESPIRATION AS OFTEN EMPLOYED IN SINGING.

BY O. J. STEIN, M.D.

INSTRUCTOR IN RHINOLOGY AND LARYNGOLOGY, NORTHWESTERN
UNIVERSITY MEDICAL SCHOOL,
CHICAGO.

My attention was directed to this subject by observing that among a certain class of singers who practiced the abdominal type of breathing, there existed a marked disproportion in development of the chest and abdomen. Not alone this, but in seeking for a causative factor for some deranged conditions of the generative organs my investigations brought me to the abnormal employment of abdominal respiration as used in their singing. As soon as I became cognizant of the fact that the over-indulgence in this form of breathing was to blame for the trouble in hand, I readily saw the irreparable amount of damage that may come to these organs of generation by following such a method; and I thereafter made it a special point of observation and inquiry in all cases of this character to observe the type of respiration employed and to inquire as to the method taught them in their singing. In one case I was told the singing teacher laid particular stress upon the forcible employment of the abdominal muscles in the expiratory act. This was done, he explains, to add force to the act and hence volume and power to the voice. And thus regardless of all consequences, ignoring one of the important elements of physics—that no two things can occupy the same space at the same time—he tells his pupils to force down these powerful abdominal muscles, displacing the contents of the abdomen, so as to press up on the diaphragm and thus add force to the act of expiration. Apparently there is but one object in view and that is to add strength and power to this expulsive act of respiration. But in selecting the abdominal type the teacher disregards all laws of physics, physiology and health, and as a result of exercising these muscles for the purpose indicated we are so liable to see, and in many cases where we do not see, they really exist unknown to us, the want of symmetry and proper development of the chest, the over-developed and protruding abdomen, and the train of symptoms resultant from a constant and forcible displacement of the contents of the abdomen. Like any other muscle or group of muscles under persistent exercise, there is bound to result a highly developed state of its fibers, and as a consequence we often

² While this paper was under preparation, the writer received the very instructive and interesting article on "The Importance of Systematic Microscopic Examinations of Uterine Scrapings and of Excised Pieces as an Aid to Diagnosis," by Hunter Robb, M.D., of Cleveland, Ohio, reported in the American Journal of Medical Sciences. This report is based on Records of 100 cases, and strongly emphasizes the importance of such examinations.

find in these cases a very perceptible protrusion of the abdomen; and in one case that I had under observation, the muscles were so developed that in placing my hands in the attitude of palpation upon them they felt like bands of iron, so firm and strong and contracting were they. It is then only too apparent with such powerful muscles acting synchronously, pressing down through their contractive action upon the underlying organs, that everything is displaced to a more or less extent, and that this constant displacement, and often too under great force, by its pushing and crowding, drags upon and stretches the natural lines of moorage that anchor the different organs in their proper and respective places. And hence on account of the peculiar position, suspended as they are in the very center of the pelvis, the generative organs are more easily and disastrously displaced. Like its sister evil, the tight corset and girdle constrictions, many of these generative disturbances may

and cramming the much suffering stomach to adapt itself within a space not any too roomy for a chicken's gizzard.

In pursuing my investigation upon the lines of inquiry, I learn from most all of the singers interviewed that there exists a manifested degree of abhorrence to the prominence of motion assumed by the shoulders and bosom in the normal and physiological mode of breathing and hence I have been led to believe that the employment of "abdominal respiration," upon the principle that strength and force is added to the voice production, has been used more as a guise under which to parade a fad or a new method. That the natural type of breathing among women is the costal is an admitted physiologic fact and scarcely needs any substantiation in connection with this article. A reason for this form of breathing in the female sex may find an explanation in an anatomic condition, namely, the existence of the uterus and its suspended position allowing and providing for its

Fig. 1.—Appearance as a result of abdominal breathing.

Fig. 2.—Same as figure 1, but to a less degree.

be attributed and directly traced to these displacing forces. Only in the factor under consideration I consider the evil a still greater one, in that by the alternating contracting and relaxing action of the muscles, there necessarily results an unstable position of location in the organs much at variance with the more natural and healthy conditions, which reciprocal successions putting the ligaments now taut, now slack, ends in such a stretched and useless condition that malposition is the only inevitable result. I am directing my remarks now more toward the uterus and its appendages, but what is true of these organs is also, but probably to a much less degree, true of other organs in the abdomen; and particularly here I may mention the stomach. Now just imagine in what an embarrassed position this so often abused organ is placed when the singer with her herculean-like belly muscles causes them to forcibly contract, pressing in upon all that lies underneath causing a general scattering, as it were, of everything within and crowding

Fig. 3.—Appearance as a result of costal breathing.

child-bearing function. It has been claimed by some that the costal type of respiration in the female depends upon the constriction of the chest by corsets or other causes (Landois and Stirling, Text Book Human Physiology), but this again seems refuted by others maintaining that this type is quite distinct and characteristic, even in sleep when all constrictions are removed. Then, too, there exists in women a greater flexibility of the ribs, allowing the muscles of the chest to act more efficiently upon the ribs (Landois and Stirling, Text Book Human Physiology). In my mind the whole subject hinges upon the recognition that respiration consists of but one active movement and that is the inspiratory one. The act is a muscular one under the influence of the central nervous system. The muscles involved are the diaphragm, the two sets of elevators (levatores costarum longi et brevis), the saw-tooth muscles of the back (serratus posticus superior) and the intercostal (intercostales external, et intercartilag.) The stimu-

lus coming from the center of respiration in the medulla oblongata causes the muscles in question to contract. The diaphragm through its nerve, the phrenic, contracts and consequently on account of its dome shape descends, causing an increase in the vertical diameter of the chest. The levatores through their branches of the dorsal nerves, and the serratus through the cervical nerves, likewise contract and arising as they do from the spine as their fixed point and passing obliquely downward and forward to the ribs, they necessarily raise the ribs, which movement is of a rotary as well as elevatory nature. Thus the lateral and antero-posterior diameters of the chest are increased. In short, the chest is an air chamber; the muscles attached to its walls are endowed with the power of enlarging the cavity of the thorax so as to draw air through the windpipe into the lungs, which therefore become inflated. The lungs have not in themselves any ability to increase their capacity, but are merely blown out by force of the air which rushes into them according as the chest expands in order to prevent the formation of a vacuum (Holmes' Voice Physiology).

Now presuming we have in object an exaggerated form of inspiration as employed in singing, we set the accessory muscles of inspiration in operation. And these are the muscles of the hyoid bone, the sternum, upper ribs, collar bone and a few less important ones of the chest.

Now comes the second part of the respiratory act, which is non-muscular and hence purely passive. The cavity of the chest is diminished simply by the weight of the chest wall. It is the elastic recoil of the chest and lungs, which diminishes the cavity and by the relaxation of the diaphragm, which again resuming its dome-like shape presses up and against the lungs. But as in the exaggerated inspiration we have accessory muscles of expiration, in which the chest is squeezed, so to speak, by an extra effort. This extra effort lies in the muscles that depress the ribs, like the internal costals, the triangularis sterni, serratus posticus inferior and quadratus lumborum, and also by contraction of the abdominal muscles, which retaliate upon the diaphragm which had by its contraction and consequent descent pressed out the belly muscles. It is this fact that the abdominal muscles, being accessories to the expiratory act, are so often taken advantage of, and on account of the ready control one has over them and the power they contain, that their use is so shamefully abused. The mere fact of these muscles being accessories does not admit of their forcible use and hence abuse. One might say then that the levator ani should be forcibly used, for it is also an accessory muscle of expiration.

In following the drift of argument that I have I do not wish to be interpreted in advocating so called clavicular breathing, a form of breathing accredited to many singers, wherein the shoulders are prominently elevated. It is a very pernicious habit of respiration and should always be discouraged. The very first point of counter argument heard from singers and teachers when confronted with the evil effects following the employment of the abdominal type of respiration is the ill appearance presented by one using clavicular respiration; thus at the very outset disregarding the great difference between costal breathing and shoulder breathing. In fact, elevating the shoulders has but little influence in dilating the chest, as they raise the ribs only to a comparatively

small extent, because their power is mostly exerted over the upper ribs which have little freedom of motion and hence the effort is greater than the result warrants.

CHAPTER III.—AT THE UNIVERSITY.

Academical training; The German student; Rough students' life; Göttingen Woodmen union (Hainbund); The student in war; Number of those who study medicine; Lectures, Latin language, dictation; Gatherings, libraries; Professors, their rank and income; Misdemeanor of the doctor-graduation, dissertation factories, our time; State examinations; Ceremonies, religious confusion at the graduation; Women doctors; Study of anatomy, public prejudice; Anatomical theater, scarcity of cadavers; Pathologic and surgical anatomy.

"Young people positively must learn Latin; I insist upon it. Moreover it must be reduced to the easiest and best rules for teaching it to young people. Whether they become merchants or turn to something else, it is always useful and the time will come when they will find it so." So ran a cabinet order of Frederick the Great, although this monarch knew Roman and Greek authors almost wholly through French translations. Latin was the soul of the *Gymnasia*, but the instruction in many of them was very poor and to little purpose. Monks, for the most part rude, ignorant and superstitious, did the teaching in the Catholic countries. In the Palatinate schools the Catechism of Kanisius was taught as the basis of religious instruction, and Latin from Alvari's Rudiments, and a few abridged authors. For history there was a text book, which related, on one page in the most absurd Latin, on the other in dreadful German, events according to the Jesuit point of view, with a multitude of fables. The monks early inculcated in the boys a hatred of heresy and innovation. The Lutheran and Reformed schools were even worse, since the lazy teachers there did not even understand Latin. Many gymnasia cultivated mathematics to the neglect of history, geography, physics and languages, and taught only a miserable monk's Latin. With this meagre instruction many young people went to the universities without the requisite preparation. A searching reform became necessary. Gessner brought in new life when he ingrafted the Greek language in the schools, and advanced the new principle, enthusiastically received, that not the stuff of the grammars but the spirit of antiquity is the essential thing. In general people were inclined to send boys to school as early as possible and they often finished the course at the age of 14. They then pursued philosophical studies, began medicine at 16, and finished at 19 or 20. A. von Haller became a student at 15, Mauchard at 16. Schlözer met at the Catholic universities boys of 16 who heard lectures on Institutes and Pandects, spoke Latin and were well versed in philosophy and mathematics. Schlözer's daughter Dorothea, at the instance of her father, was, in her eighteenth year, examined by the Philosophical Faculty in Göttingen and was made Doctor of Philosophy. Still there were always a large number of students of medicine who did not begin to study at a university

be ore 18 or 20. A few did considerable preliminary studying before they turned to medicine. It is known of G. G. Richter that aside from his favorite study, Oriental languages, he attended the philosophical and philological lectures for a long time, and it was only after he had obtained his degree of Master of Philosophy that he began the study of medicine. Likewise A. von Haller went to Basel for over a year especially for the study of mathematics.

We are captivated by the picture of the *German student*. At the beginning of the eighteenth century he wore a three-cornered hat over long curled hair, a broad-breasted coat lavishly decorated with embroidery and buttons the size of a dollar and slashed to the elbows, black knee breeches, black stockings and buckled shoes, with a parade sword hanging at his side. The life and activity of the students were still sunk deep in the barbarity of the foregoing century. Any high devotion to science was almost wholly lacking in universities whose chairs were given to spiritless pedants and ignoramuses. No wonder then, in view of the laxity and weakness of the administration, that the beastly drinking bouts, fighting, duelling, harrying of townsmen and ribaldry were the order of the day. The student songs of that day were coarse and insipid and teemed with unredeemed vulgarity. With the most extravagant wantonness, rioting and gambling, there prevailed the darkest superstition among the students. We find the same crudity in the second half of the century in the so-called seats of learning (Musensitzen). Frederick Lankhardt, in his autobiography (1792-97) gives the following picture: "The tone of the students or Bursche at Giessen was quite like that at Jena, and this indeed because of the many expelled Jena students who came to Giessen. Whoever wished to be a good fellow went, at least in the evening, to one of the many beer kneipes—the Rhenish Maass of beer cost two kreutzers—drank till 10 or 11 o'clock and then moved on. It was considered pedantic to speak of literary subjects, so student affairs were discussed and generally indecent stories were related. I know very well that in Eberhardt's student kneipe, lecture on obscenities (Zotologie) were regularly held and there was a compendium on the subject in manuscript. Drinking bouts were permitted in Giessen, and we have held drinking bouts (kommersirt) four times on the street. Most of the students walked like swine. A jacket (Flausch) was a part of a student's dress Sundays and week days. He wore with it leather breeches and long riding boots. Fighting was very frequent and they fought in the public streets. The challenger went to the window of his adversary, rapped a few times on the wall with his sword and cried: "Pereat N. N., the puppy, the hog!" Then the challenged party appeared, the fight proceeded and at last the beadle came and stopped the disturbance, the brawlers went to prison and so the sport came to an end. Among the gross vulgarities which were the fashion at Giessen were the Generalstallung (the general's stabling) and the Wüste Gesicht (bad face). The former consisted of twenty or thirty students filling themselves completely with beer and going before some house where women lived, when, at a regular command, with a neigh such as horses give, made some indecent display. The Wüste Gesicht was a mask of horrible appearance, which was fastened to a bundle of rags on a long pole. With this mask the students went in the evening to a house where the people lived in the second story, and rang. When some one

came to the window to ask who was there, they held up to him the ugly face, and the good people were frightened to death. The feverish desire to scribble full great notebooks did not bother the Giessen students. In every university I have found lusty scribblers, but never more than in Halle, where the students filled many quarto volumes with academic college wisdom. In other respects the tone of the Hallensers was very rude. In Jena every student had his so-called charmante, a common wench with whom he went about, so long as he was there, and whom at his departure he forsook for another. In Göttingen, on the contrary, the student sought entrance to the house of a gentleman and paid his court there. In general it stopped with courting and it had no further consequences than to empty the purse of the gallant. But many times things went much further and there followed living witnesses of an intimacy which just as often ensnared a knight's daughter as a pretty, buxom serving-maid." Letters about Jena (1793) relate that even in the seventies there was dueling in the market place on clear days. The Jenenser wore an overcoat, a jacket, leather breeches and a great laced hat. He possessed the extraordinary ability to pour down his throat a half a cask of beer; everyone who came near him he struck behind the ear and stood ready to settle the case upon the spot. His ideal of perfection was a consummate fighter, and the lowest creature a man, who had no desire to riot every moment in the night and devote himself to dressing with a certain delicacy and elegance. The docents often vied with the students. The academic secret societies were in full bloom in the middle of the century. Growing out of the propensity of that time to form secret societies, the Moselbund, one of the oldest in Jena, was founded in 1746. Brawls between the different orders were not long in coming and led in Giessen in 1777 to bloody riots. Peter Frank is quite beside himself over the uncurbed excesses of the students, the wildness of whose life surpasses that of the lowest rabble. If in general the medical students participated less in these things, because of lack of money, yet they indulged in nonsense enough. The mania for dueling prevailed everywhere to such an extent that this professor (Frank) remarked that "yearly thousands (?) perished in this most disgraceful way. From early morning till late at night there was no end to the fighting and swaggering. All the Landsmann and other riotous societies owed their existence to the fencing-room. Whoever went to the university, on the very first day fell among these murderous bands, who thought it disgraceful to let a week pass without bloodshed." One exception to all this was the new University of Göttingen, where they had no Middle Age traditions and would not recognize the absurdities of student usage. A number of students lived there who formed the so-called Hainbund (Woodmen), in sharpest contrast to the above described rude student life, as the well-known letter of Voss to a friend described it: "Ah, you should have been here the 12th of September (1772). The two Müllers, Hahn, Hölty and I went in the evening to a neighboring village. The evening was clear and the moon bright. We gave ourselves up entirely to the contemplation of beautiful nature. We drank milk in a peasant's hut and then betook ourselves to the open field. Here we found a little clump of oaks and immediately it occurred to all of us to take the oath of friendship under those holy trees. We wreathed our hats with

oak-leaves, laid them under the tree, seized each other by the hands and danced around the encircled oak tree and called the moon and the stars to witness our bond and promised each other eternal friendship, etc." The Hainbund founded the Göttingen Musenalmanach, but was scattered when the bonds of association were broken.

From 1780 the academic conditions improved. The entrance of Karl August and Goethe at Jena had an influence for earnest scientific work and limited the barbarities. It was an event for the city when Schiller delivered his inaugural address as professor in May 1789, and he was given a serenade by the students, with loud *vivats*. The theater began to fascinate them and sometimes to throw them into real paroxysms of enthusiasm. Iffland reigned supreme. Once in Lauchstädt, when the curtain fell at the end of the play, one of the wildest students of Halle dashed up to another Hallenser, whom he scarcely knew, and with streaming tears swore he would never again touch a card. Poor students saved for a week in order to visit the theater in Lauchstädt once; then they ran back to Halle in the night, that they might be at the college the next morning. The student life became less rude when its administration instituted a stricter police supervision and more sharply opposed the misuse of arms. No Prussian students, except the nobles, were allowed to wear swords. And in Göttingen, where in 1763 the student was obliged to part with his favorite animal, the bulldog, and the university gave stipends to a number of hunters instead of the soldiers in order to keep peace, neither teacher nor student carried a weapon. There the surgeons were bound upon oath to report to the authorities the wounds of students as soon as they were bandaged. The students at Pavia and Padua wore swords when visiting as late as 1787. The Chancellor Boco took the swords from the English students and the French surrendered theirs to the rector.

With the war for independence came a new impulse into academic life. In 1813 lectures were suspended in Berlin, Breslau and Königsberg and almost all the students departed from Jena, Göttingen and Halle to Breslau. From Halle they went stealthily, in little groups, for the University was still under Westphalian jurisdiction. In Breslau they voluntarily entered the rank and file to defend the Fatherland. And in the gymnasia the oldest and stoniest pupils donned the uniform and became the pride of their classes, envied by the younger boys. In the bloody battles for German freedom the student learned a better use for arms than to whet them on "stupid boys," heavy with drunkenness, in the beer rooms at home. After peace was declared, when the lecture rooms were filled again, the academic life was carried along with the great movement of the time. In Berlin there arose, as a new form of the old secret orders, the "Burschenschaft," and in Jena, then the center of the German universities, another such society was solemnly founded in 1815. The idea of sometime serving the Fatherland with honor has contributed not unworthily to curb the wild life of the universities. When in our day *la grande nation*, which is always marching at the front of civilization, loosened against us her *Turcos* and *Gums* in this great struggle to be or not to be, the German students were under arms. Two thousand seven hundred and forty-five grasped their swords in the summer of 1870, and 914

served as hospital attendants; 248 of them met their death. Further, 15 university teachers went to battle and 253 consecrated themselves to the service of the wounded; of these 4 fell.

Germany was rich in universities and in 1792 possessed over forty. Many of these have decayed with time; among others, Altdorf, Bamberg, Erfurt, Frankfurt-on-the-Oder, Helmstadt, Ingelstadt, Mainz, Rinteln, Wittenberg. Concerning the *number of medical students*, Göttingen, where the majority always gathered, had in the years 1767-78 an average of 50 to 80 medical students, in the following ten years between 80 and 100, among 600 to 900 students. The thousand mark was reached there for the first time in 1816, when among 1,005 students 206 were in medicine; in 1866 there were 189 to 769. In Jena in 1768 there were 17 medical students; in 1773, 42; in 1785, 73; in 1792, 162; in 1866, 65. Marburg in 1793 had 56; in 1866, 32. In Vienna in 1723 25 studied medicine. This extraordinarily small number was in part due to the great number of prescribed holidays, which kept many young men from the Catholic universities. In 1795 there were only 24 students practicing in the Vienna clinics, where there were 300 but a few years later. Many German universities could not compete with those in foreign countries. In 1772, 364 students attended the medical lectures in Edinburgh; in 1787 there were 400; in Pavia in 1782 among 2,000 students 200 were in the medical department.¹

The study of medicine was free. Every young man, whether he had an education or not, if he came from the apothecary or the barber shop, could, if he had means enough, attend the medical colleges. It was considered desirable for those studying medicine to understand Greek and Latin, so they could read Hippocrates in the original. And the modern languages should not be neglected; Conrad Sprengel even desired a knowledge of Arabic. Philosophy, history, belles lettres, and especially the mathematical sciences (pure mathematics, mechanics, physics, optics and hydraulics), were considered very valuable to steel the mind against vacillating theories. Finally, the medical student should be sufficiently informed in botany, mineralogy and zoölogy; in short there were few supplementary sciences which were not considered, by this one or that one, as absolutely necessary. That was an educational luxury before which the mind recoiled and which diverted the young men from the special line of study. For the rest the medical instruction was by no means in a position to satisfy these large pretensions. In the majority of the universities there was much left to be desired, as in the smaller states they were not sufficiently endowed to support the necessary number of teachers. At first Halle and Göttingen boasted only two professors, one for theoretical and one for practical medicine, but this number was soon increased. In 1750 Leipzig had five professors: in therapeutics, pathology, anatomy and surgery, physiology, and botany; in 1763 Heidelberg had four professors. In Vienna until 1775 there were only three professors; under Maria Theresa a fourth, for chemistry and botany, was added, and in 1780 under Joseph II. still another, for natural history. In very many of the universities there was a total lack of practical facilities. It was proposed

¹ In the winter semester, 1872-73 there were at 21 German universities, 1,620 teachers and 17,853 students; at 10 polytechnical schools, 300 teachers and 4,500 students.

therefore to make one large institution out of two small schools and wherever possible to establish it in a populous city.

(To be continued.)

PECULIARITIES OF THE SURGICAL DISEASES AND INJURIES OF THE NECK.

BY EDMOND SOUCHON, M.D.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY, TULANE UNIVERSITY.
NEW ORLEANS, LA.

(Continued from page 501.)

SURGICAL DISEASES AND INJURIES OF THE PAROTID REGION.

Congenital absence of the parotid and atrophy of the gland are very rare. However, occasionally subjects are seen with a deep hollow between the ramus of the jaw and the mastoid process, showing the partial atrophy at least of the gland.

Congenital hypertrophies are not on record. Branchial fibrochondromata are sometimes found over this region. *Acquired atrophy* or destruction of the gland has been observed as the result of neuroses, injuries, congestions (mumps), inflammations and gangrene due to general fevers. *Acquired hypertrophies* are represented by the various kinds of swellings of the region. *Swellings* may be due to some forms of injuries or neuroses.

Injuries of the parotid region are rare; they are grave, on account of cicatricial disfigurements and injuries to the facial nerve and to Steno's duct. Punctured superficial wounds are of no consequence, nor are the deeper wounds unless the instrument be large and the great vessels be injured. Incised superficial wounds may injure the facial nerve and the duct and may be followed by paralysis; when large, the divided nerve and duct should be at once stitched. Incised deep wounds are most serious. The diagnosis of the penetration of the gland rests upon the escape of saliva. When the wound is narrow, the hemorrhage, and later the suppuration, prevent the diagnosis; if the pus is very liquid, it is probable the gland is seriously injured. To prevent fistulae, stitch tightly and procure rest of jaw. Deep wounds are more serious, because of the presence of the temporomaxillary vein, which becomes the external jugular; also of the other deep vessels. The bleeding is profuse and sometimes terrific; it should be at once stopped by plugging; then a provisional loop ligature should be applied on the common carotid close to the bifurcation; the bleeding points should then be ligated. If this fails, it should be determined with care which vessels furnish the hemorrhage. If the external carotid, ligate it; if the internal carotid, ligate it separately or ligate the common carotid at the very bifurcation to prevent the return through the collateral circulation. If the jugular vein is injured, ligate it as high up as possible, at least above the facial and lingual, or ligate there. After the ligation or ligations have been done, the accidental wound should be packed tightly with bits of aseptic sponges to prevent hemorrhage by the distal end of the vessels; this plugging will usually accomplish this, but plugging should never be relied upon if the trunk has not been ligated; the hemorrhage is almost sure to recur, and often the patient thus loses so much blood that when the ligations are at last performed the patient still succumbs to hemorrhagic anemia. When the hemorrhages are

unmistakably venous, the thorough systematic sponge plugging may suffice even in wounds of the internal jugular. *Contused and lacerated wounds* call for the same remarks, but it must be remembered that although the primary hemorrhage may not be copious, the secondary hemorrhages are most to be dreaded, and proper instruction in consequence must be given.

Gunshot wounds call for the same remarks, with the aggravation of the presence of the ball in the deeper structures, in the pharynx, in the bones or in the brain. *Poisoned wounds* present nothing peculiar.

Neuroses are represented by paralysis due to the injury of the facial or auriculo-temporal nerve by blows or operations in this region; or they may follow disease of the nerve or pressure upon it by products of inflammation or tumors. *Nervous hypertrophy of the parotid region* has been recorded; it is characterized by a rapid congestion of the gland, in a few minutes, with a constant desire to swallow; sometimes the two glands are affected at the same time; the cause seems to be a mental excitement. It is soon dispelled under proper antispasmodic remedies. Softenings and indurations present nothing special.

Hyperemia of the parotid is here represented by the disease called *mumps*. It is considered a specific infectious disease; it is contagious in schools; it is most serious in spring, in damp or cold weather; young male children are more commonly liable; sometimes it follows orchitis, but it is usually the reverse. Its pathology is obscure. The most remarkable symptoms are pain and swelling without redness or heat, softness of the part; no induration, no fluctuation; the pain is increased by biting, chewing, swallowing; there is little or no general reaction. The beginning is often sudden, also the termination; it sometimes removes suddenly to the testicles, ovaries or breasts. The duration is about ten days. Termination by resolution is the rule; it is altogether exceptional when suppuration takes place. The treatment consists of soothing liniments and keeping the parts warm. It may affect both sides and also the submaxillary gland; it is sometimes epidemic; it may be due to the localization of a microbial infection coming from the mouth, and following the mucous membrane of Steno's duct.

Adenitis or adeno-cellulitis of the lymphatic glands situated on the parotid gland is usually due to lesion of the scalp or face; the symptoms are not so severe, the motion of the jaw is not so painful. *Simple and non-virulent inflammation* of the parotid may be due to cold, traumatism, obliteration of Steno's duct by a calculus or to the presence of a calculus in the gland; to mumps, to goitre (parotid goitre), mercurial salivation, iodid of potassium or menstruation. The symptoms are those of ordinary localized cellulitis; the pain is usually great on account of the capsule.

Acute parotiditis is a comparatively rare disease. Its causes may be mumps (rare), a debilitated state of the system, an infectious disease (typhoid fever, sepsis); it may be complicated with ear, eye, tonsil or brain syphilis, but it is always very rare. A pathologic peculiarity is that the capsule of the gland prevents the pus from coming to the surface quickly.

The symptoms are those of deep cellulitis with the addition of the general symptoms due to the lesion which is the cause of the parotiditis. The mouth is closed; there is facial edema, earache; the speech and deglutition are painful. The course is usually rapid; it may be sthenic or asthenic; the pus forms rapidly,

almost at the very outset. The duration is about fifteen or twenty days. It terminates almost always by suppuration; the pus may open into the ear, pharynx, vessels, down in the neck and chest, in the space behind the pharynx; it may terminate by several successive abscesses; it may terminate also by gangrene. Its prognosis is most grave.

The treatment consists in keeping the mouth disinfected and in an early evacuation. In superficial abscesses be mindful of the course of the facial nerve and of Steno's duct; in deep suppurations, of the external carotid; in these cases follow Hilton's method or dilatation upon a guide. The complications are extensive dissection of pus, hemorrhages from ulceration of large vessels, venous thrombosis of facial, external and internal jugulars, of cavernous sinuses. Its sequelæ are cicatrices, fistulæ, paralysis of facial nerve, parotidean ephidrosis. The forms and varieties are: Deep parotiditis with abscess opening in the pharynx; purulent catarrhal inflammation of the gland; multiple abscess, lobular abscesses, having to be each opened separately; diffuse parotido-cellulitis.

Gangrene of the parotid region may follow injuries and inflammations; its usual sequels are salivary fistulæ or paralysis of the facial nerve. *Ulcers* of this region present nothing peculiar except that they may be followed by fistulæ.

Fistulæ of the parotid are not very common. The causes are abscesses, furuncles, carbuncles, gangrene, ulceration, operations and diseases due to calculi developed in Steno's duct or in the gland itself, or abscesses due to microbic infection, or from any other cause. The symptoms are an orifice through which the saliva runs, increasing during mastication and meals; it is increased by lemon, salt, vinegar; the orifice is usually single, is situated on the center of an ulcerated fungosity; it may be small or large; a probe penetrates more or less deeply. They sometimes cure spontaneously, but the prognosis is generally bad, because they are often difficult to cure. The treatment consists in local cauterization; if this is insufficient, in making a large hole in the region and closing the surface opening by a plastic operation; in persistent cases in destroying the parotid. The forms and varieties are, multiple capillary salivary fistulæ; they are also called ephidroses; they are caused by obliteration of the duct or traumatism or loss of substance; they are characterized by a sort of transudation through the skin of the region of the parotid of a transparent liquid which forms numerous drops at the time of meals.

Tumors of the parotid.—The lymphatic nodes while not situated in the parotid, may present almost all the tumors that develop in the salivary gland; they are called supraparotid tumors; they are usually movable, whereas the tumors developed in the parotid gland are not. Gaseous tumors of the parotid region do not exist. Liquid tumors, such as liquid hematoma, angioma, varix, present nothing peculiar; aneurysms are almost unknown; lymphangiomas of the parotid are congenital cysts and show after birth. Glandular angioma of the parotid is usually called glandular hypertrophy; it usually shows at birth; the skin is sometimes bluish; it has been observed only in children; perhaps they change with age. Salivary cysts due to the obliteration of a duct of the gland may be followed by fistulæ if treated by mere outside incision: it is best to try and open them from the inside of the mouth. Mucous, mucoid, serous and

dermoid cysts are rare; they present nothing peculiar. Hydatid cysts have been reported. Purulent cysts or chronic abscesses are not common; tuberculous abscess of the parotid gland itself has never been observed (Duplay), but in the lymphatic glands they are common enough proportionately. Solid tumors of the parotid may be of all the varieties elsewhere found. Hematoma, sebaceous cysts, dermoid cysts and keloid present nothing peculiar. Simple adenomata or lymphadenomata of the parotid itself (due to simple hypertrophy) are very rare; those developed in the interlobular tissue are also rare; at first their growth is slow, then rapid and may be generalized; those developed in the lymphatic glands are common. Adenoma of Hodgkin's disease is very rare here. Strumous adenoma presents nothing peculiar. Tuberculous adenoma has never been observed in the parotid gland itself; in the lymphatic gland it is comparatively common, especially in children; it may at the outset simulate a tumor of the parotid gland and later a salivary cyst. Syphilitic adenoma of the parotid and gumma of the parotid are doubtful. Syphilitic adenoma of the lymphatics are common in syphilis. Adenoma of the gland is rare. Lipoma may be circumscribed or diffuse and infiltrate between the acini and the lobules of the gland.

Fibroma has been observed. Myxoma has been observed; it presents a gelatinous aspect. Myomata are very rare. Neuroma is doubtful. Chondroma forms 30 per cent. of the tumors of the region. Sarcoma, together with fibroma and cystoma, is about equally often present. Carcinomata represents about 45 per cent. of all the tumors of the parotid region; usually they are mixed tumors, in which the epithelial element has taken a great development; they may be secondary to similar tumors originating in the pharynx or on the face; primary carcinoma is rare. Encephaloid develops at 41 on the average. Pulsatory encephaloids are very rare. Melanotic cancer is very rare; it usually involves the lymphatics. Scirrhous usually develops at 60 or 70. Mixed tumors are commonly those called simply chondromata; they usually remain limited to the parotid and do not invade the other regions; they may become very large so as to affect mastication; some have a rapid course, some a slow one; they may degenerate into sarcomata; they return rarely if operated upon in the first period; they return often if operated upon in the second period; generalization is very rare.

Tumors special to the parotid region are represented by the salivary calculi developed in the parotid; they are rare in the gland itself; they are said to be more frequent in males and in adults, also to be due to the inflammation of the duct-radicles which retard the flow of the saliva; also to changes in the chemie composition of the saliva. They usually cause pain, inflammation and an abscess, which upon opening, leaves a salivary fistula; using the probe through the opening or by penetrating the gland deeply with a needle, the calculus is felt; they may cause atrophy of the gland by sclerosis. They should be removed through an incision.

Surgical operations of the parotid region.—The possibility of extirpating the whole parotid has been much discussed, but it presents no practical or clinical importance; when the gland is diseased, the disease must be removed, whether it affects the whole gland or not. A partial disease of the gland with prolongations is as bad as, if not worse than, a disease affecting the

whole gland without such processes. The dissection should proceed from below and behind, upward and forward; the external carotid should be located and ligated or clamped, otherwise it might be cut several times; when the dissection leads into the deep parts, the patient's mouth should be opened, as this increases the size of the parotid cavity and renders the deep dissection easier by affording more room. A previous permanent ligation of the external carotid might be done, or provisional loop ligature applied to the bifurcation, so that if it should become necessary to ligate the internal carotid the same incision will answer for all purposes. In penetrating the region the dangerous structures are at the entrance and in front, to the inner side of the head and neck of the condyle; more deeply they are on the posterior wall. Some tumors of considerable size, and sometimes extending to the pharynx, are removed with little difficulty and little hemorrhage if the adhesions are loose; whereas adherent tumors, even of small size, are fraught with danger. The safe plan is to proceed as long as the adhesions with the surrounding structures are easily broken, and to stop as soon as they become too resistant, and as we approach the deep dangerous structures which may be adherent to the tumor. Then the cleared part of the tumor should be cut off. It is a remarkable fact that often the stump left will, in growing again, become more superficial, and it is sometimes possible to remove the stump entirely by a second operation.

(To be continued.)

SOCIETY PROCEEDINGS.

Chicago Ophthalmological and Otological Society.

Regular Meeting, held at the Chicago Athletic Association Rooms, December 8, 1896.

Dr. GRADLE in the chair.

There were seventeen members in attendance.

Minutes of the last meeting were read and approved.

Dr. COLBURN discussed a method of operation for strabismus which he had used in a good many cases with satisfactory results. The method is as follows:

An incision is made over the tendon of the internal rectus and a partial tenotomy done. This tenotomy involves the whole tendon, with the exception of a few upper and lower strands; then an incision is made with the scissors, external to the muscle, carried very deeply back toward the orbit, so as to divide the so-called check ligament. This ligament consists of a bundle of fibers from the orbital fascia, or capsule of Tenon, very firm in many cases, and extending from the orbital border to the sheath of muscle. If necessary, this procedure is combined with advancement of the external rectus.

The operation can also be performed as well in divergent strabismus, the check ligament existing at the outer side of the eyeball, as well as the inner. The point about the operation that was most insisted upon, was the necessity of section of these ligaments in a large number of cases.

Almost no ophthalmic literature mentions the existence of these ligaments, but they are described in several general anatomies. The steps of the operation were illustrated by a number of colored plates, and numerous cases were quoted.

Dr. GRADLE asked if any of the Society had noticed a peculiar condition in cases of squint of moderate degree, where on covering the squinting eye it was found that the squint became greater, but immediately returned to the original position when the squinting eye was uncovered.

Several members had noticed this condition, and Dr. Starkey spoke of a case in which the eye symptoms turned further in, and at other times rotated upward, downward or outward, there seeming to be no constant change.

Dr. COLEMAN spoke of a class of cases which did not have diplopia, but after operation, the squint not being completely corrected, the patient had crossed diplopia.

Dr. COLBURN referred to a large class of cases of recurrent

heterophoria, where the whole amount was seemingly corrected by operation, but afterward returned in large part, and sometimes the same change took place after repeated operations, in one case five being done without permanent abolishment of the heterophoria.

Dr. GRADLE spoke of some experiments that he had made with the so-called rest prisms. He had found that it was possible by means of these prisms to develop in an eye having equilibrium of muscles a marked degree of any sort of heterophoria if the glasses were worn for an hour or so. He also had found, as was well known, that an apparent amount of heterophoria could be decidedly increased by means of glasses.

Drs. HOTZ and COLBURN did not agree with Dr. Gradle as to the effect of normal eyes. They had found quite the contrary, that in those cases where the rest prisms increased the amount of heterophoria, that the indication for operation were stronger, and that it was only in cases of latent heterophoria that the rest glasses caused any manifest lack of equilibrium.

Dr. COLEMAN said that a number of years ago he had prescribed prisms to a considerable extent, but that in recent years he had found that they were of little or no value in the treatment of asthenopic symptoms. As a rule, they will give temporary relief, but the symptoms almost invariably return, and for a long time he had found it best not to prescribe prisms at all.

Dr. HOTZ showed a modified form of bifocal lens for the use of presbyopic myopes. Instead of segment being cemented to the lower part of a fully corrected glass, the glass was ground to only partial correction and the segment giving full correction was cemented to the upper side of the lens. The segment was quite long, but did not extend as far as the center of the lens. He had found after a number of months' trial in his own case, that the relief from such a combination was very great. Ordinarily, he uses simply the lower segment, but if he wishes to look at a distance he looks through the upper segment, which gives him full correction.

Dr. PINCKARD, about a year ago, had made several experiments with the solid form of bifocal in a case of myopia in a presbyope, having the upper part of the lens ground in full correction and the lower part in the presbyopic correction. A number of lenses were ground, the segment varying in size, but the distortion from prismatic action at the junction of the two segments was so great that he was obliged to abandon the experiment in that case. It seems to him that any scheme of a small segment above would probably be applicable to cases of myopia of considerable degree.

Dr. STARKEY spoke of trouble he had had with lower segments in general, in having the segments decentered inward sufficiently, most of the opticians setting the segment in the center of the glass.

The Society adjourned by limitation.

C. P. PINCKARD, M.D., Secretary.

SELECTIONS.

Some Popular Errors about Medicine.—Dr. A. L. Benedict, in the *Cosmopolitan* for February, tries to show the general public some of the errors into which they have been led, or gone without any leading, and which more or less throw out of plumb the normal relations between physician and patient. He points out the false idea that prevails as to the possibility of assigning names to cases. Terms commonly understood, such as diphtheria, croup, quinsy, bronchitis, pneumonia, etc., are applicable in only about a third of all cases; perhaps another third is covered by purely technical expressions, while the remainder embraces cases so extremely simple or so complex that they must be described rather than named. The attempts of different physicians to translate into simple language the technicalities of medical science often lead to apparent contradictions and to much undeserved criticism. In chronic cases, and these are the very ones which are most apt to apply to a number of doctors, several organs are usually simultaneously involved. Different physicians will naturally locate the disease in one or another of these organs, and, in the attempt to explain the complex relations of one organ to another and to give the patient an understanding of a diseased organ, when he is ignorant of the action of that organ in health, it would be a surprising coincidence if any two doctors used expressions which the patient recognized as identical. Neither is the phy-

sician whose tongue is nimblest in finding a name always the one who best understands the disease. Dyspepsia, for example, is a high-sounding title and the one which is very satisfying to the average patient; but a physician who really understood the stomach would feel that he was scarcely nearer the mark in using this term than in saying that the patient was sick. Neurasthenia is another dainty diagnostic morsel; but the man who serves it is scarcely wiser than the one who says, "I don't know what to call your trouble, but you are simply worn out and nervously unstrung, and you need a rest."

Fevers usually divulge their nature little by little. The clinical thermometer makes it an easy matter to say whether a patient has fever or not; mere sensations of heat or "feverishness" are utterly unreliable; but the question immediately presents itself, What kind of fever? To this question, the honest physician at his first visit must usually reply "I do not know," unless he has been summoned after diagnostic symptoms have developed. Scarlet fever can not be positively diagnosed in less than twenty-four hours, measles in less than three days, typhoid fever in less than five or six days. The dislike to avow even a pardonable ignorance has led some really honest men to use expressions that are misleading and untruthful. Not very rarely, a physician is found who will state that a patient "is threatened with typhoid" but that he hopes "the disease will be broken up." Now, the patient is most emphatically not threatened with typhoid; he either has or has not that fever, but a positive decision can not be reached for several days. If, instead of typhoid, the disease happens to be a rather common and not very clearly understood "simple fever," the doctor gets the credit of having broken up a case of typhoid, a feat which all the great medical authorities of the world declare themselves unable to accomplish.

Few persons not thoroughly versed in medical art appreciate the true value of medicines. For example, a patient has passed successfully through an attack of bronchitis, having taken a certain prescription. The common opinion is that that prescription will be "good for" another attack of the same disease, either in the same or in another patient. As a matter of fact, most medicines are given without reference to the disease which is in progress, but to produce very limited physiologic changes or to control symptoms which may be common to many diseases. There is no disease which can always be appropriately treated by the same prescription, and only a very few in which any particular drug may be said to be specific. It will be readily understood that patients of different age, sex and temperament require very different dosage, but leaving this point aside, the prescription which was excellent for one case of bronchitis may be utterly worthless or even harmful in another, while it might be well adapted to certain cases of pneumonia or gastric catarrh or other conditions. Sometimes, the range of adaptability of a drug is ludicrous enough. Thus, a patient suffering from some forms of rheumatism and also from a corn, might be relieved of both troubles by using the same chemical, internally and externally, respectively. Yet other grades of rheumatism or other forms of inflammation of the extremities would fail to respond to analogous treatment. Again, a very efficient, though not ideal, treatment of erysipelas, was discovered by a careless nurse who applied externally a certain medicine which had long been used internally to support the strength of the patient. However, these are merely coincidences and, for the most part, the limitations of the usefulness of a drug are narrow enough. The same chemical may be obtained from widely different sources. Thus, oil of wintergreen, oil of sweet birch, willow bark or various artificially prepared drugs, all contain the same active ingredient and have an almost identical field of usefulness. So it may be that Dr. A.'s and Dr. B.'s prescription for a given case may read very differently, and yet represent essentially the same treatment.

The Toxic Basis of Neural Disease.—The *Boston Medical and Surgical Journal*, February 18, is among the first of our journals to properly notice the good work of Dr. Ira Van Gieson, of the Pathological Laboratory of the New York State Hospitals for the Insane, on the above subject. New York State has set for others a notable example in the establishment in New York City, under the competent direction of Dr. Van Gieson, a central pathological institute, whose function shall be to

direct the work of the several laboratories throughout the State, and at the same time serve in itself as a center of research. There can be no doubt that the establishment of such a laboratory or system of laboratories is one of the significant steps of recent years toward the foundation of a scientific spirit regarding neurologic problems. After reverting to certain statements made in a previous address relating to the fact that he believes that certain factors are at hand for the creation of a new epoch in the evolution of the pathogenesis of nervous and mental diseases, he adds, "The first and most important of these factors is the precise and definite status which the anatomy of the nervous system attained through the investigations of the past decade by the Golgi methods; the establishment of the neuron theory in particular leads to a definite understanding of the pathology and physiology of the nervous system.

"A second great factor in this new epoch of neuro-pathology is the application of the modern doctrine of cytology and its technical methods of research to the investigation of the problems in nervous and mental diseases.

"A third factor is a realization of the absolute necessity of correlating the nervous system with other organs and tissues in the body in studying the operation of the fundamental and general somatic pathologic processes in the nervous system."

In these three statements lies the substance of our present point of view regarding the pathology of the nervous system. Certain points are of particular interest, and by no means sufficiently realized by the medical profession at large. The significance of the Golgi methods in the light they have thrown on the fundamental principle of anatomic structure received a quick recognition. The neuron theory needed only to be advanced to be accepted, so reasonable did its fundamental idea seem to be. As applied to pathology, however, it had been accorded a much more tardy recognition, on account, no doubt, of the deeply rooted conception that cells and fibers did not essentially belong together. Because of our failure to recognize in the neuron a unit of histologic structure, we have been unable to apply a true cellular pathology to our investigations of disease processes in the nervous system. When, however, it becomes a habit of thought to conceive of the highly differentiated nerve cell as we do of the simpler liver or kidney cell, it will be at once evident that we may apply to the nervous system those general pathologic principles which are everywhere else operative—a step certainly of much significance.

The second point upon which Van Gieson dwells is of almost equal importance, namely, the elaboration of new technical methods of research. It is entirely natural that the highly differentiated nerve cell should demand for its proper investigation staining methods of extreme refinement and delicacy. Until methods were found which could demonstrate minute structural alterations, it was hopeless to expect any material advance in our knowledge of the subtle anatomic changes underlying and associated with many marked clinical phenomena. This difficulty is now, in a measure at least, a thing of the past. We have come clearly to recognize that transient injuries to the nerve mechanisms leave their impress, as well as those of greater severity and longer continuance. We are now no longer deterred from histologic investigation, which a few years ago would, of necessity, have been fruitless owing to inadequate methods.

A matter of extreme general importance is Van Gieson's third factor, in which he speaks of the necessity of correlating the nervous system with other organs and tissues in studying its pathologic processes. We can not do better than quote his own words relative to this point:

"However obvious or trite," he says, "the statement of this third factor may appear, it is nevertheless true that much of the present obscurity in the pathogenesis of nervous, and especially of mental disease, is largely to be explained by the very

simple fact that the brain and the rest of the nervous system have been studied altogether too much as something apart from the rest of the body—as something beyond the jurisdiction of the laws of the great fundamental pathologic processes which operate on the whole organism.”

Van Gieson insists that the nervous system can not be exempt from the workings of pathologic laws which are elsewhere operative, and that we must recognize this fact if we are to progress. Of necessity, the manifestation of such laws in the nervous system, as elsewhere, must depend upon the peculiar differentiation of the ultimate histologic elements, but because the nerve cell is highly differentiated affords no reason that it must be governed by pathologic laws peculiar to itself.

We owe Van Gieson a debt of gratitude for having clearly stated this broad point of view, and for his insistence upon the fact that the nervous system is, after all, merely a part of the organism as a whole, and therefore must be amenable to the same laws of disease and decay.

Presence of Tubercle Bacilli In Feces from a Non-Tuberculous Intestine.—Dr. R. B. Shaw, resident physician at the Royal Victoria Hospital, in the *Montreal Medical Journal*, January, reports a case of the above nature in a male patient, aged 54 years. The case presented the following conditions: the presence of tubercle bacilli in the fecal matter of a non-tuberculous intestine; a pernicious type of anemia incident to senile tuberculosis; the association of meningeal hemorrhage and grave secondary anemia; the existence, without symptoms, of a psammoma, and the presence of an auricular endocarditis.

The patient was a mechanic by trade and entered the medical wards of the Hospital June last, complaining of persistent diarrhea and general weakness. He was born in Scotland and came to Canada when 20 years of age. Of his past history he was unable to give a very satisfactory account and apart from some indefinite statements about his having had “fever and ague” while in Cuba some four or five years ago there was nothing of importance. Late in the fall of 1884, the patient had a severe chill lasting about five minutes and subsequently suffered so much from general weakness that he was obliged to give up work. Diarrhea supervened and a week later he entered the Montreal General Hospital, where he remained about one month and was then discharged feeling restored. Within a very short time afterward the diarrhea returned and has persisted ever since. So far as he knew no blood had ever been passed in the stools, which had been more or less liquid for the past six months. His appetite had been steadily failing but there was no vomiting. He had observed for the past six months that he was rapidly losing flesh but had never suffered from cough, though from time to time slight expectoration was present.

The patient is a much emaciated and markedly anemic-looking man of good intelligence. His skin has a somewhat subicteroid hue, but the sclerotics are of a bluish tinge. He sleeps well and has no pain, but his appetite is very poor and he is so weak that he is able to sit up in bed only a few minutes at a time. He has no cough, though from time to time he expectorates a small amount of greenish muco-purulent sputum. Temperature $97\frac{2}{3}$ degrees; pulse 88; respirations 20.

Autopsy—The abdominal cavity: The panniculus is greatly atrophied and the fat is bright yellow. The muscles are thin and gelatinous looking. The abdominal cavity is dry. The intestines are collapsed, their serosa pale, smooth and glistening. The small intestines have here and there blue-black patches of discoloration opposite the mesentery. No tubercles are seen. The omentum is pale, broad, thin, non-adherent and irregularly disposed throughout. The liver descends to the costal margin. The diaphragm is at the fourth interspace at the right side and at the fifth rib on the left.

On removing the sternum, which appears normal, both lungs retract. The right is gathered up at the vertebral column in its upper half, where it is adherent behind and at the apex. There it is puckered very much. Both pleural cavities are dry. The left lung weighs 325 grams; there are slight apical adhe-

sions and much anthracosis. The lung is fairly crepitant in general, with a few nodules of consolidation here and there, and on the surface there are some pseudo-tubercles. The apex is puckered with a thickened pleura, and there is a small caseous and fibroid mass. Centrally in the upper lobe are isolated tubercles, broncho-pneumonic areas, with purulent bronchitis, all well localized. There is a slight marginal emphysema. The lower lobe is anemic and dry, but otherwise normal. The bronchi contain slight muco-pus. The vessels are free. The peribronchial glands are pigmented and calcified. The right lung is much contracted and puckered at the apex, where it is alternately eoid and emphysematous. The upper lobe on section has slight cavitation, with smooth walls and a few caseous flocculi. Around this are areas of tuberculous pneumonia with isolated tubercles and pus cavities. In the upper half of the lower lobe there is a small area of simple pneumonia, and near it a patch of tubercular pneumonia as well, each of the size of a filbert. At the lowest part is also another patch of simple pneumonia. The bronchi are filled with thick muco-pus.

The cerebral convolutions are of normal size. There is much cerebro-spinal fluid. The ventricles and substances of the brain and cerebellum are normal. Superiorly in front of the vermis cerebelli, and apparently attached to the pia, is a small bean-sized oval tumor, brownish-gray in color, and varying in firmness, in some parts being fairly soft, in others calcified.

The retina of the right eye presents several recent hemorrhages.

The bone marrow of the femur is very red, looking like red jelly. There is very little evidence of fat. Cultures taken from the heart blood and pericardial fluid gave growths of the diplococcus lanceolatus; from the liver and left lung, staphylococcus pyogenes aureus and diplococcus lanceolatus. The spleen pulp remained sterile.

Remarks.—As will be seen from the above case report, the patient was suffering from advanced senile tuberculosis, and yet the subjective symptoms were comparatively slight, a condition which indeed seems to be by no means in the tubercular processes of the aged. In the present instance, persistent diarrhea and the grave anemia had rendered the physical condition so weak as to give the pulmonary symptoms far less prominence than might be expected under other conditions and in a younger subject. The presence of a blood condition, which is indistinguishable from that of pernicious anemia, is one which has long been recognized as a possible occurrence, though the association with retinal and meningeal hemorrhages is of more than usual interest. Hemorrhages into the meninges, so far as the literature indicates, seem to be particularly rare under such conditions.

It may, perhaps, be argued by some that the relative proportions of hemoglobin and corpuscles is not such as to warrant the application of the term pernicious to the type of the anemia, and yet Eichhört distinctly refused to acknowledge that in pernicious anemia there is necessarily a relative increase in the amount of hemoglobin. The most interesting feature perhaps, however, in the present case is the occurrence of tubercle bacilli in the feces, when no anatomic lesion in the intestines, suggestive of tuberculosis, could be found. The explanation is, however, obvious, the patient having swallowed the sputum which was maintained in such a condition as to render examination for tubercle bacilli a comparatively easy matter. The lesions found in the intestines presented absolutely no evidence of tuberculosis, the pigmented scars being in all probability merely old typhoidal ulcers. The persistent diarrhea was obviously associated with the chronic colitis. The cerebral tumor present, while close to important structures, had evidently not attained sufficient size to present characteristic symptoms.

Medical Treatment of Cancer of the Stomach.—Much can be accomplished in relieving cases of this kind in which the physician is too apt to consider himself impotent. A suitable diet is of great assistance, A. Robin asserts in the *Bulletin gén. de Thérap.*, Dec. 13, 1896. It should include lean meat, tender fowls, gelatins, peptones and meat powders, to which can be added green and nitrogenous vegetables. All easily fermenting substances, such as bread, cheese, cabbage, kefir and sugar, should be strictly avoided and the stomach regarded merely as a passageway for the food, which is not digested at all until it reaches the intestines. Albumin and milk is usually digested with difficulty, and the latter is only indicated to increase the appetite, taken for a short while occasionally, in hematemesis and in incoercible vomiting. Three meals a day are enough, as the digestion is slow. The medical treatment is of course only

palliative. To increase the appetite give: 1. Condurango, taken as a tonic; 15 grams cortex condurango alb. are boiled down in water from 250 grams to 150, filtered and sweetened with syrup; a tablespoonful of this is taken fifteen minutes before each meal. 2. Strychnin (tinct. nuc. vom., tinct. fab. St. Ignat.). 3. Theriaca wine. 4. One powder ten minutes before each meal as follows: Ammon. chlorat. 0.15; natrii. bicarb. 0.26; pulv. Dover, 0.10. To assist digestion, have the patient sip a glass of a solution of 1.66 hydrochloric acid in 1,000 grams of water at the close of the meal, and during it take a powder: Pepsin, 0.50; maltin and pancreatin, aa 0.10. To diminish the amount of fermentations, prescribe sulf. sublim. or præcip. 0.15 to 0.20, or sulf. iodat. 0.25 to 0.50 in a powder at the end of each meal, or during the meal a large tablespoonful of a 1 in 300 solution of fluorammonium. To arrest vomiting, prescribe: 1.5 to 7 drops of the following solution, five to ten minutes before eating: Picrotoxin and morph. mur. aa 0.05; atropin sulf. 0.01; aq. lauroceras. 10.0. 2. A teaspoonful of a cocain solution (0.15 in 150 water), a teaspoonful chloroform water or aq. menth. 3. A vesicans over the stomach. 4. A suppository on waking in the morning made of pulv. opii. 0.10; pulv. fol. bellad. 0.02; butyr. cacao q. s. Hemorrhages can be combatted with ergot injections in severe cases, and in less severe, a tablespoonful of the following solution: Ergotin Bonjean, 4.0; acid gallic. 0.50; syr. terebinth. 30.0; aq. til. 120.0. Or, acid tannic 0.60; opii pur. 0.15; sacch. alb. 1.0; M. f. pulv. div. in dos. vi. One powder every four hours. To relieve the pains: For merely sensitiveness in the gastric region, apply locally, empl. diachyl. empl. theria. aa 5 parts; extr. bellad., conii, hyoscyam. aa 1 part; ammon. acetic. 2 parts. For severer pains prescribe one to four teaspoonfuls daily of the following: Ka. bromat. 6.0; morph. muriat. 0.50; aq. laurocer. 10.0; syr. æther 30.0; aq. tilia. 120.0. For very violent pain, morphin injections loco dolenti. In pyrosis, prescribe magn. decarb. 0.60; opii pur. 0.02; bismuth subnit. 0.20; natr. bicarb. 0.75. M. f. pulv. tal. dos. no. xx. For constipation order one of the following pills to be taken every evening before retiring: Aloes 2.0; resin., jalap-scammon, turpeth veget. aa 1.0; extr. bellad., hyoscyam. aa 0.15; sap. amygdal. q. s. M. f. pill. no. xxv. Treatment of diarrhea: Electuar. diascordii, bismuth. subnit. aa 4.0; f. boli no. xx. One every two hours. Or, in case of violent diarrhea, a pill every six hours made as follows: Cal., pulv. ipecac and extr. opii, aa 0.01. The cachexia is best combatted by the administration of glycerin phosphates per os or subcutaneously; 5 to 6 grams of a solution of natr. glycerino-phosphoric. 0.20 to 20 water, injected each day. Robin has treated thirty-nine patients in this way and nineteen are still living; seven have gained in weight, among them patients from 50 to 72 years of age, who gained one to two kg. in the course of two to five weeks.

PRACTICAL NOTES.

Percussion of the Vertebral Column.—Bechtereff draws attention to the diagnostic importance of percussion of the sacral region in some cases, as shown by the following instance: A patient was admitted under his care with symptoms of compression of the cauda equina. There was plantar and perineal anesthesia, spontaneous pain in the joints, etc., pain on percussion of the sacral region and the sphincters were affected. The history was that the patient had suffered from a severe contusion in the lumbar region in falling from a horse eight months previously and for the last six months the symptoms had been gradually increasing, till at the time the case came under observation there was considerable hectic. On account of the grave condition of the patient and his severe suffering it was decided to perform laminectomy. This showed considerable caries of the sacrum with caseating material compressing the

cauda. After the operation the anesthesia and pain disappeared, but the condition of the patient prevented his ultimate recovery. The postmortem examination showed tuberculosis of the sacrum, suppurative prostatitis and tuberculous pyelitis. During life percussion of the sacral region gave a marked dull note, while in the healthy condition percussion of the triangular area which has for its base the upper part of the sacrum and for its apex the coccyx, should give a slightly resonant note. In the case just quoted the dullness corresponded exactly with the tuberculous mass which was found post-mortem.—*Gazzetta degli Ospedali di Milano*.

To Differentiate Appendicitis from Acute Catarrhal Salpingitis.—Vineberg notes that the pains are more violent in appendicitis but more strictly localized, without radiating pains, while in catarrhal salpingitis, especially if the ovaries share in the inflammation of the tubes, the pains radiate toward the thigh. The alarming symptoms also show a noticeable remission toward the third or fourth day, which is a useful point in deciding dubious cases, as the alarming symptoms in appendicitis may persist and increase in intensity. If differentiation is impossible, the patient should be examined in narcosis. The treatment of appendicitis should be prompt operation, while in salpingitis a waiting policy should be preferred, as it often heals spontaneously without the necessity of an operation.—*Gaz. d. Osp. e d. Clin.* February 11.

Tardy Traumatic Strictures of the Urethra.—Professor Bazy describes a case and quotes one other on record, in which the symptoms of stricture were preceded by fracture of the pubis forty and fifteen years previously. As the retention of urine was not complete, the idea of prostatism was rendered less probable, and in exploring the urethra the bulb could not be felt through the perineum, but only through the rectum. He considers this fact a valuable means to differentiate spasm of the membranous portion from stricture located in the remotest part of the perineum, and thus close to the membranous portion. In his case the bladder was two finger-breadths above the umbilicus, prominent and painful. With a No. 23 blade, he sectioned the stricture which seemed as hard as any gonorrhœal or other premembranous stricture, and the section was absolutely bloodless. Evidently a slow process of sclerosis had terminated in the production of a stricture. The treatment was successful.—*Presse Méd.*, February 13.

Connection Between Lead Poisoning and Gout.—The *Semaine Méd.* of February 13 contains a long study of this subject, showing beyond a doubt the intimate connection between gout and long-continued lead poisoning. The special characteristics of this form of gout are that the lead has produced pallor, anemia and emaciation, before the gout appears, while in other gouty subjects there is usually the appearance of good living and a tendency to obesity. In other respects the disease manifests itself in about the same way, and is treated alike in both cases, as what is good for gout also serves to eliminate the lead from the system. Hot and vapor baths stimulate nutrition and favor the elimination of the poisons, but sulphur baths are contra-indicated, as they are injurious in gout, increasing the formation of uric acid, as Bouchard has shown, although beneficial in saturnism. For internal medication, potassium or sodium iodid is indicated, in moderate doses, if the condition of the digestive apparatus allows their use. They favor the elimination of the lead through the kidneys, either by combining with it to form lead iodid, soluble in alkaline liquids, with a tendency to combine with the alkaline iodides and form a double salt, still more easily dialysable, or by promoting disassimilation, which is the end sought in administering them in gout. Anemia requires a tonic and invigorating treatment, but it must not be exaggerated. The state of the kidneys must be carefully watched, and if nephritis is discovered, it should receive the usual treatment, as there are no special indications

for this variety of renal atrophy. The prognosis depends upon the severity of the saturnism, and whether it is combined with a hereditary tendency to gout, when it becomes much more grave. Plumbers, painters, printers, machinists and all who handle lead are exposed to it, but hearty eating predisposes to it.

Direct Diagnosis of Hernia of the Diaphragm.—It is so difficult to diagnose hernia of the diaphragm, that only 7 out of 266 cases reviewed by Lachner were diagnosed *intra vitam*. Prof. E. Maragliano has rendered it much easier by his application of the Lieberstein method of insufflation of the intestines to this purpose. He describes a case of hernia of the diaphragm, preceded by a traumatism two months before, which had evidently weakened the diaphragm. An attack of influenza caused severe coughing and the hernia suddenly occurred with its attendant phenomena. After differential diagnosis, certainty was attained by insufflating the intestines rhythmically with a pump *per rectum*. The insufflated gas did not produce any increase in the endo-abdominal pressure nor upward displacement of the thorax, but the left thorax increased a centimeter in volume, and simultaneously with each insufflation a sound was heard in the fifth intercostal space, while at the back, the hypophonic area was smaller and higher. Auscultation also showed a murmur at a certain point in the left thorax. Further certainty was obtained by introducing an aspirating needle into the left thorax, connected with a syringe filled with a liquid, when the insufflated gas could be heard bubbling up in the liquid. A third test was made with liquid introduced with an ordinary syringe into the intestines, when an area of dulness was noticed in the left thorax, where it had been clear before. These tests produced such dyspnea in the patient that they were arrested as soon as the result was observed, but they were continued at length on animals, and the experiences confirmed. M. advises prompt surgical intervention in these cases, although many instances have been known in which the hernia produced no inconveniences, and was only discovered at the necropsy. But the danger of strangulation is always imminent, and he therefore recommends an operation.—*Gaz. degli Osp. e delle Clin.*, February 15.

Hemoglobinuria in Malaria.—Prof. G. Baccelli classifies the cases of hemoglobinuria accompanying malarial attacks into 1, those in which the hemoglobinuria is caused by the malarial infection and is cured, with the malaria, by the administration of quinin, and 2, those in which the hemoglobinuria is independent of the malarial infection and may be caused by the quinin administered. He ascribes it in these cases to an individual idiosyncrasy and states that clinical experience has shown that hemoglobinuria can be caused by the unnecessary administration of quinin, viz., without simultaneous malaria. These statements are based on his own, Tomaselli's and Murri's experiences, which he does not attempt to explain, remarking that hypotheses live but a day, while carefully observed clinical experiences last and are the constant source of the discovery of new truths. He adds that hemoglobinuria unchecked leads to hemodyscrasia, and always requires special treatment, whether it accompanies as a satellite the febrile process of malarial infection, of which it is a pernicious symptom, or whether it complicates a mild attack, originating independently of the infective cause, or whether it follows malaria, after a shorter or longer interval, appearing spontaneously or induced by even the smallest doses of quinin. Baccelli has found useful the administration of ferric persulphate, combined with inhalations of oxygen, and a strict removal of all the causes that, beside malaria, have been found to possess a tendency to produce hemoglobinuric phenomena. When the severity of the malarial attack requires intervention with quinin, he does not hesitate to use it, even although he may have well founded

fears that the hemoglobinuric phenomena of the fever may be increased by it. He has been conducting a series of experiments, administering quinin to healthy persons, to persons suffering with the various forms of malaria and with other diseases, and analyzing the quinin as it was eliminated in the urine. He has found that the quinin thus eliminated, while retaining its bitter identity, has lost its crystallizing faculty more or less completely and the shape of the crystals is noticeably different from that of the original crystals. This demonstrates that "the quinin has certainly lost something in its journey through the organism, but what? Can the action of quinin be of an electro-chemical nature? Mystery!" His experiments in administering this quinin derived from the urine to other patients with malaria, will be watched with interest.—*Gaz. degli Osp. e delle Clin.*, February 14.

Dual Infection in Diphtherial Cases and their Treatment by Two Serums.—Dr. C. C. Fite, in the *North Carolina Medical Journal*, January, advocates the use of both the anti-diphtheritic and the anti-streptococcic serum in cases of mixed infection. He says: "Marmorek and others have used anti-streptococcic serum in cases of diphtheria showing the streptococcus as well as the Klebs-Loeffler bacillus, also in scarlet fever, puerperal fever, general septicemias, infective tonsillitis, erysipelas and other diseases, whether due to, or complicated by, the appearance of the streptococcus pyogenes, and it seems as if it will prove of great value in other cases, perhaps in multiple abscess and in broncho-pneumonia, or, in fact, wherever the streptococcus is found as above stated." Dr. Henry Dwight Chapin has been giving some attention to its use in the two diseases last named. In reference to its use in diphtheria, I am firmly convinced that it is indicated in all cases where the microscope shows the streptococcus, and we almost invariably find it in cases which do not yield to the anti-diphtheritic serum and where we see a zone of inflammatory action extending beyond the area occupied by the true diphtheritic membrane. Therefore, if a case does not yield promptly to the anti-diphtheritic serum, we should, I believe, use the anti-streptococcic serum, without waiting for the report from the bacteriologist. The method of producing the anti-streptococcic serum is in the main a similar process to that used in the production of the anti-diphtheritic serum, or by injecting virulent cultures of the germs instead of the toxin. I am indebted to Dr. Charles T. McClintock of Ann Arbor for advice in regard to this matter. Dr. McClintock writes as follows: "As regards the difference in methods for producing the anti-diphtheritic and anti-streptococcic serum, I may say in general that the streptococcus, like a number of other germs, does not readily give off its toxin to the surrounding liquid. If you want to get the toxic properties of the germ, you must take its own protoplasm. On this account we are compelled to use the germs themselves, in order to successfully immunize an animal. The filtered toxins are not very powerful. This is the essential difference between the two materials. In the case of the streptococcus we use a living virulent germ in bouillon culture." There has been a great deal of good work done quite recently in this investigation of the anti-streptococcic serum, and I feel confident that we are near a solution of the problem. The New York Board of Health is having it carefully studied in the Willard Parker Hospital, and the great reputation and well-known ability of the scientific corps of this board and of the gentlemen composing the staff of the hospital is a sufficient guarantee that the work will be well done. The profession of this country owes much to Drs. Biggs, Park and Prudden.

Fat as a Factor in Hernia.—It is known that emaciation has a tendency to produce hernia, but J. Lucas-Championnière asserts that fat is still more important as a factor, and that it plays a preponderant role in the evolution of hernia and also in the evertations that follow radical operations. He empha-

sizes the fact that fat at the temperature of the body is not a solid but a fluid, and does not act like a stopper when an opening presents itself as it would if it were cold, but flows through it dragging other tissues with it, and tends to enlarge it. It also renders everything slippery, which favors the easy displacement of the viscera. Accumulations of fat also cause such pressure that the viscera are forced out of any chance opening. It also renders the tissues so friable that a radical operation has little chance of permanent success, and eventration is almost inevitable. For these and other reasons, presented in the *Journal de Méd. et de Chir. Pratiques* for Sept. 10, 1896, he urges the importance of seeking for traces of impending hernia in persons either young or old, who are acquiring obesity at a rapid rate so that they can be treated at an early stage, and also emphasizes the necessity of reducing the obesity. Even in inoperable cases, he has rendered life-endurable by reducing the obesity, which combined with the inconveniences of the hernia made life a burden. The obesity should also be carefully reduced as a preliminary to a radical operation. He describes one obese case in which three months of preparatory treatment transformed the patient, until she was able to undergo a two-hour operation that restored her to complete health. The treatment in this case was, decrease in the amount of liquids taken, especially with the meals, a mixed diet, excluding nitrogenous substances almost completely, regular exercises and massage (massage of the bowels alone excepted). The medication included the administration of Santenay lithiated water, as much as three glasses a day, small interrupted doses of potassium iodid, and the administration of thyroïdin, most carefully watched. He considers regular exercise of the utmost importance in preventing hernia and as post-operative treatment, avoiding merely those gymnastics that suspend the body from the arms, and high leaps. Exercise is especially indispensable after severe abdominal operations, when the long repose in bed and the generous diet predispose to accumulations of fat. Regular exercise is not productive of hernia which are due to sudden violent shocks, or extreme efforts in defecation or coughing. He warns against an excessive meat diet and the use of alcohol in tonics or any form, as fat-producing. His experience of hernias has been extensive, as in 1894 he published a report of 275 radical operations. He concludes his vigorous denunciation of fat as a cause of hernia, with the remark that the sole advantage of fat in the matter of hernia is that it makes the wearing of a truss or bandage more endurable. His method of administering the potassium iodid is 25 centigrams a day in an aqueous solution, for two months, and resumed again after suspending it for two months more.

Ambulatory Lobar Pneumonia.—Dr. Gordon Campbell reports in the *Montreal Medical Journal*, January, a fatal case of this rarely observed affection. In hospital practice, where the great bulk of patients come from the poorer classes, it is not unusual to meet with acute pleurisy with effusion in the out-patient department. Several times I have been consulted for "shortness of breath and slight cough" of a few days' duration and found one pleural cavity almost completely filled with fluid. Pneumonia, or at least that form which sets in abruptly with a severe chill, met with during adult life is extremely rarely encountered in an out-patient hospital practice. The following are briefly the particulars of the case:

N. M., aged 49, a wood carver by trade, came to the clinic of the Montreal General Hospital on October 23, complaining of cough with slight expectoration and general malaise. Inquiry into the history of the disease revealed the fact that it had been induced by a severe wetting which he got on October 18. On the morning of the 19th he rose as usual at 4 A.M., but shortly after he had a severe chill lasting one hour and followed by pain in the side. During the day he took to bed, and at night cough and expectoration set in. During the 20th he

remained in bed, but on the following day got up and sat about the house, not feeling quite able to go to work. On the 23d, feeling that he was not improving, he came to the hospital, a distance of over a mile from his home, and walked a part of the way. The personal and family history contained nothing of interest. He had been a hard drinker in his early manhood, but had been temperate for a number of years. On examination the temperature was found to be 101.5 degrees, the pulse 120. The right lung showed dulness from the spine of the scapula down, and at the side and front, corresponding very closely with the lower lobe. Over the dull area there was intense dry, blowing breathing and bronchophony. The vocal fremitus was slightly if any increased. A diagnosis of acute lobar pneumonia was made and the patient advised to remain in the hospital. To this, however, he demurred, not feeling, as he said, that he was "ill enough for it." After the grave nature of the disease was explained to him, he consented to be admitted, but insisted on going home first, which he did. The same afternoon he was admitted to the hospital. The temperature shortly after admission rose to 103 degrees, and remained between that and 101 degrees until death occurred on the tenth day of the disease. The expectoration was rusty, viscid, and contained pneumococci. The urine contained no albumin. On the 26th, two days before death, an area of consolidation was detected at the base of the left lung. The autopsy revealed acute lobar pneumonia, total gray hepatization of the right lung with commencing red hepatization of the left lung; acute bronchitis; chronic right and acute plastic left pleuritis; old apical tuberculosis; spleen large and firm; "hog's back" kidney with mixed nephritis and some fatty degeneration; slight cirrhosis of the liver; very marked dilatation and hypertrophy of the heart; polypoid white thrombus of the right ventricle and slight pulmonary embolism.

Asepsis and Anesthesia in Urethral Surgery.—Dr. John A. Wyeth, in the *New England Medical Monthly*, January, treats of the modern technic of urethral surgery, noting that two important branches of the subject are worthy of closer attention than they commonly receive. The first and most important is urethral asepsis. A urethra which is about to be incised should be made sterile, if this is possible, and the urine of such a patient should always be sterilized at least twenty-four hours before the operation, and should be kept sterile during the time of treatment. We recognize the fact that the so-called "urethral fever" is a form of septic infection. The administration of twenty drops of a mixture of 1 drachm of salol and 2 drachms of oil of gaultheria, three or four times a day, will sterilize the urine within twenty-four hours. "It is also claimed that the administration of boracic acid, 5 grains four or five times a day, will effect the same result, but I have used the first formula with such satisfaction that I have never tried the boracic acid. We are indebted to the late Prof. E. R. Palmer of Louisville, Ky., for popularizing this important point in treatment. In addition to this, the urethra should be irrigated with permanganate of potash, 1-3000 for five minutes before the operation, or it should be thoroughly 'ballooned' with this antiseptic solution by using the ordinary conical syringe introduced at the meatus, and the canal thoroughly distended with the fluid. This should be repeated three or four times, and a sufficient pressure employed to overcome the resistance of the cut-off muscle, in this way reaching the entire canal. The second point is the question of anesthesia. The vast majority of all strictures of the urethra can be treated practically without pain with cocaine anesthesia. From the meatus to the cut-off muscle, the urethra can be anesthetized by using from 1 to 3 drachms of a 2 or 4 per cent. solution. I give varying quantities and strengths of solution, because no given prescription would fit every case. It is my rule to study carefully the susceptibility of every new patient to this agent, and disregard of this rule has given the unfortunate results

that now and then find their way into the journals. When the entire urethra is injected, 1 drachm of a 2 per cent. solution should first be employed, and the degree of susceptibility of the patient, as well as the anesthetic effect produced, can be ascertained in five or ten minutes. If the anesthesia is incomplete and the patient shows no susceptibility to the drug, another drachm of the same or a stronger solution may be injected. It is also very important to remember that a patient is much more susceptible to the absorption of cocain when it is employed for the introduction of sounds for the first few times after, than at the time of the operation, for the simple reason that an incision, more or less extensive, has been made, which incision is covered with granulation tissue, rich in capillaries and ready and capable of absorbing under pressure a considerable quantity of cocain. Anesthesia of the membranous portion of the urethra may be obtained by carrying the Keyes-Ultzman syringe point down to the cut-off muscle, pushing it slightly within, and injecting 10 to 15 minims of a 4 per cent. solution. Anesthesia beyond the cut-off muscle is practically impossible, for the reason that the urine is in contact with this part of the urethra and so dilutes the cocain as to make it practically inefficacious. In meatotomy a few crystals applied just within the meatus or 10 minims of a 6 per cent. solution injected, limiting the application by digital closure of the canal one inch behind the opening, will effect complete anesthesia in division of the meatus or of an organic stricture here."

Prevention of Hemorrhage in Operations on the Liver.—A couple of Russian surgeons, Kousnetzoff and Pensky, have been experimenting with a view to find a process that would enable the liver to be resected without danger of hemorrhage. They now announce in the December *Revue de Chir.* that they have succeeded experimentally and in attempts on cadavers, and prophesy that ablation of large tumors and resection of part of the hepatic parenchyma will soon enter into current surgical practice. They find that ligature of the mass of the liver, slowly and firmly drawn tight, closes the lumen of the vessels, and thus prevents hemorrhage. After chloroform the peritoneum is opened and the lobe of the liver drawn out through the wound. A row of ligatures is then made through the liver, with a blunt needle and a double silk thread, the entire length of the piece to be removed. A sharp needle would injure the vessels and produce hemorrhage, possibly. The needle is pushed into the mass of the liver and drawn out the other side. It is thus passed through the substance of the liver several times, a few centimeters apart. The holes made by the needles each contain therefore two threads, the ends extending out above and below. The nearest threads in the different holes are then tied together; one thread in a hole thus acts on the hepatic substance to the right of the hole, and the other to the left. When these ligatures are drawn tight, the piece to be resected in front or back of them is then removed. If the ligatures have not been drawn tight enough, some vessels will bleed, when they must be separated and pulled up out of the parenchyma with a pair of Péan forceps and tied with a silk thread, or the surrounding tissue compressed with an intervening ligature. Compresses of gauze should be applied to control hemorrhage of the parenchyma. In secondary hemorrhage the bleeding surface may be thermocauterized after the row of ligatures has been made, but this is unsatisfactory and usually the vessels have to be tied finally. But hemorrhage rarely occurs if the ligatures through the hepatic mass have been drawn absolutely tight. After the ablation the hepatic stump is sutured to the edge of the abdominal wound, or the great omentum can be sutured to the cut surface of the liver or the stump can be put back into the abdominal cavity and the walls closed with a suture in three stages, after dressing with collodion gauze. This means of hemostasis is almost invariably successful; it can be sup-

plemented by suturing the edges of the wound in the liver together, after interposing a gauze tampon, leaving the end of the tampon protruding from the cutaneous wound, and removing it in a few days in one or two sittings. Mikulicz has treated a case of syphiloma of the liver in this way with great success. Experience on the cadaver shows that the most convenient cutaneous incision is parallel to the arch of the false ribs, one or two finger breadths below, 10 to 15 cm. in length, starting at the right parasternal line for the right lobe, and at the median line, swerving to the left, for the left lobe.

Surgical Intervention in Tuberculosis of the Kidneys.—Tuffier reports fifteen operations performed on the kidneys for tuberculosis, about a tenth of his operations on these organs (152 in all), in the course of the last eight years. He only operates when all medical treatment has been found ineffective, and considers the three principal indications: intense hematuria, pains and evidence of infection and intoxication. Benign hematuria does not require intervention, but only severe cases, with sufficient loss of blood to weaken the patient to a dangerous degree. He has operated twice under these conditions. The first was a woman of 42, with dangerous crises of hematuria and consecutive anemia, on whom he performed nephrectomy. The ablation of the left kidney disclosed a number of tuberculous abscesses in the parenchyma. The patient has never had a recurrence of the symptoms and when seen three and a half years afterward was in perfect health. The other case was a woman of 20, with severe hematuria for three years previously. After lumbar incision, and the discovery of a voluminous kidney, he performed nephrotomy, and the patient continued eighteen months without a recurrence of the trouble. Since then she has had slight returns of it at times, but not enough to warrant another intervention. He has performed four operations to relieve excessive pain. The first case was a woman, whose sufferings had much reduced her. The kidney was found riddled with tubercles and removed; the ureter seemed intact. She recovered finely and when seen five years later was still in perfect health. One peculiarity of this case was the sudden appearance of obesity after the operation, which assumed such proportions as to be actually pathologic, as also occurred with another patient. This condition gradually passed away. The second operation to relieve pain was performed on a young Russian woman, who had been examined by Billroth of Vienna, Wood of London, and Erb, who at first all ascribed her troubles to neuralgia, and later to lithiasis, as did also Senator and Israel at Berlin. Finally Gennes discovered the Koch bacillus in the urine, and Oertel at Munich and Czerny confirmed the diagnosis of tuberculosis and advised an operation, after the whole range of local applications had been tried in vain. Her renal pain was so severe that it was impossible for her to walk, and there were also frequent desires to urinate. Morphine alone relieved her. The pain dated from a fall in 1892, after which she had suffered from the pain in the kidneys, with frequent crises, becoming worse and worse. Tuffier performed nephrectomy by the lumbar route, January, 1896, freeing the patient from her troubles. The ureter was found dilated and granulous, and by the end of the year the desires to urinate returning, she consulted Israel again, who found by cystoscopic examination a tuberculous patch at the entrance of the ureter, showing descending infection. A third patient was operated and restored to health except for a slight frequency of mictions and trifling hematuria. When a calculus forms the pain is atrocious, and in one case had driven the patient, a former pupil of his, to morphinomania. The calculus was the size of a large nut and was found in the lower end of the ureter. The suffering had undermined the patient's health to such a degree that he did not long survive the operation. Tuffier has performed nine operations to relieve the accidents of tuberculous pyelonephritis, acute or chronic, but these operations are merely palliative and with the sole hope of affording temporary relief. They emphasize anew the importance of operating at once when the diagnosis has been established with certainty. He advises nephrectomy as preferable both in the hematuric and painful variety. His experience certainly demonstrates the existence of primary renal tuberculosis, which some have denied; and the perfect health of some of his patients operated four, five and six years ago, is conclusive evidence of the value of intervention in these cases.—*Presse Méd.*, January 9.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the Association living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, MARCH 20, 1897.

CARDIAC DISTURBANCES AS THE RESULT OF
EXHAUSTION.

While physicians and pathologists are well acquainted with the clinical and pathologic changes which take place in the heart in cases of true disease, we know very little about those alterations in its nervous and mechanical government which result very often in serious functional disturbances, and some of the most troublesome and puzzling cases which we have to treat occur in patients without apparent grave organic valvular or myocardial disease, but who nevertheless suffer from cardiac disorders with palpitation and a sense of oppression and precordial discomfort. Quite thirty years ago, attention was called to at least one type of this condition by Dr. J. M. DA COSTA, who described it under the title of "The Irritable Heart of Soldiers," but although we in this country have not a sufficiently large military force to bring us in contact with persons whose hearts have been strained by the severe exertions of military life, active practitioners constantly see persons who have over-exerted themselves in athletic games, presenting symptoms of cardiac disorder which follow out in every respect the symptoms described by DA COSTA. In some of these cases any exertion develops very marked over-action of the heart so that it beats violently against the chest wall. Its sounds are exaggerated and its impulse is diffused. In other cases the action of the heart may become unduly feeble, yet the age of the patient, the condition of his blood vessels, showing an absence of degenerative changes,

and the absence of any history of infectious disease, prevent us from considering that there is degenerative change in the heart muscle.

Our attention has been recently called to this matter once more not only because we have had under our care several cases of this character occurring in young men who have been engaged in foot-ball under excessive training or no training at all, but also by a brief article in the *Journal des Praticiens* for Feb. 13, 1897. In this article it is pointed out that on the continent of Europe palpitation of the heart in soldiers and also in civilians is frequently met with. It is usually associated with nervo-vascular disorders, with over-action of the heart and sometimes conditions of asystole. Two chief factors are supposed to underlie these conditions of cardiopathy; the first of these is excessive fatigue when the heart and other portions of the body are not accustomed to over-exertion, particularly if the fatigue is continued over a considerable period of time. Probably in these cases there is both dilatation and hypertrophy. Other causes which have been considered as pathogenic have been grouped together in three theories; the first theory is the mechanical one which expresses the belief that the condition of the heart is solely produced by the mechanical strain thrown upon it; the second, or the chemic theory, rests upon the opinion that the excessive labor produces a toxemia which acts deleteriously upon the heart; and the third theory is that there is an inflammation of this viscus. Certain it is that in a number of cases there is an excessive accumulation of blood in the right cavities and in the venous circulation, associated with insufficient oxidation of the blood and the constant accumulation of poisonous materials in this fluid. Thus SEITZ and CURSHMANN believe that the accumulation of sarcolactic acid and carbolic acid is very considerable under these circumstances and in addition we must remember that the valves of the heart are strained by such excessive endeavors. It is supposed by some French authorities that the accumulation of these products exercises a very deleterious influence upon the tissues, an influence similar to that produced by the poison of typhoid fever. The symptoms of heart-strain have been divided by other authors into several classes: First, those in which there is arrhythmia, palpitation or intermittence. Second, those in which there is congestion, hyperemia, myocarditis, hypertrophy, dilatation and fleeting valvular murmurs. Third, those in which there is a myocarditis and endocarditis definitely developed, with permanent murmurs and marked cardiac feebleness. Associated with these symptoms we find in the first class loss of appetite and weight, that the patient is pale, and easily fatigued, has various pains darting and otherwise, and altogether is in a condition of asthenia. In the second class, for the more grave forms that we have men-

tioned the lassitude is extreme; there is pain in the muscles and in the joints, and general depression; digestion is embarrassed; the tongue is coated; the patient is sleepy, has a poor memory and a feeble walk, and dislikes exertion. There may also be precordial pain, some edema about the ankles, with albuminuria and even a slight degree of fever, with dyspnea and small pulse and profound adynamia. Murmurs can be heard in the heart and are usually widely diffused.

The treatment of such functional troubles consists in absolute rest, the use of cardiac tonics and an exceedingly gradual return to active muscular movements.

RECENT INNOVATIONS IN MEDICAL INSTRUCTION.

The last generation has witnessed marvelous advances in methods of medical instruction, practical demonstrations having gradually displaced merely didactic teaching, and laboratory and clinical work superseding wherever possible the ordinary lecture. Within this period of time too the various special departments of medicine have grown up and the demands upon student and teacher are today much greater than ever. The obviously crowded state of the profession, the lengthening of the period of study, the requirement of State examination and other considerations of allied character seem not to deter increasingly large numbers from taking up the study of medicine and the continual organization of new institutions of teaching.

The medical profession of the United States owes a debt of gratitude to the city of Philadelphia for a number of reasons. In the first place, Philadelphia is the birth-place of the AMERICAN MEDICAL ASSOCIATION. That city has besides furnished some of the most brilliant names in the annals of American medicine, and indirectly through its schools it has provided the country at large with a considerable number of able, conscientious and faithful practitioners and teachers. Philadelphia has also contributed very generously to medical literature. More recently it has distinguished itself by the introduction of several new features in medical education, of which we shall speak briefly.

To the observant critic it will be admitted that the true spirit of medical progress still holds sway in Philadelphia. Though a number of other cities have entered into active competition for the first place Philadelphia still occupies a leading position as a medical center. Her publishing houses turn out annually more medical works than do those of other cities; her medical men write as liberally, if not more liberally, than the medical men of other cities; her medical schools stand upon the highest educational plane and their graduates compare favorably with those of other schools; her College of Physicians possesses, next to the Office of the Surgeon-General of the United States Army, the largest medical library in

this country; and finally she has not been backward in original investigation. The occasion seems opportune to speak of a few of these things. In this connection we would refer first to some facts in connection with the development of the University of Pennsylvania in the past decade. Each year sees the organization of new departments, the extension and strengthening of old courses and the erection of additional buildings in response to the increased demands for a higher and still higher plane of general and medical education. The University possesses one of the first laboratories of hygiene established in the United States, which is doing excellent work both on its own account and in the education of hygienists who take up similar work in other institutions and in other cities. From the only recently established Pepper Laboratory of Medicine a series of original investigations is emanating and a corps of scientific investigators is developing that promise to do credit alike to Philadelphia and to the entire medical profession. All of the other Philadelphia medical colleges also have made strides, as evidenced by the erection of new buildings, the establishment of new courses and the lengthening of the period of study and of collegiate attendance, etc.

In post-graduate instruction also Philadelphia occupies an enviable position. Her Polyclinic, with its large hospital and enormous dispensary service, its numerous corps of instructors and its wide range of facilities, is affording an opportunity to graduates in medicine that will in time remove all excuse for want of expertness on the part of any practitioner in any branch of medicine, however remote from the so-called medical centers. Two innovations recently introduced by this institution seem deserving of especial notice. The one consists in the establishment of an instructorship for anesthesia and the appointment of a competent official anesthetizer whose duty it shall be to administer anesthesia whenever necessary and to instruct the student physicians and resident physicians in the practical application of this important procedure, as well as in methods of resuscitation, etc. Of the deaths and other accidents that occur during or following the administration of anesthetics a certain number at least must be attributed to faulty administration from want of training and practical knowledge on the part of the anesthetizer, perhaps sometimes from inattention and carelessness. The placing of this indispensable therapeutic procedure upon a legitimate and dignified basis commensurate with its importance and the recognition of the responsibilities attached to it, as exemplified by this action of the Polyclinic, will without question do something to make anesthesia safer, simpler and even more useful than it has been. The second innovation made by this school consists in the establishment of a lectureship for defects of speech, probably the first department of its kind in the United States, if not in

the world, with clinical facilities, etc., and the appointment as lecturer of one especially fitted by training and experience for this special work. The profound influence that speech defects are capable of exerting upon the life and usefulness of an individual is so obvious as scarcely to require elaboration at this place. Some of these defects are due to anatomic causes; others are of purely functional character. In both groups of cases intelligent training and persevering education, preceded if need be in the one group by appropriate manipulative or surgical interference, are capable of yielding remarkable results, as has already been demonstrated. The placing of this subject in this manner upon a proper scientific basis must be viewed as a distinct advance in medical education.

In Roentgen photography excellent work is being done in Philadelphia and students are afforded the opportunity of receiving instruction in diagnosis by this new means. Many of the hospitals possess their own equipment, and ready and willing assistants demonstrate daily the practical utility of this most important discovery. In the laboratory of the Philadelphia Polyclinic the presence of particles of steel in the vitreous body has for the first time, we believe, been detected with the aid of the X-rays. In the University of Pennsylvania improved methods have resulted in vastly shortening the period of exposure, so that skiagraphs can be made almost with the same readiness and celerity as ordinary photographs, and some important original observations upon the physical nature of the rays have been made.

The few facts thus somewhat indiscriminately thrown together will tend to show that Philadelphia, while not aspiring to metropolitan distinction, still holds a foremost place in the matter of medical education and sustains her established position as a medical center. That this is not mere idle boast we feel sure the coming semi-centennial anniversary of the AMERICAN MEDICAL ASSOCIATION will amply show. The welcome of a mother to a long-absent child is not more cordial than will be that of Philadelphia for the members of the ASSOCIATION that was organized in her midst fifty years ago and in whose welfare and advancement many Philadelphians have maintained an active and consistent interest. The members of the AMERICAN MEDICAL ASSOCIATION may rest assured that at the coming meeting in Philadelphia they will be made to feel not only that they are not among strangers, but that they are the welcome guests of brothers and sisters in one large harmonious family.

In addition to the regular sessions of the ASSOCIATION and the usual entertainments steps are being taken to provide a series of clinical and post-graduate demonstrations during the week preceding and that following the meeting. All in all, the coming reunion promises to be the most notable in the history of the ASSOCIATION.

COMPARATIVE ANATOMY EXHIBITS IN WASHINGTON.

No other place in the country has a finer collection of specimens illustrating the morphologic representation of form met with in the organization of the animal body than is to be found in the museums of the National capital. Disciplinary scholastic requirements now place zoöotomy side by side with anthropotomy, and the student of the present, whether intending or commenced, can not ignore the practical relativity of these two branches to the science of medicine. By way of preliminary work, most tutors agree that one's anatomic foundation should begin at least with the amphioxus and ascend the zoölogical scale. Indeed, one of the best German anatomists averred to the writer that a medical student should not attempt the human skeleton until he is thoroughly familiar with the osteology of the alligator. We may say further, that he should go back to the remotest physical basis of life; thence working up to the vertebrates, and through the embryology of the horse, for instance, he may gain sufficient insight into the phenomena of ontogeny and thereby acquire a training in the healthy use of his speculative faculties that shall enable him to begin to investigate the material substratum of the human body. Another claim for the study of the comparison of the organization of animals with that of man, is that it develops common sense and fixes the scientific habit of mind.

Properly speaking, the special domain of compared anatomy lies in the comparison of apparatus and organs in the series of beings, as well as the comparison of animals among themselves and with man. Being the foundation of all zoölogic classification, it has come to be recognized that the character of any good distribution of animals should be drawn from the particulars of their organic make-up rather than from any other consideration. Thus we have come to define the whale as a quadruped. Though fish-like and of essentially aquatic habits this animal is a mammal, has rudimentary femurs, a four-chambered heart, and the blood globules common to quadrupeds.

In addition to the aid to the anatomist in studying the organs in the series of transformations throughout the animal kingdom, physiology draws useful deductions from this study, and the comparative method also teaches that ideas formed at first sight often require to be reformed; for instance, the notion derived from human anatomy that serous membranes are shut sacs does not hold good in other animals, for the peritoneum, pericardium and pleura are not always closed sacs, as we see in some of the animal series where the texture and epiclial investment of these membranes are more essential characters than their imperforation.

The display of stuffed specimens in the National

Museum, though quite complete and intended for pedagogic purposes, is more useful to the zoölogist than the anatomist. It is rather to the osteologic exhibition that we turn for comparative purposes. Here one finds ample materials for studying the osseous system paleontologically and otherwise in the faithful images of organs represented by saurians from Pennsylvania marl pits, mammoth remains from Alaskan ice cliffs, along with most of the existing forms, upon all of which are impressed constancy of type and variety in modification.

The study and arrangement of many of these objects of biologic interest leads to the diverse paths of correlation and subordination of development, analogies and homologies, to transcendental anatomy, and to other convenient abstractions that the classification of the sciences has rendered necessary.

It is to be regretted that there is no positive fixed classification of these collections nor even a short descriptive catalogue to point out to the student even in a conjectural way the connection of many of the groups to other branches of science. Perhaps the authorities in charge of the collection may look upon the material as that of a building which there is no immediate need to begin for fear of having to tear it down later owing to vicious or faulty construction. Say what we may, however, as to the utility of such collections and of the questions of induction and generalization they introduce into science, the practical physician sees that the consideration of many things in comparative anatomy touch upon points of embryology, therapeutics and toxicology.

Without going into details we know that many of the lower order of animals are subject to the same diseases as the human species. Monkeys and other animals have rickets in confinement, while tubercle is common in pigs and cows. Among the specimens of the Army Medical Museum are the head of hydrocephalic calf, an osteo-sarcoma from a bull and from a horse, and a large collection of urinary calculi from the latter animal. There is also a series of cancer specimens from the dog; a horse stomach showing rupture and parasites; the heart of a horse with cardiac hypertrophy, and the mesenteric artery of a horse showing verminous aneurysm.

Nor is the question of immunity without a ray of filiation to the subject in hand. Recent bacteriologic experiments show the immunity of animals to typhoid fever; some are susceptible to anthrax as mice, but rats are exempt; tubercle is extremely rare in sheep, goats, horses, asses, and in most animals of active habits; guinea pigs are most refractory to pneumonia; rats, mice, guinea-pigs and rabbits succumb to plague, but pigeons do not, though this has been questioned; glanders and farcy are communicable from horse to man; and tumors in animals are histologically identical even in fishes.

We therefore can not survey the great field of biologic science without seeing how such ideas as the foregoing bear upon medicine both theoretically and practically, and how they have helped to shape the mind of the great exponents of evolution as well as that of the humble practitioner.

HYPNOTIC INFLUENCE AND CRIME.

About two years ago, there was tried in the State of Kansas a case that excited considerable general interest through the country, inasmuch as it was one of the first in which the plea of hypnotic influence had been employed by the prosecution in the criminal courts. The result made it still more notable; instead of the plea being ruled out by the court, it was employed with such effect that the prisoner was convicted and sentenced to death for "suggesting murder," while the actual homicide, whose trial came later, was acquitted. It is said that the frequently repeated assertion of the prosecuting attorney that "this big man, ANDERSON GRAY, had a hypnotic influence over this little boy," frequently repeated, though with no more basis of truth than any other possible invention of an unscrupulous lawyer, had such an effect as to carry away the imagination of the jurymen and to bend all evidence in this direction.

The case attracted much attention at the time and was variously commented on, though generally with condemnation, as an extreme application of a theory not even generally accepted by those competent to judge its worth. Hypnotism was then still in the stage of a popular fad, though medical interest in it was on the decline, and these Kansas farmers doubtless felt that they had the support of scientific opinion in their verdict. It was an excellent example of the truth of the adage that a little knowledge is a dangerous thing, and that Kansas was saved the disgrace of a judicial murder is only due to the delays in the carrying out of the verdict. The victim's friends were active, the public gradually realized that an unwise thing had been done, and to complete the case, the leading witness for the prosecution, the actual homicide, who had been acquitted of the murder on the ground of self-defense and not apparently on that of hypnotic influence, finally confessed that he and his wife had given false testimony, and the last act of the late retiring Governor MORRILL, was to sign a pardon of the innocent victim of pseudo-science.

The case is a hard one for the unfortunate who has been deprived of liberty and fortune and has been so long under an unmerited stigma of murder. It has its public use, however, as an example of what ought not to be done, a warning against the unscrupulous and ignorant use of medical facts and theories in cases involving human life and liberty. If GRAY had been executed, perhaps the moral would have been the same in the end, but there would have been then

more of a tendency to suppress the facts, and some of them might never have come to light in such a way as to demonstrate, as has now been done, the absolute falsity and fatuity of the hypnotic plea. It seems hardly creditable to the Kansas administration of justice that one man could be convicted on the plea of having exercised hypnotic influence for causing a crime, and the party whom it was claimed was thus influenced be afterward acquitted on entirely different grounds, without apparently any stress being laid on the alleged fact that was the sole or principal issue in the earlier trial, and without, at least, a prompt reversal or pardon.

In our editorial of February 16, 1895, commenting on this case the JOURNAL said:

"It will be seen, therefore, that no new psychical elements are introduced into the problem, but the old ones of criminal surroundings and environment which furnish the motive for the commission of all crimes. The logical deduction from these premises is that hypnotism as a defense for crime can have no standing in a court of law; that the commission of crime is as much determined by the moral character of the individual in a hypnotic state as it is in his waking moments."

The sequel of the GRAY case is a striking corroboration of the correctness of our views expressed at the time.

The result will be to discredit future resort to the plea of hypnotic influence as an accusation or a defense, and for this the country is the better off. It lessens the chance of what might be, if certain extreme theorists were to be believed and their views accepted by the courts and the public, a real danger in the administration of justice. It may be that this peril is a very remote one, and that we have safely passed the second cycle of human credulity as to hypnotism; but the outcome is fortunate nevertheless.

A NEW MOTTO FOR THE "RECORD."

The *Record* in a belated article on the Wisconsin Eclectic Medical College proposes a new motto: "Let us have no Diploma Mills in the Capital City of the AMERICAN MEDICAL ASSOCIATION." The *Record* is entirely welcome to any kind of a motto its Editor thinks he needs. Our valiant friend always does better when he has some back-number literature to fight about, and if a motto of this kind is essential to greater New York and the still greater SHRADY, let him print it in red ink at the head of his columns and sail right in. By the way, we printed last week a full account of the downfall of "Dr." RUTLAND and his bogus college, and several times we have published exposures of RUTLAND'S mill, but the *Record* did not find it out until the matter had ceased to be news to everybody but the unfortunate readers of the *Record*.

One other charming custom of our sweet and graceful contemporary is the confidence game it continues to play upon its patrons by the announcement "[seventy-six pages in this number]" constantly

displayed on its front page. In the number for February thirteenth, we notice that forty of the alleged "seventy-six pages in this number" were advertisements, of the publishing firm owning the *Record* and others. The poor old thing is apparently compelled to resort to desperate straits—nothing suits it—it frets about the editorials in this JOURNAL, about the Code, about Secretary ATKINSON, and about other matters. In fact we are beginning to think, and the thought pains us beyond expression, that we are not suiting the *Record*; that the ASSOCIATION itself will fall under its once mighty displeasure if something is not done quickly to quiet its nerve.

"Quick! Some civet, good apothecary!"

THE MISSION OF THE "MEDICAL RECORD."

The persistent attacks of the *Medical Record* of New York upon the AMERICAN MEDICAL ASSOCIATION, lead us to look into the matter, with a view of determining the motive underlying them, and taking the most reasonable explanation of its course that offers, we are impelled to the conclusion that the *Record*, reading the handwriting on the wall, and knowing that the healing of the old dissension on the Code question would make it no longer a potent factor as a leader, deliberately seeks quarrels and promotes discord. Should the New York State Society and the Association heal their differences, and once more come into the AMERICAN MEDICAL ASSOCIATION, there would be no market for the embroiling paragraphs of the *Medical Record*, and its peculiar mission as a promoter of discord and dissension would be ended. This is contrary to the business interests of the manufacturers of the *Record*, and consequently we observe ebullitions from time to time in the columns of our great and frequently good contemporary. We have been told that the editorial sanctum of the *Record* was usually kept at a temperature of -13° F., but when some trembling slave of the mighty incumbent, through inadvertence, mentioned the name of the ASSOCIATION, the air became blue with exclamation points, and the temperature rose to 212° F., with incredible speed.

ACCESSION TO THE NEWBERRY LIBRARY.

Prof. NICHOLAS SENN on Saturday last cabled to Berlin a telegram authorizing the shipment to the Newberry Library of the entire collection of the late Prof. DUBOIS-REYMOND of Berlin. This collection consists of 14,000 bound books, mostly on physiology, and a proportionate number of pamphlets.

It will be remembered that the former generous donation of Professor SENN to this library consisted of the BAUM Library mostly surgical. This will add to the SENN collection a complete physiologic library equaled probably by few if any in the United States,

and it goes a long way toward putting the Newberry in the front rank of medical libraries.

The generous act of Professor SENN is one which will still further entitle him to the gratitude of the medical profession of Chicago and indeed of the profession in general, for bringing these two famous collections to America.

THE MAYORALTY CONTEST IN CHICAGO.

The Democratic platform says among other things: "We condemn the appointment of health commissioners made by the present Republican administration and declare for the selection of a physician to fill such office." The Republican candidate for mayor says that he will not appoint any incompetent person to any office. So that it is not at all probable that the lay-commissioner-business-man health officer will be a factor in the affairs of the city government after May 1, 1897.

TRANSACTIONS AND JOURNALS WANTED.

We have an inquiry from Berlin asking rate at which we can supply a complete set each of 1, The Transactions of the AMERICAN MEDICAL ASSOCIATION; 2, JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. Any of our readers having a complete set of either for sale, will confer a favor by addressing this office and naming price.

CORRESPONDENCE.

Acute Otitis Media.

CHICAGO, March 16, 1897.

To the Editor:—In the JOURNAL of Feb. 27, 1897, a paper appeared on "Otitis Media" by Merrill Hopkinson, M.D., of Baltimore. After having favorably referred to Dr. Pierce's paper on this subject (JOURNAL Dec. 19, 1896) he disagrees with the latter especially as regards treatment, on account of an experience he had in his own person. Dr. Hopkinson was suffering from an acute otitis media produced by using a nasal douche in a "mild attack of post-nasal catarrh." Dr. H. should have known of the violent protests against the use of the nasal douche in every little affection of the nose. The only one indication for this procedure is the removal of crusts in ozena. Even there it is not fair to let a patient use it until the physician is perfectly convinced that it is well applied. After the douche the nose should be cleared only by snuffing the crusts back into the pharynx and spitting them out, never by blowing; this produces only negative, not positive, pressure in the nose and nasopharynx.

In consequence of this 50 per cent. glycothymolin douche an inflammation of the middle ear made a hasty appearance, which the doctor tried to check with instillations of cocain and atropin. What was the reason for this? Did he expect that these drugs would be absorbed through the epidermis of the external meatus? And even if they were, would he expect any antiseptic effect from them in the middle ear? Do we not have to add antiseptics to either one of these solutions in order to keep bacteria from growing in them? Or perhaps he thought of the anodyne effect and stoppage of secretions, attributed to these two drugs by some people who wrongly infer that they produce the same results in infected tissues and inflamed mucous membranes which they produce in healthy tissues. Even

if they would stop the secretion, is that not just the opposite from what we want? Or does the Doctor not prescribe an expectorant in cold of the lungs or nose, where the secretion is thick and dry, and does he not remember the relief a free secretion brings? In acute otitis media the great ease after paracentesis is equally produced by the abundant secretion.

The only reason for the use of cocain and atropin in otitis is therefore compliance with the well-known maxim *ut aliquid fiat*.

A little worse must be said about the advice of Dr. Chisolm, who being opposed to the use of ice, instructed Dr. Hopkinson to syringe the external meatus with hot solution of mercuric chlorid, 1 to 1000. The heat may have been agreeable to the patient at the moment it was applied, but it certainly did not have the desired effect on the course of the inflammation. Ice would have been better, though less agreeable. Furthermore, the irritation and stirring caused by ten or twelve injections daily is surely not beneficial. Does not the Doctor notice that we are giving up this terrible active treatment of acute inflammations, wherever they are located, in favor of complete rest; for example, in peritonitis, lymphangitis of limbs, etc. And finally, what effect should the bichlorid have? The best of it is that it is not absorbed. But it involves danger. A perforation of the membrane in acute otitis may happen at any moment, and then a bichlorid solution, 1 to 1000, is forced into the middle ear. What oculist would use such a solution in conjunctivitis of the eyes, and the mucous membrane of the ear is much more tender than the conjunctiva. Mind, I do not speak of old badly infected suppurations and necrotic processes, where the deepest structures of the membranes are altered and the sensitiveness lowered to almost nothing, but of acute inflammation, and there a bichlorid solution, 1 to 1000, can do only great harm. Furthermore, such a solution has a tendency to produce fibrous thickening of the membrane, which we have so much reason to avoid, since the function of the ear depends greatly upon the perfect elasticity of a great part of this membrane. All these facts have been discussed time and time again. But yet another proof that the Doctor is not quite familiar with the literature of ear diseases, is the name of "modified Politzerization" which he gives to inflating the ear by grasping the nose and blowing. This is called Valsalva's method in English, American, German, French and Italian otologic literature, from Dr. Valsalva, who described Dr. Hopkinson's "modified Politzerization" some two hundred years ago.

Later on the Doctor expresses his satisfaction with the effect pilocarpin had on him. Against this there is nothing to be said. Undoubtedly, it was one of the best things to use under the circumstances. Yet we can not help admiring his logic; he is scared of morphin and uses another more dangerous alkaloid, the pilocarpin. A Turkish bath or a hot stove and a hot bed with some hot tea or other drink would have brought about the same result. Why use a sledge hammer to kill a louse?

But the emphasis the Doctor lays upon the injunction to perform paracentesis has absolutely no reason. Yet I do not think that I can convince him. It seems that it must be easier to drive a nail in the hardest rock of the Rocky Mountains than to convince the Doctor of this error of his treatment, although it caused him much trouble and pain, which he might have avoided. All I feel bound to do is to describe the treatment as it is advised by common sense, and taught in literature by Gradenigo and Bezold and endorsed by a number of American and English writers. As soon as the diagnosis is made, the external meatus should be syringed with boric acid solution. With a well disinfected paracentesis knife a paracentesis should be made in the posterior half of the membrane, down nearly to its margin. The authorities are explicit in demanding that every general practitioner be able to perform this little operation. This may be followed by one careful inflation, then dry-

ing of the meatus and packing it gently with iodoform gauze, which may be changed once or twice every day. Ice is indicated when there is tenderness of the mastoid process. The patient feels great relief after an hour or two, when free secretion sets in. He usually sleeps soundly the first and every following night. The success is so general that, if it does not ensue, the perforation must be too small or there are complications. Should the perforation close before the symptoms have disappeared, paracentesis is repeated. As soon as the inflammation has ceased the opening will close without leaving any trace, and hearing is restored after six or ten days. Against the one experience of Dr. Hopkinson I can produce dozens of my own histories and hundreds from literature. The advice of free drainage of every acute gathering of pus is as useful in the ear as elsewhere. Why should we always go back and rely upon unsafe medical means, to repeat again and again every unsatisfactory experience? Why not at once use simple surgical treatment for such a typically surgical disease as acute otitis media? Why expose our patients to all the bad consequences that a retention of products of inflammation may bring about?

Respectfully,

J. HOLINGER, M.D.

PERU, IND., March 16, 1897.

To the Editor:—In my comments on the treatment of "acute otitis media," in the last issue of the JOURNAL, March 13, the clause reading "which would have *burned* the moisture, etc., should have read: which would have *lessened* the moisture, etc. In the same issue Dr. W. H. Daly of Pittsburg, Pa., gives instructions about blowing the nose, following the use of the nasal-douche, etc. "To blow one side of the nose only at a time."

I would suggest that the only efficient way of blowing the nose after the use of the douche, etc., as well as other times, is to simply *blow forcibly without holding either side*, on the same principle that you expectorate without holding the mouth. To be convinced of the truthfulness of this statement, you have only to follow out the above suggestion.

J. O. MALSBUY, M.D.

Respiration and Phthisis.

OTTAWA, ONT., March 6, 1897.

To the Editor:—Will you kindly give space to the following in an early issue and thus aid in this important work? Without the coöperation of the leading medical journals nothing can be accomplished in that behalf. Trusting you will so favor, I may hereby thank you in advance, and am, sir,

Very truly yours, EDWARD PLAYTER, M.D.

To Members of the Medical Profession, Individually—in the Interest of Medical Science:—

As there is evidence tending to prove the theory that all persons predisposed by heredity to consumption have a respiratory capacity or action insufficient for good vigorous health, probably a proportionately small chest with insufficiency of lung membrane, that the predisposition is mainly or primarily due to this cause; in other words, that the insufficient respiratory function is the special primary feature of the predisposition (a condition which may be, practically, acquired by habit, occupation, etc.), I desire the coöperation of the profession in an endeavor to help to establish by means of collective investigations, the correctness or otherwise, of this theory.

In this behalf I hereby ask all physicians who have patients predisposed to, or in the early stage of, consumption, to send to me on a post card (will suffice), the information below indicated. As soon as I can study and collate the replies I shall make the results known to the profession.

Give 1, name (or initials); 2, sex; 3, age; 4, occupation; 5, height; 6, weight (average, when in usual state of health); 7, circumference of the chest on a level with sixth costo-sternal articulation when momentarily at rest after an ordinary expiration, and also 8, after habitual natural expansion or inspiration (which last usually exceeds the first measurement, expiration, 7, by an increase of only about one-fourth of an inch);

finally, 9, the circumference after a *forced* expiration, and also 10, after a forced inspiration (these two measurements, 9 and 10, varying or showing a range of from 1½ to 4 inches). The patient should be as calm as possible and had better, usually, practice the *forced* breathing for a few acts before these two last measurements, 9 and 10, are taken.

To be of value, all four measurements should be taken as carefully, accurately and free from haste as possible.

Any further information, in brief, as to the degree of heredity (family history) in cases, prominent symptoms, loss in weight, cough, dulness on percussion, etc., etc., or any remarks, will be a decided advantage.

Measurements of two cases, or several, on the average, could be given on one card.

With the hope that many will comply with the above request, and with much respect for and interest in the profession, I am,

Yours truly,

EDWARD PLAYTER, M.D.

"Devil on Two Sticks."

CHICAGO, March 5, 1897.

To the Editor:—Is this an authentic quotation of a book published in 1768? As you are an authority on these matters I ask you.

Cordially yours,

E. J. DOERING, M.D.

FOOTE, "DEVIL ON TWO STICKS" 1768.

Hellebore: "I have discovered the primary cause of all distempers incidental to the human machine. And these, brethren, I attribute to certain animalculæ or piscatory entities, that insinuate themselves thro' the pores into the blood and in that fluid sport, toss and tumble about like mackerel or codfish in the great deep."

Yours,

WILL.

Feb. 24, 1897.

"This piece consisted of nothing more than the introduction of several well-known characters in real life, whose manner of conversation and expression this author had very happily hit in the diction of his drama, and still more happily represented on the stage by an exact and most amazing imitation, not only of the manner and tone of voice, but even of the very persons, of those whom he intended to *take off*. Among these characters there was in particular a certain physician, who was much better known from the oddity and singularity of his appearance and conversation, than from his eminence in the practice of his profession. The celebrated Chevalier Taylor, the oculist, who was at that time in the height of his vogue and popularity, was also another object of Mr. Foote's mimicry and ridicule."—From article upon Samuel Foote, in Baker's "Biographica Dramatica," vol. I, part 1.

Samuel Foote actor and dramatic author, born 1720, died 1777. The character of "Hellebore" was one assumed by the Devil.

Le Sage also wrote a novel with the same title. Of course there was nothing new in Hellebore's suggestion, as Redi a century before had announced it and Vitruvius the Roman architect came very near it, in advising that houses be built away from swamps so as to avoid the exhalations from the "fenny animals."

Ophthalmia Neonatorum.

PITTSBURGH, PA., March 8, 1897.

To the Editor:—Recently I had a case of ophthalmia neonatorum in which only the left eye was affected. This has never occurred in my practice before. The disease has always affected both eyes and this is the reason I report the case. My treatment for this disease is first to wash the eyes out well with warm water by means of a small wad of medicated cotton followed by a wash of muriat. ammon. gr. vi, bichlorid. hydrarg. gr. j. aquæ dest. ꝑvi. M. Sig. A teaspoonful in a teaspoonful of boiling water, immediately followed by a 20 grain solution of argentum nitrate and then by a saturated solution of chlorid of sodium. This is repeated every three or four hours. Once a day or once in two days I apply a drop or two of the solution of sulphate of atropia I grain to the ounce of distilled water. My cases have always rapidly recovered

under this treatment. If we have reason to believe that the disease is of a specific nature then small doses of calomel may be given.

JOHN M. BATTEN, M.D.

Sequela of Measles.

TIVERTON, R. I., March 13, 1897.

To the Editor:—Are measles followed as a sequela by acute or chronic articular rheumatism?

A case: W. H., exposed to measles came down sick Monday, March 1; eruption that evening. Friday or Saturday March 5 or 6, pain in joints developing articular rheumatism; at present time improving, but not able to leave bed except as removed by attendants. Query: Would W. H. have had the rheumatic attack now if he had not had measles or is it dependent upon the peculiar poison of measles. I should like the experience of the profession upon this point.

Respectfully,

E. P. STIMSON, M.D.

PUBLIC HEALTH.

Infection from Pork.—An epidemic that affected fifty persons and caused one death was investigated by the authorities, and no toxic substance was found in the suspected pork, but bacteriologic tests showed the presence of a bacillus, evidently the specific bacillus of the pneumo-enteritis of the pig. It was not found in the fecal matter of the patients, but the bacterium coli was found in them in a very virulent form. An epidemic of hog cholera had been prevailing in the district just before, and one farmer had sold fifty-seven pigs, forty-one of which had died of the disease. The meat that had been found too much diseased to be offered for sale had been buried at a slight depth, instead of being burned, and no precautions had been taken to isolate the diseased animals. Pouchet, who reports the circumstance, adds that it is the first time that bacteriologic investigation has been applied in such a case.—*Semaine Méd.*, February 13.

The Vaccination Laws of Europe.—Dr. Thorne Thorne, C.B., principal medical officer of the Local Government Board, returned to London last week after his visit to Paris and Brussels to study the means of vaccination at both capitals. Dr. Thorne Thorne, who was accompanied by Dr. Monckton Copeman, first visited Paris and was given every facility for inquiry by the professors of the Institut Vaccinal affiliated to the municipality of Paris, and the Académie de Médecine, where vaccine lymph is distributed gratuitously after admixture with glycerin, throughout the whole of France at the expense of the state. A visit was afterward made to Brussels, where the state institution, the École de Médecine Vétérinaire, and Dr. Janssen's vaccination department under the municipality of Brussels, were visited. Visits have also been made to certain stations in Germany, one of the late issues of the *Lancet* having a report of one to Berlin. The result of these investigations, caused no doubt by the report and recommendations of the Royal Vaccination Commission, may be pretty confidently forecast, namely, the gradual discontinuance of the old English method of Jennerian arm-to-arm vaccination (very little bovine virus having at any time been officially employed in Great Britain) and the substitution therefor of the more modern methods and material. It is evident that there is a more promising future before the forms of glycerinated vaccine, if it be true as has been stated regarding the new lymph of the New York City Department of Health, that it is possible to report 1,500 consecutive primary vaccinations with the new agent without one failure.

Bacterial Purification of Potable Waters.—The London correspondent of the *American Practitioner and News* refers to some recent researches of Dr. Percy Frankland, F.R.S. He has discoursed to the Institute of Civil Engineers on bacte-

rial water purification. The discussion which followed centered round the importance to be attributed to Koch's arbitrary standard that a so-called "good" water should not contain more than one hundred microbes per cubic centimeter. Dr. Frankland pointed out that this statement of Dr. Koch's was made in the infant days of bacterial investigation, and no serious meaning could be attached to it now. He reminded the assembly that many years ago he showed how, on keeping a sample of the very purest drinking-water obtainable, the original microbes present could increase to hundreds of thousands, and that yet no one would venture to condemn this water. Dr. Percy Frankland described some experiments he made recently with typhoid germs, in which he had introduced some of these microbes into deep well water, which was almost free from bacteria, into Thames water, which contained a large number, and into Loch Katrine water, in which the number was intermediate between these two. He found that the typhoid bacilli died off more rapidly in the Thames water than in that from Loch Katrine, while they persisted longest in the sparsely populated deep well water. Thus the longevity of these disease germs was inversely proportional to the bacterial population of the waters into which they were introduced.

Defense of Europe Against the Plague.—The immediate necessity of an international organization to prevent the spread of the plague is ably presented by A. Proust, Inspector General of the Sanitary Service, in an address reported in the *Bulletin de l'Acad. de Méd.*, January 26. The dangers to the rest of the world that have come with more rapid transportation and especially the Trans-Caspian railroad and steamboat route, render prompt organization of the powers necessary, and it is worse than useless to leave the task of arresting the plague to the Oriental nations, or even to comply with their wishes and entrust the frontier posts to Mussulmen physicians. Realizing the almost inevitable spread of the contagion during the annual Mussulman pilgrimages to Mecca, the French government has absolutely forbidden anyone to go from Algiers and Tunis this spring, and the Egyptian government has also announced that no one can go from Egypt unless he can prove that he has sufficient money to pay his expenses for six to eight months in the Hedjaz, and if the plague breaks out there he will not be allowed to return to Egypt. If the pilgrims did not arrive in such an enfeebled condition they would be less liable to contract disease. They are crowded on the steamers so closely that it is impossible for them to lie down, and after landing they usually sleep at night on the bare ground in the midst of miasmas and exposed to severe cold, while scorched by the sun during the day. The food and water are both bad and sold at exorbitant rates. It is politically and practically impossible to put an end to these pilgrimages, but the conditions might be made more hygienic, and Proust urges the powers to combine for this purpose, observing that the more we do for the pilgrim the less we shall have to do against him. Like all who refer to the subject, he condemns the apathy of England, who, for political and commercial reasons, refuses to allow sanitary surveillance along the Persian Gulf, where the danger to Europe is most imminent, while she sanctions the most rigorous quarantine at Malta and Gibraltar, where there is comparatively little to fear.

The Effect of Gaseous Aeration of Water on Bacteria.—Dr. G. C. Frankland, writing to *Nature*, draws attention to the results of bacteriologic research in determining the hygienic importance, from a bacterial point of view, to be ascribed to the gaseous aeration of water. Notwithstanding the large number of experiments that have from time to time been carried out, considerable divergence of opinion exists as to the precise hygienic value with which the carbonation of water can be credited. Some authorities state that in such waters the number of bacteria steadily declines, whilst others again have observed as

distinct a multiplication of the bacteria present. The possibility of these two contingencies is, however, quite conceivable without impugning the accuracy of the results obtained in either case. In the first place, it has to be remembered that widely different types of water serve for the manufacture of artificial aerated waters, the bacterial contents of which are widely divergent, both qualitatively and quantitatively. It has been shown that whereas some bacteria rapidly disappear in aerated waters, others are again endowed with fabulous powers of reproduction and longevity. Thus in one instance a sample of carbonated water was found to contain, one hour after its manufacture, 8,350 microbes per cubic centimeter; these figures rose, however, after the lapse of 210 days, to the considerable number of 213,400 per c.c.; while later on, at the end of 428 days, there were only 46 per c.c. As regards the behavior of pathogenic bacteria in carbonated waters, the results so far obtained are decidedly more unanimous. There is no doubt that a very general impression prevails that a barrier of no mean obstructive power is placed between the consumer and zymotic disease by the substitution of aerated for ordinary drinking water, at any rate during times of epidemic; and this impression is to a certain extent justified by investigation, though it can at the same time only be encouraged to a moderate extent. Although storage even for such considerable periods of time as over two years can not, at any rate in some cases, secure the entire elimination of ordinary water microbes, yet storage of considerably shorter duration is of undoubted service in the destruction of disease germs.

The Water Supply of Chicago.—The city of Chicago, in spite of the great engineering work that was carried out in 1893, has not yet secured a satisfactory water-supply, and we understand that the Department of Health has considered it necessary to shut off the town water from as many as 250 public schools with an aggregate of 208,000 scholars. The task of making special arrangements for the supply of water upon so large a scale must be a very formidable addition to the duties of the School Board. The first impression of the visitor to the city on looking out upon the broad expanse of Lake Michigan, and learning that it is an inland sea of singularly pure and potable water, is that here at least the question of water-supply is solved by nature, whatever the dimensions or demands of the city may be which stands upon the shore. But, in point of fact, the very abundance of the water is its bane. If a river of moderate dimensions flowed through the city there would be no fear of contamination. The simple expedient of placing the water intake above the sewage outflow would make the city absolutely secure against this peril. But in Lake Michigan the volume of water is so vast that the flow is imperceptibly slow, and so long as any part of the city's sewage is permitted to flow into the lake there will be a danger of its drifting into the water intakes. Experiments have shown that this danger was notably reduced by putting the intake at a distance of three or four miles from the shore; but they also showed that this was no complete protection, and now the experience of the School Board confirms our experimental results and enforces the conclusion that complete isolation of the water supply is the only safe and trustworthy course. Unfortunately for a community residing on the shores of a great lake, it is a course presenting many and special difficulties. In these circumstances it is no small matter that it has a great reputation for enterprise and public spirit to maintain.—*London Lancet*, February 20.

The *Lancet* does not seem to be aware that the great drainage canal is not only not yet completed, but that nobody knows when it will be.—Ed.

The Weather Bureau and Medical Climatology.—A few words may not be out of place in explanation of the following resolutions: From time to time, articles have appeared in the medical press,

pointing out the limitations of our knowledge of climatology and the insufficiency of data, as regards both climatic features and clinical observation, upon which to found a really scientific climato-therapy. In an article, for example, by Dr. James B. Walker, President of the American Climatological Association, appearing in the *American Journal of Medical Sciences*, January, 1897, these points are dwelt upon, and a comparison is made of the thorough study of these matters in Europe, with the somewhat rudimentary knowledge of medical climatology that has been reached in this country. It is to be regretted that all this is, at present, true, but it is well to know that the means are at hand by which this state of affairs may be greatly improved. At the basis of all scientific climato-therapy must lie a thorough and accurate knowledge of climatology; with this alone can we correlate our clinical observations with any hope of evolving therefrom any system of scientific treatment of disease by means of climate. It is the belief of this Society that in the admirable methods and appliances of the Weather Bureau we have, already provided, the means for a well-nigh perfect determination of every climatic feature. Not only is this true, but from the fact that observers at all first-class stations have the same training, the same methods and the same apparatus, and that the element of "personal equation" is eliminated by frequent changes of observers, we are induced to believe that no foreign country is better equipped for the study of its climate. For the above reasons, it is obvious that the meteorologic records of each Western Station are strictly comparable with those of every other station, which can not be the case where independent and diverse methods of observation are in use in various places; and this feature of our Weather Bureau is one of vital importance to successful results.

The accompanying resolutions speak for themselves, but their object can be fully appreciated only by those who have made a study of the statistical tables in the report therein referred to, and it is earnestly hoped that those who read these resolutions may obtain from the Weather Bureau copies of Vol. 1, Signal Service Report, 1885. It is evident that, the object of the resolutions being the adaptation of the accumulated data to the needs of the medical profession, such an end can best be reached through the joint action of a committee of medical men and the Chief of the Weather Bureau, and it would seem appropriate that such a committee be composed of members of the American Climatological Association. To such a committee it may be apparent that certain tables might be omitted or modified and that others might with great advantage be constructed from those to be made on the lines of the existing tables.

It would be a valuable feature of the new volume if it should contain also, under the head of each station, a statistical table of the mean of all observations for the whole term of existence of each station—in other words, its local climate as deduced from all data available.

It also becomes apparent that more first-class stations are needed in order to obtain a complete knowledge of the climatology of the United States, and that special attention should be given to the study of those regions whose climatic features promise most as therapeutic agents in the treatment of disease. It is equally obvious that the value of the proposed volume would be materially enhanced by the incorporation of data regarding the geologic formations, topography, natural drainage, water supply, mineral springs, etc., all of which are matters of importance to be known concerning any point to which an invalid might be sent.

Finally, the volume thus made up should be supplied at a minimum cost to the physicians of the United States, enabling them to properly estimate the value of each special region as a therapeutic agent. The work should be revised and brought up to date every five or ten years, so that the effect, if any, of agencies supposed to be at work to modify the climatic conditions in various localities may be known and guarded against, and more especially, because the data for determination of climate become more reliable as the periods of observation become more extended.

To sum up: The object we have in view is to place within reach of the profession a work on the climatology of the United States, which will be a powerful aid to the attainment of a rational climato-therapy; this to be based on the uniform and admirable data of the Weather Bureau, which data are nearly valueless until properly worked up and tabulated. The last compilation was made in 1885, when both the number of stations and the data were generally insufficient, but even then of great value; if it were repeated now the accumulated data and the new stations would render it still more valuable. If more stations are established and the work brought up to date from time to time we may ultimately attain a complete climatic record of the various portions of this country; if in addition to the

tables proposed, notes concerning topography, soil, water supply, etc., should be added, the volume would be an invaluable handbook for the physician.

Your assistance and influence in this matter is respectfully requested.

J. S. EASTERDAY,

Secretary Bernalillo County Medical Society.

ALBUQUERQUE, New Mexico, Jan. 20, 1897.

THE WEATHER BUREAU IN ITS RELATION TO MEDICAL CLIMATOLOGY.—Resolutions adopted by the Medical Society of Bernalillo County, New Mexico, at the meeting held Jan. 15, 1897.

WHEREAS, This Society is impressed with a sense of the supreme value of the methods and work of the Weather Bureau of the United States, in their relation to the science of medical climatology, as illustrated in the series of statistical tables published in Volume I, Annual Report for 1885 of the Signal Service (now Weather Bureau), said tables embracing all the data bearing upon nearly every meteorologic feature necessary to a complete determination of the climate of many points scattered over the whole of the United States, so far as these data had accumulated up to the date of that report, and

WHEREAS, The value of these tables would be greatly enhanced by working into them the data accumulated in the course of the eleven years which have elapsed since 1885, and a volume of immense value to the medical profession might be produced by appending to these tables, brought up to date, some account of the topography, geologic formation, natural drainage, nature and source of water supply, vicinity of mineral springs, etc., at each station where observations are taken; therefore, be it

Resolved, By the Medical Society of Bernalillo County, New Mexico, that the Chief of the Weather Bureau of the United States be respectfully requested to take this matter into consideration; that the American Climatological Association be requested to cooperate with the Weather Bureau through a committee appointed for that purpose, if mutually agreeable; that copies of these resolutions be transmitted to the Chief of the Weather Bureau, to the Surgeons-General of the Army, Navy, and Marine-Hospital Service, to at least three of the principal medical journals of the United States, to the American Public Health Association and the AMERICAN MEDICAL ASSOCIATION, and to every State medical association in the United States, and their cooperation invited.

Cholera Disseminated by Food Contamination in India.—Mr. E. H. Hankin of the Agra Bacteriologic Station, India, occupies the difficult position of a kind of general bacillus detective for the greater part of the Northern Provinces, being in demand all the way from Calcutta to Bombay. In the *British Medical Journal*, December 26, he narrates how he was called upon to discover the causes for frequent outbreaks of cholera or enteric fever among army officers and other foreign residents, at times and in places where the natives were not attacked.

During the summer of 1896, an unusual number of military officers and European officials have succumbed to cholera and enteric fever in India. Outbreaks have been reported in not less than ten places within a period of a few weeks from the one to which Mr. Hankin was called upon to give his professional attention. Of these cases the cholera microbe was detected in the finger bowl; in another case the enteric microbes occupied this position. In another case the cholera microbe was found in a virulent condition in each of the vessels of water kept in the kitchen for culinary purposes. In most of the cases, however, to the best of my knowledge, the investigation had to be carried out without bacteriologic help. During the same time, as far as cholera is concerned, British soldiers have been remarkably free from infection. To the best of my knowledge, in the whole of the Bengal Command during the present rainy season, cases of cholera among soldiers have only been reported from two stations, and in one at least of these places the infection appears to have been contracted while the men were on the march. I believe this remarkable immunity of the British soldier, as contrasted with the relative liability of the British officer and civilian official, is due to the strenuous efforts now being made by officers of the Army Medical Staff to sanitize the soldiers' cookhouses. The kitchens in India most in need of reform are those attached to the officers' messes of British regiments. These are private institutions not subject to official control. It is high time that officers of the Army Medical Staff should be invited to undertake the task of sanitating these kitchens. It will, I think, be clear from the facts described in this paper, that the complete prevention of cholera is rapidly becoming a matter for specialists. The ordinary mess president is no more a specialist than the average subaltern is an

epicure. Together they produce and consume horrible delicacies that are often a severe strain on the digestion of their guests. This is not an isolated opinion. I find it is a matter of common remark in all parts of India that I have visited. It is as unusual as it is to me unpleasant to go out to dinner and then to criticize the *menu* in this way; but I hope it will be admitted that the occasion is one for plain speaking rather than for ceremony. When dining at an officers' mess the other day I noticed that the soup was putrid: but my hosts, with sturdy appetites bred of healthy exercise, consumed it with perfect content. The whipped cream poured over the apple pie had the abominable taste of dirty dishcloth, noticed, I believe, by no one but myself. My host had heard vaguely of my recent researches; with the result that the next item on the *menu* had the title "crème à la microbe." It was chocolate pudding. After dinner I inspected the mess kitchen. To all appearance it was perfectly clean, and the mess president pointed out to me with pride a long row of enameled iron saucepans with which he had replaced the more usual *degchies*, apparently under the idea that they would be less suitable than the latter for the breeding of microbes. Nine or ten subalterns in this regiment have had enteric within my recollection, so the need of some precautions was obvious; but I very much doubt whether the mess president had chosen the precaution most necessary. Though in many cases, so far as he himself is concerned, the British officer can only be stimulated into sanitary zeal by attendance at a long series of funeral parties, his care of the private soldiers under his charge is altogether admirable. As an example I may quote the following incident: A few cases of enteric occurred among the privates of an artillery detachment. Every possible precaution was at once adopted. A vigorous investigation was at once begun to find the source of the infection. All sorts of things were sent to me for examination. At length I discovered the enteric microbe in water taken from the tap of an iron cistern in the Battery Aërated Water Factory. Observations made at the time tended to show that the water coming from the piped supply that was daily poured into the cistern was free from enteric. Apparently a temporary infection of the water in the cistern had occurred. But why had it persisted? The help of the medical officer in charge of the battery was invoked. On failing to find any obvious reason for the persistence of the infection by questioning the attendants in the factory, he had the cistern emptied. At the bottom and attached to the exit pipe he found a small filter. It was one made by a well-known firm of aërated water machine manufacturers, the use of which is now strictly forbidden, and the existence of which had been overlooked when these filters had been abolished. It was found afterward that the public supply had been temporarily infected with the enteric microbe. The medical officer who investigated the matter is of opinion that the presence of this filter is a probable reason why the consumers of aërated waters from this factory suffered relatively more severely than did other bodies of troops in the station. This case appears to be an apt illustration of the capacity of ordinary filters to act as breeding places for microbes. If the ordinary mess president attempts to improve his kitchen, he is likely to do more harm than good. For instance, he will issue orders that the floor is to be washed every day, instead of once a week. Under existing conditions, cleaning kitchens in Upper India is a dangerous process. Cooking the sahib's dinner is regarded as a somewhat unclean occupation by most natives. Mohammedans do not like it because we eat bacon, and Hindus look askance at the business because we eat beef. For these reasons native cooks in general are of rather low caste and low standing; hence they are apt to stand on what little dignity they have, and consider it beneath them to clean the floors of the kitchens in which they work; consequently the sweeper has to be called in to do the business. In Upper India there are no sewers. The sweeper is a man who fulfils the functions of a sewer; he is apt to carry about outside him what sewers in other countries carry about inside them—namely, dangerous microbes. I have elsewhere published an account of a very clear case in which I proved that the sweeper was introducing cholera microbes into the cookhouse because of his methodical habit of reserving one broom for clean work, such as sweeping out barracks, and another broom for dirty work, such as cleaning out latrines and cookhouses. Those who know India will agree with me that stopping this abominable custom may not be so easy as it appears on the surface. It is possible that the mess president would most readily achieve this object by insisting that the cook should sleep on the kitchen floor, if possible with his head in a *degchie*. The mess president would then have an assurance that he at present lacks that neither the one or the other would be cleaned with the broom that is used for the servants' latrines.

Both in the present paper and elsewhere I have given exam-

ples of the dangers attending the washing of dishcloths in India. I doubt whether in the whole of India there is a mess president or club secretary who has a reasonable certainty that his kitchen dishcloths are not washed in water infected with either cholera or enteric microbes. Unless the mess president can arrange for the sterilization of washed dishcloths, it might be wiser to leave them dirty.

ASSOCIATION NEWS.

Dinner of the Section on Ophthalmology.—The annual dinner of the Section on Ophthalmology of the AMERICAN MEDICAL ASSOCIATION will take place at 7 o'clock on the evening of June 1, 1897, in the Hotel Walton. Gentlemen desiring to be present at this dinner will confer a great favor by sending their names at once to Dr. G. E. de Schweinitz, 1401 Locust Street, Philadelphia, Chairman of the Section on Ophthalmology. The subscription will be \$3.

The Journal Train.—In order that physicians residing in and west of the Mississippi Valley who desire to go on the JOURNAL Train from Chicago may do so, we have perfected arrangements with the Pennsylvania Line for a solid vestibuled train to be run under the auspices of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and to be known as "The JOURNAL Train." It will consist of Pullman sleeping, dining, observation and baggage cars and be run from Chicago to Philadelphia without change. The success of our trip over the Pennsylvania lines, Chicago to Baltimore, in 1895, is assurance that no detail will be omitted that will contribute to the comfort and pleasure of our party en route and the reputation of the company is a guarantee of the perfection of arrangements and the manner in which details will be carried out. The train will leave Chicago about 11 A. M., May 30, and the schedule so arranged that the most interesting portion of the journey will be covered by daylight. After leaving Pittsburg the train will pass by the iron and coke industries of Western Pennsylvania, through historic Johnstown, where traces of the memorable flood are still noticeable, around the famous Horse Shoe Curve, across the Allegheny Mountains at a point where the scenery is magnificent. Excursionists will enjoy a fine view of the grand panorama as they are carried down the eastern slope of this romantic mountain range. The journey for miles will be along the blue Juniata. The Susquehanna River will be crossed just before the train rolls into Harrisburg, from which point the trip will be through the rich farming country of the eastern portion of Pennsylvania. About 12 o'clock, noon, we will be landed in the magnificent Broad Street Station of the Pennsylvania Railroad, located in the heart of the Quaker City. Applications for sleeping-car space may be made direct to H. R. Dering, Assistant General Passenger Agent, 248 South Clark Street, Chicago, Ill., or to any local agent on the Pennsylvania Line. Correspondence is invited.

NECROLOGY.

PETER DIRCK KEYSER, A. M., M.D., formerly professor of ophthalmology and dean of the faculty of the Medico-Chirurgical College of Philadelphia, died of pneumonia, on the 9th inst., at his home, 1832 Arch street, Philadelphia. Dr. Keyser was born in Philadelphia, Feb. 8, 1835, of German Lutheran parentage. In 1852 he was graduated from Delaware College with the degree in arts. He then especially devoted himself to chemistry, working in the laboratory of Dr. F. A. Genth, city chemist of Philadelphia, for two years. He continued his studies in Germany and returned to this country in 1858. In 1861 he entered the army as captain of 91st Regt. Penn. Infantry, U. S. V., and served in the Army of the Potomac in the Chickahominy campaign. Owing to wounds and ill health, he found himself obliged to retire from active service

and he resigned his commission August, 1862. He again visited Europe and in 1864 received the degree of M.D. from the University of Jena, and subsequently attended the clinical instruction in the Hospitals of Berlin, Paris and London. On his return to the United States he was appointed acting assistant surgeon to the U. S. Army Hospital at Germantown, Pa. He entered upon private practice in 1865, when he finally retired from military service. He founded the Philadelphia Eye and Ear Infirmary in 1864 and delivered a series of clinical lectures to physicians upon accommodation and refraction, in 1868, and two years later began a regular series of lectures upon clinical ophthalmology. He was one of the surgeons of the Will's Eye Hospital for a period of more than twenty years. He occupied the chair of ophthalmology in the Medico-Chirurgical College for ten years, resigning on May 7, 1893; during a great part of this period he had been the dean of the faculty. In 1889, Dr. Keyser was appointed a member of the Philadelphia Board of Health, and rendered such efficient service that he continued to hold the position up to the time of his death. The Board of Health on learning of his death, adjourned for the day and passed appropriate resolutions. The Trustees and Faculty and the Alumni Association of the Medico-Chirurgical College held special meetings and also adopted resolutions of regret and condolence. Dr. Keyser was a companion of the Loyal Legion of the United States and was one of the founders of this successful patriotic and military organization. He was a member of the AMERICAN MEDICAL ASSOCIATION, the Academy of Medicine, Philadelphia County Medical Society, and also honorary member of the Delaware State Medical Society. He was vice-president of the Ophthalmological Section of the Ninth International Congress in 1887 and also of the Tenth Congress in 1890. Dr. Keyser contributed a number of articles to current medical literature, relating to diseases of the eye and refraction, and was the originator of a clinical ophthalmoscope which bears his name. His wife and daughter survive him.

C. LOISEAU, M.D., Paris, aged 72. The life of this talented and public-spirited physician, hygienist and alienist is a noble example for the rising generation, and the general sorrow at his death is a testimony to the value of his services. Neglecting selfish ends, he devoted his talents to the welfare of the community and served as member of the city council on numerous important sanitary and hygienic committees. He was also connected with many scientific societies, and as president of the Medico-Psychologic Society accomplished much for the insane. His lectures on public, private and professional hygiene were significant factors in the progress of the last decades.

A. H. HUGHES, M.D., died at Auburn, Wash., March 2, 1897, age 78 years. Dr. Hughes was born in Warren County, Mo., and graduated from the Missouri Medical College of St. Louis in 1850. After practicing several years in Missouri, he removed to Dallas, Ore., in 1864, and after four years practice in that place moved to Kent, Wash., where he has since resided. He continued in the active practice of his profession in the White River Valley until 1889, when he retired on account of ill health.

EDWARD PAYSON ANNÉ, M.D., Harvard, 1852, died in New Bedford, Mass., February 24. He was a graduate of Yale College in 1848 and was a member of the Massachusetts Medical Society since 1853, and at the time of his death was consulting physician to St. Joseph's Hospital.

JOSEPH LOUIS DROESCH, M.D., of Brooklyn, died from pulmonary tuberculosis on February 19. He was a native of Brooklyn, the son of German parents, and was approaching his forty-first birthday. He was an alumnus of the College of Physicians and Surgeons, New York, in 1883.

HENRY M. BLACK, M.D., Jefferson Medical College, 1875, died at Strasburg, Pa., February 28, aged 45 years.

JOSEPH F. GALLAGHER, M.D., Jefferson Medical College, 1891, died at Freeland, Pa., March 3.

BOOK NOTICES.

Manuale Pratica della Medicatura Antisettica. Del Dr. ADELCHI ZAMBLER, con Prefazione del Prof. E. TRECOMI; con 6 incisioni. Ulrico Hoepli, Milano. 1896. (Practical Manual of Antisepsis.)

L'Impiega Ipodermica e la Dosatura del Remedi. Manuale Terapeutica del Dottore GAETONE MALACRIDA. Milano. 1895. (The Hypodermic Employment and the Dosage of Drugs.)

These two little books belong to the series of pocket-sized Italian hand-books published by Hoepli, a series which for extent and range of subjects has apparently hardly anything comparing with it in our own language. It includes at least some five hundred different publications, their subjects ranging over the fields of science, art, history, religion, etc., in cheap and convenient form. The medical publications include some fifteen or sixteen titles, which, judging from these present volumes, are meritorious handy compendiums of the fullest and latest knowledge of their subjects. The antiseptic manual gives the general principles of medical and surgical antisepsis, with a pretty full historic statement; and the other little volume, beside a general dose list of drugs, is a manual of hypodermic medication and includes a long list of formulas for hypodermic injections. Both appear to be scientific and accurate, and while many of the special methods of antiseptic detail which are being constantly added to, are necessarily omitted, they both seem fairly up to date.

Semelotica. Breve compendio dei metodi fisici di esame degli infermi, del Professore U. GABBI, di pag. xvi-216, con 11 figure intercalate nel testo. Manuale Hoepli, elegantemente legato L. 2.50. (Semeiotics, a brief compendium of the methods of examination of the sick.)

This is another of the Hoepli handy volume series, and is devoted to the method of examination in disease, more especially to the physical and rational signs, the examination of urine, blood and other liquids of the body, both chemic and microscopic, etc. It does not go into the description of bacteriologic methods of examination; these are apparently left for a future publication. For a book, its compass covering so wide a range of subjects, it seems to be fairly complete, but like numerous similar publications in this country, it is not exhaustive. For a suggester and quick reference book it seems well fitted. As will be seen by the title it is not pretentious in its claims.

MISCELLANY.

Montana State Board of Medical Examiners.—Dr. C. O. Evans, of Deerlodge, Mont., has been appointed a member of the State Board of Medical Examiners, to succeed Dr. Bullard.

The "Archiv fuer Schiffs und Tropen Hygiene," the new magazine devoted to consideration of the questions affecting maritime and tropical interests and hygiene, mentions the probability that Yersin will be commissioned by the Chinese Government to found a Pasteur institute at Canton.

The Subject of Dr. Unna's Prize Competition for 1897, "is investigation of the ability of the known stains of elastin to stain elacin also, and if so, to what extent." The prize is 300 marks. Contributions are to be sent to Leopold Voos of Hamburg, Hohe Bleichen 34. There are no restrictions to the competition.

Vaccination in the Schools of Paris.—Acting upon the suggestion of the Académie de Méd., the Paris authorities are to bestow prizes upon the teachers, male or female, public or private, who compile the most complete statistics in regard to vaccinal operations and do the most to promote vaccination and revaccination in the schools.

Aberdeen University Honors an American.—Alexander J. C. Skene, M.D., of Brooklyn, N. Y., received on February 27 information that the degree of LL.D. was conferred upon him

by the University of Aberdeen, Scotland. He is to be congratulated, for the university is exceedingly chary of its honors, and he is the first to have received the compliment on this side of the Atlantic. In 1590 an ancestor, Sir George Skene, was physician to the king and a professor of medicine in King's College, Aberdeen.

Insanity of English People.—Prof. J. Holt Schooling, Fellow of the Royal Statistical Society, has ended his investigation and concludes that one in every 360 of the population of Great Britain has some form of insanity. He gives facts to show that in every 10,000 of the English and Welsh population, 31.4 people are lunatics. In every 10,000 of the Scotch population, 33.6 people are lunatics. In every 10,000 of the Irish population 40.3 people are lunatics. As among the chief causes, with the percentage of each in classes of a hundred he gives the following: Drink, 33.6; domestic troubles, 15.1; mental anxiety, 13.4; old age, 13.2; adverse circumstances, 13; accidents, 6.5; religious excitement, 4; love affairs, 3.2.

Anecdote Regarding Lord Lister.—While going round his wards in the Glasgow Royal Infirmary one day, Sir Joseph, then plain Mr. Lister, came to the bedside of a patient whose arm had been severely crushed without the skin having received any injury. Turning to the assembled students, he said: "Gentlemen, I have frequently noticed that when severe injuries are received without the skin being broken, the cases nearly always recover. On the other hand, trouble is always apt to follow, even in trivial injuries, when a wound in the skin is present. How is this? I can not help thinking that the man who is able to explain this problem will be one who will gain for himself undying fame." Lord Lister himself has proved the truth of his prophecy.—*London Daily News.*

Amputated Foot Should not Have Been Exhibited.—On the trial of the personal injury case of Rost v. Brooklyn Heights R. Co., the physician who had amputated the left foot of the plaintiff, a little girl who had been run over by a trolley car, was asked to produce the foot, which he had preserved in a glass jar. The amputation was admitted, and no claim was made that it was not properly done. But, two reasons were advanced for exhibiting the foot: "To show the size of the child at the time;" and because the discoloration upon the foot had a tendency to establish that the electric current had not been shut off at the time the child was run over, and therefore bore directly upon the negligence of the railroad company in the operation of the car. It may be assumed, says the appellate division of the supreme court of New York, Dec. 1, 1896, that technically the rule of evidence authorized the exhibition of the foot. But such rule, it holds, is without force when the legitimate purpose for which the exhibit may be made is slight, and the strong tendency is to work improper and illegitimate results. In this instance it was perfectly clear that the direct tendency of the exhibition of this mangled foot, coupled with other considerations, was to arouse the prejudice and inflame the passions of the jury into an angry resentment against the author of the misfortune. This condition, the court holds far overbalanced any legitimate purpose for which the exhibit might have been made, and rendered the exhibition of this foot, under the circumstances of the case, improper.

A Strange Case of Postmortem Mutilation was recently reported at a meeting of the k. k. Medical Association of Vienna. The victim was a woman of 37, a newspaper carrier, who was found in her locked room extended on the floor with the lower part of her body exposed, evidently by her own hand. She had probably been dead a couple of days. The external genitals were much mutilated with an extensive and irregular wound, which the absence of all inflammatory reaction showed to be postmortem. The cause of death was found to be the closing of the coronary ostium with fresh fibrin masses due to endoarteritis. The mutilations had been made by a little dog in the room,

which the woman kept and had evidently used for perverted sexual purposes, although it was known that she had sexual relations otherwise. Cases of mutilation by fishes, insects and rats are not uncommon, but this case is unique, and if the circumstances had been less clear, it might have presented a puzzling criminal aspect.—*Wien. klin. Rundschau*, February 14.

Dr. Koch and Others will Visit Bombay.—The German Commission for the study of the plague left Germany for India last week. The members are Professor Koch, Professor Pfeiffer of the Institution for Infectious Diseases, Professor Gaffky of Giessen, Dr. Disuderich and Dr. Sticker of the Imperial Health Office. Professor Koch will travel direct to Bombay on the completion of his investigations in South Africa, and till his arrival the leader of the commission will be Professor Gaffky, who was with Professor Koch in British India during the great cholera epidemic of 1884, and assisted him in the researches which finally lead to the discovery of the comma bacillus.

A Necrotomy not an Autopsy.—Mr. A. of the coroner's office, was in a sad quandary. In one hand he held a medical dictionary; the other, which he allowed to hang listlessly by his side, grasped a pen. Before him, upon his desk lay a large sheet of paper, upon which he had been writing. "Well," he remarked, after a period of thoughtfulness, "I give it up. There's something in a name after all. I have been trying for the last hour to fill out a requisition blank. Now here's the word autopsy. Some of our smart doctors have been finding fault with the way the word has been used in this office." "Why," said I, "the word autopsy means the cutting." "There's where you're wrong," he interrupted; "it means no such thing. Listen to this: 'Autopsy: Examining or seeing one's self, self-inspection. The word is strangely misapplied to the postmortem study of the body of another.' Look at yourself in a glass and according to this definition you perform an autopsy. That ought really to be a word for the exclusive use of women. Now," he continued, "there is the word necropsy, 'the examination of a dead body.' But that hardly fills the bill. It may be a merely superficial examination. Here though, is the word necrotomy, 'the dissection of a dead body.' This appears to hit nearer the mark, but how awkward this would sound: 'Coroner B. performed a necrotomy yesterday in the case of, etc.,' but, I believe that I will stick to the first principles. Every one knows what is popularly meant by the word autopsy, and some of our most eminent physicians have used the term in the sense in which I have always understood it."

New Researches Concerning Beriberi.—Beriberi is in the Dutch Indies one of the most pernicious diseases, and at the same time yet miraculous. It does not lead to death immediately, but ends in a general or particular paralysis of limbs, hands and legs. There was no cure of it, however, till now. The disease had been noticed first at Abjeh, some twenty years ago, as of epidemic standing. It was thought it befell only the natives, but among the many hundred men sick of beriberi and brought to Batavia, there were found many European soldiers. The infectious matter was then derived from the soil, which had been thrown up and ploughed through by military works. About 1885, when the plague seemed to dissolve and lessen the army, Professor Pekelharing from Utrecht, a renowned bacteriologist, was sent to Abjeh to study the disease even in its place of birth, to find out its bacilli, and, if possible, also a cure against it. In these directions Professor Pekelharing failed entirely. He returned without any result and the disease went on. Now Dr. Eykmann, physician in the Dutch military service, seems to have been happier than his colleague and countryman. Dr. Eykmann conceived the idea that beriberi had nothing to do with the soil, but with the food given the soldiers. The natives there live on rice as their exclusive food and the Europeans also in these regions take to it. Now Dr. Eyk-

mann had marked that those soldiers were taken from beriberi who got the Saigun rice, but those fed on the native "red" Sumatra rice remained healthy. In the prison at Sourabaya he found likewise, that while on July 1, 1896, ninety-nine prisoners out of 800 had been caught by beriberi, this cipher fell to 86, 82, 43, 21 and 13 during the next month on account of giving the Sumatra rice instead of the Saigun rice. Sure, Dr. Eykmann's theory has not yet any scientific foundation, but a mark is found and a practical sign, which, no doubt, will lead us sooner or later to the discovery of the growth and evolution of infectious material in the human body.

Cathode Photography vs. the Corset.—If anything will convince the fair sex of the evils of the corset, it will be Roentgen Ray photographs taken through the corset, in which they can see for themselves how their viscera are displaced and compressed by it. Madame Gaches-Sarraute, a Paris physician, recently exhibited some photographs of the kind at the Acad. de Méd. with others showing the beneficial effect of wearing a hygienic corset she has invented, for which she was awarded a prize by the Faculté de Méd. at the close of the year. The Prussian Government has appropriated 50,000 marks to further the study of cathode photography.

Jury Decides Injury Caused Septicemia.—The supreme court of Minnesota says, in the personal injury case of Miller v. St. Paul City Ry. Co., decided Nov. 9, 1896, that the evidence as to whether the disease septicemia, with which the plaintiff was afflicted, was caused by her injury on the car of the defendant, was not simply speculative. There was evidence in the case tending to show that it is a germ disease, and that an external blow on the body would not be the cause of introducing the germs into the body, but that the germs might exist dormant in the system, and be set in motion or "lighted up" by an external blow or injury, and hence that the plaintiff's injury was the direct inducing cause of the disease. The value and weight of the evidence, the court holds, was for the jury, and that it was correctly submitted to them. The jury took the plaintiff's view of it, and awarded damages accordingly.

Embryology Researches.—The University of Chicago has issued the following circular:

In the entire domain of morphology there is perhaps no province in which the investigator is so directly dependent upon the physician as in that of human embryology. Since 1837, when Karl Ernst v. Baer's "Epistola de Ovi Mammalium et Hominis genesis" marked the dawn of this branch of morphology, repeated appeals for assistance have been made. The generous responses have made possible such works as those of Coats, 1847; His, 1880; Minot, 1892; Marshall, 1893; Mall, 1893; and have linked inseparably with the progress of morphology the names of many physicians, notably Drs. Gröppin, Ecklin, and Munch of Basle; Drs. Lomer and Leopold of Leipzig; Dr. Glaevecke of Kiel; Dr. Kittredge of Nassau, N. H., and Dr. Garrigues of New York.

Although we have acquired a vast amount of information there still remain fields almost unexplored. It is well known that we possess no information concerning the fertilized ovum, or its cleavage, and but little concerning gastrulation; the systematic growth changes have been very inadequately studied; while more facts concerning organogeny are highly desirable.

In order to obtain material for these and other lines of research, the Departments of Neurology and Anatomy of the University of Chicago ask your coöperation.

Should the request meet with your approval, we shall be pleased to forward you receptacles, reagents, etc., for the preservation of material to be sent us. Yours respectfully,
H. H. DONALDSON, Head Professor of Neurology; and A. C. EYLESHYMER, Associate in Anatomy.

Bills Cut Down.—Uncontradicted testimony that a married woman told her physician that she wanted him to come whenever sent for, and she would see that he was well paid, the surrogate of Cattaraugus County, N. Y., holds, September, 1896, *in re* Smith's Estate, was sufficient to bind her separate estate therefor. At the same time the surrogate cuts down a bill of \$412 for four visits a day for 103 days, thinking \$350 a

liberal allowance. The reason given is that the physician resided very near his patient, called in to see her when he desired, and then made a uniform or average charge of four visits a day at a dollar each, while it was also taken into account that the patient was afflicted with an incurable disease, the physician gave her but little medicine, and often called in two other doctors for counsel and advice, from a place fifteen miles distant. The woman's condition and the character of her disease, the surrogate further holds had an important bearing upon the question of the necessity of these repeated consultations and the value of the services, and because each of the consultants was in attendance upon an invalid sister of the woman's, residing with her, against whom they made the same charges, he holds that their bills should each be cut down from \$15 to \$10 a visit. In this connection, it may also be noted that the probate judge of Cook County, Illinois, holds that \$2,000 was too much to charge for eight days' medical attendance on Mrs. Ada B. Gellatly, of Evanston, Ill., although it included a trip from California to Fortress Monroe and return to Evanston with Mrs. Gellatly in a private car. He thinks \$100 a day an ample fee.

The Hindu Lying-in Chamber.—According to the *Indian Medical Record*, the mortality in childbed among Hindu women is notoriously high, a circumstance which is no doubt largely due to the very early age at which they usually become mothers. A still more potent cause is, however, to be found in the shocking and apparently deliberate barbarity with which they are treated during the puerperium. The lying-in chamber of a Hindu family is ordinarily a little, damp, ill ventilated hut or room in some remote corner of the court yard or compound. In this the expectant mother is placed and there she remains from eleven to thirty-one days, during which, according to Brahminical law, she is looked upon as unclean. There is only one small inlet in this apartment, and the door is carefully closed to exclude those evil spirits, light and air. In order, probably, to purify the unfortunate woman by heat, wood fires are kept burning in the room both night and day. The smoke has to find its way to the outer air as best it can through any chinks there may happen to be in the roof or walls, which are usually made of bamboo with a thatching of mats or straw. With the view of more effectually exorcising the unclean spirit, a powder composed of peppercorns or ginger is given to the patient during the first few days; this preparation is administered either in the form of a paste or dissolved in boiling water as a tisane. It is not surprising to learn that the result of this elaborately perverse therapeutics is that something like 40 per cent. of the women subjected to it die of puerperal fever and tetanus within the first fortnight after delivery.

The Carrier Pigeon in Medical Practice.—Mr. James Payne, an English litterateur, quotes from the letter of a friend on the above subject, as follows: "I began using pigeons (Antwerps) for messenger purposes as early as 1874. The idea of their finding their way by 'instinct,' as is popularly supposed, is all nonsense. They go by sight, and on a misty day or if started too late in the afternoon, they either lose their way or refused to go. The birds were kept at the village where the doctor lived and where all messages had to be sent, and they were sent in turn in hampers up to me at my lodge, where they were kept in a large cage till they were wanted to go a message. At the arriving place their only way of entering was through a door of wire, which they could push open, and which rang a bell to let the man in charge know that a message had arrived. Inside this door, when a message was expected, the man hung a small cage, so the pigeon instead of finding himself in his roomy home, got into what corresponds to the letter-box inside an ordinary front door and actually delivered himself both as letter and postman. I found that the message was best wrapped up like the mottoes in Christmas crackers and tied

under and to the middle tail feather; if tied to the leg they hampered him as he could not double his leg well while flying, and was apt to pick them off. Under the wing in an envelope—though that is the way they are represented by artists.—they would prevent the pigeon flying at all."

Unpaid Doctor's Bills an Expense.—In an action to recover damages for a physical injury, sustained by reason of a defective sidewalk, the court of appeals of Kansas holds, in the case of *City of Abilene v. Wright*, Oct. 17, 1896, that the reasonable cost and expense of medical attendance necessarily incurred may be recovered for, even though actual payment therefor was not made prior to the commencement of the action.

Measure of Damages for Malpractice in Setting Arm.—In an action against a surgeon for malpractice in setting and treating a broken arm, the supreme court of Nebraska holds, in the case of *Miller v. Frey*, decided Oct. 21, 1896, that the measure of damages is the damage accruing to the plaintiff in excess of that which would have accrued naturally from the breaking of his arm had he been treated with that degree of skill ordinarily possessed by surgeons. It is not the damage resulting from the breaking of the arm. That some damages would have resulted from that injury in spite of the most skilful treatment is pronounced clearly unquestionable. The defendant, no matter how unskilful he may have been, could not be liable for all the injuries resulting from the breaking of the arm. He is only liable for those resulting from malpractice; that is, for the damages resulting from his failure to exercise that degree of care and skill ordinarily exercised and possessed by physicians and surgeons in the treatment of such cases.

Hemopoietic Function of the Blood Marrow.—Roietzky has been studying this subject and announces that he finds the number of white corpuscles much larger in the blood as it leaves the bones than when it enters. The marrow therefore generates leucocytes, and does not cause their disintegration as some have supposed. The number of degenerated leucocytes is the same in the arteries as in the veins. The activity of the marrow seems to increase as other hematopoietic organs are destroyed, as for instance in the case of dogs whose spleen has been removed, the number of leucocytes originating in the marrow is much augmented. In experimental leucocythemia produced by giving turpentine to dogs, the function did not seem to be modified, but in some cases of natural leucocythemia, the number of leucocytes produced by the marrow was much increased. —*Bulletin Méd.* January 3 from Wratsch.

Coincidence or Cure.—Several pages are devoted in the *Bulletin Méd.* of January 17 to the description of a case that presented the clinical picture of the hectic fever that accompanies acute consumption. There was first acute febrile broncho-pneumonia, passing into a chronic state, with indications of a granulous infiltration of the right lung, etc. Exploratory punctures gave negative results. There was scarcely any expectoration, but Koch's bacilli were found in the sputum. The fever continued very high with two daily exacerbations, 39.5, 40.5 to 40.9 degrees C. This condition continued for two months, with the patient in a drowsy, exhausted state, gradually growing weaker. As a last resort the father begged to have the Roentgen rays applied to his son's chest. The first day after this was done the fever was higher than ever, but after the second application the fever stopped abruptly and the patient began to recover. In seventeen days he was completely restored and was removed to the country. Rendu and Castel, who report the case, do not, of course, venture to draw any conclusions whether the recovery was spontaneous and the cure merely a coincidence, or whether the rays were the cause of a cure. The patient certainly had youth and a fine physique in his favor. The rays produced a violent erythema, developing blisters and dermic ulcers, which lasted for three weeks and may have contributed to the cure.

Insurance of Unregistered Pharmacist.—Notwithstanding the Iowa statutes prohibit persons not registered pharmacists from conducting any pharmacy, drug store, or any store for the purpose of selling, compounding, or dispensing medicines or poisons for medicinal use, the supreme court of that State decided, in the case of *Erb v. German-American Insurance Co.*, May 27, 1896, that an insurance policy on the stock of merchandise kept for sale by an unregistered pharmacist was not void, as against public policy. Oct. 20, 1896, it held, in *Erb v. German Insurance Co.*, that a policy which contained the specific provision that "If the premises insured shall be used or occupied in whole or in part for an unlawful purpose this policy shall cease and be determined," was not rendered void by the mere fact that one not a registered pharmacist occupied the building as a drug store, it not being affirmatively shown that he conducted it contrary to law, for he might have employed a qualified pharmacist to conduct his business. Both of these decisions are cited and followed in principle, Dec. 9, 1896, by the court, in *Erb v. Fidelity Insurance Co.*, where it holds that a policy on the store furniture and fixtures of an unregistered pharmacist is not void, as against public policy, particularly when it was not shown that his object in procuring the insurance was to protect and aid an illegal business.

A Proposed Optometry Board of Examiners for New York.—Whether the people of the State of New York are well regulated or not, may be a question; but that they are much regulated there can be no doubt. Under the laws of the State not only the practice of medicine is regulated, but also the practice of dentistry, pharmacy, veterinary surgery, chiropody, plumbing and horse-shoeing, and a bill is now before the legislature to regulate the practice of optometry, and we are informed that the barbers are to introduce a bill to regulate the practice of the "tonorial profession." The bill to regulate optometry was defeated in the last legislature, lacking, however, only seven votes in the assembly. A new bill has just been introduced which provides that the Regents shall appoint a State Board of Examiners in Optometry, which shall examine all persons engaged in optometry in the State, and shall confine its examinations to such knowledge as is essential to the practice of optometry. The proposed act is to be construed so as not to apply to persons who sell spectacles or eyeglasses, without making pretensions to scientific knowledge or skill in adapting them to the eye. Registered physicians are exempt from the provisions of the act. The Optical Society of the State of New York, under whose auspices we understand the bill has been prepared, state that the principal object of this bill is to protect the public against incompetent and designing persons who may in the future "attempt to traffic upon postulate skill in adapting glasses to the sight." In a circular entitled "The Optician and the Oculist," published by the Society, the argument of the oculist that the testing of eyes for glasses should be done by him and not by the optician, is met by the following argument, which is, to say the least, ingenious, that "as the optician refracts, or bends, rays of light with his lenses before they enter the eye, and not afterward, he is treating light, not treating disease."—*Brooklyn Medical Journal*, February.

The State Medical Examiner of Rhode Island.—This little State is one of the few that have risen to the requirements of modern thought as to medico-criminal investigation, in the replacement of the antiquated coroner's office. There are twenty-five examiners, about one-half of whom have the care of Providence County. Dr. Swartz, in the last bulletin of the State Board of Health, explains some of the duties of the medical examiner, stating that for the time being—and at the same period of time—he must be a physician, a detective and a jurist. He must be an adept in medical lore and in legal requirements, attentive to every detail of surroundings and conditions, and

he must judge promptly as to the issue, otherwise the ends of justice may be perverted and the functions intended for his office come to naught. "The importance of the office is being daily emphasized by the frequent occurrence of deaths from violence and under suspicious circumstances, calling for knowledge and information on the subject from the medical examiner for all and more than the experiences of his predecessors can furnish. To obtain physicians from the fraternity at large who may possess all these qualifications is a difficult matter, for the subject is made only a side branch of instruction in most of our medical schools. It is not desirable to place in so important a position one whose experience with the world has been limited to a few years of study and to but a few years of actual contact with the ways of the world. It is preferable to obtain the assistance of those who have had the experience of a ripened practice, and whose judgment and action will not lead the State into unnecessary expense, nor by hesitation allow the cause of any criminal act to be lost to view. To find such men who are willing to give their time and their services to this work—for it requires sacrifices innumerable—is a difficult matter. Our State has, however, been well favored in this respect in past years, and it is to be hoped that the increased attention which it is necessary to give to this line of work will stimulate those undergraduates who have a liking for this branch to so perfect themselves that the position will seek the applicant, and not be necessary for the applicant to seek the position."

The Card Index in the Surgeon's Office.—Dr. A. T. Bristow of Brooklyn, in the *New York Medical Journal*, recognizes the growing position of periodical literature in the art of the surgeon, and the imperious need of saving time while keeping abreast of the march of that literature. He says "the greatest opportunity which our modern science and civilization offer to the medical worker of today is the abundance of literature which the printing press places at his disposal. There are the journals on special subjects and those which embrace the general field of the healing art. I need not specify the names of such periodicals to this audience. Indiscriminate and omnivorous reading is better than idleness, but the reader who does not classify his literature does not, it seems to me, utilize his material to the best advantage. A heterogeneous mass of information gathered from all sources is likely, in an emergency, to leave its owner in the position of one who always thinks of a bright retort after the opportunity to use it has gone by. But a lost opportunity in our art often means the sacrifice of a life. Knowledge, especially that which we gain from current literature, needs to be classified in order to be of full value. Accurate information in any branch is always classified information. I have found the following plan to be of great use in my own case of keeping my facts where they are readily attainable. As soon as possible after the receipt of a journal, as I read over the different articles, I check them off and enter each subject in a card-catalogue index. I devote my indexes exclusively to the subject in which I am engaged, surgery. Thus, on the subject of hernia, all the articles on hernia appearing in the various journals are entered by title, author's name, journal, page and volume. I find, on referring to my index, that I have fourteen such references on hernia; on the surgery of the gall bladder, thirteen references; on the surgery of the intestines, twelve references; on the surgery of the ureters, nine. Yet it is but two years since I commenced this system. Who can doubt but that in the thirteen references to the surgery of the gall bladder there is contained a mass of information concerning both diagnosis and technique which is unsurpassed, not a tenth part of which could be found in any three modern surgical text-books? Yet it is all at my disposal in the time that it takes to look over the card and get down the journals. The surgery of the ureters has been developed in the past few years, and, except in the most recent text-books

there is absolutely nothing to be found on this point. In the nine references on my card the subject is exhaustively treated, and I have almost a volume at my disposal, an amount of material at least for which no writer on surgery, no editor of an encyclopedia could find room in a single work. There is also in the labor of indexing the literature a sort of fixative which impresses the subject on the memory. The best system of mnemonics is that which involves an orderly classification of facts, and this cataloguing of current literature is that and nothing more. The method has been of great benefit to the writer, and I hope that I may be permitted to mention it, not as anything original or new, but as worth adopting, and to be commended as a means of rendering most useful one of the greatest opportunities of modern medicine, its rich literature."

Admissibility of Testimony as to Probabilities.—There is a clear distinction to be observed, according to the supreme court of Wisconsin, between the competency of testimony to be received with regard to the permanency of personal injuries, and its sufficiency, when received, to establish the ultimate fact to which the proofs are directed. On such questions as are not subject of absolute proof, the testimony should exhibit the nature and strength of the probability. It is then for the jury to determine whether it amounts to proof of the ultimate fact, to a reasonable certainty. Testimony which tends, in some appreciable degree, to establish the ultimate fact, is competent to be received, even if, in the end, it should be found insufficient to fully establish it. For these reasons, the court holds, in *Nichols v. Brabazon*, Dec. 15, 1896, that it was competent to ask a physician to state what the probabilities were for the recovery of the plaintiff from personal injuries. It also holds that damages can be recovered for bodily pain and mental suffering in the future, where it is established, to a reasonable certainty, that such damages will be endured in the future. And it holds that expert evidence to show that a failure of a person to properly exercise her limbs might have been the cause of the permanency of her injuries was inadmissible so long as there was no evidence to show that there was a want of proper exercise, and some affirmative evidence went to show that there was such exercise.

Apyretic Intra-peritoneal Rupture of Hydatid Cyst in the Liver.—The case described in the *Province Méd.* of December 19, presented the usual symptoms, sudden pains radiating into the abdomen, syncope, increase in volume of the abdomen, urticaria, vomiting and slight pleurisy of the right base, but no fever at any time. Professor Jaboulay performed a supra-umbilical laparotomy, which gave issue to a large quantity of fluid apparently slightly tinged with bile. The operation was followed by Mikulicz's marsupialisation, with strips of iodoform gauze reaching to the cyst in the liver. The discharge of intra-peritoneal fluid continued for two months, while the general health and appetite were good. A month and a half after the laparotomy, the cyst was punctured and quantities of bile escaped with the hydatid liquid and also fragments of the hydatid membranes. Pieces of the membrane came away for three weeks and were removed with the forceps, when the wound was dressed every day. As the discharge decreased the opening healed until only a small fistula remains after three months. The presence of bile in the liquid after both operations, shows that there must have been some communication with the biliary passages and the bile as it entered the cyst must have killed the parasite. The case also illustrates anew the extreme tolerance of the peritoneum for the hydatid liquid and the bile when they are both aseptic.

Philadelphia.

THE BOARD OF TRUSTEES of the Jefferson Medical College has appointed a Committee on Arrangement for the purpose of having the institution fittingly represented at the unveiling of the monument to the memory of Prof. Samuel D. Gross, the ceremony having been appointed for May 5, 1897, at 5 o'clock p.m., at Washington, D. C.

AT THE MEETING of the Section on Ophthalmology, of the

College of Physicians, March 16, Dr. Wm. M. Sweet, by invitation, read "A Preliminary Report on the Localization of Foreign Bodies in the Eye by the Roentgen Rays." Dr. Howard F. Hansell, at the preceding meeting of the Section had reported a case of a man who had carried a piece of steel in his eye for nearly a year, in which a skiagraph being made by Dr. Stern at the Polyclinic Hospital, showed the presence and locality of the foreign body. The eye had become atrophied and vision was lost. Dr. Hansell enucleated the eye and found the fragment of iron in the ciliary body. A case was also reported by Dr. DeSchweinitz, in which the steel was successfully extracted.

THE PHILADELPHIA POLYCLINIC is organizing an intelligence bureau for physicians visiting the city, from which information may be obtained of operations, interesting cases, etc., to be presented at the various clinics held at different hospitals, not only by members of its own staff but also by any other member of the regular profession who wishes to avail himself of the opportunity offered of inviting physicians to witness his operations. In this way it is hoped that much more can be made of the clinical facilities offered by Philadelphia than by any other method. The Polyclinic is particularly favorably situated for getting into communication with physicians coming to the city and offers to furnish the clerical work, telephone connections, etc., without expense. It is expected that this will prove a great convenience during the coming meeting of the ASSOCIATION.

THE PUBLIC SERVICE.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from March 6 to 12, 1897.

Capt. Charles Willcox, Asst. Surgeon (U. S. Military Academy, West Point, N. Y.), leave of absence granted is further extended one month and fifteen days, with permission to go beyond sea.

Change of Address.

Carmichael, D. A., U. S. M. H. S., from Vineyard Haven, Mass., to Cleveland, Ohio.
Collins, Katharine R., North College Av. and 22d St., Philadelphia, Pa.
Hall, J. N., from 1517 Stout St. to Jackson Bldg., Denver, Colo.
Hillkowitz, Wm., from 507 W. 7th St. to 704 Race St., Cincinnati, Ohio.
Leusman, F. A., from 270 E. Huron St. to 100 State St., Chicago, Ill.
McBride, M. A., from New Orleans, La., to Tahlequah, Ind. Ter.
Shepstone, J. A., from 3819 to 4844 State St., Chicago, Ill.
Vaughan, G. T., U. S. M. H. S., from Philadelphia, Pa., to No. 3 B St., S. E., Washington, D. C.

LETTERS RECEIVED.

SOME REMARKS ON MALIGNANT GROWTHS.

BY EDWIN KLEBS, M.D.

PROFESSOR OF PATHOLOGY, RUSH MEDICAL COLLEGE AND IN THE POST-GRADUATE MEDICAL SCHOOL OF CHICAGO.

The expression "malignancy" is now reserved for such pathologic new formations that will often return after removal and form metastases, if not entirely removed. As the first depends upon incomplete removal, mostly depending on dissemination of tumor-germs in the various forms of the primary growth, the latter property only is the true feature of malignant tumors.

To clear up the nature of this property is a task of the highest scientific and practical importance, and it seems always convenient to review our notions on these points, even though they are not wholly conclusive. At least, such an examination of facts will show the way for further investigation and secure the practitioner and pathologic investigator from mistakes, by removing misunderstandings.

Separating the infectious tumors from the organoid growths, in the second part of my "General Pathology" (1889) I think I have placed the question somewhat clearer. The organoid tumors spread by dissemination of tumor-cells; the infectious tumors by dissemination of microbes.

Now, in this decennium, attempts were renewed to subject the organoid growths also to the action of microbes. Sudakewicz, Ruffer and others regarded the long-known hyaloid masses, intracellular and extracellular, found in carcinomas, to be plasmodia or the various forms of those things, namely, the concentric or radial striping of globular masses, the observers of high standing, as Metschnikoff, to accept this suggestion. I have shown ("General Pathology," ii, p. 126, fig. 11, and p. 152, table 17) the formation of such bodies in blood vessels of the brain, in chorea hereditaria, in the lymphatics of the lungs, in chronic bronchial croup, and in an acute atrophic liver, processes in which the inoculation of blood and lymph seems to be impaired.

Further, if there were microbes in malignant tumors they must grow and develop under well adapted conditions of life. As all attempts of cultivation outside of the body had failed, I implanted living carcinomatous tissue from man into the livers of a number of rats, they showed very often spontaneous development of carcinoma, and seemed therefore to be highly predisposed to this disease. These particles contained human epithelial cells and the hyalin bodies. The cells showed in these experiments the first signs of farther development in the formation of microbes, but were involved later; the latter disappeared in a short time without a tendency of development.

I can not accept the objection of Metschnikoff that coccidia of one animal would not grow in another, for these suggested coccidia were included in living and to a certain degree developing human cells. That they would not develop under these conditions shows quite clearly that they are not living bodies at all.

After the coccidium theory had slumbered for years, came the blastomycete- or yeast-theory of the Italians. The extracellular disposition of these bodies shows clearly that they can not be the cause of tumor-propagation by cell-dissemination. As one of the observers contended that these bodies were only found in certain parts of the tumors, I encouraged a good microscopist working in my laboratory, Dr. Döpfner, of Chicago, to undertake the difficult task of staining and spreading lymphosarcoma, operated by Dr. C. Beck, in the Post-Graduate Medical School. It seemed more probable that we should have positive results in that case, as I had cultivated some yeast or blastomycetes from this tumor, coming into my hands immediately after the operation. The bodies, on fluid meat-peptone, found in cultures were somewhat smaller than human red blood corpuscles, round, quite circular, with a distinct membrane, forming internal spores and also external buds. (Knospung.)

From all these circumstances I do not think that it was a fortuitous incident, but that these growths came from out the tumor. Indeed, there were found by Dr. Döpfner in some of the preparations round bodies stained deep black with aqueous anilin gentian violet, and discolored with oxalic acid, 1 per cent. But they were smaller than the yeast corpuscles, some very small, and showed no signs of vegetation, either as buds or internal spores. Moreover, they seemed to be in connection with red blood corpuscles, which retain also other anilin dyes, namely, after using corrosive substances, mordants, as after the use of iron-ammonia-sulphate (Heidenhain).

The last prove what I have proposed long before R. Koch, in such cases to ascertain the etiologic connection of an organism with a certain disease; the synthesis of the same disease by the organism I have not yet shown, but it will be made later, notwithstanding that it may fail by not having suitable animals, positive results alone being conclusive.

The lympho-sarcoma having a place on the limits of infectious and organoid tumors, the result of such experiments would not invalidate our notions of true organoid tumors, which disseminate alone by tumor cells; a form of generalization that is not infection, but must be called decidedly *implantation*.

It is one of the best confirmed pathologic facts that every true carcinoma spreads by the transportation of its own cells through lymphatic spaces and blood vessels. The same is demonstrated in a very great number of malignant tumors; also of such originating from the tissues of the middle germinal plate,

the endothelioma, the enchondroma and the sarcoma. It is also true for malignant neuroma.

The demonstration of this fundamental fact naturally is the more sure, as the specific histologic feature of the disseminated cells are more evident, as is the case in epithelial, cartilaginous, nervous or mucous cells. But it is also assured by the identical composition of the youngest metastases exactly showing the same histologic structures as the primary tumor.

Further we can say, that every carcinoma commences with the formation of metastasis spreading; or expressed in another way, the true nature of carcinomatous condition is the dissemination of certain epithelial cells. If we have the opportunity to examine the first stage of carcinomatous development, we can perceive this fact and will be inclined to assert such a diagnosis if we can demonstrate this epithelial displacement.

In this fact reposes the theory of R. Virchow, declaring the carcinoma as an heterotopic development of epithelial cells. Cohnheim, *vice versa*, thought that epithelial tissue displaced in embryonic tissue may be the origin of cancer, while Ribbert, during the last year proposed the opinion that every cancer commences with epithelial developments near the normal epithelial covering, but originating from embryonic epithelial germs.

The theory of Virchow is no more acceptable, since we know the sharp division between the descendants of the different germinal plates, and the theory of Ribbert reposes on the hypothesis of germinal displacement of single cells, not demonstrated, probably not demonstrable. The broadest pathologic view showed Cohnheim's theory of the highest value for the understanding of tumor formation, but not for malignancy.

If we remember the large number of embryonic implantations, we must positively deny that they show a disposition for malignancy. All dermoids or natural graftings of skin particles in the depth of the organs can grow, and many of them, as the dermoid of the ovaries, will become very dangerous in later life, but only by mechanical influences producing irritation of the peritoneum or perforations into the intestine or the urinary bladder, seldom also of the abdominal wall. But I do not remember one case of carcinomatous degeneration.

The same benign or only locally dangerous course show the fetal implantations, the dermoids containing whole organs, as I have shown, dispersed parts of a second fetus included in the abdominal cavity of his brother. Here the destruction of the included fetus can be so great that the different tissues seem to have lost all their natural connection, lying pell-mell, and notwithstanding we observe here not the active penetration of connective tissue by epithelial cells, as in the cancer. Where two tissues develop together the relation between them is always the normal in these cases.

But there exists a second kind of tumor, apparently resulting from embryonic influences demonstrable nearly in all organs. In these certain parts of the tissues, composing otherwise normal organs, conserve their embryonic conditions. To this class belong most of the congenital multiple tumors, the multiple neuromas and neurofibromas, the multiple enchondromas and the multiple adenomas.

I will refer here only to the last, as they seem by their epithelial origin to be mostly adapted for cancerous growths. These adenomas are preferably devel-

oped in the ovaries, the liver, the kidneys and the mammary glands.

In the ovary they are found under the two forms of so-called compound cystoids and of papillomatous tumors.

The first, the mucus-producing form, is developed, as I have shown a long time ago, from the embryonic tubular structure of the ovarian glands (Valentin, Pflüger), not transformed to Graafian follicles.

Already Spencer Wells remarked that after extirpation of a cystic ovary the other oftentimes developed in the same manner. I could sometimes demonstrate the stages of this affection in the seemingly normal organ of the other side.

The exceedingly frequent recurrence of the adenoma of the breast after extirpation of the greater knots is well known; also the fact that these recurrences, starting from embryonic remains and finding place for development after removal of the first, are not at all dangerous or give a disposition to cancer. I saw such a breast operated upon more than twenty times and containing many more adenomas of microscopic volume.

The adenomas of the liver are often so numerous, forming small gray nodules, that they may resemble miliary tubercules. But some of them can develop to very large tumors without causing metastases.

In the kidney, where these tumors form also multiple gray spots, composed of proliferating uriferous tubes (not to be confounded with the disseminated germs of the adrenals), I have seen as the first case that came in my hand here an enormous tumor of this sort, operated by Dr. Ferguson, Sept. 30, 1896. The patient was a young lady from Canada, operated upon some years before for a cyst, opened through the abdominal wall, the origin of which could not be located. The kidney at this time was probably not enlarged and only one of the multiple adenomas was developed to a large cyst. Now, the whole kidney formed a tumor of two feet in length and one in breadth, reaching down into the pelvis and upward into the thoracic cavity, raising the diaphragm and displacing the heart and left lung.

The enormous tumor, enucleated with great skill and with happy result, proved to consist only of the kidney; the normal kidney-substance formed a small strip at the one pole. The other pole contained a large cyst surrounded by soft gray adenomatous tissue. The median part was composed of grayish-looking, round adenomatous nodules, varying from the size of a chestnut to that of a man's fist, separated by very small tracts of atrophied kidney tissue. The cyst was formed more by necrosis and absorption of the necrotic tumor masses, than by distension of tubules.

As the recovery of the patient was effected in a short time and she gained very much (24 lbs., Jan. 30, 1897), it is not to be considered a carcinomatous development, which is also not at all sustained by microscopic investigation, showing only proliferating tubes.

In other tumors of this class we can observe the highest possible proliferation and dissemination of epithelial tissues without formation of metastases or dangerous development. So, in one case of double-sided papillomatous tumors of the ovaries, combined with a great urachus-cyst, operated by Dr. Franklin H. Martin in the Post-graduate Medical School, there protruded enormous papillomatous masses, covered with thick layers of proliferating epithelial cells, freely in the abdominal cavity without giving rise to secon-

dary development. These masses and also the same formations filling up the distended Graafian follicles exhibited a very interesting production of ovum cells, described first by Ernst Neumann in Königsberg, a true adeno-papilloma oviparum.

All these excessive productions of epithelial cells, limited to physiologic condition in the behavior and relation of tissues are quite different from carcinomatous epithelial productions.

Further, we must say: dissemination of normal epithelium produces no carcinoma. Such disseminations occur in the female body at every menstruation. All attempts made by different observers to produce carcinoma by implantation in lymphatic spaces have totally failed.

The hitherto reported observations lead to the conclusions: 1, that the embryonic condition of any part of the body can be regarded only as one of the causes of tumor formation, but not of the malignancy of tumors; 2, that the malignancy of tumors, the faculty of spreading by its elements, is due to a modification of the tumor cells.

The next question will be to disclose the nature of carcinoma cells and, if possible, the origin of this modification of cell life.

As to the first question, it suffices to indicate the two well known properties of these malignant cells, as we can now say, the faculty to grow and proliferate in a strange tissue and the deficiency of tissue formation. The epithelial cancer cell produces in any organ into which it is transported by their own movements Waldeyer's contractile epithelial pus-cells, or by the currents of lymph or blood, irregular cell masses, resembling somewhat the original tissues, flat or cylindrical cells, but very different from the original masses. The relation of the cancer cells to the surrounding stroma is deeply altered; blood vessels and connective tissue grow, as it seems, stimulated by the cancer cells in the same excessive and irregular way as in the primary tumor.

We can express this simple fact without any hypothetical suggestion as the disturbance of the laws of tissue formation or of normal growth.

As to the second question, the causes of this lawless cancerous growth, we must refuse to accept the embryonic theory and, so far as our knowledge now reaches, also the microbic theory. If new investigations should detect an organism promoting this cancerous metamorphosis, and also present in all the other malignant tumors, as endotheliomas, neuromas, myomas, etc., certainly a very intimate symbiosis must be established between such organism and the cancerous cell, the medium of metastasis. Intracellular microbes would only cover this claim.

As every effort to demonstrate such a microbe has failed, we must ask if the clinical features of malignancy suggest such a theory. But as the observations of direct or indirect infection and the formation of endemic or epidemic development of cancer (not regarding the more seldom developing forms of other metastatic growths), are not present or available in any extent, I will not delay this exposition of facts by criticising the opposite assertions, familiar and local differences in the frequency of cancer.

But I must insist on one fact not enough regarded, as it seems to me, that in a higher way as the clinical facts invalidate the idea of infection, that is, the originating of true cancer in other benign or infectious tumors.

With very few restrictions we can point out as a general law, that the origin of cancer is always a secondary metamorphosis of proliferating tissues.

That this is the case in a considerable number of cancerous growths nobody will deny; I remember the development of cancer in lupous or tubercular ulcerations of the skin, in the chronic ulcer of the leg and the round ulcer of the stomach, also in the chronic hyperplastic affections of mucous membranes. The cervix uteri gives many good examples, by the way, oftentimes affording diagnostic difficulties. Before the ulceration they seldom can be detected to be of a cancerous nature. Therefore the microscopic diagnosis of all the hypertrophic adenomatous, papillomatous and polypous forms of vegetations of the neck of the uterus is of the highest value for the question of radical operation. Once, in the practice of Breisky in Prague, I found a very well developed cancer in a pedicled small polypus of this part.

The highest support for the successive development of malignancy is given by cases in which foreign bodies promote first the development of simple benign tumors, which later on are changed to cancerous growths. The calculi in the gall bladder and foreign bodies (once a cherry stone) in the stomach, I have observed as the causes of papillomatous; later cancerous growths.

Another instructive object is found by the papillomatous growth of the urinary bladder, developing oftentimes in younger years and leading by repeated bleedings to the highest forms of anemia. I have observed a number of these cases for years, the healing after natural expulsion of these tumors and otherwise the carcinomatous metamorphosis, if these long standing tumors are not eliminated in the natural way or by surgical help. In one of my friends in Switzerland I have followed this development for years, in vain insisting on operation.

Now, I have here received from Dr. Kovats in Milwaukee, Wis., such an object, operated as I hope at the right time, but showing as I think a partially malignant metamorphosis.

In former times it seemed sufficient to give a bad prognosis, if in the urine of such cases were detected many large and irregular epithelial cells, and indeed, many of these patients died cancerous, as the operation was not undertaken. Others, in which natural elimination occurred, recovered. Hence, the conclusion is secured that the once benign tumor becomes malignant after a time.

I can show you microscopically in this tumor one part in which, at some places the intrusion of the covering and highly vegetating epithelial cells into the stroma has commenced, and in which epithelial cells at one place forming a rounded heap, are present in a wide lymphatic space, included by a fine fibrinous network. Without imbedding in paraffin it would be not possible to obtain from such tumors complete and sufficient thin slices (1-100 millimeter).

In this case the basis of the tumors containing broad arteries was found to be quite free from such development. So I could notwithstanding express a somewhat hopeful prognosis. The future will reveal if this view is correct or not. The radical cure of cancer by total extirpation is no more questionable.

But in such cases there will remain oftentimes a doubt. We must ask if really this penetration of proliferating epithelial cells will always be sufficient for the diagnosis of cancer. If we find irregular growing

epithelial masses in great extension in an also granulating stroma, there can not be justified a doubt. But if this process is going on to a very small extent, this doubt must arise the more, as one is convinced of the harmlessness of normal epithelial cells introduced by only mechanic forces into the lymphatic spaces. I have reminded you of a number of such facts.

Therefore, we must search to point out the true features of cancerous proliferation. If the epithelium cells are the seat of this metamorphosis, the proliferating cells only can give us the explanation for this biologic change. The irregularities in mature age depend upon modified development.

The principal feature of carcinomatous cell proliferations can be denoted as *hypermitosis*, depending upon supernutrition of the cells. In the place of the normal well-known forms of karyokinesis we observe in every carcinoma or other malignant growth irregular and exaggerated forms of mitosis. I have marked out a part of these processes in my "General Pathology"; also Hansemann of Berlin has given valuable observations of the same, but regards more the phases of division as the preparatory stages of the process. Here, let me give a more complete exhibition of the process.

As I have remarked in my first publication, the epithelial cells tending to karyokinesis take up a greater quantity of coloring matter in the protoplasm and in the nuclei; both enlarge, the first staining more intensely with acid anilin dyes, as eosin or methyl orange, the nuclei with hematoxylin. In intensely proliferating objects, in which these very transient processes are fixed by rapidly killing the cell life,¹ one notices after staining the fine sections (1-100 mm. thick) with hematoxylin² and eosin, that in different parts of the preparation black (methyl orange) or deep blue (eosin) stained nuclear masses are present in abundant quantity, centers of proliferation (Flemming). In the same parts are recognized the different stages of karyokinesis and lastly a greater accumulation of leucocytes with fragmented nuclei. The last are irregularly disposed; some cells are crowded with them, others are free or we find only some leucocytes between the cells.

This seems to be the commencement of the process; the cells with richly staining nuclei contain a somewhat smaller number of fragmented nuclei, the bodies of them are dissolved and the stained leucocytic nuclear masses seem to be taken up by the nuclei of the epithelium cells. The leucocytes feed the epithelium-cells. After this supernutrition the nuclei will be swelled up more and more by a colorless fluid, the membrane of the nucleus becomes thinner and thinner, whereas the stained nuclear substances commence to show the different stages of karyokinesis.

The forms of the spirema (Clew, Knänel) are not so clear as in normal mitotic division in consequence of the tight accumulation of the nuclein. In the first time of this stage it makes the impression as if these masses form an homogenous semiliquid fluid, the limits of it being not so clearly defined.

As a consequence, there begins the separation of the nuclein into different parts, mostly forming manifold

¹ I use now for fixation a mixture of alcohol, about 4 parts, with formalin (40 per cent.) 1 part.

² My hematoxylin solution is prepared in the following manner: One gram cryst. hematoxylin is dissolved by warming in 20 c.c. kresol water 2 p.m. There is added for every c.c. of this solution one drop of a concentrated solution of ammonia alum in kresol water and filled up with kresol water to 100 c.c. The solution is ready for use in twenty-four hours, deposits very small quantities that must be taken off by filtration, and stains the thin sections in one or two minutes.

compound middle plates, often in connection with one another, often separating in three or four or more plates. But generally not all of the nuclein is transformed at once in this manner; greater or smaller quantities of it are disseminated in loose masses, showing the form of fine threads dispersed through the free parts of the clear nucleinic area, that is no more sharply defined against the red-stained protoplasm.

If the middle plates are separated or only curved a little with the concavity against the periphery of the cell one may notice one or two very small entosomes or central corpuscles exactly in the center of the circle, a section of which is formed by the middle plate; the whole constitutes one "attraction-sphere." The central corpuscles of the sphere are too small for showing a well-defined color, but they are best seen in preparation afterward stained with safranin. I suppose that these corpuscles are formed of the nucleolus not visible in this stage, but very large in all perfect nuclei of carcinomatous cells.

The formation of asters or stars, I have not observed in these hypermitoses. This stage must be very transient. But I have proofs that this metamorphosis and the formation of new nuclei is going on by repeated changes successively in one and the same cell, a feature quite characteristic of carcinomas. I can show you such cases in which the whole periphery of the highly enlarged cell contains well-formed nuclei, lying one near the other and containing a red-stained nucleolus, whereas in the central part the younger stages of karyokinesis are developed.

As a middle stage between these two phases, the curved middle plates and the perfectly developed nuclei, I have observed a few times large round vacuoles resembling the physalides described by Virchow, limited by a very fine membrane, and containing in a clear interior an indefinite mass stained red with safranin, possibly a nucleolus in formation; also a very few nucleinic threads. That in this case a deficiency of this latter substance resulted in a retarded or insufficient nucleus formation, I can not say with certainty, but it seems not improbable. If the attraction sphere acts by pulling of a part of the nuclein from the middle plate, it could be that this action has been insufficient in some instances. The spindle-shaped fiber of the attraction-spheres I have not been able to stain, but I am trying the methods of Flemming, which, as that observer remarks, are not always efficient. Possibly they will stain better in preparations fixed with osmic acid.

If we look over the whole process we see clearly the following phases of development of tumors, ending in the carcinomatous metamorphosis:

The first stage is that of chronic irritation or inflammation, originated by microbes or by mechanical, or probably also by chemical influences producing a chronic state of hyperplasia, the so-called benign growths composed of all normal tissues constituting the part. This development can lead to diffuse hyperplasia or tumor-formation.

The second stage commences with new emigration of leucocytes and progressive development of certain cells, losing through the hypermitotic production the faculty of normal tissue formation. The excessive proliferation and the possibility of living in a strange medium promotes the formation of metastasis, the true feature of carcinoma.

I will add the remark that this mode of develop-

ment seems to exclude the healing of malignant tumors by irritations, the electrical, microbic or chemical treatment. The delimitations of emigration processes would be preferable to the necrotising effects of these treatments. But the surest way will be always the removal in time. Possibly we may prevent or modify the cancerous metamorphosis by inhibiting substances with negative chemiotaxis, repelling the leucocytes, as the by no means sure healing influence of some bacterial toxins seem to show (Coley, Tavel, Emmerich and others).

For the diagnosis the early and repeated microscopic investigation of the diseased part will be the only reliable method. But to make this method effectual the small removed parts must be fixed immediately after removal. Our solution seems to be commendable, as the substances composing the fixative, alcohol and formalin, are in the hands of every surgeon.

CANCER OF THE RECTUM.

WHAT HAS MODERN SURGERY ACCOMPLISHED IN ITS TREATMENT?

Read before the Chicago Academy of Medicine, January 8, 1897.

BY JAMES P. TUTTLE, M.D.
NEW YORK.

After centuries of experimentation in which almost every known drug has been tried, we are forced to acknowledge that thus far we know of no remedy which offers the faintest assurance of the cure of cancer; if we except the arsenic pastes. The rapidity of absorption and our inability to control its action, render arsenic too dangerous to use in cancer of the rectum, except, perhaps, in cases of epithelioma at the margin of the anus. Until late years the high mortality and rapid recurrence after operation rendered this avenue of escape as hopeless to the sufferers as that of therapeutics, but since the discoveries of Lister and Kraske they have been gradually declining, and the radical removal by the knife, offers today assurance of relief from suffering, and some hope of cure to the unfortunate suffers from this disease.

The late period at which most cancers of the rectum are discovered, renders it improbable that we will ever be able to extend this hope to even the majority of such patients. Up to the present time the experience of most conscientious surgeons will agree in having advised against radical operation more frequently than in favor of it. Perhaps when the profession have become more expert in diagnosis; when the careful examination of the rectum has become more systematically practiced in all cases with intestinal symptoms, and when we shall have reduced the mortality of the operation to a minimum, the balance may move to the other side of the page, and we may offer encouragement to the large majority of such patients.

What we come to study at present is: "What has modern surgery accomplished in the treatment of these cases?" What are its limitations? What are the immediate and remote results of operation?

By modern methods we mean inguinal colotomy, resection and excision of the rectum. In colotomy we have a palliative procedure with little danger attached to it, and with no promise whatever of cure; in the others we have radical operations, with some danger attached, which offer relief from suffering

together with a more or less well-founded hope of permanent recovery.

Outside of this immediate danger, there would never be any question with either doctor or patient as to which course to pursue, and it is to this particular point that I will devote the most of this paper.

The mortality of any operation depends largely upon the selection of cases. The point to be decided in each individual case is, whether it is a suitable one in which to attempt a radical cure, or not. There is a sharp division in the two lines of treatment at this point. We must either go boldly forward in our efforts to cure, or content ourselves forever afterward in that individual case, with palliative measures. I can not endorse the doctrines of some teachers that we must either excise or colostomize as soon as the diagnosis of cancer is made. The former is imperative in its demand to be done at once; the latter is a palliative measure and is only called for when the disease has progressed to a stage of obstruction, or to that condition in which the passage of fecal matter causes hemorrhages, pain and reflex symptoms.

In a large majority of cases, these symptoms, severe enough at least to call for colostomy, do not arise until the lethal period is near at hand, and then the operation alleviates the sufferings of the last few weeks. I have gone faithfully over the statistics, so far as published, year after year, and I fail to find any proof beyond the simple *post hoc ergo propter hoc*, that this operation prolongs the lives of patients to any great extent. Because one lives two, three or even four years following this operation does not prove that it was on account of it, or that he would not have lived had the operation not been done. Some cases of cancer of the rectum, of that slowly progressive type, live long periods without any operative interference; and I am perfectly sure that all the cases which have been claimed to be cured by colostomy, have been cases of mistaken diagnosis, being either simple or syphilitic proliferating ulcerations. On the other hand, I can not agree with those who hold an artificial anus to be a painful and disgusting deformity, by which no patient was ever made comfortable, and with which he was never content. At the proper period, and under proper conditions, there is no palliative procedure more benign in its effect. When properly made, such an anus can be fairly well controlled, and the normal functions of the bowels maintained. There is no reason to suppose that such an operation would retard the metastatic dissemination of the growth throughout the body, except that there is a decreased lymphatic absorption in the parts. Nor is there any proof that the growth of the tumor *in situ* is retarded by the operation, unless we accept as such the slightly increased average length of life. The worst feature of early colostomy, however, is its absolute hopelessness. To perform this operation upon a patient without the promise of a future excision, is to consign him to a certain death, which ever slowly but surely creeps upon him, which he must look squarely in the face, and from which there is no possible escape. Such hopelessness, to my mind, is worse than that of a condemned felon in his cell, who has, at least, one comfort, in that he knows the day when all his anxieties and sufferings will end. The effect of such a discouraging condition upon any man, and the fact that the very presence of the artificial anus constantly reminds him of his fatal disease, makes death almost

preferable to life. The relief afforded to a few patients in the later stages of the disease is certainly great, and I have no hesitation in advising the operation where the conditions are not favorable for the attempt at radical cure, and where the patient's sufferings are such that relief is promised by this procedure.

Beside the inconvenience and discomfort produced by the artificial anus, and the hopelessness of colostomy for malignant growths of the rectum, it is still an open question as to how much life is prolonged by this operation.

Crespin, Mathews, Adler, Allingham, Jr., and Kelsey, the great apostles of colostomy, do not claim an average of over eighteen months of life following this operation in cancer of the rectum. The statistics which I have been able to gather are very meagre with regard to details, but certainly, would not give an average lease of life of more than one year after colostomy. The claim that the operation relieves pain is partially contradicted by its most enthusiastic advocates in that they all, eventually, resort to opium sooner or later in these cases. Moreover, pain is generally one of the least distressing symptoms of the disease, unless the growth be low down, near the margin of the anus, where all admit that extirpation should be practiced. It can only have a very slight influence in preventing hemorrhage unless combined with curettage. It does relieve the constant symptoms of diarrhea, but it does not remove the spasmodic contraction of the sphinctures when the growth is low enough down to involve the sensitive area of the gut. In fact, the most of these symptoms only appear after the period favorable to extirpation has passed by; when it is a question of colostomy or morphin; and when colostomy is done, it generally resolves itself into both.

The immediate mortality from colostomy is about 3 per cent. or less. In ordinary conditions, we can almost positively promise recovery from the operation, but unfortunately, this is about all we can promise except in cases of obstruction and stricture.

But what does the modern operation offer in place of this relief and in justification of its greater risk?

I present you herewith three sets of statistics: No. 1 showing the early results of extirpation by the perineal method; No. 2 embracing the first five years' experience with antiseptics and the sacral methods, and No. 3, embracing the last six years, including over 125 unpublished cases, contributed to me by surgeons all over the United States for use in this paper.

Let us study these tables carefully, and draw, if possible, a just estimate of the results of the modern operation, and then we can answer the above question. I have not thought it worth while to include in these tables the cases of Favet the first to perform the operation in 1763; of Lisfranc, who popularized it for a while in 1833, or of Dieffenbach, whose remarkable series of cases has been received with the greatest incredulity by the profession.

TABLE IV.—MORTALITY AND RECURRENCE, CANCER OF BREAST. (FROM CHEYNE.)

Reporter and Reference.	Mortality. Per cent.	Recurrence. Per cent.	Cases.
Bilroth, (Winnlwarter)	22	68	89
Trendelenberg, (Neuendorf)	12	68	50
Luicke, (Deltrich)	8	60	69
Czerny, (Schmidt)	6	46	82
Kronlein, (Horner)	4	68	121
Konig, (Hildebrand)	9	61	118
Bergmann, (Eichel)	7	62	43
Halsted	00	54	11
Cheyne	00	42.8	21

In the first table I have collected 487 cases, operated on by the perineal methods with a mortality of 22.4 per cent. This is not high considering the period, but unfortunately, it embraces only those cases in which the disease was situated near the anus. As will be seen later on, the operations by this method at the present day are much less fatal, the mortality being about 8 per cent.

In Table No. 2, I have tabulated 512 cases of perineal and sacral operations done after the advent of antiseptics, and the publication of the epoch-making paper of Kraske. From these there is a mortality of 20 per cent. These cases are from the clinics of special operators and there is a great difference in their individual results.

In Table No. 3. I have sought to learn the results of these procedures in the hands of a large number of operators, believing that this would be a safer test of their utility. In this table we find 259 cases with 31 immediate deaths, a mortality of 11.7 per cent. Comparing this with the previous tables, or with the statistics furnished up to 1892, we have much to encourage our hope that this mortality will eventually be so reduced as to disarm the criticism of those who still hold that it is unjustifiable on account of its danger. There is scarcely a critic of this operation but who would unhesitatingly advise the extirpation of a cancerous breast. I have thought it worth while, therefore, to insert a fourth table, the latest and most favorable upon this procedure in order to show how favorably extirpation of the rectum compares with it, and with what similarity the mortality has decreased in each with modern surgical methods and experience. With due allowance for the difficulties in diagnosis may we not hope to obtain almost as good results in cancer of the rectum as in cancer of the breast? Surely the experience of Czerny, twenty-five cases with one death, Bramann, twenty-three cases with one death, and Halsted's clinic, eight cases with no death, justifies such a hope. In my own collection no distinction or selection of cases has been made. They have been taken just as found in the journals, or described to me by the operators, and tabulated with

The following synopsis of a thesis by M. Finet, of Paris, which came into my possession after my paper was written, portrays the results of the operation in continental Europe. It is interesting to compare this with that made from the cases collected by myself, and which follows below. Including these we have over 1,600 cases from which to draw conclusions, and it seems to me they are convincing.

SYNOPSIS FROM FINET'S THESIS.

Immediate deaths	60
Deaths under 1 year, cause not given, 8; deaths between 1 and 2 years, 3; deaths between 2 and 3 years, 1	12
Deaths from recurrence in situ, under 1 year, 17; metastasis under 1 year, 12; in situ between 1 and 2 years, 2; metastasis between 1 and 2 years, 1; in situ between 2 and 3 years, 3; metastasis between 2 and 3 years, 1	86
Living with recurrence under 1 year, 18; under 2 years, 1; under 3 years, 1; over 3 years, 2	22
Living without recurrence under 1 year, 124; under 2 years, 11; 3 years, 23; 4 to 5 years, 10; 5 to 6 years, 7; 6 to 7 years, 6; 7 to 8 years, 5; 8 to 10 years, 5; 10 to 11 years, 3; 11 to 12 years, 1; 12 to 14 years, 1; 14 to 15 years, 2; 15 to 16 years, 1; over 16 years, 2	201

Died without recurrence after 4 years, 4	4
Mortality, 10 per cent.	311

SYNOPSIS FROM MY OWN TABLES.

Immediate deaths	81
Deaths under 1 year, recurrence in situ 8, by metastasis 6; between 1 and 2 years, recurrence in situ 4, by metastasis 3; between 2 and 3 years, recurrence in situ 4, by metastasis 2; after 3 years, recurrence in situ none, by metastasis 1	28
Living with recurrence under 1 year, 8; between 1 and 2 years, 5; 1 each 2, 4, 2, 2, 2½, 4 years	17
Living without recurrence under 1 year, 90; over 1 and under 2 years, 43; over 2 and under 3 years, 20; over 3 years, 23	181
Mortality, 11.7 per cent.	267
Sacral, 173 cases, 23 deaths; mortality, 13.3 per cent. Perineal, 70 cases, 5 deaths; mortality, 7.1 per cent. Vaginal, 1 death; anal, 1 death; not given, 1 death.	

the sole desire to learn the truth concerning this operation and not with the view of confirming a preconceived opinion. They embrace the results of all grades of operators, working under favorable and unfavorable circumstances, and if under these conditions such a low mortality can be obtained, what may not be done by experts in properly equipped hospitals and in carefully selected cases.

In the tables we have not separated the perineal from the sacral operations, because we hold that the latter operations should not be done when the growth is low enough to be *thoroughly* removed by the former. All of the sacral operations have been classed under one heading, because they are more or less modifications of that one method, the "Kraske." Of these, there are 173 with 23 deaths, a mortality of 13.3 per cent. Of the perineal excisions there are 70 with 5 deaths, a mortality of 7.1 per cent. In the remainder the operator failed to state just what operation was performed, except in one fatal vaginal extirpation. Cheyne, in the Letsonian lectures for 1896, gives a much wider variation between the two operations. He says "Konig's total mortality is 38 per cent; Billroth's 34 per cent., Kocher's 28 per cent., Albert's 18 per cent., Iversen's estimate as regards the Kraske operation 25 per cent. and Czerny's with the perineal operation 5.4 per cent., with the sacral operation 19.4 per cent. So far as one can judge from a large number of reports, the mortality after the perineal operation seems to be about 8 per cent., after the sacral operation from 18 to 20 per cent., but the results vary much in the hands of different surgeons, probably in accordance with the selection of cases and the after treatment of the wound and in both instances, it can in all likelihood be somewhat reduced in the future" (p. 95). Cheyne draws his conclusions, however, from three operators and admits he is biased in favor of the English or perineal method. The difference in the death rate is due, first to the magnitude of the operation, second, to the involvement of the peritoneum, third, to the disturbance of the adjacent organs and fourth, to the fact that the higher the tumor the later will it be observed, and consequently the less favorable will be the condition of the patient for operation. Hemorrhage will not account for it, as there is less of this in the sacral than in the perineal method. The two operations have each their own field and the prognosis is more grave in the one, simply because the condition calling for it is more serious.

The results of any undertaking should always be estimated by taking into consideration the difficulties encountered and the end to be attained. In the radical treatment we undertake a serious operation, and for what? First, with the hope that by timely eradication, we may permanently cure. Unfortunately, statistics do not prove that we accomplish this desire in the majority of cases, and were this result the only object of the operation, it would hardly have been advocated by the many conscientious and brilliant surgeons who have done so. And yet, our results are not without encouragement from this point of view. Of the 259 cases we have been able to trace 219 for a certain number of years. There were 8 recurrences *in situ*, and 8 metastases within one year; there were 9 *in situ* and 3 metastases, between the first and second years, there were 4 *in situ* and 7 metastases, between the second and third years, and four all told occurring later than the third year. These numbers are important as showing how rapidly the percentage of recur-

rence decreases after the first year is past, and that when three or four years have gone by, we can almost assure our patients that they are permanently cured. The balance of these cases may be summarized as follows:

Well, when last heard from:

Under 1 years, subsequent to operation,	90
Over 1 year and under 2 years,	45
Over 2 years and under 3 years,	20
Over 3 years and under 4 years,	12
Over 4 years,	14

Assuming then, that these cases which pass beyond three years without recurrence are comparatively safe from the disease, we may, without assumption, thus claim a cure of 10 per cent. of those cases which survive the operation, and a more or less well-grounded hope for the 155 cases, 70 per cent., in which no recurrence has as yet shown itself.

But the purpose of the operation is not limited to absolute cure. Even when this is not obtained it accomplishes all and more than has been claimed for other palliative measures. The relief from pain, the danger of obstruction, the vesical and sphincteric tenesmus, the irritating discharges and the impeded functional activity of the bowels, are all relieved and far more completely than by any other means. It may be said that where suppuration takes place, and it does in the majority of these operations, we have not obliterated the discharge. There is a great difference between a temporary, free and unobstructed, discharge of pus from a granulating wound, from which the surrounding skin may be protected by proper surgical dressings and the perpetual, feculent, sanious, irritating discharge from an ulcerated cancerous growth. The very substitution of the former for the latter, the removal of this odor, disgusting both to the patient and to his friends, is one of the happiest results of extirpation, and a result which no other method can attain. With regard to the control of the movement of the bowels, where typical resection or excision has been performed, and the sphincters have been left intact, this function remains unimpaired, and the operation thus possesses all the advantages over colostomy that a normal anus has over an artificial one. Where the sphincters have been removed, and where it has been necessary to attach the resected rectum to the sacral wound, other things being equal, there is little choice between this and the inguinal artificial anus. They will, each, have to be controlled by functional regulation of the bowels and the application of suitable trusses or compresses to the part. Within the past few years, however, two improvements have been devised for the relief of these unpleasant sequences of excision. Gersuny proposed in 1892, that where the sphincters had to be removed, we might in a degree restore their functions by twisting the gut twice upon itself before suturing it in the wound. This operation has been done a number of times with more or less success. It certainly does accomplish the result for a time, but those who have had the most experience with it, are not confident as to its permanent efficacy. It adds no risk to the operation, consumes no time, and should, therefore, be done in every suitable case.

The second method for the prevention of incontinence is that proposed by Jaennell and Willems, and consists in making an incision through the inner fibers of the gluteus maximus muscle, drawing the resected rectum through this aperture, and suturing it to the

skin and muscular fibers. By this method, Jaennell claims to have obtained voluntary control over the fecal movements, and moreover, to have reduced the danger of peritoneal infection by removing the fecal discharges entirely without the operative field. I have had no experience with this operation, but it appears to be logical and coming from a source in which I have great confidence, I should look favorably upon it. We shall have more to say upon the subject of fecal incontinence when we come to study the sequences of this operation. It suffices here, to quote from one of the most enthusiastic supporters of colostomy on this point:

"In a small proportion of cases there will be a complete incontinence; in a greater number there will be partial control over the evacuations; in the majority, the control will be sufficiently complete to prevent the occurrence of any annoying accident."

Prolongation of life.—If we look at the subject with regard to the average lease of life which follows excision, we certainly meet with much encouragement. In the 219 cases which we have been able to follow, the average length of life is over 2 years and 3 months. This percentage has little meaning from the fact that 181 of the cases were still living at the time of the report, without any recurrence or other reason to believe that their lives would be materially shortened.

The best authorities agree that in cancer of the rectum unmolested, the average length of life is a little over one year. Assuming that all our patients had died at the period of last report, we would still have doubled the length of their days. How much more gratifying is it to remember that, out of 259 patients there are 181 to whom there still remains a hope, if nothing more; but to most of them an assurance of immunity from the disease. This is the final and, to my mind, the greatest argument in favor of extirpation; that it lends to our patients that supreme moral support that can not be over-estimated, founded on the belief that they are cured. The possibility of recurrence will always be present to some of these patients, warning them to seek relief at the very first indication. But the fact that they have already been relieved once, will give them confidence for the future, and thus remove in a large degree the depressing influence. Contrast this position with one who lives with his cancer undisturbed, and only palliated by an artificial anus, with a dreadful avalanche, as it were, slowly but surely sliding down upon him, with no possibility of escape, with only a few brief months between him and certain death, and you have the difference between excision and colostomy. For my part I can not refuse this hope to any case suitable for extirpation.

CAUSES OF DEATH.

Let us now look briefly into the causes of death from this operation. Out of the thirty-one immediate deaths reported above, nine were from shock, one from hemorrhage, eight from septic peritonitis, one from unknown cause, two from exhaustion (some weeks after the operation), one from atheromatous disease, two from cerebral symptoms, one from purulent empyema (which developed the night before the operation), one from suppression of urine, two from iodoform poisoning and three from anemia.

Having heard so much of the dangers of hemorrhage from this operation, I was, indeed, surprised to find only one death reported from this cause, although I am firmly convinced that the operation

can be done with less bleeding than that in an ordinary Whitehead operation for piles. The question of shock depends more upon the personal equation than upon the operation or the operator. I have seen a man die from shock occasioned by cauterizing a phagedenic bubo, and another from amputating a big toe. The patients who die from shock following this operation done in a reasonable length of time, would probably have succumbed under any surgical procedure. They are not proper subjects for surgical operations, and a more careful study of the personal element to be encountered in each case, will undoubtedly reduce the mortality from this cause. Three of the cases called shock among the deaths, were patients with flabby, fatty hearts, on which the operators themselves say they should never have operated. Moreover the injection of serum and normal saline infusions, promise in the future to greatly reduce the danger from this source.

Septic peritonitis is the second most frequent cause of death from this operation. It is generally supposed to be due to infection of the peritoneal cavity by the discharge of fecal matter into it, after the operation has been completed. Of the 8 cases referred to above, only 1 could possibly have been due to this cause. My own impression is, that the infection takes place during the operation, and is due to the practice of cutting off the intestine before the peritoneal dissection has been completed and this cavity walled off or closed. It may easily occur through the operator introducing his finger into the rectum in order to facilitate the isolation of the tumor and then reintroducing it into the wound where the peritoneum is exposed. The technique of the operation, as I shall describe it later, is particularly designed to avoid this accident and to control hemorrhage. Certainly, the majority of these deaths were avoidable.

The deaths from cerebral symptoms, without any condition in or about the wound to account for such a result, could not be foreseen or guarded against. They were the results of personal diathesis, of which the patient was either unaware or failed to appreciate the importance. In my own case, the history of old meningitis, with attacks of mania, which was concealed from me until these symptoms had recurred after the operation, might have deterred me from operating had I known them. I never saw a healthier operative field than the postmortem showed in this case, and there was absolutely nothing connected with it to account for death. The death from empyema was certainly not due to the operation.

Those deaths due to exhaustion from prolonged and excessive suppuration, and those from suppression of urine, anemia and iodoform poisoning, are accidents, and complications incident upon every surgical procedure, and while they may be avoided in a majority of cases, they will continue to occur occasionally, however perfect our technique.

Of the thirty-one deaths reported above, it appears to me that at least eleven of them were avoidable, some almost inexcusable. This would reduce the mortality materially.

(To be continued.)

Decline in Cocain.—Cocain has been declining in price very rapidly of late, owing to heavy shipments of the leaves of the erythroxylon coca plant from Peru and Bolivia. The drug is now quoted at \$2.50 an ounce. A few weeks ago it was nearly \$4 an ounce.

NOTES ON MY TRIP TO ATTEND THE
SECOND PAN-AMERICAN MEDICAL
CONGRESS, IN MEXICO CITY,
NOV. 16-19, 1896.

Read before the Cambridge Society for Medical Improvement,
Feb. 22, 1897.

BY AUGUSTUS P. CLARKE, A.M., M.D.
CAMBRIDGE, MASS.

On Saturday evening November 7, we took the Fall River Line to New York and from there a train on the Pennsylvania road to Washington, where a change of coaches was made by the way of Atlanta for New Orleans, which we reached in the early part of the day. Leaving New Orleans by the evening train we passed through the famous Teche country, noted for its extensive fields of cotton and rice. Our course was then directed through the flat lands of Texas. After leaving Houston and San Antonio our grade grew more ascending. When we reached Spofford Junction we took the International Railroad for the Rio Grande and crossed by the way of Eagle Pass to Ciudad de Porfirio Diaz, on the Mexican border. The officers of the Mexican Custom House were exceedingly courteous and endeavored in every way to facilitate matters for our convenience. The grade at Sabinas was 1,000 feet and at Monclova, 2,000 feet above the level of the sea.

The next important station was Trevino, the junction of our Mexican International with the Monterey and Mexican Gulf to Monterey and Tampico. The course of the track now is almost due west with a steady upgrade to higher altitudes until it reaches 3,753 feet at Jaral.

In this vicinity were seen growing not only cactus plants but also large fields of carefully cultivated agave Mexicana or the maguey. This plant furnishes the natives with the material for their building. Its leaves are used for paper, cordage and for many other purposes. From its juice is prepared the spirituous liquor called pulque.

We pass along the borders of the great Bolson de Mapimi and come to Torreon, where the Mexican International road crosses the Mexican Central and extends to the City of Durango. Our course, however, was from Lerdo, situated in the very heart of the cotton district of the Nazas and San Juan Valley and southward along the Mexican Central until we reach the Tropic of Cancer and Fresnillo, the first city within the torrid zone. This is the great mining country noted for its fabulous wealth where silver is obtained in great abundance. We continue our ascent until we reach Zacatecas, which has an altitude of upward of 8,000 feet.

The next important place was Aguas Calientes, signifying "hot waters," noted for its hot baths, of the benefits of which we availed ourselves on our return.

Lagos, Leon and Silao are now passed. The latter is where we took train on our return to Guanajuato, a terraced city in a mountain defile. Here is one of the famous mints of the republic, coining a half million of gold and five millions of silver annually, and here are also the large smelting and reduction works, besides manufacturing establishments.

We visited the *panteon*, a cemetery containing ten acres of ground enclosed by walls, perhaps ten feet high. Bodies are deposited in chambers. Here there is an immense sub-cemetery where the bones are placed at the expiration of the chambers leases. By

a winding stairway descent is made into this great charnel-house, which is nearly nine hundred feet long, twenty feet wide, and more than twenty feet high. The room is arched and well lighted containing all that is left of more than 30,000 Mexicans. Bones and skulls are piled up at either end of this storehouse, indiscriminately, without reference to ownership.

The next important station south of Silao is Irapuato, where on our return we took train for Guadalajara. Here we visited the Hospicio, an extensive institution for charity and religious instruction, containing twenty-three patios adorned with an abundance of flowers and with numerous fountains. The kitchens and dining halls were of colossal dimensions. The large and airy wards were bountifully supplied with bedding, and the whole establishment bore evidence that ample provision had been made for its inmates, who were sick and disabled children.

Our journey is continued through Salamanca, Celaya and Querétaro, noted for its aqueduct, which conveys the water to the city five miles across the plain. Though it has eighty arches it is not so long as the aqueduct of San Cosme at the capital, which has 900, but impresses the traveler more on account of its greater height, some of its arches being upward of ninety feet in height.

From this point onward the scenery grows more and more beautiful with its mountains and valleys and extensive haciendas, owned by rich Spaniards and under a high state of cultivation. The road now ascends. The train toils and climbs to overcome the resisting grade. At Marquez the highest point is reached, being at an elevation of 8,132 feet above the level of the sea.

In approaching the great city the tourist is on the watch for a view of the Tajo de Nochistongo, the great drainage cut commenced in the year 1607 with the purpose to drain the lakes on the plain of Mexico and to prevent the inundation of the city. The work was afterward abandoned, but a drain has recently been constructed on a more magnificent scale, forty-five miles in length, having a tunnel through the mountains of nine miles, not surpassed in size by the ancient cloaca maxima at Rome. A special opportunity was afforded us by the government to spend a day in viewing this work, which was said to be the most stupendous ever undertaken for the drainage of a great city and valley. The canal, which throughout its entire course has a steep and rapid descent, opens out into the Tula River, then into the Pánuco River, where the waters are disembogued into the Gulf of Mexico and carried out into the sea.

At Huehuetoca the first view of the snow-capped mountains is to be had. The volcanoes of Ixtaccihuatl and Popocatepetl and the plain of Mexico appear. At 6 P.M. on Friday, November 13, our journey to the capital of Mexico ended at Buena Vista station of the Mexican Central Railway. The station was now crowded. The reception committee, professors of the University of Mexico, and also Mayor Camacho and his wife, greeted our coming.

Prominent among the delegates on our train were Dr. E. Persillier La Chapelle of Montreal, Canada, President of the Provincial Board of Health of Quebec; Dr. Irving A. Watson of Concord, N. H., the Secretary of the American Public Health Association; Dr. E. P. Benoit, also of Montreal, Editor of *L'Union Médicale du Canada*; Dr. James D. Spencer, Fellow of the New York Academy of Medicine; Dr. A. Wal-

ter Suiter of Herkimer, New York, Secretary of the National Federation of State Medical Examining and Licensing Boards. McGill University of Montreal was represented also by Dr. J. C. Cameron, Professor of Obstetrics and Gynecology, Dr. Stewart, Professor of General Medicine, and Dr. Blackadder. On our train were also Dr. Alonzo Garcelon, ex-governor of Maine; Dr. Joaquin Yela, Consul-General of Guatemala; Dr. T. M. Calnek, Surgeon of Hospital de San Juan de Dios, San José, Costa Rica; Dr. David Cerna, Professor of Physiological Chemistry of the University of Texas. Dr. A. W. Parsons of Mexico, sent by the Mexican Committee, met us at Zacatecas and accompanied us to Mexico. A representative of the "Two Republics" met the train at Tula and assisted in giving us a warm welcome on our approach. Several of the gentlemen on the train were accompanied by ladies. My daughter, Miss Inez L. Clarke, A. B., was with the party.

The City of Mexico to be appreciated should be seen. It has an altitude of upward of 7,400 feet above the level of the sea. In the National Theater, in Calle de Vergara, the formal opening of the Congress took place on Monday evening, November 16, and was presided over by President Diaz, who was attended by his Ministers of State, prominent military and other officers, and by many citizens of the Republic. The boxes were occupied by the leading fashionable ladies of the city. The central portion of the edifice was reserved for the officers and members of the Congress and their ladies. The exercises consisted of addresses by President Diaz and by the organizing committee of the Congress. The addresses were followed by instrumental music and by a chorus of voices.

During the meeting of the Congress we were favored with an invitation to visit President Diaz and his wife at the Castle of Chapultepec, the White House of the Republic of Mexico. Here the members of the Congress were royally entertained. Not only carriages in abundance were provided for us, but all the substantial things which go to cheer the inner man.

Mrs. Camacho, a wealthy lady, the wife of the mayor of the city, gave a reception at her Mexican mansion. Refreshments and music were generously provided. The sweet singing by the rich and cultured voices produced a striking impression upon the hearers. The entertainment given on another evening was by the Jockey Club, composed of wealthy gentlemen, and modeled after one of the same name in London. Another reception was tendered to the members of the Congress and ladies by the Honorable City Council of Mexico in the municipal palace. Here refreshments on an extensive scale were again served.

In regard to the formation of the Congress, it may be said that it was composed of representatives from almost every country of the western hemisphere. At the opening of the Congress the Secretary-General said that about six hundred physicians were in attendance and were accompanied by upward of one hundred ladies. The reading of 294 papers was announced. In the Section on Obstetrics, Gynecology and Abdominal Surgery the titles of some forty papers were entered.

The work of the Congress was divided into twenty-two sections; of these several met in the Minería, or the historic School of Mines, which was established by contributions from wealthy Spanish gentlemen during the reign of the viceroys and which is

located on Calle San Andrés. This edifice underwent repairs for the reception of Gen. U. S. Grant on the occasion of his visit to Mexico in 1880. Other sections of the Congress were held in the College of Medicine, once the "holy inquisition" building, and also in the Military Hospital.

On Sunday evening, November 14, previous to the opening meeting of the Congress, a delightful entertainment was given by the faculty of the National School of Medicine of Mexico to the delegates. The visitors met in the great hall of the school, the old building of the inquisition, as before mentioned, which, though dreary in its general aspects, presented then a scene of no unusual interest. A short address of welcome was made by Dr. Carmona y Valle, President of the University. He said that the Pan-American Medical Congress differed from other medical associations in that, while the latter extended invitations in their own name the former did so on behalf of the country where the meetings were to take place. The gatherings, he said, had therefore an international significance. The delegates, he further said, had been invited to this informal reception that he might have the pleasure of introducing them to the faculty of the school and that he might give all an opportunity of becoming acquainted with one another. After some portion of the evening had been devoted to conversation the guests were directed to the magnificent salon of the Secretary, where champagne and refreshments were liberally served.

Prominent among the members of the faculty of the school who did honors most courteously were Dr. Carmona y Valle, president of the college, and his son; Dr. Eduardo Liceaga and his son Fernando Liceaga; Drs. Rafael Lavista, José Ramos, J. Ignacio Capetillo, Manuel Gutierrez, J. M. Bandera, Tejada Hurtado, Porfirio Parra, E. Montano, Francisco Chacon, Toussaint D. Orvananos, Regino Gonzales, Tobias Nunez, Nicolas Ramirez de Arellano and Tomas Noriega, secretary of the school.

My paper was the first that was read in the Section on Obstetrics, Gynecology and Abdominal Surgery. The next paper was on "Uterine Fibroids Complicated with Pregnancy, with Report of Cases," by A. Vander Veer, Albany, N. Y. He said that some forms of fibroids, such as the subperitoneal, pedunculated or sessile, often give but little trouble on the occurrence of pregnancy, but the chief danger occurs in those cases in which the growth extends into the uterine cavity or obstructs the outlet of the pelvis. Myomectomy in the interest of the child for cases in which dystocia would in all likelihood occur, offers a means for relief; near the close of the term, when dystocia is imminent, suprapubic hysterectomy he regarded as the safest operation to undertake. In such cases the loss of the mothers may not be expected to exceed 10 per cent. and that of the children to be nearly nil. Dr. Vander Veer's remarks had reference to the larger fibroids that were often liable to take on what is denominated cystic degeneration. In many such cases he advised removal of the appendages in preference to resorting at a later date to a Cesarean operation.

"Dystocia in Women of Mexico," by J. Ignacio Capetillo, Professor of Clinical Obstetrics in the School of Medicine of Mexico, was the title of a paper read before the Section. Dystocia, he divided into three classes, maternal, fetal and ovular. The cases of maternal dystocia arise mostly from the bad direction of the axis of the uterus; it may arise from the

vicious conformation of the vertebral column and of the promontory of the sacrum, or from a peculiar conformation of the pelvis of Mexican women; these may be considered as a *modalitis*, as he termed them, and not as a defect in conformation. Dystocia from narrowed pelvis due to rickets and from osteomalacia, is extremely rare. Dystocia in the third period of labor is sometimes caused in the native Indian women in consequence of the shortness of their perineum and smallness of their vulva, as compared with those parts in the Spanish-European women. This he attributed to habits of life pursued by the native female, since these women are accustomed to occupy for unusually long continuous periods of time a squatting position while making use of the *metapile* and the metate in grinding beans, corn, or other cereals. In accomplishing these tasks, the hands, the arms and the lower portions of the trunk of the body are put to the severest test.

"Treatment of Puerperal Infection," was the subject of a paper by Dr. Manuel Barreiro, one of the leading secretaries of the Section and the chief of the clinic of the Maternity Hospital of Mexico. His paper showed that the Mexicans were thoroughly up in all that pertains to modern methods for the management of obstetric cases. He regarded placental fragments as the chief cause of infection. He said that the objections brought forward against curettage were of no value; that cases occurred in which he resorted to it two and even three times before full relief was obtained. For antiseptics he had used the tincture of iodine and the bichlorid of mercury. Strychnia, hypodermatically, for loss of blood and for cardiac exhaustion was had recourse to. A visit to the Maternity Hospital showed that all its appointments were well carried out.

A paper embracing the statistics from the Maternity Hospital of Puebla, from Oct. 1, 1894, to Sept. 30, 1896, by Dr. José Maria de Ita, brought out the fact that only one-half of one per cent. in the mortality, and the almost extinction of puerperal accidents even in the management of very difficult cases, had been the outcome since the adoption of the use of antiseptics. Bichlorid of mercury was the sheet anchor. By a strict methodical use of these means the occurrence of blennorrhagia neonatorum was almost entirely prevented.

Time will not allow me to give a synopsis of the many interesting papers offered in the Section; they were largely representative and elicited a marked degree of attention. The paper on "Penetrating Wounds in the Abdomen," by Dr. Santos Medina, Juchipila, Zacatecas, Mexico, gave evidence that it had been prepared with much care and that the writer was not unacquainted with the details of abdominal work. "A Contribution to Abdominal Surgery," by Dr. Alfonso Ortiz, Alamos, Sonora, Mexico, presented several important features for consideration. Among other things, he said that a simple abdominal incision benefits or cures radically many inflammatory processes of the peritoneum, by the same unknown mechanism which cures a painful and irritable cystitis by cystotomy, an iritis by iridectomy, an incipient glaucoma by De Graefe's classic section; in the same manner that cerebral troubles of epileptiform character are relieved by means of a trephining; and as very serious otologic accidents disappear as if by charm after making the puncture of the tympanic membrane.

The paper on "Intestinal Obstruction," by Dr.

George W. Woods, Director of the Marine Medical Department of the United States, Mare Island, Cal., would lead one to believe that there is but comparatively small danger attending an exploratory celiotomy when a perfect operative technique, anesthesia and antiseptics are employed.

A paper on "Intestinal Anastomosis" was read by Dr. Jacob Frank of Chicago. Before reading his paper he was accorded, through the courtesy of Professor Lavista, an opportunity to try or repeat his experiment at the San Andrés Hospital upon a large dog. After etherizing the animal he resected four inches of the intestine and united the divided ends by means of a bone button connected with a piece of rubber drainage tube. Within forty-eight hours the dog was killed; union by anastomosis was observed to be taking place. Dr. Frank favored me with an opportunity to witness some of his work and explained to me many of the details of his method.

All discussion of papers was carried on with great dignity and courtesy. An original feature in the management of the meeting was that after an author had read his paper and it had been discussed he was invited to sit at the president's table and to take part in the conducting of the discussion of other papers that were to follow. This measure of proceeding with the work allowed the chairman an opportunity to arrange other matters for the interest of the Section, and afforded members a special opportunity to become better acquainted with one another. The greater part of the papers were in Spanish, but in a number of instances extracts were printed in English. The *précis* of all papers would have been published in the same language had the contributors furnished the organizing committee in season with sufficient data for so doing.

Our Section was extremely fortunate in having for one of its executive members Dr. Gustave Pagenstecher of San Luis Potosi. This gentleman had long been a pupil of Sanger of Leipzig; he was not only a good German and Spanish scholar, but he had acquired a most remarkable proficiency in speaking and writing English. Of any paper which was read in the Section he was able to give without delay a good abstract, in either Spanish or English, as was necessary. Dr. Pagenstecher is, indeed, a most successful interpreter in this line of work. I was fortunate in making an early acquaintance with him and we spent many pleasant hours together.

Other Sections of the Congress were well attended; their management and the papers read before them compare favorably with work done in other great medical gatherings.

The general hospital, San Andrés, situated on Calle San Andrés, is a well conducted institution. I had an opportunity of witnessing several important operations performed there. One operation by Professor Lavista was a tracheotomy in the case of a man suffering from dyspnea, due to secondary syphilitic infection. Another was the removal of a large malignant growth from the face. Some of the wards, however, of the hospital are located in the basement where the ancient flooring of stone still remains.

There are in the City of Mexico three other large general hospitals, beside several devoted to the treatment of special classes of cases, both medical and surgical. Of late there has been founded a Pathologic Anatomy Museum. This has been extended so as to embrace sections in bacteriology and bacteriologic

chemistry. The work is designed to be carried on in connection with the instruction given in the Medical University of Mexico. In this line of investigation the Mexicans are fast rivaling the great medical centers of Europe.

The Concepcion Beistegui Hospital, the Regina Nunnery, opened in 1886, is now a flourishing institution. It is the gift of Miss Beistegui, whose father was a native of Aragon, Spain, and whose mother, Donna Paula Garcia, was a native of Guanajuato, Mexico. Its medical department is under the directorship of the head physician, Dr. Joaquin Vertis, with whom are associated Drs. Ismael Prieto, J. Ramón Icaza and Francisco P. Chacón. It is opened for both males and females and for cases, whether medical or surgical. Since its establishment, over four thousand important cases have received attention. All its departments appear to be well conducted; cases of pelvic and abdominal diseases are attended to in the most modern fashion.

The Hospital de Jesús, on Calle de Jesús, was founded by Cortez, 1531. It has within a stone sarcophagus, and is still supported by descendants of the conqueror.

On our return, while stopping at San Luis Potosi, we visited the large military hospital of that place, also the children's hospital. Great attention is devoted to the sanitary matters and to the feeding and nursing of the children.

Mexico is carrying on a great deal of work in the endeavor to prevent disease. The Supreme Board of Health has instituted many measures of reform. The work undertaken by Pasteur is being recognized throughout the republic, and experiments on a large scale for rendering immunity against rabies and hydrophobia are daily performed. I saw a number of rabbits operated upon, à la Pasteur, at the laboratory connected with the Supreme Board of Health.

We took occasion early one morning to visit the American Hospital, which is situated on a short avenue just off Calle de Rivera de San Cosme; this street is a continuation of Calles San Andrés, Mariscal, San Juan de Divos, San Diégo, San Hipólito, Puente de Alvarado and Buena Vista. Before stopping at the hospital we visited the United States National Cemetery, which was in charge of Comrade John Ayers of the G. A. R. In the cemetery has been erected a monument to the memory of our gallant and brave soldiers who had fallen in our war against Mexico. The cemetery is on the left as we went westward on Calle de Cosme. The fence on the westerly side of the cemetery abuts close to the Nochistongo, as already described. The cemetery, on its easterly side, is bounded by the ancient road leading around to the Castle of Chapultepec. It was on this road that Cortez spent that dismal night (*noche triste*), July 1, 1520, when the Spanish soldiers under him were so terribly slaughtered in their flight before the pursuing Aztecs. The giant cypress tree (*el arbol de noche triste*) under which Cortez wept is still standing. It was over the moat, then filled with dead and dying soldiers that, "Alvarado, like Ney, the last to retreat," saved himself by a most wonderful leap, and found Cortez, who had halted at Tacuba, and was saved from utter destruction only by reason of the darkness of the night. The venerable tree is now inclosed by an iron railing, and on the stone memorial erected is inscribed the story of that dismal night.

The American Hospital is supported by contribu-

tions not only from Americans, but from Germans, French and people of other nationalities. Dr. Bray, an American physician in charge, received us in a most agreeable manner; the matron, Mrs. Netteberg, and her daughter ushered us into the dining room, where had been prepared for us and a few other Americans a most bountiful breakfast. We were accompanied to the wards and other rooms of the various buildings and were shown in what manner the sick and disabled were cared for. The operating room was found to be well lighted and furnished with many modern conveniences; instruments were in glass cases; basins, bowls and other articles for use were made after the most improved style. Abundant means for sterilizing instruments and dressings were at hand. Most of the instruments had recently been brought from Paris. The rooms were light, cheerful and the surroundings bore evidence of the display of good taste; the different buildings had a striking resemblance to the Roman villas.

While visiting Tampico, on the Gulf Coast, I noticed that meat when exposed even for a long time to the sun's hot rays did not spoil but became only dry and hard. This immunity from decomposition there, as in other parts of Mexico, I am told is due to the absence of bacteria. The infrequent rains, the cloudless skies and the stillness of the air are unfavorable conditions for the spread or development of microorganisms.

Monterey, on the Gulf and Monterey Railway, is worthy of some degree of attention from the tourist. It has become Americanized to some extent. We visited the heights on which the Bishop's Palace is situated and the fields where were fought the battles between the Americans and Mexicans, 1846-48; there we picked up some bullets and other relics that had been overlooked by previous visitors.

It should be said that the final entertainment to the members of the Congress was an excursion to the Pyramids of San Juan Teotihuacan, about twenty-seven miles from the City of Mexico. At San Juan we were met by two bands of music, a troop of cavalry and the Rurales. Horses and carriages were in waiting sufficient for the comfortable accommodation of all. The party was first taken to the remains of a pre-historic Mexican house, thence to the pyramids. There are two of the larger variety, one of the Sun and the other of the Moon. The Pyramid of the Sun compares in size not unfavorably with Cheops. In the neighborhood of these are a great many tumuli, isolated and grouped. The opinion of archeologists in regard to these very curious remains, chiefly based upon the wide divergence from any known types of the clay masks found in what may be assumed to be the older of the tombs, is that they are the work of a race older than either the Toltecs or Acolhuas, of which only these monuments now remain. After inspecting the pyramids a bountiful repast was supplied by the Governor of the State, Gen. José Vicente Villada. Mr. Leopoldo Batres, conservator of the public monuments, advanced to us the theory that they had been used for places of worship, not of war, although there were those present who imagined that they might have been used as watch-towers in order to give notice of invasions that might take place from nomadic tribes of the hills. He called attention also to the resemblance that these mounds have to those of Egypt, and thought that they were coeval if not previous. They were, he said, indelible traces of an

undoubtedly high state of civilization on the part of the builders.

The Valley of Mexico is a basin of about seventy miles in length and forty-five miles in width. It extends from Pachuca on the northeast to the mountains south of Lake Chalco, and from the Sierra Nevada range on the east to the Sierra de los Cruces range on the west. The valley has an area of 1,750 square miles, or is about one-fourth greater than the State of Rhode Island. In the northern half are three small lakes and scores of small villages, but no large towns except Pachuca; in the southern half are three large lakes, many large villages and the City of Mexico. The lowest portion of the basin is Lake Texcoco, which in its normal condition is only six feet below the level of the city. The bottom of the valley has an elevation of 7,400 feet, while the highest point on the sides is about 17,777 feet above the level of the sea. We enter the northern half of the valley through the Cut of Nochistongo, and the southern half through an opening on the western side of Sierra Guadalupe.

In this valley we are in the earliest home of man on this continent. The Chichimecs settled there in A. D. 635, a hundred years after the Toltecs came, and these were succeeded by the Aztecs in A. D. 890. Their name for the region was Anahuac, signifying "the place of waters."

Beside Texcoco, there are five other lakes in the valley. Lake Zumpango is the highest in the valley and is east of the cut. The River Cuatitlan emptied into the Zumpango, but the cut was made so as to turn the river's course into the Tula River. The new canal carries the water of the valley into the Ravine of Tequixquiac before entering the Tula River.

Zumpango is thirty miles north of Mexico City; Xaltocan and Zumpango are at an elevation of twenty-five feet above the city. San Cristobal is a small lake immediately north of Texcoco, twelve miles N.N.E. of Mexico and is ten miles long. Chalco and Xochimilco are the southernmost, whose levels are ten feet above Texcoco. The largest and nearest is but six feet below the pavement of the city at ordinary stages of the water. Texcoco is a salt-water lake two and one-quarter miles east of the City of Mexico, with which it is connected by a canal; its greatest length from north to south is about fifteen miles, its greatest width nine miles. Its depth nowhere exceeds ten feet, and in some parts is not more than two or three feet, while its shores are swampy. The lake is said to have been much more extensive than at present and to have included several islands, on which the Mexico of the Incas was built. Lake Texcoco is without any natural outlet.

I should say that there were presented in the Section on Anatomy, including Physiology, two papers of unusual interest. One of these was on "Hematology of High Altitudes," by Dr. Galdino Casillas, Guadalajara, Mexico. He said that "the increase of red blood corpuscles in the system in elevated climates is real and not fictitious," that is, that the condition of the system in elevated regions is not a "physiologic concentration of blood discs from a loss of water."

The other of these papers was on "Anatomic and Physiologic Modifications Due to the Elevation," by Dr. Daniel Vergara Lope together with Prof. Alfonso L. Herrera of Mexico. They referred to the "increase of the biachromal distance, of the length of the ster-

num, of the clavicular widening of the thorax and the increase of the pulmonary capacity." Those authors referred to the relation of the thorax to the height, and to several other vital conditions that obtain in the organism of those who dwell in high altitudes. The summary was that man can become completely acclimated to elevated centers. His humors are concentrated, his respiration and circulation are accelerated and the decrease of oxygen is compensated for by the increased activity of the hematoses. These facts, they said, ought to be borne in mind by the physician who is established in high altitudes. If these conclusions are correct, may not the varying degrees of the stature of individuals be dependent in large measure upon the degrees of altitude to which the progenitors during a long course of ages have been subjected?

APPENDICITIS, WITH REPORT OF AN INTERESTING CASE.

Read before the Section on Abdominal Surgery, Obstetrics and Gynecology, Second Pan-American Medical Congress, Mexico City, Mexico, Nov. 18, 1896.

BY HENRY L. E. JOHNSON, M.D.

A Vice-President of the Second Pan-American Medical Congress; late President of the Clinico-Pathological Society; late Vice-President of the Washington Obstetrical and Gynecological Society; Professor of Gynecology in the Medical Department of the Columbian University; Professor of Gynecology in the Post-Graduate School of Medicine of the District of Columbia; Director of the Gynecologic Clinic in the Central Dispensary and Emergency Hospital; Consultant to the Woman's Clinic, etc.

WASHINGTON, D. C.

I have the pleasure, Mr. President and fellow members, of presenting for your consideration and criticism a few remarks and observations on appendicitis, the disease which is attracting so much attention at the present time, and which is possibly not thoroughly understood by the medical profession of the day. The disease is one of frequent occurrence, and its mortality is in direct ratio to the accuracy of diagnosis and treatment.

Nomenclature.—The disease is and has been variously known as iliac phlegmon, typhlitis, perityphlitis, paratyphlitis, cecitis, pericecitis, paracecitis, peri-appendicitis, ephyaditis and appendicitis.

History.—M. Mastivier, in *Journal of Medicine, Surgery and Pharmacy*, Paris, May, 1759, reports the case of a man aged 45, with a large tumor in the right side near the umbilicus, who presented himself for treatment at the Hospital of St. Andrew of Bordeaux in the year 1757. Operation: evacuation of about a pint of offensive pus; postmortem showed a gangrenous cecum and appendix, the latter containing a large corroded and encrusted pin.

Early in the present century "Phlegmons in the Right Iliac Fossa" were extensively written about, without, however, attributing the same to the appendix. In 1831 Farrall published a paper on "Phlegmonous Tumor in the Right Iliac Region," in which the cecum is set down as the cause of the disease. In 1833 Dupuytren gave expression to the same views. In 1834 Copeland recognized the appendix as a possible factor, but quite secondary to the cecum. In 1837 the ulceration of the appendix from foreign bodies is spoken of as a matter of little consequence so long as confined to the mucous membrane, but causing abscesses when the peritoneum is involved. Hancock operated on one case in 1848. In 1867 Willard Parker of New York favors an early operation. From this time on, the theory of the cecum diminished and that

of the appendix increased. In 1880 Woirth of Copenhagen expressed his disbelief in the cecal theory. In 1883 Dr. F. F. Noyes reports 100 cases, of which 90 per cent. were operated upon in America. In 1886, Fitz of Boston put on record 209 cases.

Etiology.—Appendicitis is more frequent in males than in females. The disease is most common between the ages of 10 and 20. Fifteen per cent. of all cases occur in people under 15 years of age. Among the anatomic causes which predispose to inflammation of the appendix, the blood supply forms an important part, there being only one artery supplying the organ, and that forming no anastomosis. The richness of the lymphatic tissue which is found in the appendix plays an important part. Finally, it is claimed that its position favors inflammation.

Predisposing causes.—Intestinal catarrh and indigestion; distension of bowel with chronic constipation.

Exciting causes.—The usual causes assigned are the lodging of foreign bodies, fecal concretions, microorganisms and acute intestinal indigestion from imprudence in diet.

Varieties and pathology.—Various forms of the disease are recognized by different authors, the principal ones are catarrhal, ulcerative, infective and recurrent appendicitis, and the following seems to be the usually recognized pathology:

Catarrhal.—The exact frequency of this form, when mild, can not be determined. It probably produces no symptoms and may subside without leaving a trace. Chronic catarrh is, however, frequently found on postmortem examinations and is easily recognized, as it gives a thickening to the wall. The actual changes are those of mucous membranes elsewhere. There occurs a rapid shedding of the epithelium with detachment and extrusion of the epithelial lining of the crypts of Lieberkühn. The base of the mucous membrane is infiltrated by leucocytes, and the crypts are obliterated. The lumen is found to contain an abundance of leucocytes, granular débris, mucus and casts of the interior of the crypts, and the whole is sometimes molded into a definite central mass by the muscular movements of the tube. Perfect recovery by a new growth of epithelium is at first possible, but the shedding may be so complete and over so large an area that the denuded surface can not be covered anew. The inner part of the mucous surface now comes to consist of granulation tissue. This condition happily acts often as a preventive of further attacks, as by pressure of the surrounding parts the two surfaces grow together, with obliteration of the lumen of the tube, or again fibrous tissue may obliterate the cavity, and a natural cure results. The process may be confined to only a part of the tube, in which case there will be a stricture, usually near the cecal ends. The remaining portion sometimes is largest, forming a cyst. In many cases the condition becomes chronic with great thickening of the wall, as much as one-eighth to one-tenth of an inch in some instances, rendering the appendix firm and rigid.

Ulcerative.—This form is not preceded by a general catarrh. The ulceration is due to fecal concretions or foreign bodies. Feces press on the wall and injure the epithelium, which is ulcerated and finally destroyed. The mucous membrane, submucous tissue and finally the muscular coats disappear. In twenty-seven fatal cases (St. Thomas' Hospital) fecal concretions were found in eleven. Fitz (Boston), in

152 cases found them in 47 per cent. Mathews in 63 per cent. of 169 cases.

Infective.—This form of appendicitis may result from either one of the preceding, or may have an independent origin. It seems to be associated with bacterial invasion of the tissues of appendix wall, and in all cases leads to a virulent peritonitis. The bacillus usually most active is the coli communis.

Recurrent appendicitis.—This form is prominently known but quite recently. Treves has reported a case in which there were fourteen attacks, and McBurney reports one in which twelve attacks occurred within as many months. Krafft states that of 106 cases which he studied, 23 per cent. had been previously affected.

The writer reports herein one case in which five relapses occurred within twelve months. Operation was successfully performed during the fifth attack.

The writer believes that all cases originate in a catarrh or inflammation resulting from torsion, or volvulus of the tube or from fecal or other concretions, all producing greater or less ulceration, with sometimes perforation and subsequent bacillus infection of the appendix and adjacent tissues. The rapidity and quantity of pus formation is familiar to all surgeons, two or three pints having been known to form in some cases by the fifth day of the disease. The writer believes the process in the appendix follows a similar course with the Fallopian tubes, viz., inflammation with contractions, puckering, obstruction and fluid accumulation with in some cases resolution, and in others the formation of an infected pus cavity, which bursts or perforates and on the one hand results in general peritoneal infection, or by adhesive limitation, forms a circumscribed abscess or abscesses. Sometimes the appendix is found diseased and even gangrenous and without adhesions. In other instances the appendix is almost disorganized and is surrounded by pus and quite free from adhesions. The writer has seen such a case recently in consultation in which the appendix was removed and the patient recovered. The adhesions and torsions of the appendix so often observed in abdominal sections in gynecologic practice, may sooner or later be a factor in the causation of this disease.

Previous attacks of appendicitis which appear to have undergone resolution, predispose to subsequent attacks of greater or less gravity. Perforation with septic infection of the peritoneum and death may result very early in the attack. Matterstock found perforation in 132 out of 146 cases, while Fenwick found it to exist in 113 out of 130 cases. Accurate pathology will be obtained only by early and frequent operations and careful laboratory study of specimens.

Symptomatology.—The symptoms are usually severe and very pronounced. Pain, sudden and severe, is the first symptom noted. It is not always in the right iliac region, though at the end of twenty-four hours it usually becomes most prominent there. There is usually headache, sometimes a chill. Vomiting may or may not be an urgent symptom. The initial temperature usually ranges from 100 to 104 degrees, with a tendency to fall within two or three days. Sometimes the temperature is low and not in proportion to the other symptoms. The pulse is usually rapid, sometimes intermittent. Tenderness on pressure in right iliac region, with marked tension or rigidity of abdominal muscles over the right iliac region is almost pathognomonic. In 1889 McBurney first drew attention to a spot at which on deep pressure pain was

always elicited. This spot is situated at from one and one-half to two inches from the anterior superior spine of the right ilium along a line drawn from that process to the umbilicus. Constipation is usually marked at first, but may be preceded by two or three loose movements. Abdominal distention is usually marked for the first day or two. Increasing distention is a bad symptom. The pain is later increased upon motion or coughing, and there is a tendency to flexion of the right thigh or drawing the leg up to the body. The patient is most comfortable when lying upon the back. There is usually a tumor in the right iliac region of varying size, which is detected from the first to the third day. It consists of the appendix, intestines, omentum and exudate, and usually increases in size as the disease progresses. Exaggeration or increasing intensity of pain, accompanied by symptoms of shock, with the disappearance of tumor, followed by chill, fever, tympanites and vomiting, indicate usually rupture into the peritoneal cavity. These symptoms to a less degree, however, may indicate the formation of pus without perforation or perforation into the bowel. Prostration may or may not be a prominent symptom. The condition of the urine is usually negative, but sometimes contains albumin. There is usually marked loss of appetite with increased thirst. There are, sometimes, prodromal symptoms manifested for a few days, consisting of abdominal uneasiness and soreness with some distention and flatulence. These may often be discovered to have existed without attracting the patient's attention particularly.

Diagnosis.—The diagnosis is based upon the history of the case, the physical signs and the symptoms above mentioned.

Differentiation.—Appendicitis must be differentiated from renal and hepatic colic, acute indigestion, cholera morbus, strangulated inguinal hernia, torsion and volvulus and obstruction of bowels, and the various acute pelvic diseases in women.

Termination and Prognosis.—Fitz says that 26 per cent. and Stimson that 25 per cent. of all cases of appendicitis prove fatal. According to Fitz, 60 out of 176 cases of perforated appendicitis died during the first five days, 56 during the first four days, 28 during the first three days, and 8 during the second day, though a large number of cases of simple appendicitis are said to terminate favorably by resolution. Bull, in 1894, placed the mortality at 5 to 6 per cent., although he had collected 450 cases with only 8 deaths. Deaver collected 200 cases with only 2 deaths. Robert T. Morris records the mortality as 15 per cent. under medical treatment, with an addition of 10 per cent. from numerous chronic complications resulting from previous acute attacks. The prognosis is consequently grave and will depend upon early diagnosis and prompt modern surgical interference.

Treatment.—The majority of writers concur in the opinion that there is no reliable medicinal treatment for appendicitis. Osler says ("Principles of Medicine," 1895): "There is no medicinal treatment for appendicitis. Operation is indicated for acute inflammatory trouble in cecal region whether a tumor is present or not, and when by the third day the features of the case point to a progressive lesion." The case once accurately diagnosed, most writers agree that the operation should be done at once. In cases of recurring appendicitis the operation is performed in the interval, or as soon as the

symptoms recur. When the appendix can be found and its removal does not entail the breaking up of adhesions, thereby opening the peritoneal cavity, it is removed in the usual way. When not removed, the case is treated as an abscess cavity, being packed and drained. In this treatment there seems to be a consensus of surgical opinion. Thus Dr. J. D. S. Davis, of Birmingham, Ala., in *Medicine* for February, 1896, says: "To make an extensive search for the appendix is liable to break up adhesions and allow the escape of septic pus into the general cavity. The records of operation upon appendical abscess show that the great majority of cases are cured after evacuation and complete drainage."

Dr. J. B. Deaver (Surgeon to the German Hospital, Philadelphia): "The best results are obtained when the operation is performed at the earliest opportunity."

According to Ribbert 16 out of 400 cases recover without operation. Deaver recommends the removal of the organ in all cases if the operator be a skilful one! Otherwise he simply evacuates the pus and drains the cavity.

"Murray believes the mortality to be 1 per cent. When he finds a walled-in abscess in the inguinal region, the abscess cavity is cleansed with hydrogen peroxid and flushed with hot saline solution, whereupon search may be made for the appendix and multiple abscesses in the vicinity, without the danger of infecting the abdominal cavity when the adhesions are broken down."

G. M. Gray (*Kansas Medical Journal* of December, 1895) "removes the appendix if the operation is done early; if late he opens the cavity and drains. The question of removing the appendix in these cases to be determined by the operator for each individual case."

Dr. J. William White of Philadelphia says: "In a circumscribed abscess it is bad surgery to insist on finding the appendix; should be content with treating as an abscess." He (White) has left the appendix in thirty-seven cases, all of which are living. Dr. White's treatment and teaching is thus supported.

Richardson reports forty cases with the appendix left; perfect recovery in all.

McBurney says, "the appendix is frequently destroyed before the operation." If in such cases indefinitely prolonged search were to be made for the appendix fatal results would be inevitable.

Dr. Bull says: "The plan of always looking for the appendix is fraught with the risk of infecting a healthy peritoneum, and that the mortality from surgical treatment is about 2 per cent. in cases operated upon at a time when the infection is limited to the confines of the appendix."

Dr. Senn states that "persistent search is hazardous." Halstead says the same. Cabot of Boston reports thirty-two operations on thirty-one patients in the interval of the attacks, with no deaths. Hunter McGuire reports seventeen operations with one death from chronic appendicitis.

The writer holds that these cases are not prejudiced unfavorably by early operation, nor is the danger to the patient increased, hence, all cases should be operated upon at once. Even in cases of mistaken diagnosis, operation under thorough aseptic precautions will be attended with no more danger than an exploratory section, and notwithstanding the fact that the appendix is found to be normal it should be removed,

thus preventing a possible future attack of appendicitis. When the appendix is found to be diseased, it should be removed and treated by immediate closure of the abdomen by suture, preferably silkworm gut where pus is not present, and by drainage by gauze packing without drainage tube, where pus is present. In the case of a large abscess or multiple abscesses the correct treatment is drainage, after thorough flushing with saline solution, and no hazardous attempt should be made to secure an appendix which has in all probability sloughed away. Multiple abscesses should be carefully converted into one large cavity and so treated. Should the appendix or a portion of it remain and produce subsequent trouble, a second operation should be performed at once.

In cases where the abdomen is opened for other causes the appendix should always be removed as a prophylactic measure, and the danger from the original operation is not thereby increased, the "pus cases" found in women not excepted. Every attention should be given to secure absolute asepsis both before, during and after operation. The subsequent treatment is that recognized in abdominal surgery. In the case of abscesses the greatest judgment should be exercised in selecting the point for incision, thereby avoiding the danger of opening too near or perforating the exudate boundary of the abscess, thus infecting the general peritoneum.

HISTORY OF AN INTERESTING CASE OF RECURRENT APPENDICITIS,
RECOVERY AFTER OPERATION.

Mr. —, age 37. Previously in excellent health. Had typhoid fever about thirteen years ago and was quite ill, with marked abdominal symptoms, but recovered without complications. Had his first attack of appendicitis on Aug. 2, 1895. The attack was ushered in very much like an attack of colic from indigestion, and followed by acute pain over entire abdomen, with nausea, vomiting and purging. By the next day the general symptoms had more or less subsided and the disorder was clearly defined in the right iliac region. The illness lasted one week and subsided under rest, diet, opiates and enemas. The diagnosis of catarrhal appendicitis was made.

A second attack occurred on Sept. 1, 1895, following the ingestion of a large quantity of pears. The subsequent history was identical with the first attack. A slight induration in the right inguinal region was apparent, but disappeared shortly.

A third attack began on Dec. 30, 1895. This attack was much more marked than the previous attacks, the patient being sick for three weeks. A similar induration appeared by the fifth day but promptly subsided. The temperature in none of these attacks reached 100, and the pulse at no time was above 90. The pulse generally ran along between 72 and 80. On Jan. 5, 1896, following an enema the patient passed a peculiar worm-like gelatinous "string" about twenty-four inches long, which was submitted to Dr. Walter Reed, U. S. A., who made the following report on the specimen:

WAR DEPARTMENT, SURGEON-GENERAL'S OFFICE,
WASHINGTON, D. C., Jan. 8, 1896.

Dear Doctor:—The specimen which you left at the Museum on Monday, the 6th inst., and which was said to have been passed from the bowel in a case of appendicitis, has been subjected to microscopic examination and found to consist of fine and coarse fibers of fibrin enclosing many necrotic and feebly staining columnar shaped cells. As far as we are able to judge microscopically I should say that the specimen consists of so-called membranous cast of the intestine.

Very sincerely yours,
WALTER REED, Surgeon U. S. A., Curator.

No hemorrhage followed the passage of this specimen and the symptoms gradually disappeared. The patient was out in three weeks.

During an interval of nine months between the third and fourth attacks, the patient enjoyed excellent health and congratulated himself upon having entirely recovered. The fourth attack occurred suddenly on Sept. 14, 1896, while the patient was prepar-

ing to leave the city on an extended tour. The symptoms being somewhat misleading and, but for the history of previous attacks, would not at first have attracted particular attention. A medical friend who was visiting the patient at that time, supposed the attack was one of simple indigestion, and administered a large dose of sulphate of magnesia. The temperature in this attack never rose above 99.4, pulse 72. The patient was considered well in ten days and moved into a new house.

On the 25th the old symptoms showed themselves again and by the 26th they were much more marked. On the 27th the patient had a chill which was not very pronounced, temperature reaching 101 and the pulse 80. Pain in the side became acute and induration with tension of the abdominal muscles in the right inguinal region, was well marked.

Operation was performed on the 28th, at which time the patient felt perfectly well, had no pain or soreness and none was produced by pressure over the inguinal region. The boggy sensation had, however extended, the temperature was 99 and the pulse 72, and the skin moist. The condition of the patient was decidedly misleading. The diagnosis of circumscribed appendical abscess, previously made was adhered to, and an incision resulted in the evacuation of about three quarts of greenish-black offensive pus. A small lump or mass was removed which was supposed to be the remains of the disorganized appendix, but was subsequently lost by the nurse, thus preventing an histologic examination. The abscess walls appeared to be gangrenous.

After an exploration, not endangering the exudate walls, the cavity was thoroughly irrigated with salt solution, and packed with iodoform gauze, which was permitted to remain forty-eight hours. Thorough aseptic precautions were observed in every detail. The patient made an uneventful convalescence, the wound healing promptly by granulation under gauze packing, giving a strong union without hernia.

I believe this case would have been lost through septic infection had an injudicious search been instituted further for an appendix which in all probability had sloughed away, and I re-affirm my opinion that all cases of appendicitis should be promptly operated upon.

On November 3 the patient passed an intestinal cast similar to the one above mentioned. This was submitted to Surgeon Walter Reed, who forwarded the following report.

WAR DEPARTMENT, SURGEON GENERAL'S OFFICE,
WASHINGTON, D. C., Nov. 4, 1896.

Dear Doctor:—Referring to the specimen mentioned in your letter of Nov. 3, 1896, I beg to say that microscopic examination shows it to consist of numerous interlacing fine fibers, enclosing in their meshes a large number of poorly staining cell-nuclei, and considerable granular amorphous material.

I think this specimen should be considered as a part of a membranous cast of the bowel. Sincerely yours,
WALTER REED, Surgeon U. S. A. Curator.

Baby's Turn Next Time.—Mrs. Briske—Johnny, did the doctor call while I was out?

Little Johnny (stopping his play)—Yes'm. He felt my pulse an' looked at my tongue, and shook his head and said it was a very serious case, and he left this prescription and said he would call again before night.

Mrs. Briske—Gracious me! It wasn't you I sent him to see; it was the baby.—*New York Weekly.*

DIAGNOSIS AND SYMPTOMS OF APPENDICITIS.

Read before the Detroit Medical and Library Society.

BY J. H. CARSTENS, M.D.

Chief of Staff and Gynecologist to Harper Hospital; Professor of Obstetrics and Clinical Gynecology in the Detroit College of Medicine; Ex-President American Association of Obstetricians and Gynecologists, etc.
DETROIT, MICH.

The diagnosis of appendicitis is now generally made without difficulty by the general practitioners. Still sometimes a mistake is made and the diagnosis not easy on account of obscure symptoms.

The first symptom is pain and this varies in location. It is seldom in the region of the appendix at first, but most frequently is referred to the umbilicus. In a smaller number of cases, the pain is first located in the region of the stomach, especially in cases accompanied by vomiting; and in a very small proportion of cases only, is it located by the patient in the region of the appendix. The pain is generally spasmodic, colicky, hence the expression, "appendicular colic." Sometimes, however, the pain is not so sharp and acute, but is dull and constant. Remember, I am referring to the very first symptoms.

In the acute fulminating kind, when the appendix is ruptured and diffuse peritonitis takes place, we get the characteristic pain of the latter disease. Vomiting sometimes ushers in an attack, as the exciting cause often seems to be a full meal of indigestible food. Vomiting, however, is an unreliable symptom. The condition of the bowels also varies; sometimes the vomiting is accompanied with an attack of diarrhea and sometimes constipation exists. Hence, neither the pain, nor the vomiting, nor the diarrhea, nor the constipation are at all pathognomonic of the disease.

If we now consider the temperature and the pulse, it is just the same. Some of the worst cases of appendicitis I have ever seen had only a temperature of 99 or 99.5 degrees, although as a rule, if we see cases early enough, we will find that the first day the temperature will suddenly rise to above 100, sometimes 102 and 103, although most frequently the temperature will gradually rise, the first day to about 100; second day, 101, and the third day, 102. By this time, such an exudation has been thrown around the appendix that the temperature often drops to nearly normal and both the patient and the physician are deluded with the idea that recovery is taking place. I want to call your special attention to this very dangerous condition, because many patients have been lost and an operation delayed on this account. In from twenty-four to forty-eight hours another sudden rise takes place, rupture occurs with diffuse peritonitis, and which is often beyond surgical aid.

The pulse also varies, as the temperature, from 100 to 130 and 140, and I would like to place more reliance on the pulse than anything else, as far as the prognosis is concerned. No matter what the symptoms or the temperature, if the pulse remains between 90 and 100, or even a little more, the danger is very little. But if the pulse runs up to 120, 140, or 160, even with no other serious symptoms, and a temperature of only 99, the patient is in a most critical condition and I think authorities all agree that if there is any doubt about operative procedures, there never is when the pulse goes above 110, no matter how mild the other symptoms may be.

Hence, I would say, that in cases with pain in the abdomen, no matter where located, accompanied with

vomiting or not, diarrhea or constipation, a slight elevation of temperature or a great one, with a slow pulse or a rapid one, such cases should be carefully examined for appendicitis. We can easily do that by palpation, carefully going over the whole abdomen and gently locating the greatest point of tenderness. By keeping the patient's mind diverted, we can bear down quite strong on different parts of the abdomen and get the exact location of tenderness. If it is appendicitis, we will nearly always find it at the so-called McBurney point, which is a spot midway between the umbilicus and the anterior superior spine of the ilium. But many cases vary, as the location of the appendix varies. The appendix sometimes reaches over to the left side and is attached there, or reaches downward and is attached; sometimes it reaches upward toward the liver, and the point of attachment of the appendix is generally where the pain exists.

I operated upon a case some time ago, where the pain was located just above the symphysis, and still it was so well marked that I had no doubt about the diagnosis. I found that the point of the appendix was attached to the anterior wall of the abdomen, just about the symphysis, and had become perforated. The patient recovered. We can sometimes palpate the appendix, as in acute cases an exudate is thrown around it, and we will feel quite a swelling in the right inguinal region. But in so many cases the appendix lies behind the cecum, the cecum is filled with gas, and it is absolutely impossible to do so.

Beside, the other great pathognomonic symptom of the disease is muscular rigidity over the region of the cecum, which makes it impossible for any one to map out anything unless the patient is under the influence of an anesthetic. In a few rare obscure cases of appendicitis which have come under my observation, where I had absolutely no history, I could only diagnose the case by placing the patient under the influence of chloroform and then find deep down the exudate.

Appendicitis might be mistaken for typhoid fever; in fact, I have seen quite a few cases of relapsing appendicitis which had been treated for weeks and months for typhoid fever, which simply shows a very superficial examination of the patient on the part of the attending physician.

In women, the inflammation of the right Fallopian tube has frequently been mistaken for appendicitis and vice versa. A careful digital conjoined examination should clear up a diagnosis, but there must always remain a certain number of cases where the Fallopian tube is adherent high up, and where it is impossible to make the diagnosis. There are also a certain number of cases where both diseases exist at the same time, the one exciting the other.

A few months ago, I saw a beautiful case of tubercular appendicitis, the same condition existing in the right tube, and where I moved both through the same opening.

Invagination and intussusception of the intestines may sometimes be mistaken for appendicitis. By carefully examining the case generally no trouble will exist. Often in my experience, a diagnosis of intestinal obstruction has been made when it was a case of appendicitis, and the intestinal obstruction was only one of the symptoms. Still, in the last few weeks, I saw a case of appendicitis which had been operated upon a year ago by simple incision and letting out the pus, but not removing the appendix; the man had a

recurring attack and a well-marked tumor, and there was no question at all about the diagnosis. I cut down and found an immense hollow tube, which I thought was the largest appendix I had ever seen. But I was not quite satisfied. It seemed to have curled upon itself, and after loosening the adhesions and bringing the mass to view, I found that a small loop of intestine, near the junction of the cecum, was encircled by a small fibrinous band which absolutely occluded it and had produced gangrene, so that I was obliged to resect twelve inches of intestines and insert a Murphy button. Unfortunately, the patient died, but it was as typical a case of appendicitis as I had ever seen, with forty-eight hours duration only, and I challenge anybody to have diagnosed anything different.

Extra-uterine pregnancy may simulate appendicitis, but the hemorrhage, the collapse and the progressively weakening pulse, with a bi-manual examination will clear up the case. Painful menstruation, with other pelvic disorders, sometimes simulates appendicitis. A floating kidney with twisting of the ureter, producing nephritic colic, as well as pyo-nephrosis, renal calculi, tumors, etc., of the kidneys, on account of their location, should seldom be mistaken for the disease under consideration. Gallstones and rupture of the gall bladder can be easily mistaken for appendicitis, but by carefully examining the location of the trouble, mistakes should seldom be made. However, both require operative procedures, and by making an incision high up both the region of the appendix and that of the gall bladder can be easily explored, a diagnosis readily made and the incision increased upward or downward, as indicated. The muscular rigidity of the gall bladder troubles is found in the upper part of the abdominal muscles more than in those over the cecum. That very rare condition of an abscess in the abdominal walls may sometimes lead the diagnostician astray, but the superficial swelling, the lack of deep seated abdominal pain, will clear up the diagnosis. Tubercular peritonitis, involving the right ovary and tube, or primarily the appendix, often simulates a chronic or relapsing variety of appendicitis. But a surgical treatment is indicated in either of them and no time need be wasted in making a differential diagnosis.

To cut it short, all these different conditions mentioned above should be borne in mind, but appendicitis should always be looked for, when there is pain at the so-called McBurney point with rigidity of the abdominal muscles, some fever, however slight, and an increased pulse-rate, then there is hardly any question about the diagnosis.

CONCLUSIONS.

1. In every case of acute pain in the abdomen look for appendicitis.
2. Especially look for inflamed appendix when the pain is in the right side.
3. In every case of renal calculi, gallstones, right pus-tube and typhoid fever, look again and be sure.

TETANUS ANTITOXIN—REPORT OF A CASE.

BY J. W. COKENOWER, M.D.

Lecturer on Orthopedic Surgery, College of Physicians and Surgeons
Medical Department, Drake University.
DES MOINES, IOWA.

One by one the diseases which have hitherto defied the skill of physicians are yielding to the persistent

attack of modern science. Since the successful treatment of diphtheria by subcutaneous injections of antitoxin serum was demonstrated, it has been confidently predicted that sooner or later all diseases resulting from the action of a poison secreted in the blood by a special and characteristic bacillus would be conquered by similar means. Tetanus has its characteristic microbe, which has been recognized, isolated, described and reproduced by artificial culture. The distinguishing symptom of tetanus is a persistent spasmodic spasm of the voluntary muscles aggravated by light, noise, or other disturbing influences to which the patient may be subjected. These spasms may affect any muscular portion of the body, but when, as is often the case, the maxillary muscles are principally involved, the result of the malady is usually known as "lockjaw."

I was called Dec. 20, 1896, at 8 o'clock P.M., to No. 1545 20th St., Des Moines, to see John Wilburg, age 46, who was suffering with, as they supposed, neuralgia of the head and neck. I proceeded at once to get the history of the case, as well as that of the patient, and found that he was of German descent, and had never been sick in his life, so far as he knew, save an injury or two received a few years ago, from which he had entirely recovered; but aside from this, had always enjoyed the best of health. He was married and had four healthy children, and from his story I could find no cause for the supposed neuralgia of the head, except exposure a few days previous. However, upon further inquiry I ascertained that upon December 10, he let a brick fall, striking upon the great toe of the left foot, producing a discoloration of a portion of the nail and a slight abrasion of the skin on the dorsal portion of the same toe, which did not give him much pain at the time, and caused no inconvenience in the future, and he continued his work the same as before, not thinking the injury sufficient to give it any attention whatever; but, upon the following Saturday, December 18, he fell from the roof of his barn, a distance of about twelve feet, resulting simply in a general "shake-up," without any injury whatever and even this did not prevent him from continuing his avocation as before. Upon close inquiry I succeeded in eliciting the fact that he had been having a stiffness about the neck and difficult deglutition for two or three days past, a fact that he did not think worthy of attention and simply, in his opinion, was the result of exposure incident to his vocation, that of hauling brick, but, in reality, in my opinion, was the beginning of what ultimately proved to be the end.

Upon a closer examination of the patient, I found a pulse of 120 and a temperature of 102, with spasmodic pains, the body assuming the position of opisthotonos, no part touching the bed, except the heels and head, the arch being that of nearly a semi-circle, producing typical tetanic spasms, spastic masseters, with trismus, diminution of the visual angle, and apparent permanent spastic contraction of orbicularis palpebrarum muscle, with difficult deglutition and irregular respiration. The pain was not constant, but came periodically and with it the spasm incident to tetanus. I informed the family that, in my opinion, the case was one of tetanus, or lockjaw, caused by the injury to the great toe, December 10, which very much surprised them and their friends because it seemed that they had heard or knew enough of the disease to know what it meant. I gave him nerve sedatives and anodynes for the night and called the next morning,

December 21, at 8.30. Found no material change in the patient from the evening before, save that the respirations were made with more difficulty and the temperature 101 and the pulse 140. I realized the severity of the disease and, also, that in reality the beginning of the first symptoms of the disease could be dated as far back as Friday December 18, so that there has been three and a half days elapsed since that time. I advised the family to have consultation and Dr. Lewis Schooler was called, and confirmed my diagnosis, and was of the same opinion as myself, that if anything would stop the ravages of the disease, it would be tetanus serum, and we even doubted the effectiveness of this treatment on account of the lateness of its beginning, there having been almost four days transpired since the introduction of the disease. I secured forty cubic centimeters of tetanus antitoxin or serum and at 4.30 P.M. gave subcutaneously four cubic centimeters, but not without first giving the patient chloroform inhalation to quiet the spasms produced by any noise or touching of the patient.

Perhaps it would not be out of place here to state that in using the serum I aseptitized the field of operation, as well as the Mulford syringe used, and was careful to not permit any air to enter the syringe or serum and, after using, covered the surface with aseptic gauze, retained with adhesive straps. At this time, the spasms were occurring seventy-five per hour when the patient was not under the influence of chloroform. I had taken the precaution to have the patient's bowels to move freely, after which gave food or cod liver oil, beef tea and egg per enema every six hours, and when the patient was unable to retain food given in this way, I resorted to feeding by means of absorption of olive oil and quinin, administered through the medium of a saturated cloth around the body, covered with oiled silk, as deglutition was impossible without aggravating the spasms, and the teeth being firmly set. Realizing that whatever effect I got from the serum would not be instantaneous, I gave hypodermic one-fiftieth grain physostigmin, with a half grain of morphin hypodermically, which was repeated every three hours, or as much oftener as necessary to control the spasms and produce some sleep.

December 22, at 8.30 P.M., I called and found no material change in the patient from the preceding evening, save the spasms were not quite so frequent, a fact which I accredited to the persistent use of the physostigmin. I gave at this time six cubic centimeters of tetanus serum, and in four hours, ten more, making twenty that had been given up to this time. After the last injection given of the serum the patient remarked: "My jaws feel more limber and my neck not so stiff." Believing that I was getting some results from the use of the serum, I determined to push it and secured another bottle of serum containing twenty cubic centimeters, and gave it in two administrations six hours apart, during and after which the patient seemed to be convalescing; the spasms now, instead of being seventy-five were not more than ten per hour, and even then not anything like so severe and we felt that there was some hope; but there being a question in my mind as to the advisability of using more serum and not being able to secure it even if I did, it was all that the case was given, and the patient seemed to be improving slowly with normal temperature and pulse of a 100 and respiration of 30, but somewhat irregular, due to the spasms. This condition of affairs continued without

any marked variation until Thursday morning, December 24, when there was a turn for the worse and the spasms were increasing in number and severity and the outlook was anything but favorable. I am satisfied that had I had forty cubic centimeters more of serum at my command, I should have made use of it. This, however, I did not have and all that was left to be done was to quiet the spasms with inhalations of chloroform and anti-spasmodics, which I did until the end came at 2 o'clock A.M., December 26.

My experience with tetanus serum in this case has been sufficient to convince me, beyond a doubt, that when it is used aseptically, plentifully and timely, we may expect good results from it, because in this case, even after four days had elapsed from the onset of the disease, the result from its use while being used and for a limited time afterward was entirely satisfactory and the result so marked that even the family and friends noticed the marked improvement in the case; the respirations were better, the deglutition became possible, but in a limited degree, and the heart's action was better and continued to be so, and the patient's intellect seemed to be improved; hence, I have no hesitancy in saying that there is a field of usefulness for tetanus serum in this dreadful malady and no physician should hesitate to give it a trial upon the least provocation. The experience that I have had with tetanus has fully aroused me to the importance of prompt and immediate action, and, in all cases where there is any danger of this malady, and whenever there is an injury to any part of the body that is liable to produce it, shall subsequently govern myself accordingly, and give the serum as the best known prophylactic treatment.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
BY CARL H. VON KLEIN, A.M., M.D.

CHAPTER III.—AT THE UNIVERSITY.

(Continued from page 550.)

In respect to medical lectures the various universities differed greatly. In the Catholic schools the course covered for the most part the entire year; the lectures were largely public and their duration, as well as the text-books, were prescribed by law; as a rule the lectures were held in public halls. In the Protestant universities, on the contrary, the lectures lasted a half year, were not free and were frequently given in the houses of the professors. Teacher and student enjoyed unlimited freedom, in consequence of which most of the young men studied without system. Many students took too many lectures at one time, others began with practical study and neglected the theoretical. In order to fill their lecture rooms and also their purses the different professors encouraged the erroneous choice of the student. No wonder then that even in the best German universities the number of accomplished medical students remained comparatively small.

The learned gentlemen could not divorce themselves from lectures in the Latin language, and would in general accept no pupil who could not understand Latin. But most of the pupils failed in this knowledge; in fact it was an exception if a student could speak Latin. Finally the professors were obliged to

yield to the pressure of the students. When Frank became professor in Göttingen in 1784, his colleague, Heine, asked him to give his lectures in Latin. He did so. But after the first semester forty students declared to him that if he would lecture in German they would gladly pay him in advance, otherwise they would be obliged to forego his instruction, as they did not understand sufficient Latin. The professor contented himself with the mother tongue. This victory had its effect everywhere, and in 1782 in Austria German became the official language for lectures and Doctors' examinations. Emperor Joseph said: "The German is the true national language and mother tongue, in which medical prescriptions can as well be written as syllogisms and moral precepts in philosophy, and so forth." The custom of *dictation* prevailed almost everywhere. It had continued centuries after the discovery of printing, because most books printed on parchment were very dear and the professors were very lazy. Louis XIV. commanded the dictating of special note-books. While on the other hand, in 1780 two new chairs were founded in Paris, for anatomy and surgery, with the conditions that the lectures be given in French, gratis, and without the use of note-books. Everyone knows that this bad habit has not disappeared even in our time; the celebrated Schleiermacher once said of the dictating professors: "I do not perceive why the king should appoint people who ignore the discovery of printing."

The collections and libraries should have been valuable for instruction, which had in view rather a mechanical learning by rote, than a free development of the intellectual faculties. True, there were here and there extensive natural history collections, but they were scarcely moved from their places by the professors, seldom if ever used, and only admired by strangers. In France all collections were gratuitously opened to the public, but in Germany they were as inaccessible as the holy of holies of the Jews. Joseph II. bought the Goetz collection of entozoöns, excellent for that time, and presented it to the University of Pavia. Certain scholars possessed rich cabinets. Professor Günz at his death left some thirty skeletons, 437 dry specimens and 281 in alcohol. Ruysch in Amsterdam had an anatomic collection for which Peter the Great paid 20,000 guilders. Van Swieten presented his collection of anatomic specimens, which he had brought with him from Leyden, to the University of Vienna, and thus furnished the nucleus of an anatomic museum. The specimens, mostly injections, originated with Ruysch. Albir and Lieberkühn, and were valued at 20,000 guilders. When the naturalist, R. A. F. de Reaumur died in Paris in 1757 in his seventy-sixth year, his natural history cabinet, which he bequeathed to the Royal Academy of Science, was considered the most complete in all Europe; 6,500 guilders had been previously offered for it by an Englishman. In the year 1802 the Berlin professor of anatomy, J. G. Walter, possessed an anatomic museum of 2,868 specimens which he had collected in the dissection of 8,000 cadavers, during a period of fifty-four years, and this collection he sold to the King of Prussia. We will mention later the collections of W. and J. Hunter. The accumulating of a *library* possessed a peculiarly powerful charm which our time, in which the impulse for the ownership of books is so very weak, can not appreciate. A library was the pride of the cultured.

Twice a year, at Easter and Michaelmas, regular purchases were made; at those times the book dealer brought the newest publications with him from the Leipzig fair, and displayed them in his shop. That was an important time for the book lover; the shop became the center of literary discussion. There was also opportunity to buy old books, although the antiquarian book trade outside of Halle and Leipzig had attracted little attention. Among the physicians a few were noted for magnificent libraries. Günz left such a one, whose catalogue required sixteen pages; the Arabic, Greek and Latin physicians covered five of these pages and Hippocrates alone covered a whole page. After Heister's death the catalogue of his anatomic, botanic and surgical books showed 6,338 numbers, beside an herbarium of 98 volumes, 1,744 copper-plates and 470 surgical instruments, among them many of silver. According to a note by Börner, Heister's herbarium in the year 1725 consisted of sixty-six folios and over 6,000 plants; he is said to have preserved at that time many skeletons and specimens, the greatest collection of most beautiful anatomic and surgical instruments, about 1,200 books and over 200 volumes of theses. Joseph II. bought A. von Haller's large library for 2,000 Louis d'or and had it brought to Milan. Upon his departure from St. Petersburg in 1808, Peter Frank sold his books on account of the expense of transportation to the Crown for 2,000 rubles, and they were then presented to the University of Cassan. In the universities much was done for the libraries, especially in Göttingen. This was one of the richest and was equipped with the best catalogue. By reason of the close relation between England and Hanover, the influx of English literature was always very great; the newest and rarest works came to Göttingen as soon as possible after they appeared, as presents from George III. On the contrary, as Lessing complained in 1768, English works were much more difficult to obtain in Berlin than French works. Professors and students had free access to the Göttingen library. Almost 5,000 thalers, about one-tenth of the yearly income of the whole university, was received by the library, which, during the eighties, added about 2,200 volumes yearly. There were often disadvantages coupled with the lending of the books, at least Baldinger asserts that many Göttingen professors frequently borrowed from two to four hundred books at once and returned them every half year, but immediately borrowed them again, so that they retained the books as their own property for the rest of their lives. This abuse, together with the circumstance that the university library purchased no translations, moved Baldinger (1780) to found a medical reading circle for the students.

If we enter the circle of *professors* we find, as Gruner says in his almanac, many drones on the list. Young men who had scarcely finished their studies, and who had not yet shown the least evidence of their learning and ability, were given professorships simply upon recommendation. Marry a professor's daughter and you have the best prospect of becoming an academic teacher, was at that time an approved method. There were professors of chemistry who had a year before been apothecaries' journeymen, and a teacher of veterinary medicine who had shortly before officiated as a shaver of beards, and had never studied these sciences. Many of them never thought of changing their notes for lectures, and did not trouble themselves at all over the advancement of science. To

restrain the arbitrariness of the professors an order was issued at the Universities of Marburg and Rinteln in 1782 to arrange the lectures so that it would not be necessary to double the hours at the end of the semester. In this way opportunity was given the students not only to study the profession diligently, but to do some active work in the supplementary sciences, ancient and modern languages, mathematics, philosophy and history. At the death of a member of the faculty the very bad custom was usually followed of appointing in his place, the professor of an entirely different department; for example, a former anatomist lectured later on pathology or *materia medica*. J. J. Plenck was first professor of anatomy, surgery and obstetrics in Basel, then in Ofen; with a change of places he also changed sciences, and taught chemistry and botany in Joseph's Academy in Vienna. Hildebrand was professor of anatomy in Brunswick, then professor of chemistry in Erlangen. To many it was a definite object to read and write in various fields. In this way nothing of value could be accomplished, and if such men as Boerhaave could lecture with the greatest success in chemistry, botany and pathology, and A. von Haller in anatomy, physiology, botany and surgery, yet the teachers who could excel in various sciences were always exceptions. It was from early times a custom in German universities to have only two head professorships in medicine, the theoretical and the practical. The former included botany, chemistry, anatomy and usually surgery; the practical did not represent clinical instruction, but was limited to the exposition of special pathology, medical science and so-forth. Only in the course of the eighteenth century did the *professores anatomice et botanice* disappear from the high schools, and at the end of the century there followed the separation of the professorships of anatomy and surgery. The instruction itself was generally very poor. Even at the end of the century there was a professor of physiology and obstetrics, who, in order to display his literary knowledge, had great loads of books continually brought from the library and consumed nearly the entire time in dictating the titles of these books to his pupils. Another who was separated from his wife, entertained his hearers with domestic curtain lectures, which he seasoned with obscenities. Many of them did not trouble themselves as to whether their lectures were systematic or not. In the eighties, a professor of anatomy in one of the celebrated universities in Germany, began his course with a demonstration of the ductus thoracicus. The next day he showed the muscles of the neck, on the following the veins and nerves of the hand, and he consumed fully three hours with the N. phrenicus. When the students, because of his unsystematic course, sought other lectures he was very indignant, but he made no change (Schmidtman's Medicinal-verfassung). Meiners asserts briefly and conclusively that the practical instruction in medicine and surgery in most of the universities was only a farce; dissection was not taught, only in the first half of the century. Honors and money were so distributed among the German professors, that they often had too much of the former and too little of the latter. The Austrian professors for a long time enjoyed the title of excellence, till this abuse was abolished (1755) and they were then called *clari celeberrimi*. They were admissible to the table of gentility.

Later to them as well as to the matriculated doctors, and to the wives and widows of both, "was given by

judicial act of the magistrate, the use and possession of the honorable titles of Herr and Frau." Most of the professors of medicine were poorly paid; their incomes, much the same as a hundred years earlier, were not in proportion to the increased cost of living. In Austria, since the reformation of the Vienna University under Emperor Ferdinand I. (1533), they had not received more than 120 guilders; even the professors of surgery in 1537 had a salary of only 52 guilders. This little appears better when one reflects that these guilders were golden guilders, that is ducats, and that living in Vienna was so cheap that in the fifteenth century the medical faculty paid a yearly rent of about nine guilders for their house. A measure (two quarts) of wine cost in 1497 one pfennig, and a house, such as the beadle's house together with the prison, 100 guilders. The value of money and the necessaries of life, compared with that of our time, make those 100 golden guilders worth 6,000 guilders of the present money. Van Swieten first increased the incomes of the medical professors of Austria, when, beside obtaining for them the title of royal councillors, he raised their salaries to 2,000 guilders; he even secured to the excellent scholars trained by him the triple income of an *indigène*. They had a special gratuity for the publication of a learned work according to the value of the work, and in 1791, by order of Emperor Leopold II., they received their income from real estate in order to secure them. The college fees for the philosophical and medical studies amounted to 18 guilders a year, and especially industrious students were even given free tuition. The Göttingen students paid five or six thalers for most courses, in the practical department ten thalers. The counts paid double these amounts. The anatomist, J. G. Walter, in Berlin, served the first three years without salary, then ten years (1764) as second professor with a salary of 240 thalers, finally fourteen years as first professor with a salary of 800 and 1,000 thalers. Hufeland was nine years medical director of the clinic at Jena, and like his colleague did not receive the least revenue, although he spent two hours a day in the clinic. When, about this time and at the same university, Schiller was "deluded," as he says, into becoming professor of history, he received no salary (1789). The five courts of Weimar, Gotha, Coburg, Meiningen and Hildburghausen combined did not have the means to pay one such professor as Schiller a salary. Only in 1790 the duke, "with lowered brows and an anxious face," gave him 200 thalers. Necessarily, a desire arose for new service; gold flowed freely as soon as one taught in various lines. Beireis, in Helmstadt, gave twelve lectures daily; later when he had "whetted" his tongue, only eight. A few professors divided their subjects so as to increase the number of paying students, haggled with the poor students about the price, and was satisfied with twelve groschen if they could not get more. Occasionally they even joined students' societies in order to get more hearers in that way. The result of these miserable conditions was eternal quarreling and strife among the teachers and the eagerness to better their finances through perquisites, the principal source of which was the graduation fees.

The clubs brought about social intercourse. In Göttingen, where A. von Haller complained that the professors did not get money enough to see, a club of some eighty members was formed in 1787, in which the professors, jurists, physicians and preachers of the city met one evening a week for friendly intercourse.

In foreign countries the professors usually enjoyed a high rank. Those of the University of Toulouse were knights (1776), and in Pavia the word "Don" was placed before their names. Russia gave them all the position of court councillors. The French professors were so well paid by the state that their courses were free, one paid extra only for chemistry and anatomy; in Nancy in 1779 the winter course in anatomy cost thirteen livres. The English hospital physicians demanded of the students a full purse, since they received no income from the state. In Pott's time, whoever attended the operations in Bartholomew's Hospital, as in most London hospitals, paid twenty-five guineas a year, eighteen guineas for a half year; if he adjusted bandages himself he paid fifty guineas a year, thirty-six guineas a half year. Pott charged for his practical course, which he gave once a week in the winter, five guineas. John Hunter gave free lectures in surgery to the surgical students of St. George's Hospital, but charged four guineas for a seven-months' private course in surgery, which he gave three times a week in an amphitheater in his home, built expressly for the purpose. Marshall's lectures in anatomy, physiology and surgery cost three guineas a half year; the same is true of Ev. Home's course in surgery, while he charged five guineas for his instruction in dissection. Hawkins earned so much in London that his estates alone yielded annually a net profit of £1,900 sterling. The Russians also paid well; Mohrenheim (1783) was called from Vienna as director of the Russian hospitals, with a salary of 3,000 rubles, and Professor Krackstedt, in the St. Petersburg Medical and Surgical Academy, was paid 1,800 rubles with a residence, wood, light and service. At the hospital in Stockholm, the physician and surgeon each received a salary of 3,000 thalers.

With the conclusion of study came the much desired Doctor's degree. We have remarked before that most German states prescribed three years' study of medicine; only in Austria, at first six years were required, under Joseph II. five, and finally four. The French under Louis XIV. had to study three years, under the republic four years. Pope Gregory IX. introduced academic degrees in the thirteenth century and the first "Masters" was created in Paris by his bull. The "Doctors" followed them. In the eighteenth century in Germany the graduation presented a very unpleasant picture; even at the end of the century it was attended with the most wanton abuses. "Like weaving, they ran off every year a certain number of pieces, that among the physicians often turned out worse than the worst rubbish; the title of Doctor had no longer any value because it had become a commodity which every one could buy for money as readily as a laced coat." (Frank, Tissot.) Every year a crowd of young men were made doctors, many of whom did not have more than the first principles of science. With unheard of frivolity they glided superficially from one science to another, and in examination, counted on the partiality, fellow feeling and self-interest of the professor. In short when the newly pledged Æsculapius settled himself to practice, then woe to him, who without discrimination, in blind faith in the fat letters of his diploma, "did not seek to protect himself against them as against a swarm of locusts." The faculties vied with each other in making the examinations as easy as possible, so that the students would not think of going elsewhere with their money. They even exempted

the candidate, on account of his well-known ability, from both examination and thesis. If we do not do it others will! Even at the young University of Göttingen some *in absentia* was given a degree. (1763.) The same abuse was practiced in France. Before the revolution testimonials alone was enough to secure the Doctor's degree. It was a practice with the French faculties to conform the examinations to the district where the physician intended to settle, so that the stupidest bungler could receive a diploma if he wished to practice among the peasants. Nothing was funnier than the method of becoming a surgeon. One bought from any prince for 1,200 livres the title of veterinary surgeon (*chirurgien de l'écurie*), and enjoyed thereby the right to practice surgery among men. Especially in France, at that time, the professions of physician, surgeon and obstetrician were followed with irresponsible light-mindedness. The seduction of gold was so great that many professors gave Doctor's degrees more cheaply than the artisans guilds gave their masterships. Although according to the statement of a Wolfenbüttler physician the fees for medical degrees in Vienna, in 1723, amounted to 1,000 guilders, this appears somewhat questionable, since it is certain that in 1753 the Prague medical students paid 95 guilders for the examination, 30 guilders for the thesis and 134 guilders for the degree. In Göttingen the degree of Doctor of Medicine cost 117 thalers and the certificate of the *Triennium Acad.* 12 thalers; in Marburg and Pavia 100 thalers. In Oxford and the other English high schools one paid seven times as much, 100 pounds sterling, for the Doctor's degree, and in France 1,000 livres. The periodicals of that time relate frightful stories of the trade in diplomas. Surgeons who could scarcely read German became doctors before they had submitted their theses. A shoemaker in Altona, named Menade, who had dabbled a little in medicine, applied to the University of Greifswald for the title of Doctor and presented the money. The president of the faculty took it, sent the diploma and wrote, or had some one else write, a thesis on shoemaker's pitch for him. When the matter became public the president was removed (1788). The abuse grew even worse. With the high-sounding title of palatine, easily obtained in the South German countries, was connected by imperial charter, the right arbitrarily to confer Doctors' degrees, to legitimize natural children, and so forth. The lords made use of this right to the greatest extent. Their agents traveled around and informed surgeons and apothecaries, that on account of their well-known merits, the lord wished to confer upon them titles, for which each must pay six pistoles. In this way entirely rude ignorant barbers became doctors. Even in 1806 and 1807 the University of Erfurt, which had an average of only 30 students in all departments, turned out 97 doctors of medicine, of whom 28 wrote a thesis, 69 did not.

The most shameful abuses arose in connection with the theses. It is scarcely to be believed that at many universities the professors retained the right to write theses for candidates and sell them. Authorities for the statement are Husoty (*Medic. Polizei*, 1786) and the imperially chartered *Reichsanzeiger*, which in numbers 169 and 170, in 1802, relates the following of this impious business: The student, who chose his opponents himself, had the Latin theses with questions and answers, drawn up by a master; both questions and answers he learned by heart, so as to give the

right accent to the Latin words. The thesis did not cause the least anxiety, since every university had a storeroom where one could buy these wares at all prices. But in order to avoid the thesis-dealers becoming known, and to protect the young doctor from the raillery of his comrades and of the public if this by-way should come to light, a number of physicians and philologists united for the establishment of a thesis factory. The works were gotten up from various stand-points, one, with respect to the university by which the degree should be given and the particular views of the professors there; again according to different theories, as following Brown, Reil or Hufeland and so on; finally according to price. The cheapest kind of thesis cost four pistoles; they contained a short, incomplete description of a disease, no learning and bad Latin. Every university supplied such as this. Then came a kind for eight pistoles; in these were a description and treatment of a disease, apparently complete, mixed with many quotations, but nothing original; the Latin was indifferent. These theses were suited to universities which had large libraries. The third kind cost sixteen pistoles, and handled questions of the day; they presented no new points of view, to be sure, but the Latin was good. Finally, the fourth and most expensive kind cost from twenty-four to thirty-six pistoles. New ideas (!), the newest terminologies, a description of pathologic varieties with the necessary drawings, a compact decisive diction as an indication of the energy and genius of the author, and Ciceronian Latin. Specimens of this kind seldom appeared, yet at that time Halle furnished a few. Any one who wished to become a doctor sent the price with the necessary postage, stating at the time from which university he wished his degree and according to which system he wished the thesis written. Prompt and good service and strict secrecy were guaranteed. They were always careful to have a considerable number of these theses in stock, from which one could take his choice. In the year 1802, the following subjects were offered; for Bamberg, "On the Insufficiency of the Brown System and Inadequacy for the true Physician;" for Göttingen, "On the great Usefulness of Medical Consultations," "On Scarlet Fever;" for Jena, "On the Uselessness of a Scholar's Reputation to a Professor of Medicine," "On the Necessity of rewriting all popular Papers, and adapting them to the Principles of the Excitation-theory;" for Halle, "On the Variation of the Brain-matter from its Normal Form and Substance;" and further, "A Review of all that has been done for Medicine and all its supplementary Sciences, since 1800, together with a brief Opinion as to whether the Labor has been of Value." Würzburg, Erlangen and Kiel were supplied in like manner. So much for the *Reichsanzeiger*.

(To be continued.)

Connection Between Diseases of the Eyes and Nose.—Winckler has found that 50 per cent. of the children brought to the hospital for scrofulous affections of the eyes, were also affected with diseased conditions in the nasal passages. He emphasizes the importance of finding and treating both lesions promptly, as they are likely to spread and complicate each other. He considers the use of the galvano-cautery and of caustics dangerous, as he has known serious injury to result from them, and prefers surgical intervention, cutting out tumors, treating the catarrhal conditions with appropriate means and resorting later to blood reduction of the inferior turbinate bones, or whatever surgical intervention may be needed.—*Journ. de Sciences Méd. de Lille*, February 13.

PECULIARITIES OF THE SURGICAL DISEASES AND INJURIES OF THE NECK.

BY EDMOND SOUCHON, M.D.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY, TULANE UNIVERSITY, NEW ORLEANS, LA.

(Continued from page 552.)

PECULIARITIES OF THE SURGICAL DISEASES, INJURIES OF THE LATERAL REGION OF THE NECK OR OF THE STERNO-MASTOID REGION OR CAROTID REGION.

Congenital malformations are represented in this region by the orifices of the branchial fistulæ, situated most commonly along the lower part of the anterior border of the sterno-mastoid; also by the congenital deformity of the sterno-mastoid, called hematoma of the sterno-mastoid, and congenital torticollis; also by the congenital atrophy of the same muscle. *Acquired malformations* comprise the various forms and varieties of torticollis and the deformities due to cicatrices. Cicatrices of the neck are most objectionable, especially when affecting the exposed parts.

Swellings of the region recognize the same causes, present the same forms and varieties as anywhere else.

Burns or frost bites present no peculiarity in the region of the sterno-mastoid, except when deep and reaching the sterno-mastoid or the underlying vessels and nerves.

Contusions or blows on the neck are always severe, but when striking the side of the neck over the jugular they are particularly severe and are comparatively frequent; they may cause a hematoma in the sheath of the muscle; they may cause paralysis or contraction of the muscle, producing a variety of torticollis; the muscle is sometimes ruptured, also the vessels and the nerves, these have a train of symptoms which will be described further on.

Non-penetrating *wounds*, *i. e.*, not extending deeper than the muscles and glands, are not serious unless through becoming infected. Penetrating punctured wounds of the neck may be deep without injuring the vessels and nerves, owing to the elasticity and mobility of the jugulo-carotid vessels. Penetrating wounds of the external jugular, of the internal jugular and the carotid arteries are more serious injuries. They all may give rise to circumscribed or diffused hematoma. When this is of some size and stationary it must be aspirated or incised. When it pulsates and grows, it is because a traumatic aneurysm has formed and the wounded vessel, vein or artery must be ligated above and below the injured point. When the penetration is comparatively small the sac may be incised at once, after making as good a pressure above and below as possible. When the puncture is large and there is risk of the patient bleeding much before the proper ligatures are secured, a provisional loop ligature must be applied below the wounded point. When the wound or the swelling is very low down, enough of the sternum must be resected to reach the root of the carotid and the innominate, and apply there the provisional loop ligature. Considering the gravity of a possible terrific hemorrhage this advice is not too heroic; never ligate the common or the internal carotid unless it is the wounded artery, because of the possible effects on the cerebral circulation. It is only when the persistent search for the wounded point of the vessel has not succeeded that the vessel itself should be ligated in continuity; below

only, if possible; a ligature above whenever applicable should be applied to guard against recurrent distal hemorrhage. We must bear in mind that arteriovenous aneurysm often follow punctured wounds which have gone through the vein and the artery. Wounds of the vertebral artery in this part of the neck are more common in the canal of the transverse process. At the base of the neck the wounds of the vertebral are more grave than those of the carotid.

The diagnosis of this wound will be made only when upon cutting down through the extravasated blood, it is found that the carotid artery and the jugular vein are intact. Then, when the hemorrhage is profuse, it should be stopped by plugging with the finger or by packing, and a loop ligature should be applied on the subclavian or the innominate before proceeding farther; when the wound in the vertebral is located it should be tied above and below; if necessary, the transverse process should be cut away with the bone-nippers. These remarks apply also to the wounds of the deep cervical, the inferior thyroid, the superior thyroid, the lingual and the pharyngeal.

Punctured penetrating wounds of the base of the neck are almost all fatal on account of the impossibility of reaching the artery without fatal hemorrhage. Punctured wounds of the nerves of the region (recurrent, phrenic, pneumogastric, sympathetic, spinal accessory, cervical plexus) give rise to the symptoms of irritation of the nerves.

Non-penetrating incised wounds are only serious if the external jugular vein has been injured, because air may then penetrate into the veins. When the edges of the wounds lose their parallelism these may form a considerable hematoma. Incised wounds penetrating the sterno-mastoid and severing it incompletely are not so very serious.

Wounds dividing the sterno-mastoid muscle may curtail power of the muscle from lengthening, due to the cicatrization. When the muscle has been completely severed and the head is still, it is sometimes brusquely thrown to the other side by the contraction of the intact sterno-mastoid. In case of division of the muscle from operation this does not take place, because the other muscles have gradually become accustomed by the presence of the tumor to keep the head properly balanced. The severed ends must be strongly and closely stitched with strong catgut, and the head kept in proper position by a liquid glass bandage.

Incised penetrating wounds of the internal jugular are perhaps more serious than the wounds of the carotid, because of the danger of penetration of air. When the respiration becomes embarrassed the hemorrhage increases, just as in tracheotomy, where, as soon as the tube is introduced the hemorrhage ceases. These wounds are oftenest tearing wounds during the removal of tumors. Whatever be the cause, if the vein alone is wounded the blood is black and flows continuously. The first thing to do is to plug the opening to prevent the penetration of air; then make pressure above and below with the fingers, enlarge the wound and fill it with boiled water to prevent the possible penetration of air; then look for the wounded vein and ligate both ends. The proximal end is the most dangerous, because of the penetration of air and of the abundance of blood coming from the heart. When the compressing fingers are in the way or if their pressure is ineffectual, a provisional loop ligature should be placed around the internal jugular until

the wounded ends are ligated. When the wound is low down, it may be necessary to resect the sternum and place a provisional ligature around the innominate vein or the superior cava. Incised wounds of the superior thyroid, lingual and facial veins close to the internal jugular are almost as severe.

Incised penetrating wounds of the carotids give rise to profuse, even terrific hemorrhage. When the wound is large or when the hemorrhage is moderate but not at once attended to on the spot, it may be immediately fatal. A man will thus bleed to death in four minutes from the carotid, it is said. When the larynx or trachea is, wounded the blood penetrating into them causes death also from suffocation. The hemorrhage is sometimes stopped by fainting if the wound is not too large. Upon reaching such a case the first thing to be done is to plug the wound with the fingers or to pack it quickly. Packing will stop the hemorrhage temporarily if the vessel is of any size above one-sixteenth of an inch. It is best and safest to enlarge the wound and attempt to ligate the two ends in the wound; if this causes too much bleeding a loop ligature must be applied as above described. If the bleeding has stopped of itself it must be borne in mind that it will almost surely return, and that it may do so when proper surgical assistance can not be procured and the patient may bleed to death: therefore, the case should be treated as described above for punctured wounds. Incised penetrating wounds of the root of the neck are almost all fatal on the spot. The same remarks as above apply here. It is sometimes difficult to recognize which vessel of the neck has been divided: spurting, however, is characteristic of arterial lesion; but the vein may be divided at the same time. When the vein and artery are simultaneously wounded, ligate ends of both. In all cases where clamping stops the bleeding and a ligature can not be well substituted, the clamp should be left in place thirty-six to forty-eight hours.

Punctured wounds of the nerves of the region (recurrent, phrenic, pneumogastric, sympathetic, spinal accessory, cervical plexus), give rise to the symptoms of the irritation of those nerves. Incised wounds of the nerves of the region (recurrent, phrenic, pneumogastric, sympathetic, spinal accessory, cervical plexus), are followed by the following symptoms: When the recurrent is wounded there is aphasia more or less complete. The section of the phrenic and pneumogastric on one side only is accompanied by respiratory and circulatory irregularities; they are not necessarily fatal, but it is a most serious complication. Park has shown that only about 50 per cent. of these cases are fatal. Complete wounds of the sympathetic are followed by atresia of the pupil, slight ptosis, congestion of the conjunctiva, headache, congestion of the side of the face (unless only stimulated); it produces mydriasis, pallor of face, protrusion of eyeball. Injury of the superior laryngeal nerve is sometimes very serious. When possible, the divided ends must be sutured with fine silk.

Penetrating or deep contused and lacerated wounds of the region do not expose so much to primary hemorrhage, but the suturing of the muscles, the ligation of the vessels and the stitching of the nerves can not be relied upon as safely, because of the sloughing which usually follows those wounds; for the same reason secondary hemorrhages are much more common and more grave. Penetrating or deep gunshot wounds of the region call for the same remarks, plus the frequent

penetration of the digestive and respiratory tracts and spinal canal with their possible complications; the presence of a ball or foreign bodies deeply lodged and unremovable in these wounds injures the vessels more frequently and seriously than the deep punctured wounds. Here less than anywhere else should search be made for the bullet. When, however, the wound is large, the finger may be introduced, and if the ball is felt it should be removed.

Poisoned wounds, stings, bites, etc., present nothing peculiar in this region.

Foreign bodies, represented by bullets particularly, may remain embedded in the tissues without giving rise to any serious trouble; a bullet may thus remain in contact with the large vessels without causing trouble, but not so with the nerves.

Rupture of the sterno-mastoid is the most common rupture of all the muscles ruptured; it has taken place after falls, sudden twists, violent muscular contractions. There is great pain, a depression on the course of the muscle, great hematoma; the head is often twisted by the action of the other muscle.

The treatment consists in placing the head in proper position, and immobilizing it in a liquid glass bandage. The rupture is usually partial; when complete the ends are far apart; it is well to cut down and stitch; otherwise a kind of torticollis may result from the lengthening of the muscle.

Neuroses are represented by the disease known as torticollis.

(To be continued.)

SOCIETY PROCEEDINGS.

Chicago Ophthalmological and Otological Society.

Regular Meeting, held at the Chicago Athletic Association Rooms, Feb. 9, 1897.

Dr. MONTGOMERY in the chair. There were fourteen members in attendance. The minutes of the last meeting were read and approved.

Dr. CASSIUS D. WESCOTT reported a case of

KELOID OF THE CORNEA.

In February, 1895, a baby 2 years old was seen with a disfiguring prominence on the cornea of the left eye. Parents, who were Scandinavians, gave the following history: Three or four days after birth the left eye became swollen and red and discharged yellow matter. No ophthalmologist was consulted until the cornea had become opaque. The mother says there was no change in appearance of eyeball for six months, and then the front of it began to grow and continued to do so for six months, and then ceased. Eye never seemed painful. The lids were never closed over the projecting eyeball.

From all appearances it seemed to be a case of total staphylococcal keratitis with thickening and epidermization of the cornea, and an abscession was advised. But on examination, under an anesthetic, it was discovered to be a solid tumor. On examination of the specimen after abscession and evisceration, the cornea was found to have been perforated and the iris adherent throughout its entire extent, and that the cornea was uniformly thickened, measuring in the center nearly 8 mm. in thickness. The external surface was rough and the color that of the integument. The wound healed kindly, and several months after the operation the cicatrix was normal and the stump freely movable in the orbit. The specimen was placed in Fleming's solution and the hardened cornea examined by Dr. Hektoen, who made the following report: "The sections (30 to 40 microns in thickness) were stained with hematoxylin and eosin according to Van Gieson's method. Microscopically the anterior epithelial covering is somewhat, but uniformly, thicker than normal and the cells composing it are more flattened than usual, while those upon the surface have formed a relatively thick horny layer, so that the cornea is provided with a 'distinct stratum corneum.' In some places the lower layer of cells is of a brownish color, but otherwise the anterior epithe-

lial layer of the cornea is free from pigment, but the conjunctival epithelial covering present is the seat of a light brownish diffuse pigmentation.

"Bowman's membrane is not conspicuous, its place being taken by fibrillated material. Under a low power the substance proper of the cornea is seen to consist of a densely lamellated structure, the lamellae running parallel to each other, but are broader and irregular as compared with those of the normal cornea. Distinct fibrillated bundles run obliquely or transversely across the sections and often split into smaller bundles. Between the lamellae are irregular narrow spaces that seem to contain nuclei; the interlamellar spaces are larger and plainer in the posterior strata of the sections. The substance proper seems to be avascular. In thicker sections (10 microns) the lamellae are seen to be composed of fine and coarser fibrillae that interlace rather irregularly, and the interfibrillar and interlamellar spaces contain connective tissue cells with large flattened nuclei (corneal corpuscles). Their number is not increased. The posterior basal membrane is absent over one-half of the posterior surface of the cornea, its place being taken by lamellated material; the posterior endothelial layer is absent completely, and its place is taken by an irregular layer of yellowish and brownish pigment granules and masses of varying thickness; whether the brownish pigment is all enclosed in cells or not could not be determined. The diagnosis would be, hyperplasia of the substance proper of the cornea (keloid) with epitheliosis of the anterior surface and a pigment layer upon the posterior surface due to prolapse of the iris."

Dr. WESCOTT, after an extended search of the literature, was only able to find two cases which all resembled this case. One reported by R. Simon in the *Centralblatt f. praktische Augenheilkunde*, 1882, page 193, the other by I. Szokalski, Warsaw, in the *Annales d'Oculistique*, 1865, page 209. He thinks the term keloid as applied to this case might be open to criticism. For histologic reasons it might perhaps be called a case of chronic inflammatory hyperplasia; but in its genesis it certainly resembles keloid.

Dr. LYMAN WARE reported a case of

PANOPHTHALMITIS FOLLOWING CATARACT EXTRACTION,

dacryocystitis being present at the time of the operation. The conjunctivitis and dacryocystitis were treated with nitrate of silver and other astringents without special benefit, and it was not until a solution of formalin, 1 to 5000, was used that any improvement took place. Five months after the patient was first seen a preliminary iridectomy was done on both eyes with good recovery, the eyes not being bandaged, and the formalin solution used three or four times a day. Two months later the cataract was extracted from the right eye. The wound was made at the sclero-corneal margin, coming out well back in the conjunctiva, making a good flap. The after-treatment consisted of washing the eye with a solution of formalin three times a day and having it covered with a wad of absorbent cotton soaked in the same solution. For the first two days the eye had all the appearances of making a good recovery. No pain was present and the wound was perfectly clean. On the third day the wound began to show signs of infection. The cornea soon became involved, panophthalmitis set in and the eye was totally lost. Under ordinary circumstances, Dr. Ware would not have ventured to operate on the cataract until several months had elapsed after the apparent cure of the dacryocystitis, but as the man had been blind so long, was old and feeble and thought he could not return again to the city and especially as the formalin solution seemed to control the dacryocystitis so well, he thought he was justified in making the attempt to restore vision.

Dr. A. B. HALE thought an operation for cataract should never be done if there was the least trace of dacryocystitis. In many chronic cases it was advised to excise the tear sac, the extraction being postponed until the wound had healed.

Dr. W. FRANKLIN COLEMAN mentioned a case of extraction where conjunctivitis, with muco-purulent discharge, was present, and yet a good result followed. A preliminary iridectomy was done, followed, in two weeks, by extraction.

Dr. EDWARD L. HOLMES had the same experience in similar cases.

Dr. HORACE M. STARKEY said that the only case of suppuration after cataract extraction in his experience happened in a case similar to that of Dr. Ware. The wound did well for 72 hours and then suppuration set in with destruction of the eyeball.

Dr. GRADLE asked if any member had tried obliteration of the tear duct with the galvano-cautery.

Dr. W. T. MONTGOMERY has closed the punctum with a hot wire. He thought that in cases of cataract extraction complicated with conjunctivitis a preliminary iridectomy should be

done, and he believed that there is much less danger of infection if the incision be made downward and with a conjunctival flap, followed by flushing the eyeball with boracic acid solution.

Dr. HOLMES asked the most recent method of destroying sac.

Dr. A. B. HALE thought the Kiel method gave the best results by cutting the sac out.

Dr. W. FRANKLIN COLEMAN enquired if any member present had tried Fick's method of chlorid of zinc injections into sac, thereby obliterating it.

Dr. A. B. HALE has tried it but stenosis resulted.

Dr. J. ELLIOTT COLBURN removed six sacs by the Kiel method with good results.

Dr. H. GRADLE has noticed that where the patient complains of lachrymation only when exposed to the wind, the chances of permanent cure are better than where the watering is continuous. In cases of stenosis he divides everything with the knife and does not depend on reducing stenosis by pressure.

Dr. W. T. MONTGOMERY has had similar experience to Dr. Gradle, in that the duct closes up immediately after passing probe alone.

Dr. W. H. WILDER presented a case of

PARALYSIS OF THE THIRD NERVE.

H. B., aged 25. First seen Feb. 19, 1896. Mother died at age of 26, of cancer. Patient contracted syphilis five years ago. Dec. 28, 1895, he first had diplopia, followed soon after by ptosis of the left upper lid, coming on suddenly without previous pain except slight frontal headache. At times there were attacks of dizziness. Examination shows paralysis of external muscles supplied by the third nerve. Pupils react to light and convergence and the patient can accommodate to $4\frac{1}{2}$ inches. R. V. 6-6; L. V. 6-9. No fundus changes. The lesion is probably in the nucleus of the third nerve, although it is uncommon for a nuclear palsy to be unilateral.

Not until this patient had reached a dose of 75 grains of potassium iodid, taken three times a day, was any effect seen on this syphilitic paralysis. Then power began to return to the levator palpebre and as the dose was increased the superior rectus began to act; then the inferior oblique, inferior rectus and internal rectus, in the order mentioned. At present he is taking 160 grains of the iodid at each dose or one ounce a day. Dr. Wilder presented him chiefly as an illustration of the fact that the curative effects of potassium iodid are not exhausted with moderate or even with large doses, and to show what may be accomplished in syphilitic paralysis by the administration of heroic doses of the drug.

Dr. WILDER also presented the following case of

THROMBOSIS OF THE RETINAL VEIN.

Mr. E. G., 55 years of age, and apparently in perfect health, noticed on Friday, January 15, at about 1:30 o'clock, that the sight of the left eye had failed completely. There was no pain accompanying this trouble. When he was first seen by Dr. Wilder about thirty-six hours later, there was absolute blindness of the left eye. The pupil did not react directly to light, but reacted consensually and also to accommodation. Ophthalmoscopic examination showed pronounced edema of retina. The outline of the optic disc could not be distinguished. The veins were enormously distended and tortuous, filled with dark-colored blood, and had in places a sausage shape. The arteries were obscured in many places and seemed about the normal caliber, numerous hemorrhages were seen scattered throughout the retina. These appeared to be in the fibrous layer and were striated and frequently fan-shaped, in places covering the vessels. The vision of the right eye was normal with sph. + 2 D. The patient said he had kidney disease several years before, but an examination of the urine showed no albumin. There seemed to be a roughness of the first sound of the heart over the apex, and the second sound was accentuated at the base. At the present time he has slight perception of light downward to the temporal side. The swellings and hemorrhages in the retina have disappeared in a great measure; the veins have become smaller and have changed in places into white cords. These are seen best in the region of the optic disc. The arteries are also smaller than normal. It seems almost unquestionable that we have here to deal with a case of thrombosis of the central retinal vein.

Dr. CASEY WOOD presented a patient suffering from

PARALYSIS OF THE OCULAR MUSCLES DUE TO LEAD POISONING.

The patient, aged 49, a painter, had had lead colic five years ago, followed in two years by an attack of vertigo coming on suddenly one morning, and was then unconscious for half an hour and had pain through his head for two days, at end of which time he complained of diplopia, and in three weeks noticed that his left eye turned out. There is no history of

syphilis or injury to head. At the present time L. V. is 2-5; R. V. 2-3; both unimproved by glasses. There is complete left ophthalmoplegia externa, with the exception of the external rectus and possibly the superior oblique. Ptosis is most marked when patient is not fixing. Pupils react very sluggishly to light and accommodation. With the ophthalmoscope few fundus changes are visible, but the outlines of the papilla are not clean cut; it has a woolly appearance. Fields of vision in both eyes are decidedly contracted for white and colors. Dr. Sanger Brown reports that, with the exception of the oculo-motor pareses and optic nerve defects, there is nothing abnormal about his nervous apparatus. Dr. Arthur Elliott found urine and saliva practically normal and free from traces of lead.

Dr. J. ELLIOTT COLBURN presented a

CASE RESEMBLING NEPHRITIC RETINITIS,

in a boy, who when first seen had loss of vision in the right, with lowered vision in the left eye. Slight convergent squint has been present since early childhood. He had just recovered from typhoid fever when blindness set in. The ophthalmoscope showed characteristic whitish spots, with hemorrhages, as seen in retinitis of nephritic origin, although the patient has had no nephritis.

On motion of Dr. Colburn, the April meeting was set aside for the discussion of Muscular Asthenopia.

On motion of Dr. Wilder, the Secretary was instructed to try to obtain a place of meeting with better accommodations for the exhibition of patients.

C. P. PINCKARD, M.D., Secretary.

SELECTIONS.

Increase of Mortality by Cancer.—The last report of the English Registrar-General sets forth in tabular form the facts regarding rising death rate by cancer for the ten-year periods ending respectively in 1870, 1880 and 1890. Throughout the entire period covered by the last three decennia the increase in mortality from cancer has been steadily progressive, the deaths referred to in this cause having been equal to the rate of 590 per 1,000,000 in the recent decennium, against rates of 384 and 468 respectively in the decennia ending with 1870 and 1880. If, therefore, the correctness of the published figures be accepted without question there is no escape from the conclusion that in the course of the last twenty years the mortality from malignant disease has increased by 53 per cent. Dr. Tatham, however, points out that the case is not quite so bad as would appear at first sight from the tables, and he emphasizes the fact that within the last six years alone the sum of deaths ultimately referred to cancer has been augmented by as many as 1,548 in consequence of the system of inquiry already referred to. These deaths have increased the rate of cancer mortality by 6 per 1,000,000. Apart from this, however, he thinks that the increase can not be held to be wholly real, but that a considerable portion of it may be accounted for on the assumption that the true nature of obscure cases of malignant disease is now more frequently recognized than was formerly the case, and that consequently the statements of the causes of death by medical men have latterly been made with greater precision than was possible in earlier years. Cancer mortality is known to vary widely in different parts of the country, but Dr. Tatham, having taken pains to ascertain the actual amount of variation in its local incidence, has clearly shown that the difference in the rates of cancer mortality at all ages can not be accepted as even an approximate measure of that incidence because of the enormous differences in the age distribution of the population in town and country. It is shown in the tables that cancer mortality is comparatively low among both males and females until after the 35th year of age; the mortality of a given place from cancer will, therefore, be largely dependent on the proportion of persons under and over middle age in the population. If, then, account be taken of the varying age and sex distribution of the local populations—in other words, if the cancer mortality among that part of a standard million of persons which is over 35 years of age be considered—it

will be found that the differences in the cancer rates of the various counties will be considerably reduced. To take a typical instance of this reduction: according to the crude rates Huntingdonshire showed a cancer mortality of 208, as compared with that of Durham, taken as 100; after this correction, however, the mortality of the first-named county, as compared with the last, is only as 127 to 100. It is to be remembered, however, that while correction for age constitution reduces the difference between the cancer rates of the various counties it scarcely alters the relative position of those counties as areas with high medium, or low rates of mortality from malignant disease.

A Bacteriologic Study of Scarlatinal Diphtheria.—The *British Medical Journal*, December 26, quotes von Ranke, in the *Münchener medicinische Wochenschrift*, October 20, on his researches as to the significance of exudative patches upon the fauces in scarlet fever. On 145 cases admitted to hospital in a period of two years, nearly ninety-two had more or less of membrane upon the tonsils; of these, eighty-nine cases were examined bacteriologically, and to these five other cases occurring in Munich, and also bacteriologically examined, were added, thus making a total of ninety-four available cases. The author discusses these cases under the following groups: 1. Cases admitted with scarlet fever and diphtheria and examined at once. There were sixty-seven such cases with six deaths. The streptococcus was found alone in 38.8 per cent., the streptococcus and diphtheria B. in 47.7 per cent., and the diphtheria B. in practically pure culture in 5.9 per cent. Thus the diphtheria bacillus was present in over 53 per cent. A negative result was recorded in 5.9 per cent. These cases are then compared with primary diphtheria. In 300, or 73.3 per cent. of 409 such cases the diphtheria bacillus and streptococcus were present, and in 75, or 18.3 per cent., the diphtheria bacillus in almost pure culture. Thus the diphtheria bacillus was found in 91.6 per cent., and the streptococcus alone in only 5.8 per cent. In the remaining cases the examination was negative. Thus the bacteriologic examination in scarlatinal diphtheria gives different results to that in primary diphtheria, but the fact remains that in Munich the diphtheria bacillus was found in more than half the cases of so-called scarlatinal diphtheria. The simplest explanation is that the scarlatinal angina predisposes to the diphtheria infection. The frequency of pure streptococcus pseudo-diphtheria is not due to the lacunar form of the throat affection. Of the six cases which ended fatally, the streptococcus alone was present in three, the diphtheria B. and streptococcus in two and the result was negative in one case. Descending croup existed in two cases, one with the streptococcus and diphtheria B. and the other with the streptococcus alone. 2. Cases admitted with scarlet fever but in which diphtheria subsequently developed. Here there were ten cases and all recovered. In one the diphtheria B. was found in almost pure culture, in seven the diphtheria B. and streptococcus and in two the streptococcus alone. This is different from the results in the first group, but the numbers are too small to base conclusions upon. It would seem, however, that the resemblance to primary diphtheria is great. 3. Cases with primary diphtheria in which scarlet fever developed later. Of these there were twelve cases and two deaths from pneumonia and nephritis. The bacteriologic examination resembled that in true diphtheria. It would appear as if scarlet fever were primary in these cases, the diphtheria being added during the incubation period of the scarlatina, and especially was this so in two cases. In spite of all precautions when the scarlet fever appeared in these cases the infection was conveyed to one or two other occupants of the ward. An incubation period of twenty-four hours in scarlet fever is possible, but is very rare. In every case of diphtheria careful inquiry was made as to whether there had been scarlet fever in the family, and when this was

the case the child was always placed in the observation ward. 4. Cases in which the infection with scarlet fever and diphtheria occurred in patients in hospital for other diseases. In two such cases the streptococcus alone was present. In the one fatal case there was a descending croup. Among his conclusions the author points out that considering the relative frequency of the diphtheria bacillus in the so-called scarlatinal diphtheria, it is advisable to use the diphtheria serum in these cases.

How Sir Spencer Wells Coquered the Field of Ovariectomy.—The late Sir Spencer Wells may be said to have fought a giant when he entered the lists as an ovariectomist. Some faint notion of the fight that he dared to put up in this matter may be gleaned from an article in the London *Lancet*, January, a part of which runs as follows: In April, 1854, Spencer Wells, in company with his friend, Mr. T. W. Nunn of the Middlesex Hospital, assisted Mr. Baker Brown in his eighth case of ovariectomy. This was the first time that Spencer Wells had seen the operation performed, and its result, like that of six others of Baker Brown's first nine cases, was not encouraging. In discussing the case afterward Mr. Baker Brown remarked: "It's the peritonitis that beat us," for it was chiefly in the matter of after-treatment that the results of the operation form such a discouraging picture. Temporarily disheartened by his ill-success in seven out of nine cases, Mr. Baker Brown for a time abandoned all hope of introducing the operation, although he was in his own mind convinced of its reasonableness and ultimate utility. It was not until 1857, however, that Spencer Wells himself attempted the operation, and this he did contrary to the advice of his friend, Mr. Baker Brown, who nevertheless, assisted him. The result of his first venture was not encouraging, for he lost his case. He was not discouraged by this untoward beginning, but persevered, and in the following year his hopes were realized by the entire success of his second case. From that time forward the results obtained by him are a portion of the surgical history, not only of the century, but of all time. It is not only on account of his mechanical dexterity in a particular operation that Sir Spencer Wells deserves to have his name kept in honored remembrance. At the time when he turned his attention to ovariectomy the operation was so fatal as to be generally regarded as unjustifiable; and no common force of character was required to persevere with the operation. Feeling assured with the instinct of genius of the possibility of its ultimate success he says himself: "On taking up this subject as a matter of study and trial, just at the crisis when obloquy was the thickest and opposition the strongest, I felt that nothing but the most open frankness would carry conviction of success, or in case of failure justify the operation. . . . I therefore pledged myself to make known through the press all that I did and all that befell me." Sir Spencer Wells deserves the greatest credit both for having at that time the courage to make public his failures as well as his successes, and also for recognizing that only in such a way could it be hoped to establish ovariectomy as a justifiable operation. There can be no doubt that the large number of abdominal operations performed at the present day owe their inception to ovariectomy, and to Sir Spencer Wells belongs the credit, not of inventing ovariectomy, but of taking the principal share of the work involved in establishing that operation on a recognized basis. In 1857 he became lecturer on surgery at the Grosvenor Place Medical School, which eight years afterward became merged in the School of St. George's Hospital. Between the time when Spencer Wells first turned his attention to ovariectomy and the first occasion when he practically essayed it his energies were directed for the space of a year or more to a very different kind of work. Shortly after the war broke out in the Crimea he temporarily resigned his work at the Samaritan Hospital and his private practice and proceeded to Smyrna, where he became surgeon to the British Civil Hos-

pital there, as well as at Renkioi, whither he afterward proceeded. He saw a great class of injuries which were almost entirely new to him, and in the course of his work had the opportunity of attending to many abdominal wounds, experience which afterward proved most useful in his surgical work. He frequently stated in after years that it was during the war that he realized that the peritoneum would stand much rougher handling than he previously imagined, and it was this knowledge in great measure that reassured him in the operation and gave him a boldness which characterized his later work, and which results amply justified. At Renkioi he was associated with Dr. Parkes, who was one of his oldest professional friends.

Serum Diagnosis of Typhoid Fever.—At a meeting of the Society of Biology of Paris, Drs. Widal and Sigard communicated an improvement in their method of diagnosis. Till now the reaction by agglutination has been obtained by mixing fresh cultures of the typhoid bacillus with the serum of the patient under investigation. These bacilli when killed by heat lose their agglutinating power, and investigators have remarked that when the bacilli are destroyed with due care, whether by a temperature of between 57 and 60 degrees C., or preferably by adding a drop of formol to the culture, they preserve, even though dead, their property of agglutinating the serum of typhoid fever patients for as long as three months. Tubes can, therefore, be prepared with formol and preserved in the laboratories of hospitals, preventing the necessity of using fresh and virulent cultures—an innovation of considerable importance to general practitioners. The above information is supplied by the *London Lancet*. Drs. Wyatt Johnston and McTaggart, in the *Montreal Medical Journal*, March, refer to the fact that diabetic blood has been found by Block and by W. H. Park, to give a decided agglutination. They have examined two cases of diabetes which both gave perfectly negative results. Their latest investigations lead them to offer the following conclusions. The difference in reaction observed between typhoid blood solution and blood serum is not simply due to varying intensity, but to an alteration in the relative prominence of the agglutinative, paralytic and disintegrative phenomena which constitutes the reaction. The extent of this difference varies with the virulence of the culture, but the difference probably depends also on the presence of part of the specific substances elsewhere than in the blood serum. Blood solution has a greater capacity than blood serum for producing the disintegrative (bacteriolytic) changes described by Pfeiffer. Descriptions of this phenomena are conspicuously absent from the many recent accounts of the reactions with typhoid serum as observed in hanging drops. The paralytic effect is relatively more marked with serum than with blood solutions. Agglutination without stoppage of motion is more rapidly occasioned in virulent cultures by blood solution than by serum, and does not indicate existing typhoid. It appears preferable that for the dry blood method only attenuated cultures should be used. These have the advantage of being more easily kept in readiness than virulent cultures, and are less sensitive to changes of temperature. With the serum method virulent cultures give prompt results. Dried blood serum can be readily obtained and transmitted to the laboratory by pushing aside the edge of a blood drop which has clotted for a few minutes but has not dried, and collecting the serum beneath it on the tip of an ivory vaccine point, etc. This does not however give a quantitative result. For ordinary diagnostic purposes, the simplicity of the method as originally described does not require modification, provided attenuated cultures are used. A drop of the solution obtained from a dried typhoid blood drop, mixed with a drop of the culture, will give the reaction promptly, without any special attention to the degree of dilution. In order, however, to obtain the best results, it is well to dilute freely and especially to avoid having a sticky solution of syrup-like con-

sistency. In cases where the clinical type strongly resembles typhoid and where the serum does not give the typhoid reaction, a decided reaction with cultures of the colon bacillus may explain the symptoms. Results with the dried blood test have been very satisfactory, giving uniformly positive results with genuine and well marked typhoid cases, and not reacting with non-typhoid bloods when attenuated cultures were employed. Although the use of serum undoubtedly enables the results to be recorded and compared with greater scientific precision, we find that dried blood answers just as well for routine diagnostic work. The alterations in reaction, induced by very slight modifications of the manner of testing, help to explain differences in the results reported by experienced and careful observers. With the same blood and culture, the amount of dilution possible largely depends on whether plain bouillon, bouillon culture or water is used for diluting. Opinions also vary as to what should be regarded as constituting a reaction. Personally, we do not think that anything less than complete clumping and total arrest of motion obtainable by the dry as well as the moist test in a young attenuated culture, should be regarded as typical.

"Idiots Savants."—Dr. Frederick Peterson, in the *Popular Science Monthly*, December, 1896, defines the above expression, which comes to us from the French, as applicable to all such idiots, imbeciles, or feeble-minded, as exhibit special aptitudes of one kind or another, apparently out of proportion to their intellectual developments in other directions, and often remarkable as compared with similar developments or faculties in normal individuals. There are many cases of this kind recorded in literature, inclusive of those who are exhibited as musical prodigies, calculating boys and the like. Beyond the fact of the existence of such curiosities, little has been written in explanation of these phenomena. Their psychology and physiology are alike obscure. Precocity and an extraordinary power of the faculty of mental arithmetic have been frequently noted in idiots. This faculty consists entirely of excessive powers in simple calculation and is observed only in the congenital variety of idiots, imbeciles and degenerates. In idiots, in whom the "musical faculty" is well developed in contrast to their general intellectual paucity, it is not of a high order. It consists of a remarkable auditory memory, together with a power of expression by means of the vocal musculature or fingers, of the musical memories stored up in the brain. There is no spontaneous musical expression, no power of invention. This form of memory is not limited to music; it has often included sounds of other kinds. There is a hereditary element in some cases, in respect of this musical faculty. Examples of *idiots savants* with talents bespeaking disproportionate development of the visual centers, together with the power of reproduction by modeling, drawing or painting, are occasionally to be met with. Among idiots, imbeciles and feeble-minded it is not uncommon to meet cases with an aptitude for drollery and given to witty or humorous remarks and actions. The court-fools of Shakespeare and the "drolls" of other writers, are the type of this class of degenerates. Any quick witted imbecile or feeble-minded individual in ancient times had no difficulty in securing a good livelihood, and sometimes even prosperity and fame. Under such conditions it became common for normal individuals to adopt the calling of the jester or buffoon, and these were known as "artificial fools." The author presents the following conclusions:

"The *idiots savants* are always among the congenitally defective, who usually have stigmata of degeneration. They are mere copyists in music, modeling, designing, or painting. Yet at the same time their talents stand out in strong contrast to their general feeble-mindedness. As a rule the aptitudes are precociously developed and are frequently lost before reaching adult life. The physical basis of such talents must be a precocious perfection of the cerebral organization in certain areas, together with a true hyperplasia of tissue in such regions and a tendency to early degeneration. There must be an increased

number of cellular elements and sensory-motor combinations and associations in definite parts of the brain. Cases of misplaced aggregations of such tissues in the brain have been described under the name of heterotopia of gray matter, and it is possible that some such unequal distribution of the structures underlying psychological processes will be found to account for the presence of the extraordinary talents of *idiots savants*. It is questionable whether Heineken, the 'child of Lübeck,' should be included among any of the cases described here. He died too soon (at the age of four years) for the fact of mental weakness of any kind to be established; but his precocity made him the wonder of his time (1721-25). He knew the chief incidents of the Pentateuch at the age of one year, had mastered all of sacred history at two years, and was intimately acquainted with modern and profane history and geography and spoke French and Latin, beside his native tongue, at the age of three. Surely such precocity as this must have been due to extraordinary aggregations of gray matter in parts of the brain of a truly abnormal character."

PRAGTICAL NOTES.

Connection Between Aneurysms and Syphilis.—A comprehensive study of this subject in the *Annales de Derm. et de Syph.* for January by Prof. G. Etienne (thirty-eight pages), announces that 70 per cent. of 376 cases examined were found to have syphilitic antecedents, and this is a minimum proportion, as it is so difficult sometimes to detect traces of old syphilis. With most of the aneurysms the infection dated from five to twenty-five years. No histologic difference between the aneurysms of syphilitics and non-syphilitics was noted, with rare exceptions. Mercurial treatment is successful if the gummatous infiltration is still susceptible to absorption without leaving scleroma behind it, so that the tissues can resume their elasticity. When the lesion has advanced beyond this stage, specific treatment is ineffectual. The article concludes with the statement that aneurysms, therefore, with tabes and general paralysis, can be included in what Fournier calls "para-syphilitic affections."

Sulfonal in the Insomnia of Melancholia.—Dr. Marcus Schnetzler, in the *Toledo Medical Reporter*, remarks that sleeplessness is frequently one of the most troublesome and obstinate symptoms with which the physician has to contend in the management of cases of melancholia. These patients are especially apt to yield to the seductive influence of such hypnotics as morphin and chloral, and to become confirmed habitués. For this reason these drugs, if used at all, should be employed with the greatest circumspection. In some of these cases certain non-medicinal measures, as warm baths, the cold douche, massage, exercise in the fresh air, will bring the longed-for sleep and should always be given the preference. There always remain, however, a fair proportion of cases in which a hypnotic is positively demanded, and for this purpose sulfonal is claimed by neurologists to be especially desirable. If properly administered in hot fluids, as milk or tea, one-half to one hour before retiring, it produces calm, refreshing sleep, resembling the normal, without the risk of inducing a habit or disturbing the nervous system. In the treatment of simple melancholia, the author advises administration of 15 grains sulfonal every hour until sleep is secured, and he also relies upon this hypnotic in cases attended with delirium in conjunction with *veratrum viride* and bromids. The author also emphasizes the value of hydiatic measures, as cold shower baths of short duration, especially in melancholia accompanied with stupor, where they will sometimes produce satisfactory sleep without the employment of internal medication.

Operative Cure of Otitic Phlebitis of the Lateral Sinus.—In the 118 operations on record, the more audacious the operation the larger the proportion of successes. Simple mastoidectomy resulted in 16 cures and 21 deaths; mastoidectomy with the sinus opened and washed out, 17 cures and 15 deaths; and lavage of the sinus combined with ligature of the jugular, 31 cures

and 18 deaths. Lambotte recently exhibited a patient cured a year before with a still more extensive operation. He first made a double ligature of the internal jugular in the neck, and resected the vein between them, fastening the upper end in the superior angle of the cervical wound. Then he ligated the transverse sinus as close as possible to the torcular Herophili, and consequently to the occipital protuberance. He then proceeded to the septic focus, and completed the ablation of the mastoid and antral osseous lesions, opening wide the sinusal cavity, removing all the peri-sinusal pus and the intra sinusal septic products, and opening the jugular bulb infected by the antral veins, completing the operation by establishing jugular sinusal drainage for subsequent lavages twice a day. The isolation of the septic focus preceded the removal of the septic accumulations, to avoid dispersing septic clots. The operation could be performed in more than one sitting if the patient is very weak.—*Progrès Méd.*, February 13.

Permanent Stigmata of Epilepsy.—Mairet and Vires of Montpellier, state that a genuine attack of epilepsy can always be recognized by certain unfailing stigmata: 1, the increased amount of nitrogen and phosphates eliminated in the urine. The latter rise from 33 per cent. to 50, 60 and even 65 per cent.; 2, the diminished toxicity of the urine emitted immediately after the attack; 3, disturbances in the temperature. The temperature falls during the convulsion, the period of stertor and sleep, after which it rises rapidly, attaining and even passing the normal temperature, until the average temperature of the day of the attack is higher than the average of other days. The exceptions are when the attack is accompanied by agitation; in these cases the temperature rises instead of falling, and is higher than normal, with the same tendency to remain high afterward as above noted. Also when the sleep is particularly calm and prolonged, the temperature tends to return to normal, but does not rise above it and often does not reach the normal. These modifications are constant and enable a genuine to be differentiated at once from an attempt at simulation. There is also a permanent symptom of latent or pronounced epilepsy, with or without attacks, and even when there has been no attack for years, viz., the hypotoxicity of the urine, which is evidently a function of the neurosis. It also accompanies hysteria, but to a less extent. The toxicity is tested by injecting the urine into the vein of the ear in rabbits. In some cases of epilepsy as much as 480 c.c. per kilogram of rabbit were required to kill the animal, while 50 to 86 is sufficient with normal urine.—*Bulletin de l'Acad. de Méd.* January 26.

Typhoid Bacilli in Non-typhoidal Subjects.—Schneider, in the *Comptes de la Société de Biologie*, July, has examined soil, water and also fecal matter from non-typhoidal subjects in order to ascertain whether or no typhoid bacilli could be isolated from them. Elsner's medium was employed in all the experiments. There were made examinations from thirty-six specimens of water from different localities, of which eight were found to contain bacilli identical in their morphologic and cultural properties with the typhoid bacillus. They also presented the property of toxicity, and an animal which would usually succumb to their inoculation could be protected against them by a typhoid antitoxin. In two of the cases the water was taken from places in which typhoid was present and in five others typhoid had been present some months previously. Of the ten soil cultures which were made, the typhoid bacillus was found six times. In the fecal matter from non-typhoid subjects, a bacillus identical with that of typhoid was found in the stools of three patients not having typhoid and who had never had it. A negative result was obtained in five other cases. Of the eighteen organisms which are obtained from these different sources, twelve were pathogenic to animals, and a fatal issue could be prevented by the use of an anti-typhoid serum. The above experiments are of great interest

as bearing upon the etiology of typhoid and the fact that typhoid bacilli were found present in individuals healthy as far as the disease itself was concerned, shows not only the possibility of auto-infection but also the fact that unless certain conditions favoring the multiplication and ptomain-producing powers of the organism be present they are harmless.

Glutol in the Treatment of Burns and Wounds.—Thomalla reports that in burns glutol exhibits a most beneficial action. He employed glutol in old burns where the skin was broken. After removal of the scab, which is quickly formed, several times until there is not more suppuration, he allowed the scab to remain, and with very few exceptions effected a rapid and uncomplicated healing of the burns without leaving any scar. In one case of a burn upon the foot healing was less rapid because the patient kept at work and his shoe caused continual pressure and irritation of the wound. The reason why the scab may be allowed to remain over the burn after no more suppuration is feared, and therefore further decomposition of the glutol and liberation of the formalin is not necessary, is that the clean antiseptic wound heals more quickly under the protective scab than if the latter were removed at each dressing. He adds: In minor wounds I have often employed glutol, especially in such cases in which a bandage can not be readily applied, such as wound on the hands of workmen, who have continually to dip their hands in liquids, yet at the same time can not afford to give up work on account of the small wound. In such cases I dust the wound with glutol, and then apply collodion; over the collodion I dust another layer of glutol, and thus provide a wound with a firm impenetrable covering. When this glutol covering is removed after several days, the wound is found to be perfectly healed. According to these observations I do not hesitate to pronounce glutol as thy best antiseptic we possess in the form of powder, in which respect its complete freedom from odor must not be forgotten.—*Therapeutische Monatshefte*, January.

A Radical Procedure in Follicular Tonsillitis.—Dr. Maxson recites his favorable experience in the use of caustic for the prevention of follicular tonsillitis. In so far as this treatment seems to go to the root of the matter it may with propriety be termed "a radical treatment." The method of the author has the merit of being devised with a view to thoroughness, a quality that we all know the value of when dealing with throat-affections. The author says: "A revention of follicular tonsillitis is desirable in at least two classes of cases; those occurring during an epidemic and also those where there are repeated attacks occurring about once a year. Those occurring only during an epidemic can be prevented by a mild aseptic throat wash, with or without the internal administration of benzoate of soda. The chronic cases, which are subject to frequent and repeated attacks, are very annoying to the physician and damaging to the patient's health. Such was my experience until I discovered and applied a treatment that I have lately found to be known and used by others, but which is not mentioned in any literature that I have access to. The treatment consists in destroying the contents of each follicle that is diseased in both tonsils. I think that the follicle is not destroyed, but the colonies of germs that make an abiding place in the follicles are destroyed. My custom has been to take a doubled piece of silver wire, such as is used for suture, and solder its free ends to a large wire; then dip the doubled silver loop into melted nitrate of silver, so as to make a small bead on its end, after withdrawing it from the melted silver salt. The silver wire is then bent half an inch from its distal end, so as to make an angle of forty-five degrees. This bead of caustic is inserted into each follicle to its bottom. The depth will vary from one-fourth to one-half an inch. One caustic bead will usually treat from one to two follicles. By means of several beads, all the follicles may be treated. This treatment is undertaken at

any time except when the tonsils are acutely inflamed. It requires one or two treatments to effectually prevent its return. I have used this treatment for eight or ten years, and found it entirely reliable. I know of no case that has not been given a very complete immunity, even when subject to attacks every two to eight weeks before treatment."—*Journal of Practical Medicine*, December.

Argentamin in Urethritis.—Dr. Ascher, of Buda Pesth, in the *Deutsche Med. Zeitung*, for January, records his experience in hospital cases, twenty-two in number, of gonorrhoea, with this so-called "silver nitrate substitute." Argentamin is an ethylene-diamin-silver phosphate and has hitherto had its chief field in regard to conjunctival diseases. Dr. Ascher offers the following conclusions: 1. This drug is well tolerated in the posterior urethra in solutions of 1 to 1,000, or even 1 to 250. In the urethra anterior a solution of 1 to 1,000 is also well tolerated, but solutions of 1 to 500 begin to be unpleasant, patients complaining of burning for a quarter or half an hour after injection, especially in acute stages. Ascher therefore recommends the employment of solutions of 1 to 1,000 to 1 to 250 for the urethra generally, and of solutions of 1 to 1,000 or 1 to 2,000 for the urethra anterior. After employment of solutions in any degree of concentration the purulent secretion increases at first, but in the course of three or four days rapidly abates. 2. Argentamin is an excellent gonococci destroying agent. The gonococci disappear extraordinarily quickly from the secretions, even when a solution of 1 to 1,000 is employed, either by means of an Ultzmann instillator, or by means of a simple syringe, in ten to twelve days. Argentamin has a more rapid and positive effect upon the gonococci than all other antigonorrhoeics hitherto known. It surpasses even silver nitrate. It possesses considerable penetrative action. It is much cheaper than silver nitrate, and in the above concentrations neither stains the hands nor linen. In the author's opinion, however, astringents can not be entirely dispensed with; in many cases the scanty slimy discharge of the last stage can only be completely done away with by their use.

Congenital Spastic Rigidity.—This affection, also sometimes called Little's disease—so named after an English surgeon who, in 1882, first described it—includes both somatic and psychic defects such as are seen in a class of infants born before the full term. Dr. Collins, in the *Medical News*, February 6, takes up the subject chiefly with a view to throwing light upon the still obscure pathogeny and pathologic anatomy of the disease. He desires to bring out the fact that of late Van Gehuchten has been studying the subject to some purpose. That writer, whose contributions are to be found in recent issues of the *Journal de Neurologie*, discusses both the etiology and clinical aspects of the disorder. He points out that those authors who teach the occurrence of this condition in children born at full term with the aid of instruments are in error, at least in part. He believes that obstetricians are nearly in accord that the symptom complex of congenital spastic rigidity is commonest in children born prematurely; and it matters very little whether the birth be an easy or a difficult one. At this time of life the pyramidal tracts are almost wholly non-medullated and naturally, therefore, devoid of the ability to functionate. The first tracts to become medullated are those constituting the indirect motor pathway—the pathway through the pons cerebelli—while the direct pathway—the cortico-spinal fibers—are very much delayed in acquisition of myelin sheaths, and perhaps may never develop them at all. In its downward growth during the latter years of infancy, the tract of the cortico-spinal fibers reaches first the upper and then the lower levels of the cord, those fibers destined for the lumbar and the sacral portions requiring the longest time to reach their destination. In accordance with this the rigidity and contracture disappear first in the face and head, then in

the upper extremities, and remain longest and perhaps do not disappear at all in the lower extremities. In short, therefore, the author contends that absence of the myelin sheaths of cortico-spinal fibers constituting the pyramidal tract is attended by the same clinical phenomena as degeneration of these fibers. In both conditions there is an absence of inhibitory action of these fibers upon the motor ganglion cells of the anterior horns, consequently the spasticity. If his claims are corroborated by other investigators, a very important step will have been taken for a satisfactory explanation of the pathogenesis of this condition, and possibly also for the prevention of its occurrence. If it be a developmental defect dependent upon, premature birth, the prevention of the condition will simmer down to an obstetric problem, to wit: How can delivery be delayed until the period of complete fruition?

Lawson Tait on the Treatment of Uterine Myomata.—Mr. Tait writes in London *Lancet*, February 6, objecting to a statement that had been made to the effect that the Gynecological Society of England had for three or four years insisted that total extirpation of the uterus was the best treatment for these tumors. He says: "Those who gave utterance to this sentiment as that of the Society form, no doubt, an extremely important section of it; but it is equally certain that an important minority will not give their sanction to any such opinion. I think it probable, for example, that Dr. Bantock and myself could make a larger list of cases of myoma treated in various ways than all the other members of the Gynecological Society put together, but neither he nor I have made up our minds as yet definitely on the subject—at least, I can speak for myself. I have tried a number of cases of the so-called 'pan-hysterectomy,' and have a list much longer than any yet published in England, and I do not find that it commends itself to me in preference to Koesberle's method save in the one particular of being somewhat easier. Indeed, in those cases for which it is adapted I can not understand how an hour and a half or even an hour can be spent over it, unless the proceeding is much interrupted by unnecessary conversation. Its primary mortality, so far as my own work is concerned, is much the same as the clamp operation, but it is too early to speak positively upon this important point. As adverse arguments to the operation there are several points to consider, the first being that there is a distinct group of cases for which it is absolutely inapplicable, and these, unfortunately, are the cases which demand hysterectomy most of all—I mean the soft edematous myomata. In the tumors having uterine tissue at their base, firm, not given much to shrinking, and with vessels well-defined and separate, the operation can be easily applied. On Thursday last I operated for one of the former class of tumors, and started with the intention of trying the pan-hysterectomy, but found it absolutely impossible. It is, however, upon secondary results that the fate of this operation will depend, and I have seen already enough of them to make me suspect that it will be speedily discarded. The reason is the unfortunate effects of the ligature, a paper on which I published some time ago. In this operation the ligature is not dropped into a peritoneum, which speedily digests and absorbs it, but is pressed among tissue peculiarly apt to resent interference. Concerning the lower ligatures it must be borne in mind that they are placed with nothing between them and the cavity of the bladder but part of its denuded muscular and the whole of its mucous coats. These form but a slight protection against a dead ligature finding its way into the bladder. In addition to such an accident as this, three or four other forms of accident have already passed under my notice, namely, the formation of leakage from a ureter, leakage from the bladder and leakage from intestine, all incidents occurring long after the primary success had been obtained. Personally I have been now for twelve years patiently waiting for material upon which I could emphat-

ically express my opinions as to the complete and the best methods of treating myoma, but one thing after another has arisen to alter the opinions which I thought had been steadfastly established, and even yet I am obliged to refrain from writing fully on the subject. I think with the knowledge of this that the younger members of the Gynecological Society will refrain from the positive expressions of opinions which must be premature, and at least they will not pledge the whole Society to opinions against which many of their seniors certainly must enter an energetic protest.

Treatment of Malaria (Laveran).—Laveran always prefers to administer quinin in solution when possible, as pills become too hard to dissolve, powders are not transportable, the endermic method is painful, and while enemas are useful in the case of children, they are rejected by adults. The hypodermic method ensures good and prompt results. For this he recommends the formula: Bihydrochlorate of quinin, 5 grams; aqua dest. q. s. to make 10 c.c. One c.c. of this solution contains 0.50 grams of the salt. Baccelli has used intravenous injections successfully, but they are not entirely inoffensive. The type of the fever should not modify the treatment, which should be as follows for an adult: For three days, 80 centigrams to 1 gram of hydrochlorate of quinin. The fourth, fifth, sixth and seventh days, no quinin. The eighth, ninth and tenth days, 60 to 80 centigrams of hydrochlorate of quinin. From the eleventh to the fourteenth day, no quinin. The fifteenth and sixteenth days, 60 to 80 centigrams. From the seventeenth to the twentieth day, no quinin. The twenty-first and twenty-second days, 60 to 80 centigrams of hydrochlorate. This is the usual formula, which can be modified to suit the circumstances. The same salt is given to children in the following proportions, divided into several doses during the day: Children of 4 and over, 30 to 40 centigrams; 2 to 4, 20 to 30 centigrams; 1 to 2, 10 to 20 centigrams; less than 1 year, 5 to 10 centigrams. In severe attacks we must not hesitate to administer quinin hypodermically to children. Quinin is borne better between the attacks and may abort them, but it is not necessary to wait until the fever falls. Maillot has well shown its great efficiency in continuous fevers. In very severe cases, 0.75 to 1 gram should be injected twice in the twenty-four hours. As the fever yields to the injections, the formula above should be followed. In pernicious attacks also, hypodermic injections should be made, and in the algid form, frictions, diffusible stimulants and injections of ether will be found useful to supplement the quinin. In attacks with coma, use counter-irritation, cold applications and drastic purgatives. Hydrate of chloral should be prescribed for delirium and in the case of alcoholics. Vomiting is combatted with champagne, effervescent drinks, and injections of morphin in the pit of the stomach. Diarrhea, with opium and subnitrate of bismuth. In bilious fevers ipecac and calomel should be administered, but not until after the quinin. All tonics are useful as they increase the resisting powers of the organism. Arsenic, iron and nux vomica render important services, in supplementing the quinin. Hydrotherapy is also useful, but the douche should be tepid and brief at first and the region of the spleen should not be douched at first at all, as a cold douche on that region has been known to induce new attacks. Change of climate is a powerful tonic for persons living in warm countries. In case of hyper-splenotrophy the use of counter irritants can be combined with the quinin, even the local cold douche, intrasplenic injections of 1 c.c. Fowler's solution 1 to 10, or of a 200th phenic solution. Electrotherapy (Botkin) injections of sterilized water (Nurri), and injections of ergotin have also been tried. Splenectomy has been performed, but he considers it contra-indicated. None of the substitutes proposed for quinin can take its place, and the sole objection to its use is that it is rather expensive. Preventive doses of 10 to 20 centigrams a day have given excellent results. The water in malarial districts should be boiled and filtered and taken preferably in the form of coffee or tea. Plantations of the eucalyptus, globulus and rostrata, have been found effective in reducing malaria in Corsica, Algeria and Italy.—*Progrès Méd.*, February 13.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, MARCH 27, 1897.

AN UNUSUAL MANIFESTATION OF HYSTERIA.

Physicians who have had a wide experience with hysteric patients are apt to regard all other patients who come to them with an eye strongly disposed to discover hysteric manifestations, while on the other hand, those members of the profession who have not met with many such cases often overlook the possibility that obscure symptoms may be due to this strange cause of perverted functional activity. The common symptoms of hysteria as manifested in the various disorders of sensation and hemi-anesthesia are so manifest that they often lead even the careless physician to a correct diagnosis, but the more unusual types may well obscure diagnosis unless the physician is constantly on the lookout for their underlying cause.

Our attention has been particularly called to this matter by an interesting case reported in the *Journal des Praticiens* for Jan. 23, 1897, in which there was anuria due to hysteria, which is certainly not a usual symptom, and what is more important and misleading was the fact that there was fecal vomiting. In some cases of this character the fecal vomiting is simulated, but in this instance it seems to be really present. Among those who have reported feculent hysteric vomiting in authentic cases may be mentioned JACCOUD, RICARD, FOQUET, ROSENSTEIN, DE TULLIO, DESNOS, ANDRE and BRYANT. In the case which we have mentioned and which is reported by HOORWEG in a Norwegian journal, the greatest possible precautions were taken to prevent malingering, because the

physician observing the case, believed it to be one primarily of simulation.

The case consisted briefly as follows: A woman of 26 years, unmarried, had since the age of 12 years manifested neurotic symptoms, palpitation and terrors; at the age of 15 years she was assaulted and maltreated by two young men and at this time had hysteric attacks which were frequently repeated. Menstruation was established at 16 years and four years afterward she developed hysteric paralysis and other neurotic manifestations. At 20 years of age she had hysteric attacks two or three times a day and at this time there began anuria accompanied by the vomiting of liquids with a urinary odor. Two days after this, fecal vomiting took place. From this time for the remaining six years similar symptoms continued. The general condition, however, was fairly satisfactory.

An examination of the patient revealed various hysteric stigmata, such as anesthesia, analgesia, ovarian hyperesthesia and similar symptoms. Thinking that the vomiting might be due to an accumulation of fecal matter in the rectum HOORWEG used injections of a pint of warm water, which was gently introduced and in about four to five hours afterward the patient vomited an abundance of liquid with a fecal odor. An examination of the liquid which was vomited and possessed a urinary odor, showed it to contain on analysis urea and uric acid, but on two days when the bladder was emptied by means of a catheter the liquid vomited was still abundant in quantity.

As we have already said, the closest watch was placed upon the patient to see that she did not deceive her observers, but finally the physician in attendance came to the conclusion that she was able to develop antiperistaltic movements. With the object of determining this point a rectal injection of starch water and bismuth was given. Immediately after the administration of the starch and bismuth by the rectum lavage of the stomach and rectum were performed. Five hours later the contents of the stomach contained starch but no bismuth.

The treatment which HOORWEG instituted in this case was faradization of the stomach and rectum, with what he claims good results. The psychic condition of the patient improved to a very marked degree and the serious symptoms were put aside.

We have mentioned this case editorially because we consider all cases which are particularly obscure in their manifestations as being worthy of notice, and with the gradual increase of the number of hysteric patients which we see in this country all such records are of value.

THE "REST IN BED" TREATMENT OF INSANITY.

Within the past few years there has been a considerable interest and some enthusiasm aroused in and numerous trials made of a method of treatment of acute insanity by compulsory rest in bed. The idea is not

a new one, it is as old at least as the fifth century, when it was recommended by CÆLIUS AURELIANUS, and it has been more or less advocated and practiced by alienists all through the modern period of psychiatry to the present. It is in the universal application of the treatment to all cases of acute mental disorder, and to a considerable extent in the appliances and details of the method that whatever novelty it may possess consists. Rest in bed has been a regularly recognized therapeutic measure recommended in nearly all treatises on insanity for acute cases with rapid failure of strength or notable symptoms of physical exhaustion and in some not so very recent works, indeed, it has been advised for all acute cases. That this has not been generally practiced has been due to the fact that the means that have hitherto seemed most applicable for the purpose were deemed more objectionable than the end was beneficial; the bed straps, the crib, the manual restraint by attendants, the wet pack and the sedative drugs, one or all of which seemed necessary at first sight, have been at one time or another referred to the reprehensible practices of physical or chemical restraint that only needed mention to be condemned. The tendency has been to allow the utmost freedom of movement and to check even destructive tendencies only by the mildest measures, such as the use of indestructible fabrics, the diversion of attention to harmless activities, etc. It will be questioned by some, undoubtedly, whether the enforced rest in bed, though without many or all of the most objectionable features mentioned may not be after all a return swing of the pendulum to some extent toward the older methods of the past. There are probably few, if any, alienists of experience who have not used confinement to bed to a greater or less extent in what seemed to them appropriate cases, and they would have used it more were it not that there has been a justifiable prejudice against the coercion that seemed necessary to effect it. The apparatuses of cribs, bed straps, restraining sheets, were all devised or used as therapeutic measures to prevent the weakened and delirious patient from wearing himself out by his constant activity, and were based on the principle that an insane person is an invalid and needs physical treatment for this disorder. That the tendency was toward their abuse by their employment as simple trouble-saving appliances does not alter this fact.

That we have learned better ways of enforcing the needed rest upon the excited patient is certainly a great advance, but it does not do away with the possibility of even these methods being abused for the same reasons and purposes as were the former ones. The rest treatment, according to its advocates and those who have tried it extensively, prevents a great many unpleasant accidents that are likely to happen

when maniacs are kept on the wards, such as occasional exposures, removal of clothing, destruction and injury from other patients, and the need of seclusion in strong rooms, which is so often resorted to to avoid these, is done away with. This, nevertheless, does not make it any the less restraint when even the mildest forms of compulsion or drugs have to be employed to secure it, and it may therefore be counted as the most modern development of that much abused (in both senses) therapeutic method. This does not condemn it necessarily if it is really beneficial and sentimental considerations should have no great weight either for or against its employment. The non-restraint doctrine has apparently not been thus far employed to its prejudice of the bed treatment, though, as has been shown, it may be open to objections in this general line; on the contrary the idea of the maniac being handled by trained female nurses is captivating to many minds and it does appear this is more practicable, than has hitherto been supposed. It is fair to assume, however, that some selection is, at times at least, made of the cases, as it would be no more proper to put certain male cases under the care of females than it would to permit male attendants to care for similar female patients. It is a well-known fact that the presence of proper persons of the opposite sex has a certain restraining influence over most cases but this is not absolutely and invariably an efficient inhibition.

The really important question is, however, whether this method is a real advance in the therapeutics of insanity, or simply an improvement in the methods of meeting certain inconveniences without any actual curative effect in itself. In other words, is it a mere palliative or an actual curative measure. A recent writer, BERNSTEIN of Moscou, says, after a year's trial of the method in the psychiatric clinic of that city, that the one fact proven is that recovery is not more frequent and prompt under this treatment than under the older method, with all of its disadvantages. He admits that it controls the patients better and prevents disagreeable scenes and occurrences, and also that in this opinion he disagrees with others who have expressed the opposite opinion, but he but he quotes their own statistics in favor of his opinion. If he is correct the enthusiasm for the method in certain quarters is hardly justified, and it must be said that there is apparently a tendency toward conservatism in regard to the matter by other respectable authorities.

As a routine treatment the method can hardly be justified. A little consideration of the pathology of insanity would show this. Patients come to asylums in all stages of their disorder, and even acute cases may be past the point where the bed treatment would be beneficial. In some hypochondriac cases its influence might be directly detrimental, and in a general way we can not say that the somewhat mentally obtunding influence of absolute recumbency and quiet

tends invariably to mental restoration. As BERNSTEIN remarks, more experience will be required to settle this question.

In conclusion, we can say that in the bed treatment it has been demonstrated we possess a means of assuring or at least increasing the quiet and order, and of avoiding many disadvantages in the treatment of insane cases in asylums. That it is as curative, as claimed it is, is yet to be demonstrated. That it may be detrimental in some cases, especially when employed as a routine treatment, is not only possible but even probable. When its employment is carried on to the extent of "taking the troublesome cases off the other wards," as has been reported, it is open to the charge of being directly employed as a method of restraint and is open to whatever objections, sentimental or legitimate, may apply to such methods.

STATISTICAL INVESTIGATION OF SUNSTROKE.

The abnormal heat that prevailed over the eastern two-thirds of the United States during the last few days of July and first fifteen days of August, suggested to the Chief of the Weather Bureau the propriety of studying the subject of sunstroke, in so far as it is connected with and dependent upon meteorologic conditions. To this end, circulars were sent out to various hospitals and private physicians located in the affected region.

Dr. W. F. R. PHILLIPS, in charge of the Section of Climatology, has compiled and studied the different reports returned in reply to the circular letter, and his statistics and deductions, as given in the *Monthly Weather Review*, November, 1896, present several points of extreme interest.

From such sources as were accessible there were collected 2,038 instances of death during August, 1896, directly attributed to sunstroke. This falls far short of the actual number of deaths, and even figuring on the mortality of sunstroke as 16.6 per cent. (a ratio of death deduced from one of the statistical tables), the whole number of cases would be 12,277. However, the number of unreported milder degrees of sunstroke must have been enormous.

From a careful study of the tabulated investigations it was concluded:

1. That the number of sunstrokes follows more closely the excess of the temperature above the normal than it does that of any other meteorologic condition.
2. The number of sunstrokes does not appear to sustain any definite relation to the relative humidity, the maximum fatalities having occurred in one region with a relative humidity above the average, and in another region with a relative humidity decidedly below the average.
3. That although the absolute humidity was greatest during the maximum of sunstrokes, yet it does not appear that the variations influenced the number of cases.

Dr. PHILLIPS concludes that if it be taken into consideration that the maximum quantity of aqueous vapor in a given space is limited by the temperature of the vapor, and that the relative humidity is really not a simple meteorologic element, but an expression of a ratio that depends on both the aqueous vapor and the temperature, it would seem that the statistics herein collected confirm the proposition that sunstroke is ultimately due to excessive atmospheric temperature. In other words, sunstroke will not occur unless the atmospheric temperature be much greater than that to which the individual is accustomed, no matter what may be the state of the other meteorologic elements.

As to the atmospheric temperature producing sunstroke, it was distinctly shown that both the personal equation, and the accommodation of the individual to average physical environment, or the climatic equation, are important factors to be taken into consideration. While a temperature of 82 degrees, or 13 degrees above the August normal in Boston, prostrated a number of persons and was fatal to some, the great majority of persons were unhurt by the excessive heat. Again, the climatic equation is shown by the fact that this same temperature was easily endured in New Orleans without sunstroke or any particular inconvenience. Hence each particular locality has for its native or acclimated inhabitant a special local range of sunstroke temperature.

Dr. PHILLIPS also argues that sunstroke becomes imminent during summer months, when the mean temperature of any one day, or of several consecutive days, becomes equal or nearly equal to the normal maximum temperature for the same period; and also that the liability to sunstroke increases in proportion as the mean temperature of the day approaches the normal maximum for that day.

As an argument for the reprobation of alcoholic beverages in hot weather, it is shown that in 140 deaths out of 841 cases in Table 2, of the fatal cases in which a definite history could be obtained, those using alcohol to excess constituted 60 per cent., those using alcohol moderately 30 per cent., and total abstainers 10 per cent.

As might be expected, all walks of life were represented in the reports, and the greater number of cases occurred among those engaged in occupations apparently requiring physical rather than intellectual effort.

THE FIFTY-FOURTH CONGRESS AND THE MEDICAL SERVICES.

The Fifty-fourth Congress of the United States took no action affecting the status of the Medical Department of the Army. Its influence was felt only in the appropriation bills. The Act making appropriation for the support of the Army for the year ending June 30, 1898 provides all that was called for

by the estimates of the Surgeon General in the case of the Hospital Corps, the Library and the Museum; but some economical tendencies were manifested in dealing with the other estimates. The Act makes provision for the purchase of horses for such members of the Hospital Corps on field service as may require to be mounted. The Library obtains its usual appropriation of \$10,000, to enable it to meet the literary progress of the year. Its increase during the past year compares favorably with that of any of the years of its history. A special effort was made to perfect the files of medical journals, foreign and domestic. The second volume of the Index Catalogue, including the titles under the letter "B" will probably be ready for issue about the end of May. The second volume of the First Series published in 1881 carried the Index well into the letter "C." Since then the titles under the first two letters of the alphabet have more than doubled. This shows the magnificent progress made during the past sixteen years. An estimate of \$12,000 for the continuance of work on the Catalogue was embodied in the Sundry Civil bill, which will no doubt be passed during the present extra session. For the preservation of specimens and for the preparation and purchase of new specimens for the Army Medical Museum, the sum of \$5,000 is provided. Special attention has recently been directed at the Museum to perfecting the series of specimens illustrative of the development of the human system. Roentgen ray photography has been prosecuted with excellent results as shown by the many fine skiagraphs now on exhibition. A small cut was made by Congress in the estimates for medical and hospital supplies, the reduction being from \$140,000 to \$135,000. For the construction and repair of hospitals the sum of \$75,000 was appropriated instead of \$100,000 desired, and for the construction of hospital stewards' quarters \$7,000 instead of \$10,000.

The estimates of the Surgeon General of the Navy were honored in their entirety by Congress: \$65,000 for surgeons' necessities for vessels in commission, navy yards, naval stations, marine corps, coast survey, etc.; \$30,000 for contingencies, as for expenses of examining boards, rent of rooms for various purposes, freight, express, telephone and telegraph expenses, etc.; \$20,000 for the Naval Hospital fund and some special appropriations for improvements at certain hospitals, as \$6,000 for the hospital at Chelsea, Mass., \$4,000 for that at Port Royal, S. C. and \$1,000 for the naval cemetery at Brooklyn, N. Y. An estimate of \$1,200 for two ambulances for use at naval hospitals also was approved.

No legislative action was taken to improve the status of naval medical officers and enable the Department to fill its vacancies. We pointed out the injustice of present conditions in our issue of Nov. 7, 1896. At the same time there are fifteen vacancies in

the Medical corps of the Navy; and there appears to be little desire on the part of young graduates to fill the vacant positions. We think this a mistake. Young men considering the merits of the National services should look at more than present conditions. The subject involves the service of a life-time and the possibilities of the future should be weighed as well as the actualities of the present. Improvement in the status of the naval medical officer is merely a question of time. New ships are being built, and they will have to be manned. The Navy is in progress of development. Its medical service will have to be increased and the young graduate who enters now may be floated upward into higher rank at an unusual rate by those who will enter after him.

THE ABUSE OF MEDICAL CHARITY.

The Medical Association of the District of Columbia has recently adopted recommendations intended to restrict the abuse of medical charity which has grown in the City of Washington, D. C., with a rapidity and malignancy which threatened the impoverishment of the general practitioner. These recommendations were printed in our issue of March 13, but as similar abuses are to be found in most of our cities, a few words of editorial comment appear desirable. "There is no profession" says the Ethical Code of the AMERICAN MEDICAL ASSOCIATION, "by the members of which eleemosynary services are more liberally dispensed than the medical, but justice requires that some limits should be placed to the performance of such good offices. . . . Some general rules should be adopted by the faculty in every town or district, relative to pecuniary acknowledgements from their patients; and it should be deemed a point of honor to adhere to these rules with as much uniformity as varying circumstances will admit."

Hospital and Dispensary boards of management seem to have lost sight of these requirements of the system of ethics of the profession, and as a result their annual reports present rose-colored statements of the amount of work done for the benefit of the suffering public. Much of this work, however, is done at the expense of the profession at large. Indiscriminate dispensary treatment keeps many a fee from the hardworking and poorly paid practitioner, and the pay wards of public hospitals, while adding to the financial resources of the institution, do not always add proportionately to those of the medical profession. Pay wards should be pay wards as well to the physician or surgeon in attendance as to the funds of the hospital. Were this the case, the hospitals would be restricted to their proper sphere, and family physicians would have less to say of their encroachments. The aims of the recommendations of the District of Columbia Medical Association are "to place a limit on the performance" of unrequited services, to sift

charity from its abuse, and to keep the hospitals from absorbing patients who are able to pay for medical or surgical treatment. Patients in private rooms in public hospitals are to be required to make proper payment to the physician or surgeon in attendance, as well as for their board and lodging. The seventh and eighth recommendations were drawn up with a view to protect medical members of the staff while insisting on proper remuneration in such cases; but incidentally they give moral and material support to the hospital staff in other matters. Whenever one or more members of the hospital staff resign or are dismissed, and the Association finds after due investigation that the resignation was based on just and sufficient cause, or that the dismissal was without such justification, "it is forbidden for any member of the Association to fill the vacancy created thereby."

Other local associations might profit by following the example of the Medical Association of the District of Columbia, and in doing so they would be carrying into practical effect the requirements of the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION.

CORRESPONDENCE.

The Leprosy Conference.

NEW YORK, March 15, 1897.

To the Editor:—I send you the translation of a French circular which I have received from Dr. Ehlers, the Secretary-General of the Leprosy Conference. (Copenhagen). I add my reply sent to Dr. Lassar, a member of the Berlin Committee. Will you kindly publish these papers in the JOURNAL?

Very truly yours, ALBERT S. ASHMEAD, M.D.

COPENHAGEN, Feb. 23, 1897.

Sir and much Honored Colleague:—The conference against leprosy, which will take place in Berlin, in October, 1897, with the support and approbation of the German Government, proposes to itself to seek for information as exact as possible on the distribution and geographic extension of leprosy.

In the name of the committee on organization of said conference, I have the honor to ask you to help it in this work, and to do us the honor to procure us information as to the distribution and extension of leprosy, in the form of a general sketch of the distribution and extension of leprosy.

Your report is to be as short as possible (in German, English or French); we ask you to be kind enough to send it before the 15th of May, to Professor Lassar, 19 Karlstrasse, Berlin, N. W. It will be printed before the Congress, and will serve as a basis for eventual discussion.

I have to observe that we shall have also special correspondents for each country, so that we must ask you to give us only a general sketch.

Accept, Sir, and very honored colleague, the assurance of my high consideration.

DR. EHLERS, Secretary-General.

NEW YORK, March 15, 1897.

Dear Dr. Lassar:—I have to acknowledge the receipt of a letter from your Secretary-General, Dr. Ehlers, by which I am invited to contribute a general sketch on the distribution and geographic extension of leprosy. In reply thereto I have the honor to observe that you will find about everything that I could say on the subject in my writings, some of which I sent you, with references to others which I did not send you. I do not see that there is any use of further talk about the distri-

bution and geographic extension of leprosy. All these things are on record, and nothing is easier for any person anxious to obtain some light on any subject connected with this question than to consult what all good libraries offer.

Allow me to express once more an opinion which I have declared during the last months very frequently: I do not believe in this Congress; its performance will be nothing else but a thrashing over of old straw, in which there is not a grain left. I hope you will pardon the frankness, or perhaps bluntness with which I express my feelings on this subject. I mean no offense, and I repeat only what I have declared, in and out of season, from the very first moment, when the question of a leprosy congress was mooted. In fact, it was Dr. Goldschmidt and I who first suggested it, but not in the form which it takes in your own project. We did not care for "information as exact as possible on the distribution and geographic extension of leprosy." What we wanted is expressed in one word, *isolation*.

Very truly yours,

ALBERT S. ASHMEAD, M.D.

West Virginia Law Amended.

PARKERSBURG, W. VA., March 17, 1897.

To the Editor:—In the JOURNAL of June 8, 1896, I gave a brief history of a suit for damages for malpractice, calling especial attention to the ruling of the trial judge, in denying the defendants from testifying in their own behalf in regard to any personal transaction or communication had with the deceased, whose death it was alleged, ensued because of malpractice by the defendants. The continuance of that history is, that the plaintiffs abandoned the case and allowed a decree of non-suit to be entered, thus ending the suit. The matter was brought up in the last meeting of the State Medical Society, held in Wheeling, June, 1896, and a committee appointed to ask the legislature to change the law, so as to allow a physician sued for damages arising from the death of a patient through alleged malpractice, to testify in his own behalf as to treatment used. This winter, through the efforts of this committee, aided by the counsel and votes of several physicians, members of the legislature, the law was amended. The act as passed is as follows: Section 23 of chapter 130 of the Code of West Virginia be amended and re-enacted to read as follows:

"Sec. 23. No person offered as a witness in any civil action suit or proceeding shall be excluded by reason of his interests in the event of the such action or proceeding or because he is a party thereto, except as follows: No party to any action, suit or proceeding, nor any person interested in the event thereof, nor any person from, through or under whom any such party or interested person desires any interest or title by assignment or otherwise, shall be examined as a witness in regard to any personal transaction or communication between such witness and a person at the time of such examination deceased, insane or lunatic against the executor, administrator, heir-at-law, next of kin, assignee, legatee, devisee or survivor of such person; or the assignee or committee of such insane person or lunatic. But this prohibition shall not extend to any transaction or communication, as to which any such executor, administrator, heir-at-law, next of kin, assignee, legatee, devisee, survivor or committee shall be examined on his own behalf, nor as to which the testimony of such deceased person or lunatic shall be given in evidence. (Amendment) Provided, however, where an action is brought for causing the death of any person by wrongful act, neglect or default, under chapter 130 of the Code, the physician sued shall have the right to give evidence in any case in which he is sued, but in this event he can only give evidence as to the medicine or treatment given the deceased or operation performed, but can not give evidence of any conversation had with the deceased."

Passed the legislature February 22, and signed by the Governor the same day, to go into effect ninety days from date.

As a statute stands in a number of States similar to the one from which our professional brethren suffered, and which has been thus amended, it would be wise for the profession to see that similar amendments be passed, so as to prevent any smart

lawyer raising this point, and any technical judge giving a similar ruling that would prevent the physician defendant testifying in his own behalf, in a suit for damages arising from death of a party from alleged malpractice on part of defendant physician.

There is another gratifying thing about the ending of this case in the fact that the profession had influence enough with our law makers to have them make the needed change.

Respectfully, W. H. SHARP, M.D.

The Insidious Advertisement.

PHILADELPHIA, March 20, 1897.

To the Editor:—Probably no one knows better than a medical editor that eternal vigilance is the price of other things beside liberty; and nowhere is vigilance more essential than in guarding against the schemes of the manufacturer of proprietary preparations. The JOURNAL, with its settled and well understood policy of refusing reading notices, offers an attractive field in which to spread advertisements disguised as regular scientific communications.

Many of the weekly medical journals of the Eastern cities and Europe, lend their aid to such schemes, some of them, perhaps, by inadvertence, others apparently with full intention. But this will not justify the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION in lowering its standard of requirements in the least. It is perhaps impossible to judge when the eulogy of a special preparation is entirely sincere on the part of a writer, whose judgment and originality may be unequal to his ambition to write; and when it is pure fake, gotten up for a fixed price, or in the hope that the wide circulation the manufacturer will give to reprints will prove a step toward fame (?) or fortune to the writer. But it really is not necessary to go into this question of motives. When an article shows marked enthusiasm for a new drug, the extended use of which will benefit a particular manufacturer, it must be regarded with suspicion, and if in other respects it seems of little importance the safe rule is to return it with thanks—thanks for the fact that we have not been caught by it.

It has seemed to me that in two or three recent instances good opportunities for indulging in such thankfulness have been missed, and that articles have appeared in the JOURNAL that are liable to bring a crop of such concealed reading notices regarding other patented or proprietary preparations. Of course it is very hard to refuse some member of the ASSOCIATION, who thinks he has discovered a good thing and wants it published in the JOURNAL, not recognizing that the source of his discovery was the plausible talk of the glib agent who left him the sample. This being the case, the members of the ASSOCIATION ought to make it as easy for you as possible to refuse such communications, by calling attention to them and expressing the general feeling through the columns of the JOURNAL. Even the vigilance of the editor will relax, or prove insufficient unless it is actively supported by the sentiment of the ASSOCIATION. Therefore I write to express to you my opinion of the articles in question, which need not be further advertised here, but which are named on the accompanying slip, and to ask others who notice what seem to be delinquencies of the sort, to pursue a similar course, and not to allow the unity and influence of the ASSOCIATION to be undermined by secret criticism and dissatisfaction.

Cordially yours, EDWARD JACKSON, M.D.

The Physio-Medical School?

NORTH EAST, PA., March 15, 1897.

To the Editor:—Can you give through the columns of your valuable JOURNAL a short history of what is known hereabouts as the physio-medical school of the practice of medicine. I would like to know something as to its origin, wherein it differs

from the Regular, how many colleges it has, and as to what States recognize it as a *separate school*, and especially as to whether any State law names a physio-medical practitioner as one of the legal examiners for that school upon any State Medical Examining Board?

This may seem to be a long string of wants, but I am anxious to have it answered, as I see you are in the business of exposing humbugs.

The following is my reason for asking you for the above information. We have near here a physio-medical practitioner who has never been before our State Board, and is not registered. He has been cited before the Board, but refuses to go on the ground that there is no one on the Board of his particular school to examine him. The State Board notified him to cease his illegal practicing, but so far he has taken no notice of their warning. Our society has now taken the matter in hand and has him under bonds for court. He proposes to fight on the ground that his school is not recognized by the State, and hence he is not answerable to its law. He claims to have been before the Illinois Board and to be registered in Cook County. Hence my question: Has the Illinois Board a physio-medical man as one of its members, and is that school thus recognized by the State law? By giving a short history in the JOURNAL you will greatly oblige a subscriber.

B. H. PUTNAM, M.D.

A Revival of the Kansas Case.

MILWAUKEE, WIS., March 22, 1897.

To the Editor:—In your issue of the 20th inst., you speak of the "Kansas Hypnotism Case" and say that it was "one of the first in which the plea of hypnotic influence had been employed by the prosecution in the criminal courts." In the JOURNAL for June 8, 1895 (p. 903) you published a letter written by me in which the points discussed in the supreme court of Kansas were quoted and the law journal in which the case first appeared was named. It was then shown that the supreme court had nowhere, in its summing up of the testimony, mentioned the subject of hypnotism. Soon after the publication of this letter, some magazine, which I can not now recall, published an interview with the trial judge of the case; and he rather emphatically denounced the story that the plea of hypnotism was entertained by his court, and said that it was the work of a sentimental reporter. The only basis for the story was the fact that McDonald's lawyer in speaking of the influence that Gray held over him (McDonald) said: "This influence was so great that one might almost say it was hypnotic."

J. M. MADDEN, M.D.

Muscular Dystrophy.

PHILADELPHIA, March 15, 1897.

To the Editor:—I am desirous of learning of the occurrence of muscular dystrophies, including pseudo-hypertrophic paralysis, idiopathic muscular atrophy, Erb's juvenile (scapulo-humeral) atrophy and facio-scapulo-humeral (infantile) atrophy of Landouzy-Dejerine, in colored persons and especially in those of pure, unmixed African parentage. I shall be grateful to receive information from any one who has encountered or has knowledge of cases of this nature.

Respectfully,

AUGUSTUS A. ESHNER, M.D.

224 South Sixteenth St.

The Journal Train.

PURCELL, IND., March 20, 1897.

To the Editor:—Will you kindly state in next JOURNAL the exact date the JOURNAL Train will leave Chicago, over what road, the rate for round trip from there, time limit at Philadelphia, and must passage be engaged in advance for that train.

Very respectfully, MILTON McMURTRY, M.D.

ANSWER: The JOURNAL Special Train will leave by the Penn-

sylvania R. R., from Chicago, Sunday May 30. The rate is that of one and one-third on the certificate plan. This has been granted for all roads east of the Mississippi river, and application is pending for the reduction west. Passage should be engaged in advance. Efforts are being made to extend the time limit, but so far without success.

"The History of Medicine, Etc.," by William Hamilton.

MILLEDGEVILLE, IND., March 11, 1897.

To the Editor:—Could you tell me where a copy of "The History of Medicine, Surgery and Anatomy from the Creation to the Commencement of the Nineteenth Century," by Wm. Hamilton, could be found? and oblige
J. S. SHIELDS.

ANSWER.—This work was published in London, 1831, by H. Colburn and R. Bentley. You will doubtless have to procure it through your dealer at second hand.

PUBLIC HEALTH.

The Plague at Bombay.—The total number of cases up to March 11 is 9,032 and 7,546 deaths have resulted. In the whole presidency, to this date, there have been 14,856 cases of the plague reported, and 12,204 deaths have been recorded.

Sanitation at New York Harbor Against the Plague.—The act providing a special fund of \$5,000 for Health Officer Doty's use at the quarantine station in New York harbor, and to provide the means of preventing the introduction of the plague into that port, has received the governor's approval and is now a law.

Family Epidemic of Non-Genital Syphilis.—A young girl was infected genitally and soon had a "bad mouth," which was communicated to her four brothers and sisters, who were all affected in and around the mouth. A child taken in to nurse was also infected and transmitted the infection to its mother *per mamillam*, thus infecting a second family, and an older child visiting the first family also infected its parents on its return home. Gebert, who reports the circumstances, adds that there may have been still further infection that escaped his observation.—*Cbl. f. Chir.*, February 6, from *Berl. kl. Woch.*, No. 41.

Physical Examination of the Proposed Bride and Groom.—An ardent sanitarian is a member of the Texas Legislature this year, and he has prepared a bill that he thinks will greatly benefit his fellow-citizens. The bill, if passed, will revolutionize the marriage license system of the State. The intending groom must previously undergo a thorough physical examination at the hands of a competent medical practitioner in good standing, and be possessed of said physician's sworn certificate of physical soundness. The prospective bride must also have undergone a similar ordeal and a like certificate in her behalf must be submitted. Not only this, but both parties "to the contract" must file sworn statements attesting the fact that neither of them are subject in a hereditary way to any disease that might in like manner transmit tendencies thereto in their probable offspring. The county clerk must then satisfy himself that these "credentials" are perfect before granting the license to marry. Should he give it without having these evidences of "fitness" presented to him, he would be held criminally liable.

Fish Diet and Leprosy.—In the November issue of the *Sei-i-Kwai Medical Journal* is published a translation of an article on the inoculation of leprosy by Dr. Hansen of Bergen, which introduces a new feature into Mr. Hutchinson's theory of the close connection of fish diet with leprosy. The author says: "I do not think that there is any choice given to the bacteria of leprosy as to localization, just as there is none in the tubercle bacillus. They develop wherever chance has deposited them

and wherever they find favoring conditions and no obstacles, for example, on the outside of the arm where there is little muscular movement. On the exposed portions of the body, oxygen retains and feeds them. The inoculation by insects can only be successful in these places; in others, circumstances are too much against them. An internal inoculation is also easily imaginable and even probable. Salt fish is eaten all over the world; raw fish is eaten only in some countries, like Japan. Fish, especially the carp, which is so general an alimentation in Japan, where it is eaten raw and even alive, feed on the larvæ of mosquitoes, and may be suspected of communicating the spores of disease extracted by the insects from the exposed parts of diseased bodies. If not, however, spores, then the toxins of the bacilli. In reflecting, then, upon these points, I should be disposed to conclude that external leprosy inoculation means tubercular leprosy, and internal inoculation anesthetic leprosy." These observations are of much interest, and to leprologists generally they will probably be quite new. So far as we know, they afford a reasonable explanation of the fish-diet theory as a cause of leprosy, of which Mr. Hutchinson has been the staunch but almost only consistent advocate.—*London Medical Press.*

Professor Koch's Work in South Africa.—Professor Koch's investigation of the cattle plague in South Africa forms the subject of a recent article in the *Norddeutsche Allgemeine Zeitung*. One of the first places which he visited after arriving in the colony was the leper asylum on Robben Island in Table Bay, and he is said to have expressed his satisfaction with the general arrangements of the establishment, as well as with the bacteriologic work accomplished in the laboratory. The party included representatives of the colonial government, the German consul-general and several medical men. On December 3 he left for Kimberley, where the principal part of the work of investigating the cattle plague will be undertaken. He was accompanied by his assistant, Dr. Kohlstock, and also by Dr. Turner, a medical officer of the colonial government. It was arranged that a laboratory should be fitted up at a farmhouse about two miles from the town and whilst the requisite alterations were being made, Professor Koch went to Taungs, a town in the Kaffir country about two hundred miles from Kimberley, where more than twenty thousand head of cattle have died from the epidemic, so that there was abundant opportunity of observing the disease, of performing necropsies, and of collecting morbid specimens. On December 8 the party returned to Kimberley, where the laboratory was then in working order, and eight animals were inoculated with infective material brought from Taungs. The inoculations were made in the mouth and nose, every precaution being taken to ensure isolation and to guard against any accidental extension of the disease in the Kimberley district. One of the inoculated animals very soon died with symptoms of cattle plague, and the pathogenic material obtained from it was used for the inoculation of a fresh series. Professor Koch is much pleased with the arrangements which have been made by the colonial authorities for facilitating his researches, and finds that everything has been done to render his visit agreeable. The foregoing particulars have only appeared in an ordinary newspaper; a far more detailed and satisfactory account of the cattle plague inquiry will no doubt be communicated to the medical press on the return of Professor Koch and his assistants. The German government has requested him to visit Bombay for the purpose of investigating the bubonic plague.—*London Lancet*, February 13.

Chickenpox is not a Trivial Disease.—There are text-books on the diseases of children that teach an unfailingly favorable prognosis for varicella and an absence of all complications and sequels. In the last twenty years, however, a certain number of grave cases, even those terminating fatally, has been recorded,

sufficient to call in question the correctness of the above teaching. That chickenpox is the mildest of all infections is undoubtedly true, but experience teaches that it is not absolutely harmless and trivial. The fact that the disease is so generally mild is apt to foster an over-confidence in the result, and to lead to a less careful supervision of treatment than is demanded by every infection, no matter how trivial its manifestations. In 1884, Henoeh published four cases of varicella complicated with nephritis, one of which terminated fatally, and since then similar cases have been reported by many observers, including Hoffmann, Augier, Newski, Rasch, Rachel, Vichmann, Schwab, Hagenbach, Demme, Unger and Högyes. Högyes and Hagenbach each report a fatal case. Pesa, in an outbreak of twenty-six cases of varicella, noted nephritis as a sequel in two of them. Cassel records six cases in an epidemic of twelve occurring in Berlin, in which nephritis developed during the stage of vesication. Three of these cases died, one directly from the nephritis and the other two of pneumonia. These reports emphasize the importance of repeated urinary examinations in all infections, even in varicella. Jonathan Hutchinson (*Medico-Chirurgical Transactions*, vol. xv, 1892) was the first to call attention to a complication of varicella characterized by the development of gangrene of the skin at the site of the vesicles. He termed the condition varicella gangrenosa, and since the appearance of his paper numerous European observers have reported similar cases. At least four of them have been reported in America, one each by Woodward, Büchler, Spivak and Griffith. Dr. Griffith's case was complicated also with diphtheria and rubella, and is reported in the *University Medical Magazine* for August, 1896. Paralysis is a rare sequel of varicella. Gay (*British Medical Journal*, March 31, 1894) reports a case of peripheral neuritis following varicella, and a case of paraplegia of spinal origin is reported by Marfan. Boucheron (*La Presse Médicale*, Feb. 17, 1894) first drew attention to varicellous affections of the larynx, bronchi and lungs. "Certain cases," he says, "show that not only stomatitis, but laryngitis, bronchitis and broncho-pneumonia and, perhaps, even pleurisy may be of a varicellous nature." He narrates the history of a little girl who was seized with varicella and died about the twentieth day in consequence of laryngeal spasm. At the necropsy nothing was found to explain the spasm except vesico pustules on the laryngeal mucous membrane similar to the cutaneous eruption. Marfan and Hallé (*Revue Mensuelle des Maladies de l'Enfance*, Tome xiv, No. 1) report two cases somewhat similar. The first recovered after tracheotomy had been performed, the second died on the eighth day of broncho-pneumonia. The autopsy in the latter case revealed on the right lower vocal cord an ulcer the size of a lentil. The authors remark that the laryngeal lesion of varicella usually appears early, either at the onset or very shortly afterward. This fact is an aid in differentiating from laryngitis due to secondary infection, although only a bacteriologic examination can justify the exclusion of a coexisting diphtheria. Otitis media, noma and orchitis have been reported as following chickenpox. In addition to local complications, varicella occurring as a primary affection may, by lowering the resisting powers of the subject, invite the development of other infections; thus measles, rubella, diphtheria, scarlet fever and whooping cough have each been found in connection with this disease.—*University Medical Magazine*.

Extra Pay for Health Officer During Epidemic.—When an epidemic of smallpox broke out in the village of St. Johns, Mich., in October, 1894, the board of health, being the trustees of the village, increased the pay of the health officer, one of its members, \$10 a day over and above his annual salary of \$100. The village audited, and presented to the board of supervisors of the county, a bill of expenses incident to the smallpox, which included among its items \$690 for sixty-nine days' services

rendered by its health officer at the increased compensation, which the board refused to pay. This was followed by the village filing a petition for a mandamus to compel payment. Counsel for the board of supervisors contended that the board of health could not fix the compensation of one of its members, and thus bind the county for the payment of the amount so fixed. And the supreme court of Michigan says, *Village of St. Johns v. Board of Supervisors of Clinton County*, Feb. 8, 1897, that it should doubt the power of the board of health to fix conclusively the amount of the claim of its health officer, did it appear that he took part, as a member of the board, in fixing his own compensation, and the board of supervisors were contesting the claim upon the ground that the amount fixed was excessive. But here it was agreed that the charges were reasonable for the services performed, and that the persons who were sick with the smallpox, and all others liable for their support, were unable to pay the same, or any part thereof. And while the health officer was a member of the board of health, there was nothing in the record to show that he took any part in the proceedings to fix his compensation. Under such circumstances, the court does not agree in the contention stated, but holds that the village was entitled to recover the amount in question from the county, and affirms an order granting the writ of mandamus. Moreover, while the boards of health of townships, cities and villages are required to fix and pay the ordinary services of the health officer, yet it is apparent, the court holds, that it was the intention of the legislature of Michigan, by the various provisions of the statute, to cast the burden upon the county for extraordinary services rendered to prevent the spread of contagious diseases, and for the care of indigent persons afflicted with such disease.

Tuberculosis and Health Department Regulations at New York.—

According to the *Medical Review* for February, the proposal of the health authorities of New York City to require reports of all cases of pulmonary tuberculosis, has excited much interest and comment among physicians as well as patients. We can not withhold our sanction of any means that is practicable for limiting the spread of this disease, and yet can sympathize with the general feeling among medical practitioners that their position as medical adviser should be carefully guarded by the authorities, who, notwithstanding their supreme authority in sanitary matters, are still public servants, and as such subject to the behests of the popular will to some extent.

"We firmly believe that all communications relating to house disinfection, isolation of private patients, vaccination of other members of a family where smallpox has appeared, taking of cultures in suspected diphtheria and reporting on the same to the family, should be done only through the family physician, and never under any circumstances by an employe of the Board of Health. In other words, the Department should be the *consultant* in all cases, and never assume to be the *attendant*. In that manner, and in no other, can the confidence of the rank and file of the profession be preserved, without whose coöperation the most necessary rules and regulations of the health officials can never be properly enforced. In any contest between the Board and the people the latter are sure to win, and such conflict must be avoided by a careful consideration of all phases of the question under discussion."

The above is of interest, as it is an editorial of a journal, one of whose editors is also prominent in the councils of the State Board of Health, and indicates the limit and extent of the support that the City Board of New York may expect in its fervently criticised campaign against tuberculosis. The New York County Medical Society will at its March meeting discuss a report on the same subject, and having a very similar tenor; it is believed that that Society will adopt the sentiments of the following report of its Committee on Hygiene:

"Realizing the need of proper measures to prevent the spread of pulmonary tuberculosis, and regarding it as an essential preliminary that all physicians be impressed with the importance of making an early diagnosis of the same by microscopic examination of the sputum, we earnestly recommend

that physicians avail themselves of the offer of the bacteriologic department of the Board of Health to make such examinations. We approve of the compulsory reporting of cases of pulmonary tuberculosis, if the inspectors are forbidden to visit or to have any communication with the patients without the consent of the attending physician, believing that the attending physician is capable of giving all the necessary instructions."

The *British Medical Journal* urges that "for the present a campaign of education only is in keeping with the temper of the profession; a marked disinclination exists on the part of many medical men toward any interference on the part of the sanitary authorities with their treatment of tuberculous patients. It must be borne in mind that medical practitioners have it in their power to render inoperative any procedure which meets with their general disapproval."

A "White City" for our Consumptives.—Dr. A. Walton, in the *Boston Medical and Surgical Journal*, March 4, holds that it is the duty of every one of the United States to have its own retreat for consumptives at some point to be agreed upon in the far West. "That it would be a simple matter to entirely stamp out pulmonary tuberculosis by the removal of all such cases to a dry atmosphere in a high altitude, no one who has ever visited Colorado, New Mexico or California can have failed to observe. The wonderful curative influence that high altitude has upon persons suffering from pulmonary tuberculosis is known to every well-read physician throughout the land. I have time and time again conversed with men of wealth, prominent in the affairs of Colorado and New Mexico, who only a few years ago were taken into that country in a condition of extreme emaciation, almost ready to die, suffering from the last stages of pulmonary tuberculosis. Today these men have not only gained health, but are robust, of large stature, giants in strength and strong in intellect. I would suggest that there be established somewhere in the State of New Mexico or Colorado a national home for consumptives. I can picture to myself a beautiful city—something similar to the former 'White City' of Chicago—where each State will have its State home. The population of this city, based on the present annual death rate of persons suffering from pulmonary tuberculosis, would be between 300,000 and 500,000 people. From conversation with prominent men in Massachusetts, where consumption is rampant, I am led to believe that the State of Massachusetts would infinitely prefer to have a consumptive State home some place where there was a possibility that at some time there would be an end to the enormous expense incident to carrying on a consumptive home within its own borders, where they now have such an institution, which is merely the last resting place of the persons who are received there. People do not go there to be cured; they are supported by the State until such time as death ends their sufferings. If it can be shown that after a certain period of time the expense of maintaining a State home in a section of country where, and under such conditions, a large percentage of those sent to the home will be cured, would not that be a better plan to adopt than the plan of establishing large hospitals within the limits of the State, which would become, under conditions existing here, the merest makeshift and in no way curative? I firmly believe that our national representatives would be perfectly willing to take this matter in charge—to allot or assign a certain number of acres of public land immediately adjacent to the foothills, say at an elevation of about 4,000 feet, at a point to be selected by a commission to be appointed by Congress. We have plenty of public land available for the purpose not far from the great trunk lines and within sufficient proximity to the foot hills of the Rocky Mountains to make the matter of irrigation perfectly practicable and with the expenditure of but little money, as convict labor could be employed in bringing the water down from the mountains, which has been done with one of the irrigating systems now being operated in Colorado. If the full import of this matter were properly placed before our national legislators there can be no question but that a commission would be appointed for the purpose of looking into the question and investigating the proper site for the establishment of such a national home. I believe there will be no difficulty in having this matter taken up and properly carried through, for it must appear perfectly apparent to every right-thinking man that we owe it to ourselves and to our families that we should protect ourselves from the possibility of infection from one of the most fatal of all diseases."

The "Cow Penitentiaries" of Large Towns and Cities; the Stable a Kind of Winter Garment.—Dr. August Richter is, we believe, the originator of the expressions "cow penitentiaries" and "cow dungeons" as applied to those miserable milk-producing establishments that infest the environs of nearly all large towns. Dr. Richter dwells at Williamsport, Pa., where the cow is reckoned a noble animal, having the right to cleanly treatment just as horses and babies. It is, he believes, largely because the cow is evilly treated that she takes on consumption. Dr. Richter, in *Public Health*, says: "Come with me, my friends, to the stable, which is, properly speaking, a *garment* for our domestic animals and should not only be protective but sanitary also. But how do we find them? The majority are deficient in light, ventilation and general cleanliness, with low ceilings, ornamented with abundant cobwebs, dust and rubbish. The whole interior is dark like a dungeon. Broken windows, nailed-up ventilators and all the pure air that possibly could enter enters when opening the stable door. The air within such a stable is foul and stifling. In one of these 'cow penitentiaries' were crowded together over ninety animals, most of them full-blooded Holstein, all hanging in stocks or in movable stanchions for month after month, without an hour's release, without a handful of bedding, fed on decomposing glucose, refuse full of maggots. Every year some of these noble creatures perished from consumption, yet the ignorance and cruelty of the proprietor made no change in the treatment of his suffering herd. It is the ignorance of men and insanitary keeping of the stock that brings about consumption in cows. It is fallacious reasoning of farmers to think they can farm and run a dairy also; unless they have proper help they certainly will fail, for no man can serve two masters at one and the same time. The modern doctor is not asked so much what will cure a disease, but what will prevent it—which is the great study of the sanitarian. It has been demonstrated that all contagious diseases are preventable diseases, and therefore chargeable with criminal offence, whether they kill the human or the bovine family. Ask any one of the dairy men the question: 'How many cubic feet of pure air are required per hour for each cow for healthy respiration?' Can they answer the question? Certainly not; yet a child requires 3,500 cubic feet per hour for the healthy performance of that function. Think and reflect ye dairymen what damage you inflict upon the poor animals in filth-reeking, damp, low-bank barn, without a thought further than how many can be placed in the barn. How much milk can we strip from them? Verily, it is a wonder that all the animals have not become tuberculous, for almost two-thirds of the year they are forced to breathe the foul air either in the stable or the barnyard. When will man learn to consider life in its true light? When will his mercy provide for every creature under his care a sanitary home? The stable for dairy cows should be cleared twice a day, morning and evening, unless the animals are kept under the shed in the barnyard during the day, when the stable remains clean. After a thorough morning cleaning of the stable every door should be opened and kept so for general floor ventilation; let the stable master apply over every wet spot in the stands and rear of them either air-slacked lime or gypsum to exclude the air from acting on the moist surfaces, for dryness prevents chemic action and the stable air will remain pure through one of the above applications. The stable work being done and every stand supplied with bedding, then let the currycomb and brush be thoroughly applied to every cow until their bodies are thoroughly clean. Cleanliness is as essential to the health of cows as it is to horses or human beings." Would that our female reformers and our anti-cruelty people might find an outlet for their energies in the protection of that noble and innocent female, the cow, which often treated more harshly than any human criminal, might be taken as the emblem of patience. The cow is unwittingly, therefore unwillingly, the dispenser of tuberculous milk to the human infant, innocent also; and this is a second call to duty to our would-be reformers to adjourn the question affecting the guinea-pig of the laboratory and men who expectorate, for that of those precious animals—the cow and the baby. But no, it may not be expected; they have laid out their course and will prefer to fritter away their time and strength on antivivisection bills and the like. Let us imagine for a moment that all the women of the land having taste and ability for public affairs should spend a part of their spare time in the inspection of cow stables, what good might not be done; how much of advantage to their own health and that of the human beings near to them, whose claims to their humane attention are not always scaled up to their deserts. The abolition of the "cow penitentiary" will possibly have to be effected without their aid and comfort.

ASSOCIATION NEWS.

Section on State Medicine.—Members of the Association desiring to read papers before this Section will please send in their names and titles of papers to Dr. Elmer Lee, Chairman, 103 State Street, Chicago, or to Dr. Louis Faugères Bishop, Secretary, 30 W. 36th Street, New York. The Section officers will be pleased to receive a few more papers before the completion of a very scientific and instructive program.

Section on Ophthalmology.—The following papers will be presented to this Section at the next meeting of the AMERICAN MEDICAL ASSOCIATION.

1. Address of Chairman, G. E. de Schweinitz, Philadelphia, Pa.
2. The Roentgen Rays in Ophthalmic Surgery, Howard F. Hansell, Philadelphia, Pa.
3. The Localization of Foreign Bodies within the Eye by Means of Roentgen's X-Rays. An Experimental Research. William Sweet, Philadelphia, Pa.
4. The Electro-magnet of Haab in the Removal of Pieces of Steel from the Interior of the Eye. J. E. Weeks, New York, N. Y.
5. Shot-grain Wounds of the Eye. Lewis H. Taylor, Wilkes-Barre, Pa.
6. Gun-shot Wounds of the Eye. Charles Stedman Bull, New York, N. Y.
7. Effect of Explosives on Eyes. John Chase, Denver, Colo.
8. In What Cases and When to Enucleate in Injuries of the Eye. John M. Foeter, Denver, Colo.
9. When Evisceration is Preferable to Enucleation. J. C. Dunlavy, Sioux City, Iowa.
10. Implantation of a Glass Ball for the Support of an Artificial Eye and Mule's Operation for the Substitution of Enucleation of an Eyeball. L. Webster Fox, Philadelphia, Pa.
11. Experiments on Rabbits' Eyes to Obtain an Elastic, Unbreakable Vitreous Body after Evisceration of the Eyeball. Albert Pick, Hyannis, Mass.

Five ten-minute papers, the subjects suggested by the Executive Committee, and bearing the following titles:

12. Bacteriology of the Conjunctiva and the Best Methods of Preparing this Membrane Preparatory to Operations Requiring Corneal Section. Robert Randolph, Baltimore, Md.
13. Best Methods of Sterilizing Ophthalmic Instruments and Solutions of Myotics and Mydriatics. E. A. de Schweinitz, Bio-Chemic Laboratory, Department of Agriculture, U.S.
14. The After-treatment of Cataract Cases, with special Reference to the Use of Germicides. J. A. White, Richmond, Va.
15. Best Methods of Preparing Dressings for Cataract Cases and their Character and Composition. Casey A. Wood, Chicago, Ill.
16. Concerning Astigmatism following Corneal Section. Edward Jackson, Philadelphia, Pa.
17. Statistics of Cataract Operations, with Comments. Herman Knapp, New York, N. Y.
18. Cataract Complicated with Chronic Conjunctivitis. W. T. Montgomery, Chicago, Ill.
19. Treatment of Glaucoma with Special Reference to Iridectomy and Constitutional Measures. Dudley S. Reynolds, Louisville, Ky.
20. Massage of the Eyeball as a Therapeutic Measure in Glaucoma. George M. Gould, Philadelphia, Pa.
21. Secondary Glaucoma. S. D. Risley, Philadelphia, Pa.
22. Affections of the Eye Resulting from Profuse Hemorrhage. Harry Friedenwald, Baltimore, Md.
23. Angio-Myxoma of the Orbit, with Report of a Case. S. C. Ayres, Cincinnati, Ohio.
24. Some Cases of Orbital Disease. B. Alex. Randall, Philadelphia, Pa.
25. Abscess of the Orbit. J. F. Fulton, St. Paul, Minn.
26. Cavernous Tumor of the Lid with Extensive Conjunctival Involvement. G. Oram Ring, Philadelphia, Pa.
27. Melano-sarcoma of the Conjunctiva, with the Report of a Case. A. R. Baker, Cleveland, Ohio.
28. Primary Sarcoma of the Iris. A Statistical Study, with the Report of a New Case. C. A. Veasey, Philadelphia, Pa.
29. Certain Anomalous Conditions of the Iris. W. Campbell Posey, Philadelphia, Pa.
30. Questions about Corneal Suppuration. H. B. Young, Burlington, Iowa.

31. The Use of Cauteries in Ulcers of the Cornea. B. L. Millikin, Cleveland, Ohio.

Five five-minute papers, the subjects suggested by the Executive Committee, and bearing the following titles:

32. The Surgical Treatment of Trachoma, with Special Reference to Expression and Grattage. John E. Weeks, New York, N. Y.
33. A Comparison of the Value of the Local Medicinal Measures in Treatment of Trachoma. H. V. Würdemann, Milwaukee, Wis.
34. The Present Status of Jequirity in the Treatment of Trachoma. W. Cheatham, Louisville, Ky.
35. The Treatment of the Complications of Trachoma, with Special Reference to Malposition of the Lid Borders. F. C. Hotz, Chicago, Ill.
36. The Hygiene of Trachoma and the Relation of Altitude and Climate to Its Development. Swan M. Burnett, Washington, D. C.
37. Ten Years with the Surgical Treatment of Trachoma. Harold Gifford, Omaha, Neb.
38. Observations on Trachoma. J. Elliott Colburn, Chicago, Ill.
39. Relative Frequency of Trachoma in Southern California. H. Bert Ellis, Los Angeles, Cal.
40. Hyperplastic Sub-conjunctivitis. H. McI. Morton, Minneapolis, Minn.
41. Credé's Method in Public Institutions. Lucien Howe, Buffalo, N. Y.
42. Value of Colored Test Glasses for the Detection of Anomalies of the Ocular Muscles. F. B. Eaton, San José, Cal.
43. A Combined Phorometer and Duction Indicator. A. E. Prince, Springfield, Ill.
44. Practical Points in Muscular Insufficiencies. Clark V. Hawley, Chicago, Ill.
45. Clinical Study of Hyperphoria, with Cases. John T. Carpenter, Jr., Philadelphia, Pa.
46. Amblyopia of Strabismus. C. M. Hobby, Iowa City, Iowa.
47. Amblyopia Exanopsia. A. C. Simonton, San José, Cal.
48. Amblyopia Exanopsia. Leartus Connor, Detroit, Mich.
49. Report of the Examination of the School Children's Eyes in the City of Minneapolis. Frank Allport, Minneapolis, Minn.
50. Asthenopia from Vicious Working Point. C. H. Thomas, Philadelphia, Pa.
51. Apparent distortion of Objects after Correction of Astigmatism. A. A. Hubbell, Buffalo, N. Y.
52. Lenticular Astigmatism. G. E. Dean, Scranton, Pa.
53. Studies in the Comparative Anatomy and Etiology of the Eye. Flavel B. Tiffany, Kansas City, Mo.
54. Horizontality of Vision in Relation to Certain Cranial Characteristics. George T. Stevens, New York, N. Y.
55. Observations with the Binocular Lens for the Examination of the Eye by Oblique Illumination. Edward Jackson, Philadelphia, Pa.
56. Congenital Opacities of the Cornea. Wendell Reber, Philadelphia, Pa.
57. Embolism of the Central Artery of the Retina. C. F. Clark, Columbus, Ohio.
58. Anomalies of the Retinal Pigment Epithelium and their Clinical Significance. Henry Gradle, Chicago, Ill.
59. Method of Employing Kangaroo Tendon in the Operation of Tendon Advancement, with Cases. John O. McReynolds, Dallas, Texas.
60. A Report of Thirty Cases of Cataract Extraction. Louis F. Love, Philadelphia, Pa.
61. An Improved Skiascope. J. Ellis Jennings, St. Louis, Mo.
62. Exhibition of a New Ophthalmoscope. John W. Crosby, Philadelphia, Pa.
63. Exhibition of Other New Instruments.

SOCIETY NEWS.

German Surgical Association.—The next congress of this Association will meet at Berlin, April 21 to 24. The addresses will be on Surgical Treatment of Gastric Ulcers, Use of the Roentgen Ray in Surgery and Operative Treatment of Hypertrophied Prostrate.

American Medical Publishers.—The fourth annual meeting of the American Medical Publishers' Association will be held in Philadelphia, May 31, 1897 (the day preceding the meeting of

the AMERICAN MEDICAL ASSOCIATION). Members desiring to present papers will kindly send the titles of the same as early as possible to CHAS. WOOD FASSETT, Secretary, St. Joseph, Mo.

Medical Society of the State of West Virginia.—This Society will hold its thirtieth annual meeting at Charleston, W. Va., on Wednesday, Thursday and Friday, May 19, 20 and 21, 1897. All members are requested to prepare a paper and to send its title to the Secretary not later than April 24, so that the program can be completed in time. We should have a large meeting at the Capital City this year, as the Committee on Arrangements is doing everything in its power to make it pleasant for all. The usual reduced hotel and railroad rates will be granted. Program and further details will be sent two weeks before the meeting.

Missouri State Medical Association.—Present prospects are that the meeting of the Missouri State Medical Association, May 18, 19 and 20, is going to prove very satisfactory. The committees have all gotten to work early, which is a good indication. The Committee on Scientific Communications is already in receipt of titles in numbers and character sufficient to insure the program scientifically attractive. The Executive Committee are enabled to announce the following program, the details of which only remain to be completed. The Association will meet in St. Louis May 18, 19 and 20. All the first, the second and the third day until noon will be devoted to the scientific program. On the evening of the first day the Association will as a body attend a session of the Illinois Society in East St. Louis. On the evening of the second day the Illinois Society will attend as a body a session of the Missouri Association, after which there will be a banquet and reception. On the third day both bodies will adjourn and join a steamboat excursion on the river.

National Confederation of State Medical Examining and Licensure Boards.—The seventh annual meeting of this Confederation will be held in the small banquet hall of the Hotel Walton, at Philadelphia, Monday, May 31, 1897, at 10 o'clock A.M. The following program has been arranged: 1. Address of welcome by A. H. Hulshizer of Pennsylvania State Board of Medical Examiners. 2. Response by vice-president Reed. 3. Report of the committee on minimum standard of requirements. 4. Discussion and action thereon. 5. Report of the secretary and treasurer. 6. Annual address of the president. 7. Some practical experience with, and results of, the medical law of Pennsylvania. Wm. S. Foster, Pittsburg. 8. The need for exact information as to the equipment, methods and requirements of our medical schools. J. N. McCormack, Bowling Green, Ky. 9. Address by Prof. J. W. Holland, M.D., Dean Jefferson Medical College, Philadelphia. 10. Miscellaneous business. 11. Election of officers. 12. Adjournment.

The object of the confederation is to consider questions pertaining to State control in medicine and to compare methods in vogue in the several States; the collection and dissemination of information relating to medical education, and to consider propositions that have for their purpose advancement of the standards in the United States. A cordial invitation is extended to all members and ex-members of State medical examining boards, and to physicians, sanitarians and educators who are friendly to the objects named, to attend the meeting and participate in its proceedings.

Officers for 1897: President, Wm. W. Potter, New York; vice-presidents, Chas. A. L. Reed, Ohio; J. N. McCormack, Kentucky; secretary and treasurer, A. Walter Suiter, Herkimer, N. Y.; executive council, Jos. M. Mathews, Louisville; Wm. S. Foster, Pittsburg; Hugh M. Taylor, Richmond; Jas. M. Hays, Greensboro, N. C.

By order of the executive council.

WILLIAM WARREN POTTER, Pres.
A. WALTER SUITER, Sec'y.

Twelfth International Medical Congress, Moscow, Russia, Aug. 19-26, 1897. J. Klein, president; W. H. Roth, sec.-general.

American National Committee: J. S. Billings, M.D., New York; Frank P. Foster, M.D., New York; Claudius H. Martin, M.D., Mobile; S. Weir Mitchell, M.D., Philadelphia; Charles A. L. Reed, M.D., Cincinnati; George B. Shattuck, M.D., Boston; F. J. Shepherd, M.D., Montreal; George F. Shrády, M.D., New York; W. S. Thayer, M.D., Baltimore. A. Jacobi, M.D., 110 W. 34th St., New York, Chairman.

In a letter dated Moscow, February 14, the Secretary General, Prof. W. K. Roth, communicates the following facts for the information of the American physicians who intend to participate in the Twelfth International Congress which is to be held at Moscow from August 19 to 26. The transatlantic steamship companies refuse one and all any reduction of the usual charges. In their replies, most of which are couched in courteous language (the original are in the possession of the undersigned), they admit the existence of a trust, or contract or agreement, which prevents them from lowering their prices; a few are so polite as to express their regrets. Reductions of fares on Russian railroads are expected shortly. The French, Spanish, Swedish and Hungarian railroads promise a reduction of 50 per cent.; so do the Italian for a distance of 500 kilometers, less (down to 30 per cent.) for shorter distances. The Mediterranean lines (Messagerie Maritimes, General Italian Navigation Company, Austrian Lloyd) grant from 25 to 50 per cent. The undersigned chairman is not authorized to issue certificates of any kind in favor of congressists. He will try to ascertain, however, in which way their movements may be facilitated, and may receive a reply in the second half of April. Extracts of papers to be read before any of the sections ought to reach the Secretary General before June 1 in order to be printed in the preliminary volume. A special prospectus containing the final details referring to traveling, lodging, festivities, etc., is promised for a near future. It will be communicated at once to the medical journals, and to the press of the country.

A. JACOBI, M.D.

New York, March 10, 1897.

REPORT OF THE PRELIMINARY WORK ACCOMPLISHED BY THE SECTION ON SURGERY.

[Translated for the JOURNAL.]

In response to the invitation addressed to them by the Presidents of the Surgical Section the committee announce that the following persons have consented to deliver the addresses introducing the subjects on the program (see the JOURNAL, January 23):

Dr. E. Braatz, Königsberg, "Therapeutics of infected wounds." The subject, "Methods of treating malignant tumors without operating," especially the results of serum therapeutics, will be discussed without an introductory address. Prof. E. Bergmann, Berlin, "Cerebral surgery in cases of tumor cerebri and Jacksonian epilepsy." Prof. T. Tuffier, Paris, "Surgery of the lungs, especially with regard to the formation of tuberculous cavities and pulmonary gangrene." Prof. Czerny, Heidelberg, "Therapeutics of cancerous strictures of the esophagus, pylorus and rectum. Success of the different methods." Prof. L. Ollier, Lyons, "Gonorrhoeal and syphilitic affections of the articulations." Prof. Dollinger, Buda Pesth, "Principles of the construction of bandages and protheses in tuberculous affections of the bones and articulations." (The subject as announced by the committee is: "Principles of the construction of protheses of the lower extremities in affections of the articulations, paralyzes, congenital luxation of the femur and after amputations.")

The following persons have expressed their desire to address the Congress on these subjects or join in the discussion: Dr. Credé, Dresden, "My silver treatment of wounds;" Dr. Kousnetzov, Charkov, "Methods of treating infected wounds;" Dr. M. Preobragensky, St. Petersburg, "Treatment of infected

wounds, based on experimental data"; the same surgeon "Conditions of infection of wounds and means to prevent them, with the present operative processes current in the clinics of Europe."

The communication on the third subject on the program will be presented at the meeting held in common by the surgical section and the section of nervous diseases. The first address will be made by Prof. Bergmann, as stated above. The second address will be by Prof. Oppenheim, Berlin, on behalf of the nervous disease section. Subject, "Failures in cerebral surgery occasioned by incorrect diagnoses." Co-rapporteurs, Dr. Adenot, Lyons, "Tumor of the cerebral convolutions, Jacksonian epilepsy, trephining, marked improvement"; Dr. J. Lucas-Championnière, Paris, "Treatment of Jacksonian epilepsy by trephining"; Prof. Sachs, New York, "Surgical treatment of epilepsy"; Prof. Tauber, Warsaw, "Cerebral surgery in cases of tumors and Jacksonian epilepsy"; Prof. Socin, Basel, will also join in the discussion of this subject. Dr. M. Fabrikant, Charkov, "Surgery of the lungs, principally from the standpoint of the formation of tuberculous caverns and of gangrene of the lungs." Prof. A. Ceccherelli, Parma, "Strictures of the esophagus, pylorus and rectum"; Prof. J. v. Iterson, Leiden, "Treatment of cancerous strictures of the esophagus, pylorus and rectum. Results of the different methods of treatment." Dr. G. Jastrebov, Charkov, "Syphilitic affections of the articulations." Prof. Lorenz, Vienna, "Non-bloody reposition of congenital luxation of the thigh, with practical demonstration of the process on an older child"; Dr. Robin, Lyons, "Correction of club feet, particularly in the adult"; the same surgeon, "Correction of Anchylosis of the thigh."

Others have signified their desire to present communications on subjects not included in the regular program. These communications will be heard after the discussion of the questions on the program, if time will permit. The names inscribed up to the present are the following: Dr. J. Lucas-Championnière, Paris, "Treatment of fractures with naturally mobile fragments, without complete immobilization and with immediate massage"; Prof. Zabłudowsky, Berlin, "Remarks on massage-therapeutics in surgery, based on observations in the Berlin University Clinic"; Prof. A. Tauber, Warsaw, "Surgical treatment of cerebral hernias and spina bifida, with results"; Dr. Ferd. Schultze, Duisburg, "Treatment of lupus of the face with radical extirpation and transplantation of a flap (Thiersch)"; Prof. Dollinger, Budapest, "Further experience in subcutaneous extirpation of tuberculous lymphatic glands in the neck and submaxillary region"; Prof. Senn, Chicago, "On the uses of the omentum in surgery"; Prof. Roux, Lausanne, "On perityphlitis"; Prof. Djemil-Bey, Constantinople, "On the radical cure of hernia"; Prof. J. Lucas-Championnière, Paris, "Conditions for permanence of the results in the radical cure of hernia"; Prof. E. Bassini, Padua, "The results of my method of treating hernia and my experience"; Prof. O. Bloch, Copenhagen, "Resection of the renal substance for diagnostic purposes"; Dr. H. Milton, Cairo, "Demonstration of a large collection of vesicle stones and a communication concerning them"; Prof. Bottini, Pavia, "Treatment of ischuria, consecutive to hypertrophied prostate. Demonstration of a new accumulator and instruments for galvano-caustics"; Prof. Djemil-Bey, Constantinople, "Supra-condyle osteotomy." Others who have promised to participate in the work on the Surgical Section are as follows: Prof. Albert, Vienna; Prof. J. Ashhurst, Philadelphia; Prof. Duplay, Paris; Prof. Gussenbauer, Vienna; Prof. Lannelongue, Paris; Prof. LeDentu, Paris; Prof. Lennander, Upsala; Prof. Macewen, Glasgow; Prof. H. Morris, London; Prof. Ogston, Aberdeen; Prof. Péan, Paris; Prof. Rose, Berlin; Prof. Rydygier, Cracow; Prof. M. Schede, Bonn; Prof. Scriba, Tokio; Prof. Tillaux, Paris; Prof. Trendelenburg,

Leipsig; Prof. Watson, Boston; Prof. Watson Cheyne, London. According to the regulations adopted by the Committee of Arrangements, the communications introducing the subjects for discussion on the program, will be published in full and distributed to the members of the Congress, if received prior to May 1. After that date, to June 1, only abstracts of them can be published.

Acting upon the suggestion of Dr. E. Braatz, Königsberg, the Section of Surgery has decided to collect international statistics in regard to narcosis during 1896, and announce the results at the Congress. For this purpose every physician is requested to reply to the following questions: 1, number of narcosis made during 1896; 2, anesthetic agent with which the narcosis was produced; 3, number of deaths in consequence of the narcosis. Notices of this request have been inserted in the medical journals. Physicians will please forward their communications in response to these questions to the Secretary of the Section, Dr. F. Reid, not later than June 1, 1897.

Presidents of the Section of Surgery: Prof. A. Bobrov, Moscow, Powarskaja, "Maison Postelniko"; Prof. L. Levchine, Moscow, Wolhonka, "Maison Mihalkov"; Prof. Th. Sinitzine, Moscow, Wolhonka, "Maison Wojeikow."

Secretaries of the Section: Dr. F. Rein, Moscow, Malaja Dmitrovka, "Maison Schechkov"; Dr. S. Derjuginsky, Moscow, Kalachskaja, Count Galitzin Hospital.

NECROLOGY.

FREDERICK W. BARTLETT, M.D., New York Medical College, 1854, an original Fellow of the New York State Medical Association, died at his home in Buffalo, N. Y.

CLARK WRIGHT, M.D., College of Physicians and Surgeons, New York, 1885, only son of the late Dr. Clark Wright, died in New York City, March 16. He was an active worker in the Vanderbilt Clinic and a Fellow of the New York County Medical Association.

SUMNER APPLETON MASON, M.D., University of Pennsylvania, 1868, died suddenly of an apoplectic attack at his residence in New York City, March 12, aged 58 years.

WILLIAM C. ROLLER, M.D., Jefferson Medical College, 1861, died suddenly at Hollidaysburg, Pa., March 11, aged 59 years. He was an ex-president of the Blair County Medical Society and at the time of his death was president of the local school board.

CHARLES PHYTHIAN, M.D., of Newport, Ky., died March 14, from tetanus, which developed from an attack of tonsillitis together with an alveolar abscess. Dr. Phythian was born in Newport in 1861 and graduated from the Medical College of Ohio in 1883, at which time he located in Newport and had enjoyed a large and lucrative practice ever since. The deceased leaves a widow, one child, and one brother, Dr. John Phythian, who is located in Newport.

MISCELLANY.

A Correction.—In a recent review of a book of Dr. R. Osgood Mason of New York on "Telepathy and the Subliminal Self," the name of the publisher through a typographical error was printed as Henry Holden Co., instead of Henry Holt & Co.

A New Medical Journal.—We have received a prospectus of a new medical journal from Biloxi, Miss., under the title of the *Medical Record of Mississippi*. The first number will be issued April 1. Dr. H. H. Haralson, the well-known quarantine officer, will be the editor.

Discretion Allowed as to Experiments.—Some discretion, the supreme court of Nebraska holds, in *City of Ord v. Nash*, Jan. 19, 1897, is conferred upon the trial court in receiving evidence

of experiments for the purpose of contradicting or corroborating other witnesses; and, in order to authorize the reversal of a judgment on account of the admission or rejection of such evidence, there must have been a clear abuse of discretion.

Should Appear that Expert Heard Testimony.—Where the opinion of an expert is asked upon facts not detailed in the question itself, but the witness is referred to the testimony of another for such facts, the supreme court of California holds, *Howland v. Oakland Consolidated St. Ry. Co.*, Dec. 31, 1896, that it should appear that the witness had heard the testimony.

Admissible Expert Testimony.—Evidence of opinion in respect to the probable duration of physical suffering or disability, given by medical experts, the supreme court of New Jersey holds, Nov. 9, 1896, in *Consolidated Traction Co. v. Lambertson*, is admissible, although based in part upon statements made by the suffering or disabled person relating to his past or present symptoms. And when there is physical injury, the court holds that damages resulting from the incidental fright may be recovered.

A Prolific Family.—An authentic case is described in *Memorabilien* for February, of a woman of 40 who had borne children eleven times; three times twins, six times triplets and twice quadruplets, and was again pregnant at the time of writing. It is not a recent case, but dates from 1808, although never recorded before in medical literature. The mother herself was one of a set of quadruplets and her husband had been a twin. Only three of her thirty-two children were still-born.

Right of Blind Person to Travel Alone.—A question on which there seems to be a scarcity of decisions is whether a person otherwise qualified may be rejected as a passenger for the sole reason that he is blind. It was litigated in the case of *Zackery v. Mobile and O. R. Co.*, where the supreme court of Mississippi decided, Feb. 1, 1897, in the blind man's favor, the one in question being admittedly not infirm, but robust, able to take care of himself, and to comply with the rules applying to passengers generally.

The Family Physician.—Bourneville renews an old suggestion that the family physician should have a "family note book" in which he records the medical history of the families in his charge. When it is impossible for him to respond at once to an urgent summons he should have a trusted assistant or have made arrangements with a second physician, who should have access to the books, under the seal of professional secrecy, and attend to the call until his superior is at liberty. In this way the family would not be kept waiting; much more intelligent attendance would be secured than from an outsider, hastily summoned, while the case would remain afterward in his hands.

The Statue of Pasteur.—The *British Medical Journal* announces that subscriptions in France and other countries for a statue of Pasteur now amount to more than \$50,000. Paul Dubois has been selected as the sculptor, and the site for the statue will probably be the space between the Rue de Médecins and the Luxembourg Gardens. More than \$100,000 has already been spent in the erection of statues of Pasteur in various parts of France. As an instance of the high regard in which he is held outside of that country, it may be mentioned that the municipality of the City of Mexico has given the name of Pasteur to the gardens situated in front of the National School of Medicine in that city. The Rush Monument Committee would be much pleased to record a similar showing in this country for the Rush monument. Those wishing to contribute will please send their contribution to the committee treasurer, Dr. Geo. H. Rohé, Sykesville, Md.

An Antiseptic Diet in Apples.—A practitioner, in *Life and Health*, writes that the *fons et origo* of unsightly complexions is bad digestion, and we generally trace that to a bad liver.

One of the best remedies for a sluggish liver is cheap and pleasant. Dieting is the secret of the cure. The best liver regulator for persons of sedentary habits, and those are the ones whose complexions are muddy, is to be found in apples, eaten baked if they are not well digested when eaten raw. "I attended the pupils at a well-known boarding school, and among them was a country girl whose complexion was the envy of all her associates. I found that she was a very light eater at her meals, but she had a peculiar custom of taking a plate of apples to her room at night and eating them slowly as she studied her lessons. This was her regular practice. Some of the other girls in the institution took it up and I know, as a result of my personal investigation, that the apple-eating girls had the best complexions of any in the school."

Muetter Lectureship of the College of Physicians of Philadelphia.—The next course of ten lectures instituted by the late Prof. Thomas Dent Muetter, M.D., LL.D., on some "Point or Points in Surgical Pathology" will be delivered in the winter of 1899-1900 before the College of Physicians of Philadelphia. The compensation is \$600. The appointment is open to the profession at large. Applications stating in full subjects of proposed lectures must be made before October 1, 1897 to Committee on Muetter Museum. John H. Brinton, M.D., Chairman, N.E. Cor. 13th and Locust Street, Philadelphia, Pa.

Privileges allowed Sick Jurors.—Where one of the jurors was taken ill while the trial of a murder case was in progress, so as to necessitate the services of a physician, and on several occasions he was removed for a short space of time from the presence of the other jurors, the supreme court of Missouri holds, *State v. Schmidt*, Feb. 2, 1897, that this furnished no ground for a reversal of judgment, inasmuch as the juror was always in the charge of a deputy sheriff, who testified that on no occasion did he or any one else converse with the juror about the case.

The Roentgen Ray.—Dr. E. Bock suggests in *Memorabilien* for February that if letters are painted on a sheet of cardboard, afterward varnished and dusted with powdered metal, or the letters are made as gold leaf is applied, the Roentgen ray will throw their shadow through the opaque cornea of the blind, and if the optic nerve is still sound, the blind person will see the shadowgraph thrown on the retina. He urges experts to experiment in this line with persons who have lost their sight from opacity of the cornea, etc., and quotes Professor Eder of Vienna, as authority for its feasibility.

Radiographic Delineation of the Arteries.—Dr. Nathan Raw communicated to the Manchester Pathological Society a method he had adopted of skiagraphing the arteries. He said that when trying to examine a fracture which was enveloped in a thin plaster-of-paris bandage he found it quite opaque to the X rays. The idea then occurred to him that the vessels (arteries) might be reproduced in the skiagraph by injecting them with a somewhat similar substance. Accordingly when the next opportunity occurred he injected (postmortem) a solution of calcium sulphate and carmin into the femoral artery and then took skiagraphs of different parts of the body. He illustrated his remarks by exhibiting several pictures showing the arteries perfectly even to the most minute anastomoses. In fact, so opaque was the substance that the arteries actually showed through the bones. Dr. Raw also showed a large bromid print, 24 x 18 inches, of a child showing all the arteries injected.

New York Infirmary for Women and Children.—A gift of \$30,000 was received recently by the treasurer of the New York Infirmary for Women and Children, with the understanding that the name of the donor should be known only to the managers of the institution. The money was to form a part of the \$250,000 endowment fund that is being raised for the infirmary. It has lately transpired that the money was given by Mrs.

James Walker, who has hitherto shown her interest and more than once has befriended the infirmary when the expenditures were exceeding the income. This is the second large gift the hospital has received within two weeks. The legacy of Miss Julia Cooper of \$25,000.

Vital Statistics of New York State in 1896.—The *Bulletin* of the State Board of Health of New York for December, contains a supplemental report showing that the total number of deaths in 1896 amounted to 120,683, or 1,000 less than in preceding year. Delayed returns from certain districts, which should be taken into the account, estimated at 3,300 deaths, will raise the actual mortality to about 124,000, which makes the death rate for the year 19.00 per 1,000 population; that of 1895 was also 19.00; of 1894, 18.75; of 1893, 19.30; of 1892, 20.78; of 1891, 21.43; and of 1890, 19.65. There was an average daily mortality of 340 against 336 in 1895; 324 in 1894, and 340 in 1893. In the Maritime district there was the highest death rate; 21.50 against 21.20 in 1895; in the Hudson Valley district, 19.00 against 18.70 in 1895; in the other sanitary districts from 13.00 to 16.35, or much the same as in 1895. The largest death rate was in July, 23.35 and the smallest in November, 14.75, as reported in the *Bulletin*; the summer death rate was 21.35; the winter, 19.00; the spring, 17.88; the autumn 15.75. The infant mortality was the same as the average of years past, 34.5 per cent. of the deaths having occurred under the age of 5 years. In the summer months 41.1 per cent.; in the spring and fall, 30.5, and in the winter, 29.6 per cent. of the deaths occurred in early life. The zymotic mortality constituted 16.0 per cent. of the total deaths of the year, and caused 3 deaths per 1,000 population for the year. The percentages during several years past have been about 18.0 of the total deaths. Grippe was epidemic early in the year, and caused about 3,000 deaths. Typhoid fever caused 24.4 deaths per 100,000 of the population, the highest mortality being in the Hudson Valley and Southern Tier districts, 37.5, and in the Maritime district the lowest, 16.6 per 100,000 population. Diphtheria caused 71 deaths per 100,000 population, as compared with 78 in 1895, its highest mortality being in the Maritime district, and lowest in the West Central. Scarlet fever caused the smallest mortality in ten years; measles the highest, having been excessive for two years. Diarrheal diseases caused nearly the average of the past ten years, about 9,000 deaths. Consumption caused the usual yearly mortality of a little over 13,000 deaths, and a little more than 10 per cent. of the total.

Closing Exercises of the Army Medical School.—The third session of the Army Medical School, Washington, D. C., which began Nov. 4, 1896, ended March 12, 1897. The closing exercises were held in the hall of the Library of the Surgeon-General's office. Among the audience were many officers of the army with the ladies of their families, a number of naval medical officers and many of the members of the medical society of the District of Columbia. The president of the Faculty, Colonel Charles H. Alden in his opening remarks expressed his satisfaction at seeing so many of the friends of the school present on the occasion. He considered it needless to make any statement of the purposes of the school as this was now the fourth year of its existence. Its graduates and other medical officers who have received instruction in its laboratories are now scattered among the military posts in all parts of the United States so that its influence has become widely extended. The benefits accruing to the army from the instruction given in this school are appreciated not only by the medical corps but by all army officers. Any interruption to its work would, he considered, be felt as a distinct and serious loss to the service. During the past session the instruction has been conducted on the lines laid down in the orders organizing the school in 1893. The morning hours from 9 to 12 daily have been passed in the Path-

ological Laboratory, and the afternoon from 1 to 3 in the Chemical Laboratory. From 3 to 4 p.m., each day there has been a lecture on one of the following subjects by the professors of the respective branches. Duties of medical officers, military surgery, military medicine and military hygiene, there being a weekly lecture on each subject. Lectures have also been given on Military Law by Lieut.-Colonel Davis, Deputy Judge Advocate General; on Mental Diseases at the Government Hospital for the Insane; on the Army Medical Library, by Dr. Robert Fletcher, F.R.C.S., and on Parasites in Man, by Professor Stiles of the Department of Agriculture. Practical instruction in Operative Surgery has been given by the Professor of Military Surgery. On Saturday morning practical exercises in Hospital Corps Drill and First Aid have been conducted by the instructor in that branch at Washington Barracks, and in riding by Lieut. Herbert White, 6th Cavalry, at Fort Myer, Virginia. The class which was appointed last fall and which has now completed the full course of instruction is the largest that has been through the Army Medical School. Four other medical officers availed themselves of the laboratory instruction or of such parts of it as was practicable for them to take. Colonel Alden then expressed the gratification of the Faculty at the attention to duty, diligence and interest in the work displayed by the class. He held that the success of an advanced course of instruction does not depend on the teacher alone. The zeal of the student is an important factor. He was pleased to say that the class was not lacking in this regard. Its members went out from the school with the best wishes of the Faculty for their future health, happiness and success, and with the fullest confidence that they would acquire themselves honorably and be a credit to the profession, the corps and the school. Surgeon-General Sternberg then delivered the certificates to the student officers with some well chosen remarks. The names of the officers in order of merit were as follows: Lieutenants F. M. Kemp, C. R. Darnall, W. E. Richards, B. H. Dutcher, L. A. Fuller, G. A. Skinner, M. M. Cloud and L. P. Smith. The Surgeon-General suggested to them that as many advantages had been given to them during their course of study much would be expected from them hereafter. He urged them to continue their laboratory work as practical men, pointing out that the practical men of today are those who make use of the microscope and culture media and not those who claim the title merely to cover up their ignorance of recent advances in medical science and practice.

Dr. Samuel C. Busey, president of the District of Columbia Medical Society, followed with an address to the graduates. Dr. Busey recognized the selection of a physician from civil life to deliver the address on this occasion as giving expression to that comity and fraternal friendship which should exist in the profession. He congratulated student officers on the high standard of qualification they had attained, but reminded them that the chapeau, shoulder straps and sword which signalized their position in the medical corps of the army constituted no part of the equipment of the conscientious physician. He congratulated them that limited specialism has not invaded the medical corps although so common among young graduates in civil life. To this corps he looked with confidence to arrest the progress of decadence of general medicine which at present threatens its subdivision into as many limited and minor specialisms as can find adventurers with brains enough to capture the credulous sick. To enable the young officers to appreciate their high position he called attention to the fact that the laws enacted in forty-eight States and Territories to regulate the practice of medicine and prescribe standards of education which must be attained by every practitioner exempt the members of the medical corps of the government services from their requirements, thus acknowledging that the officers of these services have reached a standard coequal with the highest demands of the most advanced development. The medical staff

of the army offered many lines of special work and study with opportunities for original research and investigation afforded by changes of station and of duties which do not come to the plodding wage-earners among the ranks of the civil practitioners. Among the unsolved problems for study he mentioned specially those relating to the influence of climate, temperature and altitude and to topographic, meteorologic, electric and barometric conditions, to the products and geologic formations of soils and to the interchangeable and intercurrent conditions of such natural phenomena upon life, health and disease in military as well as in civil life. In this connection he made a lengthy reference to the meteorologic work done by army medical officers; to Beaumont's investigations on gastric digestion; to Howard's occlusive dressing in gunshot wounds of the lungs; to Otis' announcement of the practicability of enterorrhaphy in wounds of the intestines; to Letterman's organization for field ambulance service and to Sternberg's discovery of the micrococcus of pneumonia. Several fruitless fields of research were suggested. Pathogenic germs vary in virulence according to variations in many external influences which remain to be determined. The cause of the exacerbation of pain in maimed limbs and rheumatic joints coincident with the passage of storms is another subject of inquiry. So far we know nothing of the relation of argon to vitality. The life history of the plasmodium malariae outside of the body is also unknown, as is the causation of mountain fever. Dr. Bussey then referred to the Library and Museum of the Surgeon-General's office as signaling and emphasizing the eminent distinction which the army medical corps has attained in military as in general medicine. He closed his address by urging harmonious coöperation in all the relations of professional life between army medical officers and their civilian brethren as coequals in all that pertains to the esprit de corps which should unite us in the common fellowship of a profession animated by noble aspirations to alleviate suffering, prolong and save life and broaden the scope of our usefulness for the good of mankind.

An inspection of the laboratories of the school closed the exercises and the session; but many of the audience had an opportunity of meeting Dr. Busey and thanking him for his scholarly address in the evening at a reception in the hospitable home of the president of the Faculty.

New York.

THE STATUS OF PHYSICIANS IN THE GREATER NEW YORK CHARTER.—At a recent meeting of the New York Academy of Medicine the following resolutions were adopted:

Resolved, That in the composition of the Board of Health by Greater New York there should be three commissioners appointed by the mayor, two of whom shall be practicing physicians of not less than ten years' standing at the date of their respective appointments.

Resolved, That the third commissioner should be a reputed citizen of Greater New York and thoroughly qualified by education and experience for the duties of his office.

Resolved, That the health officer of the port should be ex-officio member of the board.

Resolved, That the president of the board of police should be ex-officio member of the board.

Resolved, That one of these health commissioners should be designated as president of the board by the mayor in making the appointment.

Resolved, That in the opinion of this committee, it would be advisable to abolish the office of coroner and adopt a system in harmony with that now in vogue in Massachusetts, modified to suit exigencies that exist in Greater New York.

At another meeting in the future further consideration will be given to the matter, more especially to the power of the public functionary generally known as coroner. The duties of the office in question seem to be well enough defined, but the rather primitive politics of the East seem to tend toward putting the wrong men in the wrong places.

THE NEW BUILDING and improved hospital wards of the Home for Aged and Infirm Hebrews, West One Hundred and Sixth Street, was opened for inspection on Sunday, March 21. The home has about two hundred inmates, and as they come to end their days there, the place in its character must of necessity partake of both a hospital and a home.

THE VIABILITY OF THE BUBONIC BACILLUS.—Dr. E. H. Wilson, Chief of the Bureau of Bacteriology in the Health Department of Brooklyn, N. Y., after referring to the experiments of

Kitasato and Yarsin, relates that he obtained his bubonic cultures from Xarian of China through Dr. W. F. Arnold, U.S.N. His subjects were guinea pigs, mice and rabbits. The thermal death point according to his claim, which seems to be satisfactorily maintained by abundant experimentation, was to be fixed at 60 degrees C. (or 140 F.). The materials of different absorbent properties which Dr. Wilson used were cover glasses, pieces of filter paper and small bits of wool blanket. The investigations have been most complete and tend to fortify the conclusions: 1. The thermal death point of this organism is one or two points higher than that of the majority of pathogenic bacteria of the non-pyogenic variety. 2. Differing widely from cholera, sunlight and desiccation can not be relied upon to limit the viability of this bacillus under commercial circumstances. 3. Rags, mails, ballast and general merchandise coming from infected ports should be subjected at either the port of departure or the port of entry to a thorough system of disinfection. Experiments in regard to the effects of chemie disinfectants have been made in the laboratory only with carbolic acid. It has been found that an exposure for two hours to a 1 per cent. solution of carbolic acid sufficed to destroy the life of the bacillus. This observation has subsequently been confirmed by Kinyoun.

Cincinnati.

THE ANNUAL REPORT of the Ohio State Board of Medical Registration and Examination has just been submitted to Governor Bushnell and it shows that 6,701 certificates were granted to physicians on the basis of graduation, and 119 applications rejected; 665 certificates were issued to practitioners of ten or more years and 174 of this class rejected. The total receipts were \$38,468.06, of which \$16,202.92 was expended. After July, 1899, no diplomas will be recognized if issued by colleges requiring less than four years' study and four courses of lectures of at least twenty-six weeks each. The medical colleges of this city which were declared not to be in good standing were the Hygeia Medical College, American Eclectic College, Physio-eclectic College, Curtis Physio-medical College, Medical University of Ohio and the American Health College. The Board recognized 144 colleges in the United States and Canada as in good standing. In Cincinnati and immediate vicinity 756 physicians were registered.

THE UPPER MAUMEE VALLEY MEDICAL ASSOCIATION held its regular semi-annual meeting at Fort Wayne, Ind., March 9. The following are the officers: President, Dr. G. W. McCaskey, Fort Wayne, Ind.; vice-presidents, Drs. C. S. Williams of Columbia City, Ind., and C. B. Reid of Van Wert, Ohio; Secretary, Dr. Kent K. Wheelock of Fort Wayne, Ind.; treasurer, Dr. H. A. Duemling, Fort Wayne, Ind.

A COMPLIMENTARY DINNER is to be given to Dr. P. S. Conner on the evening of March 26 to commemorate the closing of his fiftieth consecutive session of medical teaching. Dr. Robert Carothers of Newport has charge of the arrangements.

DR. FRANCIS DOWLING of this city is preparing for publication a monograph on "The Great Ophthalmic Surgeons of the First Half of the Nineteenth Century." The work will be composed of a series of eight essays, which were prepared by the Doctor about two years ago.

THE OHIO STATE BOARD OF HEALTH has started a systematic and searching investigation as to the value of antitoxin in the treatment of diphtheria. A request has been sent to all physicians throughout the State to furnish the Board with the number of cases of diphtheria seen by them during the year together with the number treated with the antitoxin and the results.

AT THE MEETING OF THE ACADEMY OF MEDICINE March 15, Dr. J. M. Withrow reported the results in thirty-five cases of abdominal sections and Dr. Charles A. L. Reed read a paper on the "Sequelæ of Cholelithiasis." The question was considered in respect of the influence of gallstones in the causation of both local and systemic conditions. Under the former head were considered cancer of the liver and gall tract, sclerosis of the ducts, perforation of the bile passages, multiple abscess of the liver and other conditions; under the latter were considered cholemia, anemia, septicemia, etc. The article will be published in full in the JOURNAL.

Washington.

DONATION TO THE EMERGENCY HOSPITAL.—Mrs. Senator Harsh has donated an X ray outfit to the Emergency Hospital. It is one of the latest models.

THE GROSS ITEM DISALLOWED IN THE APPROPRIATION BILL.—The appropriation of \$500 toward the expenses of unveiling the bronze statue to the memory of the late Samuel D. Gross, in the Smithsonian grounds, was lost by being stricken from the appropriations bill in conference.

NATIONAL MEAT INSPECTION.—The first official order issued by Secretary Wilson, of the Department of Agriculture, concerns the exportation of beef to foreign countries and provides: "That from and after March 15, 1897, all beef offered for transportation to European ports, whether fresh, salted, canned, corned or packed, being the meat of cattle killed after the passage of the act under which this order is made, shall be accompanied by a certificate, issued by an inspector of this department, showing that the cattle from which it was produced were free from disease, and that the meat is sound and wholesome, and in order that it may be determined whether all beef exported to European ports has been so inspected and found to be wholesome, it is further ordered, that the meat of all other species of animals exported to such ports, which for any reason does not bear the inspection stamps of this department, shall be packed in barrels, cases or other packages, which are legibly marked in such manner as to clearly indicate the species of animal from which the meat was produced. Meat which is not so marked, and which is not accompanied by a certificate of inspection, will be classed as uninspected beef, and will not be allowed exportation to European ports." No clearance is to be given to any vessel having on board such meats until the provisions of the order are complied with. Until otherwise ordered, certificates will not be required with beef exported to other than European countries.

PRESIDENT MCKINLEY AT THE EMERGENCY HOSPITAL.—President McKinley called at the Central Dispensary and Emergency Hospital on the 9th instant, to see a personal friend who had been brought there with a fracture of the leg. He was very much pleased with the institution and its usefulness.

SENATOR GALLINGER CRITICISES THE ACTION OF THE CONFERENCE COMMITTEE.—When the Conference Committee made its report to the Senate on the appropriation bills for the District of Columbia, expunging certain amendments which should have been retained, Senator Gallinger said: "Before the question is taken on concurring in the report, I desire simply to emphasize an observation I made the other day concerning the burial ground at the Washington Asylum, the so-called potter's field. I notice that the Senate conferees receded from the amendment which I had inserted in the bill providing for a crematorium. I am not going to argue the question this morning, but I wish to repeat that there is here in the District of Columbia, in the capital of this great nation, a condition of things existing such as I apprehend can not be found in any other great city perhaps in the civilized world, and some remedy ought to be provided at the earliest possible moment, so that this reproach will not be laid at our doors. I regret that the conferees on the part of the Senate surrendered the amendment, especially so without providing at least for the purchase of additional ground for the burial of the indigent and pauper poor in the District of Columbia. There is one other matter concerning which I simply want to make a single observation, and that is the provision I had inserted that any legally licensed physician may attend private patients when they occupy pay rooms in any of the public hospitals in the District of Columbia. I think that this must be the only city in the United States in which public hospitals exist, getting contributions from the public fund, where pay patients are refused the privilege of having their own physicians. I believe there is only one hospital in the District where that condition of things exists. The medical profession have insisted, and very properly have insisted, that these restrictions should be removed and that physicians should be allowed the same privileges here in that respect that they are allowed in the other great cities of the country. I simply desire to say that I regret the conferees on the part of the Senate have felt constrained to surrender that amendment, because it is a very proper one and one that ought to have been kept in the bill; but I take it that the Senate conferees had to surrender something; that this is a compromise measure, and they are very earnestly desirous of reaching a conclusion and

agreement. So I find no fault concerning their action, except to say that I feel sure such a provision will in the near future be incorporated in the District of Columbia appropriation bill and that this restriction, which ought not to exist, will be removed." Senator Gallinger is always deeply interested in all medical matters of the District, and has been a true friend to the local profession in the matter of the important medical legislation which has passed Congress during the recent session and become laws.

APPENDICITIS.—The note on differentiation of appendicitis in our last number, page 555, should have been credited to the *Medical Record* of Nov. 21, 1896. The Italian notice did not mention its American origin and the original escaped our attention.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from March 13 to 19, 1897.

First Lieut. Champe C. McCulloch, Jr., Frederick P. Reynolds and Madison M. Brewer, Asst. Surgeons, are ordered to report in person to the president of the examining board appointed to meet at Ft. Leavenworth, Kan., for examination for promotion.

Brigadier-General George M. Sternberg, Surgeon-General, and Lieut.-Col. David L. Huntington, Deputy Surgeon-General, are detailed to represent the Medical Department of the Army at the Twelfth International Medical Congress, to be held in Moscow, Russia, August 19 to 26, 1897.

Major Curtis E. Munn, Surgeon (Benicia Bks., Cal.), is granted leave of absence for one month.

Capt. Paul Clendenin, Asst. Surgeon, is transferred from Ft. Warren, Mass., to Key West Bks., Fla., to relieve Capt. Jefferson R. Kean, Asst. Surgeon, who is transferred to Ft. Warren, Mass.

Capt. George McCreery, Asst. Surgeon, ordered to Ft. Warren, Mass., for temporary duty in addition to his present duties.

A board of officers to consist of: Major Henry McElderry, Surgeon; Major John M. Banister, Surgeon; Capt. William F. Lippitt, Jr., Asst. Surgeon, is appointed to meet at Ft. Leavenworth, Kan., on Tuesday, April 13, 1897, at 10 o'clock A.M., for the examination of such officers of the Medical Department as may be ordered before it, to determine their fitness for promotion.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending March 13, 1897.

Surgeon T. C. Craig, detached from the marine rendezvous, New York, and ordered before retiring board March 16, then home and await orders.

Asst. Surgeon R. G. Brodrick, detached from the "Constellation" March 16 and ordered to the New York navy yard March 17.

James C. Pryor, commissioned as Asst. Surgeon from February 27.

Surgeon H. E. Ames, detached from the "Detroit" and ordered to the "Cincinnati."

Surgeon D. H. Bertolette, detached from the "Minneapolis," ordered home and granted three months' leave.

Surgeon N. H. Drake, detached from the "Cincinnati" and ordered to the "Minneapolis."

Asst. Surgeon G. C. Hubbard, detached from the "Cincinnati" and ordered to the "San Francisco."

Change of Address.

Bullington, Travis A., from Balter and Park Av. to 304 West Chestnut St., Louisville, Ky.

Fuller, Wm., from 4704 State St. to 4701 Calumet Av., Chicago.

Morgan, E. A., from Morow to 402 new Powers Building, Decatur, Ill.

ADDRESS.

MEDICAL AND SURGICAL EXPERT TESTIMONY.

President's Address delivered at the Third Annual Meeting of the
American Academy of Railway Surgeons, held at Chicago,
Sept. 23, 24, and 25, 1896.

BY JOHN E. OWENS, M.D.

CHIEF SURGEON OF THE CHICAGO AND NORTHWESTERN, AND ILLINOIS
CENTRAL RAILWAYS, CHICAGO, ILL.

Medical and surgical expert testimony is frequently so unsatisfactory and useless to the attorney, who seeks for truth; to the judge, whose desire is the administration of justice; so subversive of the dignity and good name of the medical profession, and yet so helpful to the unscrupulous lawyer, who duly thrives and fattens at the expense of his client, that the subject must surely be worthy of your earnest consideration. As the matter now stands, it is too often a farce, and some of our ablest and most conscientious attorneys, being strongly impressed with its inutility in many cases, and disgusted with the senseless wrangle which instructs neither judge, the bar or the jury, are much inclined to get along without it. Does it not bring discredit to the medical profession that experts and medical attendants, on the side of the plaintiff, testify along certain lines, and that those on the side of the defendant so often give testimony diametrically opposite in character? Let me remind you that there is no justification whatever for this state of things in our text books, which set forth in unmistakable terms the symptoms, pathology, prognosis and treatment of the various injuries and diseases of the human being.

A physician who has gained more or less knowledge of an injured person is summoned to testify as to the facts in a case as an ordinary witness. Before his services as such are dispensed with, he is almost always put in the position of a medical or surgical expert, and his opinion is asked on certain points in the case, in this capacity. Particularly if he is a man of limited experience, or of no experience in the matters in question, he is flattered because appealed to before the court, jury and others, to give "his" opinion as an expert. It is seldom that such a witness loses sight of himself and endeavors to base his answers on those principles which guide all of us at the bedside. Usually the less experienced, the more emphatic and positive is the expression of "his" opinion. This pride of opinion often leads him to set the teachings of the books at defiance.

Questions which seek to draw out the individual opinion, are as a rule, in bad form, and particularly so if the witness lacks that experience which enables him to make a proper application of the principles and practice of medicine and surgery—experience which leads the way to correct conclusions.

A brakeman either fell or jumped from the top of a

moving freight train. The palpable injuries consisted of contusions and abrasions of the nose, left shoulder, wrist, thigh and right side of the chest. The patient ran a mile, chased a steer that escaped from one of the cars, and was on his feet for six hours. He reported at the surgeon's office the following day. Recovery from the injuries above named were speedy, but he continued to complain of illy defined pains in the right side of his chest extending to the epigastrium. A physician testified that the patient undoubtedly suffered from chronic and permanent inflammation of his solar plexus; that he could not be fooled as to the existence of pain; that the solar plexus "is something you can't be fooled on;" that the patient would keep the inflammation of the solar plexus the balance of his life. He further testified that he thought he had seen another case of inflammation of the solar plexus, but did not want to swear to it; that he never saw a case of this nature described in the most comprehensive work. And yet, on this notoriously inadequate data, derived from a patient who furnished essentially subjective evidence, a most emphatic and positive diagnosis was made, and the prognosis was formulated with equal emphasis.

Dec. 31, 1891, an engineer weighing 212 pounds, jumped from his engine to avoid a collision. He came under care immediately, and in five days went home. His injuries consisted of severe contusions of left hip and arm and of scalp wounds, the latter of which healed by first intention in a few days. Suit having been entered, in about three years the case came to trial. The evidence presented by the plaintiff's physician went to show that a marked varicosity of the veins of the left leg was produced by this accident, and that this condition was fully developed in two weeks. The physician who testified had been engaged in practice for twenty-six years. The varicosity was marked and well developed below the knee, and several veins in the same condition reached the saphenous opening. The history of the case, while the patient was under my care, did not record injuries to the leg below the knee, nor was there any complaint that directed our attention to the veins. My fault here was in failing to examine all parts whether complained of or not.

One must feel certain, however, that were this development of veins possible in fourteen days, complaints would have been inevitable. My testimony was to the effect that the development of varicose veins above noted was not only not possible in two weeks, but was not even so at the end of four months. There is nothing in the pathology of this condition, with its dilatations, saculations, and ruined valves that could justify such a conclusion. He prescribed for the patient three months. The doctor further testified that this patient having previously received "an injury," followed by a difficulty in passing water, containing sediment and possessing a strong odor,

and having obstinate constipation, probably suffered from concussion of the spine, and that if numbness of the leg existed concussion of the spine was certain; that said concussion was progressive and permanent. What would be thought of this emphatic diagnosis of concussion of the spine, should an effort be made to maintain it, on such data, before one of our medical societies? Moreover, this patient had been hunting, and had been running his engine for three years and upward. The examination of this witness continuing, he stated that he would advise a patient suffering from an injury to the spinal cord, or a concussion, to work as a locomotive engineer; and that it would not be very injurious, but that he did not know of a man suffering from such an injury of the spinal cord who was able to work on his engine, almost constantly, except this plaintiff. The treatment would seem to parallel the diagnosis. When this gentleman was asked if he found any of the authorities consulted by him, citing a case where varicose veins appeared in three or four weeks after a jar, answered that the authorities were very reticent on that point. So much for individual opinion. The thread of error, which ran through this case from the first, naturally lead the attorneys to submit this question to a professor of surgery: "Assuming that on December 31, the left leg was as healthy as the right, and that at that time he jumped from an engine, running at a high rate of speed, and received severe bruises extending down his left side, from the hip to the foot, and in front of the leg on the joint, and that, between two and four weeks, varicose veins began to show themselves, and have been gradually growing worse, what would you say was the cause?" Answer: The injury. There was no distinction made here, you will observe between bruises and ecchymosis. How to dispose of "assumptions" in medico-legal practice is perhaps not for us to determine. Certainly nothing is assumed in pathology, but assumptions are notoriously common in the court room. Many, if not all of us, must be firmly convinced that there is no claim, however absurd, no assemblage of symptoms however unique and unmeaning, and widely at variance with principles and practice as set forth in our text books, and taught in our best colleges, but that doctors can be found who are not only willing, but who do actually, by testimony, endeavor to establish. As the matter now stands, it is extremely easy to secure such favorable witnesses by the use of the attorney's dragnet. The most absurd claim in this way may be established in the courts. Let me cite another case which has not yet come to trial, but one which the medical attendant believes in and is ready to support, namely, the claim of a woman, the mother of nine children, who suffered a falling of the womb, fully one-half of the organ being external to the vulvæ, and accompanied by a cystocele, and said to have been caused by a collision, in which the patient was thrown against the front seat, and then backward against the seat upon which she had been sitting. It is maintained that this condition, in the degree above named, required only two weeks for its development. Many of you have doubtless observed that the evidence presented by the defendants, in cases of personal injury, is in no material degree essential, as evidenced by the attitude of the jury in their verdict. Judge William H. Francis in the following words reminds us of this state of things (*Medico-Legal Journal*, March, 1896): "In the verdicts of juries against corporations, a feel-

ing of prejudice is almost universally acknowledged, and the attorney for the plaintiff feels reasonably certain of gaining the case provided it goes to the jury." "The expert testimony of the experienced railway surgeon is often regarded as of less weight than the testimony of the plaintiff himself." We all know how unique are the symptoms and the details of complaints made by the patient of his sufferings and feelings in cases of personal injury, and often, how much these vary from anything found in the literature of our profession. I have more than once closely watched juries in personal injury cases and have noted the interest taken in plaintiff's testimony, and the toleration, rather than interest, that was manifested toward the witnesses of the defendant. It would seem to me that such juries, perhaps unwittingly, owing to the deep-rooted prejudices against railways, have two objects in view, namely, first to hear the plaintiff describe his or her sufferings, and the supporting testimony of medical and surgical experts. Second, to determine as speedily as possible the amount that should be paid. The evidence, to show the fraudulent nature of the claim and the exaggeration of the symptoms is but little considered. Besides, one may imagine the tumult in the mind of the honest jurors when the doctors on one side make certain statements, and those on the other offer testimony of a diametrically opposite character. How can we expect the most intelligent juror to harmonize these conflicting statements and arrive at a just conclusion, to say nothing of a juror who may be less intellectually favored? What is the natural result? Rather than to take the chance of doing an injustice to a presumably injured person, the verdict is rendered in his favor, often for a large amount. The experienced honest medical and surgical expert, in many instances, with a full knowledge and appreciation of all the facts, concludes that the verdict was rendered solely for the purpose of punishing the corporation. I have been interested in trials where witnesses were so questioned as to bring out very little information for the use of either side, and the court itself was but little if any benefited by the medical witnesses. The unbiased truth would be best for all sides, but there is no certainty whatever of securing it under the methods now in vogue in this and in other States.

The science and administration of justice in cases of personal injury, require the consensus of opinion of the medical profession as set forth in our text books, and not so much the private or individual opinion of the witness. These text books should be used more frequently in the courts, not as is usual for the purpose of entrapping the witness, but as an aid to the witness and to the court, just as legal authorities are employed. Opinions that materially vary from them should not be accepted.

In 1889 a girl 14 years old, the victim of a crossing accident, suffered a fracture of the collar bone as well as two or three scalp wounds. The patient was conscious, but in a highly nervous state. Several months after the accident a piece of loose bone was removed from the clavicle. About this time twitchings of the hands, arms and left side were observed. The day following the operation the patient had a series of convulsions. These convulsions were seen daily the following week, and continued a month. There were jerkings of the limbs, rigidity and alternate relaxation followed by a similar seizure, after which she got up, declaimed, sang songs, whistled, and then from exhaus-

tion fell over in a state of quietude. Her physician had known her to hiccough for three hours. The abdomen became tympanitic in a marked manner. Any excitement easily caused a renewal of the attacks. She had smaller seizures, such as stiffening of arms and legs. Hystero-epilepsy was diagnosed. In addition to the symptoms just noted, there existed left hemianesthesia, impairment of color sense, contraction of the field of vision of the left eye, loss of the sense of smell, and those of taste and hearing on the left side. There was no perceptible difficulty in walking, but she could not use the left hand as in washing cups, etc., longer than ten or fifteen minutes without dropping something. There was no biting of tongue or frothing of the mouth; no coma. A needle thrust into the left side, arm or leg was unfelt. The sizzling of the galvano-cautery could be heard and the vapor therefrom seen, but the result was absolutely negative. She could taste sugar with the left half of the tongue, but not with the right. The tick of a watch could only be heard when placed against the left ear; grasp of left hand was normal. She seemed to delight in trying to mislead, and her mind was in a fickle and uncertain state. She had never menstruated. This condition lasted until the time of the trial, during which she was seized with a violent convulsion in court, and was carried out screaming. The physician in attendance testified that the symptoms would be permanent. Others testified that were the patient removed from the family, freed from morbid curiosity of which she was the object, and of the unnatural solicitude that was lavished upon her, with a very little medicine, in six months, she would probably recover. A gynecologist testified that if she remained well for two years, marriage would be safe. In this case, so very interesting in many respects, we find one opinion as to the permanency of the affection, and others promising recovery with proper treatment. We think that the consensus of opinion of the profession is in accord with the latter prognosis.

Judge Abram H. Daily remarks that "surgeons of humanity and love of fairness are advancing in importance to the railroads," and I may add, likewise to the injured. The only prejudice that exists against railway surgeons is to be found amongst quack lawyers. Not long since my assistant and myself, several days after an accident, visited a patient at the request of a company, for the purpose of taking charge. We were met at the head of the stairs by a stalwart fellow who stood guard and informed us that he had instructions from the attorney not to allow any railway surgeons to enter. In this way, the case could be nursed along, and the demands on the railway company could become more extravagant. Note an additional extract from Judge Daily's paper: "The attorney who is guilty of making use of false evidence in a court of justice should not only be debarred from further practice, but subject to a criminal procedure." As railroad surgeons, our responsibility to the injured is in no sense diminished by the fact that we are employed and remunerated by railroad companies. Our first aim must be the faithful discharge of our professional duty to the patient.

I have never been called upon by the railways with which I am connected to perform the services of a claim agent in any sense, and I have moreover never encouraged this on the part of any of our surgeons. All that I have insisted on is a faithful discharge of professional duty to the patient, and a fair and honest

report of injury and disability, if any. Any activity in the direction of a settlement of claims has been the subject of grave and adverse criticism by the court, and the surgeon is thus brought into disrepute, and the profession proportionately degraded. "In venturing an opinion as to the nature and extent of the injuries of the patient under our charge, we will be held to the exercise of a high degree of skilled knowledge as well as integrity by the courts."

It is most remarkable that all of the States of the Union have not passed a law permitting, where desirable, a physical examination of parties who lay claim to injuries and seek compensation for the same. The position so often taken by the attorneys for the plaintiff, even after their client has been subjected to the study of one or more of their own doctors, is that it is disagreeable, indelicate and against the wishes of their client, and if a woman, that modesty forbids further examination, and that they themselves object to it. May we not with propriety ask who gave the plaintiff's medical witnesses and examiners a monopoly of delicacy, morality and of that gentleness and propriety that must characterize every physician in his relation to his patient, or to the patients of others? It must be quite right that both attorneys and patients, or either, should have the privilege of objecting to certain examiners, but it is not just or conducive to the administration of justice that a physical examination be denied the attorney for the defense when desirable. The new law passed in New York compelling plaintiff to submit to a physical examination in damage cases, settles the question of giving that right to plaintiff exclusively. The plea that it would outrage delicacy or modesty is not a valid objection.

In regard to the law permitting examinations, other States should follow, and there is no State in the Union where this law is so much needed as in Illinois, where quack lawyers are so numerous and so ravenous; and where, so far as I am aware, there is no restraint whatever put on them by the bar association, and little or none by the courts. The Fellows of this Academy should use their influence in this direction.

The courts desire an accurate ascertainment of facts. In personal injury cases, the erroneous conclusions and wrong theories set up by certain doctors and fanned into a flame by attorneys, seriously clog the wheels of justice. The plainest and best sustained opinions of the honest medical and surgical expert are too often misinterpreted by the attorneys as evidenced by their cross-examination. No science is so frequently called upon by the courts for evidence, and the physician should be one of the most satisfactory witnesses, but such is notoriously not the case. It might be expected that he would see nothing but the truth and established facts in connection with the matter subjected to him, but the hopeless conflict of medical testimony tells a different story and nullifies that which, under other methods, would be a desideratum. Among the causes for the present condition of the matter now under consideration may be mentioned the present method of securing expert medical and surgical experts; ignorance, dishonesty, partisanship, pride of opinion, want of preparation and the skill displayed by certain attorneys in bringing about a conflict of medical testimony in

¹ Duty and responsibility of the Attending Physician in cases of railway surgery from a Lawyer's stand-point by Judge Abram H. Daily, (Medico-Legal Journal, March, 1896).

order to weaken the evidence that may be unfavorable to the two sides respectively; a failure to appreciate the fact that *no one* is competent to testify as an expert in *all* departments of medicine and surgery. The witness employed as an expert should have the proper qualifications. Clark Bell says, "An expert is one who has made the subject on which he gives his opinion a matter of particular study, practice or observation, and he must have a particular special knowledge upon the subject concerning which he testifies."² Suggestions have been made for remedying this evil as for instance the following:

"A court should be authorized by law, or by agreement of parties, to appoint a commission of one or more disinterested and unbiased physicians to investigate the medical questions in concert, and make a report or testify as to the findings." "Every facility for investigation should be afforded by the parties." "If the parties should not agree, the court should seek to appoint only those of the highest reputation in the vicinity." "The position would be an honorable one, and the conclusions would be honest."

It has also been proposed, that, by an act of legislature, the judges of the various courts be permitted, yearly, to elect a Board of Experts in each department of the medical sciences, paying the same out of city or State funds, so that when expert testimony, relative to any subject is required, that particular board of experts should by order of the court convene to discuss the same from a scientific stand-point, and investigate by chemic and physical analysis. Either side might retain scientists to conduct examinations, but the testimony of such scientists should be confined to the board of experts, and after such testimony is submitted and the board of experts has finished its investigation, the report handed to the court by such board should be considered expert testimony. Finally whether this would be best or not, I am not prepared to say at this time, but certainly some laws should be enacted through the operation of which the dignity of a scientific profession will be upheld, and medical and surgical expert testimony be entitled to the respect of the judiciary and the honorable members of the bar.

A CASE OF ACUTE VEGETATIVE ENDOCARDITIS WITH ABSENCE OF HEART MURMUR—NECROPSY.

BY JAMES W. WALKER, M.D.
ILLINOIS EASTERN HOSPITAL FOR INSANE,
KANKAKEE, ILL.

The interest attached to the following case lies in its rarity as a clinical observation, the value in the frequent and carefully recorded examinations throughout the greater portion of the course of the disease, and in the postmortem findings. Osler, writing of malignant endocarditis, says, "In some instances the most careful examination has failed to discover a murmur" and further "Even on examination there may be no murmur present. Instances are recorded by careful observers, in which the examination of the heart has been negative." DaCosta writes, "Nor is what has been said of endocarditis invariable. If the question be asked 'Can endocarditis occur without a blowing sound?' it must be answered in the affirmative." It is not difficult to understand why the minute

vegetations frequently met at autopsy, giving the surface of the valve a roughened appearance, may not give rise to adventitious sounds, but the absence of murmur in a heart where the vegetations become large enough to fill the aortic orifice is a problem not easy of solution.

R. W. age 23, male, was admitted to Cook County Hospital, Chicago, to the service of Dr. Sintzel, July 14, 1894. Family history good. Past illnesses included the diseases incident to childhood, rheumatism, and malaria when he was nineteen. Two weeks prior to admission he had an acute attack of gonorrhea, which was soon followed by headache, malaise, epistaxis, chills and diarrhea, becoming progressively worse until he was bedridden. On admission he was very weak, had headache, diarrhea and some abdominal tenderness. Physical examination showed poor nutrition, mental clearness, eyes and tongue negative, lungs negative, heart tones strong, clear and regular, liver dulness from sixth rib to within one inch of umbilicus, spleen not palpable, temperature 103.3 F. pulse 84, urine acid, sp. gr., 1015, no albumin, no casts. I believed it to be a case of typhoid fever. On July 18, the urine contained albumin but casts were not found.

The sickness ran an atypical and uneventful course for two weeks; typhoid seemed improbable and no diagnosis was made. The temperature was irregular, the pulse increased to about 100 per minute, the patient grew weaker and lost all appetite for food. His heart was examined carefully and frequently, under favorable conditions, during the time he was in the hospital, by Drs. A. R. Edwards, H. M. Richter and myself without any adventitious sound being heard at any time. On July 28, two weeks after admission, he complained of pain in his chest. By August 1, the heart had become exceedingly forceful, so much so that pulsation was visible in the small arterioles all over the body; no increase in the area of heart dulness; cyanosis of extremities; dyspnea; dulness over the right side of the chest posteriorly and a few rales; no delirium; temperature 103, pulse 116. These symptoms continued with increasing intensity until August 4, when the pulse was terrifically strong. The day following it began to lose this quality and weakened to about normal force, increasing in frequency. Respirations 48 per minute.

² The Medico-Legal Journal, December, 1893, page 307.

At this time there existed the physical signs of fluid in both pleural cavities. By evening his face became pinched and cold, respiration rapid and shallow, pulse thrready, 158 per minute, delirium developed, speedily followed by death. During the last few days the heart was examined at least twice a day.

heart, the anterior and left posterior cusps were found to have large masses of soft, friable, nodular vegetations depending from their ventricular surfaces, the right posterior cusp being unaffected. The other valves were normal. Endocardium showed yellowish mottling. Myocardium rather firm. The spleen

An autopsy was made on the day following death in the presence of Drs. R. LeCount, E. H. Ochsner and H. M. Richter, with the following findings: Pericardium smooth and shining; heart about the size of owner's fist, weight 350 grams; the aortic orifice filled with a foreign mass. After opening the

weighed 370 grams, and at its upper border was a firm dark-red wedge-shaped infarct 3½ cm. long and 2 cm. across the base, which was peripheral. The left kidney showed an infarct at its lower border 15 mm. by 6 mu., with a bright red zone surrounding it. Straw-colored fluid in both pleural cavities. Conges-

tion of both lungs. One calcareous nodule in the upper lobe of right lung. Ecchymosis in mucous membrane of intestine. Congestion of liver.

Diagnosis.—Acute vegetative endocarditis. Infarct of spleen and left kidney. Hydrothorax. Pulmonary, splenic and hepatic congestion. Healed tuberculosis of lung.

Bacteriologic examination of the vegetations was not made, the presumptive etiologic relation of the gonorrhoea was therefore not demonstrated.

HEMORRHAGE FROM THE STOMACH.

A Clinical Lecture delivered in Rush Medical College.

BY HENRY M. LYMAN, A.M., M.D.

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE.
CHICAGO, ILL.

You have recently had an opportunity for seeing a number of cases in which hemorrhage from the stomach was the most prominent symptom. The case before you completes the series in which were displayed several varieties of the accident. Let us briefly review the more typical forms thus presented before proceeding to the consideration of the present example.

In the first place I will ask you to recall the facts in the history of the young man whom you saw a few weeks ago. Twenty-two years of age; the son of a vigorous, athletic father and a delicate, nervous, anemic woman, he inherited the joyous appetites of the one and the over-sensitive organization of the other. After a fortnight of attendance upon political meetings and active exertion in behalf of the candidates for office in his ward, he lost his appetite, became feverish, vomited repeatedly through the whole of one night, and in the morning was alarmed by the discovery of numerous streaks of blood in the mucus that was ejected from his stomach. This brought him to the clinic, where he told you that he was suffering with headache and epigastric tenderness; and you all had a sight of his thickly coated tongue and woe-begone countenance. We were able to reassure him, however, and in a few days he was quite as well as usual.

Let me also remind you of the tall and bony Scotchman whom you heard relate his experience of vomiting blood. He had not felt well for a long time, yet he was able to continue work, until one day it seemed to him as if a little stream of warm water were trickling through his body. This was soon followed by a sense of epigastric fullness and pressure, presently followed by nausea and vomiting. He threw up numerous large clots of blood, sufficient in quantity to fill an ordinary washbowl half full. Next day he voided at stool a large amount of black fecal matter which was largely composed of partially digested blood.

Then you saw a pale young woman who still retained a plump and well-rounded figure, but whose clear, white countenance was marked by deep lines of anxiety along the naso-labial folds. She gave us a history of long-continued gnawing pain in the epigastric region, culminating, at last, in copious vomiting of blood. Entering the hospital, she was treated for gastric ulceration and made a good recovery.

At one time, also, we had in the hospital a fatal case which you did not see—an elderly gentleman who had long been ailing and was suspected of a cancerous disease of the stomach. But the gastric juice

always yielded a fair quantity of free hydrochloric acid, so that it seemed more likely that he was the victim of senile degeneration of the various organs connected with digestion. One day he began to vomit blood, and continued to vomit clots or dark venous blood for several days and finally died from exhaustion. The autopsy revealed no inflammation nor ulceration, but the veins of the lower portion of the esophagus were in a dilated and varicose condition, permitting a continual diapedesis of blood into the cardiac portion of the stomach.

I once knew a gentleman, about 35 years of age, who was very fond of hunting and who became infected with malaria while duck shooting in the autumn. He had several severe hemorrhages from the stomach—probably also from the duodenum—before his recovery. Twelve or fifteen years later he was again prostrated with vomiting of blood, and died after a lingering illness of several months. The autopsy revealed a chronic, contracting inflammation of the liver.

In another instance I was called to see a young woman who was shut up in a dark room on account of hysteric photophobia and other characteristic symptoms. She had ceased to menstruate and every month vomited blood instead. She, however, recovered and took a husband shortly afterward without any untoward consequences.

I once saw a child, about eighteen months old, suffering with purpura hemorrhagica, who vomited blood, and also voided it with the urine and feces. The same thing is occasionally witnessed during the course of scarlet fever, measles and other infective diseases.

On another occasion I was called to a young man who had been struck by a piece of wood, flying from a machine in which it had been revolving at a high rate of speed. He was in great pain, vomited blood and died within twenty-four hours. The autopsy showed a rupture of the substance of the liver, and a severe contusion of the anterior wall of the stomach.

The patient to whom I wish to direct your attention this morning is a man, 54 years old, admitted a week ago to the hospital. He is emaciated and pale, without any discoloration of the skin, which, you see, is everywhere of a clear whiteness. His cheeks are sunken, his expression is that of pain and anxiety. He tells us that for many years he has been subject to attacks of painful indigestion; that they became more frequent and that for the last ten months he has continually experienced pain and discomfort in the epigastric region. His lungs present no evidence of disease, the heart is rather small and its pulsations as he lies in bed are from 100 to 120 beats per minute. The liver is decidedly reduced in volume and the spleen can hardly be discovered by percussion. Subcutaneous fat has almost entirely disappeared; the lymphatic glands in the groins are numerous and enlarged to the size of a bean. There is considerable epigastric tenderness and a decided sensation of resistance is experienced when the fingers are pressed into the space below the xiphoid cartilage. The same region is quite dull on percussion, though the cardiac end of the stomach yields a clearly tympanitic resonance. The gastric juices, withdrawn through a syphon tube, are very acid, but yield no free hydrochloric acid. In short, we have evidence sufficient to justify the diagnosis of a cancer of the

stomach. I desire, however, to show you a quantity of matter vomited by the patient a few hours ago. There is about a teacupful of slimy liquid, which has deposited nearly one-third of its volume in the form of a dark-brown, rusty colored paste that in many respects resembles the grounds of a coffee pot. This contains blood corpuscles in all stages of disintegration, broken down epithelium from the stomach, blood pigments, yeast cells, and other microbic organisms; it represents an actual hemorrhage in which the blood escapes slowly from the vessels, and is partly digested before it is discharged in the act of vomiting.

You are now in a position to recognize the fact that many causes may operate to occasion hemorrhage from the stomach. Let us review them in tabular form:

Mechanical injuries.

Chemical erosion with acids, alkalies, etc.

Heat, as when very hot substances are swallowed.

Inflammation and ulceration of the stomach.

Carcinoma of the gastric walls.

Varicosity of the gastric veins, with or without cardiac disease.

Aneurysm and rupture of the gastric arteries.

Hepatic disease and obstruction and stagnation of blood in the portal vein.

Hemorrhoidal or menstrual suppression.

Pregnancy, violent vomiting, excessive parturient effort.

Nervous derangement, hysteria, parietic dementia.

All of the so-called infective diseases, including the malarial class.

Blood diseases, such as pernicious anemia, scurvy, purpura and hemophilia.

Mineral poisons, arsenic, phosphorus, causing fatty degeneration of the vascular walls.

Auto-intoxication, such as occurs in uremia and cholemia.

Tubercular disease of the spine or other neighboring organs occasionally causes abscesses that erode the gastric wall, and thus produce hemorrhage. Sometimes an aneurysmal sac may burst into the stomach and thus excite vomiting of blood.

Gastric hemorrhage occurs among women more frequently than among men, for the reason that its most common cause—ulcer and disturbance of menstruation—are usually encountered by the female sex. Children seldom exhibit the phenomenon, except in the form of melena neonatorum, which is sometimes witnessed in the case of newborn infants.

I must now proceed to warn you that mere expulsion of blood does not by any means warrant the diagnosis of gastric hemorrhage; there are other sources from which blood may enter the mouth. Bleeding from the posterior nares, pharynx or fauces is often sufficient to cause copious expectoration of blood, and sometimes enough may find its way down the esophagus to excite bloody vomiting. In the same way blood from the air passages may reach the stomach and there arouse the act of emesis. But careful examination of the cavities in question, and observation of the quality of the blood will soon clear up the diagnosis. Sometimes, in certain cases, there is vomiting of dark brown or rusty-colored matter that may be incautiously mistaken for the coffee-ground discharge of cancer, but a microscopic examination will reveal the absence of blood corpuscles, and may sometimes detect the presence of bismuth, iron or other preparations which darken the contents of the alimen-

tary canal. It is hardly possible that a physician could be deceived by the presence of wine, coffee, beet juice, cherries, red raspberries or other coloring matters in the evacuations from the stomach. Greater difficulty would be experienced in cases of malingering, where the patient had swallowed the blood of an animal and vomited it for the purpose of deception. Observation in confinement and the absence of all symptoms of real loss of blood, such as pallor, faintness, debility and tardy convalescence, would, however, be decisive against actual hemorrhage.

Hemorrhage from the stomach is not often fatal, but I have seen patients reduced by it to the last extremity before the cessation of bleeding. In cases of chronic ulceration of the stomach the patient is usually enfeebled and pale in consequence of repeated losses of blood and malnutrition. Sometimes these sufferers appear to be plump and in good flesh, but this appearance is due to imperfect oxidation through impoverishment of the blood. The red corpuscles are not sufficiently numerous to convey sufficient oxygen to the tissues, and the nutriment of the body is therefore largely converted into fat. Hemorrhage is sometimes the direct consequence of a fatty degeneration of the vascular walls in cases of chronic anemia.

Though not often a direct cause of death, the occurrence of gastric hemorrhage is to be deplored, by reason of the profound exhaustion and tardy or incomplete convalescence that follows. In every case of gastric hemorrhage it is important to ascertain its underlying and predisposing causes, so as to guard against its recurrence. This is especially important in toxic and infected cases, including malarial cachexia. During an attack of hematemesis the patient should remain in the recumbent position, and if he becomes faint the head should be depressed by raising the foot of the bed. He should swallow small pieces of ice, an ice-bag should be laid over the seat of pain, which, in round ulcer of the stomach, is usually very definitely circumscribed, and half a drachm of purified liquid ergotin should be given every six hours by hypodermic injection. If faintness and collapse are imminent, the ordinary restoratives should be employed, mustard externally, enemas of whisky and water and the hypodermic injection of a drachm of a 10 per cent. solution of gum camphor in olive oil. The patient should be nourished for several days by rectal feeding, nothing being introduced into the stomach but ice and a little iced milk. When there is reason to believe in the existence of an ulcer, olive oil may be given in half-ounce doses as often as they can be tolerated. When there is no inclination to vomiting, styptics may be cautiously administered, but their utility is considerably restricted by the fact that they so often excite nausea and violent retching. Among the most valuable of these agents are tannic acid, dilute sulphuric acid, acetate of lead with opium, the solution of the persulphate of iron, fluid extract of hydrastis, oil of turpentine and Morek's stypticin in doses of one grain every two or three hours. A favorite domestic remedy is alum whey, prepared by the addition of a teaspoonful of alum to a pint of milk, which is then gently heated till coagulation takes place. The whey should be strained away from the curd, and drank cold in doses of an ounce every hour or two. Whatever is given should be administered in small quantity, frequently repeated, so as to avoid vomiting.

When hemorrhage is dependent upon malarial poi-

soning, quinin should be given in large doses, fifteen to thirty grains a day. If not tolerated by the stomach, it may be given by rectal enemata. In desperate cases the propriety of transfusion of blood may be presented for consideration. But experience shows that this remedial measure only too often serves to revive a bleeding that had merely subsided so long as the veins were empty. Better results have been obtained from the hypodermic injection of one or two pints of a salt solution of the strength of three-quarters of 1 per cent., or three and a half grains of salt to the ounce of distilled water. This solution may be very easily injected into the loose areolar tissue in either flank of the body, whence it is rapidly absorbed into the lymphatic vessels.

A PROPOSED TREATMENT FOR CONSUMPTIVES.

BY H. T. TILLOTSON, M.D.
CHICAGO.

Since Koch's discovery of the tubercle bacillus, and its manner of communicability, there has resulted in the medical profession, and latterly in the laity, efforts for public defense against infection. The means primarily adopted by the profession, were for the relief of the individual, as cod liver oil, hypophosphites, creosote, sulphureted hydrogen, Koch's tuberculin, and many others, all of which have been demonstrated practical failures in the treatment of pulmonary consumption. These failures have caused the laity, as city and State governments, to contemplate isolation. Modern isolation is again developing the hospital character, with a pesthouse tendency. Compulsory isolation creates a true pesthouse, to prove as unsatisfactory as prior examples, in dealing with this disease. So-called isolation is a misnomer. A befitting appellation is aggregation, and will be so used in speaking of institutions for consumptives. Voluntary isolation or aggregation is public or private. The public institutions are patronized by the poorer class, supported and controlled by the public, and necessarily located in or near cities. If not positively injurious, they are certainly of little value as curative agents, and could as well be called poor houses.

The private institution is much better, and known under various names, as homes, sanitarium, hotels, springs, etc. They are patronized by the financially fortunate. They are located in all parts of the country, taking advantage of all available climatic conditions and giving accommodation to all diseases, the only requisite for admission being the price.

Modern isolation means an aggregation of tubercular individuals, under one roof or in one colony, in all stages of the disease, causing a constant series of reinfections among the inmates, delaying recovery or rendering it impossible. It is a recognized truism that pulmonary tubercular cases are dangerous to inmates of general hospitals, and are denied admission. Is it logical to collect these infected individuals between four walls, to become a constant source of danger to each other and expect them to recover?

A striking example of irrational methods for public preservation from infection is the late contention in Boston, over the site of a Free Home for Consumptives, under municipal auspices. It was proposed to erect a cheap, faulty, brick building 60 x 100 feet, 4 stories, on Quincy street, in a residence district. The inevitable result will be a germ factory with a prolific

out-put. It will remove perambulating patients from nature's remedies, sunshine, free air and exercise, to place them in a veritable culture medium, or incubating oven, with questionable fresh air, administered in medicinal form and doses; with sunshine a rarity, a decrease in tissue resistance and leucocytic activity, and increase in mortality. Here is neither public preservation nor so-called isolation, but simply aggregation, exhibiting a clearly defined determination to defend the public at the expense of the inmates. Such institutions may be profitably used as a last home for hopeless cases only, and should be located in suburban districts. All tubercular aggregations, whether in city or country, should be condemned as improper or perilous for walking cases who may be benefited or recovered by climatic treatment.

Another and very important objection to aggregation is "mental infection." By mental infection, I mean the acquisition of a saturnine mentality, whereby a primarily favorable case becomes unfavorable by association with other invalids, giving ready credence to idle gossip, the daily comparison of symptoms, resulting in unfavorable comments; some make constant use of the clinical thermometer, shaking down the mercurial column with professional dexterity. Their daily sedentary life and habits compel their brains unceasingly to dwell upon their infirmity, subjecting them to foolish fears and apprehensions and erroneous interpretation of trivial transitory symptoms.

These invalids repair to some health resort with the expectation of relief by water, air or some other invisible means. They sit around the hotel office or town, impatiently waiting for the expected relief, which is delayed by reinfection; become despondent, which frequently initiates collapse. Many remain but a short time in any one place, producing a floating, shifting, tubercular population, found principally throughout the west and southeast. They patronize the railroads and hotels, leaving infection possible in all directions. The mental condition of female patients frequently become highly distressing from association, gossip, or ennui.

These strong objections to aggregations of consumptives were revealed to me forcefully while a member of such colonies, in the capacity, of invalid, resulting in some definite conclusions and suggestions for improvement. The substitute for isolation or aggregation may be divided into three classes, the first, a private boarding house or cottage plan, offers a much nearer approach to isolation, and avoids many of the evils of large institutions. The next, a still more promising plan, with almost true isolation, is the ranch life. Thousands of ranchers throughout the arid west will give a comfortable home to invalids, supplying the necessary sterile surroundings, exercise and climate. There should be but one invalid permitted on each ranch. Board and lodging are nominal, no more than eastern rates. Many find employment on stock ranches, because unable to afford residence at a hotel or sanitarium, and are greatly benefited thereby. The third class may be known as "camping" parties, and offers greater inducements than all others. A dry climate being the accepted standard, it is necessary to look southwest or west for it. A dry climate means a great diminution in vegetation. Often absolute deserts greet an outraged, esthetic eye, especially when exhibiting a vigorous sandstorm.

Many of the profession have found serious objection to western plains as an asylum for consumptives,

because sandstorms occur. I believe they are no particular detriment. The sand and fine atmospheric dust is sterilized by sun and pure air, and carries no infection, unless occurring in a large town or city. The thirsty, hungry soil greedily devours all moisture from sputa and other contaminating material, and the almost constant sunshine does the rest. The dry climate permits almost indiscriminate out-door exposure, without deleterious effects. The temperature is equitable as any to be found.

Form a party of four to eight invalids under the supervision of a physician, employ a cook and drivers, purchase all necessary paraphernalia, and leave the towns to lead a nomadic life under canvas, with diversions of hunting and fishing, sure to relieve the mind of morbid occupations, supplying sufficient compulsory exercise to stimulate a wholesome appetite and a rapid improvement in all symptoms, in all reasonable cases. The expenses of such a trip of four or five months will be no more than ordinary western hotel charges, and much less than expenses at some sanitariums and resorts. Much more could be said on this subject of a practical nature.

The dangers of aggregations caused me to adopt the camping plan, resulting in recovery in four or five months. I prolonged my outdoor life, through choice, for over two years. I rented a common farm-wagon and team, and made an extensive trip in western New Mexico, sleeping on the ground at night, preparing my own meals, hunting and fishing when opportunity presented, obtaining constant occupation driving, care of horses and other necessary duties. My next trip was also in a wagon across southern Chihuahua and Durango, Mexico, where our hardships were sometimes pronounced. The following winter was partly spent in the saddle near the summit of the Sierra Madra mountains. The summer of 1894 was devoted to the saddle and wagon, in northern California. The following spring and summer occurred my last wagon trip, from West Port on the Pacific Coast, across California, Nevada, Idaho, the Yellowstone National Park, to Cinnabar, Montana. By this plan I was enabled to move my sanitarium daily; every night found me on sterilized ground, never infected or host to tubercle bacilli, a plan compelling me to seek health instead of waiting for her to seek me. I enjoyed to the fullest extent nature's panorama, revealed in daily sections, and the pleasurable excitement of plentiful hunting and fishing, sound sleep and a ravenous appetite. The almost perpetual sunshine, dry air, high altitude, unavoidable exercise and exhilaration were the components of the prescription, causing my own recovery promptly, permitting my subsequent residence in Chicago in the best of health.

This is a prescription eagerly and rapidly assimilated, greatly desired by the healthy, and positively curative in others.

6301 Yale Street.

A FEW INSTANCES OF THE USE OF PROTONUCLEIN IN CONTAGIOUS AND NON-CONTAGIOUS DISEASES.

BY WESLEY G. BAILEY, M.D.

PERKIN, ILL.

This comparatively new substance has played an important rôle in the armamentarium of the up-to-date physician for at least eighteen months or two years. These two years have conclusively proved that

protonuclein has come to stay, as its action is not ephemeral; for certain diseases are not the terrors either to the minds of the laity or profession since its introduction. To be practical, it is necessary or usual to illustrate one's points by the citation of cases. We will present a few for your consideration:

Case 1.—Female, aged 5, presented every feature of the clinical aspects of true laryngeal diphtheria (Klebs-Loeffler), which was proven by microscopic diagnosis. This child had been ill three or four days before the physician was summoned; that foul odor so characteristic of the disease permeated the atmosphere of the whole house. Little did the writer think that this child's life could be saved, so livid were the lips, swollen the neck and stertorous the breathing. The vigorous use locally of the *protonuclein special powder* was immediately ordered every half hour; previous to the local use of protonuclein, this little patient could not swallow anything, was fast becoming comatose, and was with difficulty aroused sufficiently to allow the perfect administration of the remedies. After several insufflations of the powder, and during a violent coughing spell, immense pieces of false membrane were thrown out; at this time the internal use of the 3-grain tablets every three hours was commenced. From this time on our patient made a rapid, uneventful recovery.

Case 2.—Female, aged 24, multipara. This case also gave every indication of true Klebs-Loeffler diphtheria, tonsillar and pharyngeal (diagnosis confirmed by culture and microscope). This patient also had chronic Bright's disease, from which she suffered periodically with general edema, etc. Several months previous to the attack of diphtheria, she had suffered as mentioned, and was placed upon the 3-grain protonuclein tablets for three or four months, which was considerable time after the general dropsy had ceased. This patient now thought herself nearly well and discontinued the use of the tablets as above, when she was suddenly stricken with diphtheria; this was several weeks after the discontinuance of the protonuclein tablets. Strange to say, this case, though an adult, was nearly asphyxiated on account of the turgid mucous membrane; just at this time we were summoned in haste; protonuclein again scored a signal victory, after thorough and vigorous use locally and internally. Though on any treatment such a patient could scarcely be strong and well again, yet inside of two weeks our patient was up and attending to light household duties. In this family were two small children, aged respectively $2\frac{1}{2}$ and 4, who were constantly about the room and even slept in the same bed with their mother (the diphtheria case), both before and after the diagnosis was made. We immediately administered to each child a 3-grain tablet of protonuclein every three hours, and they did not contract the disease.

Case 3.—Klebs-Loeffler diphtheria (microscopic diagnosis), male, aged 23. This was a mild case, and under the control of the special powder locally and 3-grain tablets internally, made a complete recovery in eight days.

Case 4.—Streptococcus diphtheria (diagnosis by microscope); male, aged 7. This child has had since its second year similar attacks two or three times yearly. After a thorough application of the special powder locally and 3-grain tablets internally, we recorded a "good recovery," and now, though two years have elapsed since, there has been no return of the disease.

Case 5.—Female, aged 33, primipara, has usually had from one to two attacks of streptococcus diphtheria yearly for a number of years, until the last invasion of nearly two years since; was treated the same as Case 4.

Many more cases of both varieties of diphtheria could be cited, but these given are sufficient to explain our procedures. The beauty and immense value of the above methods in treating diphtheria is, firstly, you can begin exhibiting your remedy at once and be assured it will do no harm; hence, several hours of valuable time is not lost in waiting for a bacteriologist's report, besides, protonuclein will certainly cure both varieties of the scourge, barring possibly bad complications already in progress when the treatment is instituted.

In eczematous affections, or any epidermic (common) disease except scabies, due to an organism, there is in our opinion nothing equal to the external and internal treatment with protonuclein, and occasionally—when the case demands it—the hypodermic exhibition of the special powder (locally and hypo-

dermatically we always use protonuclein special powder in varying strength). No cases of the above varieties are cited, because their histories are all too well known; we have treated many such, and all successfully but one, and it was an old chronic case, of eczema from rhus poisoning, and did not continue the remedy long enough to decide for or against it.

One case of tubercular dermatitis came under my care; it was treated with daily inunctions (25 per cent. lanolin ung.) and hypodermic, daily, injections of ten to fifteen minims of the standard solution (10 grains special powder to drachms 1 of aqua dest., at 98 degrees F.) and a 3-grain tablet every three hours internally; after several weeks' treatment the diseased surface became smaller and smaller and healthy spots could be seen surrounded by the diseased tissues. At this time we lost sight of the case.

In chronic Bright's disease protonuclein is, therapeutically, without a peer in the opinion of the writer; eleven cases have been treated with it in our experience, and while we know the inevitable end of such cases is an untimely death, yet we are certain that in a number of instances, life has not only been made easier, by insuring more nearly perfect tissue metamorphosis, but actually prolonged by its use extended over a period of many months. We respectfully ask each physician reading this to calmly think what "more nearly perfect tissue metamorphosis" means to a sufferer from chronic Bright's disease, and then ask himself if this can be performed as well with any other remedy.

In tubercular joint affections we have used protonuclein in but one case, and that has the following history: Mother died of pulmonary tuberculosis, and maternal grandfather though meeting death by an accident was in the last stage of phthisis pulmonalis; paternal grandfather died of tubercular phthisis; child, a male, at the time of the first exhibition to him of protonuclein, was 5½ years old, this was two years ago; at 2 years of age the patient had scarlatina followed by infantile paralysis of the left thigh and leg, subsequently tubercular hip-joint and ankle disease developed in the affected leg; protonuclein in 3-grain tablets was given every three hours together with cod-liver oil. Early in the spring of 1896 the hip and ankle required operative measures, and was accordingly referred to Dr. J. W. Hairgrove of Jacksonville, Ill., for operation; Dr. Hairgrove has kindly furnished us with his notes while the case was in his care. We append them below:

"L. A., entered May 22, 1896. Operation under ether narcosis, May 25, followed by but slight shock. Tuberculous abscess extending around the ankle curetted and through gauze drain inserted. Large abscess on the inner anterior aspect of the thigh opened and curetted, counter opening over the head of the femur and through gauze drain inserted. After-treatment was antiseptic irrigations through and through with gauze packing. Temperature ranged about 99.5 preceding and for some time after the operation.

"On June 14, was noted some swelling around the ankle. It is evident that some irritation still exists about the epiphyseal ends of the tibia and fibula. However, nothing operative was done until July 7 so that the patient might have an enjoyable holiday on the 4th of July.

"At the operation three incisions were made about the ankle, some curetting but no pus was discovered. The discharging fistula at the thigh was widened to improve drainage and packed with gauze. Henceforth the discharge rapidly decreased and the patient went home on July 23.

"During the whole course of treatment he took protonuclein and cod-liver oil.

"I regret that I am unable to give more definite notes of the case. While there was no tubercle bacilli discovered at any

time, we must remember how difficult it is to find them in thin pus; it can generally be done by the most patient and exhaustive effort only."

[signed]

J. W. H.

The little fellow is now plump and hearty, no swelling or tenderness of ankle or hip, and though the affected leg is some inches shorter than the other he can use the short one to support his weight without difficulty; he is attending public school and is anything but a picture of tuberculosis.

We claim that such results are unattainable without protonuclein. We further wish to say the child has not taken cod-liver oil for six months, but has been constantly on protonuclein.

Three cases of scarlatina have lately been under our care and throughout the disease were given nothing but protonuclein, with the exception of a simple diuretic on two days only. Two of the cases were light, the other developed a severe cervical lymphadenitis, which under the vigorous use locally (in throat) and tablets internally, was rapidly disappearing, when, at this time we left directions and ceased to make visits; we learned from the grandfather that the mother of the child ceased the insufflations when our visits ceased; the gland again rapidly increased in size and was opened several days later by another physician. In this same family were three other children and four adults, who were immediately put upon one 3-grain tablet every three hours; none of these last seven people mentioned contracted the disease.

We can not help commenting that no better prophylactic in acute infectious diseases is known; and, further, that the scope of usefulness to which protonuclein can be put is almost unlimited.

HOW CAN WE INCREASE THE THERAPEUTIC RELIABILITY OF MEDICINAL AGENTS?

BY E. MARK HOUGHTON, M.D.

DIRECTOR OF PHARMACOLOGICAL LABORATORY, PARKE, DAVIS & CO.
DETROIT, MICH.

"Without pharmacologic knowledge, the application of remedies must ever be attended with the greatest uncertainty." As a pure science, pharmacology has taken rapid strides during the past few years; but to the physician, by elucidating the manner in which the functions of the various organs of the body may be influenced by the therapeutic agents at his disposal, it has given the greatest gain. Empiricism is disappearing, and ultimately we shall realize the hope of the centuries and medicine may justly claim a position among the exact sciences.

It is not my purpose to show what pharmacology has done in the past, but to call attention to some of the ways in which the science may be of still further service in the future. A physician may be ever so well versed in therapeutics, but if his prescriptions are filled with inert drugs, or drugs varying in strength, his efforts may be useless, or even dangerous. In the past the pharmacist has greatly aided our efforts by improving the preparation of the various remedies. But the time will soon come when he should be held responsible not only for the chemic and botanic purity of his preparations, but also for the physiologic activity of those important medicinal agents which can not be standardized by chemic methods.

I hear some one say this is impracticable, since pharmacists have not been properly educated to carry

out this work; besides, the expense is so great that they can not afford to do it. True, but today nearly all pharmacists buy the bulk of their preparations from some large manufacturing house, which can afford to employ a properly qualified person to make the examinations. Since the retail pharmacist can not do this testing, we should see to it that he supplies to our patients the preparations of some house that does determine the pharmacologic properties of its products. Or, where the retailer prefers to make his own tinctures, fluid extracts, etc., he should obtain his supplies of crude material from such houses as are willing to guarantee the activity of their drugs. It is much more important to the physician that he have a physiologically active preparation than an elegant pharmaceutical preparation. The ideal preparation is the one that possesses the properties of activity and elegance in the highest degree.

Probably to the physician the most important duty of the pharmacologist in his relation to the manufacturing pharmacist is the examination of the crude drugs and active principles before they are made up into fluid extracts, tinctures, pills, etc. Only those crude drugs and active principles should be tested physiologically which can not be assayed by chemical means. But there are quite a number of the most important medicinal agents that the chemist must at present pass, without testing, as no characteristic reactions have been worked out for them. Examples will best illustrate this point. As is well known, ergot, the sheet anchor of the obstetrician in so many hours of peril, loses much of its activity in a comparatively short time after being harvested, and if kept under certain conditions may soon become entirely inert, or if the crude drug was good when it came to the manufacturer the menstruum used may have been such that the more important constituents were left in the improperly exhausted drug; consequently the physician is never quite sure whether the preparation he carries in his obstetric bag can be relied upon to aid him in stimulating an exhausted uterus in a difficult labor, or in checking a much-dreaded post-partum hemorrhage. How much better it is for all concerned to test the ergot physiologically, rejecting the drug if found inert. Then, to complete the precautions, the finished product should be again tested to make sure that it shows the active properties manifested by the crude drug.

Out of twenty-seven samples of crude Indian cannabis, of excellent physical appearance, recently examined by the writer, only thirteen proved to be active when administered to animals; and of a large number of preparations tested, at least one-half were inert. Is it any wonder that physicians have come to believe that hemp is one of the most unreliable of drugs? Or that we occasionally have alarming symptoms following its administration? Digitalis leaves and strophanthus seeds are other good illustrations, and many other examples might be cited if space permitted.

The demand for the active constituents of vegetable drugs is prompted by the physician's desire to administer his potions either in small doses per os or with the hypodermic needle. But many of these active principles, glucosids, alkaloids and others, have thus far eluded the analytic chemist in his attempts to identify them and determine their purity. Since the chemist can not, the pharmacologist ought by all means to examine them before they are made up into preparations for the physician. Neglect this precau-

tion and the manufacturer may, perhaps, obtain a lot of inferior or worthless stock, contaminated possibly by some decomposition product or foreign substance whose action is directly antagonistic to that desired. Of four samples of strophanthin recently tested, three of which were supposed to be chemically pure, there was found such wide variation in activity that one was ninety times as fatal to animals as another. The strength of the remaining two varied between the above limits. No two samples were even approximately the same in strength. What a chance for a sudden, fatal termination of an apparently improving heart case!

Perhaps the most important work of the pharmacologist in relation to medicine is the investigation of new remedies. Synthetic chemistry has developed so rapidly during the past few years that new compounds for medicinal use are constantly being brought to the notice of the medical profession by traveling men, who strive to induce the physician to use the latest hypnotic, antipyretic, etc., promising him that the result will be most gratifying. But it behooves the honest physician to beware of using new remedies until something is known of their physiologic action. When he ascertains the functional changes brought about by the introduction of the drug into the animal economy, he can rationally begin the use of the remedy in his practice, with considerable promise of success.

The examination of medicinal plants for active constituents is greatly facilitated by physiologic testing of the residues obtained by chemical manipulations. By chemical means we can not tell whether a substance crystallizing in an alcoholic extract of a plant is the active constituent of that plant, or whether the amorphous substance dissolved by ether is the principle sought, but we can tell by physiologic methods when we have a substance representing the activities of the crude drug, whether it be crystalline or amorphous—which is the fact of real importance to the physician. Only a few years ago one of Germany's most renowned chemists isolated a beautiful white scillein, which was supposed to be the active constituent of squill. But since then it has been found to be entirely inert, and that the really important constituent of squill is a brown resin-like substance possessing in a very marked degree the characteristic action of the digitalis group.

Heretofore it has been the custom of manufacturing houses, when dealing with a new plant believed to possess medicinal properties of value, to make a fluid extract or some other preparation of the crude drug, and send it out to clinicians, at great expense, in the hope that it might prove of value. How much better it is to have the physiologic properties of the plant examined at the outset! If found to be inactive, the drug may be rejected, thus saving a large item of expense to the manufacturer and much disappointment to the physician and his patient; while if the plant is of value and the physician knows what its effects are upon the various organs of the body, he can use it intelligently, with a good prospect of success. Then, too, human beings are not so recklessly experimented upon, the lives of a few animals being jeopardized in place of so many patients. We can never analyze the action of a drug on the various organs of the human body with such precision as we can on the lower animals, but clinical knowledge obtained after we have a right conception of the physiologic action of the agent used is of very great importance in determining the value of a given remedy.

Until a few years ago nearly all the work done in pharmacology was carried out in the laboratories of the universities of Europe. Recently several leading universities of the United States have fitted up laboratories for the investigation of pharmacologic questions, and for giving the students practical instruction in the action of the more important remedies upon the various tissues of the animal body. To the University of Michigan belongs the credit of being the first institution in the world to give a laboratory course of instruction in pharmacology to undergraduate medical students. Undoubtedly this is a movement in the right direction, and will add to the ranks of the profession year by year men who are anxious to use only those drugs whose physiologic action is known. While we can expect the college workers to add greatly to our knowledge of the action of new drugs and explain the pharmacology of the old ones whose action is not clearly understood, we can not expect them to do the systematic routine work necessary to prevent the manufacturer from unconsciously placing on the market poor or worthless preparations. Neither can the manufacturer rely upon their aid to assist him in materially improving his methods of preparing of his fluid extracts, pills, tablets, etc., a work which demands at each step the careful scrutiny of a practical chemist, frequently supplementing his tests by pharmacologic reactions and not allow the manufacturer to go on year after year, sacrificing physiologic activity to pharmaceutic appearances, as has frequently been done. It should be possible for the workers in a manufacturing concern to work shoulder to shoulder with the colleges, and the result will surely be for the advancement of science and the well being of humanity.

We can not expect too much at first, as very little work has yet been done on quantitative methods of determining the physiologic activities of drugs by reactions on animal tissues alone, and we can never expect the results to be as exact as those of chemistry, but we can expect that a great deal may be done to lessen the uncertainty attending the administration of some of our most important medicinal agents.

COD-LIVER OIL A TIME-TESTED REMEDY.

BY FRANK WEBSTER JAY, M.D.

INSTRUCTOR IN SURGERY, RUSH MEDICAL COLLEGE; ATTENDING SURGEON LAKESIDE HOSPITAL.
CHICAGO.

If cod-liver oil has been able to maintain its position as a remedial agent from a time "beyond which the memory of man runneth not to the contrary," its present popularity certainly has not resulted from any lack of sharp and sustained controversy. While the literature commending its utility in a wide variety of disorders is very copious, there has likewise been an abundance of articles, papers and discussions, which contended that cod-liver oil was merely a therapeutic fetich; that it possessed no virtue that did not likewise reside in all forms of food fat; that it was no more readily assimilable than good butter; that, indeed, it was a positive bane to the patient in its loathsome taste, its disturbance of digestion, its provocation of biliousness, etc.

In my opinion these dissenting views constitute a most erroneous and deplorable heresy. Quite apart from the colossal volume of clinical testimony which bears witness to the real, genuine and positive utility of cod-liver oil in all wasting diseases, my own expe-

rience in practice sustains the view that cod-liver oil is an agent of incontestable value when intelligently, perseveringly administered. And yet such therapeutic heresies are far from being an unmixed evil. They stimulate thought. They arouse the physician out of any propensity toward routine-prescribing. Our most cherished convictions are all the better for an occasional assault, since we are thus led to examine our ground, weigh our evidence, review the basis of our belief, and place on a substantial foundation of reason and experience the views which we formerly accepted on tradition or authority.

Manifestly, the wide-spread employment of cod-liver oil has not been restricted by the assaults to which I have referred. Not alone in phthisis, but also in a wide category of other disorders, cod-liver oil continues to render substantial service, and beyond doubt it will continue to prove one of the most efficient remedies at the prescriber's command, despite any lack of unanimity on theoretical grounds.

It is commonly supposed that the general employment of cod-liver oil dates from the publication of Professor Bennett's great work in 1841. This is an error. Professor Bennett did, indeed, lend the weight of his authority to a *revival* of cod-liver oil, but it had been previously used in England in the treatment of phthisis; and long before it had been recommended for the treatment of scrofulous and rheumatic diseases. As early as 1771 Dr. Percival had introduced cod-liver oil as a remedy for chronic lithiasis, and it was employed for this purpose at the Manchester Infirmary during a number of years. The fishermen of Norway have from a remote period used it both externally and internally for rheumatic affections. Other investigators soon demonstrated that this remedy enriches the blood, multiplies the number of red corpuscles and produces an incredible increase in weight—an increase which is frequently out of all proportion to the small amount of oil ingested.

The value of cod-liver oil in phthisis pulmonalis is too old and widely known to need comment. Nelligan remarks in his work on *Materia Medica*, "I do not think I am asserting too much for it when I state that its use has to some extent removed tubercular consumption from the list of incurable diseases." Thousands of practitioners will bear out this remark, and a lesser number will join with this author in the regret that the conspicuous success of cod-liver oil in phthisis has caused the profession to lose sight of its utility in chronic rheumatism.

Desiring not to dwell unduly on the diverse applications of this familiar remedy, I content myself with the statement that cod-liver oil is productive of very great service in the treatment of many forms of neuralgia, tuberculous abscesses and chronic arthritis, rickets, strumous ophthalmia, obstinate cutaneous disorders, in chronic ozena, otorrhea and ophthalmia. Among other affections, I lay particular stress on anemia, from whatever cause, and on the obstinate constipation of infants. Brilliant results are occasionally obtained in the tubercular affections of children, especially in glandular enlargements.

For the surgeon cod-liver oil has its greatest value in tubercular affections in association with the indicated surgical treatment of the case. It is an agent which has a curative influence in tubercular disease. Not as a specific, but simply from its ability to increase the body fat, which as Butler says, is a normal and necessary constituent of the body. It is the fuel used

to supply force, and those tissues and organs which are the most energetic require the most fat. The proportion of fat in the body must be maintained in order that the various cells of the body may possess sufficient vitality to withstand by physiologic resistance the encroachments of disease and the invasion of pathogenic microorganisms. Energy is certainly what is wanted by the cells in tubercularized tissue. In tissue infected by tubercle bacilli there is a struggle between the bacteria and the body cells; a struggle which, unless the diseased tissue is eradicated by operative procedure will end in victory for the bacilli and a progressive disease or a victory for the body cells and a cure. If the bacilli exercise their specific properties, the cells of the infected granulation tissue will undergo coagulation necrosis, caseation and liquefaction. If the fixed tissue cells are able to withstand the influence of the bacteria, they can win the battle either directly by destruction of the bacilli by phagocytosis (in which they are aided by the leucocytes), or the cells which have become more or less atypically embryonal under the influence of the bacilli may undergo fibrillation and the infected granulation tissue develop into cicatricial tissue, and a cure be accomplished by encapsulation. A remedy to be of service in tuberculosis must either destroy the essential cause of the disease, the tubercle bacilli, or aid the body cells in their struggle by inhibiting the pathogenic powers of the bacteria or stimulating the body cells to increased power of resistance. All local treatment (short of complete eradication of diseased tissue by operative measures) acts in one or more of these ways. Rest, iodoformization, ignipuncture, injection of chlorid of zinc solutions, Bier's passive congestion, etc., all owe their value to their inhibiting or destroying the bacilli or stimulating the cells to increased power of development or both. Cod-liver oil acts in aiding a spontaneous cure by supplying energy to the body cells in this most important struggle.

The guiding fact in the administration of cod-liver oil should be its indisputable influence on the processes of nutrition. Hence, whenever deficient or disordered nutrition prevails, cod-liver oil is presumptively indicated. Bennett regarded the agent as a stimulant to the lymphatic glands and vessels, increasing the activity of the capillary system; and "by its action on the former the process of assimilation is facilitated and the appetite increased. The quality of the blood is thus improved and the different organs of the body become better nourished and receive more *turgor vitalis*."

It is my firm conviction that much of the dissatisfaction which we hear expressed respecting cod-liver oil is due to neglect of certain simple, practical, yet indispensable precautions in its administration. I know of no remedy which is more likely to disappoint those who trust to it, unless they are careful in respect to its quality and purity, the dose and the time of giving.

Dose.—This should rarely exceed a tablespoonful twice or thrice daily. Larger quantities either derange the stomach or liver, or else some of the oil passes, unabsorbed, by the bowels. Indeed, I should counsel the patient to begin on a teaspoonful dose, two or three times a day, increasing the quantity very slowly as tolerance is manifested. Impatience or undue haste in this respect is bound to defeat its own purpose.

Time of administration.—This varies with different patients. The rule is: Take the oil just before or just after eating. Many declare that the most suitable time for them is in the middle of a meal. Others, again, suffer no annoyance from doses administered midway between meals.

Quality.—The best and purest oil should be obtained, since the inferior oils are offensive in odor and taste. I thoroughly approve of a good emulsion when the microscope shows that it contains the *entire oil* in finely divided globules, and when I am satisfied that the percentage of oil claimed by the maker is present in the emulsion. Emulsification, moreover, forms a necessary step in the digestion of the fat, and the ready-made emulsion reduces the burden of labor devolving on the enfeebled digestive organs. The product which has given entire satisfaction in my practice, and to which I pin my confidence, is the egg emulsion of cod-liver oil. This product does not deteriorate, is most satisfactory in taste and flavor, and contains, by volume, full 40 per cent. of the entire oil. The absence of gum arabic, Irish moss, or the other emulsifying agents commonly used, is assuredly not the least of its advantages.

I have no faith in the so-called wines of cod-liver oil, containing, not the whole oil, but an extract of the alleged alkaloids. As urged by Professor Winter, cod-liver oil is a most complex body. Its beneficial properties reside in the aggregate of its constituent elements, and it is a piece of cruel jugglery to proffer a patient a part in lieu of the whole. The deception pointed out by Professor Hare—the entire absence of cod-liver oil from some of the advertised emulsions—merits the severest reprobation of the profession. There should be a fixed standard for emulsions, and the physician should have some positive assurance that the percentage asserted on the label is actually present in the contents of the bottle.

SLOUGHING MYOMA OF THE PUERPERAL UTERUS.

BY PALMER FINDLEY, M.D.

CLINICAL INSTRUCTOR OF GYNECOLOGY NORTHWESTERN UNIVERSITY
MEDICAL SCHOOL.
CHICAGO, ILL.

The controversy so long waged as to whether myoma uteri is a cause or an effect of sterility recalls the proverbial query—"which came first the hen or the egg." Undoubtedly in not a small percentage of cases sterility antedates the appearance of myoma, but that this is not the rule will appear in the statistics reported by Playfair and Allbutt, who found in 2,035 cases of myoma uteri collected by Schroeder, Wenkel, West, McClintock and others absolute sterility in 621 cases or about 30 per cent., a percentage fully double that of the average sterility in women. Then again we have the statistics of Wenkel and Susserot,¹ who reported ninety-nine cases of women with myoma uteri who gave birth to children with an average of 2.8 children to the mother or a little more than one-half the average of children to the mothers of that locality. These statistics would seem to justify the statement made by Hermann J. Boldt² that "We usually see it noted that sterility is an etiological factor, but the correct statement would be that fibro-myomata are conducive to sterility." In the experience of Mathew D. Mann³ sterility is more fre-

¹ Inaug. Dissert. Rostock, 1870.

² Clinical Gynecology. Keating and Coe. Page 561.

quently the cause of the new growth. He writes: "I think it will be found that the larger number of fibroids and myomas occur in women who have either born no children or have only born one or two and these at a period remote from the occurrence of the tumor." He gives as his reasons for this anomalous tendency on the part of the uterus that during pregnancy the uterus has the power of rapid increase in size. If this inherent disposition to grow is not afforded an opportunity by the event of pregnancy it may then be manifest in an irregular atypical growth.

Fortunately it is a comparatively rare event for pregnancy to complicate myoma uteri. This is particularly true of the submucous variety, because of the mechanical interference by the growth and the almost uniform presence of chronic endometritis which together with the new growth makes an unfavorable nidus for the development of the ovum. This is true in a lesser degree in the interstitial and to a still less degree in the subperitoneal myomata.

The effect of myoma upon pregnancy largely depends upon the size and location of the growth. Submucous myoma whether large or small constitutes a serious complication of pregnancy by interfering with the expulsion of the fetus and placenta, by causing irregular uterine hemorrhages, by the frequency with which such growths become infected resulting in general sepsis and by bringing about premature labor and abortion. The same to a lesser degree may be said of interstitial myoma. Subserous growths rarely become infected, do not usually cause hemorrhages and when small may not influence the course of pregnancy or labor, but when large and rapidly growing they may seriously interfere from increased intrapelvic and intra-abdominal pressure and by causing irregular uterine contractions. Pozzi quotes 53 per cent of mortality in pregnancy complicated by myoma. On the other hand it is of interest to note the influence of pregnancy upon uterine myoma. Little or no increase in the size of the growth may be observed during pregnancy, and atrophy even to complete disappearance of the tumor is known to take place during the time of puerperal involution. However, it is the rule for the new growth to rapidly increase in size during the development of the gravid uterus. This increase in the size of the tumor is due to the hypertrophy of the essential cell elements of the growth, which is an analogous process to the physiologic hypertrophy of the gravid uterus, also to the edema caused by the obstructed blood supply of the growth. The myoma together with the gravid uterus may tax the accommodation of the abdominal cavity to the utmost. When the tumor becomes fixed in the pelvic cavity it may prevent the abdominal evolution of the uterus. Such an incarcerated tumor sometimes rises spontaneously into the abdominal cavity permitting pregnancy to progress without further interference. Further it is sometimes possible to dislodge the growth by bimanual manipulation. *Myomata are liable to infection after abortion or labor.* This predisposition is accounted for by the low vitality of their tissues rendering them especially susceptible to bacterial infection. This is particularly true of submucous pedunculated myomata. The gangrenous process begins in the periphery of the growth and invades the interior. Orthmann³ performed an unsuccessful laparotomy upon a case of sloughing fibroid following abortion in which the

gangrenous process involved the entire thickness of the uterine wall, causing general suppurative peritonitis. The dangers from sepsis are much greater in the presence of submucous myomata because of the difficulty in delivering the placenta, which is so frequently retained, many become infected and in turn infect the new growth. The mortality of cases of infected myoma complicating pregnancy is so great where there has been no surgical interference that it becomes the duty of the attending physician in such cases to hold himself in readiness to resort to operative measures at the first intimation of infection. Such measures should always consist in the enucleation of the infected growths where possible, the complete removal of all retained products of conception and the sterilization of the uterine canal with antiseptic intrauterine douches. As a last resort the uterus and infected tumors must be sacrificed. Of 597 cases of uterine myoma complicating pregnancy collected by Stavely 220 died, a mortality of 37 per cent. and of this number 15 per cent. aborted with a mortality of 12 per cent. How many of these myomata were sloughing is not known. From these statistics we might justly infer that in all cases of myoma uteri complicated by pregnancy the safest procedure would be to induce abortion. By so doing the growth will be prevented from increasing in volume as it commonly does in pregnancy, the serious complications of labor will be avoided and the liability to infection will be reduced to the minimum if abortion is induced within the first three months of pregnancy. As argument against this radical prophylactic measure may be mentioned first, the occasional disappearance of uterine myoma after pregnancy; Pozzi writes of a case in which he observed a myoma increase to double its original size during the course of pregnancy; labor progressed normally and was followed by complete disappearance of the growth; second, the frequency with which they in no way interfere with the course of pregnancy; third, tumors which are so fixed in the pelvic cavity and of such size as to appear to offer a formidable resistance to the development of the gravid uterus and to the process of labor will sometimes spontaneously or by bimanual manipulation rise into the abdominal cavity and no longer interfere with pregnancy or labor; fourth, the results of operations upon the septic puerperal uterus have not been encouraging even in the hands of our best operators. The following case occurred in the service of the writer while resident gynecologist of the Cook County Hospital.

A negress about 30 years of age was brought to the Cook County Hospital in the patrol wagon. She gave the history of having a criminal abortion performed upon her a few days previous. She was then in the fourth month of pregnancy. Two days later she had a chill followed by a rapid rise of temperature which continued to increase to the time of admission to the hospital. On examination after admission the pulse was 140, temperature, 103 degrees F.; there was an offensive, bloody, opaque uterine discharge; and the abdomen tender to pressure and tympanitic. Chloroform was given for the purpose of making a bimanual examination and of exploring the uterine cavity. The curette was introduced with difficulty because of the tortuous uterine canal made so by the presence of two submucous myomas bulging from the left uterine wall into the uterine cavity. The placenta was found retained and sloughing. A portion of it was removed by the curette, it being impossible to remove all because of the obstructing fibroids. The uterine cavity was then irrigated with 1:4000 bichlorid of mercury solution followed by sterilized water. An attempt should have been made to enucleate the fibroids through the vagina after which the uterine cavity could have been thoroughly emptied and disinfected, but the patient refused to have further operative interference. Accordingly nothing further could be done than to

³ American Gynecological and Obstetrical Journal for April, 1896.
⁴ Centr. f. Gyn., 1886, p. 737.

give frequent intrauterine douches and supportive remedies. Three days after admission to the hospital one of the fibroids was spontaneously expelled; it was about two inches in diameter and gangrenous. The expulsion was followed by a chill and rise of temperature. Two days later a second and smaller fibroid was expelled spontaneously and again followed by a chill and rise of temperature. The abdomen became enormously distended. In the delirium which rapidly followed the patient asked that an operation might be performed but the pulse was now too weak and rapid to be counted; and collapse was soon followed by death. Postmortem findings included a large soft uterus; the locations of the submucous growths were marked by sloughing cavities extending deep into the wall of the uterus. There was double pyosalpinx and general suppurative peritonitis. The streptococcus was found in the uterine wall, the pus tubes, peritoneal cavity and thrombosed pelvic veins.

In this case, had the patient not interfered the early enucleation of the submucous myoma might have permitted of the thorough evacuation of the uterine cavity and the prevention of sepsis, and certainly had a timely hysterectomy been performed life might have been saved.

For the purpose of emphasizing the gravity of such cases a résumé of the report of a few selected cases will be presented.

M. D. Mann⁵ of Buffalo, reported a case of a woman 35 years of age who was pregnant for the first time after several years of married life. She came under Dr. Mann's observation in the second month of pregnancy, she was then suffering from a rapidly growing fibroid. She was advised to wait two months and if by that time the growth had increased in size to any great degree abortion would then be performed. At the end of the time dictated the patient returned with a much enlarged tumor; abortion was induced, the growth so distorted the uterine canal as to make impossible the delivery of the placenta. No operative measures were permitted by the husband or patient. On the second day symptoms of sepsis developed and continued with increasing severity until the tenth day when permission was given to operate. Accordingly an abdominal hysterectomy was performed. There was removed a large gangrenous subserous pedunculated fibroid together with several submucous and interstitial fibroids which distorted the uterine canal and prevented the escape of a portion of the placenta which was still remaining in a gangrenous condition. Death resulted in twenty-four hours.

Dr. Mann reported in the same paper a second case in which abortion occurred in the fifth month of pregnancy. Multiple fibroids were present, the placenta was removed with difficulty but not until it had become infected. After the removal of the sloughing placenta the uterine cavity was irrigated with bichlorid of mercury solution and packed with iodoform gauze. Three weeks after the abortion a sloughing fibroid was seen extruding from the cervix into the vagina. A hysterectomy was advised but before this could be accomplished gangrene of the lungs intervened. A thoracoplastic operation was made by Dr. Roswell Park, but death soon followed. In this case there was no pelvic or general peritonitis and the appendages were not affected.

Dr. Jacob Frank⁶ reported a case of pregnancy complicated with uterine fibroids in which abortion was performed between the fourth and fifth month. The placenta could not be delivered because of an obstructing submucous myoma. Later the placenta was spontaneously expelled but not until symptoms of sepsis had existed four days. Intrauterine douches were

given, but the temperature remained high. The uterine secretions became fetid, an abscess formed and opened through the abdominal wall and through this opening there was extracted a sloughing fibroid. Recovery was slow, but complete.

CONCLUSIONS.

1. In the majority of cases uterine myoma is the cause and not the result of sterility.
2. Uterine myomata complicating pregnancy are especially liable to infection.
3. The gangrenous process begins in the periphery of the tumor and invades the interior of the growth, and may penetrate the uterine wall.
4. Myoma uteri of the gravid uterus usually grow rapidly.
5. Submucous, less frequently interstitial myoma may so distort the uterine canal as to render impassible the delivery of the placenta; such growths should be enucleated when possible, the retained placenta extracted and the uterine cavity thoroughly sterilized and packed with sterilized gauze.
6. If the growths can not be enucleated and symptoms of sepsis do not yield to antiseptic doses no time should be lost in performing hysterectomy.
7. In every case of abortion or labor complicated by myoma the attending physician should be on his guard for the first indication of sepsis and in event of septic infection operative interference is imperative.

A CASE OF PYOSALPINX IN A YOUNG GIRL, WITH SPECIMENS AND REMARKS ON SPECIAL SURGICAL TECHNIQUE.

Read before Section on Abdominal Surgery, Obstetrics and Gynecology, Second Pan-American Medical Congress, Mexico City, Mexico.

BY HENRY L. E. JOHNSON, M.D.

A Vice-President of the Second Pan-American Medical Congress; late President of the Clinico-Pathological Society; late Vice-President of the Washington Obstetrical and Gynecological Society; Professor of Gynecology in the Medical Department of the Columbian University; Professor of Gynecology in the Post-Graduate School of Medicine of the District of Columbia; Director of the Gynecologic Clinic in the Central Dispensary and Emergency Hospital; Consultant to the Woman's Clinic, etc.

WASHINGTON, D. C.

I have the honor of presenting for your consideration an interesting case of pyosalpinx in a young girl, for the relief of which laparotomy was performed one year ago. Miss ——— consulted me in the early part of November of last year, giving the following history of her disease, the cause of which is quite direct:

She was white, single, 19 years of age, and had always enjoyed good health, the present being her first serious illness. Family, social and moral history excellent. In August, 1895, she visited the sea-shore, where she bathed daily. When she was over-heated from walking on one occasion she entered the surf, which was rather cold, during the first day of a menstrual period, remaining two hours, and while there she was taken with violent uterine tenesmus and pain in the lower portion of the abdomen, particularly in the right inguinal regions. The flow ceased suddenly and did not reappear during that month, but the pain and suffering continued to the time of operation, three months later. From Sept. 5, 1895, she had a constant and excessive uterine hemorrhage, frequently passing clots of large size. She lost flesh and had for two months more or less fever in the afternoons. The pain, flow and consequent prostration made her practically an invalid.

⁵ American Gynecological and Obstetrical Journal for April, 1896.
⁶ Annals of Gynecology and Pediatrics, Vol. IX, page 140.

Examination:—The patient showed decided effects from hemorrhage and was very weak and thin. The abdomen was distended, extremely sensitive on pressure over ovarian regions, while marked induration or masses could be detected through the thin abdominal walls. The external genitals were normal, hymen intact, which required rupture before digital exploration could be made. The uterus was small and anteflexed, the cervix was small and cone-shaped, with a pin-hole os, through which a bloody discharge was flowing. On either side of the uterus large, irregular fluctuating masses were detected, and the diagnosis of cystic degeneration of both ovaries with pyosalpinx was made.

Laparotomy was performed on November 13 and the previous diagnosis was confirmed. Both tubes and ovaries were firmly adherent in a mass of omentum, intestines and exudate. The adhesions were separated and the tubes and ovaries enucleated from their bed and removed. No injury to the bowels occurred. The pelvic cavity was sponged dry and the abdominal incision closed with interrupted silkworm-gut sutures, without drainage. Convalescence was uninterrupted and uneventful. The patient has had no return of pain or flow and has since enjoyed perfect health. The abdominal incision is firm and strong; no hernia or uterine prolapse or displacement has followed the operation. The specimens from this case are herewith presented.

Where pelvic masses are small or well defined I advise removal by laparotomy, but where pus has escaped, forming a pelvic abscess with the usual extensive bowel adhesions, etc., the better treatment is evacuation per vaginam with irrigation and gauze packing. When laparotomy is performed a small gauze pad should be placed below the tubes before excising, to catch any discharge and prevent its coming in contact with the peritoneum or intestines, and the uterine end of each tube touched with the actual or thermic cautery, or pure carbolic acid, to destroy any germ or bacillus which may be located outside of the portions included in the ligatures.

In all gynecologic abdominal operations, I adopt the following procedure: Thorough asepsis in every detail. Restricted liquid diet for at least three days preceding operation, and thorough purging or salting with sulphate of magnesia for two days previously. On the day of the operation I direct five grains of calomel with soda administered by the mouth early in the morning, and one hour before anesthetizing I have administered two ounces of sulphate of magnesia in water. The initial purging empties the intestines and causes the bowels to flatten and collapse, thereby obviating the annoyance from distension. The calomel and magnesia, which are administered before the operation, produce peristalsis and an early evacuation following the operation, thereby restoring the intestinal circulation. As soon as this is accomplished, the distressing symptoms of colic and vomiting, which cause the patient so much suffering and the physician annoyance, is obviated. I generally try to secure an evacuation of the bowel during the first twenty-four hours, and when this does not follow from the calomel and magnesia, I have a stimulating enema administered, consisting of one quart of hot water, two ounces of sulphate of magnesia and half an ounce of spirits of turpentine. Under this treatment the colic above referred to will never occur. Opiates I never used, and nothing is given by the mouth until the

bowels have responded, except teaspoonful doses of hot water at intervals of half to one hour to relieve thirst, after the effects of the anesthetic have disappeared. If thirst is a distressing symptom, notwithstanding the administration of hot water by the mouth, a pint of hot water is administered by enema.

To prevent prolapse or displacement of the uterus, I always stitch the anterior and posterior edges of the broad ligament together, drawing the anterior surface of flap very short and tense, and include by a suture or ligature the round ligament on each side, which has been previously drawn out and rendered tense. This keeps the uterus in the normal anterior position. I have never had prolapse or displacement follow an operation and I believe it will rarely occur, where this method is practiced. I remove the abdominal sutures as early as the fifth or seventh day.

CANCER OF THE RECTUM.

WHAT HAS MODERN SURGERY ACCOMPLISHED IN ITS TREATMENT?

Read before the Chicago Academy of Medicine, January 8, 1897.

BY JAMES P. TUTTLE, M.D.

NEW YORK.

(Concluded from page 585.)

THE OPERATION.

It must not be assumed that every cancer of the rectum is operable by, or demands the same method. The procedure which will enable us to remove the tumor thoroughly in the least possible time and with the smallest degree of shock should be the one selected in each individual case. The elements in the production of shock consist in the length of time the patient is under the anesthetic, the size of the incision and the hemorrhage incurred. The exhaustion which follows the operation will depend largely upon the amount of surface left to granulate, and from which suppuration will necessarily take place. It is most important therefore to leave as small an area of such surface as is possible in every case. When the tumor does not involve more than the lower inch and one-half of the rectum, it may be easily dissected out from below without disturbing any of the bony floor of the pelvis. In such cases the Cripps, or Allingham operations, supplemented by the bringing down and suturing of the extremity of the gut to the margin of the anus, whenever possible, is the most advisable method. Rapidity is of the utmost importance in these operations in order to avoid hemorrhage, as it is impossible to catch and tie the different vessels as they are cut. The utmost familiarity with the anatomy and the relation of the parts, and boldness in the operator, are necessary for success in these methods. When the tumor extends for two or three inches up the rectum, excision of the coccyx will afford abundant space for the removal or resection of the diseased area. Above these limits the Kraske operation, or some of its modifications, will generally be necessary. Operators are divided in their opinions with regard to the advantages of these different modifications, some holding that the original Kraske is superior to all others, while many believe that the osteo-plastic operation is the rational scientific and most successful method. Between the Kraske, Hoehenegg and the Kocher operations there is only a difference in the amount of bone removed, and we should always select that one which,

allowing sufficient space for operation, destroys as little as possible of the bony floor of the pelvis. Of the osteo-plastic operations the Walker, Levy and Billroth-Rehn-Rydygier methods are the most important. The first case operated upon by the Kraske method in this country was that by Willy Mayer, reported in the above tables. Since that time a great many operations have been done upon these lines, but the most of them more or less modifications of the original method. My own experience has been confined to the osteo-plastic method, and I shall here describe the technique of the operation as I have performed it in six cases. The patient is prepared for the operation by the daily administration of laxatives for three or four days previous to the operation. Intestinal antiseptics is carried out by the administration of naphthalin and salol $\bar{a}\bar{a}$ gr. x to xx, t. i. d., and the daily administration of high enemata of boric acid solution when possible. The parts are prepared for operation with all antiseptic precautions, and after the patient is etherized the rectum is thoroughly irrigated with a 1-5000 bichlorid solution. The patient is laid on his left side in the Sims position with a firm pillow underneath the hips, the legs being well flexed. An incision is then made about one-half inch from the right margin of the sacrum, beginning at a point opposite the third sacral foramen, and extending down to the tip of the coccyx. This incision is carried boldly and at one stroke, through the sacral and coccygeal ligaments into the cellular tissue posterior to the rectum. Whatever hemorrhage occurs is checked by pressure with gauze in the hands of an assistant. The rectum is now rapidly detached from the anterior wall of the sacrum by the fingers and gauze is stuffed into the space thus made in order to check the hemorrhage and avoid wounding the gut when the bone is cut across. A transverse incision is now made from the upper limits of the first incision across the sacrum and thoroughly down to the bone. The sacrum is then rapidly cut through with a chisel, and the flap formed is turned outward to the left side, giving thus a full view of the pelvic cavity and affording ample space for all manipulations. At this point it will become necessary to clamp the middle and perhaps the lateral sacral arteries, but all bleeding in the skin wound will generally have ceased through pressure. The detachment of the coccyx from the insertion of the sphincter and levator ani muscles will cause the bony flap to fall back easily and well out of the way. A fold of the gauze should now be laid over the rough end of the sacrum in order to avoid wounding the hands of the operator or the gut when it is dragged down. Careful examination is now made of the gut and the extent of the tumor upward clearly elicited. If by any chance the tumor should be found to have involved such organs or tissues as would render it inadvisable to remove the same we may, at this point, desist from further operation, restore the parts to their original position, and will have done the patient little damage. The next step in the operation is to dissect off the tissues surrounding the rectum and free it from all attachments above the upper limits of the growth, and as far as is necessary to bring it down to the point of proposed attachment. If the peritoneum has to be opened, it is better to cut the lateral folds with scissors and, where the meso-rectum interferes with bringing the gut down sufficiently, a long bladed clamp should be applied to it as close to the sacrum as possible, and it should be cut off as far away from the gut as can be, in order to

avoid wounding the superior hemorrhoidal artery, and thus interfering with the blood supply of the gut below. The application of this clamp is a precaution rather than a necessity. Having freed the gut from its higher attachments as much as is necessary to bring it down to the point desired, the peritoneal cavity should be walled off with iodoform gauze or sewed up, the gut should be clamped across or tied just below the point at which it is proposed to cut it off. A second clamp or ligature should be placed a short distance below this, and the intestine cut through between these two. Both ends of the incised gut should be cauterized with pure carbolic acid, in order to destroy any septic material which may exude from them, and they should each be wrapped in iodoform gauze to protect the other portions of the wound. The lower segment should now be rapidly dissected out, and this can be done with almost no hemorrhage, as the chief blood supply has been cut off by the clamp above. Where the anus is removed, some bleeding will take place from the middle and inferior hemorrhoidal arteries, but not of any alarming amount. If the tumor does not extend to the anus, and there is a healthy area of mucous membrane between it and this aperture it is advisable to resect the diseased portion and make an end to end union of the parts. If the lower portion of the rectum is so much involved that the preservation of a sufficient amount of gut for the attachment of the upper segment is found to be impossible, it is advisable to remove the whole growth, dissect off the mucous membrane from the margin of the anus, invaginate the intestine through this aperture, and suture it to the surrounding skin. The external sphincter when left should be well stretched, or even incised in order to prevent any obstruction to the free passage of fecal matter. Where it is impossible to preserve the sphincter we may yet be able to leave the levator ani muscles, and they will be of great assistance in the establishment of fecal continence. After the intestine has been sutured either to the lower segment or to the skin about the anus, I invariably pass one or two anchoring sutures through the meso-rectum, and the skin at the margin of the posterior wound, in order to remove as far as possible any tension which may come to bear upon the lower stitches. As to the peritoneal wound I have sutured it twice with catgut, and walled it off four times with iodoform gauze; and can really see no advantage of one method over the other.

The clamp upon the meso-rectum can be removed at the end of the operation, and a small strip of gauze packed into the space in the hollow of the sacrum. The bone flap is then restored to its position, and maintained there by silkworm gut suture passed through the skin and peritoneum, at intervals, throughout the transverse incision. The rest of the wound is left unsutured and the ends of the gauze, which wall off the peritoneum and fill up the sacral space, are brought out at its lower angle. Where it is impossible to bring the gut down and attach it to the lower segment, or to the anus, it may be sutured in the lateral wound, or treated by the Jaemell-Willems method referred to above. (*Centralbl. f. Chirurg.*, May 13, 1893.) By this method there is very little blood lost in the operation. Indeed, I have frequently seen more during an ordinary operation for hemorrhoids or an extensive fistula. In the last four cases I have done, there has not been more than four ligatures used in any one.

The questions of the advisability of end to end

sutures, the application of the Murphy button, the suturing of the peritoneal wound, the closing of the sacral incision and the preliminary colostomy, arise in this operation as in all others for cancer of the rectum, and must be settled by a wider and larger experience than that of any one operator. I have detailed the technique as practiced, with but one fatal result in six cases, and that, apparently, from a personal idiosyncrasy.

Suturing the gut.—In the cases in which reports have been made with regard to suturing the gut, the statistics show the following: 40 cases sutured, 4 deaths; 29 cases not sutured, 7 deaths, a mortality of 10 per cent. in the former, and 20 per cent in the latter, just twice as great.

Sterlein reports: 26 cases sutured, with 6 deaths; 26 not sutured, with 10 deaths.

These results correspond with my own, and I think we may conclude that suturing is safer as well as the most logical procedure. The Murphy button has been employed in only three cases that I have been able to find. In one the result was favorable and in the other two not, non-union occurring in one and death in the other, but not on account of the button. There being no peritoneal covering to the distal segment of the gut, and the thickness of its circumference being so unequal, it does not appear to me that this is a suitable place for the application of this ingenious instrument.

Preliminary colostomy.—A number of prominent surgeons have lately advocated colostomy as a preparatory operation for excision or resection. I have been unable to obtain any reliable statistics on this point, but those which I have show no marked decrease in the mortality or other great advantage.

In cases where the stricture is so close that the intestine can not be properly emptied, it would probably add greatly to the safety of the operation, and where the tumor has extended too high to be outlined by the finger, it would lead to a more certain opinion as to whether or not the tumor was a suitable one for excision. This information, however, could and should be obtained by the use of the sigmoidoscope before beginning the operation, except where the contraction renders the introduction of this instrument impossible. Otherwise it appears to me as substituting three operations for one in patients the conservation of whose strength is of paramount importance.

Limitations.—Before the development of the Kraske method, it was generally conceded that all cancers, the upper limits of which could not be reached by the index finger, were inoperable by excision. These cases were consigned to an unalterable fate, and their sufferings alleviated by such palliative methods as were at our command. When asepsis and antisepsis were still unknown to the profession, the invasion of the peritoneum was considered unjustifiable, and in cases in which this was necessary lumbar colotomy was considered our only resource. Since these improvements in the surgical art, however, we no longer place these limitations upon the operation. We have learned that other conditions have more influence in the limitation of our operations than the extent of the tumor upward into the gut. We may almost say that the distance which the cancer extends upward puts no limitations upon the operation. Ten, thirteen and twenty inches have been removed, and all of the cases have made excellent recoveries. Almost the entire sigmoid has been removed, in one case, the end of the colon clamped

off, and an inguinal anus established at the same sitting with an excellent result. It will be seen by a careful study of the above tables, that the mortality has only slightly increased in proportion to the amount of the intestine removed. The real limitations of the operation consist:

1. In the physical condition of the patient. Age does not seem to contraindicate it so much as would be expected. Old people in good health seem to stand this operation well, and recurrence is in inverse proportion to the age of the individual. Stout and phlegmatic individuals, with weak and flabby hearts, and whose kidneys are not in the best of order, are not favorable subjects for any surgical operation, much less for such a formidable one as this, which necessitates an anesthesia of one hour or more. Two of Dr. Gerster's fatal cases were of this character, and he frankly admits that this physical condition was the cause of death rather than the operation itself. The careful elimination of such cases as these would bring the mortality from this operation down very much.

2. In the length of time which the tumor has existed at the time the operation is to be done. Those cases in which the symptoms have existed for upward of a year have, as a rule, resulted in a high mortality and rapid recurrence of the disease, whereas those which have been operated on within six to nine months from the appearance of the symptoms have given a low mortality and a comparatively small percentage of recurrences. After cancer has existed in the rectum for a year or more, we may expect to find dissemination and metastatic deposits in the liver and elsewhere in the body. But we must not date the existence of cancer from the first symptoms. In this region carcinoma is generally due to the transformation of ulcer, adenoma or other benign growth into the malignant. With such facts in view, we would hesitate to advise an operation for the removal of the tumor after a well established history of malignancy for over a year without the most searching and patient examination of the case.

3. In the extent to which the tumor has involved the surrounding tissues about the rectum. If the bladder, the ureter or the urethra are involved in the neoplasm, the operation offers little if any encouragement to the patient. The vaginal wall, the uterus and its appendages may be involved, and yet, if they are moveable with the tumor upon the surrounding tissues, they may be all removed *en masse* with fair prospect for recovery, although for such a formidable operation the patient should be in excellent physical condition. The adhesion of the tumor to the sacrum may be due to inflammatory products or to involvement of the periosteum, or the bone itself. In the former condition it would offer no contraindications to the operation, while in the latter, the probability of a rapid recurrence would deter us from operating, in a majority of cases. The mobility of the tumor, therefore, is the most important symptom upon which we have to base our conclusions as to whether a tumor is or is not operable. Where the growth is movable upon the surrounding tissues, and can be dragged down from above to a considerable extent, without traction upon the bladder or the pelvic organs, the fact that our finger fails to reach its upper limit should not deter us from expecting a favorable result from operation. Transgression of these limitations easily accounts for the high death rate from this operation among continental surgeons.

Sequences.—The dangers of this operation may be divided into those of the operative, the post-operative and the remote period. In the operative period we have to be prepared for:

Hemorrhage.—In the tables furnished there are one death from this cause direct and three from anemia, which may have been caused by hemorrhage, in 259 cases. In my own experience it has been the least troublesome feature of the operation. The chief source of blood supply to the parts is through the inferior mesenteric or superior hemorrhoidal artery, and if this is temporarily compressed the dissection may be done with very little bleeding. So far as that from the gut is concerned when it is cut off, there is frequently not enough bleeding to indicate a satisfactory circulation. Twice have I cut the gut off, the second and even the third time, before I found a sufficiently active circulation to assure me that it would not slough. There is much more danger from this than from hemorrhage.

Adjacent organs.—Injury to bladder, ureter or small intestine may occur during this operation. Where the disease is so extensive as to involve these organs in the growth, extirpation rarely proves of any benefit and should not be undertaken. Under other circumstances, the operator who is well posted in his anatomy will rarely have any such accident. If, however, through anomaly of position, any of these organs should be wounded, they should be repaired at once. The few cases in which such accidents have occurred give us no reliable statistics. They are accidents which may, but are not likely to occur. Thus far, all the cases in which the ureter has been injured have proved fatal, so far as my researches show, and the greatest care should be exercised to guard against this accident.

Injury to the peritoneum is spoken of by Moulouguet (*Bull. et Mem. Soc. Chir.*, Paris, 1894), as an accident of the operation, but it appears to me to be a part and parcel of it. One should not enter this cavity recklessly, but when the radical removal of the tumor demands it, we should not hesitate to do so.

Injury to the seminal vesicles.—Even their complete removal has been found necessary in this operation. No bad results have so far been attributed to it, but it is easy to imagine that if the patient should have a gonorrhoeal vesiculitis, injury to these organs might infect the whole wound. Such a contingency must be kept in view and provided against.

Injury to the urethra in the male and the vagina in the female have frequently occurred. Their immediate repair has generally been followed by good results, however. A good sized sound kept in the urethra and the finger of an assistant in the vagina when separating the rectum from these parts, will generally enable us to avoid these accidents.

Nerves.—Injury to the sacral plexus or the third sacral nerve is spoken of by the French writers as an accident of this period. There are some remote sequences which would lead us to believe them. Too high section of the sacrum, too wide dissection of the gut, or too much tearing and pulling in the operation may result in this injury. Clear, clean cut dissection is better than dull in this operation. As will be seen from the remote sequences these nerve lesions are of no great moment, as their results are almost always temporary and can confidently be expected to disappear.

POST-OPERATIVE PERIOD.

Retention and suppression of urine.—The former is quite a frequent occurrence, in this as in all rectal operations. It is generally temporary although Boeckel and Jaennell have reported cases which lasted one a fortnight, and one, a month. The condition is identical with that which follows a simple operation for hemorrhoids and is due to the same cause, namely, spasm of the sphincter vesicæ produced by the reflex irritation from the rectal wound. It is absurd to attribute it, as Moulouguet does to destruction of the hypogastric plexus, and Morestin, to a medullary stricture due to cutting of the sacrum. There is no foundation for such reasoning in fact and the condition is easily accounted for in a simpler way. Suppression of urine has been the cause of two deaths from this operation. Shock and the prolonged etherization were probably the cause of the suppression, together with possibly some obscure nephritis before operation.

Secondary hemorrhage.—Morestin says this occurs when the inferior mesenteric artery is cut, because it retracts greatly. It occurs to me that such a vessel would bleed at once and not secondarily. This could only happen when the gut was not sutured as in the latter case the vessel would almost surely be held by the threads. The general oozing is sometimes considerable but I have never seen it alarming.

Pain.—After the third or fourth day the patient suffers very little pain from this operation. If the bowels are controlled and the wound is not irritated by fecal discharges, morphia is rarely necessary.

Suppuration.—This necessary feature in the majority of these operations may be greatly limited by careful dressing. The later it develops and the less profuse it is, the more rapidly will it cease and the sooner will the wound heal over. A solution of ichthyol 10 per cent. in glycerin has served me better for this purpose than any other. Prolonged and excessive suppuration may lead to exhaustion or to amyloid disease and hence it requires the closest attention. Perfect drainage of all the parts, putting the patient on his feet as soon as possible to assist in this and to relieve pressure on the wound, are important adjuncts in the treatment which must be carried out in the most antiseptic manner.

Sepsis.—Local or general sepsis may develop any time after the operation. It manifests itself generally in the peritoneum at first and may occur at once or several days after the operation. It may be active and virulent or obscure and resembling shock. Because there is no tympanites we should not conclude that peritonitis is absent. In the cases reported it was the cause of death in eight instances. I have already stated my own views as to its cause, and having escaped it in my operations thus far, I feel justified in reiterating this opinion axiomatically. *Keep the fingers out of the rectum, and do not open the gut until the peritoneal cavity has been closed.*

Necrosis of the bone.—This result of the Kraske method has occurred a number of times, but it has never seemed to present any serious complications. The non-union of the bones may take place and the fragments may be eliminated in their entirety after the osteo-plastic operation. Immediate suture of the bones has not proved satisfactory to those who have practiced it. The preservation of the soft parts attached to the bone is the only method to guard against this complication.

Gangrene.—Bardenhauer, Manoury, Boeckel, Terrier and Leprevost have all reported cases of this post-operative complication. The first four attribute theirs to deficient circulation. Leprevost accounts for his three cases on the theory of nerve lesions. Morestin makes a logical division of the subject into 1, gangrene from ischemia; 2, gangrene from sepsis; 3, gangrene from nervous origin.

The local anemia or hemostasis is without doubt the most frequent cause of this complication. The practice among some operators of cutting off the meso-rectum close to the gut, is very likely to cause it, as the superior hemorrhoidal artery is included in the folds at this point, and if that vessel is cut off, all the gut below will necessarily slough. Leprevost makes the strange assertion that section of the nerves will prevent this gangrene.

Pulmonary, nephritic and cardiac complications occur in the post-operative period in this as well as in all other major operations. They present no unusual manifestations, and we will not discuss them here.

Fistula.—Fistula is a very frequent sequence in resection. It comes from the point of suture through the lower angle of the sacral wound. There were four of these in the private cases reported above and two in my own patients. One was sewed up twice but the operation failed. They all healed, however, under simple local treatment.

REMOTE SEQUENCES.

The remote and more or less permanent sequences of this operation remain to be considered.

Incontinence of feces.—Where the sphincter and levator ani muscles are removed, it is not to be expected that the patient will retain any considerable control over his bowels. If the wound is left to granulate and the gut is not sutured to the skin, a cicatricial contraction will occur which may, in a manner, fulfill the function of the muscles removed. But unless this is done, or some such method as that of Gersuny or Willems-Jaennell is introduced, incontinence is likely to supervene. If the anus shall have been made in the sacral region the fecal passages may be controlled by a truss on the order of that introduced by Hoehenegg. In the cases which I have reported, there were sixteen cases of complete incontinence, twenty-two of partial incontinence, and in the remaining the functional action of the parts was either satisfactory or not mentioned. The incontinence was generally referred to gas and liquid stools. This sequence therefore, is not so much to be dreaded as is generally supposed and with the methods for its prevention at our command we may expect it to grow less and less frequent.

Prolapsus.—There have been a number of cases of this deformity following the operation for extirpation. Morestin saw four cases, but none in which the wound had been allowed to heal by granulation. Ricard reports a case, which, he says, was due to rupture of the cicatrix soon after the operation. Stertrin reports 1 case in 25, Paul 2 in 14, it is not mentioned in Czerny's 109 cases and Finet collected 21 cases in his collection of 341, 19 of them being in cases with sacral anus. This sequence of the operation is a most logical one when we consider that the passive supports of the rectum, the peritoneal folds and the fibrous bands which hold it from above are all cut, stretched or destroyed.

Bergher reports a case occurring after an operation for extirpation, in which the anus had been formed at the upper angle of the sacral wound. This case was cured by an unusual form of colopexy, the meso-sigmoid being sutured transversely to the promontory of the sacrum. The result in this case was most gratifying, and indicates the method to be pursued in future instances of this deformity, although it by no means settles the position in which the bowel should be sutured.

Prolapsus of the uterus has been observed as a result of this operation, but, so far as I can learn, it has never occurred except where the coccyx and part of the sacrum have been removed. The osteo-plastic operations will effectually prevent the occurrence of this deformity. Suppuration of the sacral canal, Morestin says, may occur much oftener than is supposed, as, in the one case autopsied there was no indication of this condition in life.

Neuritis of the sacral nerves and temporary anesthesia of the perineal area have been described by Jaennell and others, but this writer says he does not think they ever occur in aseptic wounds and, so far as my experience goes, they rapidly and permanently disappear.

Stricture.—Contraction of the caliber of the gut is a necessary sequence in perineal excision where the parts are not sutured together. It also occurs in excision and resection where the circular suture has been used. It is a deformity easily prevented, not difficult to cure, and productive of so little inconvenience that it should not be considered in deciding for or against the extirpation of cancer.

CONCLUSIONS.

From these statistics we may draw the following conclusions:

1. Cancer of the rectum can be cured in over 10 per cent. of the cases.
2. The mortality from the radical operation, though still considerable, is not alarming, and is decreasing with every year's experience.
3. The radical operation prolongs life on the average over 100 per cent.
4. As a palliative measure, excision is far more successful and beneficent than any other measure.
5. The sequences, though numerous, are not at all intolerable and should weigh little in our considerations when it is a question of so serious a disorder as cancer of the rectum.

And thus we answer the question "What has modern surgery done for cancer of the rectum?" It has cured it, conquered all its disgusting features and relieved its pain, doubled and more the lease of life, and at comparatively small risk has given to the hopeless hope, not timorous and vague, but well-founded, and which grows stronger and more confident every day they live without recurrence.

DISCUSSION.

Dr. JOSEPH B. BACON.—I was much pleased with Dr. Tuttle's paper, because it is an educational contribution, and one that we are in need of. It brings the statistics of operations for cancer of the rectum up to date. He has given us a great many practical points and has shown us how we may avoid danger in performing this operation. My experience with operating for extirpation of the rectum has been confined to six cases, five for cancer and one case of stricture of the rectum. All the cases were operated upon by the Kraske method. Of these six cases I lost one, the patient dying from shock. Most of the cases occurred in young people, and recent statistics show that recurrence is much greater in young people. In some of them the disease has recurred within six or ten months from the time

of the primary operation, up to a year and a half. The longest period that any of the cases have lived after the extirpation of the carcinoma has been twenty-one months, and this case was the most serious one of the lot. It required a more radical and severe operation. The fact that this patient lived twenty-one months, thoroughly convinced me of the importance that we should never do a colotomy for cancer of the rectum, except in those very severe inoperable cases where it is done to prolong life. Two of the patients who lived for six months after the operation, doubted my diagnosis, and I was glad to have them do so, because they felt so well and free from any symptoms of recurrence for months. One case was free from the disease for more than a year and a half and he was thoroughly convinced that my diagnosis was wrong. He lived at least one year in perfect happiness, while a colotomy would have been a reminder to him every hour that he was doomed. So I am fully convinced that I shall never resort to a colotomy except in severe cases as a last palliative resort.

With reference to the osteoplastic operation of Dr. Tuttle, I have never done it. My cases have been such that I thought it necessary to remove the anus and the rectum and always stitch the end of the gut up into the upper sacral wound, but I can readily see that the operation as modified by Dr. Tuttle, is excellent, in that it leaves the parts in a more normal condition, with better support to the rectum afterward, and does away with the immense amount of cicatricial tissue which follows the usual operation.

The point he has made of loosening and bringing down the rectum from above to its limit before opening the gut, is very good. In those cases where the anus is to be removed with the rectum and the gut stitched into the upper end of the wound, it is my plan to use the Murphy button, with a large gum elastic tube and unite the ends of the gut, doing an end-to-end anastomosis, approximating gut and tube. By this procedure we can carry the feces into a basin of water under the bed and we are able to prevent infection of the wound after the operation, for a few days. By this time the peritoneal cavity is closed. I regard it as an important point.

The statistics of the Doctor's operations are very favorable indeed, as compared with those we usually see given for this operation. It is an important operation and one that has come to stay. I believe that cancers of the rectum will be treated as successfully, if not more so, than the average case of cancer of the uterus.

A word or two with reference to the sequelæ of the operation. I have had only one case of prolapse of the bowel, from the sigmoid down to the artificial anus, and this was very annoying to the patient. The must have been a prolapse of three or more inches of the bowel, but the case was quite advanced when I operated, and there was no hope of prolonging the patient's life more than a year at most and so I did not do a secondary operation to prevent the prolapse, but used a truss pad and compress.

Dr. JOHN B. HAMILTON.—I have been very much interested in Dr. Tuttle's paper. I have had such cases of this kind as fall to the lot of the general surgeon. I have completed the operation five times and abandoned it once. The cases have been operated upon at the Presbyterian and Marine Hospitals of this city. I agree in the main with the conclusions of the author of the paper. I wish to say in reference to the statement made by the essayist, that age seems to be no bar to the operation. One of my most successful cases was that of an old woman over 70 years of age, a Scandinavian, operated on at the Presbyterian Hospital last year, and she was still alive at last account. In fact, she was so old that I hesitated very much to undertake the operation, but the patient and her friends were anxious that it be done, which was the principal reason for my undertaking it. I was agreeably surprised to find how easy it was to separate the rectum from the fascia, and as the sphincter was involved in the carcinoma in that case it was not possible to bring the gut down and stitch the end. But I brought the gut out at the wound, removed the coccyx and sewed the end into the incision. I might say a word or two as to the technique of the excision of the coccyx. I do not think it is necessary to use a chisel, unless the surgeon is obliged to excise a part of the sacrum. A stout knife will separate the coccyx at the sacral joint or the first coccygeal joint with ease, the flap turned down, and the surgeon can sew directly through the bone, just as he would do in any osteo-plastic operation, in sewing the trochanter, and the like.

In another case there has been a recurrence of the disease. The patient was operated upon about two years ago, and I understand now is at the point of death. She lives at Joliet. In this case the operation had been practically condemned, on account of the fact that the carcinomatous growth extended to the posterior wall of the vagina, but a strip of the posterior

wall of the vagina was removed, when I made the usual operation and she made an excellent recovery. I was able to bring the gut down and stitch the ends together, saving the sphincter. In this case I made an osteo-plastic section of the coccyx and sewed the parts together. The wound closed, except at the lower angle, where I inserted iodoform gauze and it healed nicely. The woman supposed herself entirely well a year after the operation, but there has now been recurrence.

The case I abandoned is an instructive one, and the man is still alive (January 1897) at the Marine Hospital. Last June I undertook the excision of the carcinomatous rectum in this patient, who was a sailor of about 35 years of age. I suppose this case bears directly on the paper, because the Doctor considered cases inoperable where there was dragging on the bladder. I could detect no dragging on it by the usual method of manipulation. But still when I began to separate the tissues from the rectum I found it so firmly attached to the posterior wall of the bladder that I considered it impossible with safety to the patient to extirpate it. I then made an inguinal colotomy, packed the wound with gauze and let it alone. The man was still alive a few weeks ago. The pain from which he had suffered was very acute and seemed to be entirely relieved by the operation, although he suffered a great deal of exhaustion and some shock immediately after the operation and remained in bed for about two months.

I have lost one patient from shock. This was a stout man, 65 years of age, a farmer from Iowa, and seemed to be a perfectly healthy and hearty looking man. He was rather too fleshy to be considered a good subject for operation. This case simply bears out the statement made with regard to this class of patients. The man died on the third day after the operation, although it was performed without the slightest difficulty. I was able with my fingers to separate all of the tissues about the rectum from the carcinomatous growth and made a complete excision. That, too, involved the sphincters, and I stitched the cut end into the upper wound. The patient began to sink after the operation; the temperature fell, and the pulse rate was diminished. He finally died in spite of all that could be done for him, and death was attributed to shock. It is the only death I have had in this series of cases.

One word with reference to Dieffenbach. I think the Doctor discredited his statistics. I think those of us who have had occasion to look into the literature of surgery of seventy-five years ago will be surprised to find what wonderful results Stromeier and Dieffenbach attained in plastic surgery and how great they were in their operations. In 1847 a book was published by Valentine Mott entitled, "Mott's Travels in Europe and the East." Valentine Mott stated that he visited Dieffenbach, and he said (I believe I recall the phrase exactly) he had never in any part of the world seen such a successful spectacle of surgical tailoring as he saw in Dieffenbach's hospital. So Dieffenbach can be credited with being abreast of his time, and Mott placed him at the head of surgeons of his day in Europe in plastic surgery.

In all of my cases excised specimens were sent to the pathologist of Rush Medical College and the diagnosis confirmed.

Dr. J. B. MURPHY.—There is very little that I have to say in addition to the most excellent paper which we have had from Dr. Tuttle on this subject. He has taken up and indeed covered every point of interest in the line of technique up to the present time. My experience in this class of cases is very limited. It includes two perineal operations with resections with the button, one perineal operation with resection with the suture; three Kraske operations, two with the button and one with suture of the intestine at the upper angle. The primary operation was with suture with resection by way of the perineum, and recovered. There was primary union of the wound in the two operations where the button was used. The button passed in one on the ninth, and the other on the eleventh day. One of these operations was done three years ago, on a lady 62 years of age. There has been no return of the growth, and no stricture. The other was a resection for an annular fibrous stricture, probably specific, four years ago, with no return at present writing. The Kraske operations with the button have not been so flattering, but they are about the same as with the suture, and the reason for that is, that we have the same conditions of circulation governing the edges of the flap, regardless of the method which we use in approximation. In the first Kraske operation with the button, I retained the sphincter, resected a number of inches of the bowel and was still able to approximate it. The button escaped behind through the fistula and the fistula healed. The second operation was an implantation of the rectum at the upper angle of the wound, in which I had to remove the sphincter and all the bowel below, brought the bowel out and sutured it to the skin. In the third operation with the button, the button also escaped

through the fistula behind. There was, however, union of the bowel, and there is a small fistula. The operation was performed during my service at the Alexian Brothers' Hospital. The patient is in good condition, has control of his bowels, although there is a slight leakage. The bony part of the operation I did differently from Dr. Tuttle. I made an incision from the tip of the coccyx up the sacrum, took bone forceps and split the coccyx and sacrum as high as desired, made a transverse division of the base of the sacral flap on one side, then a similar division on the other, fracturing the bone between both, and turned out an osteoplastic flap on each side (illustrating). When the operation was complete I put it back in position and used silver wire suture with which to close the entire flap.

In the first button operation, there was at the time of operation enlargement of the liver. I was convinced that we had a secondary carcinoma at the time to deal with, and so informed the patient, but regardless of it, he expressed the desire to be operated on. I operated on him and he died four months after, from secondary carcinoma of the liver. The condition of the circulation of that portion of the bowel which the Doctor mentioned, is the most important point in connection with rectal operations. When we cut off the mesorectum, shall we cut it close to the bowel or some distance from it? I have not made a study of the circulation at that point in the bowel, but from what Dr. Tuttle has said in his excellent paper, we should cut it some distance from the rectum. That is just in accordance with the circulation of the small intestines as I have demonstrated it. You may cut the mesentery, as long as you do not cut close to the intestinal wall in the mesentery. If the parallel vessel is preserved in the small intestine, you may cut off five inches of the mesentery without the slightest danger of necrosis taking place at the line of union. But if you cut off that vessel which supplies the collateral circulation, you will have necrosis. This matter came up a short time ago in "Approximations of the sigmoid with suture and with the button." I investigated the matter because there were a number of cases of failure of union, and I found that the mesentery was cut off too close to the bowel, and with the suture there was quite a percentage of cases of necrosis of the margin of the intestine. They called it gangrene, which is an erroneous term. It is a pressure necrosis combined with ischemia. It should not be called gangrene, because gangrene carries with it usually, but not necessarily, the idea of infection. Let us use ischemia necrosis or pressure necrosis in the place of gangrene. If we can in our operations on the sigmoid and rectum get primary union after suturing, then we shall have advanced a wonderful step. With the suture we expect to have contraction, probably less so in the cases I have mentioned, where we have end-to-end union with the button. Regardless of the percentage of recoveries in these cases, I must say that when I have finished a Kraske operation I am glad it is over. I would rather do several laparotomies than one Kraske. But the results are primarily good, and we should congratulate specialists in this line of work. The results are promising. I feel that every patient who has a carcinomatous growth of the rectum should be encouraged to have it completely extirpated, and not have an artificial anus. In that one point I feel that we as a body should congratulate Dr. Tuttle for the great emphasis he has placed upon it, and the importance his work will have in future operations on this portion of our anatomy.

Dr. ALEXANDER H. FERROUSON.—I am pleased to have been present this evening and to have listened to Dr. Tuttle's very valuable paper. It proves, first of all, that the Kraske operation has come into the surgical field to stay, although a great number of surgeons condemn it. That it has its place in surgery has been shown by the careful statistics the Doctor has collated. It shows that in at least a small percentage of cases a cure can be looked for, and that in a large proportion of cases relief is afforded and life prolonged. These are great gains for surgery in cancer of the rectum. My own experience has been rather limited in operating for cancer of the rectum. Before proceeding to briefly give my experience, I must congratulate Dr. Tuttle in not recommending the extensive operations that we read about in German literature. We are told in some of the cases that the urethra, the prostate, the base of the bladder, and goodness knows what all, have been removed, with a final report that function has been perfectly restored in some of them. It is impossible to conceive that such operations could take place, not at least in America. I have not performed a Kraske operation. I have been rather chary to remove those very high cancerous growths, although I should not hesitate to do so now, according to my ideas of the limitations of the operation. I think it very important to bear in mind that if the peritoneum is judged to be involved that the operation should not be done, and particularly if the disease has

extended to the other viscera, as already intimated. My experience has been confined largely to the low operations, four in all, with one death. The first case died. In this one I removed about two and a half inches of the lower end of the bowel, including the anus, bringing down the bowel and suturing it to the skin. The patient died on the sixth day, from general septic infection, not from peritonitis, which I attributed to possibly too much suturing and infection at the time of the operation. That was some time ago.

My other three cases recovered without a return of the disease, as far as I know.

In the second case, bearing in mind a possible infection, I removed the coccyx, split the anus and sphincters, which were not implicated, backward, and sutured the anterior portion of the gut to the skin, leaving the posterior portion open for drainage. Infection is more liable to travel posteriorly than in any other direction, and I thought by getting an open wound posteriorly and continuity anteriorly I would be more liable to have union by first intention anteriorly and proper drainage posteriorly to prevent infection. And the result was good. The amount of bowel removed above the sphincter was over two inches.

In the other two cases I removed the sphincters, extending upward fully three inches. I did not attempt to bring the bowel down, but removed the coccyx and allowed it to granulate. They did well. The infection was very intense in my first case, which led me to believe that if I had gotten exsiccation instead of absorption things might have been better, consequently I resorted to the use of gauze saturated in glycerin, with iodoform, as a packing, in the manner that the essayist has recommended. Glycerin hardens the tissues and it is hygroscopic; we get a flow externally and it prevents absorption. I have used it extensively in other parts of the body with the most happy results.

Dr. J. R. PENNINGTON.—My experience with operative treatment of cancer of the rectum has been quite limited. I removed two and a half inches of the rectum, including the sphincters, in one case and the patient died from sepsis. I saw a patient five or six months ago who had been operated upon by a most eminent surgeon and pathologist for cancer of the rectum. Regardless of the character of the growth removed by the surgeon, when I saw the patient he was suffering from the effects of tertiary syphilis, plus the results of the operation. When we remember how prevalent syphilis is, and that the connective tissue surrounding the rectum is a very favorite place for development of syphilitic gumma, is it not reasonable to suppose that some of the rectal tumors diagnosed and treated as cancer of the rectum are not cancerous, but syphilitic gumma? I would advise in all cases where there is the slightest element of doubt as to the diagnosis, that vigorous antisyphilitic treatment be resorted to before operative interference.

Dr. JAMES G. KIERNAN—Cases were cited by Dr. Tuttle illustrating predisposing factors to complications of interest from a neurologic standpoint. Even supposing no meningitis had been found in the case reported, the operation itself would be sufficient to produce, in certain constitutions, mental disorder.

Several years ago, I called attention to the fact that the psychoses resultant on drugs, febrile disorders, and surgical procedures had a close resemblance. The existence of mental disturbance after surgical procedures was regarded as a settled fact by Ambrose Paré in the sixteenth century. Billroth points out that under the title "*delirium traumaticum nervosum*," the older surgeon described mental symptoms which made their appearance after surgical operations. The symptoms usually were great motor agitation, visual and auditory hallucinations and excessive loquacity. Especially the psychosis was of a stuporous type. Still more rarely, the symptoms were of a very violent type. The patient generally made a rapid and complete recovery. Exceptionally, death resulted from the delirium, and still less frequently the patient remained permanently insane.

These symptoms were ascribed to various causes. In the philistine epoch, precedent to the advent of the antiseptic era, these symptoms were generally ignored with that sublime contempt for all phenomena, except the mere operation which marked the philistines who dominated surgery. With the advent of antiseptics greater attention was paid to detail, the patient's general condition was taken into account and reports of mental disorders became more frequent in the literature. These were charged to antiseptics, as at one time they had been charged to anesthetics.

The attempt to prevent trophic changes by cutting the sacral nerve is certainly not justified by experimental neurology. There is another factor which has some bearing of interest from a diathetic standpoint. A patient suffering from the initial stages of parietic dementia has a tendency to bowel vaso-

motor disturbances. Given a patient in that condition who is the subject of rectal carcinoma, there would be predisposition to gangrene.

Dr. HENRY T. BYFORD—I have only had two cases of excision of the rectum. In one patient I did a perineal section and the patient lived over a year. In the other case the cancer was quite high up and I attacked it through the vagina. This patient died of shock. I made a transverse incision in the posterior vaginal wall a short distance below the cervix, pushed my finger into the connective tissue, exposed the rectum, pulled it down as far as necessary, closed the peritoneum, cut out the diseased area and stitched the proximal end of the gut into the transverse incision in the posterior vaginal wall, first securing, however, the distal end of the rectum from hemorrhage by inserting some superficial catgut sutures. After stitching the rectum into the vagina, I closed the remainder of the vaginal incision so that the bowels evacuated themselves through the vagina. The tampon which had been put into the connective tissue was brought out through the anus. My idea was, if the patient had survived, to close up the vagina and establish a communication between it and the little portion of anus, thus making the vagina take the place of the lower rectum. In a woman with relaxed tissues it is easy to get at the rectum in this way, and I found I could operate with considerable facility.

Dr. W. X. SUDDUTH—I have under my care at the present time a case of cancer of the sigmoid flexure in which I have not advised operation for the same reasons as those taken by the essayist, but am treating it symptomatically. It is a case of long standing, although only recently presenting carcinomatous tendencies. The disease has now involved the structures to such an extent as to cause stricture, but the stricture, by methods of relaxation and by suggestion, has been overcome, and the patient is now in a fairly good condition. That is all I expect to do for the patient along that line.

The essayist mentioned the use of analgesics and narcotics to control pain in those cases where on operation is not advisable, and I will also say that many of these cases can be reached by suggestion better than by drugs. Pain is not a condition *per se*, but the perception of an injury. The injury may exist, but it is perfectly possible to put a patient in such a mental state that his latter days may be fairly comfortable without the use of narcotics that are apt to induce a drug habit. That is the only bearing suggestion would have in the treatment of these cases. It makes the last days of the patient comfortable without endangering his moral condition.

Dr. W. A. EVANS—Dr. Kiernan has suggested that I say something on the pathologic side of carcinoma of the rectum. We have two forms of carcinoma of the rectum, one of which is spread from the squamous epithelium of the anus, and the other which is developed from the cylindrical glands of the rectum proper. Carcinoma of the rectum arising from squamous epithelium is one of the forms of squamous epithelioma. It is easily within reach and controlled by operative interference. The carcinomas that spring from the cylindrical glands, and for which this treatment was advised, are difficult of diagnosis, as well as difficult to control. We are told that the growth is carcinomatous when the epithelial cells penetrate the membrana propria or the basement membrane of the gland tube. In ordinary squamous epithelioma, this is a proper rule to follow. In cylindrical carcinoma, however, we may not find that the epithelium has penetrated the basement membrane of the gland tube. It is very easy indeed for an adenoma to become carcinomatous, and adenoma is to be looked upon with a great deal of suspicion. We find undoubted malignant adenomas in which there is no breaking of the basement membrane by the epithelial cells. We are accustomed to say that an adenoma has become malignant, under those circumstances, when it has grown through the muscularis mucosa and into the submucosa. I have seen cases in which the gland tubes have grown into the submucosa, and these tubes were perfectly typical. They have then penetrated the muscular layers as bands of epithelial cells without any definite arrangement, and then appeared on the outer fibrous coat in a definite, typical, glandular arrangement. Referring to the remarks of Dr. Byford, the difficulty in the uterus lies in the fact that there is no limiting membrane. There is a limiting membrane to the gland tube, it is true, but there is no limiting membrane between the lymphoid structure which we call the muosa of the uterus and the underlying muscular tissue, and it is difficult to say just when the degree of penetration of the sublying structure has gone far enough for one to say that the growth is malignant. Undoubtedly, in all forms of carcinoma the epithelium reacts to some form of irritation. The epithelium in carcinoma is simply carrying out its life tendency as nearly as possible under its new circumstance. The irritation is the thing, but it is undiscovered.

As the matter now stands, an opinion based upon structural arrangement is subject to the same limitations as opinions based on the effects called symptoms, while the epithelial arrangement generally follows well-marked lines, it does not necessarily do so, and therefore there are cases undoubtedly malignant in which we do not find, by the microscope or the gross examination, physical expressions that are recognized as expressions of malignancy. These forms of glandular carcinoma form metastases very much more frequently than do the carcinomata that are due to squamous epithelium, because of the fact that the malignancy consists of this growing into the underlying structures, and the arrangement of the epithelium in gland tubes is a normal growing into the underlying structures, and therefore, the easier it grows down under pathologic conditions. Whereas in squamous epithelioma we are dealing with epithelium which always covers, which has no capacity to do otherwise, and which when it goes down lines a lymph tube. Its tendency to remain on a surface limits very greatly its malignancy. Carcinoma of the rectum gives rise to secondary infections in the sacral glands, and the operation that has been suggested by Dr. Tuttle is one which attacks the disease directly in the line in which we expect infection to travel, and it therefore exposes to view the channels of danger in this disease.

Dr. TUTTLE (closing the discussion)—Mr. President and gentlemen: I thank you most heartily for this free discussion of my paper, and I am gratified to find the unanimity with which my conclusions have been accepted. I have been particularly glad to hear from those whose reports of cases I have not seen in print and to find that their experiences do not differ very much from the average experiences of those whose cases I have reported. I am glad that Dr. Murphy has taken the view he has of the important point in the technique. It is the point with regard to hemorrhage. I have always taught, since I have done this operation the first time about six years ago, that this was the essential point in the technique which I followed, that of cutting the mesorectum away from the gut. That has not been any happy accident, but it is due to some forty or fifty necropsies that were made with regard to establishing the location of the inferior mesenteric artery as it is in that part of the body, and I find in all of the cases that it hugs closely the wall of the gut itself in the peritoneal fold, the so-called mesorectum and mesosigmoid. The leaving of that vessel intact is the most important point in the prevention of gangrene and sloughing.

Another point which I did not insist upon in the paper was with reference to the prevention of fistulae. I am perfectly confident that the majority of fistulae which have occurred in cases of end to end suture are due to obstruction to the passage of fecal matter at the lower end of the bowel, and that if we will remove that obstruction, so that the fecal matter may come down and pass out easily without any resistance at the anal margin, it will not bring tension to bear upon the sutures and break them loose. With that point in view I have in the last four cases made a complete section of both sphincters, cut them clear through, and stretched the anus well before I sutured the gut; I believe that has been the cause of my success in the last two cases of end to end suture in which I have no fistula and perfect union.

I want to correct Dr. Hamilton with regard to the remarks made by him concerning Dieffenbach's operation. In my paper I simply quoted authorities upon rectal diseases with regard to Dieffenbach's report of absolute cures. I think if the Doctor had read the reports of Dieffenbach's thirty-two (?) cases with an absolute cure of thirty, and no recurrences after five or fifteen years in the thirty cases, he would himself have some doubt as to whether all of these cases of Dieffenbach were cancer, or whether he obtained such good results. I can not conceive how a man with the methods in use at that time could have gotten such excellent results, with no fatal cases and only two recurrences. I simply state this because it is not in keeping with the results of any other surgeon of the present or past generations.

With regard to the osteoplastic feature of the operation, it seems to me the method which Dr. Murphy speaks of is more destructive to bone tissue and more liable to be followed by necrosis, and I can not see that it gives us as good an operative field as the method which I have advised. The method I spoke of is done very quickly, within two minutes from the time you begin the operation you have the bone flap out with full view of the whole part. I have seen no case of necrosis following this procedure and there has been firm union in every case, and the anesthesia and hyperesthesia which follow occasionally soon disappeared and the patients have absolutely no unfavorable symptoms or bad results from this part of the operation.

I want to refer here for a moment to a paper which happily

came into my hand after I had written my own paper. First, a student in the College of Medicine of Paris, seems to have had the same idea of working up this subject that I did and I might say here that most of my paper was prepared with the intention of reading it last year at the meeting of the AMERICAN MEDICAL ASSOCIATION. In July last Finet read his paper in which he collected 341 cases from the work of German, French, and some few English surgeons. The mortality, as I have said with regard to the continental surgeons, is considerably higher than that which I have reported, due to the fact that the surgeons over there do not limit themselves to the removal of growths that do not affect the adjacent organs. They take out everything that is connected with the cancer. As Dr. Ferguson has said, they take out the bladder, urethra and ureters, and subsequently report that the functions are all normal, or nearly so. I do not believe these operations are justifiable.

I am not here to speak of my own cases particularly. I have operated eight times for cancer of the rectum, and have had recurrence in one case, and one death. To my mind the operation has reached that stage of assurance with regard to a cure, that if the patient is operated upon at the proper period the results in most cases will be successful, and it seems to me it should be the moral obligation of every physician and surgeon to examine the rectum of every case which presents intestinal symptoms and to advise that man without hesitation that if the cancer has not existed over nine months to have it removed immediately.

I thank you, gentlemen, most cordially for listening to this thrice-told tale.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

BY CARL H. VON KLEIN, A.M., M.D.

CHAPTER III.—AT THE UNIVERSITY.

(Continued from page 600.)

A similar secret traffic was carried on in England; at least it is known that John Brown, to earn his daily bread, at first translated theses into Latin, and later wrote them, charging for the latter ten guineas and for a translation five guineas.

Is our own time free from this fraud? Without doubt the great bulk of it was abolished, through the promotion system, although only twenty years ago some of the German universities had the reputation of conferring the Doctor's degree for money, upon presentation of a thesis, without troubling themselves as to the author. During my own studies a certain dentist wished to become a doctor and had a clever thesis written, which he submitted to a philosophic faculty. It was sent back to him because they could not credit the author with so thorough historic knowledge. Thereupon a chemist wrote for him a thesis on a platinum or other combination. That worked; a doctor's diploma followed, and probably the author of the work wears to this day the gold watch chain presented to him by the dentist. In 1874 the "Philadelphia university" conducted a regular traffic in Doctors' and Masters' diplomas! They maintained in England a well-paid agent, who anonymously advertised the Doctor's degree in the newspapers. A Berlin medical assistant received from him the following letters: "Dr. P. F. H. Van der Vyver, Jersey, England, June 5, 1874, to Mr. F. in Berlin. I have the pleasure of informing you that I am the agent of the trustees of the American University at Philadelphia, which is one of the most celebrated in the United States. I can supply you with a parchment Doctor's diploma from this university, issued in your name, in the Latin language, upon payment of the total fees and expenses, amounting to 160 Prussian thalers. Anticipating your reply by return mail

I will upon request give you further information." There is appended to this letter a request that it be privately circulated among the students and candidates, and the last lines contain the following remarks: "It is very important for those persons in Europe whose wish to obtain any degree from our university without being personally present, to take note that they should impart their desire to Mr. P. F. H. Van der Vyver, Doctor of Law, Jersey, England. Philadelphia, July, 1873." This American swindle, which lasted several years, appears to have been vigorously suppressed after a suit had been vainly prosecuted against it for two years. The value of the Doctor's title has depreciated considerably by reason of these cheap doctors. How little weight is given today to the title of Doctor of Medicine appears from the fact that after the national trade regulations had made the permission to practice medicine independent of the Doctor's degree, out of 314 approved candidates in medicine in Prussia in 1874-75, 125 had not obtained a Doctor's degree.

The administrations could no longer close their eyes to these irregularities. Maria Theresa commanded (1753) that candidates be examined with greater attention and without any favor, "that the public may be given able practitioners, well trained in the science of medicine, and the life of patients not be entrusted to an untrained physician for the lowest price." In Prussia (1725), beside graduation those seeking permission to practice were required to finish a course in anatomy and to elaborate one case, in the Latin language; later (1789), an examination in the German language was necessary. Then greater severity was enjoined upon all the Prussian faculties, failing in which, they must forfeit their graduating fees. The matter did not rest with this admonition; the young doctor was required to undergo a second examination before he was allowed to practice. The Prussian state-examination (*Staatsexamen*) originated in 1798, in which each candidate must go through a course of anatomy, medicine, surgery, clinics and pharmaceuticals before the examination commission in Berlin. The examination lasted from eight to ten weeks and cost twenty-eight thalers. Hufeland was loud in his praise of this regulation. He said that if many universities were less negligent about examinations and the conferring of the Doctor's degree this precaution in regard to graduated physicians would not be necessary; but, unfortunately, this title, once so honorable, appears so no longer, and the whole graduation has degenerated into a mere formality. The theses became, generally, worse. In 1726 the medical faculty was requested to take care that not so many grammatical errors appeared in the theses, so that they would not be criticised by foreign faculties.

Austria under Joseph II. in 1785, did away with theses entirely and substituted for them a practical examination. (At the same time the degree of Master of Philosophy for medical studies was abolished.) This order, copied in Mainz, was maintained only about two years, till 1810, and the theses were again introduced in the empire. Everwhere in Europe they had to be written in Latin. This pedantry, which has not yet entirely disappeared, was first opposed in America, where the University of Pennsylvania Medical Department gave permission in 1790 to compose the theses in either Latin or English. In the same year graduation theses appeared in the modern languages.

The *ceremonies* at examinations and graduations were very much modified, in comparison with earlier times, but they were everywhere very much of a masquerade. In Austria, until 1784 the candidate, quaking with anxiety, wore a black velvet mantle of especial cut and a round, queer-shaped hat, which had once been black, but which was usually faded by the perspiration of the candidates, just right for the head of a harlequin. The examination developed into a pleasant *déjeuner*, for which the candidates who were examined together arranged. Fine wines and pastry were there in abundance and sufficient to refresh professors and students. The former grew more indulgent, the latter more assured, all stiffness vanished. The Prague professors were forbidden these feasts after 1753. A ducat pressed into the hand of the botanic gardener secured to the candidate the specimens of plants which were submitted; as a precaution they were supplied with a paper upon which the necessary symbols were written. The *famulus* had previously whispered in the ear of the student upon what points the master expected to examine him (*Reichsanzeiger*, l. c.). In Pavia (1787) the affair was conducted as follows: If the candidate had, after two years' study, passed his examination in the philosophic courses, then in order to become a Doctor he was given a written and oral examination by seven professors of medicine. First he had a little conversation with reference to the public exercises, then followed a two hours' examination. If he passed, the beadle called into the next room where candidate waited with his friends, "approbatus." The candidate entered and thanked them with a bow. On the following day was the written examination. Shut up in a room of the university building, he must answer two questions, for which he was allowed two hours' time and a certain number of books from the university library. When the time was up he read his paper aloud, and went out. Again the examiners balloted as to whether a second *approbatus* should be called. Then the dean specified a day for the graduation; but previously the thesis must be prepared, which, if approved, was printed and three days before the graduation was posted in the university building. The day came, on which the candidate defended his thesis, in which professors or doctors, as he chose, opposed him. The judges clapped their hands and he rose. Then sounded for the third time the "approbatus," the trumpeters standing below, blew their horns and thus announced the victory to the crowd. The candidate approached the bishop, heard the confession of faith and kneeling took the oath that he was a catholic. Then the dean came forward from his chair, addressed the honoratissimus or doctissimus candidate, embraced the fortunate one and gave him the Doctor's kiss. Amid the blare of the trumpets the Doctor's cap was placed upon his head.

Men were intolerant enough to make the conferring of the Doctor's degree dependent upon *religious belief*. The most of this fell upon the Jews. One Dr. Schülte in Cleve wrote in 1745 under the name of J. H. Sagittarius, a work in which he sought to prove: 1, that the graduation of a Jew as Doctor of Medicine was against the Christian religion, and was a dishonor to the science of medicine; 2, that the Jewish medicine was infamous and not to be suffered among Christians; 3, that a Christian could not allow himself to be treated by a Jewish physician without com-

mitting a great sin. Finally in the year 1784 the medical faculty in Jena, which for a long time had been allowed to announce as doctors only students of the Augsburg confession, received permission to admit Jews for study and for graduation. In Austria bigotry weighed like an incubus upon the state. Not alone because there in 1726 the Jews were first permitted to employ Christian physicians, barbers and obstetricians, and the Jewish apothecaries could sell no medicine to Christians and the Jewish surgeons could treat no Christian, upon pain of the severest punishment; not alone because even Protestants were oppressed in unheard-of ways when they were permitted to study medicine but not to be graduated as doctors, but even the conscience of Catholic physicians and patients were shackled. Doctors and professors were obliged in 1777 to take the sacrament on Holy Thursday, and to call the attention of any patient who aroused suspicion in anyway, to the sacrament, not delaying later than his third visit. If the patient hesitated to have the sacrament administered, then the physician was obliged to discontinue his visits, if he did not wish to lay himself liable to severe punishment, even to forfeit his license. Up to the reign of Joseph II., with which the sun began to shine upon the empire, only Catholics could become doctors, because they were obliged in their oath to swear by Mary's immaculate conception and by the saints. As the Protestants did not consent to this they acquired only the title of licentiates or master. Joseph II. abolished (1785) everything pertaining to graduation which had a religious bearing, and allowed the confession of faith as well as the oath of obedience to the Pope to fall into decay. From that time on any Protestant could be graduated without condition and was required to take only the usual Doctor's oath. In Vienna, Jan. 24, 1789, a Jew, Beer Joss, first received the Doctor's title.

In order to practice, an Austrian had to be graduated from a native university and if he received his degree from Vienna or Prague he had the right to settle anywhere in the whole monarchy, while those graduated from other universities could practice only in the province where they received their degree. They, together with their children, as well as the accredited surgeons, bath-keepers and apothecaries, were exempt from military service in the empire, in the second half of the century.

The medical faculties of Germany today do not care to know much about *women doctors*, and most of them, with the exception of the Swiss, exclude from their lecture rooms the wandering women students, most of whom are Russians. But a hundred years ago the sentiment was different. The daughter of the Quedlinburg physician, Leporin, was instructed in medicine from her youth up. She attended Halle regularly as a student in the medical department in order to hear the lectures, and was recommended by the king of Prussia to the faculty there for graduation. Meanwhile her marriage with the deacon, Erleben, delayed the examination. She passed it with honor, and on the 12th of June, 1754, was made Doctor in Halle. Her thesis treated: "Quod nimis cito ac jucunde curare sapius fiat causa minus tutæ curationis." At her graduation Dorothea delivered a Latin address, took the usual Doctor's oath, and thereupon received permission to practice. Until her death she pursued her practice in Quedlinburg, and won the utmost confidence of the people. In the highest cir-

cles also there were found learned women; the Duchess von Württemberg publicly opposed the Tübingen professor, Mauchard, in a disputation of an hour's length. At this time in France they went even a step farther; the medical faculty in Paris chose the learned Countess von Voisenon as their president, something which had not happened even there before, and she took the place of honor amid general applause. In the beginning of our century two women of the family of Siebold became doctors. Regina Josepha, the wife of Damian von Siebold, received the degree of Doctor of Obstetrics from the University of Giessen, in 1315. Her daughter Charlotte, after taking the prescribed studies, under Osiander, passed the examination in Giessen in 1817, wrote a thesis, "The Conception Outside of the Uterus," and after a public disputation received the degree of Doctor of Obstetrics. Her reputation became so great that she was called to London in 1819 on the occasion of the birth of the present queen.

No study in the university interests us more in respect to surgery than *anatomy*, since this, as the basis of surgery, must exercise the greatest influence on its development. From antiquity down, the great reverence of the people for the bodies of their deceased relatives and friends has been an almost insuperable obstacle to the dissection of human bodies; indeed Boniface VIII., who became pope in 1294, imposed excommunication as a punishment for dissecting. Although in the year 1315, for the first time in Italy, cadavers were publicly dissected, and the brightest men battled against the foolish prejudice, yet all to no purpose. Therefore, anatomic instruction was retarded for centuries in its development. In Vienna in the year 1404, the first anatomic dissection of the body of a man was conducted by the Master Galeatus de Sancti Sophia, in the city hospital, and lasted one week. Physicians and laity were admitted. An admission fee was collected and given to the faculty, who purchased a new seal with the money (an ox's head and beside it St. Luke with the open book). It was twelve years later when Vienna witnessed the second anatomic dissection, and it was not until the year 1452 that the rector and consistory permitted the dissection of a woman's body. As cadavers were so difficult to obtain, they used swine and sometimes dogs. So all the great anatomic discoveries of the sixteenth and seventeenth centuries were made only on animals. The dissection of swine (which at the end of the fifteenth century were bought by the Dean of Vienna for 17 pfennigs), prevailed in German, French and Italian universities. It is known that Vesalius, who with his own hands robbed the churchyard or had his pupils do it, sometimes supplied his need with dogs, and (1536) a professor of anatomy in Paris had not during his whole life dissected a human body, but had used a great number of dogs and swine. The great taste for painting and the high development of this art did more for the study of anatomy than all ancient literature. It is known that Michael Angelo removed the skin from the bodies of men and animals in order to study the position of the muscles; this is also true of Raphael and da Vinci, who drew muscles and bones. Unfortunately, the prejudice of the people persisted. When Professor Rollfink, in Jena in 1629, asked for the cadavers of criminals for dissection, the people were so wrought up that they stoned him on the street, and the poor culprits before their execution, out of fear of the anatomic knife, tearfully implored the single favor

that they should not be "Rollfinked," that is dissected. The frenzy of the people continued the same at the beginning of the eighteenth century; they attacked the anatomists in Lyons and Berlin, and persecuted the professors to the point of death, for the people were under the delusion that they dissected the bodies of living men. A. von Haller had obtained an exhumed cadaver in Paris and in his preparations he was discovered by some over-curious person, who had made a hole in the wall in order to see what was going on in the room. The police being notified, Haller could only save himself from the galleys by flight. He relates that the chemist Beccher was obliged to flee from Würzburg because he had opened a cadaver. Even in the sixtieth year, the prejudice was so great that Professor Kaltschmidt, in Jena, found it necessary to set the university seal upon a cadaver when it was received, because otherwise the students dare not touch it for fear of being considered dishonorable. For the same reason they sent the syndic, or the professor of anatomy, to the place of execution, in order to seal the bodies immediately after death.

There were anatomic amphitheatres in Germany, in many cities, outside of the universities, and these served for the instruction of the barbers. Halle was the first German university to which such an institution was annexed. Upon the advice of Holtzendorff, Berlin received from King Frederick William I., in the first year of his reign, 1713, its amphitheater, which was used in the winter for the training of military surgeons and for anatomic lectures and demonstrations, and in summer for surgical instruction. Under the leadership of the Society of Science—the present Academy of Sciences—it rose so rapidly that in the second half of the century it was among the best in Europe. Its collection of anatomic specimens was very considerable, and contained the skeletons of the two largest soldiers of Frederick William I.; all mis-born creatures in the whole country had to be sent to the anatomic amphitheater in Berlin. Hanover followed in 1716, where in connection with the collegium anatomico-chirurgicum, an anatomic chamber was opened which received the bodies of criminals. When a cadaver came in (in the year 1721—only four in number) a public announcement was made inviting the laity to participate in the instruction. The fee for each dissection was twelve mariengroschen, for all together, two thalers. If the dissection was upon a female cadaver the price was increased because of the greater crowds; it cost twenty-four groschen to see the uterus and fetus of a woman who had died pregnant. The Austrian government took the initiative in the improvement of anatomic instruction and commissioned the faculty to deliberate as to how opportunity could be created for the young doctors, students and obstetricians to get better practice in "anatomic and surgical operations;" whereupon the Vienna faculty in 1718 recommended the erection of an anatomic amphitheater, together with a theatrum chemicum and a hortus botanicus. However, a special professor was not appointed, but the supervision of the anatomic amphitheater was committed to the professor of theory. Not until 1739 was the first chair of anatomy founded in Vienna. An anatomic amphitheater was dedicated in Breslau in 1745 and in Dresden in 1748, upon the founding of the collegium medico-chirurgicum. At the opening of the last named amphitheater, when the body of a decapitated woman was the subject of demonstration, the crowd of spectators was so extraordi-

narily large that on the following day the demonstration was repeated for ladies, when some did not shrink even from touching the cadaver. Hamburg built an anatomic amphitheater in 1771.

During the whole century the German medical schools experienced a *great scarcity of cadavers*, in-so-much that many had at their disposal only three or four in a year. This was owing to the prejudice among the people, the lack of hospitals, and the abolishment of the death penalty under Joseph II. and Catharine II. The circumstance that many criminals were sentenced to hang for a long time on the gallows, or to be buried under it, that some suicides were dissected by the authorities, increased the calamity. So few cadavers came to hand in Göttingen that A. G. Richter, as professor of surgery, instead of demonstrating his operations on them, is said to have illustrated the various incisions by the only method at hand, mostly with the shears and a piece of paper properly cut, and his amputations with a large turnip. Among the students there was naturally great distress. Their student days passed away and in winter they scarcely saw one cadaver, so that there remained to them only the atrocious method of exhuming the cadavers in the stillness of night, with or without the knowledge of the gravedigger. It was a misfortune for them if within the neighborhood of the university, from time to time, at least a few men were not beheaded. Abo, Finland, was especially celebrated in anatomy on account of its wealth of cadavers. There all persons who held lands under the crown, or enjoyed pensions, must bequeathe their bodies at their death to the anatomic amphitheater. The scarcity of cadavers has not ceased even in our time in many of the smaller universities; for as late as 1866 the laws in Mecklenburg-Schwerin were broadened in order to supply the University of Rostock with more cadavers. Charts had therefore to be used as substitutes, and the farther back in the century one goes the more closely does he find anatomic instruction limited to an elaboration of the anatomic charts of Vesalius, Fallopius and Eustachius. Later came the incomparably beautiful plates of Albin, on the bones and muscles, Haller's copper-plates of the arteries and Mascagni's lymph vessels. Meckel had illustrated the nerves, Zinn the eye, Scarpa the organs of hearing, and W. Hunter the phases of pregnancy. As a complete atlas, the only thing which they had at that time were the plates of Eustachius of the sixteenth century—the first anatomic copper-plates which we possess. After these had been regarded as lost for a hundred and fifty years, the pope presented them to his body physician, Lancisi, who first made them public (Rome, 1714). The best edition was prepared by our countryman, Albinus, who republished the plates after two hundred years, having had them redrawn. In 1793 Loder began to publish a large new atlas of the entire human body.

As early as the first half of the century different measures had been taken to provide against the scarcity of cadavers. The government of Saxony ordered in 1716 that the bodies of all criminals in the vicinity of Leipzig, executed by the sword or drowned in a sack (*Säckung*), should be furnished to the dissecting room at the cost of the faculty, and that all such bodies within a radius of four miles from Dresden should be supplied to the anatomic amphitheater in that city (1752). These regulations were extended to cover also the bodies of those who had hanged or drowned themselves, or died in prison; on the con-

trary, the bodies of paupers who had died in hospitals, were given only for the purpose of sections and not for complete dissecting. The abuse of allowing the bodies of hanged malefactors to rot, by which the whole neighborhood was tainted, was still very widespread until measures were taken to prevent the stench and to send the bodies to the dissecting rooms. Berlin had (1719) the bodies of the criminals, suicides and paupers, and later those from the Charité at its disposal; beside all these from within a radius of three miles, the dissecting room in Göttingen (1736) received the bodies of prostitutes and their illegitimate children. In the Vienna anatomic amphitheater they were somewhat negligent. One tried to throw the work on to another. When in 1742 the administration complained to the faculty that in that year not a single anatomic public demonstration had been given, although there was no lack of professors, demonstrators and substitutes, they excused themselves with the reason, among others, of a lack of cadavers. Immediately there came a royal order that all who died in the Burgher Hospital, Beckenhäusel, and St. Mark's Hospital, together with all the bodies of criminals executed in Vienna and its vicinity, should be delivered gratuitously to the university. This decree was in 1749, through Van Swieten's petition, extended to all the hospitals of Vienna, and it became their duty, in a dearth of malefactors, to supply the bodies of all paupers for anatomic and surgical operations; the city magistrate, under whose direction the public hospitals stood, protested. This kind of decree of the state was of the greatest importance in view of the mania of the people, and served to dissipate their mistaken ideas.

From foreign countries also there came a fresh stimulus. This consisted in the enormous progress of the natural sciences in France, which some thirty years before the revolution was made by all classes. The spread of the movement was at that time so rapid that the sciences were considered an essential groundwork of a good education, and entirely superseded the old classical studies. You would seldom find anyone in France who understood Greek, but all the lecture rooms of the physiologists and chemists in Paris were full. When A. Petit opened his anatomic lectures in 1768 the amphitheater was overcrowded. The sessions of the Académie were so popular in 1779 that after a few years the number of admittance cards had to be diminished. Even gentlewomen hastened there in order to have the composition of a mineral or the discovery of a new salt demonstrated. Whatever came from Paris was imitated in Germany. No wonder then if soon after, in the year 1780, the Duke von Weimar called Professor Loder from Jena to give at court an anatomic demonstration concerning the brain, and the Duchess von Weimar journeyed to Jena especially to attend a clinic demonstration on some children in the anatomic amphitheater. Perhaps Goethe's influence was a factor in the movement. When crowned heads occupy themselves with that kind of amusement, it can not fail to have a favorable reaction upon the people.

The prejudice against dissection was not less strong in England than in Germany, and there it was held over the criminal to sharpen his penalty. In the year 1779 it happened in London that two young physicians who had bought a cadaver to dissect it at home, had their windows broken open at night and them-

selves denounced as hangman's servants; a third had his house attacked by the mob and scarcely escaped out of it with his life. In spite of the great number of executions in London, not enough cadavers were to be had, so they were surreptitiously stolen from the graves and with great secrecy sold to the anatomists. The dissection could be performed publicly only on the bodies of murderers, which had been supplied to the College of Surgeons and were to be used for the lectures. The usual price for a cadaver was from two to five guineas, sometimes even more, because those who exhumed the bodies were in danger of being caught. (Anatomic specimens were enormously expensive; in 1785 at the auction of the Surgeon Hawkins three lymphatic glands injected with quicksilver, and an almost complete mounted skeleton which J. Hunter bought, were sold for eighty-five guineas.) In Edinburgh the prejudice against dissection appeared even stronger than in London, and scarcely a single cadaver a year was available, so that the instruction in preparations was almost discontinued. The younger Monro is said at one time to have given one hundred and twenty-four lectures over one single cadaver! On the other hand the University of Leyden and above all, Paris, were more fortunate; the hospitals were obliged to furnish so many cadavers to the latter university that anatomy could be studied to excellent advantage. The students there demonstrated and prepared the muscles in turn. Copenhagen obtained in 1736 an amphitheater for anatomy, with the cadavers of the fortress laborers and other prisoners. Moscow obtained a similar one in the year 1764.

Pathologic anatomy, as well as descriptive anatomy, suffered limitations through the prejudice against dissection. The rulers in Europe indeed set a good example by allowing the bodies of their own relatives to be opened. The Italians seldom opposed dissection and although the intelligent Germans and French followed them, there remained among the German people, to the end of the century, a strong prejudice, which the physicians combated in the newspapers. Thus Baldinger thought many otherwise very intelligent officers would not have fought in the Seven Years' War and most of the soldiers would have run away if they had supposed that after their death their bodies would be dissected. The soldier would rather allow himself to be trampled by horses on the battlefield than to allow the dissection of his body. Exceptions were few and were found mostly among the more or less intelligent regiment commanders, although permission was given to make dissections in the Prussian field hospitals. Among the Austrians the physicians were obliged to dissect important cases, to report concerning them to the recording surgeon and to send specimens to the Medico-Surgical Academy in Vienna. In Russia the Greek Catholic and the Hebrew families never gave permission for dissections, therefore in the hospitals at St. Petersburg and Wilna only the bodies of those of other religions were available. Even as late as the last half of the century, many women died in the third or fourth month of pregnancy from simple retention of urine and no physician was able to discover the cause of this trouble. Sections first taught that the flexion of the uterus caused this trouble, which has since been remedied by mechanical means. Pathologic collections were somewhat rare. When Peter Frank was a teacher in Bruchsal he made such a collection for the

surgical school there, and later also for the public hospital in Vienna. Joseph II. bought for 30,000 guilders a collection of the most beautiful wax specimens of the human body, from the famous Abbé Felix Fontana and the anatomist Mascagni in Florence, had it brought to Vienna on mules and presented it to the Medico-Surgical Academy. In Austria in 1811 every medical and surgical institution of learning was obliged by law to establish a pathologico-anatomic cabinet and the professor was bound to prepare specimens. The growing popularity of dissections in the last decades contributed greatly to progress in pathology and surgery, because it made clear the nature, seat and origin of many diseases hitherto not at all understood.

The anatomists paid almost no attention to the practical needs of the surgeons. As this history has previously mentioned, there existed in Germany in the eighteenth century not a single text book in surgical anatomy, except the work of J. Palfyn, which appeared in Dutch in 1718 and was translated into German in 1760. The first complete, although very brief work of this kind, is said to be the Handbook of Frederick Rosenthal, published in the year 1817. This is incorrect, in so far as the Hanover physician, Otto Just Wreden, wrote a surgical anatomy in the year 1736, which I believe was the first in Germany. The full title of this forgotten and unimportant book is "Brief and clear instruction in the parts of the human body, with respect to their structure and position and also their functions; what concerns the solid and the fluid parts and also the soul. Dedicated to the best interests of surgery. Hanover, second edition, 1743." Wreden was director of the anatomic room in Hanover and instructed the surgeons. He served as field physician with the royal troops on the Rhine, and there in his leisure hours he wrote that book whose second part he called "Anatomy in particular," because everything which had no relation to surgery was left out of it. Wreden saw how difficult it was for the surgeon to find his way in anatomy and how even the best among them made erroneous diagnoses because, although they understood the separate muscles, they did not know their position with respect to one another. He published the descriptive anatomy first and gave 140 pages to a topographical description of the human body; at the end the physiology followed.

Under the conditions above described an exhaustive study of anatomy was not to be expected of German students. For the most the proper method was lacking, there was little opportunity to prepare specimens and they relied principally on charts. There was scarcely any idea in Germany of the useful application of anatomy to the practical sciences, so that not only was the groundwork lacking to the students in surgery, but even the fertilizing kernel of this science was extracted. In the first half of the century conscientious surgeons, by reason of their lack of anatomic knowledge, scarcely trusted themselves to perform the simplest operations. Partly in consequence of this fact many life-saving operations were neglected in the great German hospitals. It was the itinerant mountebanks who considered the most difficult and delicate operations as their peculiar heritage and although they sometimes murdered the people, yet, all things considered, they were in a certain measure justified as operators.

(To be continued.)

SELECTIONS.

Deep Lesions Produced by the Roentgen Ray.—It is seldom that an issue of the *Bulletin* of the Johns Hopkins Hospital does not contain at least one paper of unusual merit and originality. The current issue has for its *pièce de résistance* an admirable illustrated article on the effects of the X-ray upon osseous structure by Mr. T. C. Gilchrist, Associate in Dermatology at the Hospital. The author finds 22 recorded cases of superficial effect, but his own is the first in which the deeper effect of the X-ray have been demonstrated by a radiograph. His patient, a male, was an X-ray operator, the eruption or dermatitis occurring on the dorsal surface of the right hand, wrist and lower fore arm, after frequent and long continued exposures. There was hyperemia and swelling of back of hand, inflammation of hand and fingers; the integument became dark brown in color and later exfoliated. There was no pain at first, but later the pain was so severe as to cause the patient to stop his work. There were aching, shooting and throbbing pains. The bones of the hand were very tender on pressure, particularly the first phalanges of the index and second finger and the carpal bones. The movements of the hand became so limited that it was practically useless for some weeks. Sensation was also much impaired, but after exfoliation occurred it recovered again, but only gradually. Recovery of all the lesions has been very gradual indeed.

The photographs have revealed what has never been observed before, viz., a distinct osteoplastic periostitis, and probably an osteitis, particularly of the first and second rows of phalanges of the index and second fingers, also of the heads of metacarpal bones of the same fingers, and judging from the symptoms, even of some of the carpal bones.

This then accounts for the severe symptoms, the aching, throbbing and shooting pain which prevented sleep. The density of these bones also has been increased, showing that even bone tissue has been effected.

A complete demonstration is thus afforded of the powerful, piercing character of the X-rays, and the severe, painful symptoms which have been described by other observers are probably due to the inflammation of the periosteum, and possibly the bone, besides the softer tissues.

This inflammation has also extended into joints, which would explain the loss of movements, and pain, when they could be used later.

As the result of these observations, it proves that the X-rays are even more powerful than have been generally thought, that the deleterious effects can in some cases be quite serious, and that the cutaneous manifestations are not the most severe of the lesions, but those of the deeper tissues, and particularly of periosteum and bones, being more severe.

He consulted with Professor Ames, Associate Professor of Physics in the Johns Hopkins University, who, after reviewing all the facts of the case, kindly wrote as follows concerning the present theory of the X-rays:

"The radiation in an 'X-ray tube' may be divided provisionally into three classes: ether-waves, which may have wavelengths from 150 to 800 mm. approximately; kathode rays, which undoubtedly are streams of matter, electrically charged; X-rays, about whose nature there is no conclusive evidence at the present time. If the walls of the tube are thin enough and of suitable material, all these radiations will emerge and pass into the surrounding air. It is a matter of doubt if the kathode rays observed outside the vacuum-tube are the same as those inside; but the inner ones undoubtedly cause the outer ones. There is no evidence that X-rays carry with them particles of matter, or that they directly cause a stream of particles; in fact, all known facts seem to point to the belief that they are ether-waves of extreme shortness."

It will thus be seen that the opinion expressed here does not make it possible for the X-rays themselves to produce such deleterious effects as have already been described, but Dr.

Ames mentions the fact that the kathode rays are undoubtedly streams of matter electrically charged. Here then we have some possible grounds for the theory that the lesions may be due to the entrance of particles (platinum in our case) into the injured tissues, and that the kathode rays which accompany the X-rays may be the cause of the trouble, and not the X-rays themselves.

On clinical grounds there is considerable support for this, at first sight, improbable theory. If the lesion extends at all deeply, it leads to the formation of ulcers, which are extremely intractable, and they may be due to irritating particles still present in the tissues.

We do not think that the possibility of injury ought to deter one from using these wonderful rays in surgical work, because only a few have been affected out of thousands who have been exposed to them. By keeping, as Thomson says, some distance away from the rays, injurious effects will hardly follow their use, and when the exposure is for a short time, unless, as may happen in all other diseases, idiosyncrasy plays a prominent part.

When the hand is viewed two or three times near a new Edison bulb, through a tungstate of calcium screen, after four or five minutes a tingling sensation is distinctly felt throughout the dorsum of the hand; this symptom lasted for ten or fifteen minutes and passed away without any further results. It occurred to him that X-ray operators and experimenters should expose to the rays the palmar surface of the hand, which is protected by a much thicker horny layer, rather than the back of the hand, which is much less protected.

In conclusion we would strongly advise all X-ray operators and experimenters who develop any special idiosyncrasy, to abstain from their use if they find that the slightest deleterious results follow an exposure to them.

Nodal or Bursal Pain.—In *Guy's Hospital Gazette*, January 16, Mr. Golding-Bird treats of this subject, showing that antiseptic surgery has effected a reduction in the number of cases, as well as in their duration. Pain, he remarks, is always the most important element in the case, from the patient's point of view; but we all know it is a subjective, not an objective one; not a fact, but a feeling. You can not dispute facts, but you can dispute a pain in a number of cases. There is no doubt that the patient's personal equation largely enters into the question. Many people seem to have no "inhibitory" power over their feelings; consequently it has been the fashion to class such cases together as "hysterical," whether the subject be male or female. I consider that antiseptics have helped to alter this state of things, and the use of them has given "hysterical" people their character again; for the surgeon, without risk, explores the seat of pain, and at times drops upon a cause he never suspected. A. B., female, aged 30 years, nurse from a provincial hospital, was last year a patient in Guy's, suffering a great deal of pain in her hip without obvious cause. She was not of the hysterical type. Cases such as this are common in general practice, and one must be carefully on one's guard against thinking too lightly of them. The history of this case was that four months before admission the patient had entered a room during the night while a portion of the flooring was raised for repairs. She had fallen with one leg through the floor and had bruised her hip severely. She went on with her work, but at last persistent pain made her seek hospital treatment. Her hip was flexed, she had spasmodic pain in thigh, and had to take morphia. There was no limitation of movement. When first seen as out-patient the diagnosis of hysterical hip was given, because passive movements became greater in amplitude when the patient's attention was diverted, and because nothing objective could be discovered. Patient was examined a fortnight later by the surgeon, who confirmed the diagnosis so far that the movements were all perfect, and this

thought arose: Is this an exaggerated case which would only be cured by substantial damages paid into court? For when you suspect that a patient wants to take himself into court you should be exceedingly careful, and may discount some of his statements. In this case there was nothing wrong with the joint, and no swelling over it. It is true that there was a certain amount of tenderness in the groin, but this was totally unconnected with the movements of the hip-joint. The great trochanter was not thickened, but on its outer side I hit upon a tender area of the size of a half-penny, which was exquisitely painful and gave a creak on rubbing. This left no doubt in my mind, and I diagnosed bursitis under the gluteus near its insertion. The treatment available was either counter-irritation or operation. The latter method was chosen, and making an incision over the tender spot, I entered the bursa, which was found to be large and spread out under the gluteus maximus. This was scraped out and irrigated with perchlorid and closed up again. Immediate union was obtained and patient was entirely free from all pain and seemed on her discharge quite cured. With regard to the question of connection between bursal and local or nodal pain, it is interesting to note a point on the history of osteomata, which, as you know, are found commonly on the long bones, as the tibia and femur in positions corresponding to the epiphyseal lines. A boy will be brought up exhibiting an osteoma, which his mother will declare has only existed for four or five days, whereas it is more likely to have been present as many years. On manipulation, you will probably get the characteristic creak on rubbing the top of the boss. Whenever a bursa becomes developed on a prominence pain begins synchronously, but osteophytes may grow from the femur under the vastus internus, and may attain a very large size before there is pain; and this, when it comes, is either due to over-stretching of fascial coverings and the appearance of a bursa. Counter-irritants will have only a temporary effect in these cases, and the best treatment is to cut down and remove the tumor.

PRACTICAL NOTES.

Contraindications for Trional.—L. Kæmpffer states that patients with cancer who have reached an advanced stage of cachexia, are unable to bear the usual dose of trional (1 gram), which produces distress, pain, cardiac palpitations, and acute agitation, amounting to delirium in some cases and continuing all night.—*Semaine Méd.*, February 17.

Concentrated Tincture of Iodin for Cavities.—Dr. A. Ricci has been using a tincture of iodine much stronger than that usually employed: (1 part metallic iodine to 5 parts alcohol), in the treatment of the cavities left after operations on glands, bones, articulations, etc., and announces that he has found it exceedingly effective in promoting healthy growth of the tissues.—*Semaine Méd.*, February 17.

The Sclerogenic Method Applied to Tuberculous Osteoarthritis.—Ziématzky combines Lannelongue's injections of chlorid of zinc with Bier's bandages, and has been very successful with them in the early stages of tuberculous osteoarthritis, when asepsis is easy. More advanced cases are not adapted to the treatment.—*Presse Méd.*, March 3, from *Rev. de Chir.*, No. 8, 1896.

Ott's Method of Recto-vaginal Exploration.—Two years of this method have convinced its author of its extreme value and he therefore recommends it again to the profession. The middle finger is inserted in the rectum and the index of the same hand in the vagina. The combination of these fingers with the other hand on the abdomen, enables the parts to be explored with great accuracy.—*St. Petersburg Med. Woch.*, No 1, 1897.

Expectorant and Soothing Potion.—Syrup of ipecac, 8 to 10

grams; syrup of tolu, 20 grams; potassium bromid, 1 gram; brandy or rum, 20 grams; linden-water, 75 grams. One teaspoonful every two hours. This potion is rarely nauseating and never acts as an emetic. The amount of ipecac should be decreased to 5 grams for children, and the alcohol and bromid should also be diminished according to the age.—*A. Espagne, Semaine Méd.*, February 10.

Method of Determining the Amount of Deafness.—We notice in an exchange that a simple means to determine the amount of deafness is to insert a tuning fork in the mouth of a Y-shaped tube and place one of the branches in your ear, and the other in the ear of the patient. The tuning fork is then struck, and the one that ceases first to hear its vibrations tells when they become inaudible to him, while the other notes the length of time until he ceases also to hear them. If the physician has tested his ear previously with normal persons and others, he knows exactly his own hearing capacity and whether it belongs to the category of good, medium or bad, and uses this for his standard.

General Bath after Operation on the Pleura, to Wash out the Cavity.—Dr. Seemann places his patient, after operating for empyema, in a general bath for ten to fifteen minutes, thus allowing the pleural cavity to be thoroughly cleansed by the washing it receives from the water drawn in and expelled with each breath. The water is first boiled and then cooled to 34 or 37.5 degrees C., and the tub and the skin of the patient made aseptic beforehand. The lavage is much more complete and the patient not so exhausted as with the usual methods.—*Semaine Méd.*, February 17.

Oxygenated Water in Vomiting of Pregnancy.—The usual dose is 5 to 30 grams of the oxygenated water (10 volumes of oxygen), diluted with any liquid that does not alter the composition, and sweetened with sugar or lemon syrup to disguise its astringent and metallic taste. To arrest the vomitings of pregnancy, a teaspoon and later a tablespoon of the oxygenated water is added to a liter of water and taken as a beverage with the meals. The effect is rapid, but somewhat inexplicable.—*Gaz. Méd. de Liège*, February 18.

Imperfect Assimilation in Infants.—The combination of yolk of egg and olive or cottonseed oil made into an emulsion is found very useful in cases of rickets or chronic malnutrition in infants. The emulsion can be made as follows: olive oil, c.c. 60; glycerin, c.c. 30; yolk of one egg. Make an emulsion, and add one-half minim of creosote to each dram. Occasionally it is better to use a smaller amount of creosote when this agent is not well borne by the stomach. A full teaspoonful of the emulsion is given three times a day after feeding. The preparation seems to be readily tolerated, even when the stomach is irritable.—*Practitioner*.

Dulcin for Diabetics.—Dulcin (paraphenol-carbanid, discovered by Bellinblau of Warsaw), is 250 times sweeter than sugar. It is perfectly harmless in the doses in which it is given to diabetics as a substitute for sugar, and numbers of diabetic patients have been using it over a year to their satisfaction and benefit. The taste is more like sugar than the taste of saccharin. It is a crystalline powder, dissolving at a temperature of 173–174 degrees; in 800 parts of water at 15 degrees; in 50 parts of boiling water, and in 15 parts of 90 per cent. alcohol. The maximum dose for a patient has been 0.75 gram, administered in pastilles of 0.025 milligrams, equal to 5 grams of ordinary sugar.—*Journal de Méd. de Paris*, February 7.

Venesection and the Simultaneous Introduction of an Equal Amount of Saline Solution.—The reports recently presented at the Paris Académie de Médecine of the cases of uremia, pneumonia, cerebral rheumatism, pyelitis and severe hemorrhage arrested, and patients saved at the brink of death, by the withdrawal of 600 to 1000 grams of blood from one arm, while an equal amount

of Hayem's solution (7 grams sodium chlorid and 7 grams sodium sulphate to the liter of water), is introduced into a vein in the other arm, read like miracles. The saline solution evidently confers increased coagulability upon the blood, to which its effect in arresting hemorrhages is probably due.

Effect of the X-ray on the Central Nervous System.—Some interesting experiments are reported from Russia, that tend to show that the X-ray has a quieting effect on the central nervous system. A frog was placed in a small wooden box on which the ray was directed, while the control frog, in a similar box, was protected from the ray by a sheet of lead laid on top of the box. It even counteracted the effects of strychnin, as no traces of intoxication were noticed in the frog after the administration of 0.04 milligrams, and exposure to the ray, while the control frog was found in tetanic convulsions. Half an hour's exposure before administering the strychnin rendered it possible to increase the dose, without intoxication.—*St. Petersb. Med. Woch.*, No. 1, 1897.

New Five-minute Process to Sterilize Water.—Bromin added to water will kill all the pathogenic germs in it in five minutes, and the addition then of ammonia will neutralize the bromin. Schumburg, who makes this announcement in the *Deutsche Med. Woch.*, of March 4, has tested the process 200 times with river water at Berlin, to which germs of all kinds had been added, including cholera and typhoid germs. He uses 0.2 c.c. of the following solution: Water, 100; bromin, 20; potassium bromin, 20, for each liter, and then neutralizes it with an equal amount of 9 per cent. ammonia. The water is then perfectly clear, the taste is scarcely altered at all and the amount of bromin salts remaining in it is so small—0.15 per liter—that they do not affect the taste nor health. Marsh and other water containing ammonia requires a little more bromin to counteract it. He recommends the process as rapid, effective and cheap for sterilizing water for drinking in the army and on board ship in unhealthy localities and for medical and surgical purposes.

Nitroglycerin in Angina Pectoris.—Schott of Nauheim, in the *Therapeutische Monatshefte*, has found that: 1, nitroglycerin acts best in pure angiospastic forms of angina pectoris, not so well in cardiac pain due to aortic aneurysm, and is often of no use at all in the pure motor neuroses of the heart; 2, its action on different people can never be predicted; 3, if toxic symptoms appear after a small dose, it is best to discontinue the drug altogether; 4, if no toxic symptoms appear, gradually increasing doses can be given safely; 5, the form of administration is important, as Schott has found it to be most active given in a liquid medium, and combined with tinct. capsici, spir. rect., and aq. menth. pip.; 6, it acts surprisingly quickly and its action is generally at its height after two or three minutes; 7, it is generally necessary, when several small doses are without effect, to give larger doses. In some cases a single large dose acts best; 8, it is certain that much more than 1 mg. (1-65 of a grain) can be given as a single dose.—*British Medical Journal*.

Success of Itrou in the Treatment of Gonorrhoea.—"Werler" announces that fifty cases treated by him with itrou (citrate of silver) were relieved of the tormenting desire to urinate, and the urethritis gradually healed, with none of the complications that usually accompany it, such as abscesses, cystitis, epididymitis, etc., and even chronic cases were arrested by it and strictures thus prevented. He also reports surprising improvement in cases of chronic cystitis, after lavages of the bladder with itrou. He commenced with weak solutions (0.025 to 200), kept in a colored bottle, and injected four times a day, increasing the strength of the solution to 0.03 and 0.04 per 200. The patient is instructed to urinate before he makes the injection, which he is to retain several minutes in the urethral canal.

Werler adds that the itrou exerts its bactericidal power into the depths of the mucosa, and that he considers it superior to any other known treatment for gonorrhoea, including nitrate of silver, potassium permanganate, argonin, argentamin, etc.—*Presse Méd.* from *Dermat. Ztsch.* Nos. 5 and 6, Vol. iii.

Clinical Examination of the Pregnant Woman.—Several pages are devoted in the *Presse Méd.* of March 3, to a study of this subject by E. Bonnaire, *Accoucheur des Hôpitaux*. Among the questions to be asked we notice the age at which she first walked, the profession (washerwomen are subject to edema, others to lead-poisoning, etc.), tuberculous and syphilitic antecedents, bearing in mind that pregnancy has a tendency to arouse and aggravate old diathetic conditions. When there were troubles in walking in early childhood, examination of the skeleton becomes important on account of the presumption of rachitis. He describes the technique of inspection, palpation, auscultation, vaginal and rectal exploration, ascribing importance to each in their turn and mentioning that the bladder and rectum should be empty. When the woman is very obese, certainty can be secured by lifting the uterus *en masse* with the finger on the cervix the second or third month. A non-pregnant uterus is *light*, lifted in this way.

Bicarbonate of Soda as a Dressing for Purulent Wounds.—A Russian military surgeon, N. V. Gueorguievsky, accidentally discovered in the course of treating a severe phlegmon of the index and palm of the hand, that a compress wet with a 2 per cent. solution of bicarbonate of soda will arrest pain and suppuration almost immediately and lead to complete cure. He considers its action more effective than any other antiseptic, including iodoform, phenic acid, etc., in the treatment of purulent wounds. Whenever he suspended it to resort to iodoform, or any other treatment, the suppuration recommenced, to be arrested again by the resumption of the magic compress, as his patients called it. He first incises and cleans out all the pus and then applies the compress to the cavity and surrounding parts.—*Semaine Méd.*, March 3.

Flessinger's Treatment of Dyspepsia with Injections of Warm Water, Etc.—The "motor dyspeptic" takes a couple of injections of warm water, $\frac{3}{4}$ liter in each, and retains them fifteen to twenty minutes, an hour before dinner and supper. After the meal he reclines on a sofa and practices gymnastics of the abdominal muscles for twenty minutes, by raising himself slowly to a sitting posture and then slowly reclining again two or three times in succession, resting a minute or so, and repeating, thus exerting strong tension on the muscles. A general feeling of invigoration results; the tonicity of the muscles of the alimentary canal is increased, especially those of the stomach, as is shown by the almost immediate evacuation of gases. If there is acid fermentation the patient drinks beside, in small gulps, a series of three glasses of hot water, twenty minutes apart, sweetened or with an infusion of chamomile, vervain, orange leaves, fennel or anise. The tongue clears off and dinner is taken with relish half an hour after the last glass. The hot water is useless in motor dyspepsia alone, but is exceedingly efficacious in case of stasis and acid fermentation, and also in "hyperchlorhydrie."—*Gaz. Méd. de Liège*, February 18.

Simple Method of Measuring the Arterial Pressure.—If the hand is dipped into quicksilver, the pulse can be felt in the fingers. As the arm is further submerged, the sensation of the beat of the pulse rises along the arm until it is felt above the wrist. V. Frey has applied these facts to scientific measurement of the arterial pressure, and states that greater accuracy can be secured in this way than with the sphygmograph. As the hand is submerged into the quicksilver, there is a certain point where the pressure of the blood within and of the mercury without, exactly balance each other. At this point the circulation is arrested and the pulse-wave reflected back. If the hand is inserted into the quicksilver to the tops of the meta-

carpal bones, hand and arm extended and held as vertical as possible, the pulse is felt in the ungual portion of the middle finger and the length of the middle finger represents the height of the column of quicksilver which holds the arterial pressure in equilibrium. The hand is exposed to an even pressure all over, and the vessels are thus less liable to external disturbances than with the sphygmograph, and the test also involves a larger extent of surface.—*Cbl. f. Phys.*, January 9.

Diagnosis of the Location of the Placental Attachment by External Palpation.—Tribondani has been studying this subject at the Clinica Ostetrica of Pavia, where he is first assistant, examining the uterus of the patients immediately after the expulsion of the fetus to confirm his diagnosis made from external palpation beforehand. He announces as the result of his experience that the location of the placental attachment can be accurately determined by the following indications: 1. It is attached to the posterior wall if the tube and round ligaments are found on the anterior surface of the uterus, converging toward the top; if the anterior surface is rather flat, and if the beat of the fetal heart, the parts of the fetus and its movements, can be clearly distinguished from the front. 2. It is attached to the front wall if the tubes and the round ligaments are found on the sides of the uterus, parallel to its vertical axis, if the anterior wall is very convex, and the fetal heart and movements, and the fetus itself, are not easily distinguished from the front. 3. When the placenta is attached to the fundus, the latter is remarkably convex, almost hemispheric, and the points of attachment of the tubes and ligaments are much below its edge. 4. When the placenta is attached to the side wall, the uterus is very prominent on that side, and the attachments of the uterine adnexa are found much higher on that side.—*Gazzetta degli Osp. e delle Clin.*, February 7.

How to Avoid Taking Cold.—The *fin de siècle* toilet is not complete without rinsing the mouth and spraying the nasal passages and the throat with an antiseptic solution night and morning. By these means the upper air passages are kept in an antiseptic condition, unfavorable to the development of germs, and disease is prevented. G. Lemoine in the *Nord Méd.* of February 15, states that numbers of persons by these simple precautions have passed through the winter and rainy spring without once catching cold, although they had previously been extremely sensitive, and troubled with severe colds much of the time. He recommends to rinse the mouth with a glassful of 50 grams Labarraque's solution mixed with 1 liter of water, or the following: Thymol, 0.50 gram; alcohol 20 grams; water 1 liter. With an ordinary toilet atomizer the nasal passages and upper part of the throat should be thoroughly sprayed with some solution like the following: Phenolsalyl, 0.50 gram; chlorid of sodium 3 grams; distilled boiled water 500 grams. He adds that the teeth should be well brushed, and the fingers never put in the mouth or nose. A few menthol drops should be carried in the pocket and dissolved in the mouth occasionally. He concludes with the remark that a friend of his has always succeeded in breaking up a cold in the early stages, by taking during the first day four to six capsules or pills of essence of turpentine in addition to the rinsing or gargling and spray, with a glass of purgative water the next day, followed in a few hours by a 0.50 centigram

of quinin.

Leucocytosis in Diphtheritic Infection.—A. Filé announces that leucocytosis is always associated with diphtheritic infection, its intensity proportionate to the severity of the infection. He has always found it more pronounced in cases of diphtheritic croup than in mere throat diphtheria. The leucocytosis increases with the progress of the disease, reaches its height at the crisis and disappears as convalescence supervenes. The degree of leucocytosis is almost always in direct proportion to the extension of the false membrane, and does not depend upon

the age of the child nor upon the temperature. Neither is there any relation between the degree of the leucocytosis and the presence of other microbes in cases of mixed infection, but on the other hand, when the diphtheria is complicated by pulmonitis, the leucocytosis is more marked. The graver the infection the greater the increase in the number of polynuclear leucocytes. During protracted convalescence the number of mononuclear leucocytes in the blood increases notably, showing its renewal. The old leucocytes while retaining their shape, do not stain, or do so slowly, showing their lack of vitality. Eosinophilous cells are almost entirely absent in the leucocytosis that accompanies diphtheria. Injections of antitoxin produce hypoleucocytosis in half an hour, followed by hyperleucocytosis, at its highest point five to six hours after the injection and decreasing in the twenty-four hours following, without reaching the point it had attained before the injection. In fatal cases the leucocytosis persists intense to the end. The number of leucocytes is probably not an indifferent factor in the production of immunity. Healthy children inoculated with the antitoxin, as a preventive measure, have a slight leucocytosis after the injection, returning to normal in twenty-four hours. Non-diphtheritic anginas are marked by hypoleucocytosis, and this fact may serve to differentiate them, at an early stage, of course before the injection of any antitoxin.—*Gaz. degli Osp. e delle Clin.*, January 10.

Sclerogenic Treatment of Hernia (Laoncelongue).—The treatment of hernias with injections of chlorid of zinc has passed beyond the experimental stage and its success is now definitely established and is destined to revolutionize the treatment of inguinal hernia. The patient remains in bed eight to ten days after the operation and is then dismissed absolutely cured, with no further need of bandage or truss. The operation is so simple that it can be performed by any careful practitioner, and it is applicable to all cases and all ages. A witness describes a recent operation of the kind performed by Professor Lannelongue in his service at the Hospital Trousseau, the patient a lad of 14, affected with right inguinal hernia. The operation, watch in hand, lasted four minutes and a half, including the professor's explanations. The patient put to sleep, which is not strictly indispensable, and the toilet of the region performed, hair shaved, etc., the operator convinces himself that the hernia is absolutely reduced and orders his assistant to place his finger on the internal inguinal ring in such a way as to protect completely the peritoneal cavity. He then finds the cord as it enters the internal inguinal ring and holds it in his left hand, so that he can operate inside and around it without injuring it. The Pravaz syringe is taken in the right, filled with a one-tenth solution of chlorid of zinc (always the same in these sclerogenic injections). The needle is inserted perpendicularly to the pubis and carried down to the surface of the bone, when the point is deviated toward the under side of the cord and there, in the fibrous tissues surrounding it, five drops of the solution are injected and the needle is withdrawn. The same process is repeated three or four times each side of the cord, the points for the injections previously marked with a dermatographic pencil if necessary. The ring is thus girdled with a row of eight to ten injections, and thirty to forty drops of the solution are injected. The first injection is made in the upper abdominal wall on the upper edge of the pubis, toward the pubic spine, in the internal ring of the inguinal canal between the pillars. The second is made a little lower on the pubis about one centimeter from the first, and the third still lower toward the origin of the descending branch of the pubis. Three other injections are made inside the cord, which is pulled out of the way with the left hand. The needle is again inserted as far as the bone, still avoiding the cord, and its point is again deviated in such a way as to make the injection behind the cord in the fibrous tissue immediately in front of the periosteum. None of the liquid finds its way into the peritoneal cavity owing to the pressure of the assistant's finger, who realizes the importance of his task, and there is nothing more to be done but to apply a moist aseptic cotton tampon. The region of the injections is dressed with a compress of iodoform gauze, cotton and an aseptic bandage. Eight days in bed, suppression of the bandage and the child is definitely cured of his hernia. There is no cord to be avoided in females.—*Journ. de Méd.*, February 14.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the Association living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, APRIL 3, 1897.

THE ANTIVIVISECTIONISTS AGAIN.

On March 22 last Mr. GALLINGER of New Hampshire (Ecl. Med. Inst. of Cincinnati, Ohio, 1858 and New York Homeo. Med. Coll. 1868) introduced a bill in the United States Senate (S. 1063) for the further prevention of cruelty to animals in the District of Columbia, which was read twice and referred to the Committee on the District. This is the same bill as S. 1552 of the Fifty-fourth Congress which was reported favorably by Mr. GALLINGER from the District Committee of the Senate May 26, 1896, but which failed to obtain consideration during the short session.

The soft hearted and well meaning but narrow minded agitators of the Humane Society recognize from the manner in which the subject was handled last year in the sub-committee of the Senate, that they possess a friend at court, and there is no doubt that every effort will be directed during the sessions of the present Congress to have their bill brought before the House of Representatives with the stamp of the Senate's approval. The bill prohibits all experiments in the public schools and exhibitions to the general public. It prohibits vivisection of vertebrate animals without anesthetics, excepting inoculation experiments, tests of drugs or medicines, and during the progress of recovery from tests of surgical procedures. It requires experimenters, officers of the United States and of the District of Columbia excepted, to procure a license from the Commissioners of the Dis-

trict, and to make reports to the said Commissioners. The President of the United States is to appoint four inspectors, to serve without compensation, to inspect all places where experiments are carried on in the District, and to report to him from time to time the result of their observations, which should be made public by him.

The Senate Committee embodied in its favorable report of last year many extracts from absurdly exaggerated accounts of the observations made by sympathetic and horror-stricken members of the Humane Society in the laboratories of Paris and other European cities, and urged legislation to put an end to such atrocities in the District of Columbia. All the arguments in favor of the bill were couched in language that would be warranted only by the acknowledged or proved existence in the District of abuses to be remedied by its provisions. To such arguments is evidently due the support of many well meaning men, like the village doctor in Northern New York who humbly petitions Senator McMILLAN "to use his influence for the bill now pending to restrict the barbarous and useless practice of vivisection in the District. The practice is brutal and brutalizing to all concerned in it," etc. To similar assumptions or insinuations, or to intentional misstatement of the intent of the bill, is no doubt due the support given to it by the signatures of many notable persons in the District. A committee representing the scientific societies of the District considers that these signatures, gathered by lady canvassers in two days' time, can hardly be regarded as "the deliberate judgment of the distinguished jurists, clergymen, army officers, and others who attached their names to the petition." Indeed it is known that many who affixed their signatures were led to believe that the main object of the bill was to prevent vivisection in the public schools.

These scientific societies claim that there is no abuse of the right to experiment on living animals in any of the laboratories of the District. They invite investigation, and suggest that justice to themselves and to the biologists of this country required the Senate Committee to determine the existence of abuses prior to recommending legislation which would place honorable and humane men before the world in the character of fiends, whose cruelties required Congressional action for their restraint. The AMERICAN MEDICAL ASSOCIATION, at its meeting in Atlanta, May 7, 1896, protested against the passage of this bill or any modification of it "unless it shall first be shown by an impartial investigation that cruel and unnecessary experiments are being performed in the District of Columbia, and that existing laws do not provide suitable punishment for cruelty to the domestic animals." Medical men could smile at the sentimental outpourings and sensationalisms, the ignorance and mental limitation of the members of the Humane Society

but for the fact that such agitators may do much to retard the progress of medicine. It is asserted that no advance has been made in medical knowledge in the laboratories of the biologists; that biologic experiments have retarded rather than advanced abdominal surgery; and that the only value possessed by the antitoxin of diphtheria is a commercial value to those who deal in it. Memorials and protests from all the medical and scientific bodies of the country have already fully answered all the arguments adduced in behalf of the bill; but irrespective of these, the testimony of Mr. DABNEY, Acting Secretary of Agriculture, of itself ought to have sufficed to file the bill away with the records of the forgotten past. He pointed out that the bill, while ostensibly local legislation, would affect principally the work of the Executive Departments, and particularly the investigations of the Department of Agriculture. He explained how impossible it would have been, under such restrictive legislation, for the Bureau of Animal Industry to have done its work in suppressing pleuro-pneumonia which some years ago was so fatal among cattle, or in preventing the Texas fever which so demoralized the cattle interests of the West. "Are the vital interests of agriculture in the whole of the United States to be made subservient to the demands of an over-zealous and intolerant local society, which appears incapable of taking a broad and liberal view of the subject?"

But for the intervention of the friend at court such testimony on the part of a high Government official would have immediately quieted the harmful and unnecessary agitation. As the formal protest of the AMERICAN MEDICAL ASSOCIATION has been passed over by the Senate Sub-Committee, we earnestly suggest to individual members of the ASSOCIATION to meet legislation restrictive of progress with all their personal influence in the Senate itself; for, should S. 1063 receive an affirmative vote, the field of agitation would be extended to the legislatures of every State; and a cry for absolute prohibition would be raised in England, to be echoed and re-echoed afterward by the over-zealous and intolerant faddists of the United States.

FELONS AS PHYSICIANS.

A recent editorial in a daily paper discusses the question of the moral qualifications that should be demanded of the practitioner of medicine, taking as its text a late decision of the New York court of appeals. A statute enacted two years ago disqualified any one who had been convicted of a felony from the practice of medicine. An individual indicted under this law pleaded in defense, first that his conviction antedated its passage and that, further, the law was unconstitutional in that it prevented him from earning his livelihood in a recognized legitimate profession. The defendant was convicted, appealed the

verdict and the case was carried up to the court of last resort, where the decision was affirmed. The court held that the legislature could properly prohibit any one from practicing medicine who had been convicted of a felony before or after the passage of the act, and that the law was altogether constitutional. In the language of the editorial which probably embodies the substance of, or is quoted from, this decision:

"The preservation of the public health is one of the highest functions of the government, and the legislature may undoubtedly provide the mode by which, in its judgment, the public health may be best protected. One of these modes is the safeguards thrown around the practice of medicine, such as learning and character. The legislature may and should require that those who practice medicine shall be persons of good moral character. The most delicate and important duties are entrusted to physicians. They are admitted into the family circle, become cognizant of the most important and sacred family secrets, are permitted to administer powerful drugs and have the responsibility for and care of the lives, the health and the welfare of its members. It is only individuals of the highest character that should be intrusted with such privileges, and it is perfectly competent, therefore, for the legislature to prohibit criminals and felons from entering such a profession."

It is perhaps well that there should be a legal sanction thus given to a certain moral or legal rating for our profession. It is also a fortunate thing for the public that, as a rule, regular physicians have a high ethical and professional standard, and whatever their private lapses in some points of moral conduct may be, they seldom, or indeed almost never, violate the trusts placed upon them. The medical profession, it can be safely said, stands as high as regards its sense of right and honor, and its practical application of the same, as any, not excepting the military and the clerical professions, and there is as little need, on the whole, for enactments of the nature of the New York law, as could possibly exist with so large a class, in which inevitably some black sheep must occasionally be found. It is only on account of these, fortunately rare, exceptions that it can have its utility, but that these occur there is ample evidence. It is not very long since that, in the writer's own knowledge, an ex-convict was successfully practicing in one of our inland cities as a regular physician, and he continued to do so until a second conviction for a new offense consigned him again to the penitentiary. It is only just to say, however, that in neither case, it is believed, were his crimes for which he was convicted, directly connected with his medical practice; though a habitual criminal and probably belonging morally and physically to that class of degenerates, he still had a spark of the professional honor of the profession to which, though as a sort of a pariah, he belonged.

There is, however, a large class of men, known to every one, and who are popularly estimated as physicians, for whose benefit such a regulation as this New York law would especially be of value. Unfortunately,

they too often escape the penalty for their misdeeds, either by successful concealment of their misdoings or by failure of the courts to convict, and go on flourishing on the profits of their crimes. Still, such a law would occasionally settle one of them, and its moral effect would be good on the class as a whole. It would be only one safeguard, but it would prevent the possibility of what has repeatedly occurred, viz., the return to their old practices of once convicted abortionists and blackmailers. The rarely possible instances where such a law could work hardship, as in case of persons wrongfully convicted, could be easily met by special legislation if necessary, and this would be in its way the most thorough and satisfactory vindication. It is true that there may be on the statute books some laws under which physicians could be convicted for no actual or intentional crime—a paper, for example, was recently read before a New York medical society which demonstrated that almost any physician could be found guilty under the law of manslaughter—but this danger is not a very imminent or probable one, and need not give any concern to an honest medical practitioner.

As a measure for the protection of the medical profession, and still more for the protection of the general public, such a law prohibiting convicted felons from passing themselves and practicing as physicians, is eminently desirable and should be extended to other communities and commonwealths than the State of New York, where alone it seems to be now effective.

SKIN ERUPTIONS CAPABLE OF CAUSING ERRORS IN DIAGNOSIS.

There is probably no more frequent source of error in diagnosis, for the physician who sees a case for the first time, than the presence or development of lesions of the skin resulting from the presence of disease in other portions of the body or due to the administration of certain remedies which are not suspected of being the cause of the lesion or which may not be known to have been exhibited. Two papers dealing with this important subject have recently appeared in current medical literature, one by Dr. FRANCIS PACKARD, which was published in the *Medical News* for Feb. 20, 1897, under the title of "Scarlatiniform Eruptions following Operations for Traumatism," and the other by Dr. GUIRAUD of Bordeaux in the *Archives Cliniques de Bordeaux* for January, 1897. Some editorials dealing with the same subject have also appeared in recent numbers of *The Therapeutic Gazette* and in *Pediatrics*. The paper of Dr. PACKARD, as its title indicates, deals solely with the scarlatinous rash associated with various forms of trauma and in it is discussed the question as to whether such a rash is a sign of true scarlet fever or only a dermal inflammation, that is, an eruption due to the absorption of some toxic material from the site of the wound. While it is true that patients suffering from trauma-

tism may develop a scarlatiniform rash as a result of a coincident or early infection by the poison of scarlet fever, it seems to us most probable that the great majority of these cases are not true infections with this disease, but simply evidence of septic infection or the results of the ingestion or absorption of drugs which are capable of producing skin manifestations. This is by no means impossible and probably occurs far more frequently than is usually suspected, for cases are on record, in large numbers, in which a roseolous rash has followed the application of such surgical dressings as contained iodoform, corrosive sublimate, carbolic acid or arnica, and it is a well known fact that other drugs are capable of causing similar dermal changes. Thus VEIEL has reported a roseolous eruption following the use of bromid of potassium, this eruption usually invading the skin of the lower limbs, and it is also well known that copaiba may produce a roseola of the skin of both the upper and lower extremities which is often accompanied by febrile movement. That there are nevertheless some cases of so-called surgical scarlet fever which are really due to the infection by this disease, is proved by the fact that we have, as PACKARD points out, numerous cases on record in which the patient has not only presented symptoms of scarlet fever himself, but has in addition communicated it to others.

This proper conclusion is practically that which has been reached by STIRLING in his article published in the *St. George's Hospital Reports*, for 1879.

One of the most interesting cases of true scarlet fever complicating a surgical operation is that which was reported in 1891 by LLOYD, in which the eruption appeared in a patient who had been subjected to the operation of trephining. This case gave rise to an epidemic. Such individual instances, however, by no means prove that scarlet fever after an operation is a manifestation of the disease produced by this cause, for patients already infected by scarlet fever are doubtless admitted to hospitals because of some acute surgical condition and naturally develop the eruption after operation has been performed.

It is an interesting fact, however, that in the great majority of cases of so-called surgical scarlet fever the patient is usually very young. Thus in seventy-two patients quoted by PACKARD the average age was 6 years and 4 months.

Passing on to a consideration of the other skin eruptions, it is of interest to note that GRELLTY, DUMAS, BOURARD and several other French clinicians have reported cases of scarlatinous erythema following the external application, or the internal ingestion, of quinin, while others have seen erythema, acute eczema, urticaria and lesions by no means so common following the use of this drug. It is a noteworthy fact that these eruptions have usually appeared upon the face and have been brusque in their development

and in their rapid progress to full intensity. Further than this, all the drugs which we have named so far, as capable of producing a scarlatinous eruption, have also been quoted as having caused desquamation after the acute stage of the eruption has passed by. Turpentine applied externally, and used internally, has caused similar eruptions.

GUIRAUD concludes in his paper that very frequently the eruptions which are caused by drugs are limited to the face or, if not to the face, at least to the breast, and that sometimes the swelling may be sufficiently great to resemble erysipelas. Only when the amount of the drug which is ingested is very large are these eruptions, in his opinion, apt to extend over the entire body, and he thinks that the absence of general systemic symptoms in the majority of cases should aid us in the differential diagnosis between exanthems due to drugs and infections. In his opinion by far the greatest number of drugs capable of producing skin affections are the various balsams.

ANOMALIES OF THE MAMMARY GLAND.

Anomalies of the mammary gland furnish some very interesting evidence in favor of the Darwinian theory. These structures are now looked upon as simply a collection of modified sebaceous glands like the sebaceous glands found so abundantly in other parts of the body. CHAMPNEYS and DUVAL have shown that there is but little difference between sebaceous matter and milk. It seems probable that after the primitive stage of hermaphroditism ceased both sexes yielded milk, and that the male assisted in suckling as there were many young at a birth then. Later on, possibly from the number of young growing smaller, the males ceased to perform this function (DARWIN, "Descent of Man"). In the lowest class of mammals, the monotremata, the mammae are developed almost as much in the male as in the female. "On the whole," says DARWIN, "we may doubt if the additional mammae would ever have been developed in both sexes of mankind had not man's early progenitors been provided with more than a single pair."

Several varieties of abnormalities are met with. Amazia or entire absence of the breast may be noted first; this is excessively rare and is generally met with in connection with defects of the sexual organs or of the chest wall, such as absence of the pectoral muscles, etc. Nearly all the cases on record have been found in the female. A typical case is reported by Dr. WYLIE (*Brit. Med. Jour.*, Aug. 4, 1888) in a girl of 21. From the accompanying illustration in that journal, it may be seen that there is no trace of anything resembling mammary glands. In animals with mammae one or more may be non-developed, and in man only one may be absent. However, this is almost as infrequent as complete amazia.

As a rule, the left breast is slightly larger, on

account of the more frequent use of it in right-handed women. It sometimes happens that one or both sides are much smaller than normal, even smaller than the male gland and useless for suckling. Such a condition, called micromazia, is somewhat rare also. MCGILLICUDDY (*Med. Record*, Oct. 10, 1891) figures a unilateral case of this variety.

Congenital absence of the nipple, athelia, may be found in one or both breasts. The gland itself is not involved, so there may be abundance of milk, yet the patients can not nurse their children. In those lower forms, the monotremes already alluded to, there are no nipples, the milk escaping through ducts in a shallow depression of the skin. As we ascend in the animal scale we find the sides of this depression rising, until finally we have a complete mammillary outgrowth or nipple. Polythelia is also seen less rarely; the nipple may be bifid or the gland may have two separate nipples on the same areola, or one or more nipples, each with its own areola.

The condition of polymazia or supernumerary mammae is most frequently observed. According to BRUCE (*Jour. Anat.*, xiii, p. 425) of 315 persons of both sexes 7.6 per cent. had supernumerary mammary structures. HANSEMAN tabulates 262 cases, of which the female furnished the greater number. AMMON (in WIDERSHEIM, "*Der Bau des Menschen*") states that of 2,189 army recruits he examined, supernumerary mammary structures were found in 66; in 62 there was one extra and in 4 two extra.

Two is the smallest number of mammae met with normally in the group of mammals as seen in man, sheep, goat, horse; the cow has four, often six, the dog seven to fourteen. CUVIER states that the more numerous the glands are normally the more liable they will be to numerical variation. There is usually some relation between their number and the number of young at a birth; as a rule the mammae are twice as frequent as the number of young.

The position of the mammary gland is of interest. In the lower classes it is in the inguinal region (hoofed animals, whales), in the higher (elephants, apes, bats, man) it is pectoral, in the rest it occupies the whole abdomen. The change from polymasty to bimasty can be seen even at the present day in the lemurs. In these animals the inguinal teats are functionless and clearly degenerating, while those in the pectoral region are fully developed (WIDERSHEIM). As these creatures are strictly arboreal in their habits it is much easier to carry their young at their breast than lower down.

In man supernumerary mammary structures are almost invariably found on the front of the trunk at spots located on two imaginary lines drawn from the normal nipples and converging at the pubes, thus following the course of the internal mammary and deep epigastric arteries. Over 90 per cent. are thus located

(LEICHTENSTERN, VIRCHOW'S *Archiv*, LXXIII, 222). If the redundant structures are below the normal they are thus internal to them, if above (which is rare) they are external. It is very rare for them to be found elsewhere, though MCGILLICUDDY mentions one on the thigh. It seems probable from a synopsis of the recorded locations of these redundant structures that man at one time had seven pairs of mammary glands and that the present pectoral pair corresponds to the fourth. In polymazia the normal pair is always in its proper position, no matter how many accessory structures are present.

As regards their functions they seldom reach the degree of perfection met with in the normal glands; milk may be secreted in greater or less quantity, but owing to the absence or imperfection of the nipples it is but rarely available. Of course they become most apparent during lactation, and like the normal glands become atrophied during the menopause.

Cases are sometimes described as axillary mammæ or the "axillary lumps" of CHAMPNEYS. These are very rarely aberrant growths, but are due to processes of the mammary gland growing round the edges of the pectoral muscle becoming nipped off and wholly or partly separated. This emphasizes the necessity of cleaning out the axilla in operations for cancer of the breast.

Are these supernumerary organs more liable to malignant disease, like the undescended testicle which, as is well known, is very liable to carcinoma? The question is partly answered by ROGER WILLIAMS ("Diseases of the Breast," 1894). Of fifty cases of fibroadenoma seven originated in supernumerary mammary structures; of 132 cases of cancer thirteen originated in these structures.

The largest number of excessive mammary structures met with is in a case of NEUGEBAUER, a woman who had eight supernumerary breasts and nipples besides the normal pair. AMMON found six extra structures in a man of 22 years. *En passant* it may be stated that the Egyptian goddess Isis and Diana of Ephesus are represented with many breasts, symbolic of fruitfulness. ANNE BOLEYN, in addition to hexadactyly, is said to have had three breasts, which gave Henry VIII. an excuse for putting her to death.

Gynecomazia or enlargement of the male breast is generally unilateral. It may occur at any time of life but it is usually seen at about the age of puberty. The enlarged glands sometimes secrete milk and gynecomazia is frequently accompanied by defective sexual organs.

Diffuse hypertrophy of the female breast on the contrary is generally bilateral, and is caused by increase in the normal structures of the gland. This condition is decidedly rare. One of the most typical cases on record is related by Prof. JOHN B. HAMILTON (JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, March 9, 1895). In this case the two glands weighed no less than fifty-two pounds.

CORRESPONDENCE.

Autopsy, Necropsy, Necroscopy.

WASHINGTON, D. C., March 26, 1897.

To the Editor:—On page 571 of the JOURNAL is a paragraph in regard to the words autopsy, necropsy and necrotomy, as used to express the act of making a postmortem examination. The objection to the word autopsy is very properly stated, since it does not express the idea intended to be conveyed. As the word necrotomy simply means the cutting of a dead body, it also lacks in explicitness. But the word necropsy is a sort of corruption of necroscopy, which means (from νεκρός, a dead body, and σκοπέω, to examine) just what it says, and is therefore the word to use. It has the advantage of stating in one word what otherwise requires at least three.

The objection to the use of the word autopsy in this connection has led many writers to use simply the words postmortem examination, as in the translation of Virchow's classic work; and one of the latest, that of Hektoen of Chicago, 1894. The word necroscopy was used as far back at least as Ouelly, Paris, 1833; and Newth has a Manual of Necroscopy, London, 1878.

I have used necroscopy myself for many years and would be glad if the word, unabbreviated, might be brought into common use by physicians. Yours truly,

Army Medical Museum.

D. S. LAMB, M.D.

ANSWER:—We think our distinguished correspondent is in error as to the derivation of the word necropsy. It is not a contraction, but a literal use of the words νεκρός, "a corpse," and ὄψις, "a view." The word is also used in French and German. In those languages the term "necroscopy" is also used; but as Americans are just now engaged in cutting superfluous letters in orthography generally, it would seem a pity to use the longer word as Dr. L. suggests.

A Radical View of the Advertising Business.

MINNEAPOLIS, MINN., March 27, 1897.

To the Editor:—The short letter of Dr. W. S. Fullerton in the JOURNAL of March 13, it seems to me, touches on a subject of the greatest importance, but one in regard to which, unfortunately, medical practitioners are too indifferent.

I refer to the too common habit among manufacturing chemists of first introducing their goods to the regular profession in an ethical way, and after a time spent in such introduction and in obtaining testimonials from certain members of the profession, advertising the remedy in the secular press in the most unblushing manner for the benefit of the general public.

Scott's emulsion and vin Mariani are two of the most notorious examples of this breach of faith with the profession, but it seems that during the past year the evil is growing, and that even heretofore reputable manufacturers are boldly advertising their goods to the public, at the same time that they cultivate the favor of the medical men in their accustomed way.

After noting your correspondent's strictures in regard to Messrs. McKesson & Robbins, I examined *Harpers'* and *Century* magazines and *The New York Independent* with the following results:

Harpers': Vin Mariani, one-quarter page. Buffalo lithia water, two pages. Eisner & Mendelson Co., Johann Hoff's malt extract, one page. Pabst malt extract, one page. Schieffelin & Co., Peter Moller's cod liver oil, one-quarter page. Scott's emulsion of cod liver oil, one page.

Century: Mellin's food. Schieffelin & Co., lycetol-Bayer (cure for gout); somatose. Buffalo lithia water, again two pages. Eisner & Mendelson Co., Carlsbad salts, one page. Scott's emulsion, one page.

New York Independent and several other religious papers show the same advertisement of Moller's cod liver oil.

Now, it does seem that there are enough manufacturers of

pharmaceutic preparations to choose from, without lending our countenance to such methods and their exponents.

It seems probable, also, that quite a number of the firms named above would, if forced to choose between the patronage of the general public and that of the profession, prefer the latter.

Ought not the profession to discriminate sharply between manufacturers, and decline to prescribe anything made by houses which descend to the methods of the patent medicine men to push their goods upon the public?

J. CLARK STEWART, M.D.

Infection by Communion Cups.

PHILADELPHIA, March 25, 1897.

To the Editor:—May I be permitted to seek, through your "Correspondence" column, some information in a matter in which I am deeply interested, and have been from its inception, namely, the sanitary communion cup?

I would esteem it a great favor and personal kindness if any member of the profession throughout the United States would answer on the following points: 1, locality of church or churches using the individual communion cups; 2, denomination; 3, when adopted; 4, number of communicants—approximate; 5, if possible, and the respondent is a member of a church in which the individual communion chalices are in use, the undersigned would also like to have a brief expression of opinion as to the success of the new method, and what objections, if any, were urged against its adoption, whether pastoral or congregational?

Very truly yours,

H. S. ANDERS, M.D.

Sequelæ of Measles.

(IN ANSWER TO DR. STIMSON'S QUERY.)

NEW YORK, March 25, 1897.

To the Editor:—In 1619, attention was called by Sennert as to the occurrence of arthritis as a complication of scarlet fever and measles, and almost all the specific fevers.

At the present day the frequency with which this complication occurs is universally recognized.

Dr. Samsen is of opinion that the importance of measles as a predisposing cause of endocarditis has not been sufficiently taken into account, and he is inclined to assign to that fever a share in the predisposition of articular rheumatism. Those who possess a rheumatic tendency are most liable to suffer from rheumatism when attacked by scarlatina or measles.

Yours truly, GHISLANI DURANT, M.D.

PUBLIC HEALTH.

Barbers Should be Compelled to Boil their Instruments.—Why not? asks the *Union Méd. du Canada*, commenting on a recent case of staphylococcus infection contracted by a physician in the barber's chair. Why should there not be a municipal regulation to that effect?

Prophylaxis of Phosphoric Necrosis.—This subject has been receiving much attention in France lately. All are agreed that the best method of prophylaxis is the suppression of the use of white phosphorus in the manufacture of matches, but as this seems to be practically impossible at present, it is considered that rigid enforcement of measures requiring forced and abundant ventilation and the selection of workmen free from any lesion of the mouth, will be sufficient.

The Results of Modern Progress in Hygiene are strikingly shown by the decrease in the mortality in armies. In 1870 the mortality in the French army was 11 per cent.; in 1896 it had fallen to 5.29 per cent. The deaths from typhoid fever were less by one-half and from smallpox have dropped from 127 in

1876 to 2. According to recent regulations an apparatus for sterilizing water by steam under pressure, mounted on wheels, is to be kept at headquarters, and sent at once to barracks threatened with an epidemic.—*Presse Méd.*, March 3.

To Regulate the Sale of Food, Drink and Medicine.—State Senator Revell of Chicago, has introduced to the Illinois legislature a bill intended to regulate the manufacture of baking powder, patent medicine, breadstuffs, the preparation of spices, pepper, coffee, tea, and other articles of food. The bill provides for the appointment by the governor of an inspector of all articles of food, drink and medicine. He shall appoint a corps of assistants to assist him in his work and it shall be his duty to condemn such articles if they are found to contain anything injurious.

Precautions Against the Possible Spread of the Bubonic Plague.—At the present writing France seems to be in the lead regarding sanitary thoroughness, inasmuch as particular attention is given to the regulation of the Mecca pilgrimages and a consequent over-crowding of the various sailing vessels, together with all the conditions growing out of the excretory surroundings belonging to all improvised camping grounds. England on the other hand, has been charged with too much indifference by reason of her valuable commercial interests in the Baltic region. In our own continent the State of New York appears to feel the national responsibility, since Health Officer Doty during the present month has received information from his appointed agent in Egypt that vessels arriving at the Suez Canal from India have been duly vised, that the precautions taken in Bombay are improving in adequacy, and that from the recent investigations in Bombay of Rogers Pacha, Inspector-General of the Sanitary Department of Egypt, it is to be inferred that there is no likelihood of the plague reaching Egypt.

Expose Illinois Towns to Smallpox.—The *Chicago Tribune*, March 29, says: Springfield, Ill., March 28.—[Special].—Dr. Scott of the State Board of Health today received a message from Chicago stating that a number of smallpox suspects were on their way from New York to points in Illinois. The suspects were passengers on the steamship, *Southwark*, which arrived in New York on March 26. There was a well developed case of smallpox on board, and many of the passengers were exposed. After disinfecting the clothing of the passengers, it appears that the New York Marine-Hospital authorities allowed them to go, and twenty-six of them are on their way to this State.

A number are bound for Chicago, and the following are passengers for other points in Illinois: August Martens, Kewanee; Tanna Keyenga, German Valley; Florence Nilass and F. Weltkamp, South Peoria; Lups Mendert, wife and child, German Valley; Mrs. K. Delayk and daughter Florence, Anne Kreiler, and Katherina Kupfer, Peoria; Emil Ettinger, Aurora; John Heischberg, Rose Hill; Nicholas Olinger, Sycamore; Marie Nittenbove, Angelus Lamens and wife, and Leo-Diamers and brother, Sheffield; Charles Martens, Rock Island; Paul Mary and three children, and Victoria Muller, East St. Louis. Dr. Scott sent telegrams to the points where the passengers are expected, and notified the local health authorities to look after them. In speaking of the policy of Marine Hospital authorities in permitting smallpox suspects to leave New York, Dr. Scott said: "In view of the fact that there is so much smallpox in Mexico, Cuba, and in the far East, it occurs to me that the precautions taken by the Marine Hospital-Service are inadequate. Over twenty people who have been exposed to the disease are sent out to Illinois, and the first notice of the fact comes two days later. In the meantime they may have developed the disease and spread it all the way from New York to Chicago. The chances are that these people will have reached their destination and embraced their friends before the local authorities have an opportunity to detain them. The carelessness with which people from infected districts are examined was well illustrated the other day. A Pullman porter with smallpox traveled all the way from City of Mexico to Chicago, where he was taken to the hospital. He had been waiting on

and coming in contact with passengers all along the line, and two cases have since developed as a result of his coming into the State."

Peoria, Ill., March 28.—[Special.]—A telegram was received tonight by Mayor Allen warning him that Anne Kreiler, Katharina Kupfer and Mrs. Weltkamp were headed for this city after being exposed to smallpox. The Mayor at once ordered the erection of a temporary pest-house in the upper end of the city, near the work-house, and sufficiently far away from all other buildings. It is being constructed tonight and the force of officers has been increased at the depot. As soon as the women arrive they will be taken to the place and kept there until all danger has passed.

Medical and Bacteriologic Care of Dairies.—We have before us notes regarding two exemplary milk supplies, one in Denmark and one in New Jersey. Some of these notes, that must appeal to medical men and city dwellers generally, may be summarized thus: The Copenhagen Milk Supply was inaugurated in 1878 by the late Dr. Panum, one of the leading Copenhagen practitioners. The fact that the founder was a physician was not accidental, but reflects clearly the original purpose of the company, which has been preserved unimpaired to the present day, the attempt to improve the health of the city by furnishing a quality of milk that could with safety be recommended to children and invalids. The commercial element is kept severely in the background, the profits being limited to 5 per cent. The milk is obtained at present from about fifty farms having a total of about five thousand cows. The greatest precautions are taken to prevent any possible contamination of the milk. Every fortnight the cows are carefully examined by a veterinary surgeon attached to the company, who also reports on the general hygienic condition of the farms. The head dairy woman regularly visits the farms to examine them with regard to cleanliness, especially during milking, the cooling of the milk, etc., and an inspector sees that all instructions are followed. The Danes are nothing if not thorough. Special attention is paid to the so-called children's milk, the highest grade, of which over 60,000 analyses are made every year. All the milk is passed through filters, from which the children's milk passes immediately into bottles which are then sealed. Pasteurized milk is also furnished, both pure and mixed with water and sugar at different strengths ready for use. The danger of contagion is guarded against by a method that must be as effective as it is humane. Whenever any one connected with the company discovers that he or any member of his family is taken sick with a contagious disease he is removed from his work, and unless an attempt at concealment has been made, his full pay continues until his return. In this way it is to every one's advantage to give immediate notice of what, as a rule, entails serious loss. The working force at the time of the strike consisted of about two hundred men and women and over a hundred boys. A valuable feature of the administration is a committee of two prominent physicians who act as an advisory board, their services being rendered without any compensation. The model American dairy, of which we would briefly treat, is known as the Fairfield Dairy, in "the Oranges" of Essex County, New Jersey, and its product is known as "perfected milk." It was also founded in 1878 by Mr. Stephen Francisco. He began with only thirteen cows, and from the outset absolute cleanliness was insisted on, and great care was taken in all the details connected with the milking. In 1892 the physicians of Essex County instituted a search for a dairy that would meet all their requirements for the production of pure milk, and Mr. Francisco willingly signed the contract. Since that time the milk has been periodically examined by experts and certified to by different physicians of Essex County. The two large barns are situated on high ground, well ventilated and drained. The cows are kept in a sweet and clean atmosphere, groomed morning and night, and treated kindly. They are examined twice a month by a veterinary surgeon, who reports on the health of each, and if one be found to be

affected by any disease whatever she is immediately removed. Great care is taken in selecting the cows, their antecedents being rigidly looked into. The Jersey and Holstein breeds predominate. In the milking absolute cleanliness is the first care. The milkmen are provided with freshly washed white suits every day, and are not allowed to touch the cows until they have washed their hands and cleaned their nails. The udders are also carefully washed and the milk is then drawn into covered pails, through a small sieve opening. The milkmen are lodged and boarded on the premises, simple and healthy in their habits, and are visited weekly by a physician to prevent any sickness remaining undetected. As soon as milked the milk is gathered into large cans and sent by an overhead wire to the dairy, a building several hundred feet from the barns and near a never-failing spring of purest water. When received there the milk is quickly strained again and falls over a series of metal tubes, through which ice-cold spring water is continually forced, cooling the milk. It is then bottled and covered with ice until delivered to the wagons. In the dairy the same carefulness is observed. The bottles are all washed three times and subjected to a pressure of twenty-five pounds of steam. The pipes and tanks through which the milk passes are scalded with steam just before they are used; so the chances for germ-life to be introduced into the bottled milk are reduced to a minimum. The theory is that the bacteria in milk causes it to sour, and by taking every precaution to prevent contamination, the milk can be kept sweet much longer than is usual. In 1893 twelve bottles of milk were sent across the ocean on a Cunard liner, and brought back, a period covering twenty days, and one bottle was kept ten days longer, and in both cases the milk was found to be perfectly sweet when opened.

Voluntary Notification of Tuberculosis.—In the *Sanitary Inspectors' Journal*, January, Dr. Arthur Newsholme, Medical Officer of Health of Brighton, England, outlines the official measures of prophylaxis against tuberculosis that may be operated in the absence of a compulsory notification of cases of that disease. "In Brighton we at once disinfect all rooms occupied previously by phthisical patients, when requested to do so by the doctor or the relatives, or apart from this when we hear of them in any other way. The information thus received is, however, as yet very limited. No local authority has hitherto secured powers to include phthisis among the diseases to be compulsorily notified to the medical officer of health. My own views are fairly well expressed in a resolution by myself and unanimously passed at the annual provincial meeting of the incorporated Society of Medical Officers of Health in August, 1893: 'That the Society of Medical Officers of Health while accepting the view that phthisis is an infective disease, in the prevention of which active hygienic measures should be taken, think it premature to recommend the compulsory notification of a chronic disease like phthisis. They are, however, of opinion that it is incumbent on medical officers of health to take such steps as may secure, *a*, the voluntary notification of cases of phthisis by medical officers of public institutions and such medical practitioners as agree that precautionary measures are desirable; *b*, the adoption of such precautionary measures, including the disinfection of rooms, as can be arranged in conjunction with the family practitioner.' Much good, apart from the notification of cases of phthisis, may be done by acting upon the weekly death returns. In Brighton every death from any form of tubercular disease is fully investigated. At the same time as the information is obtained the following informal notice is served, and the thorough cleansing and washing of the sick room and its contents enforced: 'Sir, or Madam—In connection with the death from . . . registered as having occurred at No . . . , allow me to draw your attention to the important fact that consumption is chiefly communicated from one person to another by inhaling the dust of the room previously occupied by the patient. Hence it is most important that the house should be thoroughly cleansed and all trace of dust removed, wet cloths being used for this purpose. I beg to advise that the following works are necessary in order to prevent the risk of similar cases arising

in the same house, viz.: 1, to strip the wall paper and burn it in the same room; 2, to thoroughly wash the ceilings and floor and walls of the room; 3, to wash all bed linen and other articles in the room, and expose the bedding, pillows, etc., out of doors for several hours in bright sunshine. Yours obediently,, Medical Officer of Health.

The spray of a solution of perchlorid of mercury (1 in 1,000) has in some cases been used in lieu of stripping off wall papers and whitewashing, but I am not yet able to speak from wide experience as to the relative merit of this method of dealing with such cases. The above measures of disinfection and cleansing may appear to partake of the nature of locking the stable door after the steed has been stolen. But it must be remembered that such action tends to minimize the dangers necessarily associated with this disease to other members of the same family as the deceased, or possibly to the members of another family moving into the infected house. Furthermore, there is the educational value appertaining to such measures, which impresses the public mind and gradually instills into it the necessity for continued precautions. That the danger of phthisis being communicated from one member of a family to another is not imaginary is shown by the following sample cases: A man, aged 38 years, died, during last year, of phthisis. He came from Portsmouth in 1892 already ill, where in 1891 his wife had died of phthisis. A woman aged 40 years died of phthisis. She had been married twice, both husbands having died before her of phthisis. The order of events in this case was probably that she acquired phthisis from her first husband and gave it to her second husband, in whom it ran a more rapid course than in her. A married woman, aged 42 years, died of phthisis. Her first husband died of phthisis in another house. There are several instances like this. A man aged 47 years died from phthisis in October, 1894, after an illness of several years. His daughter, who helped to nurse him, died in January, 1895, from phthisis. At another house four children of the same family died in succession of phthisis, namely, a young woman aged 23 years in January, 1891; a girl aged 16 years in August, 1891; a young woman aged 22 years in August, 1892, and a boy aged 16 years in November, 1894." If the narration of cases like the preceding produced a fear of living in the same house with consumptive patients, serious and unnecessary hardships to invalids would result. Assuming that simple precautions are taken, there is little or no danger of infection. What is necessary is that all expectoration should be at once burned, or a spittoon used containing a strong solution of carbolic acid or corrosive sublimate. Pocket-handkerchiefs should not be used for expectoration. Furthermore, the state of personal health is an important factor in the production of consumption. Attention to this, along with simple means of disinfection and cleanliness, removes the danger of communication of consumption.

BOOK NOTICES.

Lectures on the Treatment of Fibroid Tumors of the Uterus. By FRANKLIN H. MARTIN, M.D., Professor of Gynecology, Post-Graduate Medical School of Chicago, etc. Pp. 174. W. T. Keener Co., Chicago, 1897. Price \$1.00.

The book is divided into ten lectures. The first lecture treats of the anatomy, histology, etc. It is of course impossible to give a complete treatise on these subjects on eleven pages. Many important questions, for instance, the recent work on the adenomyomas of the uterus, are not mentioned at all. In lecture two the symptoms are described tersely and clearly, the diagnosis and differential diagnosis are discussed with much attention to detail. The third chapter contains the medical treatment and gives an exhaustive review of remedies which may or may not be of influence on uterine fibroids and on the conditions produced by them. Lecture four is devoted to ergot. The indications, methods of administration, duration and results of this treatment are discussed. The theories of the peculiar actions of ergot, and all the expectations built on these theories, are mentioned, but when it comes to results the author quotes old authorities. Though the ergot treatment is called "one of the meritorious relics of pre-surgical days," it is not to be understood that the author has the kind of reverence for this relic

which would prevent his turning toward more modern powers. Lecture five gives a condensed description of the practical use of electricity. As the name of the author is lastingly connected with this work, it is highly interesting to read a concise statement of his experience with this treatment. After a short description of the necessary paraphernalia, the more or less mysterious, unexplained or unproved effects claimed for the electric current are enumerated. Lecture six gives a very complete description of the operative treatment of fibroids. Preparation and after-treatment of patients are also discussed in this chapter. Lecture seven gives a review of the brilliant results accomplished by the author's well known operation of vaginal ligation of the broad ligaments. The history and technique are described and the latter illustrated by drawings. The indications are fully set forth and the prognosis defined. This is followed by the description of thirteen cases operated by this method between November, 1892, and February, 1895. Complete records of the cases, with the remote results, give a clear insight into the nature of the cases. It may be well to mention that the operation, though minor as to its performance, is by no means limited to small or incipient growths. In at least five of the cases the condition of the patient must have appeared desperate before this operation was performed. The results are extremely gratifying, as not only the troublesome and dangerous symptoms (hemorrhages, pain, pressure symptoms) have disappeared, but the tumors themselves have markedly decreased or disappeared. These results are so good that it is probable the operation will grow in popular favor, which it fully deserves in consequence of its comparative simplicity, the absence of danger from it, and its excellent prognosis. In the same lecture some minor operations for fibroids are described, removal of pedunculated fibroids (submucous), of cervical fibroids, curettement for the endometritis accompanying fibroids. The author does not favor enucleation of submucous fibroids of any considerable size if their principal bulk is buried in the wall of the uterus, and regards hysterectomy as more satisfactory in such cases. The operation of enucleation of submucous or intramural fibroids by laparotomy, which is a great success in such cases, is not mentioned in this or in any other chapter. Lecture eight, removal of the uterine appendages. The history and theory of this operation, its failures and the much restricted indications are described. The technique of the operation in simple cases, as well as in cases complicated with disease of the appendages, is outlined. The question of drainage is treated in a practical way. The author's results as given are brilliant: Sixty-five operations, no deaths; hysterectomy had to be performed subsequently in four of these cases. Lecture nine treats of vaginal hysterectomy. After a short historic review the advantages of the operation in comparison with abdominal operations, are mentioned. The author does not share the opinion of those ultras who try to operate every fibroid through the vagina, but advocates the sensible discrimination which differentiates the surgeon from the routinist. The two methods of vaginal hysterectomy, with or without morcellation, the use of clamps and ligatures, the after-treatment, are outlined carefully. One is not surprised to find at the end of this lecture the author's statistics ranging with the best published. Lecture ten, abdominal hysterectomy. This subject is presented in an extremely practical and clear way, the different methods being arranged according to their principles. The author favors the Stimson-Baer operation and describes its technique carefully for simple as well as complicated cases.

The book is a creditable one from any standpoint.

A Manual of the Practice of Medicine. By A. A. STEVENS, A.M., M.D. Philadelphia: W. B. Saunders. 1896.

This little manual has reached its fourth edition—evidence of merit. Its author understands the art of constructing a clear and fairly comprehensive abstract of the contents of the

larger works on medicine, to which due reference is made in the preface. The result is a convenient pocket companion that will be found useful by the student who is preparing a cram for examination, or even by the newly fledged professor who is about to step forth into the arena. But for students who are engaged in class-work such hand-books are too sketchy, and, consequently, dry and uninteresting—mere skeletons, devoid of attraction.

We Have Received in an envelope bearing the following stamp: "Treasury Department; Office Supervising Surgeon General; penalty for private use \$300;" a document purporting to be a reprint of the Cleveland *Journal of Medicine*, February, 1897.

The question of whether it is in violation of the law to send matter of this character without payment of postage, in a penalty envelope, is one for the postal authorities to consider; but looking at the matter of the document—a compilation which contains considerable miscellaneous information, among others, an editorial from the *New York Times*, August, 1893—it is chiefly remarkable for ignoring quarantine laws enacted prior to 1893, the Organic Act of Aug. 1, 1888, in particular being omitted. This omission is apparently malicious, unless we assume ignorance, and is not creditable to the present incumbent of the office of Supervising Surgeon General.

NECROLOGY.

JOHN B. DAVISON, M.D., Moline, Ill. The following resolutions have been adopted by the staff of St. Anthony's Hospital:

Your committee to whom was referred the duty of preparing an expression of our feelings regarding the death of Dr. J. B. Davison have the honor to make the following report:

Dr. Davison was born in Westmoreland County, Pennsylvania, June 11, 1826, and graduated from the Jefferson Medical College in March, 1868. He died at his home in Moline, Ill., Feb. 5, 1897. By his death this community has lost an upright citizen and the medical profession a devoted member. We will miss him at the meetings of our society and in our consultations in the sick room. That the evidence of our affection for him may live when we have gone we recommend that the following be spread upon our minutes.

Resolved, Death has removed from us Dr. J. B. Davison, an original member of the medical and surgical staff of Saint Anthony's Hospital.

Resolved, Dr. Davison, by his exemplary life both as a physician and as a citizen, was endeared to us beyond mention. Always honorable in his intercourse with his confrères. Always kind and sympathetic to the sick and afflicted.

Resolved, We regret his death and mourn with those who are dear to him, but submit in sorrow to his last call.

Resolved, That a copy of these resolutions be sent to the family of the deceased, a copy to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and copies to the press of Rock Island and Moline.

G. G. CRAIG, M.D.,
S. C. PLUMMER, M.D.,
L. D. DUNN, M.D.

WILLIAM B. BERRY, M.D.—At a meeting of the Orange Mountain Medical Society, held March 19, 1897, the following report was adopted:

Report of a committee appointed at the February 1897, meeting of the Orange Mountain Medical Society to prepare a suitable minute on the death of William Bogardus Berry, M.D.

WHEREAS, This society has been informed that Doctor William Bogardus Berry died in Pasadena, Cal., in December, 1896, and

WHEREAS, He was one of the founders of this society, and for a number of years did his full share to promote its scientific advancement and social well being, therefore be it

Resolved, That it is with profound sorrow that we have learned of the untimely death of our late associate. And that we desire, as a slight tribute to his memory, to have it recorded that we have never known a purer nor a more sincere man, and that his professional equipment and his private character were such that his membership cast luster upon this society.

Resolved, That in his death the profession has lost a faithful

and accomplished practitioner, his family a wise and devoted husband and father, the community a good citizen, the poor and unfortunate a ready helper, and the members of this society a genial companion and a noble and high-minded friend.

Resolved, That these resolutions be inscribed upon our minutes and that copies of them be sent to Dr. Berry's family, to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, to the *New York Medical Record* and to the *New York Medical Journal*.

JNO. J. H. LOVE,
RICHARD C. NEWTON, } Committee.
THOS. W. HARVEY.

DOUGLASS EWELL, A.B., Columbia College, New York, 1888, M.D., College of Physicians and Surgeons, New York, 1891, died at the Langham Hotel, New York city, March 22, aged 30 years.

THOMAS SCOTT LAMBERT, M.D., Castleton, 1845, of New York city, died from pneumonia, March 31. He was 78 years old and had not been active in practice for years. Services and interment at Salem, N. Y.

MANOAH S. LONG, University of Pennsylvania, 1862, of Mertz-town, Pa., died of pneumonia, March, 16, aged 56.

ARNOLD SCHOTT, M.D., Jefferson Medical College, Pennsylvania, 1868, died in Philadelphia, March 18, aged 70. He was a lieutenant in the German army and afterward a military instructor at Berlin.

JAMES A. FISHER, M.D., an alumnus of the Pennsylvania Medical College (now extinct) class of 1853, died at his home in Reading, Pa., March 6, aged 56.

J. B. SAMO, M.D., of Buffalo, N. Y., March 12.—Wesley A. Dunn, M.D., of Chicago, at Naples, Italy, March 20. He had practiced in Chicago eight years.—Arnold Heinrich Arthur Scott, M.D., of Philadelphia, March 18. He was born in Germany in 1827 and came to this country in 1866 and was graduated from Jefferson Medical College.

NEW INSTRUMENTS.

CRAIG'S HERNIOTOME.

A few weeks ago I ordered an instrument from George Tiemann & Co., describing it as a pair of curved scissors, the under blade of which was a grooved director to be used in hernia operations and others of like character requiring the use of a grooved director. Mr. Tiemann replied that he had never heard of such an instrument, but liked the idea, and would make me one if I so desired. I then ordered it made.

A few days after receiving Mr. Tiemann's first letter I received another from him saying that the more he thought about the instrument the more he liked it, and requested me to write a description of it for publication in a medical journal, stating that he would furnish me a cut for illustration.

I have never posed as an inventor, but I believe I have unconsciously originated a very valuable little instrument, which I cheerfully give to the profession, hoping that those who use it will find some convenience from it, if not actual benefit. The illustration so accurately shows its mechanical construction that it is unnecessary to say anything about it. I only need to say that it can be used in any case where an inflexible grooved director is necessary. It can be used more gracefully, more rapidly, and with greater safety with one hand than the ordinary grooved director and knife can be used with both hands. It is impossible to cut anything except the tissue over the grooved blade.

have used it in one case, an operation for the radical cure of hernia, and it fully satisfied all my expectations. I believe it will meet the general approval of surgeons.

ROCK ISLAND, ILL.

G. G. CRAIG, M.D.

CHAUVAU'S IMPROVED STETHOSCOPE.

A large metal box fits over the chest, to shut out external sounds. It communicates with the close-fitting ear piece by a rubber tube, which has a side opening about 40 cm. below the ear. This opening enables the sounds to be perceived with much greater exactness, and can be connected if desired with a Marey drum.—*Cbl. f. Phys.* from *C. R. Soc. de Biol.*, April 25, 1896.

ASSOCIATION NEWS.

The Meeting of the American Medical Association.

To the Editor:—May I call the attention of those of your readers who are thinking of coming to Philadelphia to attend the semi-centennial meeting of the AMERICAN MEDICAL ASSOCIATION to be held June 1, 2, 3, and 4, 1897, that there will be in addition to the meeting of the ASSOCIATION at the same time a large mercantile convention which will to a certain extent utilize a considerable number of the rooms in the various hotels. For this reason it is advisable that physicians who intend to be present at the meeting should write at once to one of the following hotels engaging such rooms as they desire at the rates named:

Hotel Walton—Broad and Locust Streets: \$1.50 and upward per day, European plan; \$4 and upward per day, American plan.

The Colonnade—15th and Chestnut Streets: \$1 and upward per day, European plan; \$3 and upward per day, American plan.

The Lafayette—Broad and Chestnut Streets: \$1 and upward per day, European plan; Table d'hôte: breakfast 25 to \$1, luncheon 75, dinner \$1.25.

The Bingham House—11th and Market Streets: \$2.50 and upward per day, strictly on the American plan.

Hotel Stenton—Broad and Spruce Streets: \$2 and upward per day, European plan; \$4 and upward per day, American plan.

The Continental—9th and Chestnut Streets: \$3 and upward per day, strictly on the American plan.

The Windsor—11th and Filbert Streets: \$1 and upward per day, European plan; \$2 per day, American plan.

The Stratford—Broad and Walnut Streets: \$1 and upward per day, European plan only.

Girard House—9th and Chestnut Streets: \$2.25 to \$3 per day, strictly on the American plan.

Hotel Hanover—12th and Arch Streets: \$2.50 per day, strictly on the American plan.

Aldine Hotel—Chestnut Street above 19th: special rates to members of the AMERICAN MEDICAL ASSOCIATION, \$2.50 per day, on the American plan; \$1 to \$3 on the European plan.

The price quoted in each instance is for one person only. Rooms commanding only the lowest price are naturally limited in number. It is especially desirable that each member intending to be present at the meeting shall personally, or by letter, make his arrangement with the hotel at which he desires to stop.

It is worthy of note that the rate of \$1.50 per day at the Hotel Headquarters, the "Hotel Walton," is the rate for two people in one room.

All these hotels are within a few blocks of the meeting place and most of them are within two blocks. As a sub-committee of the General Committee of Arrangements has arranged clinical courses in all branches of medicine at the various teaching institutions and large hospitals during the week prior and following the week of the ASSOCIATION meeting, it has been thought that a considerable number of physicians would be glad to embrace the opportunity of brushing up upon the various branches by attendance on these courses, for which no charge will be made by the gentlemen giving them and as their

stay in this city will therefore be more than a few days, it has occurred to the Committee that some of the visiting physicians may wish to take rooms at some good boarding house. The Chairman of the Committee on Reception and Accommodation, Dr. G. E. de Schweinitz, 1401 Locust Street will be glad to send the addresses of such boarding houses to gentlemen desiring to stay here for a week or more.

The large number of gentlemen who have already signified their intention of attending the meeting, and the very large number of able and interesting papers already placed upon the programs indicate that this will be the most important meeting which the ASSOCIATION has ever had and it is hoped that every physician who is a member of a regularly organized County Medical Society will make an effort to attend.

The meeting halls for the various Sections are situated so close to one another that different papers in different Sections can be readily listened to during a single morning's session by those who do not wish to devote their time to one particular specialty.

Very truly yours,
H. A. HARE, M.D.
Chairman of the Committee of Arrangements.

SOCIETY NEWS.

Antitoxia American Pediatric Society.—The Collective Investigation (report) will be kept open until April 10, in order to secure a return of all cases beginning before April 1. The committee desire to express its appreciation of the trouble and pains the members of the profession have been willing to take in this matter. The return blanks are more understandingly made out than in the first report.

International Bureau of Penal Law.—This organization will meet at Lisbon, Portugal, April 20 to 22, 1897. Subjects announced for discussion: 1, Modifications in the Statutes of the Union; 2, Contraventions; 3, Transportation as a Repressive Penal Measure; 4, Criminal Attempts; 5, Minor Delinquents; 6, Moral and Penal Responsibility. M. Rivières, Secretary, 52 Rue d'Amsterdam, Paris.

Pathological Society of Philadelphia.—The annual conversational meeting of the Society will be held in the Upper Hall of the College of Physicians, northeast corner Thirteenth and Locust Streets, April 22, 1897, at 8:15 p.m. Dr. Ludvig Hektoen, professor of morbid anatomy in Rush Medical College, will deliver an address, entitled "Fragmentation and Segmentation of the Myocardium." After the meeting a reception will be tendered Dr. Hektoen at the University Club, 1316 Walnut Street. A cordial invitation is extended to attend the meeting and the reception.

Union Medical Society.—At a meeting held in Troy, N. Y., the Union Medical Society was organized by the leading physicians of Rensselaer and Washington Counties, New York, Bennington County, Vermont, and Berkshire County, Massachusetts. It is intended to hold four meetings a year, one in each county. The first regular meeting will be held in Troy, April 21, when the permanent officers will be elected.

The Luzerne County Medical Society held a regular meeting at Wilkes Barre, Pa., March 14.—A regular meeting of the Syracuse (N. Y.) Academy of Medicine was held March 23.

MISCELLANY.

Dr. Unna's Pamphlets.—Dr. P. G. Unna of Hamburg, has kindly sent us reprints of various addresses and articles contributed by him to medical literature. We have sent them to the Newberry Library.

Extra-uterine Pregnancy, Deliverance through the Rectum.—The *Rev. Méd. de la Suisse Romande*, No. 12, describes the case of a woman of 28, who after every indication of extra-uterine

pregnancy, passed fetal bones, etc., through the rectum at intervals during a period of almost eleven years, when she died of peritoneal complications.—*Presse Méd.*, March 3.

Personal.—Prof. Nicholas Senn of Chicago, entertained the *Verein Deutscher Aerzte* of Milwaukee, at the Athletic Club, Chicago, March 26.—Prof. Hobart A. Hare of Philadelphia, has been appointed "consulting therapist" to the well known house of Parke, Davis & Co.—Dr. Fred. H. Wines has been reappointed Secretary of the State Board of Charities of Illinois.

The Republican Candidate for Mayor of Chicago, Judge N. C. Sears, in a letter written to the Physician's Club said that while he had made no pledges and could not make any, yet he believed in lawyers for legal positions and doctors for medical positions. This is all that should be asked.

Mr. Hering, one of the candidates for Mayor, has sent a circular to physicians in which he says that, if elected, he will appoint a physician and not a politician as Health Commissioner. This commits all the candidates to the principle of a medical man for a medical office.

Seventy-Seven Cases of Extra-Uterine Pregnancy.—Wasten reports this number of tubal pregnancies occurring in his practice in three years. He operated in 52 cases, 45 celiotomies and 7 colpotomies, and considers that the sooner the operation is performed the more complete the results and the more rapid the recovery; out of 18 patients operated in *extremis*, 2 died; a fetus was discovered in 13 cases, twins in 2; 25 were treated non-surgically, but in only 3 of these was the resorption complete. In most of the cases there was tubal abortion or a retro-uterine hematocoele, complicating hematosalpinx, in 2 cases ante-uterine hematocoele.—*St. Petersb. Med. Woch.*, Feb. 27.

Effect of Venesection on the Chemical Constitution of the Blood.—Jessipow concludes from his numerous experiments on animals that the blood is altered in its chemie constitution by withdrawal of a certain amount, and that it then acquires a powerful bactericidal action, at its height twenty-four hours afterward, and gradually returning to normal. The resistance of animals to intraperitoneal cholera injections increased in direct proportion to this increased bactericidal action of the blood. Repeated venesections increased this resistance more than one single venesection.—*St. Petersb. Med. Woch.*, No. 1, 1897.

Railroad Hospitals.—The Southern Railway, according to the *Atlanta Constitution*, is to erect a chain of hospitals for the care of those injured in its service with the extension of the same privilege to all accident cases. Attention is at the expense of the road. This provision will ward off or at least mitigate damage suits. "The Plant system—and in fact most all of the great systems throughout the country," says our contemporary "have erected such institutions and from information the systems have saved many dollars and at the same time given more efficient service to the injured."

The Coming Rule of Moral Sussion in Russia.—Even Russia, perhaps over-maligned by reason of its despotic form of government and its fierce though repressed racial wars, accepts the spirit of the times. We learn from authority deemed competent that the director of a new asylum for juvenile offenders has been refused permission to introduce corporal punishment in both the male and female departments of his institution. The *Novoe Vremya* recalls that a like petition was made several years ago by the director of a juvenile correction colony, and that the petition was denied in emphatic terms by the Minister of Justice. As somewhat germane to the subject the Rev. Dr. Talmage draws vivid pictures of the charming domestic life of the cultured Russians, whom he probably saw under the best possible conditions. He fosters the view that the national characteristic is that of an indifferent, resigned melancholy, upon which according to most alienists mere physical outrages can have but little effect. Probably in this history making epoch Russia is at "stack arms."

Intoxication from the Vapors of Anilin.—An employe without syphilitic or alcoholic antecedents, was sent from a drug store in Nancy to the works at Bar le Duc for a quantity of anilin, (1892). It was kept in cemented tanks, and as he did not have a siphon, he drew the anilin in pails and emptied it into his vessels, which occupied him four or five hours. The work was done in a small, close shed, and the air was soon saturated with the vapors. The moment he emerged into the fresh air he fell prostrate, and remained unconscious for seven hours, pupils dilated, pulse feeble, skin cold, spasmodic contractions of the lower muscles and trismus. For a fortnight his urine was black and his complexion green, while his limbs could scarcely support him. He has since had two attacks of partial hemiplegia, and his mental condition has varied from extreme depression to periods of excitement, while his character has completely changed and he has become morose, and even savage.—*Presse Méd.*, March 3, from *Rev. Méd. de l'Est*, No. 18, 1896.

The Census Statistics of France.—To arrest the steady decrease in the birth rate among the French people, M. Alphonse Bertillon, the terror of the arrested criminal, and well known to everybody except, as is said, to a few New York police officials, advocates the exemption from direct taxation of every family in which there are three children. He would further have imposed an extra tax of 20 per cent. upon all without the requisite number, as a protection against loss of revenue by the treasury. In this way he hoped to establish a distinction between men to whom the nation's interests are dear and men who consider them not at all. In studying the degree of fiscal punishment a citizen, says M. Bertillon, has, as such, three primary duties; he must do his share toward the perpetuity, the defense and the financial maintenance of his country. If he shirks the first, he must undergo an extra charge for the other two. M. Bertillon, however, does not reveal whether he would begin again to tax a father, of whose three children one or more should die, nor whether exemption should cease when the children become self-supporting and leave the parents' home. Would it not be more satisfactory to discuss the whole question from the moral standpoint alone, without even a bias for the rights of posterity, which are or should be held to be inalienable. Poor France, in her history, it is to be feared has exchanged much too late her jocund shout of "On with the dance," for the yell of "Now to glory."

Wisconsin Law for Treatment of Inebriates Unconstitutional.—The manifest purpose of the Wisconsin law of 1895 (chapter 203 of the laws of that year) providing for the treatment of habitual drunkards in private institutions at county expense, the supreme court of that State declares was to benefit private parties. In other words, it says that it was to compel the county in which any citizen resided who had become "addicted to use of spirituous, malt or fermented liquors, morphin, opium, cocain, or other drugs or narcotics, to such a degree as to deprive him or her of the power of reasonable self-control," who had been committed to these private parties' private institute, in the manner prescribed, to pay such institution a sum not exceeding \$130 "for treatment, medicines, and board for four weeks," furnished to such person. This, the supreme court holds, Wisconsin *Keeley Institue Co. v. Milwaukee County*, Feb. 2, 1897, must, for one thing, stand in the way of the act being a valid exercise of the police power of the State. The mere fact that an institution is subject to visitation and inspection by public officials, it says does not make it a public institution. Nor does it think that a county can be compelled to pay any private party for treatment, medicines and board of any resident therein, having a disease not contagious or infectious, merely because such diseased person "has not the means to pay for said treatment." Upon these grounds, the court holds the law in question unconstitutional. The Maryland act that was held

valid, it points out was broadly distinguishable from this one. More like it was that of Colorado, but its constitutionality was not made to turn upon the questions considered above, so the case in which it was held valid was not deemed an authority here.

Five Hyatid Moles.—Garcia Medina describes an unusual case in the *Revista Médica de Bogotá* for October. The patient, a woman 48 years of age, had passed through twenty-one pregnancies, some terminating normally, and others by abortion, and finally presented the symptoms of an eight months' pregnancy, with evidences of tumors in the uterus. He dilated the cervix as for an abortion, and made injections of citrate of ergotinin in the hypogastric region, causing uterine contractions and the expulsion of the moles, five in number, two measuring twelve centimeters in length. Each had a pedicle and was enveloped in a sac of fibrous tissue. The immediate results were good, but a hemorrhagic endometritis that subsequently appeared required curetting. This restored the patient to health and her menses reappeared.

X Rays in Medical Jurisprudence.—The City and Suburban Railway Company of Baltimore, Md., have found the cathode X-rays an efficient checkmate for a recent fraudulent scheme. A man whose name the officers decline to disclose asserted that he had one of his arms broken by a car, and through an attorney demanded \$3,500 damages. His arm was tied up from the wrist to the elbow, and he pretended to be in great pain. Rather than go to the expense of a lawsuit, the company offered to compromise for \$100, which was refused. The company then arranged for a picture of the bones of his arm, which showed no fracture. When the bandages were removed the skin was found to be burned and discolored by an acid, said the physicians. The result of the examination was made known to the claimant who offered to settle for \$25, but the company was no longer in a compromising mood.

A One-Man Medical Faculty.—Dr. Dunglison writes in the *College and Clinical Record* that the late Prof. Robley Dunglison of Jefferson Medical College, when invited by the representative of Thomas Jefferson, then rector of the University of Virginia, to leave England to assume the duties of a professorship, or rather a combination of professorships, in that school, entered into a contract: "To teach to the best of his ability and with due diligence, anatomy, surgery, the history of the progress and theories of medicine, physiology, materia medica, and pharmacy." At the time he was invited to take upon himself this task he was but 26 years of age.

If any man in American history was ever able to accomplish so much, that man was Robley Dunglison, whose knowledge was well-nigh universal, and who touched no subject with his pen that he did not adorn.

An Ex-Post-Facto Medical Law.—The same reasons that control in imposing conditions upon compliance with which the physician is allowed to practice in the first instance, it is adjudged, may call for further conditions as a requirement of his continuance in practice. But the appellate division of the supreme court of New York holds, in *Peoples v. Hawker*, Feb. 5, 1897, that any legislative requirement imposed for the continuance of a person in the practice of medicine, whether pertaining to his professional knowledge and skill or to his good moral character, must relate to his present status or condition. Thus, the provision of section 153 of the New York public health law (chapter 661, laws 1893, as amended by chapter 398, laws 1895) which enacts, among other things, that any person who, after conviction of a felony, shall attempt to practice, or shall so practice, shall be guilty of a misdemeanor, the court holds constitutional so far as it operates prospectively, and upon persons convicted of felony after its passage, but unconstitutional in so far as it applies by its terms to persons so convicted before the law went into operation. The underlying purpose of the

act, it says, may be to purge the medical profession of members unworthy of confidence, but the real effect, so far as it is pronounced obnoxious, is to accomplish that by inflicting an additional punishment, through a newly created offense inseparably connected with the anterior crime, and thus bring about a result the constitution forbids, no matter in what form the statute is drawn. Mr. Justice Ingraham files a lengthy dissenting opinion.

Sanitarium at the Canary Isles.—The *British Medical Journal*, February 6, states that there is an undoubted need for a health resort at one of those islands for the benefit of Europeans who get run down in health at the various fever-stricken stations of the western coast of Africa. In addition to the many Englishmen whose business or official duties take them to those sickly shores, there are also the French, Belgians, Portuguese and Germans in considerable numbers, and these by coöperating together can bring about the founding of a model sanitarium in the "golden climate of the Canaries." The *Journal* points out how necessary it is that the fever stricken patient does not return to Europe in the winter, a proceeding that is especially unsafe for those who are suffering from the extreme anemia produced by African fevers. The writer has known not a few cases of hemoglobinuric fever which relapsed on the weakened convalescent after being plunged into an English winter.

Prizes Offered by the Academie de Medecine of Paris la 1899.—Works submitted in competition for the prizes must be legibly written in French or Latin, accompanied by a sealed envelope containing the name of the competitor which must not be revealed otherwise. All articles must be in the hands of the Académie by the end of February of the year in question, and they are not returned to the authors. The prizes entitle the successful competitor to the title of laureate of the Académie de Médecine. Prix de l'Académie, 1,000 francs, annual, subject: Physiology and Pathology of the Thyroid Gland. Prix Alvarenga, 800 francs, annual, for the best article on any medical subject. Prix Amussat, 1,000 francs, triennial, for the article or researches based on anatomic and experimental studies, which have realized or prepared the way for the most important progress in surgical therapeutics. Prix d'Argenteuil, 6,800 francs, sexennial, for the most noteworthy improvement in the means of curing strictures of the urethra, or for the best work on the treatment of other diseases of the urinary passages. Prix Barbier, 2,000 francs, annual, for a complete cure for diseases recognized as incurable, such as hydrophobia, cancer, epilepsy, scrofula, typhus, cholera morbus, etc. Prix Mathieu Bourgeret, 1,200 francs, annual, for the best article or work on the circulation of the blood. Prix Capuron, 1,000 francs, annual, subject: Modifications in the Placenta and Membranes of the Ovum Retained in the Uterus. Prix Chevillon, 1,500 francs, annual, for the best article on the treatment of cancerous affections. Prix Civrieux, 800 francs, annual, subject: Nervousness. Prix Daudet, 1,000 francs, annual, subject: Lymphadenoma. Prix Desportes, 1,300 francs, annual, for the best work on practical medical therapeutics. Concours Vulfranc Gerdy, for the nomination of two medical students to serve at a mineral water cure in France or abroad. Candidates must be inscribed at the Académie de Médecine. Prix Ernest Godard, 1,000 francs, annual, for the best work on external pathology. Prix Theodore Herpin, 3,000 francs, annual, for the best work on epilepsy and diseases of the nerves. Prix Laborie, 5,000 francs, annual, for the author of the work which has advanced the progress of surgery to a noteworthy degree. Prix Larrey, 500 francs, annual, for the best work on medical statistics. Prix Laval, 1,000 francs, to the medical student who has proved himself the most deserving. Prix Lefèvre, 1,800 francs, triennial, subject: Melancholia. Prix Meynot, 2,600 francs, annual, for the best work on diseases of the eyes. Prix Adolphe Monbinne, 1,500 francs: this sum is bestowed annually or biennially on scientific missions in the interests of the medical, surgical or veterinary sciences. Prix Nativelle, 300 francs, annual, for the best work on the extraction of the positive active principles of some medical substance never before isolated. Prix Oulmont, 1,000 francs, annual, awarded to the medical student who has won the gold medal in the annual "interne concours." Prix Portal,

subject: Experimental Work on Animals to Study the Inoculation and Contagiousness of Cancer. Prix Pourat, 700 francs, annual, reports of experimental work to elucidate the question of the immediate and ultimate destination of the albuminoid food substances. Prix Philippe Ricord, 600 francs, biennial, for the best work that has appeared during the two years on venereal diseases. Prix Vernois, 700 francs, annual, for the best work on hygiene. Competition is open to natives and foreigners alike for these prizes. The following is closed to foreigners: Prix Baignet, 1,500 francs, annual, for the best work on the applications of physics or chemistry to the medical sciences. Translations not admitted.

Cincinnati.

THE MORTALITY REPORT for the week ending March 19 shows: Zymotic diseases, 16; phthisis, 13; other constitutional, 14; local, 56; developmental, 10; total, 110; still births, 4; annual rate per 1,000, 14.12; total preceding week, 138; corresponding week 1896, 123; 1895, 134; 1894, 133.

THE ANNUAL ELECTION of officers of the Conner Surgical Society, a fraternity of the Ohio Medical College, which was held last week, resulted as follows: President, Dr. R. W. C. Francis; vice-presidents, Dr. Markley and Dr. Rayle; secretary, Dr. W. Koontz; treasurer, Dr. Bernheimer; masters-at-arms, Dr. C. E. Laws and Dr. P. Kennard. After the election Dr. P. S. Conner, from whom the Society is named, delivered a lecture, which was followed by a banquet.

AT THE ACADEMY OF MEDICINE meeting Dr. P. M. Ashburn read a paper on "Primary Vaginal Sarcoma," and Dr. Joseph Eichberg read one on "Treatment of Gallstones."

THE JOURNAL SPECIAL TRAIN.—Arrangements are being perfected for a special car out of Cincinnati to join the Special train to the AMERICAN MEDICAL ASSOCIATION meeting at Philadelphia, and those contemplating attending should address Dr. G. I. Cullen, 714 West Sixth Street, for rates, sleeping-car space, tickets and other information.

Hospitals.

The Mayor of Salem, Mass., has been notified by the Massachusetts State Board of Health that there is urgent need of hospital for contagious diseases. During the past six months the board has spent about \$9,000 in the management of these cases and it is thought desirable to build a hospital where they may be isolated and more advantageously treated.—Mrs. T. P. Sheppard of Providence, R. I., has announced her intention of purchasing a sterilizing plant to be presented to the St. Joseph's Hospital. The estimated cost is \$1,700.—The visiting staff of St. Mary's Hospital, Rochester, N. Y., have donated to that institution an X ray apparatus of the latest pattern.—The monthly report of the Charity hospital, New Orleans, La., shows that 1,578 patients were treated in the hospital during the month of February.

Colleges.

The Bellevue Hospital College has issued diplomas to 133 students out of a class of 160. The annual commencement has been abolished at this college.—The ninth annual commencement of the Michigan College of Medicine and Surgery was held March 23. There were forty-seven graduates.—At the annual commencement of the Missouri Medical College, St. Louis, Mo., a class of seventy-four was graduated.

Illinois Medical Practice Bill.—The following bill was introduced by Mr. Bogardus, Feb. 18, 1897. Read first time, ordered printed and referred to Committee on Education and Educational Institutions:

A BILL

For an act to establish a State Board of Medical Examiners, prescribing its powers and duties, to provide for the licensing of practitioners of medicine and midwifery, and to regulate the practice of medicine and midwifery, in the State of Illinois, and imposing penalties, and to repeal all acts or parts of acts in conflict therewith.

SECTION 1.—Be it enacted by the People of the State of Illinois, represented in the General Assembly, That a board of examiners to be known as the "State Board of Medical Examiners" shall be appointed as follows: Within sixty days after this act shall take effect, the Governor shall appoint nine (9) physicians of recognized professional ability and standing, who are residents of the State, and legally qualified practitioners of medicine therein, as members of said board, who shall hold their office until their successors are appointed and qualified. The members of said board so first appointed, shall determine by lot, their respective terms of office, so that the term of one member shall expire on Dec. 31, 1898, and the term of two members on December 31 in each year thereafter. And at the expiration of the term of office of each of the members of the board, the Governor shall appoint his or their successor or successors, whose term of office shall be for the period of five (5) years; and all vacancies occurring in the membership of the board, by resignation or otherwise, shall be filled by the Governor, and all appointments on said board shall be made from physicians having the qualifications prescribed here-

in for members of the first board: *Provided, however,* That all appointments shall be made with the advice and consent of the Senate, but appointments made when the Senate is not in session may be confirmed at the next ensuing session thereof.

SEC. 2.—The said board shall, within thirty days after its appointment, meet and organize by electing a president, vice-president and treasurer from among its members, and a secretary who shall be a legally qualified physician, not a member of the board. Such officers shall hold office until the next annual meeting of the board, or until their successors are elected and qualified. The board shall prescribe the duties of its officers, and shall require the treasurer to give a satisfactory bond. The board shall adopt and have a common seal, and the president or presiding member and the secretary shall be empowered to administer oaths in taking testimony or in any matter pertaining to the duties of the board. A majority of the board shall constitute a quorum for the transaction of any business. It shall adopt such rules, regulations and by-laws not inconsistent with the laws of this State and of the United States, as it may deem necessary or proper to enable it to properly perform its duties and transact its business.

SEC. 3.—The annual meeting of the board for the election of officers shall be held in the State Capitol on the second Tuesday of January in each year. The board shall also hold regular meetings on the second Tuesdays of April, July and October in each year, at such place as it may determine, and may hold other meetings at such times and places as it may deem necessary, or its duties may require.

It shall keep an official record of all its transactions, and a complete file of all applications for licenses, together with the correspondence pertaining thereto, and of all examination papers, and shall make a report of its transactions, annually, to the Governor, which shall include a statement of all monies received and disbursed by it, and an official list of all physicians and midwives authorized to practice in this State.

SEC. 4.—No person shall hereafter begin the practice of medicine, or any of the branches thereof, except dentistry, in this State, without first applying for and obtaining a license from said board so to do. Application shall be in writing, and in the form prescribed by the board, and shall be accompanied by the application and examination fees hereinafter specified, and with proof that the applicant is of good moral character, and has received a diploma conferring upon the applicant the Degree of Doctor of Medicine from some legally incorporated medical institution in the United States, in good standing, as may be determined by the board, at the time of issuing said diploma, or with proof that the applicant has pursued, in some institution of learning in some foreign country, a course of medical study not less in extent than the course of study prescribed for the Degree of Doctor of Medicine by legally incorporated medical institutions in the United States, in good standing, as aforesaid. When the application and proofs aforesaid have been inspected by the board, and found to comply with the foregoing provisions, the board shall notify the applicant to appear before it for examination, at the time and place mentioned in such notice. Such examination shall be in the English language, and embrace only those general subjects and topics, a knowledge of which is commonly and generally required of candidates for the degree of Doctor of Medicine by reputable medical colleges in the United States.

No person shall hereafter begin the practice of midwifery in this State without first applying for and obtaining a license from said board so to do. Applications shall be in writing, and in the form prescribed by the board, and shall be accompanied by the application and examination fee hereinafter specified, and with proof that the applicant is of good moral character, and has received a diploma from a school of midwifery, complying with the requirements of the board. When the application and proofs aforesaid have been inspected by the board, and found to comply with the foregoing provisions, the board shall notify the applicant to appear before the board for examination at the time and place mentioned in such notice. Such examination shall be in the English language, and of such character as to determine the qualifications of the applicant to practice midwifery.

All examinations provided for in this act shall be conducted under rules and regulations prescribed by the board, which shall provide for a fair and wholly impartial method of examination. If the applicant successfully passes his or her examination, the board shall issue to such applicant a license authorizing him or her to practice medicine or midwifery, as the case may be, in this State. Such license shall be in such form as may be determined by the board, and in accordance with the provisions of this act: *Provided, however,* any willful violation, on the part of an applicant, of any of the rules and regulations of the board governing examinations, shall be sufficient cause for the board to refuse to issue a license to such applicant.

SEC. 5.—The application fee for those desiring to begin the practice of medicine under the foregoing section shall be \$5 and the examination fee \$15, and for those desiring to begin the practice of midwifery the application fee shall be \$5 and the examination fee \$10, and, in all cases, both the application and the examination fee must accompany the application: *Provided, however,* if the application and proofs accompanying the same are not approved, or the applicant fails to pass the examination fee shall be returned: *And provided further,* in case the applicant fails to pass his or her examination, he or she shall, after the expiration of six months, and within a period of two years, be entitled to one re-examination without the payment of any additional application fee.

SEC. 6.—Any practitioner of medicine or midwifery, who has been licensed to practice by the licensing authorities of another State, whose standard of requirements for a license to practice was, at the time of the issuing of such license, not lower than that prescribed by this act and by the board herein provided for, may be granted a license to practice in this State, without examination by this board, upon payment of the fee hereinafter specified, to the treasurer of the board, and upon presenting to the board his or her license or certificate to practice issued by the proper authorities of such other State, together with proof that he or she is of good moral character, and is the person named in such license or certificate: *Provided, however,* the board may further require that such applicant shall furnish proof of the requirements he or she had to comply with in obtaining his or her license or certificate from the authorities of the State which issued the same.

The license fee for practitioners of medicine applying for license under this section shall be fifty (50) dollars and for practitioners of midwifery thirty (30) dollars.

SEC. 7.—That all persons who, at the date of taking effect of this act are qualified to practice medicine or midwifery, under the laws of this State, in force at the time of the passage of this act, and who desire to continue in practice, shall, within six months after the appointment and organization of the Board of Examiners provided for in this act, apply to such board for a license, which shall be issued by the board on payment of a fee not to exceed one dollar. *Provided,* the board may refuse to issue such license to any such applicant for cause hereinafter provided. All licenses issued under the provisions of this and the fore-

going sections shall expire on a date to be named therein, not more than one year from the date of issue, so that all licenses outstanding at any one time shall, as nearly as may be, expire on the same date.

SEC. 8.—That all licenses, issued under the provisions of this act, may, at the date of their expiration, be renewed for a period of one year, upon payment to the board of a renewal fee not to exceed one dollar, which renewal shall be evidenced by a new license: *Provided, however,* the board may refuse such renewal license for cause as hereinafter provided.

The failure of a licentiate to obtain a renewal of license at the date of its expiration shall render such practitioner liable to the penalties provided for by this act for practicing without a license, but will not prevent application for a renewal license at some subsequent date, not later than one year from the date of expiration of his former license, within which time, subject to all the conditions for renewals heretofore provided for, the board may issue a renewal license which shall expire at the same date as if issued at the date of expiration of his former license. *Provided, however,* retirement from practice or removal from the State shall not deprive the licentiate of the right to a renewal within five years after such retirement or removal.

All original licenses issued by the board shall be signed by all the members of the board. All renewals shall be signed by the president and secretary of the board, and attested by the seal of the board.

SEC. 9.—The board may refuse to issue any license provided for by this act, whether an original or a renewal license, if it shall appear that the person applying therefor has been guilty of persistent inebriety, or the practice of criminal abortion, has been convicted of a crime involving moral turpitude, or has, by false or fraudulent representations, obtained practice in his or her profession, or, by the false or fraudulent practice of his or her profession, has obtained money or any other thing of value: *Provided, however,* no person shall be finally refused a license until after the applicant for the same is given at least thirty days' notice of the grounds for such refusal, and opportunity given the accused for a hearing before the board to show cause why the board shall not finally refuse his or her license, at which hearing the accused shall be entitled to be represented by counsel.

SEC. 10.—That any person shall be regarded as practicing medicine within the meaning of this act who shall operate for or upon, prescribe for, or otherwise treat, or profess to heal or cure any physical or mental ailment, or any physical injury to, or deformity of another: *Provided,* nothing in this act shall be construed to apply to the practice of dentistry, to the administration of domestic or family remedies, in cases of emergency, to commissioned surgeons of the United States Army or Navy, or Marine-Hospital Service, in the discharge of their official duties, nor to practitioners of other States when acting in consultation with licentiates of this State.

SEC. 11.—That any itinerant vender of any drug, nostrum, ointment or appliance of any kind intended for the treatment of disease or injury, who shall vend or sell any such drug, nostrum or appliance, or who shall, by writing or printing, or any other method, profess to the public to cure or treat disease or deformity by any drug, nostrum, manipulation or other expedient, shall pay a license of one hundred (100) dollars per month into the treasury of the board, to be collected by the board in the name of the People of the State of Illinois, for the use of said board. And it shall be lawful for the State Board of Medical Examiners to issue such license on application made to said board, said license to be signed by the president of the board and attested by the secretary with the seal of the board, but said board may for sufficient cause refuse said license. Any such itinerant vender who shall vend or sell any such drug, nostrum, ointment or appliance, or who shall, by writing or printing or any other method, profess to cure or treat disease or deformity by any drug, nostrum, manipulation or other expedient, without a license so to do, shall be deemed guilty of a misdemeanor and upon conviction thereof shall be punished for the first offense by a fine of not less than one hundred dollars, or by imprisonment in the county jail for a period of not less than thirty nor more than ninety days, or by both fine and imprisonment, and for each subsequent offense the penalty shall be double that of the preceding one.

SEC. 12.—That the office expenses of the board, and all expenses arising from the proper enforcement of the provisions of this act, shall be paid from the fees above provided for, and from such fines as may accrue to the board for the violation of the provisions of this act.

SEC. 13.—That the salary of the secretary of the board shall be fixed by the members of the board, and shall not exceed the sum of \$3,000 per annum. The members of the board shall receive no compensation; but their traveling and other expenses incurred while employed on the business of the board shall be paid.

SEC. 14.—That any person hereafter practicing or attempting to practice medicine or midwifery in this State without having a license so to do as herein provided for, or contrary to the provisions of this act, shall be deemed guilty of a misdemeanor and upon conviction thereof shall be punished for the first offense by a fine of not less than one hundred dollars and not exceeding two hundred dollars, or by imprisonment in the county jail for a period of not less than thirty days nor more than ninety days, or by both fine and imprisonment, and for each subsequent offense the penalty shall be double that of the preceding one: *Provided,* that the provisions of this section shall not apply, for a period of six months after the appointment and organization of the first board, to those persons who are qualified to practice medicine and surgery, or midwifery, under the laws of this State in force at the time of the passage of this act.

SEC. 15.—That all suits for the recovery of the several penalties prescribed in this act shall be prosecuted in the name of "The People of the State of Illinois" in any court having jurisdiction, and it shall be the duty of the State's Attorney of the county where such offense is committed to prosecute all persons violating the provisions of this act, upon proper complaint being made. All penalties shall be paid into the treasury of the State Board of Medical Examiners.

SEC. 16.—All acts and parts of acts inconsistent or in conflict with the provisions of this act are hereby repealed.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from March 20 to 26, 1897.

First Lieut. Isaac P. Ware, Robert S. Woodson and George DeShon, Asst. Surgeons, are ordered to report in person to Lieut.-Col. David L. Huntington, Deputy Surgeon-General, president of examining board, at such time as may be required, for examination for promotion.

Capt. Nathan S. Jarvis, Asst. Surgeon, is relieved from duty at Willets Point, N. Y., to take effect upon the expiration of his present leave of absence, and ordered to Ft. Clark, Texas, for duty.

Major Henry S. Kilbourne, Surgeon, will be relieved from duty at Ft. Clark, Texas, upon the arrival at that post of Capt. Jarvis, and ordered to Madison Bks, New York, for duty.

Capt. Eugene L. Swift, Asst. Surgeon, extension of leave of absence granted on surgeon's certificate of disability is still further extended one month on surgeon's certificate of disability.

First Lieut. Francis A. Winter, Asst. Surgeon, upon completion of his examination for promotion, ordered to West Point, N. Y., to report to the superintendent of U. S. Military Academy, for duty at that post.

Capt. Charles Willcox, Asst. Surgeon, is relieved from duty at West Point, N. Y., to take effect upon the expiration of his present leave of absence, and ordered to Ft. Bliss, Texas, for duty at that post, relieving Capt. Ogden Rafferty, Asst. Surgeon. Capt. Rafferty, on being thus relieved, is ordered to Willets Point, N. Y., for duty at that post.

A board of officers to consist of: Lieut.-Col. David L. Huntington, Deputy Surgeon-General; Major Walter Reed, Surgeon; Capt. Charles M. Gandy, Asst. Surgeon, is appointed to meet at the Army Medical Museum Building, Washington, D. C., on Tuesday, May 4, 1897, at 10 o'clock A. M., for the examination of such officers of the Medical Department as may be ordered before it, to determine their fitness for promotion.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the two weeks ending March 27, 1897.

Asst. Surgeon D. N. Carpenter, detached from U. S. naval laboratory and department of instruction, Brooklyn, N. Y., and ordered to the "Brooklyn" March 15.

Asst. Surgeon F. L. Pleadwell, detached from U. S. naval laboratory and department of instruction, Brooklyn, N. Y., and ordered to temporary duty on the "Constellation" March 15.

Surgeon H. G. Beyer, detached from the "Newark" March 17, and ordered home to await orders.

Asst. Surgeon A. W. Dunbar, detached from the "Newark" March 17, and ordered to the "Vermont."

Surgeon M. H. Simons, detached from torpedo station, Newport, R. I., April 15, and ordered to the "Columbia."

Surgeon E. Z. Derr, detached from the "Columbia" on being relieved, ordered home and granted three months' leave.

P. A. Surgeon J. M. Moore, ordered to the "Alert" upon the arrival of that vessel at Mare Island, Cal.

P. A. Surgeon L. W. Spratling, detached from the "Alert" upon being relieved, ordered home and granted three months' leave.

Asst. Surgeon G. D. Costigan, detached from naval laboratory and department of instruction, and ordered to the "Vermont."

Surgeon C. A. Siegfried, detached from the "Massachusetts" and ordered to the torpedo station.

Surgeon S. H. Dickson, detached from the "Texas" and ordered to the "Massachusetts."

Surgeon W. R. Du Bose, detached from the "Terror" April 6, and ordered to the "Texas."

Surgeon Oliver Diehl, detached from the Philadelphia naval hospital April 6, and ordered to the "Terror" April 6.

Surgeon T. C. Craig, placed on the retired list from March 12.

P. A. Surgeon R. M. Kennedy, detached from Norfolk naval hospital April 3, and ordered to the Philadelphia naval hospital.

Asst. Surgeon D. N. Carpenter, detached from the "Franklin" and ordered to the "Raleigh."

Change of Address.

Arthur, Mattie L., from Oakland to 1341 South 33d St., Omaha, Neb.
Davison, C., from 1022 Madison St. to 955 Jackson Boul., Chicago, Ill.
Ehrlert, Anna M., from 22d and North College Ave. to 123 S. 26th St., Philadelphia, Pa.

Houston, J. M., from 707 Sutter St. to 502 Powell St., San Francisco, Cal.
Price, M. F., from Los Angeles to Colton, Cal.

Stegried, C. A., U. S. N., from Washington, D. C., to Newport, R. I.
Starr, J. W., from Liberty Center to Charlton, Iowa.

Whiting, A. D., from German Hospital to 1223 Spruce St., Philadelphia, Pa.

Weatherby, B. J., from Hutchinson, Kan., to 65 N. Franklin St., Wilkes Barre, Pa.

Warner, C. J., from Congress to Wooster, Ohio.

No. 15.

ADDRESS.

ADDRESS DELIVERED AT THE CLOSING
EXERCISES OF THE ARMY MEDICAL
SCHOOL, MARCH 12, 1897.

BY SAMUEL C. BUSEY, M.D.

PRESIDENT OF THE MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA,
WASHINGTON, D. C.

The selection of a physician in civil life to deliver the address on this occasion gives expression to that comity and fraternal fellowship which makes kindred of us all, and the presence of one whose professional life has been limited exclusively to civil practice adds force to the thought that the great brotherhood of scientific medicine is animated by those qualities of the heart and mind which bring together those engaged in a beneficent pursuit, however widely the incidents and environments of life of the individual members may differ.

You, gentlemen of the graduating class, have won the initial honor of your corps, and with the conclusion of these exercises you will be transferred to the active and practical duties of that department of medicine to which you have voluntarily dedicated your life work. To the doctorate of medicine, with one year of hospital experience and successful examination of the army examining board, you have today added the diploma of a school of military medicine, which attests your fitness to wear the official insignia of a surgeon in the army of your country. All this is in evidence of that high standard of qualification which your corps, under the leadership of its distinguished chief, has established, thereby keeping abreast with, if not leading, the efforts in active operation all along the line, to elevate medical education to the highest standard of a beneficent and life-saving science. The chapeau, shoulder straps and sword symbolize the distinction to which you have today attained, in a scientific corps, but they constitute no part of the equipment of the conscientious physician. They are significant symbols of authority and qualification, all the more honorable because they have been won by your own efforts, not only without aid from a paternal government, but in spite of the obstacles which your superior officers have interposed to an easy and free access to a corps, which, from its organization in 1775, has continuously advanced the requirements of examination, and now selects from those graduates in medicine who may apply only those who have attained that high grade of proficiency which qualifies them to discharge the duties and obligations of the skilled general practitioner of medicine. As yet, and fortunately so, limited specialism has not invaded the medical corps of the army. You can not follow the example of the young graduate in civil life, and go from this hall to your post of duty and swing out the sign of practice limited to a single organ or

function of the human body, but must accept the sick call from private and officer alike, and meet every emergency from a gunshot wound to a stumped toe. In brief, you must acquire expert knowledge in every branch of medical science and such manual dexterity as will enable you to fill the measure of responsibility and reach that high goal of scientific attainment which your commissions demand. With increasing and enlarged experience you will come to know your proficiency in some special work, which may lead you along the course of some broad specialism that will hold you in close touch with general medicine and widen the scope of your knowledge in one or more of its branches, and thus fit you for that higher and broader field of specialism to which skilled and expert work in general medicine will lead those seeking preëminence through the only safe channel to success. To the army medical corps will soon fall the task, and I know not to whom it can be so safely trusted, to arrest the progress of decadence of general medicine which threatens its speedy and final subdivision into as many limited and minor specialisms as can find adventurers with brains enough to capture the credulous sick.

This subdivision of work and creation of new fields of labor have contributed to the marvelous advance and present high standard of medical science. The annals of medicine furnish nothing comparable to the development which has crowned the researches and discoveries of Simpson in Scotland, Baker Brown in England, Marion Sims in America and Gustave Simon in Germany, who, simultaneously sprang up in distant lands and illuminated the civilized world with achievements that have restored millions of suffering women to health, strength and vigor. They came to this high renown along the beaten track of general medicine, but now that great specialism which they established is threatened with such minor subdivisions that women may enjoy the privilege of dying only through accident or old age. And, may I not suggest that these two causes of death may eventually submit to the expert management of some specialism as yet undiscovered, in which may lurk the hope that will inspire you to the attainment of glory that will endure forever.

You are free from the competition and rivalries of civil life, but not free from the emulation of high aspirations in scientific attainments. Your efforts have thus far been crowned with success, but he among you who will be content to rest at the point of beginning will not only fail, but will recede to the level of low repute and routine fossilism, and perhaps, low enough to accept the mastership of the drummer fiend, who dispenses free of charge, with thanks, from his wallet, a whole salvation army of cure-alls, with literature sufficient to occupy the hours of sleep and then laugh at the credulity of the victim. Liver pills, liver pads and all healing balms and salves are, fortunately, excluded

from the surgeon's requisitions. The common soldiers and enlisted sailors are the only classes of the population of this great country protected by law and regulation, alike from incompetent medical service and a mercenary pharmacy.

Those gifted with sloth and lack of force never leave the starting post, but wait in contemptuous complaint for that success that only comes to those who seek it, and those who seclude themselves in ignorance seek a livelihood through the glamour of pretence and empiricism. It may be that your corps is inadequately compensated for high grade work and low grade work in medicine is dear at any price, but you are free from the penury of emolument, from struggle with the capricious empire of fortune and monotony of scanty subsistence, and thus all the more free to utilize energy, thought and opportunity in the noble activities of the progressive, qualified and conscientious physician.

That you may fully realize the high standing of your corps and the grave responsibilities you have assumed, let me call your attention to a single fact, which has been re-affirmed forty-eight times, and lastly by an act of Congress, approved by the President. A score or more years ago the AMERICAN MEDICAL ASSOCIATION, the most numerous and powerful representative body of medical men in this country, declared by formal act that the force and fiat of law must be invoked to protect the profession of medicine from the ignorant and venal charlatans and mercenary imposters that had sneaked into it through low grade and snide medical colleges, not one of whom had gained admission into this corps. This simple act was the beginning of a new era in medical education in this country, which has continuously grown, acquiring force, power and popularity at every stage of its progress. Beginning with the State of Illinois, forty-eight States and Territories, the last this District by act of Congress, have enacted laws to regulate the practice of medicine, and to prescribe a standard of education, to which every graduate in medicine must attain before engaging in the practice of his profession. Now, mark the significant fact to which I wish to call your attention. In each and every one of these forty-eight laws there is a provision exempting the members of the medical corps of the government service from the examination prescribed for all others, who may seek to engage in the practice of medicine within the limits of its jurisdiction. Forty-eight States and Territories and the Congress of the United States have declared by law that the requirements for admission to these corps have established a standard of education and qualification coequal with the highest demands of the most advanced development. Nor is that all. The same statutory provision necessarily carries with it the obligation to enlarge the requirements, coincident with the expansion of knowledge, that this corps may keep abreast with the progress of scientific medicine, and thus fortify the honor of leadership that has placed medicine in this country in the front rank of applied sciences. No single fact or combination of facts has added such brilliancy to a career that has extended through a century and more of years of honored service. You need not then be surprised at the repetition of the injunction, that the profession must look to your corps for the restoration of general medicine to that high plane of scientific repute that gave to it a Rush, Watson, Bright, Bennett, Trousseau,

Niemeyer, Drake, Reynolds, Aitkin, Chapman, Wood, Flint, Bowditch, Loomis and a host of others too numerous to mention, and to your corps a Morgan, Lovell, Lawson, Barnes, and now a Sternberg, whose achievements in general medicine will illumine the pages of scientific medicine through all times and ages yet to come.

As if in fraternal reciprocity this corps has given to civil practice men whose good work has won high distinction in several branches of medicine, to which they have devoted themselves, among whom I may name Gouley, Weir, Smith, Curtis and Wagner of New York City; Allen, Thompson, Norris and Bartholow of Philadelphia; Conner of Cincinnati; Pitcher of Detroit and Howard of London.

The records of the Medical Staff of the Army suggest many lines of special work and study, which offer inviting opportunities for original research and investigation. Your assignments to duty will call you to stations on the Atlantic and Pacific sea coasts, from posts in valleys and along great rivers to others located on high mountain ranges, from tropical to arctic regions, from hospitals in barracks to the rude and improvised structures in the lonesome fastnesses of the frontier, from the comfortable dwelling of the city to active life in camp, always in the line of duty with soldiers in garrison or on the march, perhaps, in war as well as in peace, and always liable to summons from your study to the saddle, from the sick bed of the docile private to the sick chamber of the officer or his family, and perhaps, when opportunity offers, to patients in civil life. These constantly recurring mutations and changing scenes will add such charms to your official life as never come to vary the plodding wage-earning life of the civil practitioner. They give freedom to thought, add pleasing variety to care and enrich the mind with such observation as will widen the scope of intellectual acquirement. You will carry with you from post to post the scalpel, thermometer, microscope, barometer and all other implements necessary to complete the armamentarium of the accomplished surgeon and physician and scientific investigator. The bureau will keep you supplied with the current literature of the world of medicine that may be necessary to keep the student in close touch with new discoveries, improvements in technique, and new and improved applications of old methods, but it can not supply you with time to fritter away in thoughtless ennui and busy idleness. If you are not willing, ready and courageous enough to accept the conditions with all the hardships and grave responsibilities as they are, you had better, right here, plead the baby act and skulk away from an honorable duty.

The nomadic life of the army surgeon offers unusual facilities for the study and solution of many problems as yet undetermined, especially such as relate to the influence of climate, temperature, altitude, topography, meteorologic, electric and barometric conditions and changes, soils, their products and geologic formations, upon classes and entities of disease, and the interchangeable and intercurrent conditions of such natural phenomena upon life, health and disease, in garrison as well as in civil life. Much valuable work along these lines of research has been done by officers of the staff, but much remains to be done before the results can be formulated into law.

"Meteorologic science in this country was conceived and brought forth by the Army Medical Depart-

ment." On the 2nd of May, 1814, Surgeon General Tilton issued an order instituting meteorologic observations at army posts, and in July, 1816, Surgeon Benjamin Waterhouse made the first report, under that order, to the department. During the service of Surgeon General Lovell its usefulness was established and developed, to which Surgeon General Lawson, in 1842, gave impetus and value by supplying the staff with the most improved instruments and prescribing a series of rules for taking the observations, which were subsequently compiled by Surgeon Coolidge and published in 1855. In this valuable contribution to science are set forth "the results of observations of the thermometer, direction and force of winds, clearness of sky and fall of rain and snow, with a special report on the prominent features of general climate in the United States, as exhibited in the distribution of temperature and of rain," for each season of the year, embracing the period from 1842 to 1854 inclusive, which led up to and culminated in the establishment of the Signal Corps of the Army and the Weather Bureau, for which the Government and the people are indebted to the genius and scientific attainments of Surgeon, and later General A. J. Meyer. In 1856 another equally valuable compilation, prepared by Surgeons Wotherspoon and Coolidge, was issued, in which is contained the information "in regard to the location, topography and prevailing diseases of the various posts, the geology and natural history of the neighboring country, with observations on climate, manners and customs of the inhabitants." I have selected these citations from the records of the department that I might entice you into the open fields of investigation, luxuriant with opportunities not less attractive than profitable. Your research work need not, however, be limited to discovery, but may extend into the wider fields of re-examination and verification of accepted results and to the expansion of such knowledge in application and utility. In fact, the whole domain of medicine is open to you, and the hope is cherished that each one of you may determine some fact that will contribute to subjugate medicine to the reign of known laws. Your chances and possibilities are not less than were those of Surgeon Beaumont, whose fame is as fresh today as when he died in 1853. Through eight years of assiduous and patient investigation he established the basis upon which all subsequent experimentation has been conducted which has brought our knowledge of digestion to the present advanced stage of development, but as yet not at rest under the reign of established laws of the animal economy.

It will not, in this connection, be invidious to cite the facts that to Surgeon Smith is due the credit of pointing out the danger of lead pollution of drinking water collected from freshly painted roofs; to Surgeon Howard for suggesting the method of treating penetrating gun shot wounds of the chest and abdomen, which led to the form of primary antiseptic occlusive dressing which has revolutionized the treatment of gunshot wounds; to Surgeon Wright a recovery after a shot perforation of the chest; to Surgeon Otis for the first authoritative announcement of the practicability of enterorrhaphy in gun shot wounds of the intestines; to Surgeon Sternberg for the discovery of the micrococcus of pneumonia; and to Surgeon Letnerman for the plan of "an organization of the Medical Department of an army in the field, that not only

contributed in a large degree to the discipline and efficiency of the foremost Army of the Republic, but also robbed war of many of its horrors; who left behind him for the use of those to come, the record of the means by which these noble ends may be again achieved, and who, in rendering this great service to his country, added a brilliant page to the record of the humane character of his profession."

Investigation of all the factors likely to influence the origin, spread and disappearance of diseases in general, and especially of epidemic and endemic diseases, offers to the patient painstaking student an abundant harvest in studies in medical topography, medical geography, and meteorology. We know the occurrence, prevalence and virulence of certain diseases are influenced by seasons, temperature, humidity and barometric conditions, as for instance, the regional prevalence of diphtheria, especially during damp, chilly weather, but our knowledge is insufficient to enable us to determine whether these meteorologic conditions predispose the system to catarrhal affections which favor the invasion of the diphtheria bacillus, or supply the environments necessary to intensify the virulence of the germs. We know also that measles, scarlet fever and diphtheria appear at different times and in different localities in mild, medium and malignant epidemics, showing conclusively that pathogenic effects are not uniform in degree of intensity, and indicating that germs vary at time and places in degree of potency, but we do not know what external influences, if any, determine the degree of virulence. We have been taught and believe that certain infectious diseases find their causes in local conditions and only originate when the local environments are suitable for their development, but we know nothing of the conditions of the soil and water, which in one instance favor and in another inhibit the development of the organisms. Those of you who may be stationed at consumptive health resorts will enjoy the opportunity of contributing to the common fund of knowledge by determining the effects of the air of such places upon the life-history of the tubercle bacillus and upon the streptococcus which goes hand in hand with advanced pulmonary infection, and perhaps settle the question whether the air inhibits the development of these organisms, or whether climatic cures are after all effected by an out-door life and abundance of free air.

In connection with meteorologic studies it would be interesting to know what causes the fits of pain in the hurt and maimed limbs of men, and in tender nerves and rheumatic joints, in connection with storms. Dr. S. Weir Mitchell has made an exhaustive study in the case of Captain Catlin of the army, but could not determine which of the storm-producing factors (lessened pressure, rising temperature greater humidity or winds), caused the neuralgia in this case, or whether some other agency, perhaps electricity or magnetism, was productive of the evil. Professor Palmieri has shown that the atmospheric electricity is always positive during bright and cloudless skies, provided no precipitation has taken place within a radius of ninety kilometers, and that the rays of the hot sun diminish the electric tension. During an actual rain storm the electricity is always positive, but surrounded by a broad zone of negative electricity and the latter is again surrounded with a belt of positive electricity. These observations in connection with Dr. Mitchell's investigations are suggestive, but require further study and research.

So far we know nothing of the significance to the human organism of argon, the newly discovered constituent of the atmosphere, nor do we know anything of the role played by sudden barometric changes in the form of maxima and minima oscillations on the escape of ground air, and the possible liberation of disease germs from the soil.

In that wider field of investigation pertaining to general medicine let me call your attention to the unsettled problems in that prevalent and protean class of disease, comprehended under the term malaria, which the laity thinks it can treat as skilfully as the most learned physician. In 1849, Prof. John K. Mitchell of Philadelphia first announced the doctrine of parasitic origin of malarial and other fevers. In 1852 the late Surgeon-General Barnes, then a young assistant surgeon stationed at Fort Scott, added the weight of his opinion in favor of the parasitic nature of the malarial poison. In 1866 Professor Salisbury of Ohio presented some observations which led him to the conclusion that fevers are caused by the introduction into the system of cells or spores emanating from certain species of algoid plants. In 1879, Klebs and Tommasi-Crudelli described a bacillus found in the soil and water of the Roman Campagna and from various experiments appeared justified in assuming their microbe to be the etiologic factor of malarial fevers. In 1880 Laveran discovered an organism in the blood of a malarial patient in Algiers not found in that of healthy persons, which he called plasmodium and maintained it to be the essential cause of malaria. His conclusions have been confirmed by other investigations and it is now generally admitted that the plasmodium is a parasite belonging to the protozoa, which invades the red corpuscles of the blood, is always present in malarial fevers, never except in rare instances of mixed infection in other diseases, and that the morphologic and biologic peculiarities of the parasites differ in the various types of fever, a strong presumptive evidence of their etiologic relation. The discovery of Laveran supplies the crucial test of diagnosis and offers a scientific explanation of the specific properties of cinchona and its preparations in the treatment of malarial affections. But as yet the natural history of the microbe has not been determined. We know nothing about its external habitat and the conditions under which it develops, whether in some plant or animal or elsewhere, how it enters or leaves the body. It has never been found in the air, soil or water of malarial districts or in the secretions and dejecta of the patient and there is no record of its successful cultivation. But the fact that the microbe of malaria has not been discovered outside of the body is not proof that it does not exist, for we are dealing with an extremely minute parasite which may be found like other parasites in different stages of development. It has always been held that a certain degree of heat, moisture and vegetable decomposition are necessary for the development of malaria, and that drainage, removal of forests and cultivation of fields have resulted in the disappearance of the disease. While this is in the main true, malaria has disappeared at times regardless of drainage. It is equally difficult to account for the fact that from many localities where the disease formerly prevailed extensively it gradually disappeared, and in later years returned. Again, we are without satisfactory explanation of the pandemics of malaria of which Professor Hirsh describes a number, the

latest appearing between 1866-1872, in which the disease spread not only over a great part of Europe but visited simultaneously many parts of India and North America and showed itself, and in a severe form, for the first time in the Island of Mauritius. All this is especially remarkable because not in a single instance has the disease on a large scale been shown by observation to have spread according to the direction of the wind.

What the older writers called the malarial diathesis, and the epidemic constitution of the atmosphere, may play some role in the spread of the disease, but reason and observed facts suggest that the organism is developed in a specific soil, and that the quality has more to do with it, than the quantity. As for instance in the vicinity of Rome, we are told that malaria decreases as soon as the limits of animal soil pollution are reached. Extensive marshes, rank with vegetation, in favorable latitudes where we expect to find the poison are often devoid, while infection has taken place in the deserts of Africa, where the surface was covered with sand with a substratum of wet clay. Malarial soils have been created by temporary dams or irrigation. Some observers refer to striking examples of the influence of house-plants in the production of malarial intoxication. Salisbury's experiments with a cake of malarial soil carried to a house five miles from the locality and infecting two young men is very suggestive. Ship malaria may be due to a balast of malarial soil. It is just in such remarkable instances where the physician should invoke the aid of the bacteriologist, for it is self-evident that an examination of suspected flower pot and plants may yield satisfactory results on account of the limited fields.

If the organism develops in the soil, why should it not find its way into the drinking water, or into the atmosphere by the ascending currents? Is night air bad because the ascending currents after sundown contain ground air? The influence of ground air is illustrated by frequent infection of persons sleeping on the ground or first stories, also after excavations, as in the construction of railroads, streets, sewers and buildings. I hope you may find time and opportunity to clear up the nature of "mountain fever," a search for the plasmodium together with Widal's serum diagnosis, ought to settle the question, whether it is a malarial or typhoid fever or the result of a mixed infection.

If time permitted I might review other classes of disease, in that I might expand and multiply your opportunities for research work in clinical observation, verification and experimentation, but enough I hope has been said to interest you in some one of the multiform, composite and mooted subjects, in the final settlement of which you may find that distinction which comes only through diligence and expert work.

And now let me add the testimony of Professor Virchow, to whom scientific medicine owes as much if not more than to any man living. In his statement of the status of the doctrine of infectious diseases he referred to the progress of medical science in the United States, with special reference to the labors of the Army Medical Department and said:

"In the Crimean war the French army lost one man out of every three of the whole army, and it is estimated that of the 95,615 lives lost only 10,240 fell before the foe. About as many died of wounds in the hospitals and the remainder, more than 75,000 men were victims to epidemic diseases. It is calculated that in the American war of rebellion 97,000 men fell

in battle and 184,000 died of diseases and epidemics. But it must here be acknowledged that it was not the necessity alone that revealed the evil and brought the help. The French in the Crimea learned from their experience little or nothing and the Americans in their civil war, so much, that from that time dates a new era in military science. These results were brought about not by the magnitude of the need which the Americans had to suffer, for this was not greater than experienced by the French in the Crimea, but rather by the critical and truly scientific spirit, the open minds, the healthy and practical understanding which in America gradually permeated all departments of the army organization, and which, under the wonderful coöperation of an entire people, reached the highest point in humane efforts ever attained in a great war. Whoever takes up and reads the extensive publications of the American Medical Staff will be constantly astonished at the wealth of the experience therein found. The greatest exactness in detail, careful statistics even about the smallest matters, and a scholarly statement embracing all sides of medical experience, are here united to preserve and to transmit to contemporaries and posterity, the knowledge purchased at so vast an expense.”

You may, but those who have come to witness these ceremonies and to offer you their congratulations may not know that in this hall is the largest and most valuable medical library in the world, collected, classified and arranged at comparatively small cost to the Government by Surgeon John S. Billings. Upon its shelves are all the original publications of the bureau, among which are the volumes of the medical and surgical history of the civil war with the issue of which began the new era in military medicine. On other shelves are the seventeen ponderous volumes of the Index Catalogue, the conception and work of Surgeon Billings, which has contributed more to the progress of medicine and advancement of the higher standard of medical education than any single publication by any nation on the face of the globe. To these must be added the nineteen volumes of the Index Medicus, “a monthly classified record of the current medical literature of the world,” edited by Surgeon Billings and Dr. Robert Fletcher, which, with the Index Catalogue offers to all students the opportunity of exhaustive examination of every subject in the whole range of medical science. In another hall is an anatomic and pathologic museum unsurpassed in the variety and value of the collection, which owes its inception to Surgeon-General Hammond, its establishment upon a permanent basis to Surgeon-General Barnes, and its scientific value and importance to Surgeons J. H. Brinton, J. J. Woodward and George A. Otis. In an adjoining room is located the biological laboratory, under the immediate supervision of Surgeon Walter Reed, which, like similar laboratories in the Bureaus of Animal Industry and Marine Hospital Service, is continuously expanding our knowledge of medical and biologic sciences. All these foundations are housed in a building erected by a munificent government to signalize and emphasize the eminent distinction to which this corps has attained in military as in general medicine. These endowments, with their prospective expansion, will in the future, as in the past, give impetus to new thought and to such new and enlarged conceptions of scientific research as may,

eventually, under the fostering care of a generous Government, advance the science of medicine and biology beyond the most hopeful progress of any other civilized nation.

Many years ago the late Surgeon-General Barnes, in a conversation with me, made the statement that it was his policy to encourage the officers of the staff to affiliate with their conferees in civil life, in that the attrition and conflict of thought and experience would be active and effective instrumentalities in correcting mistake, fallacy, misconception and misapplication. In this policy he exhibited that remarkable sagacity which characterized his executive capacity. In the years since that interview, I have had, almost daily, opportunity to witness the good influence and now place upon record the testimony of one in civil life, in evidence of the wisdom of his policy. There is no reason for any division, by the sharp line of official and civil duty, of the members of a noble profession founded upon the broad principles of Christian philanthropy, and it is a pleasing reminiscence of my professional life, that I have in some measure fostered the common fellowship, that was established between the corps of the government medical services and the civil practitioners of this city in the organization, in 1819, of the Medical Society of the District of Columbia, which has continued during the past seventy-eight years and is now more closely fraternal than at any previous period. During the early years of the history of this city the influx of charlatans and pretenders was so extraordinary, and such injuries and wrongs were perpetrated by them upon the citizens, that the qualified physicians assembled to consider and discuss methods of procedure and organization by which the community could be protected from such wrongs and informed of the qualification of those fitted to practice the healing art, which culminated in a petition to Congress, signed by twenty-one physicians, including two surgeons in the army and one in the navy, for the charter which was granted and approved by President Monroe on Feb. 16, 1819. In 1820, Edmund Cutbush of the navy, and in 1822, Joseph Lovell, Surgeon-General of the army, were admitted to membership, and throughout the entire period of the life-history of that society there has been a continuous succession of membership of army and navy surgeons, now including the members of the faculty of this school. During the succeeding decade there came a class of men possessing the doctorate of medicine, but not less unscrupulous than the charlatans who had been transmigrated to some less fortunate community by the act of Congress Feb. 16, 1819, which made it necessary to segregate the men of low and doubtful repute from those who were animated by the highest impulses of honor, dignity and philanthropy. Surgeon-General Lovell and Surgeon Thomas Henderson were the intrepid leaders in the movement which culminated in 1833, in organization of the medical association, which continues in operation. The interesting and pertinent facts are, that army and navy surgeons were actively instrumental in the establishment of the first scientific medical society in this district, which has now passed its seventy-eighth year of continuous existence and is today one of the most active bodies of the kind in this country, and that the surgeon-general of the army was the founder of a medical association, now in its sixty-fourth year of continuous life, which was formed to unite the profession into one concrete body, upon the

Translated by Dr. G. M. Kober and published in Pacific Medical and Surgical Journal, November, 1874.

basis of high professional character and decorum. The attempted but unsuccessful revolt of the community against this organization was a most remarkable occurrence. It was a strange freak of public opinion that assembled citizens in mass meetings to organize concerted action to frustrate the united efforts of physicians to enforce such rules of conduct as would secure to the community the full fruition of the highest qualifications of the medical fraternity and harmonious cooperation among themselves in a common pursuit. And, it was even more strange that the same citizens should in mass meeting, in angry misapprehension, have resolved to sever the close relation of the family physician, and, to accomplish this purpose, have invited from a distance an influx of strangers to supply the places and accept the confidences of the evicted family physicians. To the sturdy independence and courage of Lovell, Henderson and their associates the civil practitioners were indebted for the failure of this unseemly outbreak. Such historical events ought to guarantee permanency of good feeling and harmonious cooperation in all the relations of professional life and association between the officers of these corps on duty in this district and the civil faculty, with so many of whom they may be brought into the closest professional intercourse, as co-equals in all that pertains to that high esprit de corps which should unite us in the common fellowship of a profession, animated by the noble aspirations to alleviate suffering, prolong and save life and to broaden the scope of our usefulness in the interest of and for the good of mankind.

Apart from considerations of a high esprit de corps, a high standard of education, high scientific attainments and uninterrupted and continuous leadership in the advancement of a scientific and philanthropic profession, there are other incidents in the history of the Army Medical Department, which add dignity to honor, and emblazon its escutcheon with the armorial bearings of Revolutionary Sires. In response to that spontaneous outburst of patriotism, following the battle of Lexington, which called "the farmer from his plough, the mechanic from his shop, and the clergyman from his pulpit," physicians in numbers, hastened with their saddle bags from their native towns, to the rescue of the sick and wounded, and to assist the cause of liberty.

On May 8, 1775, the second Provincial Congress of Massachusetts Bay ordered:

"That the President *pro tempore*, Doctor Church, Doctor Taylor, Doctor Holten and Doctor Dunsmore, be a committee to examine such persons as are, or may be recommended for surgeons of the army now forming in this colony."

"Resolved, That the persons recommended by the commanding officers of the several regiments, be appointed surgeons in their respective regiments, provided, they appear to be duly qualified on examination."

At the first examination under that act six out of sixteen applicants were "found disqualified." This was the beginning of the Army Medical Department, which has continued without a break in its history, and is now older than the Constitution, older than the United States of America, older than the office of President, older than the highest tribunal of justice, aye, older than the Declaration of Independence. Born in patriotism, baptized in battle, grown to manhood in the struggle and conflict for independence, it has

reached maturity through a century and more of years of service in peace and in war. Who, then, more entitled to wear the armorial honors of Revolutionary Sires?

ORIGINAL ARTICLES.

A GLIMPSE OF THE HISTORY OF MILITARY SURGERY.

Read at the meeting of the Association of Military Surgeons of Illinois, Springfield, Ill., March 19, 1897.

BY JOHN B. HAMILTON, M.D., LL.D.

PROFESSOR OF PRINCIPLES OF SURGERY AND CLINICAL SURGERY,
RUSH MEDICAL COLLEGE,
CHICAGO.

At the meeting of this Society in Chicago last fall; one of these pleasant reunions which I had the honor to attend, it was suggested that a paper on the history of military surgery would be of interest, and I was asked by your distinguished President if I would write a brief essay on this topic. Fortunately for the Society, he used the word brief, and all of us know what it is to obey a command. Another fortunate thing in the matter was, that it would have been impossible I think to have made it otherwise, in view of the smallness of the material at hand. If, however, the idea had been to write upon the many virtues and important position occupied by departed worthies who had filled places in military surgery, the task would have been easy. I confess my astonishment at the paucity of medical literature on this special subject. If we exclude the Homeric writings we shall find nothing, or next to nothing, about military surgeons in ancient medical literature. Indeed, we must come to the conclusion that in the early days of the human race, when wars were more common than now, and conflicts were hand to hand, the surgeon was viewed as a species of personal property, to be owned by king, conqueror, or great general, and his service utilized as the potentate saw fit.

In Malcolm's History of Persia, we are told that Taxiles endeavored to conciliate the Greek envoy whom Alexander sent to herald his approach. He said: "I shall send to the great conqueror, your master, my beautiful daughter, a goblet made of ruby that replenishes itself with liquid, a philosopher of great knowledge of the sciences, and a physician who has such skill that he can restore the dead." In other words, this ancient exponent of an effete monarchy gave away the young woman, a ruby goblet, a philosopher and a physician with the same ease that he would have given away a pet camel, a jack-knife, or any other article that might chance to have entered his mind at the moment. Nevertheless, the fact remains that physicians were held in great esteem, as Homeric writings abundantly prove, and as a matter of fact, it seems that almost all of the ancient worthies who have contributed much to the literature of our profession, at some time or other were compelled to serve in the army either willingly or unwillingly; but the civil surgeon is better situated for progress in the science of the art, and it must be confessed has contributed much more to the art of surgery in general. If we examine the progress of the art of surgery and especially as applied to the preservation of life of troops and the conservation of the wounded, we shall find that each war in its turn, down to modern times, has given better results. Our own Civil War was an immense improvement in these respects from the war

in the Crimea, although there skilled surgeons from every hospital in Europe were prepared to render service to the armies in the field. The Franco-Prussian War was a still greater advance, because the beginning of recent antiseptic methods were apparent; but the Russo-Turkish War of 1878, especially in the campaigns of Bosnia and Herzegovina, gave marvelous results. It is this difference in methods of treatment between those of the early periods of the present century and that which we practice today, that makes a study of the ancient history of military surgery rather one of curiosity and of polite recreation than of positive advantage. Even the character of arms in general and of projectiles has entirely changed. A constant change has gone on since the days of Paré, Wiseman, Joubert, Braunschweig, Felix Würtz, Gersdorf, Larrey and Percy, Heister, Guthrie and McLeod. But the greatest triumphs of the military surgeon have been in the field of preventive medicine, and in that field the medical men of our own Civil War must ever stand preëminent as pathfinders.

LITERATURE BY MILITARY SURGEONS.

Paulus Aegineta, 625-690, one of the earliest writers on military surgery, speaks of the method of cure of wounds caused by the weapons of his period, such as sling stones, darts, arrow heads, etc. He was the first to recommend that the arrow head be pushed through a wound or put a tube over the barbed arrow. In the time of Justinian, physicians of the war were mentioned whose duty it was to examine recruits and soldiers as to their capacity or disability. At the time of the Emperor Maurice, 582-602, every division of two hundred to four hundred cavalry had eight or ten stout fellows detailed as attendants to furnish water, to collect the wounded, etc. In 1042 it is said that the Norwegian King, Magnus, after a battle, selected twelve of his warriors, who had the softest hands, to care for the wounded and dress their hurts. That the stretcher has been used for an early period we may learn from *Nibelungenlied*.

"Of wounded to the death, know thou our princes high,
Full eighty stretchers, red with blood, are in our land.
—He begged for best of care,
Rest suited for their wounds he sought, and gentle heed."

That the Romans had field hospitals there is probably little doubt, but in the campaigns of Greece and in Asia the old temples which had been formerly used as hospitals were utilized just as they were in the later period.

In Germany in 1570, according to Baas, there was one feldscherer to every two hundred calvary, and each feldscherer had one assistant.

Alexander Benedetti, of Legnago in Lombardy, in 1490 removed to Greece, where he practiced medicine in the isle of Crete, in Canea, which then belonged to the Venetians. In 1493 he returned to Venice and was appointed to a Chair at Padua, but in 1495 he served in the capacity of a military surgeon in the army which the Venetians sent against Charles VIII., and which was defeated before Fornova. He died about 1525. He wrote on anatomy "in which," says Sprengel, "there is not a single new discovery, but there is enough good physiology written in the spirit of the times. His great work is crowded with rare and remarkable observations." (Alexander Benedetti, Opera in 4to, Bas., 1539). His contemporaries compared him with Celsus, "but a more exact parallel," says Sprengel, "would be Alex. de Thralles."

In 1514-1564 we have André Vesalius, who was

born at Brussels. He made his studies first under Lavigne, and afterward under Sylvius, where the ardor with which he applied himself to dissections was said to be the cause of shortening his life. He served as military surgeon in the armies of the Emperor, but later he went to Italy, where in Padua he gave his first course in anatomy. He attracted to himself an enormous number of students. He went also to Bologna and to Pisa. After the publication of his great work on anatomy, Charles V. made him come to his court, and he became physician to Philip II., son of Charles V., and among other remarkable cures he cured Don Carlos from a very dangerous wound of the head. In the last year of his life he visited Palestine, but on his return a tempest arose and the vessel was wrecked on the Island of Zante, where he perished.

"The principal merit of Vesalius," says Sprengel, "was incontestably his judicious critique of the assertions of Galen, and in which he has been sometimes accused of having altered the text, but it has been proven conclusively that these alterations were in the shape of necessary interpolations." There is one thing to be said about Vesalius' "Anatomy," that is, he had the aid of the celebrated artist, Titian, and Jean d'Calcar in the preparation of the anatomic plates. Furthermore, it is said, these are the first exact anatomic plates ever made; for those of Leonardo da Vinci, made for Mark Anthony del Torree, were scattered at his death, and the plates which the immortal Michael Angelo engraved have unfortunately been lost.

There is one point about the writings of Vesalius that must command attention, and that is, that following his master Sylvius, all of his dissections were made on the human body, whereas those of Galen were not, although it is now known that Galen did make dissections of the human body, although most of them were made on animals.

Paracelsus, the greatest medical mystery of the sixteenth century, laid the foundation of his fame as a military surgeon in the low countries, the Roman States, the Kingdom of Naples, and against the Venetians, the Danes and Dutch. He, in 1526, having been called to the University of Bâle to the Chair of Physics and Surgery, wrote in mixed Latin and German and said that the writings of Hippocrates were true enough for Greece, but were of no use in Germany. He said that every hair on his head was more learned than all the Arabs and Greeks united, and he publicly burned the books of Hippocrates and Galen that he might show his contempt for them.

Ambroise Paré, the celebrated French surgeon, followed the French army in all its campaigns from 1536 to the battle of Moncontour in 1569. He was a barber by trade, and the son of a barber. His life and the incidents of his famous career have been so frequently told that I may be pardoned for omitting further reference to him here. He is commonly spoken of as the father of French surgery. This is incorrect, as that title is due to Henri d'Mondeville, 1320, and if not to him, at least to Guy de Chauliac, 1360. But d'Mondeville is clearly enough the father of French military surgery, as de Chauliac never served in a military capacity, being a churchman at Montpellier.

Paré's first work was on the true method of treating wounds, etc., in which the ligature was brought out; but as it is now known, this had been previously recommended by d'Mondeville, by Theodoric and Galen.

But Paré was a voluminous writer, a forceful man, and as Napoleon said of Larrey, "The most virtuous man I ever knew," and popular among the troops to an extent that no modern surgeon can ever hope to aspire.

In the fifteenth century in England, as a curious reminder of the salary of army surgeons of the period, we find that Henry V. in 1415 engaged Nicholas Colnet as field surgeon, who, it is said, "must carry three mounted archers and accompany the King wherever he went. In return he was to receive yearly forty merks, at the rate of ten merks per quarter. He had also twelve pennies a day as subsistence money, and each archer twenty merks a year and six pennies a day subsistence. Morstedt, who was Chief Army Surgeon, had served at Agincourt, was engaged with fifteen men, three archers, and the remaining twelve surgeons."

The next English military surgeon is Thomas Gale, who was born in 1507, served in the army of Henry VIII. and afterward in that of King Philip at St. Quintin in 1557. He published a treatise on gunshot wounds.

A curious incident is cited by Ballingall of the first examining board. He quotes Thomas Gale, who was attached to the English Army from the time of Henry VIII.

"I remember," he wrote, "when I was in the wars at Muttrel, in the time of that most famous prince, King Henry VIII., there was a great rabblement there that took upon them to be surgeons, some were sow-gelders, with tinkers and cobblers. This noble sect did such great cures that they got themselves a perpetual name, for, like as Thessalus' sect were called Thessalians, so was this rabblement for their notorious cures called dog leeches, for, in two dressings, they did commonly make their cures whole and sound forever, so that they neither felt heat, nor cold, nor no manner of pain after. But when the Duke of Norfolk, who was then the General, understood how the people did die, and that of small wounds, he sent for me and certain other surgeons, commanding us to make search how these men came to their death; whether it were by the grievousness of their wounds, or by the lack of knowledge of their surgeons. And we, according to our commandment, made search through all the camp and found many of the same good fellows which took upon them the name of surgeons. Not only the names, but the wages also. We, asking of them whether they were surgeons or no, they said they were. We demanded with whom they were brought up, and they, with shameless face, would answer, either with one cunning man or another who was dead. Then we demanded of them what chirurgery stuff they had to cure men withal; and they would show us a pot or a box, which they had in a budget, wherein was such trumpery as they did use to grease horses' heels, and laid upon scabbed horses' backs; and others that were tinkers and cobblers; they used shoemaker's wax with the rust of old pans, and made there withal a noble salve, as they did term it. But, in the end, this worthy rabblement was committed to the Marshalsea, and threatened by the Duke's grace to be hanged for their worthy deeds, except they would declare the truth what they were, and of what occupation; and in the end they did confess, as I have declared to you before."

William Clowes was a navy surgeon, 1570, who afterward in 1585 went to care for the wounded in the low countries.

Among the early English surgeons Alexander Munro, who served with McKay's Scottish Regiment, 1626, and who was doubtless much more accustomed to the claymore than he was to the roar of the artillery, gives an account of the impression upon the early armies of the invention of artillery.

"It is thought the invention of cannon was first found at Nurenberg, for the ruin of man; being at first for a long time used for battering down of walls and cities, and for counter batteries, till at last they were used in the field to break the squadrons and battailes of horse and foot; some carrying pieces called spingards of four foote and a halfe long, that shot many bullets at once no greater than walnuts; and how soon the trumpets did sounde, the enemy were thundered on, first with these as with shours of hailstones, so that the enemies were cruelly affrighted with them, men of valour being suddenly taken away, who before were wont to fight valiantly and long with the sword and lance, more for the honour of victory than for any desire of shedding blood; but now men martyrizd and cut down at more than half a mile of distance, by those furious and thundering engines of great cannon, that sometimes shoot fiery bullets able to burne whole cities, castles, houses or bridges, where they chance to fall, and if they happen to light within walles or amongst a brigadd of foot or horse, as they did at Leipsigh, on the grave of Von Torne, his brigadd, they spoil a number at once, as doubtless the devilish invention did within Walenstine."

It will be recalled that many years were spent by surgeons in the discussions of the alleged poisonous character of the balls used as projectiles. Curiously enough, the idea of the idiopathic poisonous nature of bullet wounds was revived in the Slattery case tried in 1892, in which the acquittal of the accused policemen turned partly upon the issue whether bullet wounds were or were not necessarily septic. The acquittal decided they were not.

The seventeenth century was prolific in the annals of military surgery, especially in English. Woodall's "Surgeon's Mate," written about 1626, and the "Chirurgical Treatise" of Richard Wiseman appeared in 1676.

In the eighteenth century we have John Hunter, who was staff surgeon and general surgeon; Surgeon-General John Pringle, whose writings were far ahead of the time in regard to hospitalism, and Inspector-General Robert Jackson, and in America James Thatcher.

Jackson, who was the Inspector-General of British Army Hospitals, commenced his medical life as surgeon to a Greenland whaler, but he finally entered the British service and served through our Revolutionary War. Many traits of Jackson deserve to be perpetuated and held in remembrance. Although we are not accustomed to speak well of our enemies, yet that chivalrous spirit which should imbue all military men leads us to recognize remarkable bravery wherever found.

At the battle of Cowpens, Jackson served as Assistant Surgeon to the Seventy-first Regiment in Tarleton's Brigade, and during the heat of action Tarleton's horse was shot, and Dr. Jackson, being well mounted, rode to his side and dismounting tendered him his horse, which was accepted, and Tarleton immediately rode off, although the British were in full retreat and hotly pressed by the Americans. Seeing that many wounded British were in our hands Dr. Jackson fas-

tened a white handkerchief to a stick and as a flag of truce walked directly to the American front, where he was conducted to the rear as a prisoner, and immediately offered his services to attend the wounded. He occupied himself that night in caring for them and in default of dressings took off his own shirt and tore it up for bandages. The next morning he was sent for and examined by General Washington, to whom he tendered his professional assistance for the wounded Americans also, an offer which was readily and courteously accepted, and as soon as the British wounded could be exchanged, Washington sent Dr. Jackson with them without requiring his parole or demanding an exchange.

The biographer of Jackson, himself a Briton, relates this story, and adds that "he would have taken great pleasure to have been able for the honor of human nature to have entered upon the record a demonstration of General Tarleton's grateful recollection of the service done him by Dr. Jackson in the hour of his rout and danger. But Lieut.-Colonel Tarleton in his history remained entirely silent; although to this remarkable instance of duty and devotion perhaps he owed his life, as he certainly did his liberty and capability of usefulness." Later Dr. Jackson served under Lord Cornwallis, and after one of the battles, when the British troops were retreating, the building into which the sick and wounded had been carried was being riddled by the shot of the Americans, visiting became so dangerous that the surgeons proposed casting lots to determine which of them should go and attend the wounded soldiers. Jackson was present and when the proposal in turn reached him to cast lots, he said: "No, no, I will go and attend them." And he did.

Jackson's work on the "Formation, Discipline and Economy of Armies," the last edition of which was published in 1845, is today a book of great interest and instruction.

Dominick Anel (born 1679, died 1750), the French military surgeon, was the first to write on the cure of lachrymal fistula by the aid of sounds and injections. It is curious, in looking up the history of these smaller operations, to notice the enthusiasm with which military surgeons were engaged in treatment of affections which might be supposed to belong exclusively to private life.

The Dutch army surgeon, von der Haar, perfected the method of hare-lip operation, and recommended a preliminary bandage by which the parts were brought strongly together.

In abdominal surgery the military surgeon has long been in advance. I need not refer to that noble collection of authorities, gathered by your distinguished president, when he wrote his classical article on "Circular Enterorrhaphy," but can only refer you to Wiseman, 1676, and others of that date and of the succeeding century as to the treatment of wounds of the intestine.

Of hernial operations, one of the most remarkable was performed by Mennel, a regimental surgeon of Naumbourg, who, about the year 1753, in a case of gangrenous hernia, removed the epiploön, the testicle, the cord, and a considerable portion of the ileum. Unfortunately, all of the military surgeons of that day were not thus successful. "The operations of Michaelis," says Sprengel, "were unfortunate operations, and, for the most part, executed with much maladroitness."

Claude Joseph Gentil, Chief Surgeon of the Armies of France, paid particular attention to operations for

cataract and the prevention of staphyloma in 1752. The operation for cataract, now a prominent subject, occupied the attention of surgeons, and was a frequent topic for discussion a great many years. Among others Olof Acrel, who was professor at Stockholm and Chief Surgeon to the Swedish Army in 1766, wrote a long criticism on the best method of extraction of the crystalline lens.

John Christian Tagden was called the Machaon of the Prussian Army. He wrote a work on surgery, in 1795, which is a veritable storehouse of medical and surgical information.

Christian Louis Mursinna in 1796 wrote a work published at Berlin on the observations which he had made in the campaigns of the Prussian Army, with especial reference to wounds of the head.

J. C. Jager in the same year wrote an essay on military medicine, published at Frankfurt-on-Main.

Within the limits of this paper it is hardly possible to speak of the great work of Guthrie, Hunter and McLeod on the Crimean War, and in naval affairs of Saurel and Sir Gilbert Blane, whose "Medicina Nautica" was an epoch-making book.

In the nineteenth century a course on military surgery was established at Edinburgh by Wm. Ballingall, who had seen thirty years service. It must be admitted that a course on military surgery had been outlined by John Bell in a memoir in January of 1798, addressed to Earl Spencer, but it was not adopted by the British Government. One is impressed with the advanced views entertained by Bell at the close of the eighteenth century. They are as follows:

1. The Professor must teach the essentials of anatomy, surgery, dissection, etc.

2. Gunshot wounds.

3. Military medicine, fevers, fluxes, spasms, infectious diseases and duties of camp and hospital; scurvy, ulcers and disorders frequent in ships of war.

4. Medical geography, climates, seasons, coasts of various countries; manner of conducting soldiers on a foreign expedition; the general care of their health; the choice of encampment; forming of hospitals on shore; how to convert churches, garrisons, public buildings into occasional hospitals; how to attend an army in the field; how to lay the wounded in besieged towns; how to carry them off the field in a retreating army.

5. Military economics, diet, exercise, clothing, general medicine, and all methods of preventing disease.

For a quarter of a century Legouest remained the standard French text-book on military surgery, but it is now superseded by the latest work on military surgery, by Chauvel and Nimier, who, in speaking of the progressive improvement, say, "That frightful hecatomb, the Crimean War, has come to demonstrate the sad results of a vicious organization, more murderous than the projectiles of the enemy; the epidemics due to a neglect of the most elementary rules of hygiene, thinned the ranks of the effectives. The slightest wound became a cause of death, and in the crowded hospitals and the overloaded ambulances the surgeon sought in vain against infection which decimated them nearly to the close of a day where, worn with the enervating struggle and superhuman work he fell to rise no more, on this rotten straw, the only bed which was furnished for his needs. This was the *corps de santé militaire*: Invalids, physicians and pharmacists, who paid the heaviest tribute to the

dead. However, France, ignorant of these disasters and of their cause, wept silently for its children, and without asking if their loss could have been prevented, or if all had been done to save them.

"Michel Levy and Bégin raised in vain their voices. The cannon which thundered to celebrate the victory and the peace drowned the appeal of the physician as it concealed the cries of the dying and the tears of the mothers. The War of Italy came and we have seen reproduced the same disorder and the same results. Here were physicians without material, and material without physicians; warehouses stored with linen, charpie, surgical cases, etc., during which much of the time in the ambulances and hospitals, over the battlefield, there were a hundred physicians to give assurance of service for an army of twenty thousand men. In a word, all the evil effects which were seen in Crimea and Constantinople were here observed on French frontiers whilst still in a friendly country. The emancipation of the medical corps was not yet complete, but the example of the United States by its incontestable statistics in favor of the value of independence of the medical corps was finally adopted by a decree issued in 1882. Today in the French military service, as in other armies of the civilized world, the military surgeon is the veritable chief of his own service, and with this authority has been vested in him the responsibility."

The English Army has fared much better. It was early made apparent in the history of that enlightened nation, that not only were competent physicians needed for the military service, but that they must have autonomy and responsibility for their portion of the work.

In Germany military surgery has had the same evolution marked in other countries. Fischer of Hanover, whose historic articles are now appearing in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, notes with surprise that the great Frederick wrote exhaustively on the affairs of the sutler, but very briefly on transportation of wounded and immediate assistance on the field.

"Frederick occasionally visited the hospitals, gave money to the sick soldiers, investigated the medicine vials and showed special interest in certain wounded soldiers." But Frederick in 1781 put captains in command of the doctors and stewards, "so that arms and legs would not be amputated wholesale, and that in general no amputations should be undertaken until mortification had set in, for which the captains must also be responsible." If the surgeon did not do his duty he was to be "put in chains."

This regulation naturally brought confusion and mismanagement, and Zimmermann was finally called to rectify it.

Cothenius and Schmucker, Bilguer and Theden served with distinction in the seven years' war. Schmucker was badly wounded at the battle of Prague, but nevertheless kept on duty. He was very much annoyed by the lack of transportation; he obtained permission to have a regiment of dragoons dismounted, and "in half an hour all the wounded were on horses and the dragoons marching at their side." (Fischer.)

The very interesting chapter of Fischer's book, I must refer you to as containing in brief space the condensed history of German military surgery. I can not take more of your time now on this branch of the subject, but I wish to express my unbounded admiration for the system now carried out by that

able and distinguished and courteous officer, General Von Coler, at once an ornament to his profession and to the military service. Through his courtesy, when in attendance at the Medical Congress in Berlin in 1890, I was afforded by him abundant opportunity to study the present German method.

The German and Austrian armies have in our day shown great appreciation of their medical corps. In Germany Volkmann, Gürtl, Von Esmarch, Bardeleben, Von Bergmann and Von Coler, and in Austria Neidorfer and the immortal Billroth represent not only the most advanced military surgery, but all that is best in general surgery as well.

In Russia who has not heard of Pirogoff and the gallant Reyer?

In this outline I have omitted reference to our own country as many of those present understand its military history as well, and some of them better than myself; beside, the brilliant successes of the medical department of our Army have been adequately portrayed by Capt. Harry E. Browne of the Army, from the writings of James Thatcher, Mann, Lovell, Letterman and Otis to those of Hammond, Barnes and Baxter.

As we sit here within our now peaceful State, within the shadow of the Capitol, our eyes are turned again to the orient as were those of our ancestors of a thousand years ago, and the familiar names of Canea, Crete, Actium and Thessaly are on every tongue, and if grim-visaged war, now showing his wrinkled front on the Grecian frontier, shall actually come to that historic people, I have no doubt that the glories of ancient Greek medicine will be surpassed by our Grecian military brethren at the close of the nineteenth century by the application of the methods now in vogue.

SURGERY OF THE KIDNEY.

BEING A STUDY OF A SERIES OF CASES IN WHICH
METHODS OF DIAGNOSIS AND TREATMENT
ARE ILLUSTRATED.

BY BAYARD HOLMES, B.S., M.D.

PROFESSOR OF PRINCIPLES OF SURGERY IN THE COLLEGE OF PHYSICIANS
AND SURGEONS OF CHICAGO.

RENAL CALCULI.

In this series of cases none are more interesting from a surgical or from a pathologic standpoint than those in which calculi were found. The imagination is at once aroused to conceive the various causes of renal calculi, and the ingenuity is taxed at each effort to diagnose the condition and afterward to treat the case in the wisest manner in the emergency of the operating room.

Occasional attacks of pain in the right side of the abdomen in a multipara for twenty-five years. Insignificant renal and urinary symptoms. No interference in the general health. At last at 63 years of age suppurative pyelitis. Nephrotomy and removal of the stone, drainage of the kidney for four weeks. Closure of fistula.

Mrs. D., age 63, widow, was treated by me in St. Luke's Hospital on March 25, 1896. She had complained for some time of a pain and tenderness in the right hypochondrial region and had had a great many attacks of pains in this region during the past twenty-five years, which had been termed by her attending physicians liver complaint and congestion of the liver indiscriminately. These attacks had usually lasted five or six days and had been relieved by rest in bed and a light diet with the use occasionally of narcotics

to lessen the pain. Otherwise she had not been sick but had constantly suffered from frequent and some times painful urination though this had not been a marked symptom of the fore-mentioned attacks. Upon admission she complained of great pain in the right hypochondrial region and a very irritable bladder, loss of appetite and diminution of strength. Dr. Mary Bush, of Rogers Park, had seen her and had

FIG. 1.—Mrs. D. Diagram of abdomen made before operation, showing the location of the tumor as outlined by palpation and percussio.

bladder distended with air and a ureteral catheter passed into the left ureter. Four cubic centimeters of urine passed from this ureter in fifteen minutes. This urine was free from pus, albumin and casts. It contained a large amount of urea, 40 grams per liter.

FIG. 2.—Diagram of the vaginal and rectal examination. U, uterus; P, wall of pelvis; L.C.d.S., left cul-de-sac; A, thickened mass in right cul-de-sac.

made a diagnosis of pyonephrosis of the right kidney. Upon examination the lungs were found normal and the heart slightly enlarged, the apex beat three and one-half inches from the median line in the fifth interspace. The patient was rather fleshy weighing 160 pounds and somewhat anemic. The spleen could not be palpated and the area of hepatic dullness was increased about one and one-half inches. In the right abdominal region was found a large and smooth tumor extending about two inches above the level of the umbilicus and

Although the catheterization was readily accomplished the patient was so exhausted by this procedure that no attempt was made at this time to catheterize the right ureter. On the following day, however, the catheter was passed into the right ureter but nothing escaped the catheter except a small amount of thick greenish pus. The catheter was removed, washed and reintroduced without any other result. No long flexible catheter was at hand and the indications were

FIGURE 3.

three or four inches downward toward the brim of the pelvis. This tumor was very tender on pressure and practically immovable. Examination through the rectum and vagina outlined in its normal position a somewhat atrophied uterus. The right cul-de-sac was lower than the left and seemed to be filled with tissue that was tender on pressure and extended as high as palpation could be made. The condition is represented in the accompanying sketch (Figure 2) which was made at the time. Examination of the urine showed it to be cloudy and reddish, of which fourteen ounces were passed in twenty-four hours, specific gravity of 1.022, slightly acid containing a small amount of albumin and 20 grms., of urea to the liter, or 10 grms., per day. This urine contained considerable pus and some epithelium. Upon admission her temperature was 99.2 degrees, pulse 80 and her respirations 26 per minute.

On the second day after admission the urethra was dilated, the patient put in the knee-chest position, the

considered complete for the removal of the fluid which evidently filled the right kidney. On the evening of the fourth day several small doses of calomel were administered and on the morning of the fifth day the bowels were moved with an enema and the patient anesthetized on the morning of the sixth day. The temperature at that time was 98.6 degrees F., pulse 72 and the respirations 20 per minute. Chloroform was given by Dr. D. H. Galloway and Dr. Bush and Dr. Clark assisted. The operation lasted forty minutes. A median incision was made into the abdomen for digital exploration. A large, hard, rough and nodular kidney was found floating in the abdomen. The patient was then turned upon her side and the ordinary curved lumbar incision made. Even with a finger in the abdomen, great difficulty was experienced in holding the kidney into the lumbar wound. The wall of the tumor at its thinnest point was punctured with the seizors and a hard stone felt surrounded by about six ounces of watery pus. The opening into

the kidney was enlarged and a stone two and one-half inches long and one and one-half inches in diameter was extracted with some difficulty. It was found necessary to crush it with strong forceps and remove it piece by piece. It seemed to occupy the entire pelvis of the kidney and had no fassets behind it indicating the presence of other calculi. The cavity was explored with the finger but no other stones found. The ureter was somewhat dilated, but the thickness of the wall of the kidney seemed to suggest the presence of enough kidney substance to be useful in secreting urine. The edges of the pelvis were grasped with forceps and the pelvis itself packed with iodoform gauze inside of the Mickulicz handkerchief. A portion of the lumbar incision was closed with sutures and the abdominal opening completely closed and dressed. The patient was put to bed in good condition. Her pulse during the afternoon and evening ranged from 59 per minute directly after the operation with a temperature of 97 degrees F., to 80 per minute with a temperature of 98 degrees F., and respirations 28 per minute. There was a good deal of oozing from the wound but it was of a very pale and watery character and showed no tendency to the formation of clots. When burned in the flame it gave off a urinous odor. On the fifth day after the operation the discharge was almost entirely urinous and saturated the dressings with six ounces in twelve hours showing considerable activity in the kidney.

The accompanying temperature record (Figure 3) shows the uneventful progress of this case. The patient left the hospital on April 26 with the wound not yet entirely closed, but all urinous discharge had ceased for several days before. A few days afterward a fragment of stone was discovered in the wound and removed. Since this event and up to this writing (March 1897) the wound has completely closed, the patient is gaining in strength and the urine seems entirely free from pus and albumin.

This case illustrates the way large calculi are borne by the kidney. For many years the symptoms were so slight as to be hardly noticed. There were of course occasional attacks of pain but they did not last long. At last the ureter became partially obstructed and the symptoms were more pronounced. The case also illustrates the possibility of demonstrating the adequacy of the opposite kidney before operation. The scanty urine that was removed from the left ureter contained an excessive amount of urea and pointed at once to its health and the need of a larger amount of water to carry away the urea. Incidentally also this case shows the possibility of performing the most serious operations upon very old persons, even under such unfavorable conditions as attend the destruction of a kidney. Operations as serious as nephrotomy have been successfully performed on octogenarians.

Nephrectomy was thought of in this case, but the result shows that it is better to leave behind rather than remove remnants of a suppurating kidney provided there is no obstruction in the ureter. If necessary the kidney may be removed at a subsequent operation after the patient has recovered from the sepsis and the effects of the pain.

There are many cases of calculus which give rise to no symptoms and are only discovered postmortem. In many cases also small calculi pass into the bladder at intervals with dreadful pain. It is sometimes possible to follow such a stone along the ureter by

the point of tenderness and at last with the cystoscope see it borne into the bladder as I have once done in a man, using for the purpose a Casper ureter-cystoscope. It is often possible to prove that the stone has been discharged into the bladder by using the cystoscope. This I have done and after making a drawing of the small stone with a bloody end my patient did me the kindness to urinate and demonstrate the accuracy of my observation by passing the calculus which had irritated his prostate for several days.

Many cases of calculus of the kidney are not surgical cases at all and become surgical only when they have gone on to suppuration or to such excessive pain as to interfere with health.

THE UTILITY OF NUCLEIN.

A Clinical Lecture delivered at Mercy Hospital.

BY N. S. DAVIS, JR., A.M., M.D.

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE AND CLINICAL MEDICINE, NORTHWESTERN UNIVERSITY MEDICAL SCHOOL.

At the clinic last week I showed you this patient when he exhibited most fully the physical signs and symptoms of croupous pneumonia. He had then been ill five days and was suffering from a moderately severe attack of the disease. The lesion was limited to the lower lobe of the right lung. At that time I hazarded the prophecy that unless an extension of inflammation occurred he would be likely to pass the crisis of his illness either on the night of the day that you saw him or within the two following days. I also pointed out to you the treatment that was usual in such cases and particularly called attention to the fact that in this case I was trying in addition to the ordinary routine treatment of pneumonia nucleic acid. I made no comment at the last clinic upon the mode of action of nucleic acid or the indications for its employment in the treatment of diseases. I call your attention now to this patient in order to point out the changes that have occurred since you last saw him, and also to speak somewhat more at length in regard to the usefulness of nuclein as a remedy, not in cases of croupous pneumonia only, but in other diseases as well.

Almost immediately after you saw our patient there occurred an extension of inflammation so that the entire lung on the right side was involved. During the week after this spread our patient became extremely ill. His fever continued high, in the neighborhood of 104 and 104½ at night time. He was delirious almost continuously. His breathing was very rapid, varying from 40 to 50 and sometimes 55 per minute; it was also shallow. He gradually grew cyanotic, his lips and finger-nails were bluish, and the skin over his body of an ashen gray. At one time he seemed so ill that recovery appeared impossible. On account of the very pronounced cyanosis and because of the constant delirium and unconsciousness of our patient, it was thought necessary to administer oxygen gas freely. It produced its usual effect; the cyanosis for the time was lessened, the mucous membranes became pink and the heart grew stronger and the pulse fuller. Our patient, however, under the influence of oxygen gas did not become entirely conscious or lose his delirium altogether, but his mental state improved. As good fortune would have it his temperature during the last three days has gradually lessened, and in all respects his condition has

slowly improved. You now see him conscious, with a temperature this morning of 99 and a temperature last night of only 100 $\frac{1}{4}$. His pulse is medium in size, very regular, and from 80 to 85 per minute. The respirations, however, are still quick. You will observe that they number 35 to the minute, and are shallow. Percussion over the affected side of the chest demonstrates marked dulness over the entire right lung. It is filled with moist râles indicative of liquefaction of the fibrinous exudate.

So much for the present condition of our patient and for the history of his illness since you last saw him.

In regard to his treatment.—Aside from the employment of nucleinic acid there has been nothing unusual used. He has been given five grains of carbonate of ammonia every two hours; and during all the severe part of his illness strychnia was given in full doses. Oxygen was administered very freely by inhalation. Digitalis was given when the heart was most feeble and cyanosis was greatest. We are still administering strychnia and digitalis, but not frequently; the carbonate of ammonia has been discontinued. Of course the patient has been fed carefully and systematically, even during his delirium, but only liquid foods. His bowels have been kept regular, for the most part by the administration of enemata. In this case I prescribed nuclein as I have frequently in others, because of the excellent experimental results obtained by Vaughan with the drug in animals infected by the pneumococcus. I was, moreover, led to employ it in this case particularly because a comparatively new preparation of nucleinic acid was put in my hands for trial—a stronger preparation than has usually been employed. Whether it has produced good effects or not in this individual case we will consider a little later, I will first refer to the mode of action of nucleinic acid and its mode of administration, and then consider its therapeutic value.

Nucleinic acid or, as it is commercially known, nuclein, was introduced to the profession by Professor Vaughan of Michigan University. Professor Vaughan has been most ably seconded in his experimental investigation of nuclein by Drs. McClintock and Novy of the same institution. It has been demonstrated by them, and the demonstration has been confirmed by various observers in other parts of the world, that nuclein possesses very pronounced germicidal power. Moreover, when it is administered to animals or to man it produces leucocytosis or phagocytosis, that is, a great increase in the number of white blood corpuscles. The amount of uric acid eliminated by the kidneys is augmented when it is taken. Nucleinic acid has also been shown to be absolutely innocuous. It can be given in doses of all sizes, and can be administered either by the stomach, hypodermatically, or injected directly into the veins of animals, without causing fatal results or illness. This is a rare combination of qualities. All of the germicides that we are accustomed to employ are poisonous to animals and to man, if used in sufficiently large doses. According to prevailing theories as to the cause of immunity to infectious diseases, phagocytosis is of prime importance, and a drug which will greatly increase the number of leucocytes in the blood we would expect to be of value to combat an infectious malady. Indeed, as you know, Metschnikoff assigns to phagocytosis wholly the power of combating microorganisms that gain access to the tissues or

the blood of animals or man, and he has declared that if we can increase the number of phagocytes in the blood at will and sufficiently, we have almost a certain means of combating infectious maladies. Whether this statement is absolutely correct or not can only be demonstrated by extensive clinic trials of those drugs that provoke phagocytosis, and extensive experiments in the laboratory with the same class of remedial agents.

Vaughan showed in some of his early experiments that nuclein administered hypodermatically to those animals that are very susceptible to infection by pneumonia will produce complete immunity toward the pneumococcus. It would therefore seem that nucleinic acid should prove an important remedial agent in the treatment of croupous pneumonia. His experiments also demonstrated that it readily killed staphylococci and streptococci. Some of his experiments showed that it produced at least an attenuation of the virulence of tubercular infection. Vaughan therefore urged that nucleinic acid be tried by physicians in pneumonia, in infection by staphylococci and streptococci, and in the early stages of tuberculosis.

Some very recent experiments by Hahn are of interest at this point. He has proven by the introduction of nucleinic acid into the blood of animals that the germicidal properties of the blood serum are very greatly increased. For example, by taking a given quantity of blood serum from a healthy animal and inoculating it with the staphylococcus, he found at the end of two hours that only 19 $\frac{1}{2}$ per cent. of the microorganisms were alive; at the end of five hours, only 4 per cent. were alive. If nucleinic acid was introduced into the blood of the same animal, a marked leucocytosis was rapidly produced and the germicidal power of the blood serum was increased, so that when it was inoculated again with staphylococci, at the end of two hours only 2.9 per cent. were alive; and at the end of five hours only 1.7 per cent. The bactericidal properties of blood serum were shown to be increased more for the bacterium coli commune than for staphylococci. It is possible, as Hahn claims, to double the number of leucocytes in the blood in a few hours, and to double or even more than double the germicidal power of the blood serum by administering nucleinic acid. In order to produce a perceptible increase in the germicidal power of blood serum the number of white blood corpuscles must be increased to 13 or 14,000 per cubic centimeter.

The remedy has not been employed as extensively as it might have been, because at first it was recommended that it be used only hypodermatically, and few remedies that are employed hypodermatically gain very general use. Patients object to frequent puncture of the skin by a hypodermic needle if thereby they are not immediately relieved of pain. But it has been shown by the investigators at Michigan University that the drug can now be employed in solutions of 5 per cent. strength by the mouth, and quite as good results can be obtained in this way as by its hypodermic use. I doubt not, therefore, that we will soon see it more generally tested. We will then be better able to determine its exact degree of utility as a remedial agent.

There are several preparations upon the market which bear the name of nuclein. For the most part these are liquid preparations and are solutions of nucleinic acid. Personally I know nothing of the genuineness or value of these various preparations. Prof. Chittenden of Yale University, has made a care-

ful analysis of them, and in a recent publication has asserted that the only preparation which he has found to contain any considerable quantity of nucleinic acid (and it is the nucleinic acid which is the active principle of the preparation) is the solution which goes by the name of nuclein prepared by Parke, Davis & Co., of Detroit, Mich. My own experiments have been both with this and other preparations, but chiefly with this preparation of nucleinic acid. The clinical results which I have obtained by its employment have been conflicting. I have used it in a great variety and in a large number of cases, sometimes with encouraging results and sometimes with apparently no results at all; yet often enough with apparently good effect to make me willing to test the drug still further, particularly as we know that it is innocuous.

I have used it, I think, in ten or a dozen cases of pneumonia. I tried it at first hypodermatically, and stopped using it because it was so disagreeable to my patients; more recently I have tried it again, administering it by the mouth. In no case has the course of the disease been shortened. The difficulty of estimating the value of a drug by its trial in a given case is well illustrated in the one before us. It is quite impossible from any one or from a dozen cases to judge of the utility of a given drug. Its effects must be carefully watched in very numerous cases, in cases that occur in different years and in different epidemics, and cases of very different degrees of virulence. The patient before you has suffered from an intensely severe form of croupous pneumonia, and has been so seriously ill that at one time it seemed impossible for him to recover. The disease has been prolonged by the extension of the lesion from one part of the lung to another. In ninety-nine cases out of a hundred as severely ill as he was, recovery would not take place. Fortunately in this case recovery is taking place. That nucleinic acid has played a part in producing this recovery, we can not say with certainty. We expected, or hoped rather, that by its administration the bactericidal properties of his blood serum would be so increased as to prevent spread of the lesion in the lungs. The drug was employed in this case for about thirty-six hours before any extension of the disease occurred; but it did not, as you see, prevent the extension. It may, however, have played a part in making the patient better able to withstand the severe attack of illness that he has gone through.

The best results which I have seen from the employment of nucleinic acid have been in cases of infection by pyogenic organisms, in cases where there was plainly infection but not actual suppuration. For instance, in quinsy where a tonsil was enlarged in the way characteristic of this form of sore throat, and when suppuration seemed imminent the drug has apparently prevented suppuration. Such good results have been obtained only when it was administered early and frequently. In the treatment of bubos, variously caused, similar results can often be obtained. After suppuration is established it does not seem to influence it. It is well known that all glands infected by pyogenic organisms do not suppurate. However, I have used the drug so often in such cases as to have acquired some confidence in its ability to prevent suppuration. I have used the drug in several cases of suppuration in deep-seated organs, from which drainage could not be perfectly established, but have never gotten positively good results

Some of you may remember a case in this hospital last winter, of abscess of the lung, a simple abscess, not a tubercular one. In that case nucleinic acid was administered hypodermatically just so soon as there was any suspicion of an abscess in the lung; and it was used persistently without appreciable effect. During the last summer I have employed it in two cases of intense pyelitis. The first occurred as a complication of disease of the spine which produced a paralysis of the sphincter muscles of the bladder, causing thereby retention of urine. The bladder was so greatly and so long distended with urine that the latter underwent decomposition and provoked inflammation of the bladder. The inflammation extended to the pelvis of the right kidney. When the patient first came under my observation he was extremely ill, suffering from a continuous fever, sweating at night, able to retain no nourishment, with a very feeble pulse and apparently not likely to live more than a week, if so long. The patient was removed from his home, where he was receiving very imperfect care, to the hospital; his bladder was frequently perfectly emptied and was carefully washed. At the same time nuclein was administered persistently. Teaspoonful doses of the 5 per cent. solution were given by the mouth once in two hours at first. The kidney, which had been greatly enlarged by the accumulation of pus and urine in the pelvis of it, rapidly diminished in size, the tenderness of the organ gradually disappeared, the fever disappeared with rapidity, vomiting ceased and nourishment was taken with avidity and ease. A somewhat rapid recovery took place; not a complete recovery, for that is probably impossible, but a comparative recovery. He now voids only a small amount of pus with his urine; he has once more gained control of the sphincter muscles of the bladder so that catheterization has no longer to be resorted to, and is feeling in every way comfortable. His lower limbs are of little use to him.

In this case, too, we are left in doubt as to how much the improvement has been effected by nucleinic acid and how much was due to the fortunate thorough drainage of the pelvis of the kidney through the bladder by regular removal of urine from the latter organ. Quite as good results have been observed where nuclein was not used.

In furunculosis it has repeatedly seemed to lessen the number and size of the successive boils and to make the disease of less than the usual duration.

I have tried nuclein in two cases of malignant endocarditis. In cases of this disease above all others we would expect a drug that is innocuous and that possesses such marked bactericidal properties to be beneficial, since the infection is in the blood channel. But in neither case has improvement been observed that seemed justly ascribable to nuclein. One of these patients you know, for he is now in this ward. You examined him when he first showed symptoms of malignant endocardial trouble, and you have seen embolism occur in his arm and leg, and finally gangrene of one foot develop. Nuclein was administered to him every two hours for several weeks. The patient, as you will remember, had daily a high temperature which lasted for an hour or two only. It first reached 106, and quite constantly ranged above 104. After the nucleinic acid had been used for some days the temperature gradually fell, its daily maximum being 102 or 102½. While the temperature ranged high there was both morning and evening a

period of elevation. Usually the morning temperature was highest. The highest rises of temperature coincided with the occurrence of embolism in new localities and followed it for one or two days.

The patient is steadily failing in strength. The noticeable diminution of fever is quite as probably due to the occurrence of no new embolism as to treatment. The failure of the treatment in this uniformly fatal disease is not unexpected.

As nucleic acid increases the bactericidal power of the blood, it might be expected to be especially serviceable in those diseases in which the blood is the seat of infection. We have no clinical or experimental evidence bearing upon this point.

Vaughan reported good results from the employment of nuclein in cases of diphtheritic sore throat produced by streptococcus infection. He used it both locally upon the throat and administered it hypodermically. I have also used it in these cases both locally and internally. I have never felt so great confidence in it, however, as to be willing to discard other germicides. I use invariably in addition to it the peroxid of hydrogen either with the atomizer or with a syringe. Recovery has occurred without complications in all cases of this kind that I have treated in this way.

Vaughan's experiments with nuclein in the laboratory on animals affected by tuberculosis were sufficiently flattering, although he could not produce absolute cures or perfect immunity by the drug, to make it appear of probable utility, at least in cases of incipient phthisis. He urged the profession to try it. I have endeavored to watch its effects in a large number of cases. If it does good it probably does so in part by lessening the virulence of the tubercle bacilli and in part by preventing superimposed infection by pyogenic organisms, to which there is always so strong a tendency. I have often thought that when given in the first stage it delayed suppuration and excavation.

Since nuclein produces experimentally such marked phagocytosis and increases the bactericidal power of blood serum, it is a drug well worth a thorough clinical test. From clinical trials it seems most certain to do good in furunculosis and similar pyogenic infections of mild type. It is especially useful as a prophylactic or attenuant when such infection has just occurred. It deserves more extensive trial in pneumonia and beginning tuberculosis. I know of no contraindication for its employment except its augmentation of uric acid and consequent possible aggravation of the uric acid diathesis.

CONCERNING THE PRESENT CONDITION OF STATE MEDICINE IN THE UNITED STATES.

BY FRANKLIN STAPLES, M.D.

WINONA, MINN.

State medicine as now understood belongs entirely to modern times. It began in England just before the middle of the present century, when Edwin Chadwick, a barrister, made what has been called his "Epoch-making report" to parliament on the health of towns. By his investigations and report he secured the attention of the government and the interest of the people; laws were passed, and English sanitary work and control were inaugurated. More than fifty years have passed, and England's system of sanitary control, both inland and marine, is a strong feature of

her government. The statistics in the Register General's office show that the annual death rate for England and Wales for the ten years 1871-1880, averaged 21.27 per 1,000; while for the period 1881-1890 it was 19.8, a decrease of more than 11 per cent. The former death rate in England was given at 32 per 1,000. The present annual death rate in the United States varies slightly in different States and cities from 16 to 18 per 1000. In some favored cities and towns it is less.

The beginning of State medicine in the United States was in this wise: In 1849 the Governor of Massachusetts, by authority of an act of the Legislature, appointed a commission consisting of three citizens to prepare a plan for a sanitary survey of the State. Lemuel Shattuck, Nathaniel P. Banks and Jehiel Abbott were made to constitute this commission. The work of investigation began, but delays were inevitable, and the Massachusetts State Board of Health was not formed until the year 1869. Dr. Henry I. Bowditch was properly placed at its head. The names of Shattuck, Banks, Abbott and Bowditch of the old Bay State are well remembered.

Because of the frequent invasions of yellow fever in New Orleans the Legislature of Louisiana established a State Board of Health in 1885, whose duty was to maintain a quarantine and have some control of the sanitation of that city. This, then, was the first named as a State Board of Health in the country. The powers of this Board were enlarged in 1867. Its service was valuable for the purpose at the time, but it had not at first the means and general power of control that have since been given to State boards of health.

A little more in the line of history is best given in an account of the work of Dr. Bowditch. In the centennial year of 1876, an International Medical Congress was held in Philadelphia. The president of the Massachusetts State Board made the address on "Hygiene and Preventive Medicine." The discourse was historical, showing much of the condition of things at the time, and the work of pioneer sanitarians. He said: "I have been requested to speak to you on public Hygiene and its great resultant, State preventive medicine, as it appears to an observer looking back upon the centennial period now just closing."

"As a matter of vital importance to the well-being of any community, and, as such, worthy to be cheerfully and amply sustained by great cities and States, public hygiene, as we now understand that term, has, till within a short time, been woefully neglected, save when, under the stimulus of some great and terrible epidemic, frantic but temporary efforts have been made to stay the plague by hygiene or by other means. Of late, however, a new and better era seems opening to our view, and State preventive medicine affords us higher hopes for all coming time."

Farther on in this address Dr. Bowditch spoke of the work immediately preceding, viz., from 1869 to 1876, as that "which is destined to continue and progress while the nation itself lives, the noblest and most beneficent of all, viz., that in which the profession, joining heartily with the laity and aided by the material and intellectual resources of great States, will study to unravel the primal causes of all disease with the object of preventing it. It is the epoch of State preventive medicine." As it now seems, this

¹ Address.—Transactions International Medical Congress, Philadelphia, 1876.

was a true representation of the condition and spirit of the times and was correctly prophetic.

As shown above, the organization of State boards of health in this country began in Massachusetts in 1869. Time was required to bring the country to a general understanding and appreciation of the advantage of State sanitary laws and management. Eight years were required for the establishment of the first ten boards. A little more than a quarter of a century has passed, and in the forty-six States there are thirty-eight State boards of health, which are operating under laws of uniform general requirements.

The following figures represent the sanitary machinery of a single State; 1,804 local boards of health; 40 in cities, 355 in villages, and 1409 in townships. These report vital statistics and anything notable in disease-prevalence to the State board monthly, and receive its directions (Minnesota).

Some ways and means.—Interstate and sea-coast notification is now an important means of protection from the importation of contagious diseases. This is possible only by coöperation between sea-board quarantine and State organization. To illustrate: A steamer arrives with immigrants, is inspected and passes quarantine at New York. No cases of contagious disease are found on board, but the vessel is from an infected port, and certain passengers are supposed to have been exposed to contagion. The New York quarantine telegraphs the secretary of the State of Minnesota, for instance, that suspected immigrants have left ship and are on their way to such a town in the State. The health officer of this town is notified and his inspector is on the lookout. The same arrangement for notification to the State holds with the United States ports and with the Canadian quarantine in the St. Lawrence River; this much for complete organization, interstate and international reciprocity and governmental control.

The great discoveries and advances in bacteriology made in late years have laid a foundation for practical work in preventive medicine not before known. Laboratories are provided for by State and municipal authorities, and expert bacteriologists and chemists are employed not only in the analysis of water and food products, but in furnishing the means of diagnosis of disease, and, of late especially, in developing the various means for rendering the human body immune to the poison of infection. Physicians and scientists make the discoveries and improvements, and the State may well aid in supporting the same and extending the advantages in the public service.

The department of diseases of animals in the work of State boards of health is an important one. The flesh of animals as a food product, and the liability of the communication of disease from animals to man through milk products and in other ways, make this an essential part of State sanitary management and control.

The influence of State medicine in the United States on the advancement of the standard of medical education has been notable. The position and work first of the Illinois State Board of Health, then of other States by their examining boards, in fixing a lawful standard of requirements for admission to the practice of medicine in the States, has given character to medical practice in this country not before possible. Competing medical colleges of the lower grade have been allowed the choice of elevating their courses and standard of instruction or of retiring from busi-

ness. The condition of the few States which have not fully advanced to the enactment of wholesome laws has been pitiable. The quacks of the country, being refused admittance to or driven out of the better States, have sought refuge here, and are doing their work in communities whose State governments have not yet advanced. Time is required to advance a whole people by education, but the higher civilization lies in this direction.

The great American Public Health Association has for its territory the United States, the Dominion of Canada, and the Republic of Mexico. Its membership includes the leading sanitarians of these countries, and its published literature covers the field of modern public hygiene and State medicine. Prof. Stephen Smith of New York City was the founder of this Association and its first president (1872, 1873 and 1874). Dr. Irving A. Watson, Concord, N. H. is the secretary.

The National Association of State Boards of Health maintains an active existence, and holds annual sessions for the discussion of matters pertaining to sanitation and for promoting unity of action.

The economic advantage of public sanitation has been shown as an argument in favor of the public support of State medicine; that to prolong the average time of active human life by the suppression of preventable disease, is of much greater advantage to the State than is the cost of the means employed. Moreover, it is agreed that to ward off the calamity of disease and to prevent the coming of pestilence, is to increase the sum of human happiness and to elevate the race. The standard of what is done in this way now indicates the degree of intelligence and the virtue of a people.

Attempts have been made from time to time to establish a National Board of Health, and at one time with temporary or partial success. Different plans have been proposed with reference to having the different States and State boards represented in the National Board; also to having this a Department of State, with its chief officer a member of the cabinet. The national control is now in the hands of the Marine Hospital Service in the Department of the Treasury. All matters of quarantine are in charge of this office. Reports, foreign and domestic, are made to it, including vital statistics, disease prevalence, and weather reports. A weekly bulletin of Public Health Reports is issued and distributed regularly to health officers throughout the country.

At the first Pan-American Congress held in Washington, D. C. in 1893, a Committee on Department of Public Health was appointed, which committee when complete consisted of Dr. Henry L. E. Johnson of Washington, D. C.; Dr. William Pepper of Philadelphia, Pa., and Dr. Charles A. L. Reed of Cincinnati, Ohio. This committee reported to the second Pan-American Congress, held in the City of Mexico in November, 1896, the draft of a bill to be presented to the Congress of the United States which, becoming a law, would create a National Department of Public Health and provide for its support. This bill specifies the duties of the Secretary at length, showing the extent and importance of this department. This report was accepted by the Congress and the bill has been presented to the U. S. Senate. (SEE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, March 6, 1897).

A committee of the AMERICAN MEDICAL ASSOCIA-

TION, of which Dr. U. O. B. Wingate, Secretary of the Wisconsin State Board of Health, is chairman, is also engaged in the preparation of a bill for the establishment of a National Department of Public Health.

It remains for the American people to understand the case, take a lively interest therein, and help the action that shall be for the greatest good.

GONORRHEAL OPHTHALMIA—REPORT OF A CASE TREATED WITH ARGONIN.

BY FRANK TRESTER SMITH, A.M., M.D.

PROFESSOR OF DISEASES OF THE EYE, CHATTANOOGA MEDICAL COLLEGE, CHATTANOOGA, TENN.

C. D. R., male, aged 33. First seen Nov. 25, 1896. Two weeks before, right eye became sore, for which he was treated by his family physician. It was extremely painful until two days before, when something seemed to give way and water gushed from between the lids, after which it became easier.

There was an abundant purulent discharge. The cornea was not clear at any point but had a fleshy appearance and bulged from the general curvature of the eyeball (total staphyloma).

The man lived at some distance in the country and failed to attend regularly, coming only once or twice a week. For two weeks he was treated in the usual way with boracic acid, bichlorid and nitrate of silver with very little effect on the discharge, which was abundant from the time first seen. A microscopic examination by Dr. E. C. Anderson, chief of the Microscopic Laboratory of the Chattanooga Medical College, showed the presence of gonococci in abundance. The patient had gonorrhoea.

Thinking this a favorable case to test argonin, as the eye was hopelessly lost, a 5 per cent. solution was instilled into the eye. The application caused no pain and a solution was given the patient for use at home. Four days later he reported that the discharge had almost entirely ceased after the first use of the argonin. He had kept samples of the discharge, which were preserved on cotton swabs made by wrapping pledgets of cotton on toothpicks. These were sealed in envelopes as soon as obtained. An examination of these failed to show a single gonococcus. A sample of the discharge taken direct from the inside of the lid was found to contain a few, very few gonococci.

The argonin was continued. A few days later the eye again became very painful. The tension was increased to plus 1 and the staphyloma was larger. The ball was incised and the clear lens escaped. There was no pus inside the eye. There was no further pain and the patient ceased his visits owing to sickness in his family. One of his neighbors reported that he had no further trouble. The fellow eye was unaffected during the whole of the treatment.

This case seems to indicate that argonin can be used safely in the eye; that it is less irritating than nitrate of silver and from its wonderful effect on the discharge and the development of the gonococci it appears to be the ideal remedy in purulent ophthalmia. Further tests will demonstrate its true value.

ONLY A DROP OF WATER.

BY D. LICHTY, M.D.

ROCKFORD, ILL.

Dr. Jacobi, after deploring the fatality following

tracheotomies in diphtheria and membranous croup, says: "The results of *any* treatment in *membranous croup* are of so *doubtful* a character that *any* observation both faithfully made and reported may be of service."

This passage, italicized by myself, will be the apology for offering and having recorded a single successful item in the after-treatment of croup with tracheotomy.

Every one with experience in the after-treatment and care of the tube in tracheotomy whether for croup or diphtheria, must be painfully conscious of the inefficiency of the methods thus far suggested and employed to maintain a sufficient degree of moisture in the tube to prevent the hardening and drying of the exudate and the sticking of the membranes in the dry metallic tube; sprays and vapors can not be generated in volume great enough, or be induced to enter the narrow aperture of the tube in sufficient quantity to even dampen its lumen a quarter of an inch from its distal extremity, while the dry air passing on at each inspiration impinges on the tracheal mucosa only to *absorb* the little remaining moisture the diseased conditions have created; the result is, a hard brown plug soon forms within and around the proximal end of the canula that neither swabs or hen's feathers can remove; and the distress of flap-valve respiration, or the hazard of occlusion and the prompt removal of the tube and its re-insertion confronts the anxious attendant; it is this difficulty more than any other that interferes with the successful local after-treatment of tracheotomies, and makes the postponement of this surgical procedure often too long deferred.

A recent experience in this line, when every modern means of supplying moisture to the trachea through the tube was being employed, with the threatening failure that usually follows, it was suggested, by recalling the experiments along the line of Rossbach and Calvert in supplying moisture to the inner tracheal area by hypodermic means that "normal salt solution" might be safely supplied through the canula in quantities sufficient not only to moisten the interior of the tube, but to also diffuse over the mucous surface of the trachea and membranes; the experiment was so satisfactorily successful that the nurses, the patient, a little three-year old, and the attending physician were all wonderfully relieved of the further impending peril of occlusion of the tube, and progress, from the introduction of this feature, went on to complete and uneventful and uninterrupted recovery, the tube being removed on the eighth day.

The salt solution was warmed to the temperature of the blood and allowed to trickle down the canula by means of the ordinary medicine dropper, one, two or three drops, in slow succession until the to-and-fro respiratory rale indicated that there was moisture enough, and soon the patient would pass into calm repose; this would be repeated as often as the indications called for it, and instead of the violent paroxysms of dyspnea, with coughing and straining to expel a plug of dried and hardened mucus and membrane, the exudate poured out a stringy, purulent stream easily caught up by the nurses on pledgets of gauze, or wiped away with an easy whirl of the sterilized hen's feathers in the tube.

Did this normal salt solution mingling with the remaining tracheal mucus have a solvent or bactericidal effect on the pathologic membrane?

If this observation will reach those who have oppor-

tunity for more extended trial, and it should prove repeatedly as beneficial as it seemed to in this case, the offering of a "Drop of Water" will have added to it the blessings of medicine as well as those of charity.

A CASE OF CONGENITAL SYPHILIS COMPLICATED BY A MIXED INFECTION WITH THE STAPHYLOCOCCUS AND STREPTOCOCCUS PYOGENES.

Read before the Chicago Pathological Society, Jan. 11, 1897.

BY H. GIDEON WELLS, PH. B.

STUDENT-ASSISTANT IN THE PATHOLOGICAL LABORATORY OF RUSH MEDICAL COLLEGE.

On April 29, the body of a child was brought to the laboratory of Rush Medical College for examination. The autopsy was performed immediately, before postmortem changes could have possibly occurred. The child was born in the practice of Dr. A. B. Strong, who furnishes the following history:

The mother was 20 years of age, a primipara, with a good personal and family history. She had been married one year. The labor was an uneventful one, a vertex presentation. The child was alive when born, but died after gasping a few times. The father was 23 years old and denied any specific history, as did the mother, and presented no suspicious scars. Dr. Strong, his interest in the case having been aroused by the condition of the child, conducted a careful investigation into the history of the parents, but was unable to obtain the slightest evidence of a primary specific infection in either. The mother was troubled after the birth of the child with constant dreaming, a symptom not present before that time, and which was not relieved by administration of potassium iodid. The father spoke of aches and pains in the lower extremities which he said he had had for years. On examination two subcutaneous swellings were found attached to the crest of the tibia, just below the tubercle, and a third on the inner side of the right femur. Treatment with the iodid of potassium and the biniodid of mercury was followed by some reduction in the size of these swellings and the disappearance of the subjective symptoms. On cross examination the patient stated that these swellings had been present since he was a boy. Asked about his father he stated that he knew little about him beyond that he was a sailor. Beyond this reference to the third generation there was no obtainable evidence as to the source of infection.

The findings at the autopsy were as follows:

The body was that of a child, 50 cm. long, and weighing 2500 gm. The abdomen was rounded and firm, and the umbilical cord, which was moist and fresh, was tied with a silk ligature. The skin was covered over almost the entire body with eruptions, most numerous about the ears, face, forehead, hands, feet and buttocks. Most of these eruptions contained a serous fluid, but many were filled with a purulent fluid, and some with a firm, cheesy substance. The peritoneal and pericardial cavities were normal, as were the pleural except for a thin, white, pellicle, covering the pleural surface of the base of the left lung. The heart muscle showed several white, indurated areas, the largest lying on the ventral surface, and about the size of a dime. The heart was not opened, but on account of this rather unusual condition was preserved

for a more complete special examination by Dr. Le Count. The thymus contained several soft, light colored areas, which on section yielded a gray viscid, fluid. Otherwise the organ appeared normal. Beyond an unusual amount of blood the thyroid and salivary glands showed no changes. The lungs were firm, non-crepitant throughout, and pieces placed in water sank quickly to the bottom. They presented both under the pleura and in the deeper parts of the lungs, white areas, firm and smooth on the cut surface—a typical pneumonia alba. The liver was large and firm, the right lobe reaching nearly to the level of the umbilicus. On section it was found to be very full of blood, but there were no other changes. The biliary system was normal.

In the stomach was found a large amount of jelly-like mucus, and the intestines contained the usual amount of meconium. The cecum was attached to all the adjacent coils of intestine by firm, fibrous adhesions, except the vermiform appendix, which was free. The mesenteric glands were enlarged.

The kidneys and supra-renal capsules appeared normal. The spleen was slightly enlarged and full of blood. No changes could be detected in the central nervous system. At the epiphyses of both the long and short bones the line of ossification was very broad, irregular and hemorrhagic. Ossification had not begun in the lower epiphysis of the femur.

Under the microscope many changes very typical of syphilis in the new-born were observed. The description of the various organs follows:

Lungs.—Both lungs were almost completely consolidated, the air vesicles having been dilated in but a few places. The expanded vesicles contain a granular substance which in most places completely fills the lumen, and contains many poly-morpho-nuclear leucocytes and some flattened epithelial cells. The walls of the vesicles are quite thick, with some infiltration of leucocytes, and with greatly dilated capillaries. In many places the epithelial lining of the alveoli is absent. The formation of the consolidated portion by non-expanded alveoli can be determined only with difficulty, because of the degree of infiltration of the tissues. Everywhere, within and between the alveolar walls are poly-morpho-nuclear leucocytes, for the most part scattered singly but in some places collected in groups of a dozen or more. Occasionally the alveolar walls have been separated by slight hemorrhages, in which the blood contains many leucocytes but is not disorganized. Practically all of the bronchi and bronchioles have been filled with masses of cells, in some of which the nuclei stain deeply, in others scarcely at all. The walls show a diffuse infiltration with leucocytes, many of which are also to be found in the contents of the lumen. All the vessels are dilated with blood, and the walls of the smaller arteries are greatly thickened so that the lumen is practically occluded. The pleura, which is quite thick, is not as much infiltrated as the subadjacent tissues, but in the outer portion many of the nuclei fail to stain, and the tissue elements are much disorganized. The vessels in the pleura are much dilated with blood, and in some places slight hemorrhages have occurred.

Liver.—The vessels are greatly engorged, but nowhere can the blood be found outside the regular channels. The connective tissue is everywhere infiltrated with leucocytes, which are also collected in groups in many of the intra-lobular capillaries. The parenchyma cells in some places seem slightly vacu-

olated and their nuclei stain faintly. The capsule is not thickened nor infiltrated, although the engorgement is most marked immediately beneath it.

Kidney.—The glomeruli completely filled Bowman's capsule, the capillaries being filled with blood. In a few cases the glomerulus is forced to one side by an extravasation of blood. In the convoluted tubules some of the epithelial cells lack nuclei, and a few of the collecting tubules contain blood. Occasionally poly-morpho-nuclear wandering cells can be found in the inter-tubular connective tissue. The blood vessels are generally filled with blood containing an unusual number of leucocytes.

Spleen.—This organ is extremely hyperemic, every vascular space being filled with blood. The Malpighian corpuscles appear small in contrast with the superabundant pulp surrounding them, but no changes can be detected in any of the structures.

Adrenal.—In the capsule of this gland are a few collections of epithelial cells packed closely into columns, with very little stroma, probably accessory suprarenals. Beyond a large amount of blood no changes are observed.

Gastro-intestinal tract.—Beyond a slight infiltration of the connective tissue of the villi of the small intestine no changes can be detected.

Thymus.—The follicles show no change except those located near the walls of the abscesses before described. Here there is a marked increase in the connective tissue between the gland elements, and a considerable infiltration with poly-morpho-nuclear leucocytes. In some follicles the glandular cells have mostly disappeared and many fragmented and faintly staining nuclei are seen, beside numerous concentric bodies staining with eosin and containing no nuclei, probably degenerated corpuscles of Hassell. Surrounding the abscess is a wall of varying thickness, consisting of an embryonal form of connective tissue with numerous large and deeply staining nuclei. This wall contains very few vessels, and is infiltrated with many poly-morpho-nuclear cells. The contents of the abscess consist chiefly of a granular matrix containing fragments staining with hemotoxylin, cells with a granular protoplasm and faintly staining nuclei, leucocytes and occasional red corpuscles. The leucocytes are the most numerous of these elements and are collected, especially near the walls of the abscess.

Thyroid.—Only a small proportion of the alveoli contain colloid material, most of them having their walls in apposition and showing no evidences of secretion. Colloid material is found in some of the lymph spaces of the secreting areas. There is a marked dilatation of the capillaries, especially about those alveoli which contain colloid. No other changes can be observed.

Skin.—A section through one of the eruptions shows the stratum corneum separated from the stratum granulosum by a homogeneous substance staining faintly with eosin and containing leucocytes, red blood corpuscles, squamous epithelial cells, epithelioid cells and shreds of necrotic tissue. In the center of the vesicle the stratum granulosum is entirely gone, only a thin membrane separating its contents from the connective tissue below, which contains many round and poly-morpho-nuclear cells, especially just below its floor.

Cultures were made from the heart's blood, liver, kidney, thymus, lung, pleural exudate and the eruptions on the skin.

From the skin, cover slips showed many groups of cocci. The cultures contained but one form of organism, a coccus staining by Gram's method, arranged in groups and agreeing in its growth on culture media with the staphylococcus pyogenes aureus. Cover slips made from the exudate on the pleura showed numerous short chains of cocci. The cultures showed the presence of a streptococcus staining by Gram's method, and agreeing in its culture growths with the streptococcus pyogenes. Inoculations with this streptococcus into guinea pigs showed it to be very virulent, producing death in a short time. Cover slips and cultures made from the abscess in the thymus showed the presence of an organism apparently identical with that obtained from the pleural exudate. All the other organs gave negative results.

It is therefore evident that we have here to deal with a case of congenital syphilis, complicated by a mixed infection with the staphylococcus and streptococcus pyogenes. The diagnosis of syphilis is based upon the typical pneumonia alba and the universal and characteristic osteo-chondritis. The mixed infection is proven by the presence of the microorganisms in smear preparations from the thymus, pleural exudate and skin eruptions, and by the growth of similar organisms in cultures made from these sites.

Such a complication of infections is very unusual, at least, for a search through the more recent literature has failed to reveal any reference to a similar case. In fact, mixed intra-uterine infections of any kind have been demonstrated but a very few times. One of the most recent of such cases is that reported by Dürck (*Münchener med. Wochenschr.* No. 36, 1896), who obtained from the tissues of a child born of a typhoid-stricken woman, which had lived but a few minutes, the typhoid bacillus and the staphylococcus pyogenes.

Infection with the pus microbes seems also to be a rather rare occurrence, by far the largest part of cases in which intra-uterine infection has been proven being cases of typhoid fever. Of the pyogenic organisms the streptococcus seems to make its way to the fetus much more often than the staphylococcus, as would be expected from its greater tendency to produce a general infection. Gustav Ricker (*Centralbl. für Allgem. Path.*, 1895, p. 49) has reported two cases of intra-uterine infection with the streptococcus, in one of which the mother had a streptococcus diphtheria, in the other a streptococcus infection following an injury. Lebedeff (*Revue Mens. d. Mal. d'Enfance*, March, 1887) has reported the case of a woman with erysipelas of the legs giving birth to a child with an erysipelas, and in whose skin a streptococcus was found. Here, however, the infection was traced from the mother to the child through the lymphatic system.

Chotzen (*Vierteljahrschrift f. Dermat.*, 1886) has observed that a streptococcus can be found in the tissues of a large proportion of the children dying of hereditary syphilis, basing his work on similar results obtained by Kassowitz and Hochsinger (*Wiener med. Blätter*, 1886). However, these results have no bearing on intra-uterine infection, as the cases were all of children who had lived some time, whereas in the body of a six months fetus Chotzen failed to find the organism.

It is to be noticed that in all cases of intra-uterine infection reported there is some evident infection of the mother from which the infection of the fetus has been derived, while in this case there is absolutely

nothing in the history that throws any light on either of the infections. It is possible that the mother, being in vigorous health, resisted infection by the organisms that had gained entrance into her system, while the diseased tissues of the fetus offered a favorable site for their localization and multiplication, it having been shown by Lubarsch (*Virchow's Archiv*, Bd 124, Heft 1) that organisms can and do pass through the intact placenta. It has also been suggested that the infection might have occurred from outside, say from a preëxisting endometritis, through the medium of the fetal membranes. As to the possibility of such a transmission nothing can be said, as, unfortunately, the placenta and membranes were not available for examination. That the infection did not occur either just after or a very short time before birth is shown by the presence in the tissues of a reaction to the infection, as for example the formation of a connective tissue capsule about the abscesses in the thymus, which must have required a considerable period of vital activity after the inception of the infection.

It is interesting to note that in the thymus of this case there existed abscesses produced by pyogenic organisms (as is proven both by the bacteriologic findings and the microscopic appearance of the lesions) since similar areas have been generally considered as quite typical of congenital syphilis. They were first described by Dubois (*Gaz. Méd. de Paris*, 1850, p. 393), and by many authors named after him Dubois' abscesses. Orth (*Pathologische Anat.*, p. 89) considers them as due simply to the syphilitic virus, and no relation between them and pyogenic processes seems to have been demonstrated. This case suggests, therefore, the possibility that in many of the cases of thymus abscess observed in syphilitic children, careful bacteriologic investigation would have demonstrated the presence of pyogenic organisms, although it is possible that the abscess formation may represent the site of a preëxisting syphilitic lesion.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

BY CARL H. VON KLEIN, A.M., M.D.

(Continued from page 652.)

CHAPTER IV.—NOTICE ON HOSPITALS.

Charité in Berlin; The Allgemeine Krankenhaus in Vienna; Small German hospitals; Hospitals in England, St. Bartholomew Hospital in London, and others; Hospitals in France, Hôtel Dieu and Charité in Paris, and others; Hospitals in Sweden, Denmark and Russia; Diet; Mortality, small number of operations; Ventilation, J. Pringle; Proposition to improve hospitals; Experiments in putrefaction; In-lying hospitals.

Whoever, in the middle of the last century, strapped his pack to become acquainted with the German hospitals was soon at the end of his wanderings, for no country possessed fewer hospitals than Germany. In the Catholic countries the sick were better cared for than in the Protestant, in so much that in the seventies Vienna, Prague and Olmütz are said to have had more hospitals than all the Prussian cities taken

together. In those countries, wherever public hospitals were lacking, their place was filled by the hospitals of the Brothers of Mercy, and the Sisters of St. Elizabeth.

In the first half of the century the most important hospital in Germany was the *Charité in Berlin*. King Frederick William gave for that purpose a large house which, in the year 1710, on account of the plague, was built outside of the city. In this the poor patients from the army and among the citizens of Berlin were to be treated without charge and the infirm aged cared for till their death; domestics with tedious diseases had to pay. Besides these, patients with contagious diseases and skin diseases, and all venereal women were received. If the harlots were cured, they were taken to the work houses "in order to drive out of them their former desires." To check infanticide, pregnant women were received in the hospital without charge, eight days before delivery. According to a plan projected by the surgeon-general and body-physician Holtzendorff, the new institution was to serve at the same time as a training school for military physicians. The monarch himself gave the institution the name Charité. "Because this institution was a public work of Christian love, benevolence and generosity, so His Royal Majesty, himself gave this house the name Charité, and commanded that it should be called so in future, and particularly for this reason, that it be always free to everyone, out of its abundance, from Christian love to them, to succor the poor and sick, or as they say, to render *charité*." (Eller). The hospital was opened in 1727, after they had brought together 300 sick and poor with the infirm street-beggars from Berlin. The latter were taken into the lower story, called the hospital; the patients proper, who when bedridden were carried out from the city in litters, into the upper story, the so-called Lazareth. This consisted of four equal wings, which abutted upon a common court, and were provided with a gallery running between, from which one could enter any of the halls. There were separate rooms for men and women, medical and surgical patients, for soldiers, maternity cases, and contagious diseases. There was no discrimination made in admission, although the subjects of His Majesty had the preference. A special bed was provided for each patient, with white linen, a straw bed, mattress and one woolen cover, beside special hospital clothes. (At that time very few Germans were accustomed to the English habit of sleeping on mattresses.) The sick wards had a chimney place for ventilation and were fumigated every two hours. The *personel* of the administration consisted of an inspector, a sworn scribe, a house steward and several waiters and waitresses, two of whom served in each hall; special women attended to the cleaning of the basins. Under the supervision of the Surgeon-General Holtzendorff, Dr. Eller directed the medical department, and the regimental surgeon G. Senff, the surgical department. The pensionary surgeons of the army were ordered to the Charité for practical instruction. As one man alone could not attend to two hundred patients, he was allowed a few under or sub-surgeons, two of whom lived with him in the Charité. He examined the newly arrived patients, conducted the journal and ordered the medicines, which the court apothecaries furnished free (just as for all the royal servants, and the city poor). Eller and Senff came twice a week for visits, to serious cases oftener, and on the other days had reports made to them. If operations were to

be performed, they were previously announced, and the pensionary surgeons and stewards of the garrison gathered in the operating room. The difficult operations Senff performed himself, the pensionary surgeon did the simpler ones under his direction, and one of the under-surgeons had to watch beside the patient, regularly for the first nights. Professor Budens conducted the directions. Great stress was laid upon the care of the soul, since those first received into the Charité were "a brood of dissolute sinners who had for the most part forgotten God and honor." There were daily lessons by the bedsides, and a sermon on Sunday morning. Not satisfied with this, the clergy examined the older people twice a week, which was very uncomfortable for them, since they knew little of the teachings of religion, and manifested very little curiosity to make themselves better acquainted with them. This catechism was kept in store for Sunday afternoon after the service, and once again gone through. The capacity of the Charité was increased in the following years through generous gifts: The General Field-Marshal von Wartensleben presented a large field lying next to the hospital, and this was converted into a garden, the General Field-Marshal von Arnim 1,000 thalers, a pious nobleman 5,550 thalers, and so on. They built in one wing a third story for contagious diseases, more domestic buildings, stabling for cattle for the shambles, and a brewery, and projected a chapel and a botanical garden (*Eller Med. and Chir. Anmerk.*, 1730). Under Frederick II. there was a new enlargement, and the new building was completed in 1736. The insanity ward was also added. After Eller's death Schoarschmidt became director of the medical department, but he was dismissed by a cabinet order in 1744, and replaced by Muzell, who officiated as director for thirty years. His son succeeded him, then Selle, and in the year 1800 Hufeland was called from Jena as body physician and first physician of the Charité. When Senff died in 1737, the regimental surgeon Neubauer received the place of directing surgeon and obstetrician; after him Professor Pallas served for twenty years, then Henckel in 1770, Voitus in 1779, Mursinna in 1787. In 1816 Rust assisted Mursinna, on account of his age. Along with the first physicians, officiated so-called second directing physicians and surgeons, who lived in the Charité. The "operator and chief surgeon in the Maison de Charité," made semi-weekly visits, examined the surgical patients, dictated his orders to the pensionary surgeon had the patients bandaged in his presence by the pensionary surgeon and the hospital stewards. In all important operations and for internal treatment he had to consult the physician. He performed the operations himself and could not trust them to an unskilled pensionary surgeon; besides he treated the maternity cases. The second directing surgeon took the place of the first in his absence, consulted with him concerning all important cases and treated them according to the method mutually agreed upon. Of the pensionary and staff surgeons, one was assigned to the medical, another to the surgical departments, a third to the maternity ward and the venereal cases, and a fourth to the insane ward and the patients with skin diseases (1799). They had special supervision of the nursing, medicines, diet and the writing of the history of the cases. Among them were assistant surgeons who every two or three months alternated in the main departments, so that in the course of a year they had filled most of the positions. They saw the patients allotted to them four or five times

a day, watched by them at night when it was necessary and looked after the proper distribution of food, but their prescriptions must be inspected by the pensionary surgeon.

One would expect that the Charité, as the largest hospital at the capital, would be a model for all the others in the country. But how dark is the picture which the directing surgeon, E. Horn, draws of it in 1806, when he makes a public report of his twelve years' service! Dirt and stench that defy description, prevailed then everywhere in the hospital. Instead of bathing the patients when they were received they were left in their filthy rags and packed away in dirty beds. The bed-linen was left dirty for a whole week and it was washed so badly that the clean linen was scarcely to be distinguished from that which had been used; there were no baths. Under almost all the beds stood basins which smelled as foul as the wooden buckets used for carrying refuse. Vermin bred in the straw beds and the feather covers, soaked with perspiration and urine, infected everything around. The bedsteads, which they had not thought it necessary to paint, became loose and fell apart, and they were breeding places for bedbugs. Wherever one looked, whatever he touched, wherever he stepped, everywhere indescribable filth. Nearly all the windows were closed fast for fear of a draft and colds. The food was so bad that the waiters made a business in the institution of selling sausage, cheese and brandy to the patients. Nowhere was the attendance worse than here; the people understood nothing and were very much underpaid—one thaler a month and no supper in the hospital. Nothing can enable the imagination to picture the results of this wretched management. The hospital was crowded with patients. Although the space sufficed for at the most 750 patients, 800 or 900 were taken in, so that patients with contagious diseases and those in delirium lay among the convalescents. For years hospital fever infested the place and carried off many, even patients not seriously ill, attendants and assistant surgeons. If you ask the causes which made the Charité a veritable den of murder, you find that they lay chiefly in the defective administration and the disadvantages of war time. It was a misfortune that the physicians were entirely excluded from the administration of the hospital. The chief inspector reigned alone; he regulated, without reference to the physician, the temperature of the wards, the change of linen, the food, the lighting and cleaning of the rooms, and so forth. According to his principle, the less expense and labor the better, and dirt and vermin got the upper hand from day to day. Fuel was either denied or supplied so scantily that one could hardly warm a poultice with it. Horn requested some wood; when he received none he looked about for it; after a while he got some and begged earnestly for more; all this depended upon the caprice of the administration. The light was so bad that even in 1815 a suicide could occur in the presence of fifteen patients, which with proper lighting could probably have been prevented. The other reason for this great distress was the lack of money during the war, in which the French cleaned out the Charité as far as possible and converted it into a military hospital. Even before 1806 the allowance of the King did not suffice, and from 1806 to 1814 it was discontinued entirely. They seized its capital and increased the debts. In the year 1810 the purveyor of the Charité had a claim of 50,000 thalers.

and the interest of 5,177 thalers must be collected by suit at law in a court of the second resort. Even after the restoration of peace the stringency continued inasmuch that the purveyor was informed of the state of affairs and the authorities were notified that the supplies would last only one day longer. Under these circumstances the complaints of the physicians were lost in the air. It was due to the extraordinary efforts of Horn and Hufeland that greater cleanliness was maintained in the Charité and that the other unhealthy conditions were bettered.

In the second half of the century all eyes looked to the newly founded *General Hospital* of Vienna. In the time of Maria Theresa Vienna possessed several small hospitals and poorhouses. Among others the St. John's Hospital, the Imperial Hospital, the Burgher Hospital and St. Mark's Hospital (for syphilis and maternity cases), the Beckenhäusel (a refuge for the poor), the Spanish Hospital and the Triple Hospital. In the last was the medico-surgical school created by Van Swieten. Emperor Joseph II. had convinced himself by repeated observations of his own of the error of maintaining those small pest hospitals which regularly cared for about two thousand patients and poor, and had a yearly income of about 200,000 guilders. He closed these and in place of them established a large general hospital at great expense. Vienna letters of that time relate that "everyone is excited over the important change, and the Vienna physicians are stirred up because the end is made of many old institutions." The Emperor was generous enough not to expend any public money but defrayed all expense from his own purse (aside from the revenues of the disestablished institutions). They used the old buildings of the former poorhouse, making such alterations as were necessary, and built two additional two-story buildings, so that the whole included beside the regular hospital, a maternity hospital, a house of refuge, a home for incurables and a foundling house. The hospital was opened Aug. 16, 1784. The principal entrance was adorned with the inscription in gold: *Saluti et Solatio Aegrorum Josephus Secundus semper Augustus*. Through the gate we entered into the first court, over six hundred feet long, which was laid out with avenues, trees and fountains. Behind this were six more courts, smaller but just as elaborate. The whole hospital would accommodate 2,000 patients (the German periodicals said 6,000), and for medical and surgical patients had 86 rooms, of which in the first year 72 were occupied; 34 for men and 28 for women. The former contained at that time 812 beds, the latter 676, a total of 1,488. The ophthalmic and venereal patients were allotted to the surgical department. Most of the rooms contained 20 beds, some 40, and the largest rooms, for venereal patients, contained 90 beds. All the rooms were 14 feet high and 26 feet wide, and had windows on both sides, under which stood the beds 3 feet apart. The ventilation was so arranged that when the windows, 6 or 8 feet above the floor, were opened upon both sides of the room the air passed through without harming the patients. Beside this there were air-holes in the wall through which pipes led to the open air, also in the floor under the beds and under the stoves. The greatest cleanliness prevailed everywhere to a degree which could not be excelled or surpassed in a princely palace; beds and linen were frequently changed and washed. Every patient had his own bed; beside it stood a small table with drinking vessels, a metal ves-

sel for refuse and a wineglass. Over the table hung a black tablet upon which were noted the number of the room and the bed, the name of the patient, the day of his entrance, the medicine, diet and the most important symptoms. They divided the patients into four classes. Those in the first class paid one guilder daily and received a separate room, board, medicines, treatment and a special attendant. The bed consisted of a horse-hair mattress, a straw bed, two fine sheets and several cushions. In the second class they paid half a guilder and received the same as those in the first class, only they had no special attendance and fewer dainties in food. The third class, made up principally of servants, were charged ten kreuzer, while the fourth class consisted of paupers taken gratis. The hospital furnished clothing and linen. In the acceptance of patients there was no discrimination, either in respect to nativity or religion, only the hopeless cases were sent to the house for incurables. Six physicians and six surgeons alternated daily to take care of the incoming patients. The body surgeon, Quarin, who had originated the plan of the hospital, acted as director and was accountable only to the Emperor. The medical patients were under four physicians-in-charge, so-called *primarii*, of whom two had free residence in the house; under these were fifteen assistant physicians. Of the five over-surgeons, who supervised the surgical department, the chief must be called to counsel in all important cases and large operations. He visited all the surgical patients daily, without treating them officially, and had the oversight of instruments and bandages. Beside these there were seven other surgeons whose position was similar to that of the assistant physicians, beside ten assistants and a number of practitioners. The surgical cases which came to light in the medical department were taken care of by one of the over-surgeons, while on the other hand the important internal diseases which appeared in the surgical department were taken care of by one of the first physicians. The hours for visiting patients in summer was from 7 to 8 in the morning, in winter from 8 to 9, and afternoon, from 3 to 4. Every twenty patients were served by three attendants, who received 9 guilders a month and lived at their own expense. The economy of the institution, the inventory and property of the patients were looked after by four stewards with twelve assistants; at the same time all the food, which in general was very good and appetizing, was carefully contracted for by three cooks. The hospital had an apothecary of its own, the equipment of which had cost 20,000 guilders; this had four dispensing tables for one apothecary and six assistants, also a laboratory in which seven persons worked. They held a polyclinic every morning where one physician and one surgeon presided, gratis. The attendance was so great that in the first half year 16,659 patients received free medicine and within three years the total number amounted to 116,041. As to the salaries of the hospital physicians, the director received 3,000 guilders, the *primarii* 600 to 1,000 guilders, the chief over-surgeon 1,500 guilders, the other over-surgeons 800, the assistant physicians 300 guilders and the certain practitioners from 100 to 200 guilders. Most of these had free residence in the hospital. (*Oestreichische Gesetze in John's Lexicon; München, Scherf's Archiv d. med. Polizei*, v, 1786.) In the year 1874 the director of this greatest European hospital in which 20,000 patients annually were treated, who was

required to superintend the university clinics and twenty-seven departments and to command a force of 220 men, received the same salary as that which Joseph II. had paid to the director one hundred years before!

With the Berlin Charité and the Vienna General Hospital, which included a beautiful hospital in Prague, founded by Joseph II., we exhaust the list of the most important hospitals in Germany. It is only in the last decade that the number of hospitals has increased in a gratifying way. The people grew ever more conscious of the fact that their value lay not alone in the help which they extended to the sick, but that science was indebted to them for the greatest part of its riches. They improved the old hospitals; new ones were erected by Joseph II. in all the great garrison cities, or the empty monasteries were used for that purpose. Dresden obtained in 1751 a small surgical hospital, which in 1778 was joined to the collegium medico-chirurgicum. Frankfurt-on-the-Main owed its Burgher Hospital to the well known philanthropy of one of its physicians, Dr. John Christian Senkenberg, who in 1770 presented to the city his whole very considerable fortune. Out of this they built the hospital, an anatomic amphitheater, a botanic garden and a chemic laboratory. In Brunswick a hospital with fifty beds was established in 1780. But most of the German universities as yet possessed no hospital. What then was to be expected in the way of achievement from professors of surgical training of the young, or of progress in surgery, when the patients were lacking, and thus the science deprived of its most important and vital nerve? Göttingen existed as a university forty-three years before it obtained a small hospital with fifteen beds (1780), although many years previous A. G. Richter, at that time professor, had pointed out that without a hospital neither medicine nor surgery could truly thrive. In Würzburg these conditions were reversed; there the bishop-prince Julius first founded the Julius Hospital for paupers, sick and orphans (1576), and afterward founded Julius University in 1582. But true appreciation of the hospital for the purpose of instruction did not begin until the end of the eighteenth century. Julius Hospital received about four hundred patients, when, according to one Brande (1704), a large new building had been erected. Beside this there was in Würzburg (1786) a hospital for journeymen mechanics and apprentices, erected by the hat-maker, Heydenreich, out of voluntary contributions. Kiel, which was raised to a university in the year 1665, obtained a hospital over a hundred years later, built by contributions, as a result of the activity of Professor Weber (1787). In Halle University also a hundred years passed before they obtained, in 1806, and at the suggestion of Reil, a hospital of twelve beds, which was erected at a cost of 1,800 thalers. In the last two decades of the century they began to establish special schools for the training of nurses. Dr. May founded such a one in 1782, in Mannheim, for twelve nurses, and a few years later there arose similar schools in Carlsruhe, Magdeburg, and still later in the Berlin Charité.

If we look at the hospitals in foreign countries in the eightieth year of the century, we find that Germany was far behind England and France, where almost every city of any considerable size had its hospital and possibly also a house of refuge, a maternity hospital and a smallpox hospital. In no

country were the sick better cared for than in England. There nearly all institutions for the public health were founded and maintained through the private benevolence of certain rich citizens, and no city in Europe was richer in charitable institutions than England's capital. The hospitals in London in 1784, twenty-seven in number, had an excellent internal management, which was nearly everywhere the same. The oldest and best was *St. Bartholomew's Hospital* and also one of the most beautiful buildings in London. Founded in the year 1102 by Rayhere, the prior of St. Bartholomew, little by little it fell into decay, and was newly organized at the dissolution of the monasteries by Henry VIII. Harvey, the discoverer of the circulation of the blood, had worked there. The new buildings, erected in 1730, formed a large quadrangle. Two wings contained each sixteen halls, twelve of which were continuously in use; the third wing was reserved for sick women, the fourth for the members of the household and service. In the hospital, where the greatest cleanliness prevailed, there were almost always over four hundred patients, among them one hundred surgical cases, ten to fourteen of whom lay in each hall, about six feet apart. Great chimney places served for ventilation, and all the doors stood open, except in severely cold weather. The water was led into the house through pipes and was dispensed to the patients in leather pitchers. The meager equipment of the apothecary, which consisted of scarcely a dozen bottles and glasses was very striking in comparison with that in Germany. They usually had so-called sisters, two to four, for each room, who received a moderate salary. Three physicians and three surgeons, with as many assistants, treated the patients. They made visits three times a week and alternated weekly, so that within that time each received the new patients for his department. So it happened that the surgical patients were often unevenly allotted and one surgeon had thirty while another had fifty. Admittance was possible at all times, but Wednesday was the regularly appointed day. Upon his entrance the patient paid 24 shillings, or gave a surety for the possible burial expenses; at his departure he received the money back. The surgeons consulted mutually over important cases and each operated upon his own patients, with the understanding that no one of them should specialize in a certain line of operations. Pott, who was assisted by Sharp and Earle, did most of the ophthalmic and almost all the lithotomic operations in the hospital. There was a great deal of operating, mostly done on Saturdays. Else operated in St. Thomas Hospital and Chandler performed many lithotomic operations. Guy's Hospital was founded in 1722 by the book-dealer Guy, by which act he deprived his house-keeper, whom he had wished to marry, of 240,000 pounds sterling. There Lucas, Warner and Cooper had charge of the surgical cases. The London Hospital, founded in 1758, was mostly filled with sailors and therefore had abundant wounds and operations. There were also a large number of patients in St. George's Hospital (founded in 1773), where, after 1786, John Hunter worked, under whose hands came very many patients with aneurysm; together with him worked his brother-in-law, Ev. Home, and Hawkins. Of these four London hospitals the St. Thomas Hospital contained 500 beds, the others from 300 to 400, of which one-third were required by the surgical patients. The Westminster Hospital (founded 1719)

was maintained entirely by the oratorios, which all the musicians in London together, at least 800, gave every year in Westminster Abbey, the admission being one guinea. For this reason, sick musicians enjoyed the preference of admission into the hospital. The Lock Hospital, founded by Bromfield and others (1746), received only syphilis patients; according to its by-laws it would receive each patient but once. There were already in London at that time, special hospitals for certain diseases, as for smallpox and insanity. Two houses of correction, each accommodating 300 patients; among these was the Bethlehem Hospital (founded in 1553) in which prevailed, until 1770, the abominable custom of exhibiting to the public for a fee of one shilling, the half naked patients chained to the wall; there was also St. Luke's Hospital. London possessed also a Magdalen Hospital as an asylum for penitent fallen women, and several maternity hospitals and charitable institutions (infirmaries) where physicians, surgeons and apothecaries twice a week dispensed their counsel and medicines gratuitously to the poor. A private citizen provided a fund, the interest of which was devoted to caring for twelve cancer patients. There was as yet no hospital for ophthalmic patients; there was, indeed, three miles away in Kentishtown, a beautiful building with the inscription, "Infirmery for Blind People," but there were no patients there. Greenwich and Chelsea had Invalid Houses, the latter accommodating 2,000 sailors. In all the London hospitals the visits were made at eleven o'clock, and the operations were performed at twelve o'clock, in a special room which had most light from above. As to the provincial towns, Portsmouth had a large hospital, which was situated by itself upon a large peninsula, and had 120 sick rooms with 2,100 beds. There principally sailors and patients with scurvy, also from 500 to 700 surgical cases were treated. Edinburgh possessed a very beautiful hospital for 200 patients. In this twenty-four surgeons alternated every month, two serving at a time, and performing the operations in a great amphitheater. But no operation could be undertaken without the approval of four surgeons; whenever an operation had been postponed, a notice must be posted at the gate of the hospital a day in advance.

Entrance to the London hospitals was made difficult to foreigners by a high admission fee. Once only would they admit a stranger with a letter of recommendation; but the second time, the porter stopped him at the entrance of the operating room, if he had not been enrolled. Most foreigners, for this reason, saw only one or two operations, went through the hospitals and contented themselves with buying a few instruments, attended one lecture and took their departure. On this account many foreigners went to Edinburgh, where living and lectures were very much cheaper and the admission to the hospitals was free. (J. Hunczovsky, "Med. chir. Beobachtungen auf seinen Reisen durch England und Frankreich, besonders über die Spitäler," Viennos, 1783. Briefe aus London in Baldinger's *Med. Journ.* 15 Stück, 1787.)

If we turn to France before the revolution, we find in Paris the imposing number of fifty-one hospitals, among them twenty-two for the sick, eighteen for incurables and chronic cases, two for soldiers and the rest for the aged and orphans. Most of the hospitals were very old and had been founded by some monastic order, therefore they were almost always sit-

uated in monasteries or near the churches. The archbishop with the general-procurator of the assembly had supervision of them; beside, each separate hospital was administered by priests or citizens of repute. Within, the monks and nuns ruled to such an extent that, to the great detriment of the patients, the physicians were almost wholly excluded from the administration; indeed they had no power, and must beg the most necessary medicines as a favor from a nun. It was so difficult to prevail against the monastic rule that although the administration was made acquainted, through several decades, of the unfortunate condition of the maternity cases in the Hôtel Dieu, every improvement was thwarted by a crowd of cabalists. While in the civil hospitals the greatest abuses were found the administration of the military hospitals, where the physicians and the laity alone were in power, was excellent. At the outbreak of the revolution it was even worse. The priests no longer begged for the hospitals, so that a large part of their revenues was lost, and the rich people concealed their money. When the opportunity came priests and nuns were thrust out of the hospitals, but their successors discharged their duties so badly, that finally a veritable anarchy arose in all branches of the administration. In 1772 when a part of the Hôtel Dieu was burned, a reform was earnestly considered. Many propositions were, made, until at last in the year 1787, the conclusion was reached to build four new hospitals. Within a short time two million livres were collected through subscriptions, and over ten millions subscribed, but the royal treasury swallowed up the money, and built nothing. Under these conditions the constitutional Convention came on and while it improved the administration in many respects, and provided certain revenues, it left everything else to the legislative assembly. When all these properties were declared to belong to the nation the hospitals were at one blow robbed of their means and left to their fate. The revolution broke forth. The confusion in the hospitals mounted to the highest, but nevertheless the patients during the reign of terror never suffered want. The state was generous to their needs, and their fare was better than that in the families of the poorer citizens. There was never a time when the patients had less than eight ounces of bread, an eighth of a pound of meat and a quarter of a bottle of wine. On the other hand the stringency during the summer of 1797 became worse than ever; once the treasury of one hospital contained only 36 livres.

(To be continued.)

PECULIARITIES OF THE SURGICAL DISEASES AND INJURIES OF THE NECK.

BY EDMOND SOUCHON, M.D.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY, TULANE UNIVERSITY,
NEW ORLEANS, LA.

(Continued from page 602.)

TORTICOLLIS.

Torticollis, also called wry-neck, is a deformity of the head and neck in which the face is turned upward and to one side. It is not a very rare disease. The causes are numerous and will be studied with the forms, varieties and complications. The pathologic lesions vary also with the causes. The symptoms are the deviations mentioned above, accompanied by other lesions according to the forms and varieties. There

is also atrophy of the face and cranium of the affected side; sometimes strabismus, impairment of vision, dysphagia. There are usually no general symptoms. The course, duration, diagnosis, prognosis and treatment all vary with the forms, varieties and complications.

Acute, transient or rheumatic torticollis is that due to cold; it presents no cranio-facial deformity; it may affect the sterno-mastoid, the trapezius, or all the muscles of one side. The peculiar point in the treatment is to immobilize the head in a liquid glass bandage for a few days.

Chronic torticollis comprises all the following forms and varieties.

Intermittent or spasmodic torticollis is characterized by a sort of convulsive to and fro movement of the head with cessation for short intervals or during sleep. The name is a bad one, because there is no spasm, but simply a loss of dynamic action, a lack of muscular synergy. The head is easily restored to its proper position, but it returns to the vicious one; the muscles behind and in front are of the same consistency on both sides; the contractions are clonic spasms returning by attacks more or less frequent, followed sometimes by a more or less lasting contraction; this may become permanent; it is then called tonico-clonic. The spasms are limited to the sterno-mastoid, trapezius and splenius; when the patient is lying down with the head flat there is no deviation; when sitting up, the head loses its equilibrium; it is first inclined laterally, and then in rotation; the movements are slow, gradual, without jerks. The head is easily straightened by an assistant, but it falls back immediately when the support is withdrawn. Electricity and massage are the most usual means employed, together with a collar apparatus; stretching or section of the spinal nerve has been done in one case with only temporary improvement.

Permanent torticollis may be cutaneous and cicatricial, muscular or articular or osseous; the muscular may affect the lateral muscles (sterno-mastoid, platysma, scalenes), or the posterior muscles (trapezius, rhomboid); the latter will be described with the diseases of the posterior region of the neck. Torticollis may be hysteric or may be simulated or affected (dude's torticollis). Torticollis due to affections of the sterno-mastoid is by far the most frequent; it may be due to retraction or to paralysis.

Cutaneous or cicatricial torticollis is easily recognized; the head is not twisted as in the regular torticollis.

In articular or osseous torticollis due to tuberculous osteo-arthritis, and in that due to tumors, the head can not be budged from its absolute immobility on the vertebral column; the head is not twisted as in the real torticollis.

In torticollis by contraction the head can be straightened; the muscle retains its shape and its contractility; it is the trapezius that is most commonly affected.

In torticollis by retraction the head can not be thoroughly straightened, and there is the persistence of a hard stretched muscular cord. Sometimes it requires the administration of an anesthetic to determine those points, and whether it is the sterno-mastoid or the trapezius which is affected or the deep muscles. Torticollis by retraction of the sterno-mastoid is also called torticollis by contraction, meaning a permanent strong contraction and retraction of the muscle. It is the most common; it is characterized by a hard

stretched cord along the course of the sterno-mastoid, especially when the head is rotated in a proper manner. That it may be congenital is recognized, but it is rare; it is sometimes called obstetric when it is thought to be due to the traumatism produced by the forceps; it may be due to myositis syphilitica or to a gumma. It is called physiologic when it is due to vicious attitudes, voluntary or involuntary; or it may be due to disease of the central nervous system or to the nerves of the muscle. Or it is called ocular when induced by defects of vision, *i. e.*, headache, diplopia, astigmatism, amblyopia. It is sterno-clavicular torticollis when it affects only that head of the muscle, or double-headed when it affects the two heads; the sternal head is the most commonly affected. The pathologic lesions are a fibrous degeneration or transformation of the muscle; it usually occupies the lower two-thirds; the right side is more frequently affected. Cranio-facial atrophy is due to the defective nutrition of the parts.

The prognosis is that the deformity always tends to increase.

The treatment consists in performing tenotomy, subcutaneously or openly, of the affected head or of the two heads; the best time to operate is not before the third or fourth year. The disease has no influence on the development of the skeleton up to that age; after the tenotomy a proper collar apparatus, with or without suspension, must be used.

In permanent paralytic torticollis the head is inclined to the opposite side of the hemiplegia, due to the action of the sterno-mastoid of the opposite side; it may in the course of time bring on a retraction of that muscle. No other form of paralytic torticollis is recognized by most writers. The head can be straightened, and remains so only as long as it is supported.

The treatment presents nothing special except to apply also a supporting apparatus.

Torticollis of the platysma has been observed, also of the scaleni. Hysteric torticollis is diagnosed by anesthesia. Also the simulated torticollis and the affected torticollis of the dudes; in these last cases the two sterno-mastoids are simultaneously contracted.

Induration of the sterno-mastoid in the newborn will be described with hematmata. Induration of the muscles in adults is syphilitic; it may be diffused sclero-myositis; it may occupy the whole muscle, which is transformed into a cord, or it may be localized in one spot.

Congestion or hyperemia of the region of the sterno-mastoid presents no peculiarity.

Inflammations of the side of the neck are comparatively frequent. They present peculiarities in almost all of the tissues of the region.

Inflammations of the skin and subcutaneous connective tissue, however, present no peculiarities not already described with the neck in general.

The external jugular vein is sometimes affected with phlebitis, recognizable by the long hard cord on its course, with pain, etc. The sterno-mastoid muscle itself is seldom inflamed (sterno-mastoid myositis) except in acute rheumatic torticollis due to cold or sprains of the muscle; the muscle may be destroyed in cases of abscess developed in the sheath; when the muscle itself is inflamed and suppurates, it is in one of the general infectious diseases.

Inflammations in the sheath of the sterno-mastoid are common; sometimes they begin in one of the

small lymph-nodes situated in the sheath itself; when originating from these, it is remarkable that the inflammation and the pus that usually follows it remain limited to the sheath very strictly and descend toward the lower third of it, near the clavicular attachment, where they become superficial. This inflammation leaves after it a stiffness and a shortening of the muscle.

Acute cervical adenitis and adeno-cellulitis or adeno-phlegmons are the most common of all the forms of inflammation of the neck.

Diffuse cellulitis is usually due to the fact that although probably originating in the glands from some infectious products, in angina, scarlatina, etc., conveyed from the face, neck, mouth, pharynx, esophagus, larynx or trachea, it quickly spreads into the surrounding connective tissue and form those grave cases of diffuse cellulitis which spread all around, and became very extensive, already described above, where the pus may burrow in all directions as also said above. Phlebitis of the internal jugular vein is not very common; it is usually due to infection from the interior cavities or to metastasis. It is accompanied with great pain and swelling along the course of the vein; it is often complicated with phlebitis of the lateral sinus and with cerebral symptoms. It is diagnosed with the exploring needle; it is of the utmost importance to diagnose early and to evacuate early by incision or dilatation on a guide.

Arteritis presents no peculiarity.

Neuritis of the nerves of the region are most uncommon.

Chronic inflammation of the glands or chronic cervical adenitis is most common; it is usually strumous or tuberculous. Chronic inflammation of the other tissues of the region is most rare.

Gangrene presents no peculiarity.

Ulcers are usually strumous or tuberculous or cancerous from the ulceration of the lymphatic glands; they leave ugly scars.

Fistule of the region are sometimes congenital branchial; but they almost always are due to the tuberculous glands.

Tumors of the lateral region may be pharyngocele, esophagocele, laryngocele, tracheocele and emphysema; they present nothing peculiar here.

Liquid tumors containing blood are all represented here. Hematoma due to contusions, to ruptures of the sterno-mastoid, to narrow penetrating wounds of the vessels, when they are persistent should be aspirated but not until full time has been allowed for resorption. Varix or dilatation of the external jugular vein is usually due to heart disease; it requires no treatment. Varix or dilatation of the internal jugular also.

Angioma of the neck is sometimes called sanguineous cyst. It must not be confounded with a cyst in which hemorrhages have taken place or have opened into a cavity; they may be superficial or deep or cavernous. Angioma sometimes presents a single vein opening into the jugular by one or several orifices; sometimes several angiomas open into the jugular. The neck is a special seat of ampullar venous dilatations, forming cavities in an erectile tissue with narrow spaces. Angioma is often completely reducible. In operating it is advisable to place a ligature on the large vessels as soon as possible before extirpating the tumor, thereby diminishing very much the hemorrhage during the removal and facilitating

the removal. A sanguineous cyst is sometimes due to a serous cyst with a hemorrhage in its cavity. A sanguineous cyst is also a cyst which originally was serous and has opened into a vessel, usually a vein. Sometimes a sanguineous cyst is found completely isolated and closed on the course of absent veins; other sanguineous cysts are either an angioma developed in the walls of the jugular or due to venous dilatations or varices of the jugular. We do not consider as sanguineous cysts those cysts formed by an encysted hematoma, by a sarcoma with a cystic degeneration and hemorrhage in its cavity, nor of central cysts developed in the lymphatic glands, or hemorrhage in cystic tumors or serous bursæ.

Aneurysms of the neck may affect the three carotids, or their branches, *i. e.*, the superior thyroid, lingual and facial; but these are rare. They may also spring from the first and second portions of the subclavian or its branches, especially the vertebral, then the inferior thyroid, deep cervical; but the two last are most rare.

Clinically and practically the aneurysms of the neck form two groups: The aneurysm of the root, *i. e.*, situated low down nearer the clavicle and sternum; they should be treated as detailed above in the supra-hyoid region. The following are the diagnostic signs of the seat of the aneurysm: Increase in the retardation of the right radial pulse is a constant sign of innominate aneurysm. In aneurysm of the ascending arch the inequality of amplitude of the two radial pulses is frequent. It exists only on the right side in innominate aneurysm. The increased retardation of the pulse exists simultaneously in the radial in subclavian aneurysms. Increased retardation of the temporal pulse characterizes carotid aneurysms. We should not take an arterial dilatation of the whole artery for an aneurysm. Spontaneous aneurysm is exceptional.

The aneurysms above the root are those where there is room to penetrate between the tumor and the arch. They are aneurysms of the carotids and branches and of the vertebral.

The aneurysms of the carotids are seldom traumatic; however, they may be the result of contusions. The common carotid is more frequently affected (18 per cent.); it is comparatively frequent in females, more so surely than the other aneurysms; it is also more common in young subjects than the aneurysms of other arteries. These aneurysms may be confounded with vascular or aneurismal goitres, pulsatile sanguineous cysts of the thyroid when they exist on the course of the carotids; also with pulsatile encephaloid; also with other tumors of the neck situated on the course of these carotids.

The treatment of aneurysms of the carotids by the methods of Anel, gave 22 per cent. mortality; the special complications being cerebral anemia, thrombosis, softening, ocular symptoms, laryngeal and pulmonary troubles. Incision of the sac without previous ligation is most dangerous. Ligations below and then incision of the sac gave 100 per cent. cures. In regard to ligation both below and above end then incising the sac, we have no data, because usually after ligating below and incising, the upper end is also secured. Extirpation has never been done on this artery; but it should be unless the sac be very large and closely adherent to the important vessels and nerves.

Aneurysms of the external carotid have been most

frequently treated by ligation of the common carotid with twelve cases and two deaths. The external carotid itself has been ligated in three cases, with one death and one return. The sac has been extirpated once with success. Aneurysms of the internal carotid, *i. e.*, of the extra-cranial portion, often project into the pharynx; ligation has been performed seven times with only one recovery.

Arterio-venous or jugulo-carotid aneurysms require no treatment unless they grow and cause grave pressure symptoms. Then the artery and the vein should each be tied above and below and the sac incised, or better, extirpated, because if left in place it may still cause trouble by pressure symptoms. This has been done in this region. Arterio-venous aneurysm of the external carotid present three cases on record; in two the ligature was applied above and below with one death. Arterio-venous aneurysms of the internal carotid, *i. e.*, the extra-cranial portion, have two cases on record, no operation was performed; both died.

The diagnosis of the affected artery in cervical aneurysms, etc., is often most difficult. Clinically and practically the diagnosis is made by operation. A provisional ligature should be applied below the tumor. When this stops the pulsations another ligature should be placed above; if this is not possible the ligature below should be tightened, the sac incised, the upper end of the artery secured and the bleeding points, if any, clamped and the sac extirpated if not too closely adherent to the important vessels and nerves. When, after placing the loop ligature, the pulsations are not affected, it is because the wrong artery is attacked; the loop should still be kept in place and the vertebral should have a loop ligature under it, when the pulsations will stop; then another ligature should be placed above, if possible, and as described for the carotid. Lymphangioma of the region presents no peculiarities.

Serous congenital cysts of the neck are most frequently situated in the lateral region of the neck; they are usually seen at birth; the multilocular cysts specially occupy this lateral region, whereas the unilateral occupy more frequently the median line, but there are many exceptions. Serous acquired or post-natal cysts of this region are really but congenital cysts. We will only mention the following, which are not truly cysts: Sanguineous cysts, due to contusions, which is an hematoma; sanguineous cysts due to sarcoma with an internal hemorrhage. Mucous, mucoid, dermoid cysts are all congenital cysts and present no peculiarities not already mentioned with the cysts of the neck in general. Hydatid cysts of this region are very rare; sixteen cases in all. Cystic degeneration of glands and tumors are not described as cysts. Purulent cysts or chronic abscesses or abscesses by congestion are sometimes observed in the sheath or the sterno-mastoid. We do not consider the softened tuberculous glands as cysts. Chronic abscesses are most frequently situated in the sheath of the large vessels, whence the pus may pass down into the mediastinum.

The solid tumors of the lateral region are: Hematoma, clotted or solidified, from contusion. It has been observed, also, from rupture of muscles and injuries of blood vessels. Senn had a most interesting case of persistent solidified aneurysm of the common carotid. Hematoma of the sterno-mastoid in the new-born is most remarkable and unique. It usually appears after birth; it is more frequently on the

right, it occupies the body of the sterno-mastoid, partially or totally forming a part of its substance; it is firm, elastic; it is oval; it is stationary; there is no pain except on pressure; the head is inclined as in torticollis; there is no tendency to grow nor to suppurate; it usually disappears by resolution in a few weeks or months. It is thought to be due to obstetric traumatism or a malformation; it is common after breech presentation when traction has been made to extract the head; it may cause a permanent torticollis. It must not be confounded with enlarged glands.

Induration of the sterno-mastoid in adults is syphilitic; it may be a diffused sclero-myositis; it may occupy the whole muscle, which is transformed into a cord, or it may be localized in one spot.

Gummata of the sterno-mastoid are found usually at the inferior insertion of the muscle; they may attain the size of an orange. This muscle is a point of election of gummata; they develop rapidly, in four weeks, without traumatism and without trace of pain. One case of hereditary syphilis of the sterno-mastoid is reported.

In connection with adenomata of the lateral region we will note here that tumors of the lateral region of the neck are usually glandular; a median tumor is most commonly connected with the thyroid body, larynx or trachea. Simple adenoma or lymphadenoma or pure hypertrophy of the gland is rare. In some cases of anemia there are peculiar hard glands of stony hardness, commonly unilateral, usually affecting the whole set of the glands (Miller). Adenoma of Hodgkin's disease, or adenia or adenoma of leucocythemia very commonly begins by the neck; in leucocythemia there is increase of white blood corpuscles; in adenia there is no increase. Strumous adenoma is very common in this region. Senile scrofula is represented by strumous adenomata in old people. Tuberculous adenoma is most common here; it is almost a seat of predilection. Syphilitic adenomas are very frequent; also, next to the nucha it is the part of the body most frequently presenting the symptoms of chronic syphilis; the glands are usually painless, of the size of a hazel nut, indurated; they never suppurate. Adenoma of glanders presents no peculiarities. Lipoma in this region presents no peculiarity not already mentioned in the description of the diseases of the neck in general; however, we must bear in mind that they often adhere to the vessels and bones. Fibroma is rare. Myxoma and myoma present no peculiarities. Neuromata of superficial nerves are cutaneous, plexiform; they are common in the neck, but not more frequently so in the lateral region. Chondroma is more commonly found as originating in the glands; they often adhere to the sheath of the vessels and to the bones. Osteoma has not been observed except as a possible calcareous degeneration or ossification of some structures. Encephaloid, melanotic, colloid or pulsating sarcoma, epithelioma, carcinoma and scirrhous are almost always secondary to such diseases of the head, face, pharynx, esophagus, larynx or trachea.

Tumors special to the region.—The hematoma of the new-born is the only tumor special to this region.

Surgical operations of the lateral region of the neck or region of the sterno-mastoid and of the carotids. The only operation requiring peculiar mention is that of tenotomy for torticollis, when the innominate vein may be wounded.

(To be concluded next week.)

SOCIETY PROCEEDINGS.

Chicago Academy of Medicine.

Regular meeting held March 12, 1897, at the Leland Hotel.

Dr. W. X. SUDDUTH in the chair.

The subject for discussion was

AUTO-INTOXICATION IN ITS MEDICAL AND SURGICAL RELATIONS.

THE CHAIRMAN said: Auto-intoxication, *i. e.*, self-poisoning, may arise from perverted cell metabolism or through deficient elimination of the ordinary waste products of cell katabolism produced in the regular course of functional activity, but which become deleterious by reason of their retention within the organism. Both conditions may be truly classed as auto-intoxications if we consider the body as a unit, a perfected whole, made up of many parts all working together for the general good. An organ is a complicated structure and its functions are simply the sum total of the functions of the individual cells that go to make up the organ. It is therefore a matter of indifference, pathologically speaking, whether the poison is produced by the cells of the particular organ that is affected by the product or whether it is evolved by the cells in some other portion, and carried to the part involved by the vascular or lymphatic system. If the poison is produced within the organism by reason of some fault of the organism itself, or if the ordinary waste products of the body, which are invariably poisonous to the body producing them when retained, are not quickly removed, the result is a true auto-intoxication and comes within the scope of this discussion.

The only phase of the question that I desire to present is the auto-intoxications that arise from the poison produced by perverted or excessive emotional activity. From time immemorial it has been known that the emotions, when excessively indulged have a direct action upon secretion. Clinically, we are all familiar with the interference in the normal functional activities of the several organs of the body by excessive grief. The derangements of the stomach and alimentary tract, that produce dyspepsia and faulty assimilation with the consequent long line of disorders, physical and mental, that follow in the train of mal-nutrition, are also well known.

Every mother knows the danger that lies in permitting a child to nurse soon after she has indulged in an uncontrolled fit of anger or suffered a severe fright. The sympathetic diseases that a nursing child has in common with the mother, while not in themselves true auto-intoxications, yet conclusively prove, when related thereto, the effect of toxic agents produced within the body of the mother through the operation of emotional prodigality. It has only been within the last few years, however, that physiologic chemistry has taken up this question and even more recently that psycho-physiologic investigation has demonstrated the nature of these processes. Professor Gates in an elaborate series of experiments has shown that each and every emotion has its own particular secretion which, if retained within the body, produces an auto-intoxication. These psycho-neurotic processes are undoubtedly the source of many of the trophic derangements found in the practice of the nervous specialist. Quite recently the theory has been advanced that insanity is many times the result of auto-intoxications from these products of emotional prodigality, exacerbations of mania frequently having been observed to follow a more or less prolonged period of emotional excitement. Professor Gates' experiments conclusively show that the emotional toxic agent is a constant product and can be extracted from the secretions, sweat, etc., at each successive recurrence of the emotional state in which it has previously been found, and further, that when separated and injected into man or dog, that the special emotional state may be reproduced, thus proving by experiment that there is a characteristic chemical action taking place in the system as the result of excessive emotional indulgence that may be determined by laboratory methods.

The other question, as to whether these products are always toxic in character, depends upon the nature of the emotion producing them, and opens up a field for discussion that transcends the scope of this symposium and will be deferred until some other more favorable time.

DEFINITION OF AUTO-INTOXICATION.

Dr. W. A. EVANS—I have been requested to devote my time to a definition of auto-intoxication. Intoxication comprehends: 1, production of the intoxicants; 2, absorption thereof; 3, reaction thereto. The three are embraced when we speak of

auto-intoxication. This is poisoning of an organism with matter produced by itself.

Assimilation or the making of tissue is the passing of the simple into the complex, of stability to instability, with the storing of energy. This instability is a necessity of life. Disassimilation, divided into two divisions, death and energy, the last being a modification of death, is the passing of the complex to the simple; the instable to the stable with the liberation of energy.

In the building-up process the unused portions of the absorbed foods may be said with fair propriety to produce auto-intoxication. In the breaking-down process the ash can produce auto-intoxication. So long as these two processes, tissue building and tissue waste, are normal, intoxication can only ensue from faulty action of the destroying organ of which the liver is the chief, or of the eliminating organs of which the kidney is a type. This constitutes then the first group, those due to faulty elimination. It applies to food remnants and to tissue waste, both normal and pathologic.

The second group is due to errors in cell life. It has three sub-heads: 1, by some reason food elements are left unused; 2, the ash from food-burning is unusually toxic or unusually difficult to absorb; 3, the secretion of the cell is toxic.

The third group is where the production of a toxin is beyond the capacity of the lymph and vascular channels for absorption.

As you will see, poisons secreted by germs located in any recess of the body or metabolism induced by those germs can not be considered as auto-intoxication. Ergo, it has no bacteriology. In a general way leucomains are mild irritants and their lesions are those of a mild irritation long continued—the interstitial inflammations.

CHEMISTRY AND PHYSIOLOGY OF AUTO-INTOXICATION.

Dr. JOHN A. WESENER—I will first discuss the decomposition of the proteid molecule while it is undergoing digestion. According to Kühne proteids under the action of gastric and pancreatic juices are changed into an hemi and an anti group. The anti group is broken down to anti-albumose and a anti-peptone, but very little of the last body is formed. Anti-peptone is a most stable compound resisting the further action of the digestive juices and even that of dilute sulphuric and hydrochloric acid. It is absorbed by the small intestine, but does not replace any waste of the used-up proteids of the body. Anti-albumose is changed to serum albumin and is the one that furnishes the body with its proteid food. According to some of the late experiments a true peptone is not poisonous, whereas both albumoses are very poisonous. The albumose when injected subcutaneously cause death; the blood fails to coagulate by reason of the fact that the lime salts are precipitated by this body. If for any reason the epithelium of the intestine fails to perform its function of changing this body into serum albumin toxic symptoms will arise. Brunton attributes lassitude, depression, sense of weight in the limbs, dulness in the head, etc., occurring in the well-fed inactive man after his meals to absorption of anti-albumoses.

Taking up the hemi group we find an entirely different arrangement. This group is burned up entirely; the stages are: Hemi-albumose, hemi-peptone, leucin, tyrosin, glutamic acid, and finally, by the action of the liver, urea. The assimilative apparatus, and especially the liver, converts the toxic hemi-albumose to the harmless urea.

Nuttall and Thierfelder have demonstrated positively that bacterial life is unnecessary in the digestive processes; that the juices alone will decompose the products perfectly. Furthermore, Senator has shown that in the newborn, indican is never present in the meconium or urine. From this standpoint poisons elaborated in the intestines through putrefactive changes can not be considered as the cause of auto-intoxication.

Before leaving this part of the body a word must be said about the bile. Bouchard in his experiments has shown that the bile is very toxic. After removing the coloring matter it is poisonous to a less degree. A certain portion of the bile is reabsorbed and stimulates the liver to renewed work. This continued circulation of bile through the liver stimulates the liver to destroy the toxic substances of the digestive tract and of the body as a whole.

Uremia.—In diseases of the kidneys where elimination is bad toxic symptoms will rapidly appear, for it is by this channel that the greatest amount of extractives are removed. In Bright's disease urea has been found in the stomach; nature has merely tried to throw off waste matter. Urea, however, is not poisonous, but whenever there is an accumulation of this in the blood toxic products are also increased, so that the amount of urea may be taken as a guide to the amount of toxic material present. Uremia, according to Bouchard, is probably due to the absorption of mineral matter, especially potash col-

oring matters and alkaloidal bodies. Landois laid bare the surface of the brain in dogs and rabbits and sprinkled the motor area with creatin, creatinin and other constituents of the urine. Urea, ammonium carbonate, sodium chlorid and potassium chlorid had but slight effect, but creatin, creatinin and acid sodium phosphates caused clonic convulsions on the opposite side of the body, which later became bilateral. He concludes that chorea gravidarum is a forerunner of eclampsia.

Cellular Secretion.—Under this head I will only mention the glands of the stomach and the pancreas. Pepsin and pancreatin, when injected into the circulation, produce death. Hildebrandt finds that a fatal dose of pepsin for dogs is from .1 to .2 gram per kilogram of body weight. The pepsin is destroyed in the intestines by the action of the bile and the pancreatin by the acids of fermentation; if this process is perverted, and if the liver and the cells of the intestines have lost their destroying and converting property auto-intoxication will arise.

Brieger is of the opinion that a great many toxic symptoms in gastritis are due to peptotoxin. This body is produced by the action of the pepsin upon albumins. When the function of the pancreas becomes arrested from disease or otherwise, the formation of glycogen in the liver is interrupted and diabetes results. The same is true of other organs in the body, interference with any organ upsets not only its specific function, but causes disturbances through the body generally.

Uric Acid.—Recent investigation shows that uric acid represents the metabolism of the nucleins of the body, and is in no way related to the albumins taken in as food, for these last bodies are burned to urea. Uric acid is non-poisonous, but some bases of this group are very poisonous. According to Milroy nucleinic acid combines with proteids to form nucleo-proteids. Frölich says gout is due to a leucocytosis. The necrosis arises as follows: the immature leucocytes break down easily because the carbon dioxid remains too long in the tissue spaces; the nucleinic acid which is liberated in this way attacks the connective tissue *i. e.*, irritates it, and this forms a good basis for the depositions of urate salts which are produced by the destruction of nucleins. This theory to my mind fits much better than that of Haig's.

In conclusion, I will say that I have tried to make five points: 1. Albumoses are poisonous. 2. Bile is poisonous; that the liver uses the bile as fuel to strengthen it to destroy poisons. 3. Uremia is probably caused by several anabolic and katabolic products. 4. Cell secretion. Perverted function in one organ will affect disturbances through the body generally. That the secretions are toxic. 5. Uric acid is non-poisonous. The preceding necrosis is a perverted cell metabolism. The toxic symptoms I have not considered, because I am not ready to answer just how these arise in this condition.

THE CHAIRMAN—In the absence of Dr. Fütterer, who was to speak on the clinical relations of auto-intoxication, I will ask Dr. Waugh to take up that phase of the subject.

CLINICAL RELATIONS OF AUTO-INTOXICATION.

Dr. WM. F. WAUGH—It has been a matter of interest to me to watch the development of this question as it has appeared in the medical press. Practically starting from the publication of an article by Sir Andrew Clark on "Fecal Anemia," some years ago, there has been a continual increase in the number of articles which devote attention to it. Bouchard's book gave it considerable impetus, and the question has been steadily growing in importance; the clinical field of auto-intoxication has been gradually widening until about a year ago in the *London Lancet*, it was claimed in an editorial that not only is the materies morbi of such diseases of the alimentary tract as the cholera group, typhoid fever and all affections characterized by fetor of the stools and so on, generated in the intestinal canal, but rheumatism, epilepsy, uremia, headache, diabetes, chorea, skin diseases, and many of the chronic diseases of the brain and spinal cord. And in the current number of the *Dosimetric Medical Review* I note an editorial that opens with the assertion that he who comprehends auto-toxemia fully has but little of practical medicine to learn.

There is one phase of the question to which very little attention has been paid, though it is rather an important one. I refer to the part played by auto-intoxication in fevers. We know that in all fevers the secretion of the bile is interfered with; it is greatly lessened. We know that the bile is the natural antiseptic of the system, consequently it stands to reason that in all fevers on account of the lack of bile and the increased temperature, we have an increased tendency to decomposition of the contents of the alimentary canal. There is in fevers, then, necessarily a certain amount of auto-intoxication, and the symptoms of auto-intoxication are added to those which are due to the fever proper. By a system of efficient intestinal antiseptics these can be separated and when

the effects of auto-intoxication have thus been eliminated, we find that the severity and the danger of the attack have been materially lessened. It is a question, of course, whether it is better practice to stimulate the liver, already suffering from the fever in such cases, or whether antiseptics should be secured by the use of antiseptic drugs.

UNTOWARD EFFECTS OF DRUGS AND THE DERMATOLOGIC AND VENEREAL RELATIONS OF AUTO-INTOXICATION.

Dr. WM. L. BAUM—The untoward effects of drugs in the production of cases of auto-intoxication are well known, and are described in almost every department of medicine. Certainly, almost every drug in the pharmacopeia is capable at times of causing such chemic changes in the system as to produce auto-intoxication. This is very frequently pointed out as being a peculiar condition or idiosyncrasy of the individual. Any drug can, in its ordinary physiologic action, produce a form of auto-intoxication, which may be increased or diminished, not according so much to the quantity of the drug taken, but according to some previously present condition. The subject of untoward effects of drugs is very intimately interwoven with the effects of auto-intoxication. A large number of the diseases of the skin which we are called upon to treat are the results of auto-intoxication. For instance, gouty conditions are frequently expressed in the form of eczemas. In other individuals we have urticarial eruptions, these being often one of the untoward effects of the drugs. I might say, that among the untoward effects of drugs, so far as skin lesions are concerned, the entire life-history of the untoward effects of drugs indirectly upon the skin is that they produce upon the already altered condition of the patient a chemic change in the products of digestion which are resorbed, the result being that they exercise a very profound influence upon the vasomotor centers. If there is a decided irritation we will have the formation upon the skin of urticarial wheals; if the irritation is more intense, we have not only the formation of urticarial wheals, but erythematous or hemorrhagic infarcts due to the long-continued distention of the smaller capillaries. If the irritation continues for a long time you may have the formation simply of papules, beginning eczemas, or beginning erythematous conditions, subsequently followed by the appearance and bursting of vesicles and the red weeping eczemas. If the irritation continues, pustular conditions subsequently form and may in themselves become auto-intoxicants, such as in small-pox. Here there is a rise of temperature coincident with the change from vesicles to pustules. You have then an example of a dermatosis producing a direct auto-intoxication from the resorption of the toxins present. It would be almost superfluous to dwell upon those drugs which are apt by their untoward effects to cause similar symptoms. We find, moreover, that the irritation may be of an entirely different character; that instead of having the untoward effects of drugs in manifestations upon the skin of the patient, we have profound impressions produced both upon the nervous and genito-urinary systems. It is not always a direct mechanic irritation produced by the drug which is responsible for certain manifestations in the genito-urinary tract, but it is due to altered chemic condition, which produces intoxications which are not confined to particular portions of the anatomy, but which may become general, and for that reason I do not wish at this time to dilate very much upon this phase of the subject. Auto-intoxications also take place as a result of some disease process which allow resorption of altered urine or septic material through the destruction of some portion of the lining of the genito-urinary tract.

THE EAR IN ITS RELATION TO AUTO-INTOXICATION.

Dr. NORVAL H. PIERCE—It is not my purpose to consider the general aspect of auto-intoxication, but rather to confine myself to the very small sphere that has been allotted to me by "the powers that be." In order, however, to have a basis for my remarks, I shall assume that the term auto-intoxication means an intoxication produced by an excess of normal chemo-physiologic substances elaborated within the body, or by toxic substances derived from them in the course of a perverted metabolism, or by the absorption of toxic substances from the gastro-intestinal canal, produced by a faulty or perverted digestion. While I am not prepared to give proof of the fact, yet I am sure from clinical experience that a great many cases of so-called catarrhal inflammations, if not entirely dependent upon the absorption of toxic substances from the intestinal canal, are, at least, greatly influenced by them. Thus, cases of simple subacute ear disease will resist local treatment unless attention is given to a coexistent intestinal disease, for instance, constipation. That intestinal auto-intoxication, by its depressing influences, renders infection elsewhere more easy, there can be little doubt. We frequently

find cases of otitis precipitated by an excess in eating or drinking with derangement of the digestion, and symptoms of fermentation in the bowels. But it is more especially the diseases produced by an excess of normal chemo-physiologic substances elaborated within the body, or by toxic substances derived from these in the course of a perverted metabolism, such as urea, diabetes, etc., that I wish to consider. Disturbances of the ear are probably much more frequent in Bright's disease than we have formerly believed. Thus, Doumergue, with the object of finding the frequency of ear troubles in Bright's disease, examined seventy-two cases of nephritis, and found 35 per cent. concomitant otitis, which was probably due to uremic poisoning.

Moos has divided ear troubles occurring in Bright's disease into two groups. First, those which are directly due to increased tension of the aortic system. Second, those in which otoscopic examination gives negative results. In the first class of cases, one of the most prominent and frequent pathologic conditions found upon postmortem is ecchymosis of the mucous membrane of the middle ear. In other cases there is actual hemorrhage in the cavum, or there may be a serous exudate in the tympanum. Those cases are more readily infected than the ordinary cases of catarrhal inflammations, and are especially liable to go on to suppuration. All these cases manifest the symptoms of catarrhal inflammation of the middle ear, tinnitus, more or less deafness, more or less pain, according to the pressure in the middle ear. The symptoms in the second class of cases are tinnitus with or without hardness of hearing. When deafness occurs it may be only partial or total. Fournier says that sudden failure of hearing power in these cases may be regarded as a prodromal sign of uremia. Indeed, there is sufficient reason to believe that a sudden loss of hearing in cases of Bright's disease should put us on our guard against approaching general anasarca. The important symptom in all of these cases which we wish to accentuate is the intermittent character of the deafness. Thus, there may be daily intermissions, or the attacks may occur several times daily. It begins suddenly, and almost as suddenly disappears. Or there is a pause of two or three or eight days, or a month, and then another seizure. It has been noticed that the amount of deafness often bears a relation to the facial edema and to the general anasarca. After the disappearance of the uremic condition the ear symptom may clear up. In other cases the deafness is lasting. In some of the cases there are symptoms which lead us to believe that the labyrinth is involved, such as dizziness, nausea and vomiting. Cases are on record in which a diagnosis of gastric trouble has been made, when in reality the stomach symptoms were produced by disturbances of equilibrium. On postmortem the middle ear may be entirely free from pathologic manifestations. The greater number of authorities believe that these symptoms are produced by edema of the acoustics. One writer compares the changes found in the acoustic nerve with those found in retinitis albuminurica. The tuning fork is of little value in the diagnosis of this class of affections. Galvanic reaction of the acoustic nerve is much more preferable. The appearance and the disappearance of the symptoms are explained by the resorption and reappearance of the edema.

As regards rheumatism, while it may often cause forms of dry and moist catarrh of the middle ear, there are no peculiarities in the local manifestations which differentiate them from others due to different causes, and we only gain a knowledge of the rheumatic character of the disease by the manifestations elsewhere in the body. As regards gout, we are all aware of the peculiar susceptibility of the external ear to gouty concretions. Gout may cause disease of the middle ear by concretions about the joints of the ossicles, and especially by concretions in fenestra ovalis, binding the stapes down, so that it can not possibly oscillate. In speaking of diabetes, I will pass over the eczemas and furuncles which occur so frequently in the external auditory canal, because they are of no special importance, inasmuch as the same conditions occur elsewhere in the body, and will say that perforative inflammations of the middle ear in diabetes are probably always purulent and of bad prognosis. This is due to two facts. First, a lessening of the resistance of the tissues to microbic invasion; secondly, the presence of sugar in the tissues, which produces a more salubrious nidus for the growth of germs than the ordinary plasma. Diabetic otitis media hemorrhagica is a well-marked type of ear disease occurring in diabetes. It occurs suddenly, with few or no prodromal symptoms, blood gushing from the ear, more or less great in quantity, with perhaps little or no pain. On section, little is found except necrosis of the tissues, and Bujwid has found in such cases the streptococcus pyogenes aureus in the blood-vessel walls, and he has suggested that the action of these microorganisms directly on the

blood-vessel walls, together with the inherent tendency to necrosis caused by the sugar, has produced these hemorrhages. We all know the proneness of the diabetic to mastoid disease, and we know, too, that up to late years surgeons have been divided as regards the advisability of operating on these cases, first, because of the uncontrollable hemorrhage; and second, because of the danger of infection.

At a late meeting of the German Society of Naturalists, held at Basel, this question was put to rest apparently by the greater number of authorities there, who said that they believed we may operate on these cases with impunity under strictly antiseptic conditions.

THE EYE IN ITS RELATION TO AUTO-INTOXICATION.

This subject was assigned to Dr. CASEY A. WOOD, but in his absence the chairman called upon Dr. WM. H. WILDER.

Dr. WILDER—On such short notice I do not feel competent to discuss satisfactorily the topic assigned Dr. Wood. In such a highly organized structure as the human eye, we should naturally expect to find more or less disturbance from the circulation in the blood of any of the toxic substances that arise in cell metabolism. There is one disease that occurs very frequently in the eyes of children which, notwithstanding its frequency, is up to the present time very little understood. We have had very little light thrown upon the pathogenesis of so-called phlyctenular keratitis, or phlyctenular conjunctivitis.

As far as the histologic pathology is concerned, it appears to be simple enough, but there is something deeper than that, which seems to elude investigation, and I have always thought that a more accurate knowledge of the subject of auto-intoxication would enable the ophthalmologist to get some light upon this intricate topic. It certainly will repay a more thorough investigation. This disease, with which you are more or less familiar, comes on in children possessing peculiar idiosyncrasy or diathesis, and in certain individuals in whom the processes of the body are not performed as readily as in others. It appears also in certain children who are predisposed to gouty manifestations.

All are familiar with the influence exerted upon the mesoblastic structures of the eye by such diseases as rheumatism and gout, intoxication from syphilitic poison, etc. I refer now particularly to those inflammations, sometimes of a peculiarly low grade of asthenic type, that affect the iris and other uveal structures of the eye so disastrously. More light can be thrown upon the pathogeny of these affections by a more careful study of the problems that are included in the subject of auto-intoxication. Nothing can be more disastrous to the individual than a severe inflammation of the iris, or of the choroid, because it not only affects these structures but the refracting media as well.

We know also that certain of these general diseases influence very profoundly the nutrition of other refractive parts of the eye, structures which, if they lose their transparency, are unable to perform their functions. I refer now to the lens and the vitreous particularly, which having no blood supply of their own, depend upon other structures for their nutrition. Fatty degeneration, or cataractous change in the lens, is frequently induced, as we know, by diabetes.

Every general practitioner is aware of the changes that occur in the retina, that delicate nerve structure which modern histology has shown us is really a part of the brain, as a result of certain general diseases. This part is profoundly influenced by the changes that are brought about by auto-intoxication. And we are all more or less familiar with the effect of degeneration of the elements of the retina that occur in the so-called albuminuric affections of the retina. We speak of a retinitis, of an inflammation of the retina, but these changes are due to degenerative processes going on in the nerve elements, similar to the degenerative changes that take place in the glandular elements of the kidney. A more intimate knowledge of this subject of auto-intoxication will throw some light also upon the peculiar effects produced in the retina by albuminuria. The circulation in the blood of toxic substances not only affects the blood vessels of this part, but influences profoundly the nerve elements as well. There is one change that takes place in the eye, under certain conditions, which seems to demonstrate positively that this most delicate structure in the eye may be profoundly affected by the circulation in it, or near it, of some of the deleterious products of cell metabolism. I allude to the change which takes place in the head of the optic nerve as a result of tumors of the brain. It was formerly held that the so-called choked disc or optic neuritis that occurred because of brain tumor, was due merely to the stasis of circulation in this part, together with the distention of the optic nerve sheath by the fluids forced into it because of the increased intra-cranial pressure. A more rational explanation of this

condition has been advanced by Leber, in which he claims that this change in the head of the optic nerve is brought about by the direct influence of toxins generated in the tumor itself, circulating through the lymph spaces of the optic disc, and his conclusions seem to be borne out by clinical evidence, because in many instances it is impossible to find any such distention of the optic sheath as former theories would require.

(To be continued.)

Chicago Pathological Society.

Regular meeting was held January 11, 1897.

Dr. JAMES B. HERRICK, President, in the chair.

H. GIDEON WELLS, PH.D., read a paper on "A Case of Congenital Syphilis Complicated by a Mixed Infection with the *Staphylococcus* and *Streptococcus Pyogenes*." (See p. 688).

PRESENTATION OF SPECIMENS.

Dr. JAMES B. HERRICK exhibited a specimen of *Gummata of the Myocardium*. This heart, taken from the museum of Rush Medical College, was obtained at an autopsy made by the coroner's physician, on an adult male of average size who had been found dead. There is, therefore, no clinical history save that of sudden death. Other anatomic evidences of syphilis were present. The heart is a trifle large, the wall of the left ventricle thickened and the cavity somewhat increased in size, the endocardium showing a few grayish areas over the underlying gummata. The pericardium is free and smooth. The valves are unaffected save for some grayish plaques in the mitral close to a gumma. In the upper third of the interventricular septum, close to the aortic valve is a firm nodule the size of an olive bulging into either ventricle. The endocardium over the mass in either ventricle is thickened, grayish, somewhat uneven from slight irregular eminences in the nodule. One of the chordæ tendineæ running from the tip of a papillary muscle in the right heart to the posterior tricuspid leaflet, is firmly adherent about its middle to the thickened endocardium over the gumma. Some interference with the closure of the valve probably resulted. A few smaller nodules are found in the wall of the left ventricle, and here and there are a few grayish streaks in the myocardium.

Microscopically a section from one of the smaller nodules from the wall of the left ventricle shows the accumulation of round cells between the muscle fibers with consequent atrophy of the latter. In places an encircling wall of fibrous tissue is forming. No marked central necrosis has as yet taken place.

Dr. HERRICK further briefly discussed the subject of acquired syphilis of the heart as it affects the endo- peri- or myocardium, in fibrous or gummatous forms. The difficulties of anatomic and clinical diagnosis save by exclusion of other causes of cardiac disease and definite proof of constitutional syphilis, were also referred to. The therapeutic test of improvement under anti syphilitic treatment was not conclusive. Rosenfeld's asthma syphiliticum and Semmola's twenty-seven clinical cases of syphilitic disease of the heart, must be viewed somewhat skeptically in the light of Mracek's finding of only six anatomic diagnoses of syphilis of the heart in 100,000 autopsies in Vienna.

The effects of gummata of the myocardium were 1, weakening of the wall with perhaps aneurysm or rupture; 2, obstruction of a cardiac orifice by pressure, or 3, interference with the valvular mechanism by involvement of the valves themselves or by deformity of papillary muscle or chorda tendinea (see specimen); 4, the breaking down of the gumma, discharge of contents into the circulation with emboli in distant organs (cf. case of Oppolzer); 5, from pressure upon, or involvement of cardiac nerves, vessels or muscle, marked interference with performance of function as shown in palpitation, arrhythmia, dyspnea, angina. Sudden death, as in this case, was common in gumma of the heart.

Dr. E. R. LECOUNT exhibited a specimen of *Gummata of the Heart in Congenital Syphilis*. The gummata of the heart were found in the body of a child born in the practice of Dr. A. B. Strong of Chicago, to whose kindness we are indebted for the following findings:

Death occurred almost immediately after birth and the autopsy done at the Pathological Laboratory of Rush Medical College resulted in the anatomic diagnosis of: 1, syphilitic interstitial pneumonia (nodular); 2, syphilitic osteo-chondritis; 3, gummata of the heart; 4, pustular syphilides of the skin; 5, multiple foci of suppuration in the thymus; 6, hyperemia of the liver and spleen.

The heart showed a large white area on its anterior surface and three similar smaller areas on its posterior surface. On section these all showed irregular margin, lessened consistency

and a disposition to spread out near the pericardium. The columnæ carneæ were involved in the larger area.

Microscopic examination of these areas revealed a proliferation of the connective tissue elements in the shape of oval or partially fibrillated cells. This was most marked around the vessels where proliferative changes in the adventitia were extensive. Widely scattered foci of necrosis of heart muscle fibers were present and these were the seat of infiltration with leucocytes.

The diagnosis of syphilis was confirmed by the microscopic examination of the liver in which a characteristic interstitial hepatitis was found, also by the examination microscopically of the osteo-chondritis and the interstitial pneumonia.

The literature on congenital heart syphilis has been thoroughly summarized by Ludvig Hektoen in a case reported of multiple foci of interstitial myocarditis in hereditary syphilis (*Journal of Pathology and Bacteriology*, Edinburgh and London, January, 1896) and a search through the *Index Medicus* failed to show any additional cases reported since. The above author was able to find only nine previously reported cases of hereditary heart syphilis, these being collated in the well known treatise by Mracek (*Die Syphilis der Herzen bei erworbenener und erbter Lues*. *Arch. f. Dermat. u. Syph.*, Wien, *Erganzungsheft* ii, 1893) and the syphilitic nature of some of these was doubtful.

Dr. WELLER VAN HOOK briefly discussed *Syphilis of Bones*, as illustrated by specimens from the museum of Rush Medical College.

DISCUSSION.

Dr. R. H. BARCOCK—With reference to the location of the gumma in Dr. Herrick's specimen it is interesting to note that of Grenouiller's nineteen cases, gumma was found nine times in the wall of the left ventricle and but once in the septum, six times in the wall of the right ventricle, twice in the wall of the right auricle, and once in the wall of the left auricle. The specimen which Dr. Herrick presented illustrates the frequency with which an individual suffering from syphilitic disease of the heart may die suddenly. Mracek says that out of sixty-three cases twenty-one died suddenly without previous symptoms, while if those cases were also counted in which there were some symptoms of cardiac weakness the cases of sudden death amount to 50 per cent. Such figures emphasize the gravity of this disease and the desirability of our being able to diagnose it during life; and yet, unfortunately, this is a disease in which the diagnosis is of the greatest difficulty and is to be arrived at oftentimes by exclusion and the history rather than from physical signs or symptoms. However, if the clinical experience of such an eminent man as Semmola counts for anything, it would seem that one of the very earliest symptoms which should direct our attention to the possibility of this disease is irregularity of the heart's action. This irregularity may be manifested for a considerable time, may appear even during the secondary manifestations of the disease.

So far as symptomatology is of aid in diagnosis, we can only say it is that of heart disease in general. Before coming over to this meeting I stepped into the syphilitic wards of the Cook County Hospital and looked over some half a dozen male cases there. The first man I examined, one with tertiary lesions, has an enlarged area of cardiac dullness. The relative dullness extends an inch and a half to the right of the right sternal border, and four inches to the left of the left sternal border, a total transverse distance of more than six inches. The heart was rapid; the first sound a little valvular. It would be absurd for a physician to claim that this patient, although suffering with syphilitic disease in the third stage, has cardiac syphilis.

Another man, who gives a history of having had syphilitic infection twenty-four years ago, stated that last summer he suffered with irregularity of the heart's action and shortness of breath, but as he is five feet three inches in height and weighs 189 pounds, has great abdominal corpulence, one would meet with considerable difficulty, it seems to me, in saying that his symptoms are due to syphilis of the heart. Another man, a fireman, stated that last summer while at work he suffered greatly from shortness of breath. Since coming into the ward and being put on antisiphilitic treatment his shortness of breath is much less. The transverse area of cardiac dullness is six and one-quarter inches; the first sound is feeble and when the man is in a recumbent position it is almost absent; the second sound in the aortic area is accentuated; the heart's action is quite rapid, over 100. Would anybody dare say that that man has cardiac syphilis? Would anybody dare say that the diagnosis points to cardiac syphilis because the man has been put on appropriate treatment and his symptoms have been relieved, when rest from work alone would explain his improvement?

This illustrates the difficulties we encounter in making a diagnosis and the extreme caution we should exercise. Nevertheless, it seems to me not unreasonable to assume that very many of these patients have cardiac disease of one kind or another, perhaps a very much larger percentage of them than we assume or have any means of determining, for the changes in the heart do not involve any one particular structure of that organ, but all of them. The development of the disease in the heart is so insidious and the symptoms are so latent that the disease escapes our recognition through the importance and prominence of other symptoms and the fact that the patients complain of nothing with reference to the heart.

The relative frequency with which the various structures of the heart are involved interested me very much in reading Mracek's article; he states that out of 61 cases 10 showed myocarditis gummosa, 9 myocarditis fibrosa, 8 gummosa et fibrosa, 15 myocarditis with endocarditis or pericarditis, 2 endocarditis alone, 1 pericarditis alone, 1 endocarditis with pericarditis, 1 pericarditis and endarteritis, 3 disease of blood vessels, 4 diseases of the ganglia and 6 of all the parts.

The prognosis is exceedingly grave because of the fact that a considerable percentage of these cases die without previous symptoms and because of the difficulty of recognizing the disease during life; the physician, as well as the patient, is thrown off his guard and allows the cardiac disease to run its course without special treatment. It is a well known fact that any treatment addressed to this form of cardiac disease is useless unless it be appropriate and specific; that is, ordinary cardiac tonics, and so forth, are utterly useless in the absence of specific treatment.

Dr. JOSEPH M. PATTON—I am glad to hear it admitted that the obliquity of failing to apply the pathologic lessons, such as have been given us tonight, to clinical medicine, does not rest upon the internalist alone. There are several reasons why we should not be able to apply these lessons to clinical work. In those cases of cardiac syphilis where there are fibrous changes in the muscle or septum, or where gummata of the heart are developing, the symptomatology would be similar to that pertaining to any other affection of the heart muscle wherein the dynamic integrity of the muscle was directly affected. Again, in those cases where the changes due to syphilis are limited to the vessels of supply, the symptoms are identical with those pertaining to stenosis of the cardiac vessels from obliterating inflammation of any variety.

I would emphasize a point brought out by Dr. Herrick to the effect that it is unfair to accredit to certain lines of therapy curative powers for syphilitic cardiac changes. The fact is that all cases of chronic cardiopathies do quite well under the same medication as would be used in suspected cases of cardiac syphilis.

Dr. LUDVIG HEKTOEN—You have seen the beautiful specimen of so-called pneumonia alba in congenital syphilis. I present here a specimen of another form of congenital syphilis of the lung, namely, the gummatous form. You will see scattered throughout the lungs foci of a light grayish color. Under the microscope these foci are seen to be composed of areas of round cell infiltrations with focal necroses. Surrounding these areas are the characteristic desquamative changes of pneumonia alba, showing that the two forms of congenital syphilis of the lung may coalesce.

Dr. VAN HOOK made some very appropriate remarks concerning the difficulties of diagnosis between syphilis and true tumors. He stated that the microscope should be resorted to in order that the question may be definitely decided. I desire to go further and to emphasize the point that even the microscope can not always decide whether the growth is syphilitic or sarcomatous; that instances have come under my own observation in which I was unable to determine from the microscopic appearance whether a given growth was syphilitic or sarcomatous, so much similarity may there be between the structures of these proliferations. In connection with this, attention may be called to the fact that there is great likelihood that many testicles are being removed for sarcoma and other diseases that are really syphilitic. I am not able to prove this assertion at this time by any concrete example, but I have seen specimens which lead me to suspect that such things may occur.

Finally, a remark with reference to congenital syphilis of the heart, namely, that such changes have a marked practical importance because children so affected may live for a time after they are born and present no external marks of syphilis whatsoever and die suddenly.

Dr. W. L. BAUM—Dr. Hektoen called our attention to the removal of testicles for sarcomatous conditions which are really syphilitic. Until within a few months I had a case under antisypilitic treatment which had done very well, but the patient upon removing to another city had his testicles taken out for tuberculosis.

A second case, a young man, had one of his testicles amputated for what was believed to be sarcoma, but which from the testimony of his family physician was undoubtedly syphilis of the testicles. Another physician in this case made a diagnosis of gumma of the testicle and had advised the patient to place himself upon antisypilitic treatment.

As regards the heredity of syphilis in the third generation, it reminds me too much of the tendency we all have when attacked by gout to lay great stress on the way our grandfathers lived. I am inclined to think that a large percentage of the so-called cases of syphilis that occur in older individuals are cases of the disease acquired during infancy. When we consider that by far the larger percentage of cases of so-called hereditary syphilitic children die at birth, are born dead or die within three months after birth, it is also strange that we should see so many examples of hereditary syphilis where we find the eruption appears two months after birth with a clear history of acquired syphilis. In the majority of cases, if the attending physician examined his cases thoroughly, he would have no difficulty whatsoever in locating the primary lesion.

The cases of gumma of the heart are interesting from a pathologic point of view, but I doubt very much whether they will have any great clinical significance for the reason that a large per cent. of the cases have died suddenly at a period far remote not only from the date of the initial lesion, but far remote from the time when any active specific lesions were present; so that while the attention of the physician may be called to the fact that the patient has had syphilis, yet in these cases of sudden death it is practically worthless. Discussions upon such cases as reported point out another fact, that we should impress upon the mind of every physician who treats cases of syphilis, that the treatment means not simply the gathering of a fee from the unfortunate patient, as is too often done in large cities; the idea seems to prevail that there is a specific treatment for syphilis which is of value in every case, and which is simply routine, and no attention is paid to the fact that the patient can acquire other diseases during the time he is suffering from syphilis. No attention is paid to the fact that one individual will react violently to small doses of iodids or mercurials, while others with apparently the same conditions present requires extraordinarily large doses of these remedies.

Dr. EMIL RIES—I wish to say a few words concerning the case of Mr. Wells. The complication of hereditary syphilis with infection with streptococcus and staphylococcus is highly interesting. It is to be regretted that we do not know more about the history of the case and that no examination of the placenta could be made. It is possible that infection with the streptococcus and staphylococcus took place after premature rupture of the membranes. The membranes may have been ruptured two or three weeks or a month before the child was born, as such cases have been observed. A few weeks or even days may be sufficient for infection of the fetus with the germs mentioned. If the placenta had been obtained for examination we might have known something about its condition and the route of infection. I refer here to the white infarcts of the placenta which by some authors have been considered characteristic of syphilis, which they are not by any means, and which by others have been regarded as a product of inflammation, which is not so, at least not in every case. Such infarcts may undoubtedly have a bearing upon infection, the infection following the paths of the circulatory system through the mother into the fetus. Such an infection may have taken place in this case, but we do not know whether there have been such infarcts. Beside, under confinement, within a few hours, infection of the fetus may have taken place if instruments had been used, or the vagina had been packed for hemorrhage or some such condition and such an infection may have spread rapidly after the death of the fetus. Examinations of fetuses of mothers with typhoid fever, which were made in Strassburg, and some of which I witnessed, showed how difficult it was to differentiate between intrauterine infection, infection during pregnancy or labor, and an infection after death. Fetuses of mothers infected with typhoid fever were found full of bacterium coli commune, and as there was no reason to suppose that during the life of the fetus the infection had gone so far, it had to be assumed that after death the germs had spread rapidly. Such might have been the case in the case reported where there was streptococcus and staphylococcus infection. Of course it is impossible that the streptococcus and staphylococcus could have produced abscesses after death. Wherever there were abscesses and accumulation of round cells, these conditions must have originated and then produced during life.

With regard to the cases of syphilis of the heart that were discussed to-night, they interested me very much because of

another organ consisting of muscle tissue, the syphilis of which organ we know so little, and which is so near the usual gate of infection, the uterus. Cases of syphilis of the uterus have been described in literature, but most of these descriptions are of very doubtful character. Gumma of the uterus has been described in extremely few cases.

Mr. H. G. WELLS—In regard to my statement of the impossibility of the infection in the case reported by me occurring after death, I will say that it was made because the lesions show a vital process to have taken place at the site of infection. For instance, in the abscess of the thymus shown under the microscope, the abscess is walled off with connective tissue, showing that the lesion must have occurred before death.

Dr. L. HEKTOEN presented specimens of: 1. *Brain Tumors Hardened in Mueller's Fluid 95 Parts and Formalin 5 Parts.* About a year ago I showed to this Society some gross and microscopic specimens of brains and cords hardened in a mixture of Mueller's fluid 95 parts and formalin 5 parts. Particular attention was then called to the great advantage of this method of hardening on account of, 1, rapidity (one to three weeks); 2, the desirable consistency produced; and 3, the plainness and distinctness of the markings of the cut surfaces, making the specimens very useful for museum and teaching purposes, at the same time the tissue is properly prepared for various kinds of staining procedures. Since then, this method has been adopted in the anatomic department of Rush College as well as elsewhere.

I now desire to present several specimens of brain tumors; these brains were hardened *in toto* in the above mixture, and then divided into transverse sections 1 cm. thick by means of this board, which you see presents a series of grooves 1 cm. apart in which the point of the knife is held as the brain hemisphere is divided from before backward. This board I first saw used in Henschen's laboratory in Upsala, and it is a useful contrivance. Brains divided in this way allow of accurate comparisons between corresponding parts in the two sides.

The above mentioned advantages of this method of hardening and of cutting are well illustrated in the specimens from these cases.

2. *Mixed-celled Sarcoma of the Pons and Left Crus.*—The hemispheres show no changes except dilated ventricles. The upper or dorsal half of the pons presents an enlargement which at the posterior end assumes the form of an oval prominence lifting up the roof of the fourth ventricle, projecting into this cavity and pressing upon the vermis of the cerebellum. This mass is a little more prominent upon the left side. It is quite firm and homogeneous. It is sharply differentiated from the rest of the pons, but its exact upper limit can not be outlined, it being lost in the substance of the left crus.

Microscopic examination shows the tumor to consist of small round and spindle-shaped cells between which are interspersed a few small multinucleated giant cells, all being imbedded in a granular matrix. The tumor is rather vascular, and the vessels and vascular spaces have thin walls. Hemorrhages are not present.

This specimen came from a 30 year old woman in the service of Dr. Davis in the Cook County Hospital. In July, 1896, she complained of headache, dizziness and blind spells. On October 7 she entered the hospital, and it was then observed that the reflexes were exaggerated; that there was ankle clonus, nystagmus and retinal hemorrhages. On November 23 an exploratory trephine opening was made over the left hemisphere, but careful exploration failed to reveal anything abnormal. She died rather suddenly on Dec. 15, 1896.

3. *Glioma of the Left Temporo-Sphenoidal and Occipital Lobes. Anatomical Diagnosis.*—Craniotomy, encephalocoele, intracerebral tumor of the left temporo-sphenoidal lobe, optic nerve atrophy, diffuse nephritis and hypertrophy of the heart.

Extract from postmortem record: Circumference of the skull 59 cm. Over the left parietal region is an oval opening in the skull 10 cm. in antero posterior diameter and 6 cm. transversely. Through this opening protrudes a soft, round mass. Over this opening the pericranium is adherent to the dura, but the dura is not adherent to the pia. The protrusion corresponds to a hernia of the brain substance. The skull cap is thin: the antero-posterior diameter is 17½ cm., the transverse 14½ cm. The margins of the opening are beveled from within outward. The dura is tense, the convolutions flattened, the pia mater anemic, the brain firm. The total weight of the brain is 1860 gms.; of the left hemisphere 940 gms.; of the right 740 gms., and the cerebellum, pons and medulla together weigh 180 gms. The optic nerves are hard and white. The basal ganglia of the left side are prominent. The spinal cord is normal. After hardening the brain in the formalin, Mueller's fluid mixture, for two weeks, the hemispheres were divided into transverse, vertical sections each 2 cm. in thickness. In the

left hemisphere was a large tumor that commenced in the apex of the temporo-sphenoidal lobe and extended backward in the brain substance for the distance of 10 cm., the transverse diameter being 8, the vertical 6 cms. This mass was infiltrating and intracerebral, except in the fissure of Sylvius, where it reached the surface of the convolutions and caused pressure upon and distortion of the convolutions of the island of Reil. The left lateral ventricle was much deformed by the pressure of the tumor, the posterior horn being greatly enlarged. The tumor contained many large and small cystic cavities filled with a viscid fluid. The probable microscopic diagnosis is glioma.

In May, 1896, Dr. Van Hook operated upon this man under the diagnosis of tumor of the left hemisphere, but exploration failed to discover any growth. The diagnosis had been based upon failing vision, headache, difficulty in speaking and right sided paresis. He entered the service of Dr. Edwards in the Cook County Hospital, Oct. 2, 1896. At that time there was total blindness, slow and thick speech, choked disk and a diffuse tenderness over the top of the head. Shortly before death he was transferred to the surgical service of Dr. Davis, where he died on Dec. 27, 1896.

4. *Sarcoma of the Left Temporo-sphenoidal and Frontal Lobes Springing from the Dura.*—The patient, a man, age 50, came under the care of Dr. Butler in Cook County Hospital Dec. 29, 1896 and died Jan. 4, 1897. The exact onset of the present trouble could not be found out. The left eye was protruding, the left eyelid drooping. The right eye had normal vision, and reacted to light and accommodation. There was tenderness when the head was tapped on the left side. His gait was slow, the legs being spread wide apart. On January 3, shortly before his death, the patient had a convulsion during which the head deviated to the right, and the muscles of the right side being then most involved in the clonic contractions.

The postmortem shows the body poorly nourished, the left eye prominent, the dura tense. Along the under surface of the left frontal and temporo-sphenoidal lobes, the brain is firmly adherent to the floor of the skull so that removal is impossible without considerable laceration of the brain substance. The brain weighs 1710 grams. There is a large mass extending into the left frontal and temporo-sphenoidal lobes from below, the tumor springing from the dura mater, more particularly the part lining the apex of the left middle fossa. The tumor is about the size of a hen's egg. It is but very loosely connected with the brain substance and threatens to fall away from the brain. On the cut surface it is reddish gray in color and firm in consistence. Microscopic examination shows the tumor to be a small round and spindle-celled sarcoma with much fibrillar stroma and many large thin-walled blood vessels.

SELECTIONS.

Pre-Columbian Leprosy.—The *Berliner Klinische Wochenschrift*, Nov. 16, 1896, states that a discussion in the *Berliner Medicinische Gesellschaft*, March 4, 1896, following a paper by Havelburg on "Einige Bemerkungen zur Lepra, nach Erfahrungen aus dem Lepra-Hospital zu Rio de Janeiro," Professor Virchow said: "We have only a short time for the discussion of this pamphlet. It has been reserved at the last sitting when the patient was presented here, that at this occasion when Dr. Havelburg made his communication we could come back to the question which was stirring at that time, especially to the hygienic question, What was to be done with the people? Before I open the discussion, I should like on my side to observe in regard to the observation of Dr. Havelburg that it is historically established, that leprosy was brought into Brazil by people coming from Europe; that is at least how I understood it. That this is rather a well meaning than a sure interpretation of historic facts; as far as I know, there is nothing sure in that direction, and I will only emphasize, what I have done before, that just recently more researches in America, as well in North as in South America, have commenced in order to decide the question whether there has been a pre-Columbian leprosy. I have on the occasion of the Jubilee Lewin already called the attention of the public to this that there are really all kinds of objects which may be interpreted in an affirmative sense. The most striking according to my opinion are certain earthen or

clay figures which have been found in old tombs of Peru, and which certainly show mutilations and changes of other sorts which might easily be referred to leprosy. These researches are not concluded, because we have not to do with real works of art, which might be used as authentic interpretations. Nevertheless, the things are very strange, and Mr. Ashmead, who at this moment is traveling about America in order to pursue the question still further, would probably have much to say against the theory that leprosy has surely been introduced into America. The reverse opinion is according to my mind, still discussible."

The same journal of Dec. 7, 1896, gives the concluding remarks of Mr. Havelburg: "Speaking the last of the assembly, I have only to take notice of a few observations made in this discussion. The much honored Chairman has criticized my historic indications that leprosy was imported into Brazil by the Portuguese. No evidence that leprosy existed in pre-historic times in Brazil, so far, has come to light. In a work based upon historic foundation, of Dr. Marquez Pinheiro, a jurist, and which I shall like to bring to your library, there is a historic representation of the appearance of leprosy in Brazil, and the development of the Hospital dos Lazaros in Rio de Janeiro. The Portuguese are supposed, in that work, to be the importers of leprosy. In the year 1420, the Portuguese discovered the island of Madeira; in the year 1498, under Cabrel, Brazil was discovered. Into the same period falls likewise the discovery of the Canary Islands by the Spaniards. According to the communications of different authors, and especially of two gentlemen in the 22d volume of the *Archives for Pathologic Anatomy*, as answers to an appeal made in the year 1861, by Professor Virchow, in the case of leprosy it was most probably brought by Spaniards into the Canary Islands. In the 15th century leprosy was absolutely existing in Spain and Portugal. In 1542, the first leprosy was established in the Canary Islands, by means of the men who under the Portuguese flag, populated Madeira. At that time leprosy reached that island, so that in the year 1640 an especial lepra hospital had to be established there. But the greatest part of the emigrants directed themselves to the greater colonial possessions of Portugal and Brazil; hence that the same was done there as in Madeira. I have received by good chance a small pamphlet by my colleague Azeoedo Lima. He has much to do with the leper hospitals of Portugal. He mentions it as a fact, that in the 16th century, leprosy was carried into Brazil by Portuguese colonists. Two years ago I was asked by Dr. Ashmead, of whom Virchow also makes mention, to give him some information about this matter. As he was occupied with a work on the spreading of leprosy through the Spaniards of the American continent; and on that occasion, I found that the Brazilian authors were unanimous in this idea that the Portuguese carried leprosy into Brazil. Of course this is not a proof, and I am thankful to Professor Virchow for the appeal which he made to me, to search after the foundation of this historic idea, so generally admitted in Brazil."

NEW YORK, March 26, 1897.

DR. WM. HAVELBURG, Hospital dos Lazaros, Rio de Janeiro, Brazil.

Dear Doctor:—In the discussion in a certain paper of yours, published in the *Berliner Klinische Wochenschrift*, Nos. 46, 47, 48 and 49, (1896) Professor Virchow disputes your claim that it is historically established that leprosy was brought into Brazil by people coming from Europe. He does not think this to be a sure interpretation. The earthen images, the huacos of Peru, he says, show certainly mutilations and changes which could easily be referred to leprosy, and the question of pre-Columbian leprosy is still open. I think with you that the disease was imported by Spaniards and Portuguese, perhaps negroes, by the last not very probably; there is not a scintilla of evidence that leprosy was here before Columbus. I have sought

over all America for some possible evidence of that kind, and have not found it. As to the deformations on the huacos pottery, I have shown to the satisfaction of the Washington Smithsonian Institution and Professor Brinton, the ablest American paleontologist, that these potteries show no evidence of leprosy; they are to be interpreted as syphilis and lupus, both of which diseases undoubtedly existed before the arrival of Columbus on this continent. In the matter of syphilis, Virchow is the last to hold out against a pre-Columbian syphilis. He will not admit it. Professor Brinton wrote me some time ago, that I should endeavor to convert Virchow to my view, and I wrote to Prof. Putnam of the American Museum of National History, to forward to that German scientist, a Pachacama skull which was sent to the museum by Professor Bandelier, now at Lake Titicaca, Peru. This skull was dug out from a depth of twelve feet at Pachacama. There has never been found at Pachacama, any *post*-Columbian bones buried at such a depth. Bandelier wrote me that this skull was without question pre-Columbian. It bears osseous evidences of pre-Columbian syphilis, so that we have two evidences in favor of the latter, the huacos pottery and this skull. The bones of Colombia, the most ancient seat of leprosy in South America, have never been studied. Now Colombia is the country where this disease is most prevalent. It is my desire some day to go through this bone work for such evidence. I do not think I shall find it. As far as negative evidence can count for anything, leprosy did not exist in pre-Columbian days, in the Micmacs of Nova Scotia, the Aztecs of Mexico, the Aymaras and Iacas of Peru, nor among the Indian tribes of Brazil, *nor in Alaska and British Columbia*. You are at liberty to send this letter to Professor Virchow, or to any Berlin authority you please.

Very truly yours,

ALBERT S. ASHMEAD, M.D.

The Terrible Stiletto of the Italians.—Baron Garofalo, an eminent criminologist of Italy, has said of the accursed knife of his countrymen, that it claims a homicide every two hours, or an average of twelve victims daily. It would be a curious and instructive inquiry, that of ascertaining how far offences are aggravated by the medium through which they take effect—drunkenness, for example, being a more brutal phenomenon when the drinker incurs it with ardent spirits and not with wine or beer. Similarly, personal violence is one thing when it takes the form of fisticuffs and quite another thing when it is inflicted with the knife. A people, not necessarily more depraved, may appear technically more criminal by giving vent to its passions or propensities, not in themselves worse, through agencies of deadlier power. Italy possesses an unhappy priority in lethal offences, and Northern exceeds Southern Europe in drunkenness; just because in the one case the knife is used instead of nature's weapon, and in the other because raw whisky is the available beverage and not the juice of the grape. The Italian senate on the initiative of the Marchese Vitelleschi had a full-dress debate on the prevalence, nay, the increase, of crimes of blood during the last decennium, and many were the causes, primary and secondary, adduced in explanation of the fact. Vitelleschi saw much that was answerable for these crimes in the lack of sound education, even where it is given at all, deploring, for example, the total suppression of religious instruction in schools. Again, he thought the abolition of capital punishment directly favorable to homicide. To some of his arguments the Minister Costa replied not ineffectively. Admitting the prevalence of lethal crime, he showed that it was not universally distributed throughout the kingdom—that the Southern provinces contribute to these crimes out of all proportion to their population. This would confirm Vitelleschi in his impeachment of defective schooling as a cause, these provinces being far ahead of the North in the number of *analfabeti* (unlettered). On the other hand, he drew attention to the striking fact that in Italy alcoholic

excess is not attended with increase of violence. The provinces of Italy where homicides are most frequent are, he proved, precisely those where the lower orders are exemplary for their sobriety and abstemiousness. Indeed, the supineness of Italians—the absence of all sense of citizenship—runs through their whole attitude toward every detail of national life, from representative government downward. But, again, the speaker redressed the balance in his favor when he proved that the suppression of religious (as distinct from secular) education in schools had nothing to do with the increase of lethal crime. In 1870, in Latium, where there was also religious instruction more than compulsory, there were also many more homicides. But the abolition of capital punishments he did not at all succeed in justifying. Thirty years ago in the House of Commons the whole subject was threshed out thoroughly. One of the most powerful speeches in favor of such punishments being John Stuart Mill's, who, on the ground of humanity, advocated execution as preferable to the slow torture of lifelong imprisonment with, or still more without, hard labor. But the speech of the occasion was Sir George Bowyer's, who, in answer to the pleas that capital punishment was not deterrent, adduced the following fact: A Neapolitan wanted to kill his wife. The guillotine was still the penalty for murder in the kingdom of the Two Sicilies, so he took her to Tuscany where that penalty had been abolished and put her to death there. Yet in spite of that historic debate on the subject—in spite of the fact that Switzerland, having abolished capital punishments, was compelled by sad experience to legalize them once more, the Italian Government (though not without numerous and authoritative dissentients) made the abolition of these punishments the law of the land, and we now find the Minister of Grace and Justice defending that reform in presence of "a homicide every two hours." The truth is that Italy, in many aspects of her life, has not emerged from the middle ages; that hardness of living at once inspires crime and robe detention in prison of its terrors; that the administration of justice is so perfunctory that the people, knife in hand, settle their differences among themselves; that, in fact, D'Azeglio's watchword thirty-five years ago: "Now we have to make Italians," has lost none of its significance, and that Italy's most dutiful sons are those who, like the mass of her medical men, act strenuously in the spirit of that watchword, beginning with the rising generation and so guiding its growth as to exclude the vicious and give the healthy subjects such advantages of training and environment as can alone form the groundwork of a civilized and progressive state.—*London Lancet*, January 23.

PRACTICAL NOTES.

Anti-leucorrhœa Injection (Lutaud).—Tannic acid 60 grams; spirit of lavender and creosote aa 30 grams; aq. dest. 250 grams. One tablespoonful to a liter of tepid water.—*Journ. de M. de Paris*, February 28.

Influence of Food and Inaction on the Effects of Certain Microbian Toxins. Teissier and Guinard have been studying the effects of the administration of the diphtheritic toxin and of pneumobacillin to well fed dogs and to others in a fasting condition. They found that the fasting dogs resisted the toxins to a much greater degree than the others. When they succumbed to the effects of the toxins, the lesions were much less severe than in the others. The *Progrès Méd.*, February 27, remarks that these experiments may throw a new light on the question of diet in infective diseases.

Jalaguier's Method of Securing Solid Reconstitution of the Abdominal Wall.—After incising the aponeurosis of the large rectus muscle, Jalaguier pushes the muscle to one side and enters the peritoneum through an incision in the rear wall of the aponeu-

rosis. By this means the muscle when brought back to its former position covers and supports the suture in the peritoneum and the aponeurosis and ventral hernia from distention of the cicatrix becomes an impossibility. The details are given in full in the *Presse Méd.* of February 3. It is not adapted to cases requiring drainage, nor where extensive indurated adhesions can be palpated beforehand, but for children and the usual category of cases operated upon *à froid*, or after the attack has subsided, it has proved extremely effective in his practice during the past year.

Treatment of Intestinal Troubles with Iodin.—A writer in *Wratsch* states that iodine is very effective in typhoid and other intestinal disturbances, but that the iodine, as usually administered, is absorbed by the stomach and fails to reach the intestines. He has been using it for three years in the form of amyllum iodatum and recommends it in high terms. In this form the iodine reaches and exerts its influence upon the intestines, while it does not combine with the ptomaines and alkaloids to form poisonous compounds. In typhoid he administers rectal injections of dec. amyli to which is added tinct. iodi 10.0 and ol. cinnamomi gtt. xxv. Internally, amyllum iodatum, 0.6 four times a day. This treatment commenced before the fourth day arrests the attack; after the first week it only attenuates it. The tongue clears off and becomes moist, the pulse becomes slower and stronger, the evacuations acquire normal odor and consistency, and the appetite improves. The temperature is not affected, but the duration of the disease is much shorter, five to six days in light cases and eleven to twelve in severe. The writer has also secured "the best" results with the same treatment in 100 cases of dysentery and several cases of cholera asiatica.—*St. Petersb. Med. Woch.*, No. 1, 1897.

Modification in the Bone Marrow Produced by the Staphylococcus and Its Toxins.—The pains in the bones we have observed in the course of certain infections are perhaps explained by some recent experiments of Drs. Roger and Josué, who injected staphylococci or their toxins into rabbits and then examined sections of the bone marrow, comparing them with normal sections. As soon as the injections in the flank had produced an abscess they found enormous proliferation of all the cells in the marrow and modifications in the giant cells, with marked congestion. After intravenous injections the proliferation was much more rapid and pronounced. Similar effects were produced by subcutaneous injections of staphylococcus toxins. Experimental septicemia also produced the same effect even more rapidly. All the elements of the bone marrow start at once to proliferating with energy, which is doubtless a phenomenon connected with the defense of the organism against the infection, as the marrow generates the leucocytes that destroy the germs. What is the mechanism by which a distant local lesion can thus act with such rapidity on the medullary tissue? It can not be ascribed to the direct action of the microbes, as marrow strewed on the culture media does not promote the growth of any microbial colonies. More than this, staphylococcus toxins injected under the skin produce the same modifications. It is therefore a question whether the cellular activity of the marrow is started by the toxins secreted by the microbes, or by nervous system. Whatever the mechanism may be, it is another demonstration of the solidarity of the different parts of the organism, showing how a local lesion may react on the most distant organs. The results of these experiments may also explain the rapid growth of the skeleton in certain affections.—*Presse Méd.*, February 20.

Voracity After Head Injuries.—Mr. Stephen Paget read a paper before the London Clinical Society on cases of voracious hunger and thirst after injury or disease of the brain. He had collected notes of fourteen cases of this kind pointing to the existence of special centers of hunger and thirst close to the

centers of speech, probably in the anterior extremity of the temporo-sphenoidal lobe, near the uncinatè gyrus. A short account was given of each case, including one in his own practice. The primary injury or disease in each case was as follows: Four of the patients had received a severe blow on the forehead, two had been struck on the side of the head, two had fallen heavily on the back of the head, two had presented signs of a fracture of the base, and one had fallen from a height, coming down in a sitting posture. In addition to these eleven cases of injury there were three cases of disease; one had abscess of the left temporo-sphenoidal lobe, one had a suppurating cyst in the right temporo-sphenoidal lobe, and one had embolism of the left side of the brain. Eight of the fourteen patients suffered from voracious appetites for solid food without much thirst; three suffered both from thirst and hunger; and three had intense thirst without hunger. In none of them was the primary injury or disease fatal; it was therefore, certain that the centers of hunger and thirst were not situated in the immediate neighborhood of the vital centers. Three of them had well-marked aphasia; it was, therefore probable that these centers lay close to the centers of speech, and not improbable that they were connected with the olfactory center. This hunger and thirst was not the natural appetite of convalescent patients or of the result of any general mental derangement, and it was not secondary to traumatic diabetes. With regard to treatment, no harm had come in any case from letting the patient freely indulge his craving for food and drink. The voracious desire lasted, as a rule, for many weeks or months and then came to an end of itself.

Cerebellar Ataxis.—Dr. Campbell Meyers reports a case of this affection in a male, 17 years old, an only child, who had been attending school regularly. His paternal grandfather died at 75 of diabetes, his maternal grandmother of consumption, and his maternal grandfather of locomotor ataxia. His mother was of a nervous disposition but otherwise healthy. He was born by the aid of forceps, but the labor was not prolonged nor attended by any serious difficulties. He began to walk early, and no defect in his development or health was noticed until he was 3 years of age, when he began to suffer from diabetes insipidus, which has continued. Three years ago it was first noticed that his gait was affected and it had become steadily worse. His speech, at times, was peculiar. His general health was good. Thirst had always been extreme. Condition on examination showed the patient to be a well developed boy without any noticeable deformity about the head or body. The knee jerks were decidedly increased and there was moderate ankle-clonus on both sides, the wrist, elbow and superficial reflexes were very active. The gait was uncertain and staggering, the feet being placed widely apart. He could not start to do anything quickly. When attempting to walk he hesitated for a moment, started, walked with uncertainty and turned around with difficulty. His speech was slow, the separate syllables being all pronounced. His movements were awkward and often it was with difficulty he could prevent himself from falling backward. He could not stand steadily when his feet were together, nor could he maintain his balance when one foot was placed immediately before the other, even with the eyes open, but he at once fell sideways if the eyes were closed. There were no defects in smell, hearing or taste. A chart of the field of vision showed a bilateral contraction in the outer part for white, a more marked concentric contraction for red and decidedly contracted field for green. Central color sense was good. There was no irregular contraction of the pupils; no appreciable heterophoria with the phorometer, though the right eye appeared to roll upward. Slight nystagmus if the eyes were fixed in an upward position.—Abstract in *Montreal Medical Journal*, January.

Section of the Cervical Sympathetic in Exophthalmic Goitre.—Every new operation confirms the success of this measure, and as ablation of the thyroid gland is so often fatal and fails to remove the cause, and thyroid treatment only aggravates this disease, much is hoped from the new operation. Jaboulay now has a record of six cases, and in all the exoph-

thalmus was immediately and enormously improved, but the tachycardia was not benefited in the same measure, although all the symptoms were much attenuated. These results confirm the theoretic basis for the operation, viz., that the disease is due to some permanent excitation of the vaso-dilating fibers of the cervical sympathetic. As the vessels are dilated to an abnormal degree, the eyeball is forced forward, the thyroid gland becomes enlarged, and all the other symptoms of exophthalmic goitre follow, all caused by hyperdistension of the blood vessels dilated by the vaso-motor fibers of the cervical sympathetic or their nuclei. Cutting the fibers therefore prevents further dilatation, and the symptoms pass away. The cardiac fibers, however, are so low down that they are not affected by the operations hitherto attempted, and sectioning the sympathetic or extirpating the ganglia, as has been done, only relieves the region innervated by the sectioned fibers. Total resection of the sympathetic and its three ganglia, which Jonnesco has performed, seems more than is necessary to Abadie, as he remarks in a study of the subject in the *Presse Méd.* of March 3. Theoretically, section of the cervical sympathetic above the middle ganglion, or the extirpation of the ganglion, should put an end to the exophthalmus by cutting the fibers that dilate the retrobulbar blood vessels, and section of the cervical sympathetic below the middle ganglion should arrest the hypertrophy of the thyroid gland. And in fact, experience is confirming the theory. When the exophthalmus dominates the scene, section of the sympathetic between the middle and superior ganglia should be the preferred operation, as it is simple, easy and effective. But if the goitre is troublesome, the sympathetic should be sectioned below the middle ganglion, a more difficult operation, and in the rare cases in which the tachycardia still persists after all other means have been tried, the efferent fibers of the inferior ganglion should be sectioned.

Tetanus Caused by Bite of Ape, Treated with Antitoxin; Recovery.—

A student of the Budapest Veterinary College who had been bitten by an ape on the palm of his left hand was imprudent enough to dissect on the same day a horse which had died from tetanus, and on the following night he was seized with pain in his left hand, but waited till next morning, when he went to Professor Reczey's clinic. The wound of the hand was at once enlarged, thoroughly cleansed with a solution of perchlorid of mercury and subsequently cauterized with caustic potash. He was then sent home, and although advised to present himself at the clinic next day, did not do so, but stayed at home, where he was seized on the following night (November 12) with tetanic convulsions. A neighboring practitioner who was called in ordered large doses chloral-hydrate to be taken every two hours. On November 13 the convulsions increased in frequency and intensity. The patient was conscious, his secretions and excretions were normal, he perspired freely, and his temperature was 107.3 degrees F. He was now given a subcutaneous injection of pilocarpin, which arrested the convulsions for a few hours, but in the evening he was seized again every thirty minutes with convulsions lasting from a minute to a minute and a half. On November 14 pilocarpin was again administered, giving relief for several hours. On November 15 the pilocarpin ceased to be effective, the convulsions came on again twice every hour, and sometimes respiration stopped owing to the spasm of the respiratory muscles, so that artificial respiration had to be resorted to. It was consequently resolved to give the tetanus antitoxin a trial. The antitoxin was given in doses of 3 c.c. thrice daily on November 15, 16 and 17, and once on November 18. The patient's nights were quieter from the beginning of this treatment, and the last of the fits occurred during the night between November 17, and 18. He has been free from convulsions ever since and may be safely considered as recovered. His highest temperature was 109.7 degrees F. on November 17, and the lowest was 95.3 degrees F. on November 20. The special features of this case were: 1. The early development of the tetanus, the period of incubation lasting generally from eight to fourteen days; this rapid onset may be attributed to the obvious fact that the disease was in this case not due to bacillary infection, but rather to the absorption of toxins. 2. The absence of trismus and the absence of troubles connected with the secretory and excretory functions. 3. The marked predominance of very violent clonic convulsions, the characteristic tonic contractions being but little marked.—London *Lancet*, January 23.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the Association living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, APRIL 10, 1897.

A WATER SYMPOSIUM.

A special double number, for the months of March and April 1897, of the *Albany Medical Annals*, the journal of the Alumni Association of the Albany Medical College, contains a series of papers on the relation of impure waters to disease, read at the annual meeting of the Medical Society of the State of New York, Jan. 27, 1897. The intention was to present to physicians the many important facts that have been developed by special workers during the past twenty years. Some of the papers are rather elementary, and from their character we would be at liberty to form a somewhat unflattering opinion of the standard of progress among the members of the Society; but we prefer to believe that the authors were in fault in lowering the tone of their papers to the popular instead of merely to the professional plane.

Nothing new is presented in the various contributions, but all the subjects are brought up to current date. The latest observations, investigations and opinions are cited. Malaria is not regarded as propagated by water supplies. It is said that a close study of the literature shows but little reliable evidence in favor of its water-borne origin. This is the view recently taken by the bacteriologists, because they have been unable to find the causative microorganism in water; but it is to be remembered at the same time that they have as yet been unable to find it in air. The evidence of water transmission in amebic dysentery is held to be equally unsatisfactory, but

here it is considered that the probabilities are in favor of the theory. The propagation of cholera by infected water is undoubted, as the presence of the spirillum has been demonstrated. Nor does there appear to be any doubt as to the causation of enteric fever by water, although in no well authenticated instance has the typhoid bacillus been isolated from contaminated water by competent observers in the past few years. It is difficult to detect it even in the stools of typhoid patients. It has been found with a larger percentage of success in the urine; but when found its identification involves so much careful bacteriologic work that a simpler test of its presence is needful for diagnostic purposes than that dependent on its detection and identification. This appears to have recently been discovered by WIDAL in the action of the antitoxin in the serum of the blood of a typhoid patient on pure cultures of the bacillus. The dried blood test as applied by JOHNSTON of Montreal to attenuated cultures is now in use in most of the laboratories of the United States. This, it is hoped, will determine the presence of typhoid infection in the individual. To determine its presence in a water supply, we have only to look at the records of typhoid prevalence or mortality in the community supplied by the water. With a pure water supply the typhoid death rate is low; with a contaminated supply it is high. European cities have low rates because care is given to the purity of water. American cities have high rates because the supply is distributed without purification. Dr. THOMAS B. CARPENTER gives an excellent discussion of methods of bacteriologic purification. All the evidence is in favor of the efficiency of natural sand filtration. Bacteriologic data are not available to determine with precision the efficiency of mechanical filtration, with or without coagulants such as alum or iron; but the typhoid rate of cities supplied by these filters is considerably higher than that of communities having efficient natural filtration. Chemic and electrolytic methods have not proved satisfactory. The nitrification of organic matter in polluted water or sewage in its disposal by irrigation or soil filtration, is held by E. K. DUNHAM to be the best method of preventing the fouling of river waters because this is nature's method of operating.

The discussion thus far was mainly of interest to bacteriologists, health officers and sanitary men; but as so many of the auditors were practicing physicians, it was deemed advisable to give some consideration to the management of typhoid fever, the most important of the diseases caused by contaminated water. It was held that the WOODBRIDGE treatment should be accorded further trial; that the depressant action of the coal tar derivatives should be carefully watched; that the diarrhea of typhoid is salutary and should be gently promoted, but that the main dependence must be placed on hygienic conditions, milk diet and care-

ful nursing. The BRAND treatment, immersion in cool water with active friction of the surface, repeated every three hours so long as the temperature is above 102.5 Fahr. and with the free use of water internally was strongly advocated. The discussion closed with an article on disinfection in the individual case—the disinfection and disposal of the intestinal discharges, urine and bath waters, the disinfection of the bed pan, the thermometer, the rectal syringe and tubes, the hands of nurses, attendants and physicians, door knobs that may have been touched with soiled hands, and of course the bed and body linen of the patient.

The subject of contaminated water is one of great and increasing importance in this country, where cities are growing with phenomenal rapidity. The State Board of Health of Massachusetts led off in the effort to protect the purity of public water supplies, and a few other States are following her example. Discussions such as that under consideration can not fail to have a powerful influence for the public good, and Dr. HENRY HUN of Albany, who organized it and all those who contributed to it deserve the highest credit.

PLUMBING SIMPLIFIED.

Modern sanitary plumbing establishes two lines of defence against the intrusion of sewer air into our dwellings: 1. An exterior line consisting of a water trap on the house drain, with a fresh air inlet to the soil pipe on the house side of the trap. 2. An interior line consisting of a water trap beneath each fixture with a vent pipe on the soil-pipe side of each trap. The first prevents the pipes in the interior of the building from being in any way affected by varying air pressure in the sewers and establishes a ventilating current in the soil pipe itself. The second protects the interior from the intrusion of soil-pipe air and insures the traps against siphonage. The plumbing regulations of most of our cities require each trap to have a vent pipe of suitable size at or near the crown of the trap and extended to the roof, or connected with the soil-pipe line above the highest fixture. No sanitary plumber, sanitary engineer, or sanitarian, has questioned the efficiency of a system constructed in accordance with these requirements. On the contrary, the suggestion occasionally made that internal pressure in the sewers might be relieved through the soil pipes, implies that in the opinion of those making the suggestion the water trap in the house drain and the fresh air inlet to the soil pipe are not essential to the protection of the house; but the objection to the general acceptance of this view is that if any one of the house traps should become unsealed, sewer air would be drafted through it by the warmth of the interior instead of passing up into the atmosphere above the roof through the extension of the soil pipe.

And now comes a sanitary engineer of some prominence, Mr. WILLIAM PAUL GERHARD of New York, who while retaining intact the first line of defence considers the interior line to be unnecessarily complicated and expensive. He is led by years of observation to believe that the trap venting law is a mistake which will ultimately be remedied by repeal. He makes use of non-siphoning water sealed traps and in the case of water closets common S traps with such a depth of trap seal as will not be destroyed by the discharge of other fixtures. In a small building having only one or two fixtures on each floor, he leads each waste into the vertical soil pipe by a separate entrance and, when untrammelled by plumbing regulations, does away with the separate vent pipe for each trap, maintaining that the air movement through the soil pipe will prevent siphonage and that the rush of liquid through the short wastes will keep their interior clean notwithstanding the absence of vents or ventilation. In a large building where several water closets, basins and baths are aggregated on each floor he leads each waste by a separate opening into a branch of the soil pipe. This branch does not begin by a dead end at the distal fixture, but by an open end above the roof, whence it descends of full size to its junction with the soil pipe, receiving its separate wastes near this junction. Its free opening above enables it to act as a vent for the traps connected with it, while its communication below with the ventilated soil pipe gives free passage to an air movement through it. It is not to be expected that this air movement will be as free as that through the direct vertical extension of the soil pipe, but the frequency with which the branch is flushed by the use of its fixtures keeps it practically clean.

There is no question that the separate venting of each trap complicates the piping and adds largely to the expense of our present system of plumbing. If Mr. GERHARD'S experience is sustained by further investigation an important modification of the Plumbing Regulations would be warranted. Ten or fifteen years ago every sanitarian would have protested against a proposition to modify them, and even now many who have not given this subject consideration would no doubt promptly vote it down as a backward step in the progress of modern sanitation; but we must remember that the present Regulations with their positive requirement of a vent for every trap were formulated when sewer air was regarded as *sui generis* in its deadly and penetrating qualities, and when it was considered that any deviation from the accepted system might be followed by the most dangerous consequences. In effecting protection at that time it is possible that the pendulum may have swung too far to one side. The knowledge of typhoid fever causation possessed by the profession is better defined now than it was then, so that when a proposition of

this kind comes from an experienced worker and observer in this particular field of sanitation it might be well for municipal authorities to consider the subject with a view to determining whether security with simplification and materially lessened expense might not be attained by a revision of their Plumbing Regulations.

OSTEOPATHY.

The attempts in certain States to legalize the practice of "osteopathy" have attracted the attention of the *Medical Record*, which wonders what this new eccentricity of the West means. It fails to recognize an old exploded quackish system, based on one of the many distorted hypotheses of the reflex origin of the disease, known as "bonesetting." This system, starting from the results of massage, claimed that diseases were the results of irritation about bones, which could be relieved by manipulation. Probably coeval with the evolution of medicine from fetichism, it has always maintained itself among the degenerates who constitute most of the devotees of quackery. In the middle of the 18th century it had such a predominance as, like other forms of quackery, to encounter the satiric pen of HOGARTH. In his "Company of Undertakers" are three prominent quacks, the most recognizable of whom is Madam MAPP, a famous "bonesetter," or "shape mistress" of the third decade of the 18th century. The other two quacks in HOGARTH'S caricature were "drop and pill" WARD (whose remedies gained royal patronage through fees paid the mistresses of GEORGE II.) and "oculist" TAYLOR, who cured all sorts of diseases by operations and manipulations on eyes, after the fashion of the cylinder quackery of today. Both were in great esteem in the society world when its attention was, according to JEFFERSON ("Book about Doctors"), suddenly attracted by a female bonesetter (who, like the "snapping doctors" of early days in Illinois, gloried in enormous feet and hands). "Crazy SALLY of Epsom" was an enormous, fat, ugly, drunken woman, a haunter of fairs, about which she loved to reel screaming and abusive in a state of roaring intoxication. This attractive lady was so much esteemed for skill in her art that the authorities of the watering place at Epsom offered her \$500 yearly to reside there.

"Crazy SALLY" awoke one morning to find herself famous. Patients of rank and wealth flocked in from every quarter. Attracted by her success, an Epsom swain made an offer of marriage to SALLY, which she accepted. Her maiden name of WALLIN (she was the daughter of a Wiltshire "bonesetter" of that name) she exchanged at the altar for that of MAPP. If her marriage were not in all respects fortunate she was not burdened with much of her husband's society. He lived with her only a fortnight, during which he thrashed her soundly thrice and decamped with her

earnings. She found consolation for her wounded affection in the homage of the fashionable world. She became a notoriety of the first water, "a gem of purest ray serene," and every day some interesting tale appeared about her in the London newspapers. The most prominent of these stated that "the cures of the woman bonesetter of Epsom are too many to be enumerated; her bandages are extraordinarily neat and her dexterity in reducing dislocation and setting fractured bones wonderful. She has cured persons who have been twenty years disabled and has given incredible relief in the most difficult cases. The lame come daily to her, and she gets a great deal of money through persons of quality who attended her operations making her presents." How much she paid for this "write up" is not known, but paid "write ups" of quacks were then, as now, essential to "newspaper enterprise."

Mrs. MAPP continued to reside at Epsom, but visited London once a week. Her journeys to and from the metropolis were performed in a chariot drawn by four horses, with servants wearing splendid liveries. She used to put up at the Grecian Coffehouse, where Sir HANS SLOANE (the founder of the British Museum) witnessed her operations, and was so favorably impressed by them that he put under her charge his hysteric niece, who was suffering from a "spinal" affection. On the stage the following ditty was sung, which (like similar performances in the English music halls and French guinguettes) served at once for satire and (paid for) advertisement:

You surgeons of London, who puzzle your pates,
To ride in your coaches and purchase estates,
Give over for shame, for pride has a fall,
And the doctress of Epsom has outdone you all.

What signifies learning or going to school,
When a woman can do, without learning a rule;
What puts you to nonplus and baffles your art,
For pettlecoat practice has now got the start.

In physie, as well as in fashion, we find
The newest has always its run with mankind;
Forgot is the bustle 'bout Taylor and Ward,
And Mapp's all the cry, and her fame's on record.

Dame Nature has given a doctor's degree,
She gets all the patients and pockets the fee,
So if you don't instantly prove her a cheat
She'll loll in her earriage whilst you walk the street.

On one occasion as this lady was proceeding in her carriage and four, dressed in a loosely-fitting chonise, manifesting by her manner that she had partaken somewhat too freely of gin, she found herself in a very trying position. Her fat frame, indecorous dress, intoxication, and dazzling equipage were in the eyes of the mob such sure signs of royalty that she was immediately taken for an unpopular mistress of George II. Soon a crowd gathered around the carriage, and with the proper amount of swearing and yelling, were about to break the windows with stones, when the spirited occupant of the vehicle, rose from her seat and letting down the glasses exclaimed with an imprecation more emphatic than polife, "Don't you know

me? I am Mrs. MAPP the bonesetter." This brief address so tickled the humor of the mob that the lady proceeded on her way amidst deafening acclamations and laughter.

Bonesetting early made its appearance and had its own literature in the New England and Middle States, especially in Connecticut. In 1696 the "library" of a certain "Dr." PORTER of Hartford was advertised for sale. It consisted of a "bone-sett book valued at two shillings." Up until 1890, descendants of this Porter did "bonesetting" in New England and extended their ravages to New York City. Bonesetting skill was hereditary and generally transmitted in the female line. In certain respects the female magnetic physician, so boomed of late by the septuagenarian editor of a Chicago newspaper, is a practitioner of the "boneset" hypothesis, who like her Epsom predecessor of old, owes her fame to the "thrill of the touch of her sex." The bills for legalizing "osteopathy" are attempts to evade medical practice acts under pretense of regulating bonesetting practice. Under these bills, could practice the before-mentioned female "magnetic physician," whose circulars have been excluded from the United States mails on the score of indecency. The Iowa legislature has defeated one of these bills and that of Illinois will doubtless do the same. The *Medical Record* however should not be too severely criticised for its ignorance of "osteopathy" albeit a female "osteopathist" or "bonesetter" in the days of its editor's youth created a great furore in New York City. The *Medical Record's* knowledge of either medical history or medical science is, it must charitably be admitted, an unstable quantity. It revived Alexander II., after his encounter with the nihilist, by the use of "oxygen sulphate." A medical journal capable of such a chemical extravaganza can hardly be taken seriously on any subject.

THE DISPENSARY AND HOSPITAL ABUSE IN NEW YORK CITY.

The dispensary and hospital abuse war has virtually opened. The promise is that of long duration, with much acerbity of feeling and a probable ending in much confused legislation. The seat of war is in the Greater New York. Greater demoralization—to continue the favorite adjective of the Knickerbocker State—likewise prevails. Very unexpectedly, the discovery has been made that human nature is no better there than in the distant territories, for committees have made patent to all that "the dispensaries and hospitals, more particularly the out-patient departments of hospitals, were guilty of gross negligence in discharging the trust committed to their care." Worst of all, there comes likewise the usual unhesitating declaration that the abuses are chargeable wholly to the medical practitioners themselves. "And," says the committee, "the doctors, who really lose heavily by the practice of

treating free persons who are abundantly able to pay, are so eager to get dispensary and hospital appointments, and to establish small dispensaries of their own, that, in the opinion of the committee, they cannot be influenced or restrained except by legislative exactment."

Passing by our Excelsior sister's "faith-cunist" bias toward law-making and hospital Saturdays and Sundays, there is after all a modicum of sense in the clearing-house system for the riddance from overlapping charity. We confess to the suspicion that after all there is no monopoly of pauperism or fraud any more than of intelligence or honesty. The Charity Organization Society may do its work effectually, and the enlarged State Board of Charities much more, but self-examination should not fail to reveal the fact that the sinners are very near to home. Let us concede for the sake of argument that the profession itself, somewhat addicted to signing petitions with a mechanical persistency, is really culpable. Let us not gainsay the fact that there has been an over-preachment of benevolence to every medical student in the land, that there has been much beckoning into the halls of learning, that there has been no lack of gaudy perspectives and that there has been an unstinted flow of gold from the reservoirs of the rich. Let us, however, confront the situation at once by the question, Wherein lies the remedy? Let us leave behind us the topic of pauper-making and with it the hope of relief by special legislation.

New York has adopted a general leveling process and requires of her charlatans a better equipment. Might it not be charged that there has been a mingling of codes without much improvement in morals, and that a free field had been given for a sham battle? Furthermore, might there not be a more thorough probing of our own wounds without considering at all the minor plaints of the discouraged whose purses may or may not have been depleted by reason of the counter-prescribing or the fakir with ingenious devices? In very justice, might we not still further ask, have the hospitals or dispensaries done much more than take what the profession has refused? Again, the individual has from time immemorial resented the demand of "your money or your life."

The profession, along with the multitude, of which of course it is only a puny part, has keenly felt the depression of the financial condition and much envied incomes have been at a discount. But the paucity of fees can hardly be chargeable to the rapacity of institutions. The only allegation can be that there has been a lazy distribution of benefits and a quieting of conscience, after the fashion of the revolving prayers of the Chinese. As an outcome of newspaper exploiting, some one or other "memorial" institution enters merrily upon its duties with a political corporation at its back, or a millionaire far in the van. In

the revolution which settles the ultimate distribution "the outs" become "the ins" and the public contents itself with visiting its wrath upon the ambulance surgeon, as the incarnation of the concentrated brutality of his superiors.

We may speak warmly of the commercialism of the day, which is ever coaxing the roar of traffic into every channel, but at the same time can much be looked for in legislation run mad? Can we yet accept the ultimatum of being split into guilds in preference to submitting with dignity to our own calamities? For the present we may have less to do, but can we be deprived of the satisfaction of more thorough work or more deserved if not achieved success? The poor may have marble hearts, but let us not therefore descend to cataloguing our own attainments in the public prints, or express our surprise that photographs should ever be purloined by reporters. Let us remember that we need not give what can not be sold for the highest price, nor preach that common code that the rich must pay for the poor. Let us recall the long ago when we parted from the clergy that we also shared the vows of poverty, chastity and obedience. Above all, "let us have peace."

CORRESPONDENCE.

Reduced Mortality from Consumption in Massachusetts.

BOSTON, MASS., March 29, 1897.

To the Editor:—In your issue of March 27, just received, I find the following quotation from a paper by Dr. A. Walton, entitled a "White City for Consumptives":

"From conversation with prominent men in Massachusetts, where consumption is rampant, I am led to believe the State of Massachusetts would infinitely prefer to have a consumptive State home somewhere where there was a possibility that at some time there would be an end to the enormous expense incident to carrying on a consumptive home within its own borders, where they now have such an institution, which is merely the last resting-place of the persons who are received there. People do not go there to be cured; they are supported by the State until such time as death ends their sufferings."

The foregoing paragraph contains so many remarkable mis-statements that I am constrained to make the following comments upon it:

When present times are compared with past, consumption is not "rampant" in Massachusetts. As a matter of fact, it is steadily diminishing, the death rate from this cause having fallen off just one-half in fifty years, and if the same rate of decrease continues, we may look for its extinction in the first half of the next century. The death rate from consumption in Massachusetts is no greater than that of Germany, France, Austria or Belgium.

"Massachusetts would infinitely prefer to have a consumptive State home" somewhere else. In reply to this statement, it is only necessary to say that Massachusetts has already indicated her preference by establishing a home within her own borders.

"An end to the enormous expense." Is not the expense of transportation of some thousands of people from New England to New Mexico something of an item?

"The last resting-place of persons who are received there." No persons having been received there, this statement may be discounted.

"People do not go there to be cured." Very true, since no one has ever been there for any purpose except the construction of the hospital.

"They are supported by the State till such time as death ends their sufferings." The writer probably intended this as a prophecy and not as a fact. All honor for good intentions!

The State has indeed established a hospital for consumptives, now in progress of construction on elevated land; a sunny southern slope, 1,200 feet above the sea and about sixty miles from the seacoast. It will be ready for occupancy some time next year, possibly earlier.

With reference to the curability of consumptives by treatment in favorable climates, I have no doubt whatever, but this method does not apply to persons of slender means living at distances of 2,000 miles or more from such regions. Moreover, there is reason to believe that a very considerable proportion of consumptives may be cured, even in unfavorable climates, under proper treatment.

The German government has recently issued a circular in which it commends the establishment of homes for consumptives in the highest terms, stating that by the returning of a small percentage of consumptive wage-earners to their families, nearly two million dollars a year are saved to the government, after deducting the cost of treatment. The circular closes with these words: "If there is any work which is at once a blessing to mankind and also of pecuniary value to the community (*menschenfreundlich und nutzbringend*) it is the establishment of homes for consumptives."

Yours truly, SAMUEL W. ABBOTT, M.D.

"Fish Diet and Leprosy."

NEW YORK, March 29, 1897.

To the Editor:—In your issue of March 27, under heading "Public Health," a paragraph labeled "Fish Diet and Leprosy," you quote from the *London Medical Press*, giving credit to Dr. Hansen of Bergen of some views of my own, which were published originally in the *University Medical Magazine*, January, 1896. The article was translated by Hansen into Norwegian. I sent also a reprint of it to the *Sei-I-Kwai* medical journal, from which Japanese paper the *London Press* quotes. Whether it is originally the *Sei-I-Kwai* which attributes these views to Hansen, I do not know; it is not likely; it may be the *London Medical Press*. At any rate, there is here a slovenliness of medical journalism and literature that is really remarkable. I do not see why these views should seem so very new to most leprologists. I began to expose this theory six years ago. It might be possible, nevertheless, that these views were new to most leprologists, if only the art of printing, electricity, etc., had not been invented some time ago.

Strange to say, Hansen is not one of the advocates of the fish theory, as is shown by the following passage from his book, "Leprosy in its Clinical and Pathological Aspects": "Against Hutchinson's hypothesis there is in the first place the fact that

we have never succeeded in cultivating the bacillus, which, if the bacillus lived as a saprophyte on decaying fish, would be a very simple matter. And there are, secondly, places where the inhabitants certainly and frequently employ decaying fish without the disease appearing. And thirdly, there are many places authoritatively indicated where leprosy is present, and where no fish is eaten."

Very truly yours,

ALBERT S. ASHMEAD, M.D.

Reply to Dr. Anders.

CHICAGO, April 5, 1897.

To the Editor:—In reply to Dr. Anders' inquiry I can say that the First Methodist Episcopal Church of Waukegan, Ill., which has a membership of 300, has used the individual communion cup for four years. It met with general approbation from the beginning, only two or three members refusing to participate. It is a complete success, as the details have been conveniently arranged.

Respectfully,

J. M. G. CARTER, M.D.

NEW INSTRUMENTS.

A MODIFICATION OF BOSWORTH'S NASAL AND AURAL SNARE.

BY P. L. ANDERSON, M.D.
CHICAGO.

Long experience with the various snares on the market has demonstrated that while they all have their individual points of excellence, no one snare combines all of the good qualities without some of the bad ones. The accompanying cuts show by comparison, the simplicity and advantages of the Bosworth snare as modified by the author.

ANDERSON'S MODIFICATION OF BOSWORTH'S SNARE.

Instead of the long wire loop, there is substituted a flexible steel stilette, with one end flattened and having a round eye large enough to receive a double thread of No. 5 piano wire; the other end terminates in a circular hook, the central point of which is in line with the long axis of the stilette. The stilette is inserted into the canula of Bosworth's snare with the eye projecting just beyond the distal end, in position for

BOSWORTH'S SNARE.

threading with the short loop of wire. The other end is hooked around a screw-post set into the upper finger-ring of the sliding handle. This post is provided with a thumb-screw which securely holds in place the hook, allowing the stilette to slide either forward or backward. The advantages of this modification are:

1. The facility for threading the stilette with a short wire loop instead of using the long wire loop and having to pass it through the canula and fasten to the retention pin.

2. The wire loop may be bent to any curve and withdrawn

into the canula so that but about one-half inch of the loop projects, thereby leaving it small and very convenient to introduce into the nose. After it is in the nose, the loop is easily projected farther by the sliding handle, and being of the flexible steel, assumes its original upward, bent position. This allows the operator to introduce the instrument, adjust the loop and complete the snaring by the use of one hand only, which gives the eye a complete view of the entire field of operation and leaves the other hand free to hold the speculum.

3. It is easily taken apart and cleansed after each operation, and is no more expensive than a Bosworth.
84 Dearborn Street.

PUBLIC HEALTH.

The Water Supply at Greater New York.—Among the liberal concessions to the public, may be noted the local Board of Health agitation regarding the water supply of the village of Flushing, Long Island. A communication to the State Board has been forwarded requesting the adoption of a resolution providing for the same protection as is already in effect in the Brooklyn water supply. It is to be hoped that the "Borough" of Brooklyn will balk the efforts of its contractors to become of themselves suddenly rich at the expense of the already overburdened tax-payers. Luxuries are very costly.

Contagion in Public Schools.—The New York Health Board staff of medical inspectors reported as the result of their first day's work: Number of boys examined 2,565, girls 1,690; cases of measles, 3; diphtheria, 14; scarlet fever, 1; mumps 3; eye diseases, 35; parasitic diseases of the head, 55; parasitic diseases of the body, 12; chickenpox, 8; cutaneous diseases, 8. These cases were presented by the teachers of the primary departments as being the most under suspicion, the remainder and the higher grades to be examined are not expected to give near the number just reported. The Board, however, think the result justifies the importance of the system, inasmuch as very many parents studiously avoid calling in a physician at all, rating school advantages above every other consideration.

The Bacteriology of Rinderpest.—This epizootic disease was recognized as early as 1715; it again made its appearance in 1745, and in 1865 there was a tremendous outbreak, which led to the Royal Commission and the stamping-out order of 1866. Since that time only a small outbreak in 1872 has been recorded, and this was stamped out almost immediately. It is, however, stated to be epizootic in Asiatic Russia, in Hindoostan, Persia, China, and even Ceylon, but on this point it is difficult to obtain very accurate information. From the very first the disease was stamped as contagious, and several attempts have been made to trace the fons et origo mali. Murchison maintained that the cattle plague resembled smallpox in all but the cutaneous eruption, but further acquaintance with the disease did not allow of the analogy being carried very far. The disease, however, runs the course of a specific infective fever, the incubation period is short, the symptoms are marked, and the pathological changes are definite.

The contagion was by Burdon Sanderson localized in the blood as well as in the discharges, and in his report to the commissioners appointed to inquire into the origin and nature of the cattle plague, he pointed out that the serum separated from the blood of an animal suffering from this disease contained the contagium which could be transmitted by experimental infection to other animals. Beale described cocci; Sanderson and Smart of Edinburgh, saw them also, and in 1883 Semner brought up the subject again, and described streptococci as the cause of the disease. Whether these cocci are primary or secondary still remains to be seen and proved, but from the whole nature of the disease we should expect to find some "contagium vivum" as its primary cause—a contagium which is

easily carried, which may be inoculated by flies, and which it is very difficult to render inert in the countries in which the disease is enzoötic.—*British Medical Journal*.

Public and Private Filtration of Potable Waters.—Dr. Maxwell Ross, in the *Sanitary Journal*, January, traces the advances made in the last decennium in the above department of sanitary work. It was in 1887 that Piefke, the resident engineer at the Berlin Waterworks, came to the conclusion that the effective barrier to the passage of microörganisms through the sand-filter was the coating of slime which forms on the top. A filter constructed of sterilized sand was found to be absolutely useless. It increased instead of diminishing the number of the organisms. Examination of a section of one of the ordinary working filter-beds showed that nearly five-sixths of all the organisms it had retained were to be found in the surface layer, and that the numbers in successive layers rapidly diminished from above downward. In 1890 Frankel and Piefke, using first a pigment-producing organism, bacillus violaceus, and afterward the organisms of cholera and typhoid, showed that sand-filters, even under the most favorable conditions, did not offer an absolute barrier to their passage, but that the numbers which made their way through depended on the rate of filtration and the formation of the slime coating. A study of the Altona outbreak gave origin to the classical paper by Koch on water-filtration and cholera. During the serious epidemic in Hamburg in 1892, Altona, which took its water from the Elbe, contaminated with the Hamburg sewage, but filtered it before distribution, was practically free from the disease.

"At the water-work of that city, which," says Koch, "is fortunately managed by one of our ablest and most experienced filtration-technicians, the rate of 100 millimeters (per hour) was never exceeded during the cholera epidemic, and it was evidently due to this precaution that Altona suffered in so strikingly slight a degree. According to the information at my disposal regarding the cholera in Altona, there were about 500 cases there, of which, however, at least 400 were found to have been introduced from Hamburg, or to have originated through intercourse with the harbor, or must be regarded as emanating from such cases by direct transmission. Of the remaining 100 cases, which can not be directly or indirectly traced to Hamburg, a certain number will nevertheless have been of the same origin, though it was not possible to prove it. Whether among the remnant of cases left after these deductions, which, as having originated independently of Hamburg, form the Altona epidemic proper, there were a certain number of cases which were due to the imperfect cleansing of the infected Elbe water in the sand-filters, can, I suppose, never be decided. After the investigations of Frankel and Piefke, however, which have shown that, at a filtration rate of 100 millimeters, the cholera bacteria are not completely kept back by sand-filters, I think it very probable. But the number of cholera cases that originated in Altona in this manner can not have been at all considerable, and it will probably not be possible to demand that, in order to prevent such isolated cases with certainty in the future, the sand-filters must be enlarged to two or even three times their present dimensions. All that we yet know of sand-filtration, therefore, compels us to admit that, even under the most favorable circumstances, it can not afford absolute protection against infection, though it does afford a protection with which, considering the practical conditions of life, one may rest content."

That such protection is not absolute was shown by the experience of Altona during the following winter. The epidemic had almost entirely died out in Hamburg when a series of cases occurred in Altona which could in no way be connected with Hamburg. The water was suspected, and an investigation showed that the number of germs in the filtered water, which was examined weekly, had increased rapidly immediately before the fresh outbreak.

"The water coming from each filter-bed was then examined separately, and it was found that the increase came from one of them. When the water was drawn off it was seen that the sand-layer was frozen at the top, and was in consequence unable to retain the bacteria. The filter-bed had been cleaned during the cold weather. Other natural agencies may have a similar effect. One of these may be an excess of vegetable growth in summer. When this happens the working of the

filter is liable to be stopped, and if the consumption of water is at its height, too little time may be given for rest after cleansing, and it is immediately after cleansing before the slime coating has properly formed, that the filter is least able to retain bacteria. In addition to these natural agencies, careless or ignorant manipulation of the filter-beds may also expose the consumer to the risk of infection if it should happen that the organisms of infectious disease are present in the water when the disturbances in the filters are allowed to occur. An example of this is the Paisley typhoid epidemic of 1893. There is no doubt that the water supply was implicated in the spread of the disease. Professor Frankland, it is true, did not find the typhoid germ, but, as he very properly pointed out to the commissioners, the failure to find it did not prove that it was not there. He did find an organism closely allied to it, the bacillus coli communis, which is normally present in the feces of man and the higher animals."

Koch suggests that a daily bacteriologic examination of the filtrate should be made. Except in times of danger this is hardly necessary, but a frequent examination of the effluent from each filter-bed will always be of value, indicating whether the filter is acting properly or not. Lastly, it must never be forgotten that the protection afforded by sand-filtration is relative, not absolute, and it is therefore incumbent on local authorities and water commissioners and companies to select their supplies from sources as pure as possible.

"To the subject of domestic filtration I can only refer very briefly. Where filtration is done on the large scale it should not be required, but as unfiltered water is not unfrequently disturbed, domestic filters have their use. Their name is legion. Practically, only two can be relied on to remove disease germs. These are the Pasteur-Chamberland and the Berkefeld. The former is made of porcelain clay, the latter of a diatomaceous earth. Both yield a sterile water, but after being in use for a time bacteria begin to appear in the filtrate. The filters must then be re-sterilized. This may be done by boiling or by the use of hydrochloric acid, but some care is required with the Berkefeld as it is brittle. The opinions of experts appear on the whole to be less favorable to it than to the Pasteur-Chamberland. Though it yields a more palatable water it becomes non-effective much sooner. Dr. Johnston's experiments in the public health laboratory of the University of Edinburgh showed that, while the Berkefeld allowed bacteria to pass, in periods varying from three to ten days, after continuous use, the Pasteur filter remained sterile for over six weeks. To the use of this latter filter in the French army has been attributed a great decrease in the mortality from typhoid. At Darjeeling its use in a large institution has been followed by the cessation of a prevalent dysentery, and a large installation is now being prepared for the central water supply of the place—that is to say, utilizing this which has hitherto been a laboratory and domestic filter for filtration on the large scale. The experiment will be watched with much interest."

SOCIETY NEWS.

American Climatological Association.—This Association will hold its annual meeting in Washington, D. C., May 4, 5 and 6, 1897. The sessions will be held daily from 10 A.M. until 1 P.M., in the Columbian University Building. The general sessions of the Congress will be from 2 until 5 P.M., and an annual dinner will be held at the Hotel Normandie on the evening of May 4. The following are the officers: President, E. Fletcher Ingals, M.D., Chicago; vice-presidents, S. A. Fisk, M.D., Denver, J. C. Munro, M.D., Boston; secretary and treasurer, Guy Hinsdale, M.D., Philadelphia.

Texas State Medical Association.—The Texas State Medical Association will hold its annual meeting in the city of Paris, Texas, April 27 to 30. Would be pleased to have you contribute a paper to my section, General Medicine. It is our desire to make this the most pleasant, important, as well as profitable meeting in the history of the Association. Will you notify, at once, either Dr. Horatio L. Tate, secretary, Lindale, Texas, or myself, of the title of a paper on some medical subject to be presented by you.

L. ASHTON, M.D.
Chairman Section on General Medicine, Dallas, Texas.

Chicago Medical Society.—The annual meeting of the Chicago Medical Society was held April 5. The election of officers for the ensuing year resulted as follows: President, Dr. Ferdinand Henrotin; first vice-president, Dr. A. D. Bevan; second vice-president, Dr. J. C. Hoag; secretary, Dr. A. R. Edwards; treasurer, Dr. A. R. Reynolds. There was an informal discussion on the outcome of the election and the appointment of a new commissioner of health. It was reported that each of the mayoralty candidates had promised in case of his election to appoint a physician, and no action was taken on the matter. Speeches advocating the passage of the amendment to the medical practice act now before the Legislature were made.

NECROLOGY.

JOHN O. BRONSON, M.D., died March 28 at his home in Rhinebeck, N. Y. He was born in Glastonbury, Conn., Nov. 9, 1827. In 1857 he became professor of anatomy in the New York Medical College (now extinct) from which he was graduated in 1855. During the war he served as a medical director in the departments of the Pacific and of the South, having been commissioned a Surgeon of U. S. Volunteers. He returned to New York, retiring in 1880. He was interested in Florida railroad building and had a country seat in that State. He leaves a widow.

SAMUEL G. ARMOUR, M.D., it has been learned in Brooklyn, died of jungle fever last January in Central Africa, while in the service of the Belgian government. He was graduated at the Long Island College Hospital in 1892, and served as interne for two years. He sailed from New York City for Brussels in February of last year. He landed at Boma, a town at the mouth of Congo River and proceeded overland to Stanley Pool. A part of the mission of his party was to deal with Arab slave hunters. From a letter received about a month before his relatives learned that he was slightly ill. In this he said the command to which he was attached was about to be reinforced by Europeans, after which it would push further into the interior. Dr. Armour had gratified his taste for travel to an unusual extent, having made several trips to Europe, and at the time of the Brazilian revolution having also secured the appointment of surgeon on the dynamite steamer *Nietheroy*, formerly the New Orleans steamer *El Cid*, and refitted in New York City.

GEORGE B. TWITCHELL, M.D., died at his home in Keene, N. H., March 30, aged 77 years. He was a Virginian by birth, an alumnus of the University of Pennsylvania Medical College, class of 1843, and surgeon of the 13th New Hampshire Infantry, discharged March 21, 1863.

JONATHAN STRONG CURTIS, M.D., Dartmouth, 1844, died in Hartford, Conn., March 31, in his 76th year.

HENRY WALDRURG COLEMAN, M.D., College of Physicians and Surgeons, N. Y., died in Trenton, N. J., March 30, 1897.

MISCELLANY.

The Columbus Medical Journal has removed from 150 E. Broad St. to its new quarters, 68 Buttles Ave., Columbus, Ohio.

A Long Honorable Life.—Dr. de Bossy of Havre, who has just died at the age of 103 years, was the *doyen* of French doctors. Up to the end of January he gave consultations and attended patients regularly.

Good Evidence that Strychnin is a Poison.—The supreme court of South Carolina holds, in *State v. Green*, Jan. 6, 1897, that a physician may be permitted to testify that in his opinion, based upon his reading of standard medical works, that strychnin is a deadly poison.

A Good Prescription.—The *New England Medical Monthly* and *The Prescription* have been consolidated and will hereafter be

published as one journal. This consolidation is a wise one, and we doubt not *The Prescription* will be even more agreeable to its progressive readers than in the past and *taken* with avidity. Dr. Wile will continue as editor-in-chief of the joint publication.

College Proceedings.—At the commencement exercises of the medical department of the University of Nashville, held March 23, there were fifty graduates.—The commencement exercises of the Chattanooga Medical College were held March 23; thirty-four students were graduated.—The annual commencement of the Southern Medical College was held March 30.—At the annual commencement of the medical department of the Western University of Pennsylvania, at Pittsburg, there were 105 graduates.—The eighteenth annual commencement of the Central College of Physicians and Surgeons, Indianapolis, was held March 24. There were thirty-four graduates.

Verdict Conclusive.—In *Hedenberg v. Graham*, which was an action brought to recover for professional services as a physician and surgeon, where the defense was neglect of professional duty in the case, the appellate court of Illinois holds, March 8, 1897, that, whether or not, under the evidence, the plaintiff was guilty of neglect of duty, was a question of fact and not one of law, and it being determined in his favor, then the further question of what was the reasonable value of the services rendered by him, became, likewise, one of fact and not of law, and upon both questions it must consider the verdict as conclusive upon it.

Labor for Convicts.—The State Prison Department of New York State "reports the following schedule as being in complete operation. At Auburn, for the manufacture of baskets, cloth, bed-ticking, hollow ware and furniture; at the women's prison, women's underwear and women's clothing; at Clinton, wrappers, tinware, baskets, knit underwear, hosiery, wheelbarrows, shirts, collars and cuffs; at Sing Sing, printing, men's clothing, boots and shoes and office desks; at Auburn a school for instruction in wood carving has also been established." The trades unions, naturally staunch adversaries of competition, procured the introduction of the prohibition clause in the new constitution chiefly on politico-economic theories of what was in reality class legislation. The prisoners themselves now joyfully accept the new conditions as a needed relief from the ennui of solitary monotony and at the least of an imbecility that is inevitable. Dr. Austin Flint, in his address before the New York State Medical Association nearly two years ago, ably advocated the policy now in vogue as benefiting both the State and its criminal wards. "Idleness," said a far-back ancient, "is the devil's workshop."

Bad Indictments.—In the two cases of *State v. Julius A. Pirlet* and *Alexander W. Walter*, respectively, the indictments charged merely that the defendants "did unlawfully practice medicine and surgery, for reward and compensation, against the form of the statute," etc., without setting forth in what the unlawfulness consisted. These indictments, the supreme court of Rhode Island holds bad, and orders quashed, Jan. 22, 1897. In explanation, it says that the rules of criminal pleading require that the offense shall be charged specifically; first, in order that the accused may know precisely what he is to defend, and secondly, that the record of his acquittal or conviction may be a bar to a subsequent prosecution for the same offence.

An Eclectic Pest in England.—The quack, John Ferdinand, was tried before a London court December 17, on the charge of having committed perjury at the coroner's inquest on the death of a woman named Sophia Holliday. The evidence of the prosecution showed that Ferdinand had been a most dangerous pest to society for a long period. Twenty-six years ago he had been convicted of stealing bread, at which time he seems

to have been a plumber and glazier in Somersetshire. He had since carried on business as a quack in Stockton-on-Tees, Manchester, Birmingham, Cheltenham and Swindon, and had advertised himself largely as the possessor of a certain method of curing cancer. He claimed to be a Doctor of Medicine of the United States of America and to have a diploma from an eclectic medical school in Pennsylvania. Doubt was thrown upon the truth of these claims, though from all that we can see they might have been admitted without bettering his case. There is, we need hardly say, no such degree as "M. D., U. S. A.," although certain of these eclectic institutions have long been known to be shops for the sale of licenses to practice gross quackery. Ferdinand was sentenced to twelve months hard labor for perjury, in Mr. Braxton Hick's court, and no one can consider the sentence a heavy one. This fellow has lived for years on the credulity of the sick, has buoyed up miserable men and women with false hopes, has cozened them out of the money that might have been spent in alleviating their misery, and, lastly, in many a case by his pretensions of ability to cure, has prevented them from seeking medical assistance until too late. What is this last crime but manslaughter?—London *Lancet*, December 26.

Porro's Operation Under Difficulties.—Six village midwives struggled to relieve a primipara of a child in pelvic presentation with such force that the body of the child was torn from its head, which remained in the uterus with the placenta. The woman was brought to the hospital the seventh day, with severe hemorrhage and an advanced septic endometritis. Lesin performed Porro's operation with success.—*St. Petersb. Med. Woch.*, No. 1, 1897.

Doctors Not Scapegoats for Murderers.—Similar, in effect, to the Iowa decision referred to on page 331 of this volume of the *JOURNAL*, comes one from the supreme court of Alabama, handed down Jan. 27, 1897, in the case of Daughdrill v. State. It says that a defendant can not escape the penalties for an act which in point of fact produces death because death might possibly have been averted by some possible mode of treatment. The true doctrine, it holds, is that where the wound is in itself dangerous to life, mere erroneous treatment of it or of the wounded man suffering from it will afford the defendant no protection against a charge of unlawful homicide. Nor is it necessary to a conviction that the wound should have been "necessarily fatal."

The Pancreas and Other So-called Sweetbreads.—Dr. Parry in *British Medical Journal*, hints at a possible danger to health in the use of thyroid and thymus glands, that may be sold by butchers under the name of sweetbreads. He has made some investigation of the subject and finds that there is a confusion of terms, intentional or otherwise, in the minds of the sellers of meat. He says: In talking to a butcher I was surprised to hear him say that there were three sweetbreads in an animal. I asked him where they were situated and he told me, at the root of the neck, in the cavity of the chest, and in the belly of the animal. I questioned him more closely and discovered that his three sweetbreads corresponded respectively to 1, the thyroid gland; 2, the thymus gland; and 3, the pancreas. To make quite sure that no mistake had been made I watched him, a day or two after, kill and cut up a bullock. The thyroid gland in this animal is situated low down at the root of the neck over the trachea. The thymus (which he told me was bigger in the calf than in the bullock) is placed in a somewhat similar position to where it is in man; while the pancreas (the most important organ) he regarded as the least significant, and told me it was "given in with the liver." He told me, moreover, that if he were asked for calf's sweetbread he would always give (what we call) the thyroid and thymus glands. I have been informed that all butchers do the same thing, though I can not vouch for the accuracy of this statement.

At any rate it seems to me to be right for every physician to be on his guard when ordering "sweetbreads" for his patients that the pancreas be provided and not these other glands. An undercooked calf's thyroid gland being repeatedly given in the place of a real "sweetbread" might, as we know, produce untold mischief in a patient, as well as perplex the mind of the prescribing practitioner in a peculiar and undeserved manner.

Not Evidence of Illness that will Excuse Witness.—An attorney made affidavit that he had had a personal interview with a certain witness, in the presence of her physician, and was informed by her and her physician that the condition of her health was such that it would be impossible for her to attend the trial, and be examined as a witness in open court, without exposing herself to great danger, she being a sufferer from a form of nervous prostration which the excitement of an examination in open court would be certain to aggravate. Upon this affidavit, an order was granted for the examination of the witness before trial. Feb. 12, 1897, the appellate division of the supreme court of New York reversed the order, *Montgomery v. Knickerbacker*, holding that the evidence of the illness of the witness which would prevent her from appearing at the trial was altogether too slight to justify the order.

Inquiry Necessary.—Before a member of a board of governors of an association formed under the provisions of the New Jersey act entitled "An act to provide for the incorporation of associations for the erection and maintenance of hospitals, infirmaries, orphanages, asylums and other charitable institutions," approved March 9, 1877 (Supp. Revision, p. 372), can be removed from his office, the supreme court of New Jersey holds, in *Welch v. Passaic Hospital Association*, Jan. 30, 1897, that there must be an inquiry, and a determination of the neglect of duties imposed upon such member by the constitution and by-laws of such association; and this inquiry and determination can only be made upon notice to him, and an opportunity for him to be heard in his defense. An irregular removal of such member, the court further holds, will warrant the use of the writ of mandamus to restore him to his corporate rights in said board. And the mere fact that a member of such a board, who is a physician, is a member of the medical staff of another hospital, the court apparently does not believe shows a neglect of duty as such board member, or ground for his removal, where neither statute, constitution, nor by-laws renders it inconsistent with his serving in the latter capacity.

Differential Diagnosis of the Cocain Habit.—A medical writer in the European edition of the *New York Herald* has a note on a new diagnostic symptom. The symptomatology of the cocain habit is very similar in its main features to alcoholism and other intoxications; it would even be difficult in the absence of other data to make the differential diagnosis if we did not know the truly characteristic signs, which M. Magnan of Paris, has ascertained. Thus, independently of the marked symptoms of exaltation of the cerebral functions, soon followed by profound depression of the whole system, as is also the case in alcoholism, there occurs a form of hallucination, of general sensation, consisting in the feeling of the existence of foreign bodies beneath the skin. These bodies generally seem to be round in form, similar to grains of sand, and the patient complains of feeling microbes, worms or insects between the skin and flesh. These disagreeable, multiple and movable sense disorders have also been observed by M. Rybakoff of Moscow, who considers them truly characteristic of the chronic use of cocain. On several occasions he diagnosed the cocain habit, which he otherwise would not have suspected, merely by having the patient speak of a sensation of worms beneath the skin, and in each case the hallucination disappeared simply by stopping the cocain habit. Complete and definite suppression of the

alkaloid is naturally the first indication in the treatment of the cocain habit. The disorders that follow the adoption of this radical means, such as loss of appetite, palpitation, insomnia and moral and physical depression, are sufficient to put the patient's will power to a severe test; but they improve little by little, particularly if the physical weakness is treated by tonics, iron, cinchona bark and arsenic. However indispensable it may be to give up the use of cocain, there are nevertheless cases in which half measures are necessary; in other words, in which the dose must be first lessened. This must be done with nervous or weak patients, and with those who have pulmonary or cardiac lesions, with whom absolute suppression may give rise to serious symptoms, such as syncope, collapse or complete loss of control amounting almost to mental disorder.

Washington's Attack of Smallpox. Authentic history records several marvelous instances in which the life of Washington was saved under circumstances seemingly little less than miraculous. One of these wonderful escapes from impending peril occurred during the period of Washington's sole recorded absence from the American continent, when he accompanied his brother Lawrence (then fatally ill with consumption) to the Barbadoes. They sailed in September of 1751, George being then in the twentieth year of his age. Before the brothers had been a fortnight in the island, the younger, the future hero of the Revolution, was attacked with smallpox in its "natural" and virulent form. This disease was not then the fangless monster with which we are familiar, but was terrific in its assaults and almost invariably fatal; yet Washington recovered in something less than three weeks and retained through his life but slight marks of the malady. One of General Washington's biographers well says in reference to this incident in the life of the first president, that, "It may be doubted whether in any of his battles he was in equal danger. If the disease entered an army it was a foe more to be dreaded than embattled hosts. . . . But it belongs to that class of diseases of which, by a mysterious law of our nature, our frames are, generally speaking, susceptible but once. . . . Thus it came to pass that in the morning of his days Washington became (humanly speaking) safe from all future danger from this formidable disease." The reader of our history will remember that the smallpox appeared among the British troops in Boston in the fall of 1775; that it ravaged our army in Canada in the following spring; that it prevailed the same year at Ticonderoga, and in 1777 at Morristown. Regarding this last occasion of its appearance, Washington said, in a letter to Governor Henry, of Virginia, where vaccination was not permitted: "You will pardon my observations on smallpox, because I know it is more destructive to the army than the enemies' sword, and because I shudder whenever I reflect upon the difficulties upon keeping it out." This was the tremendous peril from which Washington was comparatively safe after his twentieth year. "If," says a very eminent writer, "to refer this to an overruling Providence be a superstition, I desire to be accounted superstitious."—*Independent*, February 18.

No Grounds for Damage in Alleged Mental Sufferings.—Before supreme court, appellate division, in New York, the theory held in some States that damages may be awarded for injuries to the emotional nature was negated in the suit of Curtin against a telegraph company, by reason of delay in the delivery of a certain telegram. Justice Barrett, in giving the decision, considered one question only, namely, whether the plaintiff could recover damages for mental distress, causing, as was claimed, physical suffering. This question, the court says, was the crucial one and it must be disposed of adversely to plaintiff, both upon principle and authority. The recent case of Mitchell against the Rochester Railway Company was cited, where the court of appeals held that, although a miscarriage

and consequent illness resulted from fright occasioned by the negligent management of defendant's car and horses, yet the plaintiff could not recover, for the reason that there was no immediate personal injury. "The law looks upon the strict physical injury alone," Justice Barrett says, "and the proximate consequences of the negligent act; not upon the secondary ailment resulting from the primary mental suffering. An injury to the feelings, independently, alone, is something too vague to enter into the domain of pecuniary damages; too illusive to be left, in assessing compensation therefor, to the discretion of a jury. The extent and intensity of such injuries depend largely upon individual temperament and physical, mental and nervous conditions. These conditions are shadowy, unequal and uncertain in the extreme. When they exist in connection with physical injury, they can be examined and tested. Existing alone and independently, they are easily simulated and the simulation is hard to detect. There is, in fact, no genuine congruity between pecuniary loss and isolated mental pain. And if there were, there is no certain means whereby such mental pain can be fairly and accurately compensated."

A Method of Untying the Knots of Silk Ligatures.—At a recent meeting of the New York Obstetrical Society, Grad (*American Gynecological and Obstetrical Journal*, February, 1897, p. 105) described an ingenious method of untying the knots of silk ligatures, especially after hysterectomy. For this purpose a ligature proper is required with one end knotted for ready identification, together with a number of so-called traction-strings. The latter are made of pieces of braided silk, preferably No. 13, about twenty inches long, the two ends of which are tied together. These are designated 1, 2, 3, etc., and are distinguished by a corresponding number of knots. Thus when the operator is ready to fasten his ligature, he slips over the knotted end, let us say, traction-string No. 3, and ties over this with the ligature a single or double knot as he prefers. Then traction-string No. 2 is slipped over the knotted end of the ligature and a second knot is tied. For additional security a third knot may be tied in the ligature, traction-string No. 1 being first slipped over the knotted end of the ligature. The knotted end of the ligature is now cut short and the three traction-strings, with the remaining long end of the ligature, are tied together with a piece of fine silk. At the completion of the operation the separate bundles of traction-strings and ligatures are brought down into the vagina and they serve to facilitate drainage. The same process is repeated in turn with each ligature. If the traction-strings have been properly applied, their subsequent removal and that of the ligature can be easily effected. The patient is placed in the lithotomy position, the bundles of traction-strings and ligatures are pulled out of the vagina, each bundle is separated from its fellows and the thread binding the selected bundle is cut, thus releasing the traction-strings and the long end of the ligature. Traction-string No. 1 is now picked up, and slow but steady traction is made on one-half of it until it is felt to move out of its position. After making this forward and backward motion two or three times the traction-string suddenly comes away and the first knot (the last one tied) is untied. The same maneuvers are repeated with the other traction-strings. All the knots are now untied and the ligature alone remains. A slight pull will suffice for the removal of this. Each bundle of ligatures and traction-strings is treated in the same way until all are removed. An aseptic douche follows, and the patient is returned to her original position in bed without having suffered material discomfort.

A Great Scottish Scholar.—The *Lancet* points out with regret how a great British scholar has had his memory slighted, remarking that since Dr. Milligan has been in his grave a half-century, his countrymen are better able to take the measure of his scholarly attainments. He it was who re-discovered

Celsus, "the Roman Hippocrates," but we hunt in vain for his name in the important Dictionary of National Biography; and the same may be said of certain other encyclopedic works of reference that have been consulted. It should not be overlooked, however, that di Renzi, the medical historian of Italy, has given to Dr. Milligan, in his *Bibliographia Celsiana*, an adequate and admiring credit for his rehabilitation of Celsus. We should remember also that Daremberg, the ablest of French historians of medicine, to whom the text and interpretation of Celsus owe so much, makes honorable mention of Milligan's labors; nor do we forget that, in such standard works as Riddle and White's Latin Lexicon, Milligan's edition is the only one referred to. It is, indeed, the single serious attempt yet made by British scholarship to edit the Roman Hippocrates with due regard for purity of text and sufficiency of explanatory comment, and its merits are not passed over in the great *Biographisches Lexikon der Hervorragenden Aerzte aller Zeiten und Voelker*, which was published recently at Vienna and Leipsig. To that treasure house we go for further information as to Edward Milligan, and we learn that he was born in 1784 in Dumfriesshire, that he was destined apparently to the humble lot of a bootmaker, but that he educated himself *zu einem ausgezeichneten Gelehrten* (to be a distinguished scholar) at Edinburgh, where, turning to medicine, he graduated as doctor in 1815, and besides his three editions of Celsus (1826, 1831 and 1839), edited with Latin text and English translation Cullen's "Nosologia," wrote on "The Doses of the Ancient Physicians," and on "The Theory of the Frontal Sinus," and was for years conjoint editor of the *Edinburgh Journal of Medical Science*. He died in London about half a century ago, leaving a record as medical teacher and scholar eminently worthy of notice in his country's "Dictionary of National Biography," and surely deserving of something better at the hands of his compatriots than to be relegated to the pages of a German encyclopedia for a brief acknowledgment of his meritorious life-work.

Liquid Air.—The *Monthly Weather Review* for January, 1897, invites attention to a lecture on "liquid air" delivered January 6, by Dr. Karl Linde of Munich, before the Berlin Society of Engineers. From the report of this lecture we summarize as follows: At certain pressures every gas has certain critical temperatures at which it begins to become fluid. For atmospheric air under a pressure of 39 atmospheres the critical temperature is -140 degrees C; at ordinary pressure or a pressure of one atmosphere -191 degrees C. The question is how to produce this low temperature. One way is first to prepare liquid carbonic acid and by the cold of the evaporation of this substance (-50 degrees C.) to prepare acetylene or some other liquid gas whose boiling point is considerably lower than that of the liquid carbonic acid. This method has now been abandoned as too laborious and expensive. A simpler method is by the compression of the gas and its expansion after cooling. When a gas is compressed it becomes warm; when released so that it occupies its original space there occurs a cooling back to its original temperature. If, however, the heated gas be cooled off while it is still compressed and then allowed to expand there will result a cooling to some point below the original temperature, and this temperature will, in fact, be lower in proportion to the cooling of the compressed gas. An ingenious apparatus has been contrived by which the cooling of the condensed gas is effected by means of its own cooling by expansion. A small metal tube is placed within a larger one, and the compressed gas is forced into the small tube. A throttle valve on the end of the small tube allows a diminution of pressure and at the same time the conduction of a part of the expanded and cooled gas backward through the larger tube. The direction of the flow of the gas through the large tube is therefore opposite to that in the small tube, so that the cooling takes place in the most perfect manner. By the repetition of this process the second diminution of pressure brings the gas down to the ordinary atmospheric pressure and by a second application of the cooling flow in the opposite direction extraordinary

low temperatures are attained and the air itself may be liquefied. Since the liquid air thus obtained will not remain liquid under ordinary conditions but will very rapidly evaporate, it is collected and preserved in glass flasks having double walls. The space between the two walls is exhausted of air but contains a few drops of quicksilver. The mercury evaporates into the vacuous space and forms a mirror by condensation on the cold inner glass wall. This mirror hinders the radiation of heat while the vacuum hinders the conduction of heat. In this way scarcely a thirtieth part of the heat enters the liquid that would under ordinary circumstances penetrate into the interior of the flask. Air is a mixture of nitrogen and oxygen and as nitrogen requires a temperature for its liquefaction lower than that at which oxygen is liquefied it is apparent that at first more oxygen than nitrogen passes into the liquid condition. The liquid exhibited to the audience consisted of about one-third nitrogen and two-thirds oxygen. It demonstrated its richness in oxygen visibly by its delicate blue color, for oxygen is blue and nitrogen colorless. The extreme coldness of the liquid was demonstrated by the formation of fog in the neighboring air, as also by the behavior of the liquid when poured into an enameled dish having the temperature of the room. The liquid circled around until the dish was cooled precisely as in the Leidenfrost experiment when water is dropped into a heated platinum dish. Such extraordinary cold produces burns on human skin similar to those produced by great heat. The lecturer closed by referring to the possible industrial application of liquid air or oxygen. In one hour and with the expenditure of one horse-power five cubic meters of air can be liquefied. When we reflect that for industrial applications pure oxygen is not necessary, but that a mixture of oxygen and nitrogen will suffice, we see at once that here there is really much promise for the future.

The Essentials of Hypnosis.—Dr. Liebault, of Nancy, France, who has been conducting hypnotic experiments for two or more years, avers that he has found males far more susceptible to hypnosis than females, in the proportion of three males to two females. Opinions widely differ as to the reason for this. It is generally thought, however, that it is, strangely enough, because the mind of woman lacks the strength of that of man. It is often true that a person of exceedingly nervous temperament, lacking in a measure ability to concentrate thought, is a very poor subject for the hypnotist. This is shown by the fact that it is rarely possible to actually hypnotize a person whose mind is unbalanced. It is possible to hypnotize 95 per cent. of mankind. The remaining 5 per cent. are impervious to the direction of the hypnotist, let him be of as strong mind as he may. All these persons who are susceptible to the influence of hypnosis are not affected to the same degree by any means. The influence of the hypnotist on woman is very different than upon the sterner sex. It is more difficult for a woman to fix her attention upon a given object than for a man to do so. Just why this is, is not known. Dr. Liebault says that "persons who are easily distracted, who from nature or training have not the power of fixing the attention or concentrating thought, and persons in agitation, those who are heavy and dull, idiots whose brains lack the power of understanding what is required of them—these are the least capable of hypnosis. It simply amounts to this. Sense and activity are subtracted from the subject's mind, and in their place is sleep. That is all there is of it. Once the subject accepts the suggestion of the operator it naturally follows that he will accept suggestions other than those which are first given, but it is absolutely impossible to make a person who is hypnotized perform a crime. No person can be hypnotized against his will. I am fully aware that in saying this, particularly the first assertion made, I am contradicting generally accepted beliefs. Yet I do not hesitate to say what I have said is not only true, but that the statement is the result of thorough, extensive and complete investigation and experiment. It is no deduction from theory, but fact, pure fact. The reason why a man can not be induced to commit crime while under the influence of hypnosis is simply because the power of the hypnotist does not extend that far. A person may be made to become thoroughly

insensible to pain, and his mind may be turned in various directions, up to a certain limit, but, that limit reached, then a halt must be called, or rather, the hypnotist finds himself incapable of forcing further action on the part of his subject. Truly he may make the subject think of crime by offering such a suggestion, but he can not force him to commit action of that sort. It is very plain to the hypnotist who has given the subject thought and who has tested his ideas by experiment that hypnosis, as applied to women to relieve them of frightful pain, is of inestimable value. For instance, in the matter of therapeutics it is exceedingly useful. You see for centuries it has been admitted that there was no medicine that equaled sleep. Therefore, the doctor who can place his patient at a critical time under the influence of hypnosis is really giving her an opportunity to find in that blessed oblivion the relief that can be gained in no other manner, except by the use of anodynes. I am sure that there is no woman who would object to being placed under the influence of hypnosis if she understood how beneficial it would be to her under such circumstances. I do not hesitate to make the assertion that hypnotism is of far greater benefit than the ordinary sleep. Neither sleep nor medicine can approach in power the effect of thought reacting by suggestion upon the organism."

New York.

A GROWING NEED.—The New York Infirmary for Women and Children, beginning as a dispensary in 1854, with a hospital added in 1857 and chartered as a Woman's Medical College in 1864, is receiving not a little encouragement in the way of funds for a suitable building. The last annual report shows a total of 752 patients for hospital and 1,319 for home treatment. A contribution of \$10,000 from a lady who does not wish to exploit her name, has brought the fund up to \$69,000. This institution is both ethical and discriminating, inasmuch as all persons applying for free attendance at home are asked if another doctor has been called in; if so, a letter is required from the doctor stating that the family can no longer afford to pay for medical care. But then, charity should not be too punctilious, lest the tramp falter between the fragments of a plate-glass window and the comforts of the workhouse.

SALE OF THE COLORED HOME AND HOSPITAL PROPERTY.—The Colored Home and Hospital Society, organized in 1839, has prepared to move its site to somewhere in the upper section of the island by the sale of its property to the "City and Suburban Homes Company" for \$210,000, which is a more recent philanthropy. The latter was incorporated only last year, and offers to capital a safe 5 per cent. investment, and at the same time supplies to wage-earners improved wholesome homes at current rates. The first undertaking of the company was the purchase of a tract in 68th and 69th Streets, between Amsterdam and West End Avenues, from the Clark estate, upon which it is now constructing a group of model tenements.

ANOTHER NEW HOSPITAL.—The Nassau Hospital Association are preparing to erect a new hospital on a prominent site at the extreme end of the Garden City Company's property, which will cover an acre of ground. The aim is to complete the building during the summer. The location is more exactly described as being west of the Hempstead and Mineola Railway line and on the outskirts of Mineola township.

A LITTLE BETTER.—Governor Black of New York signed on March 30 a bill providing a fee of twenty-five cents from the municipality in which they reside for physicians and midwives reporting births. Clergymen or judges are to receive the same amount for reporting marriages. The reform was undoubtedly suggested by a Massachusetts law, to forestall the objection to the right of any State to demand a service without an equivalent remuneration.

Hospitals.

A NEW BUILDING to replace the present Hospital for Women and Children is to be erected at Central Avenue and Tenth Street, Newark, N. J. It is to be five stories high with two open wards, eighteen private rooms, operating theaters, and as far as practicable the usual modern equipments. The structure is to be of white brick and to be in part ready for occupancy in September.

A FIRE AT A STATE LUNATIC ASYLUM.—The northeast section of the Manhattan State Hospital for the Insane, on Ward's Island, New York city, was burned out early in the evening of March 30. The damage done was to the extent of \$2,000. The 170 male lunatics who were confined in the section escaped without injury and stood with 1,100 other inmates on the broad lawn for over two hours enjoying the work of the island fire brigade and of the city firemen that went to their aid. Efficient use was made of the drill which is gone through with twice daily. The Manhattan Hospital became a State institution on March 1, 1896. Before that it had been called the New York City Hospital for the Insane, part of which was burned down in 1883. The city purchased Ward's Island from the State for \$2,000,000 in 1894 and early in February, 1896, gave the State the free use of the grounds and buildings, without consideration, but with the provision that the State should vacate the premises on fifteen years' notice from the city, the latter to pay for the buildings. Accounts agree in the statement that the mood of the lunatics was that of a subdued jollity, coupled with the dominant delusion that the performance, continuous and spectacular in character, was for their amusement. The estimated loss by this fire is between \$75,000 and \$100,000, but by about August 1 new fire-proof quarters are to be provided. At the present writing arrangements have been made for fifty patients to be sent to the King's Park Department of the Long Island Hospital, a like number to the Central Islip Department of the Manhattan State Hospital, and fifty more to Blackwell's Island.

THE PUBLIC SERVICE.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from March 27 to April 2, 1897.

Capt. Julian M. Cabell, Asst. Surgeon, having been found by an Army retiring board incapacitated for active service on account of disability incident to the Service, is by direction of the President retired from active service this date, March 23, 1897. He will proceed to his home.

Major Louis M. Maus, Surgeon, will be relieved from duty at Ft. Sam Houston, Texas, upon the arrival at that post of Major Augustus A. De Lofre, Surgeon, and ordered to repair to Washington, D. C., and report in person to the Surgeon-General of the Army for temporary duty.

Change of Address.

Burchard, W. M., from Lemon City, Fla., to Uncasville, Conn.; Bunta, F. E., from 380 Pearl Street, to 275 Prospect Street, "The Osborne" Cleveland, Ohio; Bradley, C. M., from Decatur to Sublette, Ill.; Bacon, Jehn, from Philadelphia, to Andalusia, Pa.

Crile, Geo. W., from 380 Pearl Street, to 275 Prospect Street, "The Osborne," Cleveland, Ohio.

Ferguson, H. M., from Chicago, to Washington and Liberty Streets, Morris, Ill.; Frlaby, E. G., from 803 to 734 Sutler Street, San Francisco, Cal.

Hector, W. S., from 3656 to 3673 State Street, Chicago, Ill.; Hanna, E. A., from 1869 Jackson Blvd., to 725 W. 69th Street, Chicago, Ill.; Hanley, A., from Melbourne, Fla., to Fairmount, Ind.

Kerr, Norman, from 111 to 107 Chicago Avenue, Chicago, Ill.

Oyen, A. B., from 807 to 801 N. Rockwell Street, Chicago, Ill.

Smith, J. W., from 2301 to 2313 Washington Avenue, St. Louis, Mo.;

Steele, D. C., from Wahpeton, N. Dakota, to Colcato, Minn.

LETTERS RECEIVED.

Anderson, P. L., Chicago, Ill.; Allan, B. A., Louisville, Ky.; Alma Sanitarium Co., Alma, Mich.; Ayres, S. C., Cincinnati, Ohio.

Backen, H. M., Minneapolis, Minn.; Boehringer, C. F. & Soehne, New York, N. Y.; Brooksher, W. R., Ft. Smith, Ark.; Bean, W. B., Latona, Ark.

Cathcart, Cleland & Co., Indianapolis, Ind.; Chadwick The Company, Chadwick, N. Y.; Cole, G. E., Girard, Kan.; Colorado Sanitarium, Boulder, Colo.

Elliott, A. R., New York, N. Y.; Erwin, C. R., Chicago, Ill. Falconer, R. C., Lexington, Ky.; Ferguson & Goodnow, (3) Chicago, Ill.; Fessenden Mfg Co., The (2) Pittsburg, Pa.

Green, George W., Battle Creek, Mich.; Guthrie, F. A., Alledo, Ill.

Harvey, G. F., The Saratoga Springs, N. Y.; Hudson, S. E., Austin, Texas; Haldenstern, I., New York, N. Y.; Hitz, Henry B., Milwaukee, Wis.; Horton & Wilbur, North Wilkesboro, N. C.

Joseph, S., St. Louis, Mo. Knight, T. Howard, Philadelphia, Pa.

Lord & Thomas, Chicago, Ill.

Murray, J. A., Clearfield, Pa.; Manning, W. B., West Acton, Mass.; McDavitt, Thos., St. Paul, Minn.; Marshall, John S., Elyria, Ohio.

ORIGINAL ARTICLES.

THE USE AND ABUSE OF EXPERT MEDICAL AND SURGICAL TESTIMONY AND SOME RECOMMENDATIONS FOR INCREASING THE VALUE OF SUCH TESTIMONY.

Read at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Sept. 23, 24 and 25, 1896.

BY ROBERT MATHER.

GENERAL ATTORNEY OF THE CHICAGO, ROCK ISLAND AND PACIFIC RAILWAY.
CHICAGO, ILL.

Expert testimony has no logical place in the common law theory of trial by jury. The admission of it, indeed, violates one of the cardinal principles on which the system is founded. The legitimate function of testimony in courts of law is to make known the facts relative to the cause in controversy. Inasmuch as these facts in general rest in the knowledge and recollection of persons, the ordinary medium for the ascertainment of them is the living witness. Owing to the infirmities of human nature, it results that the facts made known in a legal controversy through this medium are often, if not always, uncertain, confusing and contradictory. To deduce from this mass of uncertainty, confusion and contradiction a just conclusion as to the truth of the matter is the proper province of the jury. It is the theory of the law that in the process by which the jury deduce from the mass of facts laid before them the ultimate conclusion of fact which forms the basis of their verdict, both the judge and the witness are rigidly excluded. The judge is confined to the dry domain of the law; the witness to the bare region of fact. Into the bright realm of speculation upon the facts, where are conceived and brought forth those marvelous children of chance known as jury verdicts, neither may enter. The lot of the witness in this respect is even harder than that of the judge. The latter is not confined to telling the jury what he *knows* the law to be; he may, and frequently does, instruct them as to what he *thinks* it to be. But the pent-up witness is limited to the bare recital of what he knows. He may not enliven his wearisome tale by interspersing the facts with his theories; nor may he lighten the arduous labors of the jury by giving them the benefit of his opinion on the facts. Indeed, the rigid and constant effort of the theory of the law of evidence is to prevent any expression of opinion on the part of the witness.

To this general rule, the expert witness is the anomalous exception. Indeed, it is a misnomer even to call him a witness. He may have, and as a rule has, no knowledge of the facts out of which the controversy arose. He is called to tell not what he knows but what he thinks; not to relate facts but to rehearse opinions.

The reason for such a startling departure from the

fundamental rule of evidence which excludes the opinion of a witness, rests on a recognized defect in our jury system. It is admitted, as the basis of this exception to the general rule, that there are certain classes of fact from which the ordinary juror is not so well qualified to draw a just and correct inference as are men who have made such facts, their phenomena and their laws, the subject of special investigation and study. And so, such facts being in evidence, the expert—the man experienced in the science or art to which these facts belong—is called, not to add to the mass of facts involved in the controversy, but to assist the jury in the performance of its legitimate function of deducing inferences from the facts. In other words, the expert witness is not properly a witness at all, but rather an assistant to the jury.

The expert was an early graft on the growth of the law of evidence; and it is an instructive and significant fact that it was in the capacity of an assistant to the court that he first won his anomalous place in our system of jurisprudence. His first appearance was as an adviser of the court or judge in matters of science or learning in which the court admitted its deficiency. In a case decided as early as 1555, it was said by Saunders, J.: "And first I grant, that if matters arise in our law which concern other science or faculties, we commonly apply for the aid of that science or faculty which it concerns. Which is an honorable and commendable thing in our law. For thereby it appears that we do not despise all other sciences but our own, but we approve of them and encourage them as things worthy of commendation. And, therefore, in 7 H. 6 in a case that came before the judges, which was determinable in our law, and also touched upon the civil law, they were well content to hear Huls, who was a bachelor of both laws, argue and discourse upon logic and upon the difference between *compulsione previsa et causativa*, as men that were not above being instructed and made wiser by him. And in an appeal of mayhem the judges of our law have used to be informed by surgeons whether it be a mayhem or not, because their knowledge and skill can best discern it." (Buckley v. Rice Thomas, 1 Plowd. 122.)

How much the science of medicine and surgery owes to this complacent approval and encouragement of it, as a "thing worthy of commendation," by this ancient spokesman of the law, is not for a lawyer, speaking to physicians and surgeons, to say. We of both professions are more interested to note that, when the law first pressed the physician and surgeon into its service as an expert, it was in the capacity of instructor to the court.

The case from which my quotation is taken is both instructive as to the then position of the expert witness in the law, and prophetic of his fall from grace. It was a contested election case. Buckley, a Knight of Anglesea County, in Wales, sued Rice Thomas, sheriff of the county, to recover a penalty for return-

ing one Lewis as the duly elected member of Parliament, whereas Buckley claimed the election. Buckley's lawyer alleged in his declaration that although (*licet*) he was elected, nevertheless the defendant did not return him, but Lewis, as the chosen Knight. The sheriff's lawyer, with scholastic acuteness, demurred on the ground that this allegation did not amount to a positive affirmation that Buckley *was* elected. The discussion of this important issue was opened by Staunford, Puisne Justice, thus learnedly:

"Then it is to be seen how the plaintiff has here alleged that he was chosen a Knight to come to Parliament. And it seems to me that he has not alleged it by a full affirmation. And thereupon the meaning of this word (*licet*) ought to be weighed and discussed. And in order to understand it truly, being a Latin word, we ought to follow the steps of our predecessors, judges of the law, who, when they were in doubt about the meaning of any Latin words, enquired how those that were skilled in the study thereof took them, and pursued their construction. . . . So in 9 H. 7, it appears that one was bound in an obligation upon this condition, that if he paid £5 of fine gold, that then etc., and the obligation was *puri auri*, and there the judges were in doubt what was Latin for *fine* gold, and (as it appears by the book) the masters of grammar were put to give their opinion what was Latin for *fine*, and they could not tell. So that our predecessors have always consulted about the meaning of Latin words with grammarians and others that best understood them, and such sense as the grammar warrants and allows they have admitted; wherefore I apprehend that the grammar is the most proper judge of the meaning of this word, *licet* being a Latin word."

Whether recourse was had, in this case, to the grammars, rather than to the grammarians, as in the case cited from the time of Henry VII., because of the unsoundness of the latter experts on the gold question, does not appear; but it is certain that the result of calling the grammars as expert witnesses foreshadowed the modern decadence of expert testimony. The grammars called upon seem, like the modern experts, to have taken sides and swore point-blank against each other, so that when their testimony was duly considered, the judges were unable to agree. The plaintiff's grammar, however, prevailed over that relied upon by defendant; the majority of the court were convinced that *licet* could, and did, introduce a full and precise affirmation, and the plaintiff was successful in his suit. Posterity would doubtless reverse that judgment if the record were thus open to review, not on the ground that the court misconstrued the Latin word, but because civilized sentiment would deny that the plaintiff had suffered damage by the sheriff's false return. For the parliament to which the litigious knight was elected, but in which he was saved the odium of sitting, was the execrated body that revived the barbarous statutes of Henry IV. for the punishment of heretics; and while the sapient judges of the law were maundering at Westminster over the meaning of *licet*, the recalcitrant Protestants were burning at Smithfield. The man who was prevented from sharing in that infamy ought not to be heard to complain.

The disgraceful disagreement of the grammars in Buckley's case, I have said, foreshadowed the decline of the expert witness both in usefulness and in the public estimation. It was, however, an early, though a sure antetype, and for more than two centuries after

that case was decided the expert maintained his honorable and trusted position as *amicus curiæ*. A case decided in 1782 is the first, so far as I know, to reveal him in his well-known modern character of the retained advocate of a party. In that case Lord Mansfield granted a new trial on the ground that the witness had been surprised on the trial by the testimony of an expert called by his adversary on a question of science involved in the cause. It was held that he was entitled to pit his expert against that of his opponent, his Lordship saying: "In matters of science, the reasonings of men of science can only be answered by men of science." (*Folkes v. Chadd*, 3 Doug., 157.)

This was the first step in the downward path of the expert. The right, thus established, on the part of the suitor to call his own expert to help prove his case was eagerly embraced and promptly abused. The expert was soon no longer consulted by the court or called to aid the jury, but was retained on one side or the other of a controversy, in the expectation, which was seldom disappointed, that his testimony, like that of other witnesses called on the same side, would help that side to prevail. The skill, the wisdom and the reputation of science were employed through the medium of the expert, not to work justice, but to win cases. The high place that was set apart, by a modification of the true genius and theory of our system of evidence for an expert adviser and assistant of the court and jury, was filled by the paid partisans of litigants. And thus the humility of the law, which was willing to be instructed and aided by its sister sciences, in its efforts for the attainment of equal and exact justice, has been cheated of its hope.

I do not mean to say that science and its devotees are alone responsible for this departure by the expert from the high path of usefulness and honor which the original conception of his functions opened up before him. I think it more than probable that he was seduced from that path by the allurements of the advocate of the law, though it must be admitted that the retainer which now always accompanies the employment of the expert witness, has been both the price of his honor and the cause, in part at least, of his downfall. When the practice of paying fancy retainers to scientific witnesses first came in vogue I do not know, but I doubt if the grammarians, the doctors of the civil law, the physicians and engineers called upon to advise the court and assist the jury in matters relating to their respective sciences, from the troublesome times of Philip and Mary to the golden age of the English common law when a Mansfield sat in judgment, took pay for their opinions from either side of the controversy in which they testified. The modern plan of paying such retainers still has its bitter opponents. (See article on "Expert Testimony," 138 *N. Am. Review*, 605.) The force of the proposition must be admitted that a witness should not be compelled to devote to the public good the special knowledge and skill which he has only been able to acquire by special study and investigation, without receiving special compensation therefor. This much might be conceded and there would still be room in the argument for the proposition that the witness who parts with his knowledge only for such a consideration, is hardly entitled to be called *amicus curiæ*.

The real evil, however, is not in the fact that the expert is paid a special retainer, but that the retainer is paid by the party who calls him to testify. The

influence of this fact reaches in two directions; it corrupts the witness and it weakens the weight of his testimony with the jury. I make no apology for the statement, in the presence of men who are constantly called as expert witnesses, that the practice of paying such witnesses retainers on one side or the other of a legal controversy, corrupts the witness. No charge of moral turpitude is intended by the assertion. It is no doubt natural that a witness thus retained, knowing the result which the party who retains him hopes for in the verdict of the jury, should begin his investigation into the facts of the case with a lively hope that they might justify inferences tending to produce that result; that he should seize eagerly upon the facts that have such a tendency, and look coldly and with critical eye upon those that point another way; and that he should finally reach a conclusion in harmony with the spirit that has controlled his investigation and in consonance with his client's desires. The influence of the retainer upon both process and result, in such a case, is more insidious than open. The most mentally honest may not even be sensible of its operation, nevertheless it is there, working out its result with more or less directness and certainty.

In no class of cases is this influence unfelt. I venture to say in this presence that the discriminating railway lawyer frequently has occasion to doubt the entire fairness of the report and prognosis of the surgeon of his road in cases involving what may be called concealed injuries. The interest of the surgeon in his employer's affairs, his natural desire to save that employer from heavy loss, a pardonable pride to justify his selection as its medical adviser, trace their origin directly to the retainer or salary that secures his services. These sympathies, together with the conviction that long experience in the similar cases of his client has forced upon him that many of such claims are wholly feigned or largely exaggerated, have all, consciously or not, entered into the process that has led him to the opinion given to the legal adviser of the company. He may be, and undoubtedly is, mentally and morally honest in his conclusions, but to the extent to which his view has been perverted and his judgment affected by these considerations, he has been corrupted by them. The situation would not be so bad if the corrupting influence of the retainer were always of the unconscious character which I have described. Unfortunately, it must be admitted that the retainer is often both given and accepted in the literal sense of the term, as a sum paid to retain the knowledge, skill and reputation of the so-called witness in the sole interest of the party who pays the fee. In such a case the influence of the retainer is direct, open and convincing. The effort of the expert thus retained, is not to lead the jury by correct and impartial deductions from the facts in evidence to a just conclusion as between the contending claims, but to develop, fortify, present and defend a theory, which, if accepted by the jury, will win his client's cause. I think I have not been unduly harsh in stigmatizing such a sale of professional standing, learning and skill as corruption; a better term would be prostitution.

A second effect of the practice of retaining experts as witnesses is to minimize and degrade the value of their testimony. A prime requisite to the credibility of testimony is that it should be disinterested and impartial. The witness to the ordinary facts of a legal controversy, though called by and friendly to one of the parties as against the other, must, if he would

have his testimony weigh with the jury, relate his facts with absolute and apparent impartiality. The least inclination on his part to color his narrative for the benefit of the party producing him, discredits him as a witness and casts a cloud upon his testimony. What, then, must be the position of the expert, who it is known in advance has been *hired* to testify in favor of the party calling him, and whose sole effort on the stand is to demonstrate that the laborer is worthy of his hire? I could weary your patience with extracts from judicial opinions which describe in more or less forcible and picturesque terms, the degraded position of the expert before the courts and the slight esteem in which his testimony is held. Your own experience, no doubt, makes such a recital unnecessary. One writer, speaking of the fee system, has said:

"Hence it is that, apart from the partisan temper more or less common to experts, their utterances, now that they have as a class become the retained agents of the parties, have lost all judicial authority, and are entitled only to the weight which a sound and cautious criticism would award to the testimony itself."—Isaac T. Woodson in *III Kentucky Law Reporter*, 477.

The method provided by the machinery of the courts for testing the worth of the expert's testimony by "a sound and cautious criticism," deserves a passing notice. The reason for calling the expert as a witness must be borne in mind:

"It is not because a man has a reputation for sagacity, and judgment, and power of reasoning, that his opinion is admissible; if so, such men might be called in all cases to advise the jury, and it would change the mode of trial. But it is because a man's professional pursuits, his peculiar skill and knowledge in some department of science, not common to men in general, enable him to draw an inference, where men of common experience, after all the facts proved, would be left in doubt."—Shaw, C. J., in *New England Co. v. Lovell*, 7 Cush., 319.

The man thus qualified to draw an inference which the jury must deduce before they can reach a verdict but which, owing to their want of knowledge and skill in that branch of science, they are unable to draw, is called before them to tell them what the proper inference is. He gives his opinion and his reasons for it. An advocate, more or less learned in the law, and superficially prepared for the purpose with the assistance of the opposing expert, puts the witness through a cross-examination, the object of which is not to learn the truth, but to demonstrate that his opinion is wrong, his reasons unsound, and the witness himself either ignorant, dishonest or ridiculous. The expert on the other side is then called and gives a contrary opinion, with grave and weighty reasons in support of it. The opposing lawyer then tries by cross-examination to show that this witness is as ridiculous, dishonest, ignorant and unsound as his own expert. The whole matter is then referred to the jury, who were admittedly, at the outset, incapable of drawing a correct inference, but who, edified and instructed by the dignified performance that has taken place before them, are now expected to give to the conflicting theories of the experts "the weight which a sound and cautious criticism would award" to them. The wisdom of such a final reference must be apparent; the capacity of the ordinary jury for "sound and cautious criticism" in matters of science needs no eulogy here.

This evil, however, if it be an evil, can hardly be

remedied until we shall change materially our method of determining questions of fact. The really vital abuse of expert testimony, and the one which is susceptible of speedy correction, is the practice of retaining the expert as a partisan advocate. Indeed, I am inclined to think that the correction of this evil will tend largely to the lessening, if it does not accomplish the abrogation, of the other. I believe, in my optimistic ignorance, that when experts shall resume their true relation to the court and jury, as advisers and assistants, there will be fewer disagreements among them than under the present system, and that such as shall occur, being honest differences of opinion, uncreated and uninfluenced by interest or partisan zeal, will be more readily and more decently reconciled. None would more quickly recognize or more readily bow to this changed condition of affairs than the members of the bar. There is no occupation that is less fruitful of results to the client or of reputation to the lawyer, than the cross-examination of an honest, intelligent and impartial witness. It is only against the ignorant, the prejudiced or the corrupt, that cross-examination is a fatal, or even an effective, weapon. And when science occupies, in the presence of its experts, the position of an honest, wise and disinterested adviser of the court and jury, the efforts to discredit both its processes, its conclusions and its representatives, to which the legal profession is now driven perforce, will, by losing their efficacy, lose their place in our trials.

The remedy for the apparent abuses of expert testimony lies in the designation by the court in each case of the experts who shall be called to testify. There is no novelty in this suggestion; it has been frequently and ably urged and, I believe, already commends itself to the honest judgment of both our professions. It will be observed, however, that I have used the term "designation" rather than "selection" by the court. If we always and everywhere had a judiciary that was able, impartial and strictly just, from which prejudice, partisanship and demagoguery were absolutely removed, I should favor the sole selection of experts by the judges. But even my limited experience and observation make it safe to say, without injustice to the judiciary here or elsewhere, that there are tribunals in which both the parties and the blind goddess herself would prefer that the experts whose opinions are to guide the jury to a correct conclusion, should be selected by the litigants. The parties, therefore, should be given an opportunity to agree, the court to make the selection in case of disagreement. But whether agreed upon by the parties or selected by the judge, the experts should receive their appointment from the court. They should be officers of the court, sworn and acting as its commissioners for the better ascertainment of the truth.

This plan would remove the root of existing evils, the retainer system. The cause of the discredit in which expert testimony is now held being thus removed, the effect would disappear. The expert would be restored to his ancient and legitimate function of adviser to the court and jury, and, in this character, would win back his place in the confidence of the courts and the community. The use of science in the courts would be consecrated to the task of solving, instead of obscuring and confusing, those difficult questions which the law, without the aid of science, admits its incapacity properly to solve. More than this, the plan would insure the selection of actual *experts*. The medical

profession, especially, knows how little this term means in our courts. As the law now stands, the preliminary examination into the qualifications of medical men who are presented as expert witnesses is mere mummerly, meaning nothing. With but very slight reservation the statement may be made that any one who practices medicine, no matter of what school, or with what little pretension to preparation, scholarship or experience may be permitted to swear to his opinion of the cause, course and probable duration and effect of the most hidden injury or the most mysterious malady. The veteran practitioner and the novice; the disciple of approved schools and the herald of a new propaganda; the profound scholar and the sciolist, all are presented to the jury with the equal sanction of the law, under the comprehensive description of "experts." Under this common guise trickery poses as skill, and assurance as wisdom. Those are the most efficient experts who can most plausibly present and most boldly defend the theory required by the exigencies of the side on which they are retained. This faculty is not a necessary accompaniment of professional learning, skill and reputation, and is not seldom found, in most effective degree, among that class of whom it has been said that their "confidence, in many cases, bears a direct similitude and ratio to their ignorance." The appointment of expert witnesses by the court would exclude this class of men and would insure the calling of experts who are not only impartial and disinterested, but who are best qualified to express an opinion on the case before the court. The parties, knowing that neither could make use of a partisan witness, would both be interested in having the witness whom the court should call chosen from those most competent to form an opinion on the particular case. The learned would not be called upon to pit their opinion against that of the ignorant, nor the honest against the unscrupulous. Character, rather than acuteness, would count in the choice of experts; learning and skill would take precedence of glibness and pretension. Thus science would be represented in the courts by its nobler disciples, and, while justice would be better served, science would gain in reputation.

Of course practical difficulties present themselves, as they do in the path of every advance. What shall be done with the practitioner who has attended a case from its inception to the time it has become the basis of a suit, and on to the time of trial? He is clearly a competent witness to detail the facts as to his patient's condition. Shall he be confined to a recital of these facts? Or shall he be permitted, though not a court expert, to express his opinion on those questions as to which expert testimony is admissible? Assuming him to be the equal of the official experts in learning and skill, he would seem, from his long and intimate acquaintance with the case, better qualified than they to form an opinion on these questions. Yet he comes in the character of the partisan and has the taint of the retainer about him. Professional pride, as well as personal pride of opinion, sway him irresistibly to the defense of the diagnosis on which his treatment of the case has proceeded, especially if that view of the case should be questioned or assailed by the experts. But, while there is danger in the admission of his testimony as an expert, there seems to be injustice in the exclusion of it; and the better judgment, I am satisfied, would admit it, trusting that his prejudice or ignorance, if his testimony should reveal either, would

find their foil in the wisdom and disinterestedness of the experts of the court.

A minor difficulty might be met in disposing of the question of compensation for the experts. Such is my opinion of the value of professional services, being a professional man myself, that I concede the right of an expert to a reasonable, and even a liberal fee. Nor would I keep the word of promise to the ear and break it to the hope by leaving him, for the payment of his fee, to the hazard of the collection of a bill of costs. The payment of his fee should be required of the party demanding the appointment of experts, and as a condition precedent to the appointment.

A more serious difficulty would be encountered in determining in what manner the expert should give his testimony or make his report, and how it should be treated when received. A logical adherence to the theory that the expert is the assistant and adviser of court and jury in matters about which both are ignorant would require that he report his opinion, with his reasons, orally or in writing, and that the jury should accept the opinion as conclusive of the question on which it bears. Of course, where opinions of experts differ, the jury, as in the case of conflicting testimony as to facts, must reconcile them, when possible, and accept that which is most reasonable, where the conflict is irreconcilable. And in this process of reconciling, accepting and rejecting, I suppose that cross-examination must be admitted to play its part, though the moment the official expert submits to cross-examination he loses something of his dignity and independence as an agency and officer of the court. In France, where the plan is in operation of appointing experts as court officials, the court not only selects the experts where the parties can not agree, but determines what questions shall be put to them. American lawyers, I think, would object to that method of procedure here. In Scotland the experts make a written report, upon which they are subject to cross-examination. Such a system might not be wholly unacceptable in our courts. Certain it is, that doubts as to the proper mode of procedure should not long obstruct such a needed reform.

(To be continued.)

PERIODICITY, A PHYSIOLOGIC LAW IN THE MALE SEX AS WELL AS IN THE FEMALE.

BY H. L. GREEN, M.D.

MT. PLEASANT, IOWA.

"The proper study of mankind is man."—Pope.

The importance of a physiologic law of periodicity in the male, granting for the sake of argument such to be the fact, must needs be in its effect upon the human understanding so vast as to be scarcely of comprehension. And in its politico-economic influence of no less importance to the statesman than it is to the physician. Let us look at the scope of its application in figures in order to gain an approximate idea of the vastness of its application and influence. Just when puberty and the first orgasm, accompanied by the elimination of the male fecundating fluid, begins is not fixed at any definite year. Approximately, however, we know this with even more certainty than we do when it ceases.

"That women are menstruant and men pubescent at the year of twice seven is accounted a practical truth," Browne, "Vulgar Errors," Book, iv, chapter xii.

We know its beginning is nearer 15 than 21. It will be of interest to note, as we are endeavoring to obtain some idea of its proportions, how often it will recur in the course of the individual lifetime, in that of all virile average men, in each generation and also its volume, its comparative and its intrinsic value, etc. Supposing that under the assumed physiologic law of periodicity we place it in round numbers at once a month or every thirty days, as we often do with women and for convenience in figuring, although we know it to be considerably oftener than this. Such laws are rather empiric at best. But what are we to consider a natural lifetime. Can we assert with certainty a physiologic law for the duration of life? Here we are again at sea. If there is such a law, where are we to find it? We may take tradition for it, but here we find nothing definite. Taking history we find it in the first place to be fixed at 120 years—Genesis, i, 3, or again at 70, Psalm, xc, 10. Preferring a scientific view of the matter, while wishing to be just to all sources of evidence we will examine the theories of M. Flourens, the distinguished French physiologist and "perpetual secretary of the Paris Academy of Science," deceased 1867, sets the normal period of life at 100 years. The grounds upon which this conclusion rests are based on the fact in natural history that the length of each animal's life is in exact proportion to the period it is in growing. M. Flourens, from his own observations and those of his predecessors, concluded the life in the different species of animals to be *five* times as long as the period of growth. The period at which animals leave off growing, or, to speak more correctly, the precise circumstances which indicates that growth has ceased, M. Flourens ascertained to be, "in the union of the bones to their epiphyses. As long as the bones are not united to their epiphyses the animal grows; as soon as the bones are united to their epiphyses the animal ceases to grow." Now, in man the union of the bones and their epiphyses take place at the age of 20. Consequently M. Flourens preclaims that "the natural duration of human life is five times twenty years, or one century." Applied to domestic animals, M. Flourens' theory has, he tells us, been proved correct. "The union of the bones with the epiphyses," he says, "takes place in the camel at 8 years of age, and he lives 40 years; in the horse at 5 years and he lives 25 years; in the ox at 4 years and he lives 15 to 20; in the dog at 2 years and he lives from 10 to 12 years; in the lion at 4 years and he lives 20." That man does not in these latter days live out his allotted time M. Flourens triumphantly explains in these words: "With our manners, our passions, our torments, man kills himself." Viewed in these modern days sixty-five years would seem a fair guess at the duration of life. In the medical profession the duration of life has been approximately given at sixty years (JOURNAL, Jan. 2, 1897). Let us strike an average on these different estimates—120, 70, 100, 65 and 60 years—we find 83 years to be the period for a lifetime where the uninterrupted course of nature runs her consistent course. Lopping off fifteen years as an equivalent of the period preceding puberty for the time in old age when vitality may be considered to cease, we have left 68 years. This physiologic period is subject to further reduction by war, pestilence, disease, accident and unphysiologic living to about one-half, giving us 34 years as the basis on which to figure virile activity to the individual; and at once a month he will have

in a lifetime 12 times 34, or 408, recurrences of the physiologic sexual cycle.

On the basis of the statistics which show the *pater familias* in the proportion as one to five, or, on that of the voter, which is the same ratio, and taking the earth at 1,500,000,000 inhabitants, we have 300,000,000 cycles recurrent 408 times in a life period (34 years) or 122,400,000,000 to the generation. If a person were able to count at the rate of 200 in a minute and were to work without intermission 12 hours in a day he would take 850,000 days, or 2,328 years and 280 days to count them. Again, taking the volume of these at each individual cycle (*vide infra*) at half an ounce we have 478,125,000 gallons; which to count as before would require 9 years and 25 days. What is the value of this vast amount of fluid in which such latent possibilities lie dormant?

Now what of the intrinsic value? Only one-fifth, that which vitalizes the ovum (*vide supra*) may be considered as having any intrinsic value at all. The balance having no value serves as a wash-house calculation. The intrinsic value of the good fifth, however, transcends all calculation, for it is that of the totality of human life itself above all things else.

"All life is divine and God's way of doing things is the way of continuous progressive change according to certain laws."—Lyman Abbott.

Periodicity in the female claims the dignity of physiologic law. May this claim really, after all, be made with greater justice than for the male? We think not. In the female menstruation regularly recurring and associated with the maturation of a Graafian vesicle and production of an ovum are taken as the evidences.

"With the immediate causes of menstruation we are unacquainted, we express only our ignorance when we assert it to depend upon periodicity; it is evidently connected with the condition of the ovaries and—it is generally supposed—with the periodical discharge of ova from them. The menstrual secretion is the separation of the catamenial discharge from the uterine glands and vessels." (Dunglison.)

Striking at the beginning, the cause of the ovarian activity, as we shall have to make a comparison of it to the testicle, let us note the facts. A definite inherent law of balance and mutual dependence of action in the minute cell elements of the ovaries, the Graafian vesicles, the blood vessels, the blood, the lymphatics and the nerves, exists. This balance is primarily identical with the vital essence or spark and so delicately and accurately fixed that the ovary completes its work at regular intervals, giving rise to its natural product, the ovum. The Graafian vesicle gradually rises in the ovary to its surface, where it ruptures, liberating its perhaps precious contents, the ovum, which is seized by the fimbriated extremity of the Fallopian tube or *morsus diaboli* and conveyed through this tube into the uterus, where it may grow, or wither, as many a flower, and come away with the general flow of the catamenial discharge in from one to seven days. Now we contend that there exists in the testicles this same balance among the minute cell elements of reciprocal action and dependence as we have shown necessarily to be the case in the ovaries or *testes muliebres*.

"If the testis is the male ovary, it will comport itself in all essential respects as an ovary. Semination is a distinct function corresponding to that of ovulation. By minute morphologic studies the con-

viction of the identity of testes and ovaries has been confirmed. Identity of structure carries with it identity of function." (Lewes). Under comparatively similar circumstances it will take a certain length of time for the testicles to produce a given amount of semination, *the work equivalent of the ovaries as represented by the ovum*. "One striking result of modern histology is that germ-cell and sperm-cell, ovum and spermatozoön, are identical, only modifications of one and the same anatomic element and in the earlier phases of their development they are indistinguishable." (Lewes.) The other organs of the body, under the same conditions of activity, produce each a *fixed result*, the brain of speech or thought, the liver of bile, and why should not also the testes? Moreover, taking the *temporary* destination of the testicular seminal product to be the vesiculæ seminales, these being *in this respect* the analogue of the uterus, there must needs be for it a corresponding capacity, we find this in the system of double reservoirs represented by the vesiculæ on the one hand and the epididymis with its annex tubuli on the other. Allowing for the small amount of secretion by the vesicles the main bulk of it remains to be attributed to the testicles working, as already shown, under periodic limitation. It follows therefore that the amount of product by the testicles in the given period of one month, which we have assumed, will require the capacity of these two reservoirs. Hence, if these were entirely drained they would refill in exactly the same period, that is, under absolutely physiologic or normal conditions. That this is so our observations and experience fully convince us, and if it could be carefully noted and recorded, we have no hesitation in asserting our belief that ample statistics would back us up in the truth of it. Statistics are, however, fallacious, and especially hard in these matters to get. Unless it be in the payment of the doctor for his care of genito-urinary diseases, there is no field in practice so given over to the lie as mankind's sexual orgies. But why *two* reservoirs? The first, vesiculæ, supply the earlier and the second the later orgasms of a period one to seven, say five days, of what may be called in the mammalia, the phenomena of heat or rut. This takes place physiologically when the two reservoirs are full. The first one either overflowing or being drained by coitus, or perhaps by masturbation. Coincident with the orgasm the semen flows from the vesiculæ, filling the empty space in front of them, priapism usually being already well advanced. As the orgasm approaches its climax the powerful prostate gland joins in the chase and in harmonious sympathy with "pushing a good thing along," adds its quota of fluid and contracts violently. This latter has the effect of dividing the seminal current. The strong involuntary muscular fibers of the prostate are intimately associated with those of the ductus communis seminalis passing through it and these conjointly acting as a sphincter stop the further flow from the vesiculæ and turn it backward, for future reference; while the forward current, reënforced from the glands of Cowper and of Littré is forced onward in its career of destination or destiny as the case may be, to the germinal spot, the shrine of Hygeia; or to the fate of Cæsar's ambition:

"Swift fly the joys to anxious mortals known,
Swiftest the sweetest, ere yet tasted, gone."

The first (vesiculæ) reservoir is now presumably nearly empty, but may yet, however, be still the

source of supply of one or more orgasms. The period, so to speak, of heat or rut continuing the second reservoir is drawn on to complete the physiologic periodic cycle and drained to the ultimate tubuli seminiferi within the testicles during the remaining days of the rut. The five days' work, product of the testicles during the rutting period is also drained, reducing the time of the periods to nearer the true twenty-eight day mark as we find it in point of fact to be, as with women in their menstruation. After the emptying of the first reservoir there is no difficulty in seeing how the draining of the second reservoir will occupy the remaining days of the cycle, constituted as it is of over 9,670 feet of fine, mostly capillary tubing, in which fluid is of comparatively slow movement. It is made up of the vas deferens, 4 feet; epididymis and globus minor, 40 feet; coni vasculosi, 26 feet, and the tubuli seminiferi, 9,600 feet (3,780 feet, Lauth). A physiologic period of quiet should now ensue and continue until the reservoirs are again filled, when another series of eliminations should take place as before, accompanied by a correlation or concurrence of action between the different parts of the body, both premonitory and concurrent, as observed in the female at menstruation. This law of periodicity in its sociologic issue admits of almost infinite application. It furnishes a criterion where now there is no criterion. There is no page or paragraph in the whole range of medical books which we can cite in the elucidation of any criterion bearing upon this subject, and yet we find man seeking to know what is reasonable and natural in this regard. As many men as might discuss this subject would have as many different opinions concerning it. None would agree for there is no common ground to rest opinion on, all is chaos. False premises, self interest, erroneous notions, misguided experience, solitarism and chance are among the chief factors which determine the drift of this matter. *Sub rosa* indulgences, criminal opportunity and ignorance come in for their share. Indeed, man, as we find him, knows no law save that of the Billy Goat. The law of "know thyself" does not primarily occur to him, and so that gynocracy of advantage enjoyed by women through her knowledge of herself is denied to man. Like the radicle of the mistletoe he avoids the light, becomes a victim of his ignorance and perhaps to crime. He becomes miserable, has fears for the present and the future. He may become superstitious and seek solace in religion only to be disappointed with some such platitude as this: "He truly Lent observes who makes the inward man To fast, as well as make the outward feed on bran."—Howell.

He may then seek some one "who quacks of universal cures." (Hudibras.) Should he seek a physician, what is the latter's criterion for advice? As well might he say a tight rope between two chimneys when wetted will not pull over one of them as to say the seminal emission must not be of frequent recurrence, as is usually done and the patient dismissed with a little vague general talk about it and a placebo prescription. Disappointed again and without a guide he is thrown onto the world's buffoonery to learn. He may marry and the domestic relations suffer. We recall the case of a young man whose wife, seven months *enciente*, gave birth, or aborted. The babe which came, *notens volens*, was small and with umbilical hernia, capable of enduring only about three months. The "husband" said he had held sexual intercourse with his wife every night from the

hymenial to the night of the birth, inclusive. "No organs of the body are so prolific and none so quiescent, *mutatis mutandis*, as the testicles." (Ultzmann.) This latitude, according to Ultzmann and which we know to be true, illustrates *à fortiori* the importance of physiologic periodicity if there be any such a law or anything approaching to it in this our vast sea of trouble. Parents and progeny as well as the commonwealth are mutually interested in such natural physiologic laws as have the least bearing on their welfare. That departure on the part of the parent from the physiologic principles of his being can not fail to have a corresponding effect upon the progeny, and as those suffer so suffers the commonwealth. According as such laws are departed from for any length of time there will be a corresponding defect in the product of the physiologic part, and in the case we are considering, the semen, spermatozoa chiefly. The quality of this may be thus varied considerably. The fertilization by the sperm-cell of the germ-cell in every relation of physiologic law is thus seen to be of fundamental importance. "The phenomena which occur even in the simplest of so-called 'direct' cell-division, are of themselves enough to prove that the process is vital or physiologic." (G. J. Romane's "Darwin and After Darwin," Vol. i, p. 106.) "The form of the embryo varies with the *quality* and the quantity of the sperm." (Haller, Bonnet.) The spermatozoa are potentially of the same nature as the whole body, and hence contain the possibilities of all its organs. Both parents furnish their quota to every part of the offspring. Soon after Leenwenhoeck discovered the spermatozoa the wildest and most preposterous ideas arose regarding them until the facts became known. For instance: "Following Audry, each one was supposed to set out to find the ovary, and to glide into an egg, close the door behind it with its tail and develop itself; if several wished to enter at one time into the same egg, they became angered, fighting together, breaking and luxating their members, which gave rise to monstrosities." (Burdach, "Traité de Physiologie," Vol. ii, 287, Paris, 1838.)

We are familiar with the laws of heredity. We know that there are transmitted from the parents in whatever relation to physiologic law, both their good and their bad qualities; their taints, such as the alcoholic for instance, and their diseases; whence come these unless by the elementary anatomic product of the original prototype? The spermatazoa are the primary motor, and in their mysterious power have the quality of communicating movement long after their original impulse has ceased, "as the twig is bent the tree is inclined." They are the cause primarily of development, and in them are the conditions which determine the subsequent development. "It is not contact alone, but the entrance of the spermatozoon into the ovum which determines fecundation. An exceedingly minute quantity of spermatozoa suffices, but the development takes place much more slowly than when the quantity is abundant, and below a certain minimum the impregnation is only partial, the yolk is imperfectly segmented and in extreme cases the formative principle is so far checked that the child ceases to resemble human beings." (Lewes, Aristotle.) When fertilized as we have seen by the spermatozoa the ovum gives rise to the whole body. By a series of successive differentiations of cells, or power or tendency impressed on cells whereby they grow into different forms, epigenesis, the embryo

arises from a simple homogeneous mass into a complex heterogeneous organism. This unknown power or tendency impressed on cells varies, as we have seen, with the quality and quantity of the primary motor, the spermatozoa, and continues to operate long after its original impulse has ceased; exerting its influence in the formation of all the tissues, histogenesis, in the new being, and even long after the latter's independent life. Continuing in the life of the individual this unknown power or tendency impressed on the cells and later on the tissues, and which science may reasonably seek to know, may have been so checked or diverted as to bring about an imperfect segmentation in the ovum, with what diversity of result no one may presume to say. It would range from slight effect upon the size of the individual, a malformation, a monstrosity, or even idiocy, or any other macroscopic evidences to those involving the microscopic tissues of the circulation, brain, liver, ganglia or any section of the body. The interferences in function corresponding to these defects would likewise be unlimited. To such matters then as these do we find the question of a law of periodicity in the male, in the issues, having logical effect. Surely these are matters of personal and public interest. Modern science has given to microscopic research all germs but the chief of germs, spermatazoa.

How do we know how these would comport themselves in variegated coats of methylene blue and fuchsin red, or Bismarck brown and gentian violet? Much has been learned of other microorganisms by these methods, and why should we not so learn more of these? It is to this radical point of investigation that we must direct our attention for the understanding and alleviation of many of our human ills. How do we know but many defects in spermatozoa may yet be demonstrated under the microscope? Almost insurmountable obstacles seem to stand in the way of this method of research; but less than twenty years ago bacteriology, which now has thousands of volumes written on myriads of all sorts of wonderful cocci, bacilli and spirilla, was scarcely the subject of an hour's study by the average medical man. Until bacteriology was established in its highest sphere of practical utility to man by Robert Koch, that splendid confrère and pioneer in this field of research, its resources were unknown and its obstacles insurmountable. But recent research through exact methods by trained investigators has changed all this, and now bacteriology is one of the first and most essential "stones" laid in the construction of a medical education. Closely allied to this method of study of the spermatozoa is the study in the fertilized ovum of the nucleus formed by the union of the male and female pronuclei, as already pursued. It is but a step from the latter to the former.

"These researches, chiefly due to Fleming, have shown that the nucleus, in very many tissues of higher plants and animals, consists of a capsule containing a plasma of 'achromatin,' *not deeply stained by reagents*, ramifying in which is a reticulum of 'chromatin' consisting of fibers which readily *take a deep stain.*" (Romanes.)

In conclusion, let us add that whatever research may show to be modifications in the qualifying properties of the spermatozoa by reason of departures from physiologic law, it is hardly to be expected these would be altogether heeded, nor would we be able to prescribe one fixed remedy, such for instance as exci-

sion of the vas aberrans. We have heard of a nervous, timid person having pinned to his shirt these words: "My appendix has been cut out," and we would not wish to drive another to the words: "My aberrant oats have been sown." Just here it would seem the finger of medical science may point the way, and the profession constitute itself of right a veritable *corps de garde*.

No man can do the work of humanity; no one man can anticipate the labor of ages. It was by a succession of labors that the works of Harvey, of Jenner, of Pasteur and many others, reached their climax. Gravitation and evolution had to run the gauntlet of "ist" and "ism," but now are undeniable laws. The medical man has now, so to speak, to devote himself to the astronomy of microscopic bodies. When we consider the remarkable phenomena set up by the spermatozoon on entering the ovum, and the ultimate result of its deficiencies to individual and world at large, we can not inquire too closely into the physiologic laws, however remote, which affect them.

Should the physiologic law we are considering land us in an improved condition of sociology somewhere between the perfect ideal organism of Plato, and the best possible under existing conditions, of Aristotle, it would be as much as might now be hoped for along the lines of our argument on its periodicity.

DILATATION OF THE STOMACH.

A Clinical Lecture delivered in Rush Medical College.

BY HENRY M. LYMAN, A.M., M.D.

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE.
CHICAGO, ILL.

I place before you, this morning, a patient whose sallow complexion and expression of distress declare him to be a sufferer from chronic disease. He is about 50 years of age, though his whitened locks and bald crown seem to indicate a greater number of years. He is quite thin; his muscles are flaccid, and readily discernible through the dry and inelastic skin. In the left side of the scrotum hangs a considerable varicocele; the veins of the lower extremities are enlarged and tortuous; he is constipated and has long been a sufferer with internal piles. During the winter he complains of a hacking cough, but his thorax is everywhere extremely resonant; he has a chronic bronchitis with some degree of vesicular emphysema. The heart is not enlarged; there are no valvular murmurs, but the second sound is decidedly accentuated over the right ventricle. The liver is of normal size, though somewhat displaced upward. The spleen is also normal. But the abdomen is decidedly prominent and resonant.

The patient tells us that he has been for many years employed as a mechanic, both in Germany, where he was born, and in this country. His occupation compelled him to stand at a work-bench for many hours each day, with only such intermissions as were required for two or three luncheons, consisting chiefly of bread and beer. About twenty years ago he began to feel an uncomfortable sense of distension in the stomach after eating, and there was frequent eructation of gas for several hours after meals. The bowels were not then constipated as they have been during the last four years, in which he has ceased to drink beer, and has resorted to whisky instead of the four or five quarts of malt liquor that previously formed his regular daily allowance. Gradually, his appetite failed,

his tongue became coated, his breath exhaled an offensive odor, and his weight fell off from 210 pounds, till he now tips the scale at 130 pounds. You can observe for yourselves the anxious expression of his countenance; he is thirsty, though frequently drinking water in considerable quantity. His urine is scanty, slightly alkaline in reaction, deficient in chlorids, and its sediment contains crystals of the triple phosphates. He has been told that he was suffering from Bright's disease, but the urine today contains no albumin, nor any renal casts or epithelia.

The history of the patient should attract our attention to the condition of the abdominal viscera. From what has been already said we may proceed to exclude the liver, spleen and kidneys from further consideration. The greater part of the abdomen is resonant with retained gases, and no tumor can be anywhere discovered. Introduction of a long rectal tube permits the escape of considerable gas from the colon, but the upper half of the belly remains unchanged by this operation. Still, there is no excessive abdominal distension. Let us proceed to an investigation of the stomach. In the first place we will inspect the belly while the patient stands erect. This gives no positive result. Percussion over the abdomen elicits a tympanic resonance over the epigastric and left hypochondriac region. At the level of the navel, and for two inches downward and to the right of the median line, is a somewhat cup-shaped region of dulness, with intestinal resonance below it and in both flanks. Now, causing the patient to lie down, the area of dulness disappears, and every part of the anterior wall of the abdomen returns a resonant sound. Palpation discovers nothing. Auscultation reveals a variety of bubbling and gurgling sounds in the gastric region, and on shaking the patient with considerable force, a distinctly audible splash, as of water shaken in a bottle, can be heard at quite a distance. These facts point toward dilatation of the stomach. Introducing a sound through the esophagus, we find it arrested at a depth of twenty-five inches, whereas in a normal subject it is only sixteen or eighteen inches from the lips to the lower wall of the gastric fundus. But, inasmuch as there may be an element of doubt due to the possibility that the sound may have moved upon itself, slipping along the wall of the stomach till it was arrested at the pylorus, let us employ another method of measurement. We will blow air with a pair of bellows through the tube until the stomach is fully inflated. By this method the organ is readily inflated, and as the man lies upon his back, you can see the outlines of the gas bag into which it has been converted bulging distinctly under the abdominal wall. This is one of the best methods of ascertaining the fact and the extent of stomach dilatation. When the normal stomach is inflated, its lower border reaches only about halfway down from the tip of the xiphoid cartilage toward the umbilicus. If it be found on or below the level of the navel, dilatation exists, unless you are dealing with a case of normally large stomach, such as occasionally is found in health.

The method which you have just seen illustrated has, however, one rather serious objection to its general use. You observed the retching and involuntary resistance that was excited by the introduction of the gastric tube. This can be often prevented by the administration of half a dram of potassium bromid an hour before the operation. The patient can be taught to accustom his fauces to the presence of the

tube by carrying it himself through the sensitive pharynx, and then making the movements of swallowing. In this way, with a little practice, many patients learn to introduce the syphon tube without difficulty. But you will generally find it impossible, in dealing with a delicate woman or a neurotic man, to pass any kind of sound or catheter through the fauces into the stomach. You must then have recourse to the method of inflation by the liberation of gas in the stomach. This can be easily accomplished by giving two teaspoonfuls of sodium bicarbonate dissolved in half a glass of water, followed immediately by the same quantity of tartaric acid similarly dissolved. The union of these two solutions liberates carbonic acid gas enough to distend the stomach, which can be then examined by inspection, palpation, and percussion through the walls of the abdomen. This method enables us to dispense with the use of the stomach tube, and it is practically devoid of danger. Only in cases of gastric ulcer or advanced cancer, when it would be imprudent to sound the stomach, would I advise you to abstain from this mode of investigation.

Returning to the patient before you, we will withdraw the tube after syphoning out such liquids as are stagnant in the gastric cavity. The patient has eaten nothing since last evening, yet in the foul, sour-smelling fluid thus brought to view, you can see various remnants of former feasts. There are visible fibers of meat and shreds of vegetable matter—probably apple parings and potato skins. I once discovered in such ejecta a recognizable fragment of the kernel of a cocoa nut which could not have been swallowed less than a month previously. The reaction of this fluid is strongly acid. Testing it, after filtration, with litmus paper, we find the blue paper instantly reddened. This indicates the presence of something clearly acid—either a free acid or an acid salt. A piece of red Congo paper is turned blue on immersion, so we know that free acids are present. Adding to a few drops of the phloro-glucin-vannilin reagent in a porcelain dish a drop of the filtrate from the stomach, and heating it over the flame of a Bunsen burner, we at once get the bright carmin color that indicates the presence of free hydrochloric acid. That it is present in less than the normal proportion can be shown by diluting the filtrate with water. Under ordinary conditions, eight or ten parts of water to one of the filtrate would be needed to extinguish the reaction, but with this specimen the color fails to appear when only three or four parts of water have been added to one of the filtered juice. The smell of the liquid renders it probable that lactic and butyric acids are also present. In fact, in the laboratory the other day, from this patient was obtained an appreciable quantity of those acids, together with a trace of acetic acid.

Turning now from this patient, let us consider more fully the subject of gastric dilatation. It is evident that over-distension of the stomach may at any time follow excessive eating. This is not uncommon among children and childish adults, but it is a transitory condition which soon relieves itself by evacuation of the stomach upward or downward. It may be considered an acute dilatation of the organ. But there are causes that produce long continued, yes, even permanent dilatation of the stomach, either because of deficient energy in the gastric muscles, or by reason of pyloric obstruction to the onward passage of food into the duodenum. Most frequent among the causes of such obstruction are the scars of gastric or duodenal ulcers

that have encroached upon the pyloric orifice in the course of their contraction. Polypi that grow in the vicinity of the pylorus, sometimes reach a size that permits them to fall into the pyloric passage, and to obstruct it after the manner of a valve. This, and somewhat analogous obstructions caused by chronic gastritis, may occasion true hypertrophy of the muscular coat of the stomach, comparable to cardiac muscular hypertrophy. But, after a time, such overgrowth will be followed by degenerative atrophy, and then dilatation is developed. A similar effect is sometimes induced by pressure from without, when tumors in the adjacent organs are large enough to compress the pylorus or the upper end of the duodenum. It has been asserted that the right kidney can be so displaced as to produce pressure upon the outlet of the stomach and thus occasion dilatation of its cavity; but it is more probable that in such cases both conditions—floating kidney and gastric enlargement—are due to the same general laxity of the tissues. It is conceivable that under such conditions the pylorus might be displaced and twisted to such an extent as to interfere with its proper mode of opening for the passage of food, and thus the stomach might become dilated without actual constriction of its orifice.

Dilatation of the stomach may be occasioned by diseases affecting the muscular coat of the viscus. This often occurs as a consequence of chronic catarrhal gastritis, or by extensive ulceration or cancerous growths in the gastric wall. If the branches of the pneumogastric nerves are involved, there may be a loss of normal muscular tone, and dilatation will follow. A relaxed condition of the abdominal walls, permitting the stomach to gravitate downward, localized peritoneal adhesions, internal herniæ and violent concussions, are all mentioned among the possible causes of progressive dilatation. The general loss of tone throughout the muscular apparatus that follows the course of infective diseases, chlorosis, anemia, consumption, neurasthenia, hysteria, hypochondria and nearly all chronic diseases, is often the occasion of gastric dilatation. Especially true is this in diseases of nutrition like diabetes, where the patient habitually consumes an inordinate quantity of food and drink. Great eaters, who take little exercise, and vegetable feeders who consume roots and herbs like the cattle in a meadow, are liable to be similarly affected. Children who have the free run of an orchard, particularly those who have been rachitic in early infancy, and who are frequent victims of gastric catarrh, are often sufferers with dilatation, which may be recognized by the abnormal size of the abdomen. Since the male sex is most subject to gastric disorders, it is among men, from the age of puberty till the forty-fifth year, that the disease is most common.

The extent to which dilatation may reach is exceedingly variable. Sometimes the enlarged stomach seems to fill the whole abdominal cavity, crowding the liver and spleen upward, and pushing the intestines backward and into the flanks. Sometimes the lesser curvature of the stomach is dragged down below the border of the liver, and the pylorus may be found in the region of the cecum. In recent cases, the cardiac end of the organ is usually the first to yield; occasionally, the stomach presents a pouched appearance as a consequence of local traction through peritoneal adhesions, dragging outward a portion of the gastric wall, just as diverticula from the esophagus are sometimes formed. When there is great pyloric obstruction the

esophagus shares in the consequent dilatation of the stomach.

The gastric mucosa exhibits the appearances of catarrhal inflammation. When there is pyloric stenosis the muscular coat of the stomach is sometimes considerably thickened; but when dilatation is dependent upon general causes of a debilitating character, the muscular layers are atrophied.

The symptoms of gastric dilatation depend upon physical changes in the stomach itself, and upon chemic changes in its contents. Mere enlargement of the organ does not necessarily indicate dilatation, for we occasionally meet with congenitally large stomachs that are perfectly healthy. In like manner, fermentation, or even putrefaction, of the substances that have been swallowed as food and drink, may occur as an accident without permanent dilatation. Again, these symptoms may be so insignificant that they are ascribed to catarrh alone, and the fact of incipient enlargement of the stomach may be for a long time overlooked. But when physical and chemic changes persist for any length of time, there can be no doubt of the existence of the disease. As it progresses, the patient slowly emaciates, becomes pale and cachectic, with a countenance expressive of suffering and exhaustion, and finally presents all the appearances of slow starvation. Appetite usually fails; but when there is obstruction of the pylorus, and consequent vomiting, hunger and thirst are experienced in a high degree. In many cases there is hiccough, pyrosis, and belching of gases that are sometimes odorless, but which are sometimes highly charged with hydrogen sulphid. Occasionally, the gas that is thus eructated is actually inflammable from the presence of marsh-gas among the products of fermentation. It is probable that the old stories of the spontaneous combustion of the human body had their origin in such occurrence of conflagration from too near approach of a lighted candle at the moment of eructation, setting fire to the beard and neck-cloth, and so producing suffocation, with more or less charring of the flesh as the clothing was consumed.

Prominent among the symptoms is vomiting. This is particularly common when the pylorus is obstructed. As the stomach enlarges it is thus evacuated less frequently, but the quantity thrown off is proportionately increased. The act of vomiting also often degenerates into a mere form of retching, so that the contents of the stomach are returned with very little effort. Many patients thus bring to light considerable masses of undigested food, hawked up every morning as they clear their throats on rising from bed. The vomited matter is usually very acid, sometimes setting the teeth on edge, and taking the color out of cloth with which it has been brought in contact. Sometimes, on the other hand, it may be rancid or sweetish, or, if there be cancer of the stomach, of an offensive character. The consistence and color of the vomitus depends largely upon the quality of the food—it is usually thin and watery, containing macerated and partly decomposed fibers of meat and particles of vegetable food. In cancerous cases, the liquid may be of a chocolate or coffee-ground color, from the presence of altered blood pigment and corpuscles. Allowed to settle in a test-glass, the upper portion is usually frothy, the middle portion is a slimy liquid, while the sediment contains the débris of food, numerous epithelial masses, exudative products and microbic organisms. Among these, sarcinæ ventriculi and yeast

cells are commonly present, giving rise to fermentation that continues in the vessel, sometimes causing it to overflow like a fermenting beer keg. Chemic examination reveals the presence of lactic, butyric and acetic acids, together with peptones, unchanged albumin, sugar and starch.

On inspection of the patient an unusual swelling of the abdomen, often extending below the navel, is visible. When there is considerable emaciation, it is sometimes possible to discern the outlines of the stomach through the abdominal wall. When there is obstruction of the pyloric orifice, the peristaltic movements of the muscular coat from the cardia toward the pylorus, are occasionally visible in like manner. These movements are sometimes attended with considerable uneasiness, which has been described as *peristaltic restlessness* of the stomach. Their appearance below the navel is diagnostic of gastric dilatation, because in a healthy condition the lower border of the organ lies wholly above the umbilicus. By careful pressure or percussion over the stomach it is sometimes possible to make out the line of the greatest curvature of the organ as it lies in the lower part of the abdomen; and on smartly shaking the patient, it is often possible to hear loud splashing sounds, caused by the commotion of air and water in the stomach. This, however, is not a diagnostic symptom, for the reason that similar splashing and gurgling sounds are often produced in stomachs that are not enlarged—notably among women who lace themselves tightly. But, in connection with other signs of dilatation, it is a valuable symptom. Sometimes the stomach contains so much air and water that actual fluctuation can be detected when the palm of one hand is pressed against the side of the abdomen while with the other hand the opposite side is tapped with short, quick strokes from the ends of the fingers.

Percussion of the abdominal wall, after inflation of the stomach with gas, affords the most satisfactory evidence regarding its dimensions. Only in the exceptional cases of congenital enlargement, or low position of the viscus, will the greater curvature of the stomach descend to the level of the navel when distended with gas. Air may be forced through a syphon tube by the aid of a bellows, so as to fill the cavity of the organ; but by far the most convenient method consists in the administration of a glass of water in which two teaspoonfuls of sodium bicarbonate have been dissolved. This should be followed by an equal quantity of tartaric acid similarly dissolved, or by the juice of one or two lemons, diluted with sufficient water. Unless there be evidence of severe ulceration in the gastric walls, this treatment is devoid of danger, and seldom causes any feeling of inconvenience on the part of the patient. Occasionally, the gas passes, as soon as it is liberated, into the intestines, indicating pyloric insufficiency, but it is almost always retained in the stomach, which distends like a rubber balloon, so that often its outlines can be readily discerned through the abdominal wall, or can be easily defined by percussion. If the ear, or the stethoscope, be applied to the abdomen, it is possible to hear the bubbling and sizzling that is produced by liberation of gas in the liquid contents of the stomach. Sometimes it is difficult to decide whether resonance in the abdomen is due to dilatation of the stomach, or to distension of the colon with air. In such doubtful cases, the colon may be filled with water from a fountain syringe, while the stomach is inflated with gas. Or the experiment

may be reversed by causing the patient to drink a considerable quantity of water after the colon has been inflated by pumping air into the rectum with a spray-balloon.

Other ingenious methods of determining the dimensions of the stomach have been devised, and some of them give very satisfactory results in the laboratory; but in private practice, so far as possible, it is desirable to avoid the use of sounds and stomach tubes until you have secured the confidence of the patient, and are fully assured of his loyalty under all circumstances. Some idea of the capacity of the stomach might be obtained from the administration of measured quantities of water, were it not the fact that in many cases the patient feels so much discomfort from drinking, even before the limit of repletion is reached, that it is impossible thus to measure the cavity of the organ. Dr. Einhorn has devised an ingenious method of electric illumination of the gastric interior so that its outlines become visible like those of a shade over the flame of a lamp. But the apparatus is expensive, and its use necessitates the disagreeable introduction of a tube through the esophagus.

In all cases of gastric dilatation the functional power of the stomach is seriously reduced. Six or seven hours after a meal the healthy stomach contains no trace of food; but when dilatation exists, remnants of previous meals, sometimes even after the lapse of several days, can be brought up from the depths in which they have stagnated. The absorptive power of the mucosa is reduced, under such conditions, so that if iodid of potassium be taken, instead of ten or fifteen minutes, as in health, it will be two hours before the drug can be detected in the saliva of the patient. As a consequence of the diminished mobility of the muscular coat and the resultant stagnation of food, the stomach becomes a receptacle in which takes place an inordinate fermentation of carbohydrates, and even putrefactive decomposition. Hence the appearance of alcohol, carbonic acid, marsh-gas, acetic, butyric and lactic acid in the gastric contents. If a carcinoma be present, the gastric juice will cease to contain free hydrochloric acid; but when dilatation is due to obstruction by round ulcer of the stomach, the opposite condition obtains, and there will be found an excess of the free acid.

Constipation of the bowels is usually experienced; partly because of general intestinal atony and partly by reason of vomiting, when that occurs, so as to hinder the entrance of food into the intestinal canal. For similar reasons the quantity of urine is often reduced. Its reaction is usually alkaline and its solid constituents are diminished, just as they are in any case of slow starvation. The sediment contains triple phosphates and the phosphate of calcium. With the appearance of cachexia, traces of albumin and peptones are discovered in the urine.

As the disease progresses the symptoms of indigestion and mal-nutrition become more pronounced. The patient feels incapable of effort and complains of oppression in the precordial region, with palpitation of the heart and breathlessness on slight exertion. These sensations are aggravated by the accumulation of gas in the stomach, crowding the diaphragm upward against the heart and lungs so that the apex beat may be found in the fourth intercostal space, while the upper surface of the liver approaches the level of the right nipple.

The course of the disease is lingering and tedious.

If dependent upon cancerous obstruction of the pylorus, its duration will be limited only by the termination of the carcinomatous disease. Under other circumstances a miserable existence may be prolonged indefinitely. Sometimes death occurs after an experience of painful cramps in the muscles ushering in collapse and death from exhaustion. This mode of dissolution is probably the result of profound auto-intoxication with products of decomposition formed in the alimentary canal. In such intoxication of the nervous system is to be found the explanation of the attacks of tetany that are sometimes experienced during the course of dilatation of the stomach. The danger of death, in such cases, is very great—the majority of them prove fatal. In certain other cases, where convulsive phenomena are absent, the brain shows evidence of disturbance in the form of delirium, perversion of sensation and transient mania or melancholia.

The recognition of well-marked dilatation of the stomach is not difficult. Congenital enlargement or normally low position of the stomach may be differentiated from morbid dilatation by the fact that they are not attended with ill health. Gastric dilatation that is dependent upon duodenal obstruction may be recognized by the fact that the patient vomits bile—since the obstruction is usually placed below the orifice of the common bile duct—while in cases of pyloric stenosis the vomited matters are free from admixture with the biliary excretion.

The prognosis in this disease is always doubtful. When dilatation is caused by malignant obstruction of the pylorus, death is inevitable. Under the most favorable circumstances, relapses are frequent and cures are uncertain.

For the treatment of gastric dilatation, the first thing to be attempted is the emptying of the stomach. This can be most easily and safely accomplished by the use of a soft rubber stomach tube, to the upper end of which a funnel is attached. Considerable difficulty usually attends the introduction of the tube before the patient has become accustomed to its intrusion into the pharynx, but with a little practice he learns to swallow the pliable syphon without irritating the nervous centers for retching and vomiting. Once carried to the bottom of the stomach, warm water, of a temperature of about 90 degrees F., should be poured into the funnel until it ceases to flow rapidly into the tube, or until the patient complains of too great pressure. The funnel should then be inverted and lowered below the level of the stomach, the tube being compressed by the thumb and finger of the operator, until the necessary adjustment of everything has been completed. Removal of pressure from the tube is then promptly followed by the evacuation of the contents of the stomach through the tube which is thus converted into a syphon. If the opening of the tube should be obstructed by the entrance of fragments of food, it may be cleared by pouring a little water into the funnel or by raising it up and down or by making pressure with the hand over the gastric region. So long as the water that returns is turbid the operation should be repeated—filling and emptying the stomach until its cavity is thoroughly cleared. It may then be washed out with a solution of table salt—a drachm to the pint, or with a similar solution of Carlsbad salt—a half drachm to the pint. In this way the stomach may be completely relieved of its fermenting contents. The syphon tube is preferable

for this purpose rather than the stomach pump, which is less convenient and much more liable to wound the gastric mucous membrane. In all these operations great care must be taken to avoid violence to the mucosa, otherwise the appearance of detached fragments of membrane in the wash-water will not be uncommon. Certain experts would have us believe that such evidences of injury are symptomatic of special forms of disease within the stomach, but this is doubtful. Under any circumstances the passage of sounds and tubes into an unsophisticated stomach is no trifling matter. Patients sometimes become convulsed and unconscious when thus treated for the first time; but, usually, they soon become accustomed to the contact of a syphon tube and find great relief through the removal of the offending matters. The renewal of decomposition may then be at least delayed by the administration of drugs that arrest fermentation, such as sodium salicylate, resorcin, creosote, benzosol and carbolic acid. The daily use of the syphon should be continued until satisfactory evidence of improvement is apparent. It may then be introduced every other day, and with less frequency as the case progresses more favorably. In all cases the treatment must be continued for a long time, and when the disease is caused by pyloric obstruction it is impossible to lay aside the tube before the end of life, unless the difficulty can be removed by a surgical operation upon the pylorus. Patients can be taught to introduce the tube and to wash out the stomach themselves, but as a general thing the physician should maintain a careful supervision of the case in order to prevent mechanical injury of the food passages or to avoid the effects of ignorant use of healing methods.

Having provided for the cleansing of the stomach, it is needful to take measures for increasing the tone and vigor of its muscular coat. For this purpose the patient should remain in bed for several hours after each operation of lavage, and should apply to the epigastrium and gastric region an ice bag wrapped in a napkin. A sponge bath with cold water should be taken every morning on rising and on retiring at night. If so situated that he can use shower baths of cold water they should be taken every day—preferably in the morning. If the patient is feeble and oversensitive he should stand in a little warm water while taking the bath. Daily massage of the whole body is another valuable means of increasing the muscular tone of weakly individuals. Light gymnastic exercises and walking in the open air must be enjoined, and the patient must be taught to aim at procuring at least two hours of such exercise—an hour in the morning and another in the evening. If the heart and kidneys are free from disease, horseback exercise and moderate bicycling will be found useful. The daily application of faradic electricity—placing one pole behind the spleen and moving the other over the region of the stomach for five minutes once or twice a day—is often very beneficial. Good results are also derived from intra-ventricular faradization—passing one electrode into the stomach while the other is applied externally in the usual way. But one should be very sure of the loyalty of his patient before employing this method.

The patient must receive his food in small quantities every two hours. Liquids must be largely withdrawn from the diet list. Thirst may be relieved by rectal injections of cold water thrown high up into

the colon with a long tube. Sugar, starch and fat should be given in very small quantity, because of their tendency to fermentation. The food should consist chiefly of tender meat well minced, toasted bread, milk, soft-boiled eggs, oysters and concentrated broths. As improvement appears a larger variety may be gradually introduced.

In the administration of medicine it is necessary to provide for an increase of motor and digestive power while endeavoring to prevent the process of fermentation in the gastric contents. For the first object, one-fiftieth of a grain of nitrate of strychnin may be injected hypodermically every six hours. Ten drops of dilute hydrochloric acid should be taken in four ounces of hot water after the three principal meals each day. One-half hour before each of those meals the patient should take five grains of salol or of salicylic acid, or a grain of resorcin or of carbolic acid, or five grains of sodium hyposulphite, to check the fermentative process during the approaching period of attempted digestion. As soon as the patient begins to feel able to remain for a considerable time in the open air the anemia that is present may be controlled with large doses of carbonate of iron.

Recently, the aid of surgery has been invoked with some degree of success in the relief of those forms of gastric dilatation that are dependent upon stenosis of the pylorus. Notwithstanding the high degree of mortality, it is sometimes the only resource, and, fortunately, with increasing experience the death rate is slightly diminished. In certain obstinate cases without pyloric obstruction, the operation of folding the anterior wall of the stomach upon itself and sewing the border of the greatest curvature to the margin of the upper curve of the organ—just as a sailor takes a reef in a sail—has been performed with tolerable success.

TREATMENT OF PERIUTERINE SEPTIC DISEASES.

Read at the Richmond meeting of the American Association of Obstetricians and Gynecologists.

BY W. E. B. DAVIS, M.D.

PROFESSOR OF GYNECOLOGY AND ABDOMINAL SURGERY, BIRMINGHAM MEDICAL COLLEGE, BIRMINGHAM, ALA.

Only recently has the extremely radical procedure of hysterectomy been practiced in this country for septic diseases of the internal genitals. A wave, which had its origin in Paris at the hands of Péan, aided by Richelot, Segond, Jacobs and others, reached our shores three years ago and has found a considerable following among our leading operators. There has been much rivalry for some years in this country as to who could do the largest number of hysterectomies most successfully, but I will not say that it is possible this innovation was more readily embraced as it afforded great opportunity for such ambitious ones, who had almost ceased to be interested in the more simple operation of salpingo-oöphorectomy, to increase their cases of hysterectomy more rapidly. They claim that there is no use in leaving the uterus behind after the removal of the appendages; that "in every operation for septic diseases of the generative organs which demands the removal of the tubes and ovaries hysterectomy should also be performed, unless there are plain contradictions forbidding it."

It should be the aim and pride of the surgeon to preserve everything consistent with thorough surgical work, and not to sacrifice important organs because it

can be done with only a small mortality. We are told that the uterus has no function after the removal of the appendages, but this has not been demonstrated; and, on the contrary, we know that the sexual life of the woman is very much better preserved by leaving the uterus, and that the mental effect is also much better. A slow convalescence, or even a second operation, is preferable to its removal, unless very much diseased. It is a reflection on the correctness of the reports of complete recoveries of such a large per cent. of cases by many most excellent surgeons, when the uterus was not removed, to accept the argument now being used in favor of hysterectomy in all these cases. As stated at the last meeting of the AMERICAN MEDICAL ASSOCIATION, "I can not agree with Dr. Sutton and others that pus in the tubes is due to gonorrhoea in 75 per cent. of cases. I think that puerperal infection is the cause of more than 50 per cent. Tubercular infection is rarely the cause, and is not so important as has been claimed. However, the importance which has been attached to gonorrhoea is against the argument for the removal of the uterus, as the infection from this source is not deep and can be removed with the curette. Because some cases are not completely cured by the removal of the appendages is no argument for hysterectomy in every case where the bilateral operation is required, for nearly all these can be relieved by a thorough curettage. Some large uteri will require, in addition to this, a high amputation of the cervix. Only a small number will need hysterectomy."

It is a notable fact that some of the surgeons who claimed most for curettment of the uterus a few years ago and who taught that total ablation of the appendages was seldom necessary are now the most enthusiastic advocates of hysterectomy. It is granted that there are some cases in which it is best to remove the uterus, those in which the uterus is flaccid and its walls infiltrated with pus, surrounded with pus tubes and ovarian abscesses. However, such cases are rare. Tubercular infection of the uterus, too, is sufficient cause to require its removal. Extreme injury and mutilation of the organ in removing the tubes and ovaries would also call for the operation. Vaginal incision for the drainage of pus in the pelvis not confined to the tubes and ovaries has been practiced for a long time with very gratifying results. This procedure is so old that it is hard to say when it was not resorted to. Such cases would recover, almost without exception, from the immediate attack and a large number recovered completely and bore children afterward. This result was due to the drainage of the tube or ovary through the peritubal and periovarian abscess, just as cases of appendicitis are cured by the rupture of the diseased appendix producing an abscess, which is evacuated by the surgeon, the appendix being drained through the abscess. In cases of abscess from lymphangitis and phlebitis this treatment was all that was required, but cases of abscess due to the tube or ovary were not all entirely relieved, due to the fact that the pus tube or ovarian abscess was not drained satisfactorily.

More recently pus tubes and ovarian abscesses have been incised and drained through the vagina with permanent recoveries in a good proportion of cases. These are the very cases where the vaginal operation and hysterectomy have been commended so highly by the French surgeons. Yet a large per cent. of these cases can be relieved by vaginal incision and drain-

age. If not relieved the patient's condition will be made better by getting rid of the pus, and later on an abdominal operation can be done and the patient cured by the removal of the appendages—and perhaps of one side only.

The French surgeons, in some cases, when unable to remove the diseased tubes and ovaries after hysterectomy, have been contented to open the masses containing the diseased appendages and to pack with gauze. The drainage in such cases has brought about complete cures. The same result could have been accomplished without the removal of the uterus, by vaginal section and the breaking up of adhesions with drainage. I would not be misunderstood as believing that all cases can be cured by incision and drainage, but so large a per cent. can be relieved, without the loss of the uterus and adnexa, our cases should be given the benefit of this conservative procedure before more radical measures are resorted to. Especially should this be done in young women, to whom the loss of the appendages and uterus means the loss of so much that is necessary to their happiness. This treatment has been highly commended by Henrotin, Pryor and Kelly, and my own experience with it, which is limited, has been so satisfactory that I am convinced of its great value and the necessity of its more general adoption. The following is the plan I have adopted:

Peritubal and periovarian abscesses.—When there is a considerable collection of pus and the patient is suffering from marked sepsis the uterus is not curetted and no attempt is made to find the tube or ovary. An incision is made into the abscess, hugging the posterior-uterine wall, and after thorough irrigation gauze is packed in the cavity, the vaginal incision being well filled so as to keep a large opening to allow the gradual withdrawal of the gauze—permitting of the escape of any collection that may occur in the cavity. The vagina is also filled with sterilized gauze. The gauze in the vagina is removed in twenty-four hours and from the abscess cavity in forty-eight hours. A rubber tube is introduced into the abscess cavity at the end of a week and kept in place from four to eight weeks. Douches are given twice a day after the removal of the gauze from the vagina. Water is passed through the tube twice a day. Carbolic acid may be used with advantage in the wash. In small peritubal and periovarian abscesses the same treatment should be adopted as in cases of tubal and ovarian abscesses, which I will describe. If there is a considerable mass some weeks after the drainage of large pelvic abscesses (peritubal and periovarian abscesses) the same treatment will be indicated as for tubal and ovarian abscesses.

Tubal and ovarian abscesses.—In these cases the uterus is always curetted and pure carbolic acid applied to the cavity. The cervix is grasped by a strong vulsellum forceps and pulled down and lifted to the front. An incision, with scissors, is made in the posterior vaginal wall, hugging the cervix and large enough to admit two fingers. When the peritoneum is reached the mass or masses can be easily outlined by bimanual palpation and can be opened with scissors or uterine forceps, the finger being used as a guide. The cavity is thoroughly dried with gauze and irrigated. If the general abdominal cavity is entered it is best to make the opening large so as to prevent a secondary abscess. Gauze should be packed into the tube and extend into the abdominal cavity, a

large quantity being used in the vaginal incision. The vagina should also be packed with gauze. The gauze is removed from the vagina in forty-eight hours, and from the abdomen and tube in five or six days, except the withdrawal of a few inches each day to keep the vaginal opening patent for the escape of fluid. A rubber tube is introduced after the removal of the gauze and managed as directed for peritubal abscess. As Henrotin says: "It seems only reasonable that such operations may be successful, even in the most chronic forms of pyosalpinx. What happens in such cases? Septic material traveling up the Fallopian tube, when the process is not too rapid, finds itself arrested at the abdominal opening by a closure of the ostium abdominale. An abscess cavity is developed in the walls of the tube proper. After a time the uterine end becomes closed, and then we have independent pus sac, not communicating with either the serous or the uterine cavity. This may rupture into the fold of the broad ligament and work its way toward the vagina. If widely opened and drained and packed, after a time all the so-called pyogenic lining membrane disappears, granulations fill the gap, the Fallopian tube becomes obsolete and the patient is cured."

Hydrosalpinx and hematosalpinx should be dealt with as outlined for pyosalpinx. I have treated some cases of ectopic gestation by this method, and was recently consulted by a young woman who had become pregnant in the uterus after recovery from such an operation for pregnancy in the right tube.

Pelvic masses following an abortion or delivery at term should be treated in this way. Pus should not be waited for. I have treated a good number of such cases by incision and gauze packing before pus formation, and thus cut short a protracted illness.

I have operated a few times in cases where the uterus was retrodisplaced and bound down by adhesions. The adhesions were broken up, the uterus replaced, the tubes and ovaries lifted up and gauze packing resorted to as heretofore described. The results so far have been quite satisfactory, but I am of the opinion that a large number of such cases will require salpingo-oöphorectomy before they are entirely relieved.

When double salpingo-oöphorectomy is necessary the choice of operation will depend largely upon the decision as to the disposition of the uterus. If the uterus is to be removed, in such cases the vaginal route could be adopted with advantage in a good proportion of operations. Fortunately that is not necessary and hence the abdominal operation is preferable, "as the aid of positive sight is given, thus affording a wider field of operation and an opportunity for conservatism."

EFFECTIVE REMEDIES IN TYPHOID FEVER.

BY THOMAS B. HEIMSTREET, M.D.

TROY, N. Y.

About five years ago, being called to a patient who had prodromic symptoms of typhoid fever, and insisted on some prompt remedy, I gave him a half-grain pill of hydrarg. protiodid, knowing it to be one of the most powerful antiseptics and having frequently prescribed it in cases of specific disease, for several days in succession, without causing any trouble. After one pill daily for two days he was so much improved

that nothing more was given and on the fourth day he went out and remained well.

Later, in two similar cases, it was used with like results. Some time after, I was sent for at night to see a young man who had diarrhea and had been sick for a week, but not in bed. His family had considered it as merely a bilious attack, until the delirium alarmed them. I found him with a temperature of 104, pulse 118, wandering delirium and distinct rose-colored eruption. Anticipating that if he recovered quickly, that the diagnosis might be doubted, I caused the parents to note the various symptoms, and being educated people they fully understood. I gave that night a half-grain pill of hydrarg. protiodid, prescribed phenacetin 5 grs. and a mouth wash of sodium salicylate in water. Next day his temperature was morning, 101, evening, 102.5. Number of passages the same but thicker. No delirium, tongue moist; gave at night another half-grain protiodid pill. Third day, morning temperature was 100, evening, 101.8; brain clear, tongue clearing, passages less in number and contained some solid matter. Pill and phenacetin were omitted. Fourth day, morning temperature was 99.5, evening 101.6; three solid passages, tongue nearly clean, but red. Fifth day, morning temperature was 99, evening 101.2. Two nearly solid passages, felt and looked well. Sixth day, morning temperature was 97.8, subnormal, evening 99.6. Seventh day, morning temperature was 98.5, evening 99. He felt well, was up all day and had two nearly natural passages. Two days after he went out and had no further trouble. This case was in the second week of typhoid fever and is a fair example of the general course of symptoms under the use of mercuric protiodid. Two pills were sufficient to determine recovery in nine days. I have since used this remedy in typhoid cases, some with pneumonic complications, and found that in ten days or less from the time of taking the first pill, they were practically well. None were seen later than the second week, by that time a person is sick enough to call a physician. As what would otherwise have been a third week was one of convalescence, I can not say how it would act late in the disease, but should not hesitate to use it, perhaps in smaller doses combined with opium or whatever else seemed indicated. If ulcerations were present they would be converted into aseptic ones.

Fears of a hypercathartic action seem groundless. In only one case griping happened, which soon passed off with a nearly solid evacuation. The old method of "locking up the bowels" simply converted the individual into a vast bacterial culture field. It is the typhotoxin which causes the diarrhea, and when the bacilli are eliminated or destroyed, the passages gradually become thicker and approach their normal condition.

But few doses are required: I have never in any one case, given more than three half-grain and two quarter-grain pills at intervals of twenty-four to thirty hours. They are small and if placed on the center of the tongue, and a drink of water taken, are easily swallowed. The pill form is preferable, as it is not likely to all dissolve in the stomach, but acts as a local antiseptic in passing through the intestines. Mineral acids are incompatible.

Miquel found mercuric iodids to be the strongest of all antiseptic substances. Sternberg places mercuric biniodid first; bichlorid second; protiodid third, and rates them all lower than Miquel.

The Woodbridge carbonate of guaiacol treatment is at present prominent and, I fully believe, will do all that is claimed for it.

The chlorids are valuable from the strong affinity of chlorin for hydrogen, causing it to break up and destroy morbid material. In the JOURNAL of March 14, 1896, Dr. W. L. Schenk cites cases of typhoid fever showing the direct effect of tinct. chlorid of iron and hydrochloric acid, evidently taken in volume and thereby reaching the seat of the disease. Previous to using the protiodid I found the following gave the best results. Chlorid of lime 10 or 15 grs. to a pint of water drank freely, the intent being to fill the intestinal tube with it, as astringents and aromatics for tympanites and diarrhea, cinnamon and clove teas; morphia and potassium bromid for delirium; phenacetin as an antipyretic; castor oil and turpentine as needed. Some cases seemed aborted by the chlorid of lime solution, the bowels being kept open by castor oil and turpentine. The antiseptic powers of some of the above remedies is as follows: Nissen found that the typhoid bacillus and the cholera spirillum are destroyed with certainty in five minutes by a solution containing 0.12 per cent. of chlorid of lime. Kitasato states that the same germs are killed in five hours by a 12 per cent. solution of potassium bromid. Cadéac and Meunier found that essence of Ceylon cinnamon kills the typhoid bacillus in twelve minutes; essence of cloves in twenty-five minutes. In bacterial diseases there is a tendency to rely on quinin, founded on its positive antidotal effects in malaria.

The plasmodium malariae of Laveran is an animal-cule of the monad family, which enters and destroys the blood corpuscles, while the bacteria are vegetable microorganisms multiplying rapidly, the pathogenic species secreting virulent poisons. The cause and actions differ. Quinin is not a strong germicide. Most authors have considered it useless in fevers, some as an unsafe remedy. Bartholow says "the subsultus and delirium are increased by it." I remember a case, over twenty-five years ago, in which mania, coma and death in a few hours, was the sequel of a 10 gr. dose of quinin. Congesting poisoned blood at the base of the brain can hardly be beneficial. As some bacteria have less resisting power than others, notably that of croupous pneumonia stated by Sternberg, its discoverer, to be "very sensitive to the action of germicidal agents," it is not improbable that some of the previously mentioned substances would be efficient in that disease and perhaps in what has some similarity, membranous croup.

In 1862, Dr. A. Tweedie suggested that the rarity of typhoid fever after fifty years of age (being about 1 per cent. of cases reported), was due to the atrophy of Peyer's patches, which takes place at that time of life.

CONTINUED AND EPHEMERAL FEVERS. A NOTE ON THE SERUM TEST FOR TYPHOID.

BY A. L. BENEDICT, M.D.

PROFESSOR OF PHYSIOLOGY AND LECTURER ON DIGESTIVE DISEASES,
DENTAL DEPARTMENT, UNIVERSITY OF BUFFALO.

There have been two disease names in common use which are nothing but names, and are in no true sense of the term diagnoses. These are *ephemeral* and *continued* fever. Cases of this nature (or of these natures?) may be explained as due to intestinal fer-

mentation or to some other form of sui-intoxication, and they have been regarded, respectively, as abortive and atypical manifestations of some other disease. In some parts of the country, continued fever is regarded as malarial; in Buffalo there is seldom any suspicion of malaria, since typhoid is, for practical purposes, the only definite protracted but acute fever, aside from the exanthemata and miliary tuberculosis. The writer does not care to discuss the merits of the arguments for and against classifying ephemeral and continued fever as manifestations of typhoid. Repeatedly have febrile cases been diagnosed as typhoid from the temperature curve, the subjective symptoms and the prevalence of this disease, and have disproved the diagnosis—at least so far as a typical course of the disease is concerned—by defervescing within a week without producing the cardiac weakness or conferring the immunity of the genuine disease. The writer has seen such cases in which the diagnosis has been confirmed by four or five physicians. Again, there are cases which have had fever for weeks, which have been kept on typhoid regimen and which have finally recovered, but which have never shown an abdominal spot, which have not been marked off into periods by differences in the temperature range, which have shown no delirium nor other evidences of the typhoid state. Are these typhoid or not? The difficulties of cultivating and of differentiating the typhoid bacillus and the trouble of making routine bacteriologic examinations, have thus far left the question to the arguments of theorizers.

A short time ago, the writer was asked to see J. D., aged 20, male, single. He had been well till the day before, but now complained of pain in head and back, of slight constipation and of chilly sensations. At 4 P.M., the pulse was 90, the temperature 100.4 degrees F. Physical examination was negative. The next day at noon the pulse was 81, the temperature 99.5 degrees. At 4 P.M. the temperature was 100.2 degrees. On the third day, at noon, the pulse was 62, the temperature 98.5 degrees; at 4 P.M., 98.7 degrees; at 9:30 P.M. 99.3 degrees. Thereafter, the temperature was normal, and after a day or two, the patient was allowed to get up. During the fever, milk diet and intestinal antiseptics were employed. The urine of the second and third days of attendance showed what seemed to be a plain Ehrlich reaction, namely, a marked garnet-red ring. The first sample also showed a little indican, otherwise the urine was practically normal. The serum test, applied by Dr. Frank J. Thornbury of the University of Buffalo, resulted negatively from blood taken on all three days of the fever. The Ehrlich test was certainly misleading here. It is possible that some one more expert in this test would have said that the shade of red was not the proper one on which to base a diagnosis. Such statements are sometimes seen, but they only go to show that the test is worthless except in the hands of those who have opportunities for extensive observation, while authorities apparently equally good have reported, as the writer has observed, marked Ehrlich reactions in urine from non-typhoid patients. In contrast with this, the results obtained from the examination of blood serum seem, from the reports of Johnston and others, to be almost positive, while the technique is simple and the test conspicuous.

Last fall, the writer had what he supposed to be a case of typhoid fever, though the spots noted were not absolutely typical and the temperature was com-

paratively low after the first few days. The favorable temperature range was, however, attributed to the use of intestinal anti- and asepsis. The case was somewhat protracted for this method of treatment, a temperature of about 99.5 degrees persisting for a month after the subsidence of serious symptoms, so that the possibility of tuberculosis or of malaria was entertained. Although the parasites were not demonstrable in the blood, the case yielded to quinin after a total duration of about ten weeks from the beginning of the typhoid (?) fever. In this case, indican was absent. The Ehrlich test, through a misprint, was performed with sodium nitrate instead of sodium nitrite, hence its failure is not significant. In February, two samples of serum were examined by Dr. Thornbury, with negative result. It is questionable what is to be considered the minimum duration of antitoxic material in the blood after typhoid. In another case treated by the writer, Dr. Thornbury demonstrated the reaction two years and a half after convalescence, and much longer persistence has been noted by him as well as by others. At least, the result throws some doubt on the diagnosis of typhoid.

The serum test for typhoid is one which should be added to the repertoire of all municipal boards of health, since neither the expense nor the labor involved compares with that for the diphtheria test, and since very little care is necessary in transmitting the suspected material to the bacteriologist. If future study shall confirm the argument of those who have upheld the individuality of ephemeral and of continued fever, the profession will be in a position to attack the problem of the nature of these diseases and to determine whether they are due to specific or varying causes, and whether they are identical except in duration.

REPORT OF SEVENTY-SIX CASES OF CATARACT EXTRACTION, WITH REMARKS.

BY FRANK S. MILBURY, M.D.

Ophthalmologist, Otolologist and Laryngologist to the Bedford Dispensary and Hospital.
BROOKLYN, N. Y.

Although the operation for cataract extraction is the most important in the field of ophthalmology, still it may not require more, and probably not as much skill and judgment as many other eye operations, but the beneficial results of restoring vision to the blind are so great and marvelous to the patient and gratifying to the physician, that the operation takes first rank in surgery and its value can not be overestimated.

In this paper I wish to report the results in seventy-six consecutive cataract extractions, including complicated and uncomplicated cases, that have been done by me since November, 1891, in individuals ranging in age from 18 months to 87 years.

In all cases where the party has passed the age of 25 or 30 and the opacity interferes with useful vision, whether the cataract is mature or not, it is my practice to remove it.

However, some of the cortex is likely to be left behind, but experience has taught that when it has free access to the aqueous humor, absorption rapidly takes place. I do not think that any who have tried it will regret the removal of an immature cataract. I prefer operating with the patient on a table or something about that height, and as soon after the operation as possible get the patient into bed, where absolute

rest may be had. In the seventy-six operations a general anesthetic was not used in a single instance, and today is rarely ever resorted to by any oculist in cataract extractions, but, of course, occasionally it is indicated. Two fresh cocain solutions are made, one 4 per cent. and a 10 per cent., the cocain being dissolved in a saturated boracic acid solution. Instillations of the 4 per cent. are begun about twenty minutes before operating, several being made during that time. And before beginning the operation two or three drops of the 10 per cent. is used. The lids are thoroughly cleansed with soap and water, followed by douching outside and inside the lids with a bichlorid solution (1-6000). To prevent the corrosive action on the sublimate on the instruments, the eye is deluged with boric acid solution. Hands and finger nails are made scrupulously clean. All instruments are carefully sterilized by boiling and then placed in an alcohol bath, and by the assistant again dipped in boiling water when handed to me. Usually the operation on either eye is done while standing behind the patient, using the right and left hands, but occasionally I find it better to do the right eye standing behind the patient and the left standing in front. Fixation forceps and a spring speculum with stop screw is preferred. In nervous cases the speculum, or rather lid elevator, invented by Dr. Edward Swasey of Worcester, Mass., will be found a most useful instrument. With this the upper lid is held completely out of the way without exerting the slightest pressure on the eyeball; the lower lid is kept back by the fixation forceps. With this in place it is impossible for the patient to close the eye. The instrument is made by Geo. Tiemann & Co., New York. The incision is made upward with the Graefe knife in the limbus, and is made to include about two-fifths of the circumference of the cornea. This gives an opening large enough to permit of the easy exit of the lens. The Graefe cystotome is used to open the capsule; the edge of the short fine hook being made very sharp, is carried under the margin of the iris, bringing it across the pupil, making the opening as large as possible. If I am using the spring speculum, it and the fixation forceps are removed as soon as capsulotomy is done, thus, in a measure, preventing the rupture of the zonula and escape of vitreous when ready to remove the speculum after exit of cataract.

I impress upon the patient the necessity of not tightly pressing the lids together, as is the tendency after being stretched apart, but let them close slowly and gently. In expressing the lens the tortoise-shell spoon is generally used by pressure on the lower border of the cornea. And sometimes counter-pressure above the wound, which appears to make the escape of lens easier. It is made steadily until the lens has passed its greatest diameter, and then the pressure is released and the spoon follows the lens upward over the cornea, causing as much of the soft cortex to escape as possible. If much lens substance remains an attempt is sometimes made to remove it by Wecker's spoon or lavage with a boric acid solution, but usually it is left alone as it is rather quickly absorbed, and I have seen it give rise to no bad results; the restoration of good vision being simply retarded. The presence of cortical remains is recognized by the pupil not having become quite black, or the vision not being as good as it should be. Oblique illumination may also be used for its detection, or an examination of the removed cataract. In cases where the

iris remains in the wound or is partially prolapsed I endeavor to replace it by gently manipulating the upper lid of the closed eye, and where not successful in this way the spatula is used, and by this method I have never experienced any of the bad results claimed by some of introducing the spatula into the anterior chamber.

Too much importance can not be attached to the toilet of the wound; every particle of blood clot, tag of capsule, etc., are carefully removed. The lips of the wound are made to lie in as close apposition as possible, and it usually can be done so perfectly that it is difficult to see where the incision has been made. In every case of simple extraction I formerly used a drop of a 1 per cent. eserine solution, but this has been abandoned excepting in cases where there is a possible paralysis of the sphincter in the passage of the lens. In a few cases after the use of eserine iritis has been observed, but it is a question whether the eserine was responsible for it or not. In dressing the eyes a little vaselin, made up with yellow oxid or bichlorid, is applied to the lids to keep them from sticking together, then a pad of gauze is placed over both eyes, then a wad of cotton, and over this the four-tailed bandage as used in the Royal Ophthalmic Hospital, London, and lastly the shield suggested by Dr. Ring.

Unless pain is complained of in the eye or the bandage is too tight, or irritation of some kind is present, no inspection is made until about forty-eight hours have elapsed. If the eye is doing well, both are washed and re-dressed as at first. On the third day the use of atropia is begun and continued twice daily. The eyes are kept bandaged for four or five days, or until the wound is thoroughly healed, for, if the well eye is left uncovered and moves about, irritation of the operated one will be caused and delay the healing, and possibly produce other complications. The operated eye is kept covered until about the eighth or tenth day, and then smoked glasses prescribed. The fitting of reading-glasses is deferred until all redness has passed away from the eye. The simple extraction is always done where possible; but in cataract with glaucoma and extensive posterior synechia, iridectomy becomes necessary, as well as from accidents occurring during the operation and other indications; some of which may be a severe wounding of the iris when making the incision, great difficulty in expelling the lens, a persistent tendency of the iris to prolapse, etc. In cases of a thickened and opaque anterior capsule, as much as possible is removed with the forceps.

Of the seventy-six extractions, ten were of a complicated nature, including detachment of the retina, three, none of which could be determined before operating; foreign body in eye, one; total posterior synechia, one; adherent leucoma, one; dislocated lens, one; penetrating wound, one; chorio-retinitis, one; disseminate choroiditis, one. In one case of detached retina, the projection was so imperfect and the results of visual improvement so uncertain, that it was only at the request of the patient that I consented to remove the lens, and that for the cosmetic effect alone. Almost complete detachment was found, which probably occurred some years previous from a piece of flying wood, as from that time he dates the beginning of impaired vision. After the operation perception of light was better and by turning the eye outward he could count fingers. In the other two cases the pro-

jection was fairly good, and after operating vision in one eye was 20-70 and the other 10-200. The results in the other cases of complicated cataracts were, foreign body 20-20, total posterior synechia 20-100, adherent leucoma 18-200, dislocated lens 20-30, penetrating wound 20-20, chorio-retinitis 10-200, disseminate choroïditis 18-200. In case of the foreign body it was found imbedded in the lens substance. In seven of the above cases iridectomy was done.

In my sixty-six cases of uncomplicated cataracts done by simple extraction the visual results were as follows: 20-15 in three eyes, 20-20 in twenty-eight eyes, or nearly 50 per cent. with full vision or better: 20-30 in ten, 20-40 in twelve, 20-50 in seven, 20-70 in one, 20-100 in two, 20-200 in two eyes, and in one case no vision. Two of these cases were zonular cataract in children, one 18 months old and the other 7 years, both boys. In both eyes of the infant I needled three times, getting complete absorption and perfect vision. In the boy discission was performed on the right eye twice and on the left three times, obtaining vision 20-15. An exceedingly small particle of opaque anterior capsule lies in the lower part of the pupil, but causes no inconvenience or deformity. The case that resulted in no vision was produced by the firm pressure of lids together, expelling lens and considerable vitreous and prolapse of iris, which was at once excised, but later it became incarcerated, covering the entire pupil. Iridectomy was done by de Wecker's method, but was unsuccessful. The secondary operation of discission was done in about one half the cases, in all of which vision was improved. Beside the above-mentioned cases, there was slight loss of vitreous in two cases of simple extraction, and in one with iridectomy, but the patients made good recoveries. Prolapse of the iris followed in three cases, and was excised in two, one eight days after extraction. Twice during the operation the iris fell before the knife and was wounded.

In looking over the report I find that about 90 per cent. of the operations were successful; that is, giving vision of 20-200 and better to about seventy of those operated on, which is about the usual average among good operators.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

BY CARL H. VON KLEIN, A.M., M.D.

CHAPTER IV.—NOTICE ON HOSPITALS.

(Continued from page 694.)

The oldest, largest, richest and worst hospital in Europe was the *Hôtel Dieu* in Paris. It is said to have been founded in 660 A.D. by St. Landry, the Bishop of Paris; it is certain that Louis the Good and Henry IV. enriched it considerably. The old building was situated on the Island of Notre Dame, the new one on the opposite side of the river, connected with the old part by a bridge. In 1783 the old house contained twenty-three halls, the largest of which accommodated 400 patients. There were almost always in the hospital about three or four thousand patients, sometimes even more, but there were only 1,233 beds. Therefore there were often four or five in one bed; it even happened that a dead man, two dying and a convalescent lay together. In spite of the order of the king that each one should have

his own bed, and only when the hospital was overcrowded should two be put in one bed, it was thought sufficient to separate the patients by a board slipped between them so they could not touch each other. Patients were admitted without distinction; only those with skin diseases and syphilis were sent to Bicêtre. The surgeon on duty (*chir. de la porte*), who was changed every month, examined the new-comers. There were special wards for patients who had been operated upon, ophthalmia patients, the wounded and those with scurvy, although the medical and surgical patients, to whom hospital clothes were furnished, were often promiscuously put into the same room. There were 92 nuns with 50 novices and 18 other women engaged for attendance. The nuns dispensed the food, but troubled themselves so little over the orders of the physicians that many patients died simply because of the boundless disorder. They used 4,000 pounds of bread a day. Eight physicians and a chief surgeon (*chir. major*), with a hundred student surgeons, were entrusted with the treatment of patients. Of these, 13 were called surgeons internes because they had board and lodging in the hospital, and 15 surgeons externes, who ate in the hospital but lived outside. The other 72 did not enjoy these benefits, but must appear punctually for visits, which were made at six o'clock in the morning, in the winter at daylight, and at five in the afternoon. Two of the oldest internes were, after several years' service, called *gagnants maîtrise*, that is, they treated the patients by themselves and referred only the most important cases to the first surgeon for advice. This position they held a few years, when they were advanced to *maître*. As a rule there were more than 500 surgical patients in the hospital. Nevertheless the students learned little, because during the visits the chief surgeon did not remain long by a patient's bed, and seldom spoke. Most of the operations occurred in spring and autumn, often ten or twelve in one day. The bad plan prevailed here as in the other large French hospitals, of operating upon all the stone patients on a certain day; therefore many must wait weeks, even months, and in consequence of the bad air and food in the hospital they became much weakened. In 1761 Moreau performed fifteen operations for stone in the *Hôtel Dieu* in a single day. A few days before the operation they gave especially the younger patients worm cake, because many would be killed by the worms! The mortality was frightful, as we shall see later; the people died like flies in the infected air. This statement of the Vienna physician Hunczovsky was not exaggerated, and was confirmed by French authorities. The Academy of Sciences commissioned some of its members to make a report on the *Hôtel Dieu* (1786). They called attention to the fact that it was situated on a street where the whole day long wagons with wood and stone, sometimes 168 in an hour, were driven. For 4,800 patients there were only 2,000 beds, and at times six lay together. Here one found three wounded men in one and the same dirty bed, these three in delirium, who could maim or kill themselves in their frenzy. Convalescents lay between the sick and the dead. Two or three hundred wounded were crowded together in St. Paul's Hall, which was the sole passage to the kitchen and cellar. The operating room was situated close to this ill-smelling hole, and over the morgue. The French commissioners declared publicly, with the consent of the government, that the *Hôtel Dieu* was

the most unhealthful of all hospitals. Let us look at one more picture from the hand of G. Wardenburg in 1796, of this ill-famed house, called at that time, with the greatest irony, "*Grand hospice de l'humanité.*" Even before one passed the door of death, he was met at a considerable distance by a smell of cadavers. In the house, daily falling to ruin, the number of patients had decreased since the revolution to some 2,000 or 2,500 and, chiefly through the influence of Desault, more comfortable beds were in use. More than two patients were never in one bed, separated by a board. The nuns still held their powerful influence, and they were never more intriguing than here. The refuse was carried to the outhouses in narrow pipes, but they leaked, and a dreadful smell was the consequence. But most horrible of all was the fact that the morgue and the anatomic room were situated at the end of two wards, opening into them. The dead were all carried through these wards, and the odor infected everything. The low, dark operating room was just as bad, where the patients were operated upon by candle light on the clearest days. Smoky lamps burned at night. The noise of the street was so great that neither the internes could work quietly in their rooms, nor the patients find rest. Tenon reckoned that ninety-two carts and freight wagons were driven under the operating room every hour; for this reason Desault performed operations in the amphitheater. The Hôtel Dieu has him to thank for a better arrangement of the wards and distribution of provisions. At his instigation the archepiscopal residence, chapel and church were annexed to the hospital, and a great amphitheater erected in the chapel. Beside twelve physicians, for the most part unknown men who had received the positions by preferment, Peletan directed the surgical clinic at that time. The hospital also employed an oculist and a special truss-maker (*chir. herniaire*).

Next to the Hôtel Dieu, the Charité, later called *Hospice de l'Unité*, was the most important hospital in Paris for practitioners, as in the two were gathered generally the difficult surgical cases. It was the oldest of the thirty-two hospitals in France belonging to the Brothers of Mercy, who were themselves the physicians and surgeons there. The revolution drove them out because they would not take the oath, though the Charité brothers were everywhere among the best nurses. The hospital, with somewhat more than 200 beds, took no women patients and no patients with syphilis, contagious diseases or rupture; further, priests were excluded, because they could live from their masses, and soldiers because they were paid. All other sick and poor were admitted at any time, not, as in many hospitals, only on certain days and hours. The larger of the wards, which were all connected, were separated from one another by iron gratings, while the smaller ones communicated with the larger by open doors. The patient had his own bed; between two beds stood a basin which was cleansed between 2 and 3 o'clock at night. The monks also held free polyclinics which were attended by large crowds. In the Hôtel Dieu, indeed, there was a greater variety of surgical cases, but in the Charité the visits were much more thoroughgoing; each patient was examined daily. Unfortunately there was no special operating room, so that with the exception of stone patients, those with hare-lips and so forth, all the patients were operated upon in the beds. With the so-called Hospice de Charité, which was established in an old monastery, in 1779, for 120

patients, the experiment was first made to learn whether it would be advantageous to put a small hospital in every parish for the poor patients found within it. The Hospital of St. Louis was for contagious diseases, the Hospital of St. Anna especially for the plague stricken. The Hospice de St. Sulpice was among the the best hospitals, as was also the Hôpital Necker, which was founded at her own expense in 1778 by Susanne Necker, wife of the Necker afterward Minister of Finance.

Among the provincial cities Rouen, since 1754, had a Hôtel Dieu with 400 beds; there, too, several patients often lay in one bed. Le Cat officiated as surgeon, and after him his son-in-law David. Whoever, in this ill-smelling hospital, was not cured after a six-months' sojourn was taken to another hospital. In Brest the patients were so crowded in large, poorly ventilated halls, that people used to call the hospital "the grave of sailors." Lyons, Bordeaux and Montpellier had larger hospitals. There were also hospitals only for stone patients, for example in Luneville, where within fifty years 1,483 operations for stone were performed.

Let us end our travels in Northern Europe. *Stockholm* owed its hospital to the suggestion of Dr. Bäck and the surgeon Acrel. For several years collections were taken at weddings and christenings, at first only in the capital, but later throughout the whole country, till King Adolphus Frederick had a building bought, in which in 1752 a hospital with eight beds was opened. Two Knights of the Order of Seraphine directed it. The number of beds increased in the following thirty years to forty-four, each of which cost 1,744 thalers a year. In 1775 the contributions amounted to 67,500 thalers, including the proceeds of the royal lottery and of concerts and plays. For the conferring of the Order of Seraphine on the Empress of Russia she gave the hospital 70,000 thalers. It was a model institution in respect to cleanliness and administration; each patient had his own bed with curtains, and hospital clothing. When in 1780 the King of Sweden broke his arm, in the region of Loulais, the citizens for joy at his fortunate recovery, collected 4,000 thalers, to keep always in the hospital a few surgeons for special instruction in treating fractures of the arm and leg; these were called Loulais-physicians. *Copenhagen* followed the example of her sister city, and built in 1757 the Friedrich's Hospital for 280 patients, with the same number of beds. The annual cost of 25,000 thalers the government of Friedrich V. defrayed, among other ways, by reserving a monopoly of the printing and sale of playing cards. Winslow was surgeon, and he lectured once a week in the Danish language, on the cases as they came up, while Callisen, the professor of surgery, and first surgeon at the Marine Hospital, lectured in the German language. St. Petersburg possessed, in 1786, a hospital with 300 beds, a house of refuge and a hospital for syphilis, beside two smallpox hospitals, a school of obstetrics and an electrical institution of medicine. Likewise in *Moscow* the Empress had built hospitals, and Emperor Alexander gave the considerable revenues of two starosts to the hospital in Wilna. Russian noblemen followed the royal example. Count Scheremeteff set aside a capital of two and a half million rubles, the interest of which was to be turned over to the hospitals and charitable institutions. Von Demidoff gave the University of Moscow a million rubles for a library and natural

history collection, and for schools; he would also lend 1,500 serfs if the Emperor decided to found a university in Jaroslow. The following table may give an idea respecting the diet in the different hospitals:

Hospital.	Rigid Diet.	Full Portion.	Small Portion.
Charité in Berlin (1727).	Daily fresh meat, soup with entrées. Brown or white beer, occasionally wine.	
General Hospital in Vienna (1785).	In morning broth; at noon <i>trinkpanatel</i> ; in the afternoon, when necessary, broth; in the evening, soup with pieces of bread.	In morning burnt flour soup with pieces of bread; at noon soup with barley, rice, grits or meal pudding, 1½ viertling of beef, vegetables; in the evening, soup, beer or wine (one maass for 8 kreuzer) according to orders of physician.	¼, ½, ¾ portions. (This diet was especially for those who paid nothing, or only 10 kreuzer daily; in higher classes it was better.)
French Hospital regulation (1781).	Broth, three or four times daily.	Daily one pound of meat (¾ beef, ¼ veal or mutton), which must be weighed in presence of the <i>Controleur</i> , and which, boiled, must weigh ten ounces without bones; 24 ounces of bread, out of white flour, one pint of red or white wine or beer, salt and vinegar, extra food according to order.	
Charité in Paris (Huneczovsky 1783).	Clear soup, light milk or fruit foods.	Soup, 8 ounces of meat, 10 ounces of bread, noon and evening; ¼ maass of wine.	½ and ¼ portions.
Hospital in Portsmouth (1780).	Warm milk with water or pomade soup, barley water as a drink.	One pound of boiled beef, one maass of beer.	½ portion.

Although these regulations were not strenuously opposed in general, yet it must be remembered that in consequence of the gross irregularities and the farming out of certain hospitals, the contractors not only kept back fuel and linen, but even preyed upon the food for the patients, and supplied a poor quality in order to make as much money as possible. By comparing the two French tables of diet it appears that the patients were not furnished the full legal rations of bread and meat.

The following table shows the attendance and mortality at the various hospitals:

Hospital.	Year.	Total Number.	Deaths.	Percentage of mortality.	Surgical Patients.	Deaths.	Percentage of mortality.

(To be continued.)

PECULIARITIES OF THE SURGICAL DISEASES AND INJURIES OF THE NECK.

BY EDMOND SOUCHON, M.D.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY, TULANE UNIVERSITY, NEW ORLEANS, LA.

(Concluded from page 697.)

PECULIARITIES OF THE SURGICAL DISEASES AND INJURIES OF THE SUPRA-CLAVICULAR REGION.

Congenital atrophic malformations.—A sort of atrophy of the region is presented in subjects, young and old, in which the supra-clavicular fossa is unusually deep, causing the deformity called "salt-cellar neck." Orifices of congenital branchial fistulæ are sometimes met with in this region.

Acquired atrophies call for no special remarks. As for *hypertrophic malformations* it sometimes happens that carriers, especially plank-carriers, develop a thickening of the skin and connective tissue of the region called a pad. In emphysema the hollow of the region is filled by the apex of the lung; also, in pneumatocele; also in aneurysms and other tumors.

Swellings of the region are rather frequent but present nothing peculiar, except what has been said.

Burns or frost-bites are rare, as the region is usually well protected.

Contusions sometimes present hematoma so large as to painfully compress the branches of the brachial plexus. In fractures of the clavicle the brachial plexus may be injured.

Punctured or superficial *wounds* may open the external jugular, the terminal part of the external and anterior jugulars and of the cephalic, but they are seldom serious unless infected. Punctured wounds of the subclavian vein and artery may also give rise to serious hematoma. When persistent they should be aspirated or incised. We should bear in mind that hematoma may be due to a wound of the vein, and that the connection may still exist. This will surely be the case if after aspiration it fills up again. In case of incision the deeper clots should not be disturbed, so as not to open the wound in the vein in case that lesion has occurred.

Injury to the subclavian artery is recognized by the pulsations of the hematoma; it is then a traumatic aneurysm. The artery should be ligated. When the swelling is moderate, the ligation should be made in the supraclavicular region, using, if necessary, an aneurysmal needle with a detachable point. In the majority of cases this simple ligation will suffice to cure the aneurysm; if not, compression of the axillary or its ligation should also be done; then the sac incised and the injured points ligated above and below. When on the right side, the artery can only be reached and encircled in its second portion after dividing the anterior scalene; no permanent ligature should be applied there; a provisional loop ligature should be placed, the sac incised, and the injured point of the third portion ligated permanently above and below. On the left side the ligation of the second portion can be made permanent at once, as it is as safe on this side as a permanent ligature is unsafe on the second portion of the right side. When the swelling is so great as to cause the failure of the above procedure, or so as to discourage even the attempt, but only then, a provisional ligature should be applied upon the first portion of the subclavian; the axillary should be compressed or treated in the same way, then the

sac is incised and the two ends ligated. In some cases these ends can not be found; packing with bits of aseptic sponges should then be resorted to, with compression over it. Should the hemorrhage return, the clavicle should be sawed through and the two ends secured. When the artery on the right side is wounded close to the scalene so as to compel ligation of the second portion, this should be done with double catgut, without rupturing the coats and with a bloodless space between the ligatures. On the left side the second portion can be ligated with safety after the old method; but the new method should be applied there also in preference. The permanent ligation of the first portion on either side should not be done unless it can be done thoroughly with double catgut, without rupturing the coats and with a bloodless space between. As this can not be safely done, as a rule, without resecting the inner extremity of the clavicle and the corresponding part of the sternum, this should only be done when the ligation of the second portion can not be performed satisfactorily as above described. Arterio-venous aneurysm, due to punctured wounds of both the vein and artery simultaneously, should not be interfered with unless they grow or cause serious pressure symptoms. Then both the artery and the veins should be ligated above and below and the sac extirpated unless too adherent to surrounding structures; if left in place it should be incised to diminish its pressure effects, sometimes these continue although abated.

Punctured wounds of the nerves rarely cause paralysis, but may cause persistent pain, neuralgia and trophic changes in the area of distribution.

Punctured wounds of the lymphatic duct on the right and of the thoracic duct on the left, may produce a chyloma, which should be treated as a venous hematoma; usually it is only then that it is recognized.

Punctured wounds of the apex of the lung may be followed by emphysema, at first limited and then generalized.

Incised superficial wounds, are not serious unless infected. The wounding of the external and interior jugulars and of the cephalic is easily arrested; however the wounding of these veins near their point of discharge into the subclavian may be followed by severe hemorrhage and by entrance of air into the veins.

Incised wounds of the third portion of the subclavian artery when large are followed by rapid death; when smaller they often cause traumatic aneurysms; the treatment is the same as indicated for punctured penetrating wounds. Incised wounds of the subclavian vein are most serious because of the amount of bleeding often causing rapid death, and also because of the quick penetration of air into the vein. The vein should be at once plugged with the finger, or better, an aseptic packing; then an attempt should be made to enlarge the wound and to clamp it and then ligate the two ends. When this is impossible, a provisional loop ligature should be applied on the first portion of the vein; also compression should be made on the axilla and the two ends ligated; the ligation of the proximal end is to secure against hemorrhage and also entrance of air, but the ligation also of the distal end is of course indispensable.

Incised wounds of the lymphatic duct on the right side and of the thoracic duct on the left are diagnosed by the oozing of the peculiar fluid they contain. If possible, the distal end should be ligated, and this

usually stops the flow, since there is a valve on the proximal end. There is seldom if ever any, discharge from it. When ligation is impossible, compression will often suffice. It is very seldom that any further trouble is noticed, because there exists usually two or three branches of that duct, and the uninjured ones carry on the circulation. When this fails and a chyle fistula is established, then the patient loses flesh and succumbs.

Incised wounds of the brachial plexus are followed by paralysis of the affected area; they should be stitched at once. The lesions from whatever cause, may affect only one branch. Those neuroses never affect the internal, anterior, and posterior surfaces of the arm, because these are supplied by the anastomoses of the intercostal filaments with the internal brachial cutaneous. They must not be confounded with the anesthesia and paralysis resulting from contusions of the shoulder in hysteric subjects (hystero-traumatism). The treatment is by electricity. If a callus includes a nerve it must be resected.

Incised wounds of the phrenic nerve are most serious. However, when the nerve has been pressed upon by a tumor for some time, the wounding of it is not so dangerous. Incised wounds of the apex of the lungs are not so apt to be followed by emphysema as the punctured wounds.

Contused and lacerated wounds are much more serious than clean wounds because of the impossibility of primary union and because they expose more to secondary hemorrhage. Gunshot wounds also are serious for similar reasons.

Poisoned wounds, stings, bites, present no peculiarities here, nor do foreign bodies in wounds of this region.

Dislocations of the head of the clavicle are a frequent cause of serious contusion of the region.

Fractures of the clavicle sometimes cause wounds of the vein or of the artery or of the brachial plexus. Shock accompanying the injuries of this region is sometimes very great on account of the large nerves of the region.

Neuroses.—Sometimes the callus of a fracture of the clavicle includes a nervous branch, hence neuralgia or paralysis, requiring resection of the callus. A simple contusion without fracture, may produce a paralysis of the plexus. Repeated slight contusions may produce paralysis, as in the case of the strap of the carriers, especially water carriers. *Softening and induration* present no peculiarities. *Congestion* of this region present nothing special. *Acute inflammation* of the skin presents no peculiarities. Superficial or supraponeurotic cellulitis and abscess present no special characters.

Deep or subaponeurotic cellulitis and abscess are not rare; they may develop in the region and burrow in the axilla. They may be the continuation of abscesses of the neck or axilla; these abscesses have a great tendency to burrow because of the resistance of the fascia of the region. In some cases the vessels raise the abscess and this may cause errors of diagnosis. Pneumonia of the apex may give rise to an abscess of the region. Superficial adenitis presents no peculiarities beyond being the most frequent starting point of primary cellulitis as a result of some affection of the upper extremity, side of chest and posterior region of neck and head. Deep adenitis also; these are more painful, being bound down by the fascia. Chronic inflammation of any of the tissues of the

region presents no peculiarities, except when propagated from the lung.

Gangrene from whatever cause may be serious if it penetrates to the vessels and nerves. A number of cases of gangrene are recorded as following the compression of the artery for aneurysms below; many of them terminated fatally from hemorrhage. Gangrene may be propagated from gangrene of the lung.

Ulcers are rare in the region and present no peculiarities.

Fistulae are sometimes congenital, they are most commonly due to chronic tuberculous glands; rarely to bony lesions; more rarely still to tubercles of the apex of the lung.

Tumors of the supra-clavicular region—Gaseous tumors are represented by pneumatocele of the apex of the lung; also by emphysema in cases of wounds, and of general pulmonary emphysema. Liquid tumors—liquid hematoma is not rare on account of the frequency of the wounds of the region. Varix or dilatation of the subclavian vein is not rare in some forms of disease of the heart. Angioma presents nothing peculiar. Idiopathic aneurysms are comparatively frequent; the modern treatment is thorough asepsis, more especially here than anywhere else; resection of the inner extremity of the clavicle and corresponding part of the sternum; ligation of the first portion of the subclavian with double catgut ligatures without rupturing the coats and leaving a bloodless space between; also ligation of the vertebral in a like manner at the same sitting. Recurrent aneurysms should be treated by the ligation of the vertebral (if not already done) and of the axillary artery above the subscapular.

Inflamed aneurysms should be treated by placing a provisional loop ligature around the first portion of the subclavian, also a permanent ligation around the axillary above the origin of the subscapular; then incision of the sac, clamping and ligating the subclavian where it enters the sac and also of the other bleeding points; extirpation of the sac if not too adherent to important surrounding structures. Lymphangioma is not rare and presents no peculiarity. Serous cysts are frequent in children; they are very soft and feel reducible, but they are not. Mucoid, soft dermoid cysts present no peculiarities. Bursal cysts may develop under a "pad." Hydatid cysts are most rare. Purulent cysts or chronic abscesses usually come from other glands, most seldom from the lungs. Abscesses by congestion are not comparatively rare in this region, coming from the base of the skull, or from the neck, and on their way to the axilla following the sheaths of the vessels and nerves more particularly.

Solid tumors.—Cicatricial keloids are not so rare here, when the cicatrices draw the head to one side. Clotted hematoma may follow injuries of vessels as explained above. A fibrinous hematoma following a cured aneurysm was removed by Dr. Shopf. Sebaceous cysts and hard dermoid cysts present no peculiarities. Simple adenoma or lymphadenoma presents nothing peculiar. Adenoma of Hodgkin's disease is commonly met with here; also strumous adenoma, tuberculous adenoma, syphilitic adenoma; adenoma of glanders rarely. Lipoma may be superficial or deep. There exists here a pseudo-lipoma occurring in women over 40, due to arthritis and diabetes; it is diffused, projects between the sternomastoid and trapezius, and causes serious pressure

symptoms; it may reach the mediastinum; it should be operated upon if pressure symptoms occur. Fibroma, myoma, myxoma, neuroma present no peculiarities. Chondroma is rare. Osteoma may arise from the first or second ribs, clavicle or vertebræ; seven cases of the last are recorded; they must not be confounded with an anomalous "cervical rib." Encephaloid, melanotic, colloid, pulsating, encephaloid, epithelioma, carcinoma, sarcoma, scirrhus, are very rarely primary; they are mostly consecutive and most often come from the glands of the axilla, themselves commonly affected by cancers of the mammary glands. A peculiar tumor in this region is a possible aberrant goitre, already described with the thyroid region.

PECULIARITIES OF THE SURGICAL DISEASES AND INJURIES OF THE POSTERIOR REGION OF THE NECK.

Congenital atrophy and hypertrophic malformations of the posterior region of the neck are rare. The most common is rare and is represented by a peculiar form of spina bifida. Congenital deviations are due to the congenital affections of the vertebræ and to torticollis.

Acquired or post-natal malformations, atrophic and hypertrophic deviations are due to neuroses (torticollis, paralysis), to injuries, to inflammations, gangrene, ulcers, fistulæ, tumors, operations, cicatrices.

Swellings of all kinds, due to the same causes, may be observed, but present nothing peculiar; the most common is the one produced by the chronic arthritis of the articulations between the occipital and the vertebræ, and between the first vertebræ themselves, and called the post-cervical or occipital arthritis or suboccipital disease.

Burns and frost-bites are only particularly important here because of the cicatrices which may follow, causing disfigurement in an exposed part, and also possibly causing deviations of the head from retraction.

Contusions are more frequent than in front; they are particularly painful because the muscles contused are those which keep the head in balance; they are often accompanied by fracture of the spinous processes and laminæ, contusion and concussion of the spinal cord and even of the brain.

Punctured, non-penetrating wounds, *i. e.*, not penetrating the vertebral artery and the spinal cord, are simple wounds and seldom give rise to any trouble. However, should they be large punctured wounds and strike the deep cervical artery, or the posterior jugular vein, they may give rise to serious hematoma. When this persists, it should be aspirated or incised. When it pulsates it is a traumatic aneurysm of the said artery and it should be treated as such. Punctured wounds of the vertebral artery may give rise to an aneurysm also which must be treated as such, that is, by ligating above or below, or both, when possible, and then incised. Much hemorrhage must be expected from the untied end and the surgeon must plug tight with aseptic sponge and make firm pressure with a bandage.

Punctured wounds of the spinal canal through the interlaminar spaces, when the head is flexed forcibly, or through a fracture of the laminæ, are serious only if becoming infected. Incised wounds reaching the spinal cord itself are followed by paralysis of the parts below. If the wound is and remains uninfected, the cicatrization by primary union may take place and the paralysis disappear; if not, it will be perma-

ment. If between the occipital and the atlas or axis the oblong medulla is severed, death is instantaneous. Infanticide is often produced by a long needle or pin driven between the occiput and the vertebra. If the lesion is above the origin of the phrenic, death follows quickly by paralysis of the diaphragm. Incised wounds of muscles are usually due to saber cuts; they may include almost all the muscles; they may reach the vertebræ when the head drops forward; the hemorrhage is great. Incised wounds of the vertebral artery give rise to profuse hemorrhage. The peculiarities of the treatment of these wounds is prompt attention to the vertebral, the impossibility of ligating both ends if it has been wounded high up, the suturing of the large muscles, the difficulty of keeping the head steady and to secure drainage; a liquid glass bandage or a jury-mast apparatus will assist materially.

Wounds of the posterior region are said to be followed by sexual impotency when the membranes of the cord are involved; also by paresis and wasting of the lower extremities; also of the testicle. Larrey contends that this may take place even when the cord is not affected. Contused or lacerated wounds present nothing particular.

Gunshot wounds are usually serious if they reach the membranes on the cord. When pressure symptoms are present, very extensive and deliberate dissections must be done to remove the ball, the fragments of broken lamellæ, or clots, or foreign bodies, which cause the pressure. Poisoned wounds, stings, bites present no peculiarities. Foreign bodies causing pressure symptoms on the cord must be removed at almost any cost.

Ruptures of the muscles of the nucha are reported in those who carry heavy loads on the head; the symptoms are those of other muscular ruptures.

Ruptures of the attachments of the rhomboid and of the elevator of the angle of the scapula have been seen in farm laborers. Sprains, dislocations, fractures of bone belong to another chapter. Shock accompanying the injuries of the posterior region is usually great, being often complicated with concussion and contusion of the cord or of the cerebellum or of the whole brain.

Neuroses are represented by the acute torticollis (posterior) of the trapezius. It is said to be even more frequent than the torticollis of the sterno-mastoid. When in the trapezius and complexus the head is inclined on the affected side, but the face is turned toward the opposite side; the head is slightly thrown backward. There is no cord, no diffuse induration, no atrophy of the face; the pain is near the atlas and is increased by pressure; under anesthesia the head can be straightened. This torticollis may be confounded with occipital arthritis with inclination of the head. The treatment consists in applying a liquid glass bandage or plaster apparatus; it should be worn one year. When both the trapezius muscles are affected the head is thrown back. In cases of torticollis of the trapezius the sterno-mastoid is often also contracted, but it is a contraction of immobilization; the pain is along the trapezius and not along the sterno-mastoid. Very often the torticollis affects also simultaneously the deeper muscles, the splenius, the elevator muscles of the scapula, the rhomboid. The scalenes and the platysma are sometimes the site of torticollis. Chronic or permanent trapezius torticollis is rare.

Softening or induration present nothing of special interest.

Congestion of the posterior region presents nothing special.

Acute *inflammation* of the skin is represented specially by large boils and carbuncles; they are comparatively very painful; they give great pain because the tissues are inextensible; sometimes they are followed by extensive sloughing, when the general health is low, specially if diabetes be present; they are also serious because the veins of the upper part of the region open into the sinuses of the dura mater. The circumscribed anthrax is not as grave and is usually amenable to ordinary treatment. Diffused anthrax extends continuously from the superior curve line of the occipital to the seventh cervical and from one ear to the other; nothing stops it, not even the largest or deepest incisions, until it has reached the above limits. It is as though a certain extent of tissue was infiltrated with microbes or as when an artery is obliterated and gangrene continues until all the area of the artery is mortified (Tillaux). Extensive incisions are even hurtful until limitation has been established, on account of the shock of the operation. When limitation has taken place, then incisions or the curette assist in removing the mortified tissues. Acute cellulitis, extensive gangrene or post-cervical abscess, phlegmons, are sometimes observed here when the general health is low, specially if diabetes be present, and for the other reasons explained above. They are really adeno-cellulitis or phlegmons because all inflammation here begins in the glands; they are usually due to disease of the scalp and skin; they may be superficial or deep; deep abscesses usually cause great pain on account of the thickness of the skin, they give rise to but very little redness and edema; they have a tendency to flatten and spread because of the thickness of the skin; they are slow in becoming superficial for the same reason; the knife must penetrate deeply to reach them. Acute lymphadenitis, however, is itself rare; it is due to lesions of the scalp and skin. Chronic inflammations are represented specially by acne, by syphilitic eruptions and by the well-known syphilitic adenitis of the suboccipital and mastoid regions; these lesions are so constant in syphilis that Ricord used to say that was the place to feel the pulse of syphilis.

Gangrene of the region is serious when extensive or deep, on account of the cicatrices and their consequences. *Ulcers* are rare and present no peculiarities. The same is true of *fistulae*.

Tumors of the posterior region of the neck.—Gaseous tumors are represented only by the extension of an emphysema.

Liquid tumors.—Liquid hematoma presents no peculiarity. Varix and angioma are very rare. Aneurysms of the vertebral artery are not rare in this region; they are usually traumatic and are often high up. The artery should be ligated above and below, if possible; or above or below whenever possible, and the sac incised and immediately plugged with aseptic sponges; if possible, the distal bleeding end should be ligated. In case a secondary hemorrhage should occur through the distal end and be uncontrollable by plugging, the ligation of the vertebral on the other side must be considered and weighed.

Lymphangiomas are rare here. Serous cysts and congenital cysts are sometimes median and sometimes lateral; they may reach as low down as the dorsal region and from the rachis to the acromion; they are

usually met with in children born prematurely and presenting other malformations; they are sometimes transformed into lipoma; according to Lannelongue they are congenital cystic lymphangioma. Mucoid cysts and dermoids are rare and present no peculiarities. Bursal cysts or hygromata are sometimes met with over the spinous processes of the seventh cervical. Purulent cysts or chronic abscesses, idiopathic or symptomatic, or by congestion, are rare here.

Solid tumors.—Comedones are not rare, neither is keloid. Clotted and solidified hematomas present no peculiarities. Sebaceous and dermoid cysts are usually difficult to dissect because they are so intimately adherent to the surrounding tissues. Simple adenoma or lymphadenoma, adenoma of Hodgkin's disease, strumous and tuberculous adenoma are comparatively rare. Adenomata syphilitica, *i. e.*, the chronic enlargements spoken of above, are very common and almost pathognomonic of syphilis. A case of gumma of the trapezius has been recorded. Adenoma due to glanders is most rare.

Lipoma is common. The circumscribed form is the most frequent; this region is a site of predilection; it sometimes sends fibrous processes to the vertebrae. A peculiar circumscribed form of lipoma is described in prostitutes over the point of junction of the neck and back of the curve seen there, and due, it is said, to the position they so often have to assume. Diffuse lipoma is sometimes limited to the region and sometimes a part of the diffuse kind of lipoma which occupies the whole circumference of the neck like a cravat; it is such in some cases that it is impossible to fix the limit of its margin, *i. e.*, to say where it ends and where the natural fat begins. Fibroma of the region sometimes also presents adhesions to the vertebrae. Cervico-dorsal fibromata are common (Guyon); myxema, myoma, neuroma, chondroma, osteoma are rare. The same is true of encephaloid, melanotic, colloid pulsating sarcoma, epithelioma, carcinoma, scirrhus and they present no peculiarities.

The surgical operations of the posterior region of the neck present no peculiarities.

SOCIETY PROCEEDINGS.

Chicago Academy of Medicine.

Regular Meeting held March 12, 1897, at the Leland Hotel.

Dr. W. X. SUDDUTH in the Chair.

AUTO-INTOXICATION IN ITS MEDICAL AND SURGICAL ASPECTS.

(Concluded from page 701.)

Dr. WM. L. BALLENGER—I shall briefly refer to a few conditions which result from pathologic processes in the nose and throat, and to some which manifest themselves in the nose and throat, but which have their origin elsewhere.

AUTO-INTOXICATION RESULTING FROM DISEASE OF THE NOSE AND THROAT.

Guye, of Amsterdam, first called attention to a mental disturbance occurring as a result of lymphatic obstruction in the nasal mucous membrane. In the cases he reported there was hypertrophy of the turbinated bodies which pressed against the septum, thereby occluding the lymphatic circulation. A symptom common to all his cases was inability or difficulty in fixing attention. He called the condition "aproxexia," which means difficult attention. Axel Key and Retzius have shown that the lymphatics beneath the dura mater and those of the nasal mucous membrane communicate.

Guye based his conclusions upon his clinical observation of *a*, stenosis and mental disturbances; *b*, the rapid relief following the reduction of the hypertrophy; *c*, the experimental work of Key and Retzius demonstrating the communication between the lymphatics of the nose and dura mater. He

described three types of aproxexia: 1, physiologic aproxexia resulting from brain strain and overwork; 2, neurasthenic aproxexia in which nervous debility plays a part; 3, nasal aproxexia, where the chief pathologic condition is hypertrophy of the inferior turbinated body, or post-nasal adenoids. In the type denominated nasal aproxexia he claims lympho stasis with resulting absorption of the static lymph by the brain tissue; that reduction of the hypertrophies, adenoids, etc., overcame the lympho-stasis and the resulting intoxication of the brain cells.

Scanes Spencer (1890) has shown us that chronic rhinitis, hypertrophic rhinitis, post-nasal adenoids, etc., in children are attended by one or more of the following symptoms: Derangement of sleep, temper, spirits, energy and intellectual power. He also found that relief from the above pathologic conditions greatly improved all the foregoing conditions. Whether the explanation is lympho-stasis, or veno-stasis, or over-production of carbon dioxide, the general proposition of auto-intoxication resulting from stenosis of the nasal air channels can scarcely be denied.

Ziem has produced scoliosis of the vertebral column in high degree in rabbits by obstruction of one-half of the nose. He observed one patient who became scoliotic after a traumatic stenosis of the nose. I mention his experiments as suggestive at least.

The thyroid gland is thought to excrete a fluid which is taken up by the lymphatics and finally emptied into the general circulation and distributed to all parts of the body. This substance, although its chemical nature is unknown, seems to perform a very important function, for when the thyroid gland is removed a grave systemic condition results, which is known as myxedema. This excretion may act as an antitoxin to other poisons in the circulation, or it may act as a stimulus to the activity of certain cellular functions. My deduction is that auto-intoxication may result from extensive destruction of the gland by disease or traumatism.

Stenosis of the nasal respiratory tract results in an over-production of carbon dioxide. To explain: The function of the respiratory tract of the nose is to warm, moisten and filter the air; if it fails on account of stenosis to sufficiently warm, moisten and filter the inspired air, an irritation is excited in the air cells of the lungs. When these cells are thus irritated they do not abstract enough oxygen from the air to completely oxygenate the tissues and carbon dioxide is a result. Carbon dioxide is a violent poison to the leucocytes, hence their germicidal power is impaired and the system is open to the invasion of the various morbid germs. Then stenosis of the respiratory tract of the nose causes auto-intoxication by the over-production of carbon dioxide.

In 1893 Professor C., aged 36, a scientist, consulted me for relief of a headache which had been with him constantly for two years. He said: "I do not care so much for the headaches as I do for the inability to fix my attention as I used to do." Upon examination I found great hypertrophy of the inferior turbinates. I removed the major part of the one on the left side, and although nearly four years have elapsed since that time he has been free from headaches and is relieved of the aproxexia.

Feb. 27, 1897, Mr. John N., aged 42, janitor, consulted me at the Polyclinic, stating that he had "catarrh of the nose." I obtained the following history: Has had nasal catarrh for years, but about two years ago it became much worse. Complained of pain across bridge of nose. Said he could not remember little duties as he did formerly. Had dull headaches in frontal and parietal regions. This has continued up to the present time. Examination showed that he had ethmoiditis. The middle turbinated bodies were much swollen, pressing against the septum. In this case there was in all probability a lympho stasis, and a morbid secretion which was reabsorbed in part, thereby poisoning the brain cells, the clinical expression of this auto-intoxication being the headache and mental hebetude.

To one who is clinically familiar with hypertrophic rhinitis, post-nasal adenoids, etc., the relief following operative procedures is a familiar picture. That the relief is due in part to improved oxygenation of the blood I can heartily endorse. The retained, decomposed secretions are undoubtedly reabsorbed in a measure and act as toxic agents. I have seen children who were pale, emaciated, stupid and peevish, who after an operation for post-nasal adenoids rapidly regained robust health and mental vigor. That this happy result is in part due to relief from absorption of static lymph and decomposed or modified secretions I think is a reasonable proposition. I believe it is also due in part to the lessened production of carbon dioxide, and the consequent increased activity of the leucocytes.

AUTO-INTOXICATIONS OF THE NOSE AND THROAT WHICH HAVE THEIR ORIGIN ELSEWHERE.

Rheumatism is recognized as an auto-intoxication, unless we except the acute inflammatory type which is caused by germs entering the system, starting chemic laboratories and emptying the products of their skill into the rivulets, streams and rivers of blood as they flow past the laboratory doors.

In one of my clinics this winter I saw a case of lacunar inflammation of the pharyngeal tonsil during an attack of rheumatism. The patient said she had had several attacks of rheumatism of a mild nature, and each time it was attended by an "ulcerated sore throat." Anti-rheumatic treatment promptly relieved her of the lacunar tonsillitis.

There is a condition in which the inferior turbinated bodies are red and turgescens, but which will not collapse under local applications of cocain, but which will yield very kindly to colchicum.

Gouty intoxications or irritations have been observed in the nose, pharynx and larynx, especially by English specialists.

Morell Mackenzie records two cases of gouty deposit around the crico-arytenoid joints causing permanent dysphonia, and another producing fungous ulceration of the ventricular bands.

Conclusions.—There are other conditions which might be mentioned if time permitted, but I am content if I have succeeded in suggesting the strong probability that nasal or naso-pharyngeal stenosis is attended by serious poisoning (or intoxication) to the general system, and that poisons or toxic agents which pervade the general system are sometimes the cause of local pathologic conditions in the nose, throat and larynx.

EPILEPSY AND NEURASTHENIA IN THEIR RELATIONS TO AUTO-INTOXICATION.

Dr. H. C. B. ALEXANDER—It has now been proved that under normal circumstances the toxins and ptomains which are produced in the organism are eliminated by various channels. These poisons are necessarily produced in the splitting up of proteids; but under conditions of strain the normal elimination is interfered with. The great organ concerned in the destruction of poisons is the liver. This is true alike of the poisons generated in the system, as well as of those introduced. The bowel very often, through a conservative diarrhea, carries off the excess which if absorbed would poison the organism as a whole.

The lungs oxidize these poisons and change their character, while the kidneys may eliminate nearly all the products except the gases. Under conditions of strain of a mental or nervous type every one of these organs has its functions interfered with, and a vicious circle results. The atonic condition of the nervous system produced by strain checks the normal elimination, and is in its turn increased by the influence of the retained toxins; furthermore, the organs themselves fail to do even their ordinary duty because of the strain put upon them in the attempt to supplement each other.

Thus, the same toxins, which are either broken up in the liver or pass off through the bowel, are in cases of neurasthenia found in the urine, the quantity of which is reduced, at the same time, below normal. In this way not only are the nervous symptoms of neurasthenia—the helmet sensation, etc., produced by a blood surcharged with toxins, but metabolism is interfered with and temporary states of lithemia, oxaluria and glycosuria result, which increase the nervous exhaustion and increase also the overwork of the digestive and eliminative organs, producing by the accumulations of gas enteroptosis, etc., which Glenard claimed as a cause of neurasthenia, but which is one of the results of the disease, long ago recognized (by alienists) as occurring in melancholia.

As the effects of these toxins are generalized or localized in the nervous system, so will prominent features of the clinical picture vary from stupor to general depression and from vertigo to epileptiform attacks. Indeed, it is by no means improbable that a recurrent epileptiform condition may be set up which closely simulates true epilepsy and, it is by no means improbable, ultimately passes, in some cases, into that condition. In some cases of neurasthenia the action of the toxins seems to be largely localized in the spinal cord, and in these cases demarcation from locomotor ataxia is by no means easy, but the rapid disappearance of the spinal symptoms under treatment leaves no doubt as to their source. The relationship of neurasthenia to epilepsy, just described, leads to a clearer idea of the exciting factor of both the epileptic attack and the epileptic status.

Meynert pointed out that the epileptic status was best explained by the presence of, as he called it, a cyanid-like, or as it would be called today, a proteid body in the cerebral circulation. The researches of Féré on the urine of epileptics have since demonstrated the correctness of Meynert's proposi-

tion. The long continued action of toxins can safely be accepted as producing secondary sclerosis, and in long continued cases of epilepsy these secondary scleroses have sometimes been found. These influences of auto-intoxication in producing the various symptoms of neurasthenia and epilepsy give an excellent indication for treatment which is too often neglected. The dietetic and hygienic treatment is eminently calculated to remove many of the links of the vicious circle which tends to keep up both these conditions. Furthermore, the proper regulation of elimination by all the organs, so as to prevent undue strain on any one, is preëminently indicated. Herein is found at once the explanation and the indication of balneotherapy. The last of the eliminative factors explains the evil effects of nervins like the bromide.

THE RELATION OF AUTO-INTOXICATION TO THE PSYCHO-NEUROSES

Dr. DANIEL R. BROWER—I shall present a few conclusions which I think may be safely asserted with reference to this subject:

1. That some of the psychoses, especially those that occur in the fully developed normal brain—mania, melancholia, stuporous insanity—are the products sometimes of auto-infection.

2. That this auto-toxis in its effects on the nervous system, acute or chronic, may result in destruction of the structure and functions of the nerve cells.

3. The peculiar arrangement of the lymph channels in the nervous system makes auto intoxication possible by the blocking up of these canals.

4. The principal factors in auto-toxis are a disordered gastro-intestinal tract and renal insufficiency.

5. Dilatation of the stomach and colonic impaction are conditions producing gastro-intestinal intoxication in some cases.

6. The diagnosis is to be made, 1, by regional examination; 2, by examination of the gastric juice and contents; and 3, by examination of the urine.

7. The urine will show an increased amount of indican, diminished total sulphates, and an increase in the amount of aetherial sulphates.

8. There will also be found, in consequence of this auto-toxis, a diminished hemoglobin record and red blood corpuscles.

9. The treatment should consist of lavage, enteroclysis, gastric and intestinal antiseptics and hematinics.

THE NEUROSES IN RELATION TO AUTO-INTOXICATION.

Dr. SANGER BROWN—I am content to adopt the very concise and clear definition of auto-intoxication laid down by Dr. Evans, and yet there is a lingering skepticism in my mind as to whether it would really bear investigation. It might bear investigation in the present state of our knowledge; at the same time, there are a great many so-called auto-intoxications which we can not demonstrate, and yet may be part of something that is introduced into the system from without. As it stands now, it simply shuts out what we regard as the products of bacteria, something that the bacteria develops of itself. I do not think it is conclusively proved that bacteria necessarily do anything more than derange the metabolic processes, and that, after all, the poison of the bacteria is the result of metabolic changes. Here is a fine point that it would be hard to settle definitely. But at present, I believe it has been accepted by those who have taken part in this discussion, that gout, uremia, diabetes, myxedema, acromegaly and perhaps exophthalmus, are auto-intoxications. Limiting ourselves to those, so much importance pertains to them as nervous diseases that they are included and discussed in nearly all works on nervous diseases at more or less length, and it is mainly the functional aspects of these subjects that are dwelt upon. Now, to take up each subject *seriatim* and discuss it would consume more time than present circumstances will permit.

In a general way, it may be said that in all these diseases, the reduction they cause in the general health of the individual, and the extent to which they depress all the functions of the body, the nervous system included, tend to the development of functional disease of the nervous system, more especially if any predisposition to such disease exists. We will get in most of these conditions in people who are predisposed to hysteria, hysterical manifestations, and sometimes we will get neurasthenia. This may be said of any disease which tends to lower the vitality very much, whether it be an auto-intoxication or not. The main point for consideration in this connection is, however, the functional disorders which are peculiar to the auto-intoxications. Time will only permit the mention, not the discussion, of a few of these. In diabetes a coma often develops very rapidly, sometimes preceded by distressing dyspnea or delirium, and frequently fatal within forty-eight hours. Then, too, severe and obstinate neuralgia is not infrequent. Convulsions and coma are more frequent in uremia than in diabetes, but are less immediately fatal. Each may have to be

diagnosed from the other, and from coma due to other causes.

I will only mention the rapid pulse, flushing and local sweating of Graves' disease, and the slow pulse, dry skin and mucoid discharge from the mouth in myxedema. The active mental state of the former disease might be contrasted with the apathy of the latter.

THE ANESTHETIC AND SURGICAL RELATIONS OF AUTO-INTOXICATION.

Dr. ALEXANDER HUGH FERGOUSON—Without saying anything about anesthesia at present, I shall touch upon it incidentally in connection with the surgical relations of auto-intoxication. From the remarks that have been made, one would suppose that surgery and auto-intoxication have no relationship one to the other. I wish to point out, however, that the surgeon is as much interested in auto-intoxication as any of the other specialists. Auto-intoxication was forced upon the surgeon long before physiologic, pathologic, and bacteriologic chemistry were known. From time immemorial it was learned that certain cases operated upon did not do well after the operations and many of the phenomena shown by them have since been cleared up by the researches of pathologists in laboratories.

Auto-intoxication and its relation to general surgery is allied with the preparation of the patient for operation. It was noticed that patients who were operated upon without preparation, without thorough purgation, without the body being properly cleansed by baths and attention paid to the condition of the kidneys, did not do well afterward; that there was a tendency to sapremia, to septicemia, and pyemia; that there was a greater tendency to suppuration, and that all the waste substances in the body were not properly eliminated. It was also found that even antiseptics and asepsis did not completely fulfill the desired wish of surgeons in securing excellent results; therefore we must look to the preparation of the patient before operation and also to the after-treatment. The relationship of surgery to the excrementitious substance by the kidneys, the urine, has been known for a long time. Cases that were operated upon were immediately followed by anuria. When a patient is properly prepared there is less tendency to it. If there should be kidney complications we should call in a physician to treat and fortify the patient before operation.

Venesection and intravenous transfusion are closely related with anuria, and very frequently the surgeon deems it wise to perform venesection. It is pretty well established that second to the excretion of poisons by the kidneys themselves, it is more rapidly done by venesection than by purgation or sweating; but we can not repeat venesection many times. It is only of temporary use, and intra-venous transfusion should be done at the same time. Here I wish to report the case of a man upon whom I performed the operation of amputation above the knee joint and complete suppression of urine followed. His pulse was full and bounding. I performed phlebotomy twice with saline transfusion, and even had to do it a third time when the kidneys began to properly perform their functions and the patient got well. Of course, he might have gotten well without this, but I fancy he would not. Suppression of urine and its poisonous effects of the system is also allied to surgical procedures.

The presence of indican in the urine is brought before the surgeon in a very forcible manner, and although we are told tonight that indican is caused by bacteria, which is new to me still the surgeon even from the standpoint of auto-intoxication has to make use of it in a negative way by excluding such a thing as obstruction of the bowels. If we have complete obstruction due to strangulation, then we have indican in the urine, while in coprostasis we are likely to have none. A good deal more might be said regarding the surgical relations to the excretion of urine, but we will pass on and briefly consider bile.

The surgery of the gall bladder and bile ducts is to be considered in connection with auto-intoxication from bile. When the common duct becomes obstructed with gallstones the bile is absorbed, threatens the life of the patient from cholemia, and the surgeon has to give relief by performing an operation. The bile is poisonous; it produces a true toxemia, and were it not for the modifying influence of the liver upon it again, death would shortly ensue. It is mentioned, I think, by Roewell Park that the liver secretes sufficient poison in eight hours to kill the individual. The excrementitious substances in the bile, particularly the toxic portions of it, have been made the subject of a good deal of investigation. We know that chloroform is taken very badly by patients who are poisoned with bile or with urine. We know, too, that hemorrhage is much more liable to take place from operations performed upon patients who are cholemic.

When we come to the alimentary canal, there the definition that has been laid down by Dr. Evans is very clear, but too restricting. Entero-intoxication and entero-sepsis are so closely associated that I think it would be difficult to draw a sharp, practical line of demarkation. For instance, in a case of ileus, how are we to tell whether it is an auto-intoxication that causes death? We operate on a case of strangulated hernia the blood returns to the parts, but the patient dies not from inflammation as the postmortem shows and the surgeons call it auto-intoxication. How are we to tell whether that poisoning is caused by the germs which happen to be present in the alimentary canal, or whether it is caused by the absorption of partially digested food and the reabsorption of the secretions and excretions pouring into the alimentary canal. This is a snag which I think we are compelled to take cognizance of. There is another form of auto-intoxication which I should like to mention briefly, and that is the form which follows aseptic operations, which we now designate for want of a better term, surgical fever. Notwithstanding that the work was well done, we find a certain amount of fever following operative interference. This fever comes on soon after the operation; it reaches its acme in a short time and passes away about the third day. At present we attribute it to absorption of the secretions which have taken place into the wound cavity from the blood and tissues. This form of intoxication is brought before the surgeon more or less frequently, and it was in fear of this surgical fever predisposing to sapremia and to septicemia that drainage was so freely resorted to by surgeons in the early days. Since the antiseptic era began surgeons went to the other extreme and used no drainage at all, but we have more surgical fever unless we employ some method of drainage, and now we resort to capillary drainage in large wounds. This form of constitutional disturbance may be caused by the absorption of the fibrin-forming elements. That is what I have been teaching; I do not know whether I am correct or not.

Chloroform disturbs the digestion, interferes with the secretions of bile and urine, causing auto-intoxication. It disturbs the alimentary canal and causes auto-intoxication, which a free purge clears away. The system is already engorged with effete matter and there is an extra tax on its eliminating powers. Auto-intoxication in this connection predisposes to suppuration, sapremia, septicemia, etc.

In regard to urethral fever we know that soon after passing a catheter or after doing an operation upon the urethra, there is no fever, until the urine passes over the raw surface. It may be in a few hours the temperature runs up to 103 or 104. If the catheter be retained in the bladder, we have no urethral fever until the catheter is removed and the urine comes in contact with the raw surface. The question before us is whether this fever is due to the absorption of poisonous materials in the normal urine, or the germs of ptomaines which may be present in it.

Another subject that has been attracting the attention of surgeons of late years, is the thyroid gland. Whether the thyroid gland secretes that colloid material which is always inside of it for the purpose of body metabolism or excretion, the two theories being put before us, I am not prepared to say. The close relationship between exophthalmic goitre and the condition of the thyroid gland, probably causing an auto-intoxication, is not clear. Surgeons have been so bold as to cut down and remove a portion of the thyroid gland for exophthalmic goitre with good results. Some surgeons claim to have had 50 per cent. of successes. So that the subject of auto-intoxication is forced upon the surgeon at every turn. Even in the surgery of the prostate gland, I do not know but that auto-intoxication may have something to do with it.

There is perhaps no doubt that rickets is caused in a measure by malnutrition. The various deformities in children caused by rickets such as coxa vera, genu valgum, and so on, may be directly or indirectly influenced by some form of auto-intoxication.

PEDIATRIC RELATIONS OF AUTO-INTOXICATION.

Dr. ROSA ENGELMANN—It is difficult to discuss this subject within the limitations assigned by Dr. Evans, since he excludes a bacterial genesis of the auto-intoxications. My conception of the gastro-intestinal diseases of children has been that of an auto-intoxication, namely, a poisoning within the body, from food decomposition to begin with and a later and consequent cellular perversion. I can not see how the question of intestinal intoxication can be at all discussed without including the decomposition of foods and the relation of the body through the intestinal canal to the outside world. I can not see why the pathologic cellular metabolism in this location is not as much of an auto-intoxication as the poisoning from a syphilitic tumor of the brain, for syphilis comes from without.

A cell perversion and toxemia obtains in the first as well as in the second instance, except that the one has a closer, but more superficial connection to external causes. The results of pustulation in smallpox was mentioned as an auto-intoxication. Is it not true that the pyogenic germs in the skin simply penetrate a region of minor resistance, namely, come from without as truly as do the many intestinal bacteria, perfectly innocuous until some perversion or disease of the intestinal mucous membrane causes them to assume a pathogenic role?

Another speaker named the auto-intoxication of rickets as productive of the bone lesions. We know nothing of the etiology of this disease and can as well speak of the lesions of any and all diseases as auto-intoxications, for whatever produces diseased cell action will produce diseased cellular products for absorption. I am, therefore, with those members of the society who believe that the line has been too closely drawn.

AUTO-INTOXICATION IN RELATION TO THE JAWS AND TEETH.

Dr. EUGENE S. TALBOT—From what has been said to night we might say that the entire practice of dentistry is based upon the results of auto-intoxication, including the initial cause of decay of the teeth and all diseases resulting therefrom. School-strain, over-work, mental anxiety, mental and spinal diseases, such as parietic dementia, locomotor ataxia, injuries to the spine and improper mastication of food, producing trophic neurosis and also affect the peripheral nerves to such an extent that decay attacks the teeth with more vigor and disastrous results. Abrasion and erosion of the teeth are also due to these causes. After the pulp becomes exposed, toothache with neuralgia, extending over the face, the head, neck and sometimes arms takes place. When death of the pulp occurs, alveolar abscesses form and pus may accumulate in remote parts, frequently producing blood poisoning, as observed in similar conditions in other parts of the body. Deposits of tartar, scurvy, mercurial and lead poisoning, produce pyorrhea, with destruction of the peridental membrane and alveolar process, thus causing the teeth to loosen and drop out.

Diseased teeth and gums produce indigestion and fermentation in the stomach and small intestine, due to a want of proper mastication and proper hygienic condition of the oral cavity. Thus we have malnutrition and trophic neuroses affecting all parts of the body.

The teeth and jaws, unlike other structures of the body, register their defect, due to auto-intoxication in the mother and after birth in the child. They remain living examples throughout life of malnutrition and the date of such poisoning.

Deficiencies in nerve centers produce excessive and arrested development of the jaws and teeth. Inherited diseases produce malformed teeth, hastening decay. Thus defects in tooth structure produce malnutrition and vice versa.

TREATMENT OF OBSTETRIC RELATIONS OF AUTO-INTOXICATION.

Dr. WM. H. RUMPF—The various forms of post-partum infections, as also the intoxications arising from death of the fetus, might well be classed under auto-intoxications, but I shall confine my remarks only to the condition known as eclampsia.

At the International Gynecological Congress, held at Geneva in September of last year, the question of treatment was thoroughly discussed by various authorities, and it may be of interest to note a few of the conclusions arrived at. We must formulate our methods of treatment in accordance with the practical experience of those who have large clinical material to work with. Charpentier of Paris, sums up his experience in the following sentences:

1. As on the one hand every pregnant woman whose urine contains albumin is in danger of eclampsia, and on the other hand, an exclusive milk diet in Bright's disease and the common nephritis of pregnancy has given excellent results, it is necessary to examine the urine with the greatest care and on the least suspicion of albumin insist on an exclusive milk diet.

2. In all cases of eclampsia venesection is indicated when the patient has a robust constitution and is cyanosed. After that chloral hydrate with milk per os, or if necessary stomach tube, gives the best results.

3. The eclamptic attacks themselves are best subdued by chloroform: at the same time diuresis should be increased by subcutaneous injections of normal salt solution.

4. If the patient is weak, the cyanosis less pronounced, and the attacks infrequent, the chloral treatment alone should be tried. Whenever it is possible, the confinement should be allowed to continue without artificial help. Premature labor should be induced in the most extreme cases only.

Halbertsma, of Utrecht, arrives at the following:

He recommends an active procedure in the following cases: *a*, When the prognosis is very grave in consequence of very frequent and very pronounced attacks or complete anuria. *b*,

When good reason exists to believe that labor pains will not begin, or that the pains will last a very long time as in old primipara, twins or narrow pelvis. *c*, At the end of pregnancy, under the above conditions, Caesarean section should be performed. He also advocates deep cervix incisions to increase the labor pains when there is a possibility of a spontaneous birth.

Veit, of Leyden, concludes:

1. It is impossible at the present state of our knowledge of the etiology of the disease to recommend any definite treatment of eclampsia. A large number of cases certainly get well with any kind of therapy.

2. The proof that a forcible termination of labor with rubber dilators, cervix incisions, Caesarean section, etc., visibly improves the prognosis, has not yet been brought.

3. The reported results of venesection are not sufficiently numerous to be able to judge of its merits.

4. The results obtained by systematic treatment with large doses of morphia seem to be the most satisfactory.

5. As long as the pathology of eclampsia is undecided we can not decide upon any rational therapy. It is very probable that there are various etiologic factors that produce it.

6. Hastening delivery without endangering mother and child, as rupturing the bag of water, forceps after complete dilatation, giving large doses of morphia to lessen the attack, avoiding all food by mouth in patients who are unconscious, and exciting diaphoresis by external means, promise the best results.

7. There is no reason for regarding eclampsia as a cause for some immediate active procedure and to recommend dangerous operations which are not in the scope of the general run of physicians.

In conclusion, I should again lay particular stress on the prophylaxis. Examine the urine frequently from the first months of pregnancy, and at the least indication of albumin or of edema, order an exclusive milk diet, diuretics and mild salines. When the symptoms of eclampsia have arisen, I should incline rather to procrastination and conservatism than to radical operative procedures. We must not be misled by a few brilliant results from one particular form of treatment. Many cases get well with no medication, you might almost sometimes say in spite of all medication, and it is difficult to say whether venesection, veratrum, chloral, or whatever agent may have been employed, is the real cause of the cure. When our methods of chemic examination of the blood and urine will have been more perfected, and when we have a clearer understanding of all the etiologic factors at play, we shall be able to find a more rational therapy.

SELECTIONS.

Diagnosis of Malarial Fevers.—Dr. William Osler, in the *Medical News* for March 6, treats of the diagnosis of malarial fevers. He prepares his way by declaring his belief as to the undeniable facts that have great clinical interest. Whether his fourth postulate is as firmly founded as the others will be a question to stir up those who deal in the statistics in our boards of health. The four postulates are: "1. It was the disease best known to the old Greek and Roman physicians, some of whom gave very clear clinical pictures of the chief varieties. 2. It remains, after 200 years, the only acute infectious disease for which we have a positive specific. 3. It is the most important known disease due to protozoön parasites. 4. North of Mason and Dixon's line physicians are prone to diagnose malaria for other diseases; south of the line they are more prone to diagnose other diseases for malaria: in both regions it is a source of greater errors in vital statistics than any other affection."

Dr. Osler considers the rarity of a double infection by the hematozoa and bacillus of Eberth. He has had 1,500 cases of malarial and typhoid fevers, passing through his wards, nearly every one of which has had a careful blood examination; and only one case of dual infection was detected. It is an important subject and it is well worth while that in doubtful cases coverslips be preserved for examination by an expert.

"Certain symptoms, particularly chills and sweats, are prone to deceive the physician who has not learned to recognize them as not infrequent events in typhoid fever, associated with complications or with septic infection. I need scarcely here refer

to other forms of irregular malarial fever—the more pernicious types. They are not very common with us, though in the autumn we have to be on guard constantly to avoid mistakes, and we have, as a rule, one or two fatal cases a year.”

In his last paragraph he treats of what he curiously styles the “spurious malaria of the health boards,” meaning the supposed inexact diagnosis of physicians whose certificates of death are uncritically accepted by the registration officers of boards of health. The registrars of New York and Brooklyn are especially referred to, but we “suspect,” to use Dr. Osler's own verb, that they are not sinners above others, the certificate of death being seldom anywhere the subject of verification, except possibly where malpraxis or other criminality or vagueness is surmised. But this is Dr. Osler's view of the case:

“What is spurious malaria (meaning malarial fever)? I do not know. One form of it—the health board form—is a serious and very fatal disease, killing according to the last United States Census Report in New York city as many persons as does typhoid fever; in Brooklyn about one-third as many more. I suspect the Eberth bacillus, not the plasmodium malaria, is responsible for the major part of these cases. Other maladies, a motley host, from headache to biliousness, from keratitis to chilblains, are attributed to ‘a touch of malaria.’ Any slight ailment with a periodic tendency, any dubious trouble for which a diagnosis is not forthcoming, is put in the same category. While I do not deny that in regions where malaria is endemic and everybody comes under its influence, many obscure troubles follow in its train, I claim that the fatal forms have become so rare that no health board should take a death certificate signed ‘malaria’ without investigation, and, lastly, that the widespread belief in an occult influence of the disease, in masked forms, and the modification by it of other affections, has no rational basis of support. It is just eleven years since I began the study of malarial fever in Blockley Hospital, Philadelphia—a skeptic as to the value of Laveran's work, to which attention was called in this country by Surgeon-General Sternberg and Dr. Councilman. I soon became convinced of its truth, and the results of my study of seventy cases was published in 1887. Since that time, at certain seasons, I have had almost daily opportunity to see malarial fever, and I have of late years been fortunate in having as my associate Dr. Thayer, who has made a special study of the disease, and in Baltimore has kept us in touch with the progress of knowledge in this department. A widened experience has only served to strengthen the conviction that in the practical diagnosis of the infectious diseases, the discovery of the hematozoa of malaria by Laveran takes rank with the finding of the tuberculosis bacillus by Koch.”

Medico-Legal Testimony in Cases of Drowning.—Professor Brouardel, the dean of the Paris faculty, commenced a series of lectures on Medical Jurisprudence in 1895, which may possibly prove the crowning work of his career. He is devoting a year to each of the following subjects, and hopes to complete the series with the century: 1. Death and Sudden Death. 2. Asphyxia. 3. Hanging, Strangulation, Suffocation and Drowning. 4. Explosions. 5. Infanticide. He is considered the greatest living authority on Medical Jurisprudence in Europe, and his experience is based on innumerable observations, experiments and researches, assisted by the light of recent discoveries in science, which have thrown light on many subjects still inexplicable even in Tardieu's day: We translate his lecture on drowning in full as it appeared in the *Jour. de M. de Paris*, January 3.

The expert is summoned to state whether the person was drowned accidentally or committed suicide, or whether it is a case of homicide.

1. *Accidents.*—Generally speaking, when a person is accidentally drowned, the presumption is that there should be no traces of violence on the body. But there are cases in which they are found and incorrect interpretation of them has led many an expert to false conclusions. When a body is taken from the water, naked, and without traces of violence, the presumption is inevitable that the case is an accident. But it sometimes happens that persons are accidentally drowned

under circumstances that convey the idea of homicide. Chaussier describes the case of a man found lying in the road with his face in a rut filled with water. Devergie relates a similar case, an individual drowned in a ditch containing only a foot of water. Another person, mentioned by Taylor, was drowned in a little melted snow. Tourdes also relates the case of a soldier who fell from the top of the ramparts at Strasburg into the fosse, which was frozen over, breaking the ice with his head as he fell, and drowning with absolutely nothing but his face in the water. In these cases the persons were drunk, and they were not only unable to rise, but even to make the slightest movement which would have removed them from danger. Similar accidents may happen to epileptics falling during an attack, or to persons seized with vertigo, or temporary loss of sight. Drunkards can even be drowned in their own vomit. An individual is found drowned, his head lying in a little water; the rest of the body is free. Is it an accident, a homicide or a suicide?

It is easy for a strong man to plunge and hold the head of a weak person in a pail of water. Should we therefore conclude that it is a case of homicide? Not absolutely. One old woman had the courage to drown herself by plunging her head into a pail of water. A letter she wrote just before committing the deed left no doubt as to her intentions. One can even be drowned with only the nose and mouth submerged. Even in cases of accident, traces of violence may be found on the body, which may have been acquired before, during or after the fall into the water. It is possible that the individual may have been engaged in a brawl the day before. It is necessary to be able to differentiate between the lesions made anterior to the submersion and those which may have been made at the moment. You know the story of the two students who had invited a couple of girls to supper. One of them becoming unbearable, they took her home, each holding her by the arm, as policemen take criminals to the station. When the girl awoke, in despair at finding herself cast off, she went and drowned herself in the canal. The police carried the body to the morgue as the arms were covered with ecchymoses. I performed the necropsy and testified that the ecchymoses had been made while she was alive, probably several hours before death; they were clear and circumscribed, but there was a slight suffusion around them, an extension produced by blood which had begun to change color. To determine the age of ecchymoses we have only vague data. In these cases we can only find our opinion on what we observe in the ecchymosis that follows a blow on the eye. “A black eye” varies in its dimensions and coloring for twenty-five days. It first presents a radiating aspect and a black coloration, after which it turns blue, then green and finally yellow, like bile, as the extravasated blood changes its color. Virchow has established the fact that in ecchymoses the final coloration of the blood is identical with that of the bile. When you find colored zones encircling ecchymoses you can assert that they were made prior to the drowning.

A person may make lesions on himself by falling into the water and they may be more or less serious and more or less singular. Taylor relates the case of a man who dived from London Bridge into the Thames. Instead of holding his arms together above his head as customary, he leaped into the water with his arms spread like a cross, dislocating both humeri. I have frequently had occasion to note the existence of fractures and enormous sanguine suffusions on the drowned. I remember especially one case. He had jumped into the water from the top of a bridge and struck his shoulders against the side of a boat. The ribs were fractured and there was a large accumulation of blood in the dorsal region. Sometimes the person falls on pointed objects, or on stones below the surface of the water. In other cases the skull is fractured by hitting the bottom of the river, shallower than anticipated. Tourdes relates the case of a man who was diving when another person dived on top of him; the contusions were very violent and he was only revived with great difficulty. Even after death the victims of an accident might receive lesions. In certain rivers, the Seine particularly, where there are numerous ferries, singular accidents might be produced in this way. Delens has published a very interesting work on the subject of the fractures and osseous lesions that are found on bodies taken from the Seine. His purpose was to prevent the errors in expert testimony which had been due to this cause. One case he describes was that of a body taken from the water, with a lesion of the mastoid apophysis, perforation of the parietal bone, and lesion of the breast, as the expert ascertained. Drawing his conclusions from these facts he deduced a crime and asserted that the individual in question had been stabbed in the breast and afterward shot, the bullet entering by the mastoid apophysis and emerging through the parietal bone. He failed to notice that the wound in the breast was 21 cm. long,

which is rather extensive for a stab wound. He also overlooked the fact that the mastoid apophysis was not fractured but worn through, and that the parietal bone had not been perforated. He also failed to notice that the fourth and fifth cervical vertebræ had disappeared. It was not difficult to explain these lesions; the idea of a crime should have been abandoned at once. The body had been caught on some towing chains and the movements of these chains had gradually produced the lesions, by friction. Delens relates other cases of the same description. I have seen entire limbs cut off by the screws of steamboats; the body of an infant was completely emptied of its viscera, in one case, by the stroke of a paddle wheel. Bodies may be dashed against the piers of a bridge; they may be mutilated by an oar or boat hook, or the grappling irons with which they are taken from the water. The body may be caught between two boats at the moment it rises to the surface of the water; it may be caught in the lock of a canal or mill dam and the head or a limb be cut off. After the Billoir murder when the victim was cut up into small pieces, every mutilated cadaver taken from the water was assumed to be a crime of the same nature.

I wish to call your attention to one other point; a lesion which is not made in the water, but which it is important to bear in mind. When a drowned person is taken from the water, attempts are made to restore him to life. If he has not been too long in the water, he is frictioned vigorously. These frictions rub off the epidermis and in the course of a few hours the body assumes a peculiar aspect which might mislead an inexperienced expert, causing him to ascribe them to lesions which do not exist in fact.

2. *Suicides*.—The presumption is also that there should be no traces of violence in drowning from suicide. But in reality all the lesions I have just been describing may be found on the body, and others besides, which it is well to note. In England the women who commit suicide by throwing themselves into the water, often wrap their heads in their skirts, and the impression arises that they might have been suffocated and then thrown into the water. Persons are found drowned with their members tied in front or at the back; sometimes the arms are tied to the legs. This suggests again the idea of a murder, but I do not believe that murderers could tie their victims in this way without considerable trouble, unless they had previously made resistance impossible, and in that case traces of violence would be found on the body. These ligatures must be regarded as precautions taken by the person who wishes to commit suicide. He knows that he can swim perhaps, and mistrusts his ability to resist the instinct of self-preservation. Other suicides have been known to tie a stone or a heavy weight with a rope around their neck, to prevent the body from rising to the surface. The neck in these cases show the mark of the rope. Tourdes relates the case of a student who drowned himself after fastening a 25 pound weight around his neck; the body remained seventeen days in the water. The mark of the rope is not very evident as long as the skin is still softened from the effect of soaking in the water, but it grows more distinct and shows a deeper groove as putrefaction swells the cellular tissue.

It is important also to note the presence of the menses. Tourdes states that one-third of all the women he has examined who had drowned themselves, were found to be in the menstrual period. Some women at this period are peculiarly depressed with melancholy, even maniacal ideas, which may lead them to commit suicide. Double or family suicides present no medico-legal complications.

3. *Homicides*.—It seems as if the assassin must be much stronger than the victim to drown a person. However, this is not necessarily the case, as the victim may be taken unawares, and pushed into the water without a chance to defend himself. Casper mentions a case where a husband and wife were seated on the brink of a river, quietly conversing. Suddenly the husband pushed the wife, who fell forward into the river and was drowned. There was not a trace of violence on the body. *It is well never to reply in a positive manner to the question of the authorities in such cases.* Never say: "There are no traces of violence, consequently there has been no crime." Nor: "There are signs of violence, consequently there has been a crime committed here." Be satisfied to reply: "There are traces of violence. They can be explained variously." Or: "There are no signs of violence." Leave it to the authorities to interpret the facts you present. That is their task, not yours. As an example I mention a case that occurred a few years ago. A young man was found drowned in the Seine. The body showed no indications of violence, and the medical expert who examined it stated in his report his conclusion that it was a case of accidental drowning. It was not an accident, it was a crime. The young man had been amusing himself with another by

climbing on the parapet of the quay, and his companion had suddenly pushed him into the water. The scene had been witnessed by others who testified to the fact. The medical expert therefore, who had been so positive in his report, found himself in an awkward predicament.

I had a similar experience recently when summoned to testify in the case of the Marquis de Nayve. You remember that the Marquis was accused of having murdered the young Menaldo, as the husband killed his wife. The Marquis had been out with Menaldo all day, and in the evening they reached an elevated spot on the road between Naples and Sorrento, where there is a sheer descent of 30 meters to the sea. Menaldo's body was found at the foot of this precipice. I was asked to state whether it was an accident or a homicide. It was too late to inspect the body. The report of the Italian medico-legal expert described the lesions that had resulted from the fall; fracture of the arm and fracture of the skull, such as characterize falls from an elevation. I stated that it was impossible for me to form a decision from the evidence. The question was also asked in this case whether a young man of Menaldo's age could have contemplated suicide. We know that the suicide of children is unfortunately by no means exceptional. The idea was also suggested that Menaldo might have been the victim of pederasty followed by assassination. The first expert asserted thirty-six hours after death, that all organs, especially the anus and penis were in perfect condition. The second expert who saw the body three months later, stated that the widely dilated anus denoted long established habits of passive pederasty. When gaseous putrefaction occurs, it dilated the anal orifice and obliterates the folds. By the end of three months all the characteristics of the skin and the rectal mucosa are effaced; all is uniformly green.

Homicide by drowning is frequently the result of a surprise. Hencke relates the case of a man who after seducing the daughter, invited the father to supper, under pretext of a reconciliation, and took advantage of his intoxication to push him into the water. The case is also known of a lad of 10 years in a boat with his weakly 5 year old sister; he lifted her in his arms and threw her into the water.

Zacchias remarks that a *necropsy imperfectly performed can never be performed over again*. This axiom should be graven on the memory, as it is of the utmost importance. An instructive instance is the case of a wealthy butcher who had retired from business and settled down at Cabourg. One day he went crab-fishing with his housekeeper and drowned her by holding her head under water. Some fisherwomen, behind a rock near by had witnessed the scene, and exclaimed: "That man is drowning that woman." The butcher went home alone, followed at some distance by the fisherwomen who wanted to find out where he lived. One stayed near the house, while the rest went to inform the mayor. He came and asked the man what he had done with his housekeeper, and finally had him arrested. The woman's body was found next day at low tide. A medical expert from Caen, inexperienced in such matters, stated that the woman had been drowned. His local colleague was astonished that the expert did not perform the necropsy, and that he did not consider worthy of notice certain lesions on the chin and lower part of the face, but assumed that these were caused by crab bites. He opened the chest, found the lungs congested, but did not remove them from the body and considered his diagnosis of death from drowning established.

Skin from the chin was sent to me for examination. I found it covered with small irregular excoriations, with a sanguine suffusion in the subcutaneous cellular tissue. It was evident to me that these small wounds had been made by the skin having been pressed violently against some hard and irregular substance, such as sand. I have repeated this experience on cadavers and have always secured the same cutaneous lesions, but of course without the suffusion of blood. When the affair came into court, something very instructive for us happened. The lawyer for the defense asserted: "This woman died of cerebral hemorrhage, and I defy the experts to prove the contrary!" As the necropsy had not been made, they were unable to bring any proof to the contrary, and it was even impossible to prove that the woman had died from being drowned. The medical experts connected with the case were severely censured by the authorities. The moral to be drawn from this affair is, always to perform a complete necropsy when such a case is placed in your hands, no matter what the evidence of the facts may be.

As a general thing the affair is not a homicide by drowning, but the victim is thrown into the water to conceal a homicide. A few years ago Mme. Penayrou, wishing to be relieved of Aubert, who was her lover, accompanied him to Chatou with her husband and her brother-in-law. Like a thrifty woman, she bought return tickets for herself and her family, but only a ticket one way

for Aubert, who was not to return. In their house at Chatou Aubert was killed by being pounded on the head with a hammer, and Fenayrou, drawing a sword cane, passed it three or four times through his heart, "that heart which has caused me so much sorrow!" as he exclaimed. To get rid of the corpse, they removed the clothing and wound around it 8 meters of lead pipe the size of gas piping, and threw it into the Seine from the bridge, never expecting to see it again. But in eleven days Aubert was found floating on the water near Pccq, dragging his 8 meters of lead pipe with him, buoyed up by the might of gaseous putrefaction. If Fenayrou before throwing him into the water had made an opening into the abdomen, the gases of putrefaction would not have accumulated there and altered the specific gravity of the body. It would have remained at the bottom of the river and Aubert would probably have vanished for ever. I relate this affair to show you the rapidity and power of gaseous putrefaction. The F'ualdés sensational affair in 1817 was due to this cause. The victim was bled to death and the corpse thrown into the water, where it came to the surface in a few days.

One point more. When a physician without much experience in expert medical work is summoned to examine a body found in or near water, he prefers to accept the case as a drowning. If the body is putrefied, he shrinks from the necropsy. As an instance I mention the case of two physicians of La Manche, summoned to examine a body that had been found on the ground with the head in a pool of water. They concluded—without investigation—that the case was one of cerebral congestion, which had caused the person to fall into the water, when death had ensued from suffocation. The authorities, however, were informed of other details which rendered the assumption of a crime probable. Another expert was summoned, who was amazed that any one could draw the conclusion of cerebral congestion without having opened the cranium, which he proceeded to do, ascertaining that it was fractured. The two physicians were arrested and prosecuted for false testimony. This is the only instance of criminal prosecution on record in medical jurisprudence. They were acquitted on the ground that an error had been committed in entrusting them with a task which they were incapable of properly fulfilling.

4. *Survivals.*—The question arises when several members of a family lose their lives in an accident: Which member of the family survived the longest? It is often to decide the question of inheritance that medico-legal advice is sought, and this question seems to be the prerogative of accidents from drowning. In an accident that occurred between Honfleur and Havre, more than 200 persons were drowned—whole families wiped out of existence—and medico-legal testimony became of great importance to decide the settlement of estates. Fortunately for the expert, who is often unable to form any opinion in the matter, the French law states explicitly that when several persons due to succeed each other in turn all perish in the same accident, . . . the presumption is that survival depends upon the strength of age or sex. . . . If those who perished were all under 15, the presumption is that the oldest survived the longest. . . . If they were all over 60, the presumption is that the youngest survived. . . . If some were under 15 and others over 60, the presumption is that the former survived the longest. . . . If those who perished together were over 15 and under 60, the presumption is always that the male survived the longest, when the ages are equal or when there is only one year's difference. . . . If they were of the same sex, the presumption is always in the order of natural succession, that the younger survived the elder. . . . The presumption that under 15 the oldest survives, is contrary to the experience of science, which shows that infants survive longer than adults, especially in submersion.

The Levainville case is an example of the questions that arise in such cases. M. Levainville was mayor of Finisterre. Accompanied by his wife and daughter and others he went for a walk along the shore in very stormy weather, in October, 1870. The whole party ventured out on a narrow strip of land to an abandoned coast-guard building. A tremendous wave broke over the peninsula and washed away seven or eight persons, among them his wife and daughter. All perished. According to the law, if Mme. Levainville died first, all her property passed to her daughter, and from her to her husband. But if the daughter died before the mother the property reverted to Mme. Levainville's family and the husband did not inherit. The code referred to above was applied in absence of knowledge of the fact and the daughter was assumed to have survived the mother, and Levainville was declared the inheritor. The wife's family protested and Tardieu was summoned by them to investigate the case. Strange to say, his investigations established the fact that the wave did not sweep the

whole peninsula simultaneously, but dashed over one part of the crest and carried off the group there before it swept the rest. The mother was in the first group and was dashed against the wall of the building. The authorities therefore decided that the mother died first, as she was swept away first and the severe lesions she received must have hastened her death before the daughter perished.

I was consulted in an analogous case. A husband and wife were boating in a small river when the boat sank and both were thrown into the water. The husband was seen struggling on the surface again and again, trying to save his wife, and then both disappeared. The question of inheritance then arose. Should the property pass to the husband's family or to that of the wife. Beauvais testified that the wife must have died first and the husband afterward, as he rose several times to the surface. The wife's family resided at Marseilles, and experts there testified that a person struggling at the surface drowns sooner than a person lying in a syncope at the bottom. They asserted that the wife survived the husband. I was called upon to decide the case, but I declared that I could not find anything in the evidence submitted to decide the case either way. It was possible that the wife may have been in a syncope, but there was nothing to prove this and no necropsy had been made. The general trend of opinion, however, was in favor of the husband's family, and the families finally compromised the matter out of court. It would have saved them considerable trouble and expense if they had done this in the first place. I do not wish to criticise the opinions of the experts who had preceded me, but I want to warn you against what I may call moral influences; it is very easy to allow one's self to be convinced by the arguments of the interested party who lays the facts before you, presenting them in the most favorable light and biasing the expert's opinion unconsciously to himself. In cases of this kind we must have courage to state frankly that we can not decide; we do not know, and let the articles of the code be applied. Tourdes in his excellent article in the "Dictionnaire Encyclopédique" gives some points on which a decision of the kind may be based, but they are not satisfactory. He says that we must bear in mind the relative strength and emotivity, and that the most impressionable are the most likely to survive as they are the most likely to succumb to syncope. Heart disease or any previous affection of the kind diminishes the resistance. He believes that a woman would survive a man as her garments would buoy her up for a while. Fodéré asserts that persons who know how to swim survive those who do not, which is evident. In accidents at sea we must ascertain, if possible, which person had life-saving appliances, and if they were injured by falling upon rocks.

These are all the data I can give you upon which to found your decision. In the vast majority of cases when you are summoned to decide the question of survival all you can do is to state your inability to decide the matter, and say frankly: We do not know.

Dr. Hughes on "Homeopathic" Physicians to the Insane.—Dr. C. H. Hughes makes the following reply to the contentions of Dr. W. A. Wilcox, the homeopathist, with regard to introducing homeopathic treatment in the Missouri State insane Asylum at Fulton.

"I make no war on homeopathy. I plead only the rights of the insane. And what I claim I concede. It is the insane man's right in a State hospital to have such medical treatment as he would have chosen for himself when sane and free to choose. Where the institution can have but one medical head, the rights of the majority interested should rule in the selection. The minority interest might be provided for in an annex institution restricted to homeopathic practice for the followers of that faith only. It might even be justifiable for the State to construct and provide a new institution conducted on that theory only, if it be sound policy now to do so after the light of clarifying science has dawned so full and free and with such dissipating force on this quasi-therapeutic delusion of the past, when visions of the fancy and fanciful personal 'provings' rose out of the scientific darkness of the first decade of the century.

"The searchlight of scientific observation and deduction has dispelled the delusion that disease implicates the spiritual nature of man; that drugs contain spiritual essences or dynamic potentialities evolved by trituration and dilution, and not sufficient of the apparent law of *similia* now remains on which to longer justify the maintenance of even the semblance of a sectarian medicine.

"Today in other States, as in New York, the more enlightened homeopathists have forsaken this dogma as an exclusive tenet of medical practice, dropping their distinctive homeo-

pathic designation, which is more suitable as a business man's trade-mark than as the proper title of a doctor of medicine, and, practicing on the broader precepts of a more liberal practice, simply as physicians, they are admitted to equal fellowship with the regular practitioners. The law of *similia similibus curantur morbi* had some appearance of a truth in therapeutics at the time that Hahnemann published his organum 80 years ago. But the revelations of physiologic science and the provings of biologic experiment, the lens of modern bacteriology and the crucible of bio-chemistry have enabled all but the blind to see the fallacy of the Hahnemannian law and the foolishness of the homeopathic dictum, 'the smaller the dose the greater the effect.' The high potentist is a *rara avis* now, even in the ranks of homeopathy.

"The present asylums were provided for under regular medical auspices. The newer school of scientific medicine, always called the old school, or allopathic school by sectarian physicians, was instrumental in providing them for the mentally afflicted of the State, just as it was the first to strike the shackles from the lunatic, bringing him from his darkened and neglected dungeon into the light of day, and treating him as a mentally maimed and afflicted friend and brother.

"Regular medicine refuses to be dominated by any exclusive dogma, visionary theory or rule of practice as too restrictive, inadequate and unscientific in the light of modern medical progress for a profession whose mission is to rescue and restore by all and every possible means potent to save.

"If the believers in homeopathy or any other theoretical system of sectarian medicine wish a State institution founded for their benefit, the proper way to secure one is to induce the Legislature to vote a new building for that purpose. The homeopathic asylum at Middleton, N. Y., was built for such purpose by authority of the Legislature of that State as an exclusive homeopathic institution. It was not built as a regular institution, then seized and appropriated to homeopathy with its hundreds of inmates and thousands of tax-payers supporting it, all opposed to the system, yet forced to accept homeopathic ministrations.

"In the present instance it is proposed to seize and divert to a purpose not originally designed, without due notice or legislative action. Governor Stephens will not on mature reflection I think do this. To seize the Fulton Asylum for the purpose proposed would be executive robbery and assassination of the rights of the insane there domiciled.

"The relative merit of homeopathy and regular medicine is not the question. Nor is the question one of 'crushing truth to earth'; nor of curing by similars or contraries, but of justice to the insane now in the Fulton Asylum. Nor are my qualifications as an alienist and neurologist germane to this question though I hold a parchment, not held by any other in this vicinity, of honorary membership in the British Medico-Physiological Association, never that I know of bestowed upon the unqualified, unless it be in my own case.

"My friend, Dr. Wilcox, was a pretty good regular practitioner before he put the new wine into the old bottles of regular medical experience. He practiced the regular way the best he knew how, pretty much, as he does now. In fact, most of my homeopathic medical acquaintances who have achieved success in practice in this city have been regular practitioners and do not disdain to use the elegant tabloids and tablets hypodermically, and the alkaloidal pilules of modern regular medicine. They are naughty fellows and steal our thunder and ought not to do it, and call it homeopathy. But they do it all the same.

"But in medicine as in theology a man may go in as a hard-shell Baptist and have to stay with his brethren, even though his views of salvation may broaden as he grows older in Christian experience."—*St. Louis Republic*.

PRACTICAL NOTES.

The Antitoxic Power of the Thyroid Gland.—Recent experiments on dogs have shown that after extirpation of the thyroid gland toxic substances are found to much greater extent in the circulation than before, and that administration of thyroid extract will diminish this amount.—*Cbl. f. Chir.*, March 13, from *Rivista Md. e Terap.*, 1896, No. 9.

Menorrhagia due to Uterine Arterio-sclerosis.—Reinicke has become convinced by the information derived from several necropsies that menorrhagia is frequently produced by sclerous degeneration of the uterine arteries. The impossibility to contract is therefore the cause of the continuous sanguine flow

from the arteries, and the usual methods of treatment are necessarily impotent. He states that the failure of ergotin to arrest the flow may be considered presumptive evidence of the sclerosis. The only cure is ablation of the uterus. Except in very severe cases, he advises waiting for the menopause, with repose in the horizontal decubitus if possible, and vaginal tampons in the case of workingwomen.—*Semaine Méd.*, March 17.

Coccionella in Whooping Cough and Asthma.—A Swiss physician has found in an experience of 80 cases that whooping cough disappeared in six to eight days with the following treatment. It also relieved bronchial asthma when all other remedies had failed: Coccionell. sub. pulv., 0.05 to 0.2; ammon. carbon., 1.0 to 2.0; syr. aurant., 20.0; aq. dest. q. s. ad 100.—*Therap. Woch.*, March 7.

Treatment of Metritis with Intra-uterine Applications of Aiolol.—The simplicity and harmlessness of this treatment recommends it as well as its efficacy. It does not require repose in bed, and the improvement is manifest in a couple of days. A tampon moistened with an emulsion made of 4 c. c. of glycerin mixed with 1 gram of aiolol, is inserted into the cervix, $\frac{1}{2}$ cm. from the external orifice, and the vagina plugged with a large cotton tampon dipped in the same emulsion diluted one-half with glycerin. Extreme gentleness in dilating the cervix and antiseptic precautions are imperative. The tampons are renewed every other day.—*Semaine Méd.*, March 17.

De Marsi's Operation for Vaginal Cystocele.—He first makes a longitudinal, median incision through the mucous and submucous tissues of the anterior vaginal wall, extending from the fornix to the suburethral tuberculum, if necessary, and then two small transverse incisions, perpendicular to the first incision, at each end of it, and raises the square side flaps thus formed. He next sutures the two attached edges of these square side flaps together, and reduces the prolapsus, completing the operation by suturing the free edges of the flaps. By this means a solid foundation for the vaginal wall is secured and threatening prolapsus uteri averted. The same process could be applied to rectocele, with slight variations.—*Gaz. d. Osp. e d. Clin.*, March 7.

Therapeutics of Epilepsy.—Dr. F. C. Müller concludes an article on this theme in the *Wien. klin. Rundschau*, March 21, with an urgent appeal to the physician in such cases to bend every energy to seek and remove the cause, instead of blindly prescribing bromid in every case. He describes a typical and puzzling case, a girl of 16, who was immediately cured by appropriate treatment after the discovery of large numbers of the oxyuris in her intestines; others by putting an end to unsuspected onanism, or alcoholism or mental over-exertion, that had been the predisposing cause.

Extirpation of the Gall Bladder and Part of the Liver.—Ullmann presented a patient at the meeting of the Vienna k. k. Med. Gesellschaft, March 12, whose gall bladder he had removed six weeks before, on account of a tumor and accumulation of stones. The neoplasm involved the liver also and the corresponding portion was resected. After using the Paquelin the hemorrhage was serious until a wedge shaped piece was resected, and the liver tissue folded and laterally compressed, fastening the stump extraperitoneally. The *Wien. klin. Rundschau* remarks that it is the fourth case of extirpation of a tumor of the liver on record.

Medico-legal Importance of the Excrements.—Prof. Moeller has an article in the *Wien. klin. Rundschau* of March 14, calling attention to the value of the testimony afforded in criminal proceedings by microscopic examination of the dejecta. He suggests that criminals arrested on suspicion should be interrogated as to what and where they had eaten recently, and the feces will confirm the truth of their assertions or the reverse, disprove an alibi, etc. He mentions two separate

instances where the criminals were traced and brought to justice by casual discovery of fig seeds in their excreta, and adds that the microscope should be used more frequently than at present in criminal proceedings.

Favorable Effect of Laparotomy on Tuberculous Peritonitis.—Gatti has produced experimentally tuberculous peritonitis and then cured it with a laparotomy; gradually the tuberculous cells and the bacilli disappear, the products of degeneration are absorbed and a process of reorganization ensues, in the course of which the peritoneum becomes normal not only to the eye, but to histologic and bacteriologic tests also. The process requires six to eight months, and the laparotomy, to succeed, must be performed at the proper moment, neither too soon nor too late, the tubercle fully developed and before the caseous degeneration has begun. As it is difficult in the clinic to determine the exact moment when the operation is needed, Gatti recommends a second laparotomy if the first proves ineffectual, and it was noticed that caseous degeneration had not begun. Burci ascribes the effect of the laparotomy to the combination of trauma, change of temperature, admission of light and air, etc.—*Gaz. d. Osp. e d. Clin.*, No. 13, 1897.

Resection and Extirpation of the Larynx for Malignant Tumors.—Many lives could be saved if the diagnosis of malignant tumors could be made earlier. A writer in the *Beiträge z. klin. Chir.* urges physicians and students to master more thoroughly and universally the technique of laryngoscopy, so that malignant neoplasms could be discovered more frequently and removed in their incipient stages. Mikulicz has found that a normal function can be retained if two-thirds of the larynx can be saved. Important in this respect is the secondary suture to decrease the size of the wound, and the prevention of the formation of epidermis from the edges in. In thirteen cases operated, four have remained in good health since, one and one-half to eight and one-half years. One succumbed shortly after the operation; another died later of phthisis. In five cases the tumor grew again in three to ten months, with a fatal result in four. In six cases superior tracheotomy was performed, and inferior in the rest. Hemostasis was secured by ligatures and lateral compression; only once was the thermo-cautery necessary. He considers frequent changing of the bandages very important. Food was taken by the sound through the wound or lower nasal passages. He has never applied an artificial larynx.—*Obl. f. Chir.*, March 13.

Diagnosis of Primary Malignant Tumors of the Pleura and Lungs.—Dr. G. Zagari of Naples, having had occasion to observe seven cases of this character, has made a special study of the difficult subject of diagnosis *intra vitam*, and groups the special clinical symptoms as follows: 1, insidious commencement of the affection; 2, marked general debility; 3, absence of fever; 4, persistent, increasing pain; 5, circumscribed edema of the chest; 6, development of the lymphatic ganglia on one side of the thorax, exclusively or more prominently; possible turgescence of the veins in the anterior and lateral parts of this side; 7, sweats and more elevated temperature on one side of the thorax; 8, distress in breathing and more intense oppression than can be ascribed to the quantity of fluid obtained by puncture; 9, irregular distension of the thoracic cage, especially in the superior and anterior region of the chest; 10, intercostal spaces neither prominent nor dilated; 11, complete dulness, without the slightest elasticity, in the superior and anterior region of the thorax; zones of dulness close to zones of resonance; 12, dulness over the manubrium or the sides of the sternum, which indicates not only the displacement of the mediastinum toward the sound side, but also the irregularity of this displacement; 13, Skodaic resonance over the clavicle and sternum; 14, the laryngo-tracheal murmur distinctly transmitted to the superior regions; 15, persistence of the plessimetric and acoustic phenomena even after evacuation of the

fluid in the pleural cavity; 16, this fluid is very thick, rich in fibrin, hemorrhagic, with histologic elements special to the neoplasm; 17, peculiar sensation of having penetrated into a compact, deep, thick mass, when inserting the needle; 18, puncture is without effect, or the fluid forms rapidly again; 19, displacement of the heart and liver, out of all proportion to the amount of liquid withdrawn.—*Arch. Clin. de Bordeaux*, March, 1897.

Treatment of Persistent Vomiting in Pregnancy.—The pulse and the loss of weight must be carefully watched by the physician after he has established the fact of pregnancy. If the pulse is still normal and the emaciation is not extreme, he still has time to attempt mild therapeutic means, but if the pulse has increased and the emaciation is approaching the inevitably fatal limit (loss of 40 per cent. of the original weight), then the uterus must be treated locally, first with digital dilation of the cervix and straightening the uterus. It sometimes happens that straightening a slight flexion will arrest the vomiting at once. The last resort is abortion, which should never be done without the presence and advice of one or more other physicians. The mild means are inhalations of oxygen, spraying the epigastrium with ether, application of a bag of hot sand along the spine, purgative and nutrient enemata, hypodermic injections of artificial serum, etc., and especially galvanization of the pneumogastric. The positive pole of an apparatus with continuous current is applied above the clavicle at the attachment of the sterno-mastoid, while the negative electrode, a plate 9 by 13 cm., is placed on the epigastrium. The current should not be strong, 8, 10 or 15 ma., and it should commence and end very weak, to avoid irritation and excitement of any kind. The séance should last fifteen to thirty minutes and be repeated several times in the course of the day. This electric treatment is perfectly harmless.—*Delbert in Jour. de Prat.*, 6, 1897.

Phosphorus in the Treatment of Rickets and Neurasthenic Conditions.—Hartcop, in conformity with other observers, finds that rickets has been declining in frequency within the last twenty years, a result that is doubtless due to the more or less rigid prophylaxis that is maintained in families by the practitioner. There can be no doubt that at every suitable opportunity the mother should be enlightened as to the nature and results of the disease, but should at the same time be instructed as to its curability. The instruction of midwives on this and similar questions, would do away with much prejudice, but the physician himself should demolish the old fable, that painful teething is a cause of rachitis, when it is well known that it is rather an effect. The treatment of rachitis with phosphorus, since Kassowitz, of Vienna, in 1883, introduced it as a remedy, has given the best results. The failures which have occasionally been reported, were due to its administration during too short a period or to doses that were too small. The remedy is best administered in cod-liver oil, which given from a warmed spoon is usually well taken; in summer, or when it is not well borne (which is rare) it may be given in an emulsion of linseed oil. A cure is always obtained even in the most stubborn cases, not only of the bone symptoms, but of all the complications, which are so numerous in rachitis. Even intestinal catarrh is no contraindication to its use; it is only necessary to add a small amount of opium to the mixture. It is of the greatest importance, however, that both parents and the physician have patience enough to carry on the treatment for a long period. He orders children from 1 to 5 years of age, 0.0006 grm. of phosphorus twice daily, one hour after meals; and 0.0006 grm. to children 5 to 12 years old in increasing doses. Proper food, fresh air, and attention to the skin are adjuvants which must not be neglected. The improvement in their mental condition was particularly noteworthy. Sleep became quieter, sweating disappeared, their nervous irritability improved, and the intelligence increased. This induced him to administer phosphorus to other cases without rachitis, but suffering from brain irritation, and also to others who were suffering from brain fag, notably with a tired feeling and continual headache. The result was very satisfactory.—*Münchener med. Wochenschrift.*

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the Association living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, APRIL 17, 1897.

DRINK AND HARD TIMES.

An admirable trade journal, the *American Grocer*, has published, with comments, the figures furnished by the Government, the Internal Revenue and the Customs Bureau, chiefly the former, as to the consumption of liquors in the United States. It finds that there has been a marked decrease, so that in 1896 the amount of spirits used is almost one gallon per capita less than it was in 1888, thus discrediting apparently the theory so often advanced that in hard times when men are out of work they drink more to drown their troubles. It also claims that the decrease in spirit consumption is not compensated for by an increased usage of fermented liquors, such as beer; in support of this it shows that while the consumption of these rose to about sixteen gallons per head in 1892, it has since fallen off to about fifteen and a half gallons, not a very striking but still a perceptible decrease. The total expense for intoxicants in the country, it states, has decreased from over a billion in 1892 to less than nine hundred millions in the year just closed. From these it draws the conclusion that hard times make men less dissipated perforce and, for the time being at least, cause this to be a more temperate nation.

There is no just reason why the liquor business should not share in a general business depression, in at least a reduction of its total sales, though it is almost the only line of trade that does not lower its retail prices, on which there is certainly a very large

margin of profit. The average drinker who is not a drunkard ought naturally to be hardly expected to indulge his occasional appetite as freely as in flush times, and the remarkable fact that these figures indicate is not that they show this to be the case, but that the consumption of beer, the popular drink, has decreased so little. A loss of a little over three per cent. in four years of hard times after a rise of over thirty per cent. in the preceding six years is not a very striking decrease, as it still leaves us using annually nearly one-third more per capita than was the case ten years ago.

The decrease in spirit consumption is more striking, but it is a question whether that means all that it might appear to. The general depression in trade and manufactures would necessarily affect the amount of alcohol used in the arts and generally for other purposes than that of drink. What proportion of the whole decrease is thus to be accounted for, we have no ready means of estimating, but it must be a very appreciable one. The apparent fact that over seventy million people in this country used less strong liquor in 1896 than did about sixty million in 1887 is, however, encouraging, and is in accordance with the probabilities. The average moderate drinker when overtaken by hard times naturally would give up his most expensive drinks first, and we therefore can probably account for some of the 30 per cent. decrease in our national whisky bill since 1892 in this way. But while a large part of this has to be reckoned as due to the lessened usage of alcohol in the arts, etc., and our total drink bill is only reduced some fourteen per cent. in the same period, one can not so certainly assume that we are very rapidly progressing toward a higher practical temperance standard.

These facts have a medical as well as a sociological bearing, since the drinking habits of a people bear directly upon their physical as well as their moral and economic welfare. It is somewhat encouraging to think that the milder intoxicants are replacing in common use the stronger alcoholic beverages, and there is, from an analysis of the figures, perhaps some reason to hope that this is the case. The excessive use of beer is not to be recommended from a medical point of view, but it is better than the excessive use of whisky or other stronger distilled liquors. Whether the greater extension of the habit of beer-drinking among the general population, which the statistics might be held to indicate, has a lesser tendency to produce a race degeneration than the less extended but individually more disastrous habit of spirituous imbibition, may be a question for settlement by the experts. But if hard times will do anything in any way to check the ever aggressive evil of intemperance, it will be some compensation for what we at present have to endure and another instance of the chastening uses of adversity.

THE ETIOLOGY OF CHOLELITHIASIS.

A very convenient classification of the causes of cholelithiasis is that of GUMPRECHT (*Deutsch. Med. Woch.*, 1895, 224). He divides them into: first, *physical*, such as age and sex; second, as *sequelæ* of other diseases; third, *chemic* alterations in the composition of the bile; and fourth, *bacteriologic*.

Age is an important predisposing factor. With advancing years we find an increase in the proportion of cholesterin in the blood, and gallstones are recognized as an appendage of middle and late life. BRINTON gives the average age at which they are found as 53½ years. They are occasionally seen even in newborn children, though of 395 cases collected by HEIN only 15 were under 25, and only 3 were under 20 years of age.

As regards sex, all authorities seem to agree that they occur more frequently in the female. Authors differ, however, as to the relative proportion; thus BRINTON says they are four times more frequent, others give five to two, three to two, two to one, etc. The predilection for the female sex would seem to be due to sedentary habits, which are universally recognized as a potent factor. Obesity is closely allied to the foregoing, and BUDD and MURCHISON state that they are more common in persons of stout habit. FRERICHS, however, makes no mention of obesity apart from sedentary habits, and some authorities advance the view that obesity is merely a coincidence of cholelithiasis and depends on the same causes as the latter.

Confinement has been noticed to favor gallstone formation, for instance, in prisoners and stall-fed cattle. According to THUDICHUM these calculi are not found in wild animals until they have been in captivity for some time. Lunatics lead rather sedentary lives, so we may expect to find biliary concretions more frequent in them, if this factor has any influence. On examining the statistics we find this to be the case. BEADLES (*Jour. Mental Science*) found them in 36 per cent. of necropsies on insane females. GORSTELL stated that in 1,400 examinations at the West Riding Asylum calculi were found in 20.28 per cent. SNELL (*Neurolog. Centralbl.* June 1, 1893) in 1,000 necropsies found them in 9.2 per cent. of the 500 examinations of the insane males, and 19.4 per cent. of females. The forms in which cholelithiasis most frequently occurred were dementia following melancholia, epilepsy and senile dementia.

Here it may be pointed out that statistics as to the frequency of gallstones vary. THOMA, in his *General Pathology*, says they occur in 25 per cent. of all bodies over sixty years of age, MAYO ROBSON and NAUNYN in 10 per cent. and SCHRODER, from the necropsies at the Strassburg hospital, 4.4 per cent. of males and 20.16 per cent. of females. PAULSEN (*Centralbl. f. Chirurg.*, Feb. 4, 1893) calls attention

to their infrequency in Denmark. From 1870-90 only 111 cases (30 males) were treated in the Copenhagen hospital, and during the same period 9,172 necropsies were performed. Of the 5,448 males calculi were found in 2.34 per cent., and of the 3,724 females in 5.9 per cent. HARLEY thinks the influence of locality, if there is any, is due to the dietary and states that in his experience patients suffering from this affection are usually fond of fatty foods. He found these calculi very frequent and of large size in Russia, where oleaginous food is much used, while in Finland, Sweden and Denmark, where fish is the main article of diet, he states they are much less common.

In regard to gallstones as sequelæ of other diseases FRERICHS states that they frequently develop after long illness. In most instances they are apparently due to the long confinement to bed, which would seem to corroborate the theory of sedentary habits being a factor. The frequent association of gout and cholelithiasis is looked upon by several authors (HARLEY, MURCHISON, TROSSEAU) as pointing to a close relationship between these two affections. As calculi are usually found in carcinoma of the gall bladder, the question arose as to which was the primary affection. At first opinions differed on this point, but recent statistics all agree in looking upon the calculi as the cause, not the result. COURVOISIER found them in 74 out of 84 cases, BRODOWSKI in all of 40 cases, BERTRAND 14 of 15, and SIEGERT believes they occur in 95 per cent. of primary carcinoma. ROGER WILLIAMS, in a note to the *British Medical Journal* (Sept. 9, 1893) says in his experience gallstones are more frequently found associated with cancer of the breast than that of most other parts of the body. According to DUFORT (*Rev. de Med.*, 1893, p. 274) phlegmonous or gangrenous cholecystitis is sometimes met with following an attack of typhoid fever. HAGENMULLER collected eighteen of these cases in 1876. BERNHEIM states that he has seen the first attack of biliary colic occur during the course of typhoid. As we shall see later, CHIARI found the typhoid bacillus in the gall bladder in several cases of typhoid. DUFORT thinks the *B. coli* may also cause the cystitis in typhoid.

Coming now to the *chemic* causes of cholelithiasis it is evident that all the constituents of gallstones can be found in normal bile, save mucus, epithelium and foreign bodies, such as parasites and their eggs. It is also probable that if the bile continues healthy, the elements forming the calculi will remain in solution and not separate. What then causes the formation of these concretions? According to NAUNYN biliary stasis is the primary cause. As we have seen they are more common in the aged and in persons of obese or sedentary habit, all conditions favoring stagnation. With biliary stasis we get a catarrh with casting off of the epithelial cells; these furnish quan-

tities of albumin. This albumin leads to the precipitation of bilirubin, which combines with the lime salts. In addition we have cholesterin, which is usually the principal component of gallstones. Cholesterin is found in many vegetables, in eggs, red blood cells and the brain. As it is so important a feature in the production of calculi it has been suggested that the use of foods containing it be restricted as much as possible in persons subject to cholelithiasis.

With the catarrh it is possible to have infection of the contents of the gall bladder, so we may have *bacteriologic* causes added. When the normal bile of man or animals is contained in the healthy biliary passages and periodically discharged it is sterile (GILBERT and GIRODE). While bile is aseptic it is not antiseptic, so pathologic changes allow the entrance of microorganisms from the duodenum or from the blood, thus infecting the bile. Microbes have been found both in calculi and in the contents of the gall bladder. GALLIPA in 1886 was the first to announce "il y a des parasites dans les calculs biliaires." LETIENNE found *B. coli*, *S. albus* and *S. megatherium*, and DUPRE found the *S. albus* in three cases. CHARCOT and GOMBAULT, after ligating the common duct, found that the bile above the ligature became infected. Here as elsewhere in the intestinal tract the *B. coli* plays an important role. NAUNYN, after ligating the ductus communis so as to produce stasis, injected *B. coli* into the gall bladders of healthy dogs and found the animals speedily died with evidences of acute cholangitis and general septic infection. NETTER, GILBERT and GIRODE also found the *B. coli*.

CHIARI has lately investigated a series of twenty-two cases of typhoid fever. In all these cases save three typhoid bacilli were obtained from the gall bladder. They were generally present in considerable numbers and in fifteen were obtained in pure culture. In thirteen out of the nineteen cases there was inflammation of the gall bladder with infiltration of small cells, edema and hyperemia. Cultures from the heart's blood, the contents of the thoracic duct, and the cerebro-spinal fluid were all negative. The diagnosis of typhoid was confirmed in the entire series of twenty-two cases by cultures from the spleen, mesenteric glands, etc. The routes by which the bacilli reach the gall bladder may be, according to this author, either by the blood, by the bile ducts, or directly through the walls of the gall bladder itself. CHIARI regards the last method as very unusual and owing to the difficulties in experimentation he does not attempt to decide between the other two. The bacilli undoubtedly multiply in the gall bladder and thinks they possibly may cause post-typhoid cholecystitis, gallstones and relapses of typhoid.

GILBERT and FOURNIER have lately published a paper (*C. R. Soc. de Biologie*, Feb. 14, 1896) on the role of microorganisms in the formation of gallstones.

These observers examined a number of stones from human beings mostly, with a few from cattle, and of different ages. In the old stones the cultures were sterile, save in one case. In more recent stone, coverslips showed organisms from time to time which could not be cultivated. The fresh stones gave cultures and coverslips of *B. coli*. As a result of their observations these authors conclude that the gallstones are due to the action of the microbes contained in them. They are also of the opinion that while different organisms may cause cholelithiasis the *B. coli* is most frequently found.

INSANE KINGS.

BISMARCK, who opposed the marriage of Frederick (Crown Prince of Prussia), with the daughter of Queen Victoria (on the ground that she was a scion of the "crazy and scrofulous Guelphs") showed a prophetic insight into the results of those hereditary defects which Dr. E. S. TALBOT of Chicago demonstrated to exist in aristocracies and royalties generally.¹ The eccentricities of William II. of Germany seem to fully justify BISMARCK's objection. The recent performances are curiously like those of King Ludwig of Bavaria antecedent to that suicide and homicide which resulted in a great loss to medical science through the death of the cerebral anatomist GUDDEN. The socialist newspapers outline the artistic, architectural, sartorial, musical and pugilistic performances of William II. in a style that strikingly resembles the Suetonian sketch in 1884 of Ludwig's performances and which testimony taken in 1886 by the Bavarian Lunacy Commission (Drs. GUDDEN, HAGEN, GRASHEY and HUBRICH) demonstrated to be correct. The stigmata of degeneracy notoriously present in William II. of Germany, the insanity of his grand-uncle Frederick William IV. and that present in his paternal grandmother's ancestry lend emphasis to the fear BISMARCK expressed of the taint in the Guelph-Wettin blood, which extends even to the inheritance of hemophilia. The *British Medical Journal* (a decade ago, anent the political complications consequent on the larynx cancer of Frederick) remarked that the short reign of a wise ruler stricken with a fatal disease is better than the long rule of a half-imbecile ruler affected with chronic disorder. The *British Medical Journal* here recognizes fully the difficulties, even in constitutional monarchies, of securing regencies in case of even notoriously insane kings. The sea-kings were able to ravage Christendom through the mental defects consequent on epilepsy of the Carolingian and Merovingian dynasties. The lucid period of the paroxysmally excited paranoiac is peculiarly dangerous in this respect, as witness the cases of Wencelaus (Emperor of Germany and King of Bohemia), Charles VI. of France, Richard II. and

¹ JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, vol. xx, p. 111.

Henry VI. of England, Eric XIV. of Sweden, Christian VII. of Denmark and Ivan the Terrible of Russia. Much stress has been laid on the case of Charles II. of Spain, who concluded the dynasty which ruled Spain for nearly four centuries; but the European difficulties resulting therefrom would probably have occurred on the extinction of the dynasty irrespective of the mental state of its last member. The instances of most importance were those of George III., Christian VII. of Denmark and Ludwig of Bavaria. George III., though the scion of a dynasty created by a parliament representative of the people and destitute of hereditary right, attempted throughout his reign to be an absolute king. His shrewd grandfather gave him credit in boyhood for just sufficient intelligence to read to his mother. In mental make-up he resembled closely his famous insane ancestor, Ernest the Pious of Hanover. His mother had filled him with religious cant just sufficient to make him conceal his liaisons in brutal fashion. He had an admiration for art of the artificial, weak, classic style; for music of the street band style; for drama of practical joke, realistic type, and for church architecture of packing-box type. In these proclivities he displayed less intellectual power than his morally insane son, George IV., than Christian VII. of Denmark, or than Ludwig of Bavaria. In all these particulars he closely resembled his descendant, William II. of Germany. George III. was several times violently insane and died chronically insane.

The country was ruled as a regency for several years by the moral imbecile afterward George IV., who himself had delusions about having won the battle of Waterloo. George III. was, like all paranoiacs, most dangerous when least demonstrably insane. During his periods of seeming lucidity he had all the cunning, inventive, stupid egotism of the paranoiac and, as GREEN ("History of the English People") remarks, the shame of the darkest hours of English history lie wholly at his door. Lord CHATHAM, whose counsels might have thwarted much of this shame, was stricken down with gouty insanity during the critical period of the American troubles. The Americans were taxed in defiance of CHATHAM'S denunciation of the unconstitutionality of this and King George III. ruled the country through the ministry formed by CHATHAM. Harsh laws, repellant to the spirit of the English common law, made death the penalty for almost all offenses against prosperity of person, in order to swell the coffers of the King with goods confiscated from the felon.

George III., when he became demonstrably insane, was placed under the care of Dr. WILLIS, who kept a private insane hospital conducted on excellent principles. When the paroxysmal excitement quieted down, the tories asserted the king had recovered, and in this were supported by Dr. WILLIS and his son,

and opposed by Dr. WARREN. George III. was declared sane by the English judges. Dr. WILLIS was given a pension of 7,500 annually for twenty-one years, and his son one of 3,250 annually, for life. Insane paroxysms recurred from time to time, until it became demonstrated that the case was a chronic one, and a regency was established. George III. reigned fifty-eight years.

The same arbitrary characteristics and artistic tendencies, but with greater demonstrable sexual perversion and greater intellectual powers were legally shown to be present in Ludwig of Bavaria and Christian VII. of Denmark.

Christian VII. was coarser but less hypocritical in sexual debauchery than George III. He was equally suspicious, and while he had greater intellectual power than George III. in art, science, music and architecture, he was as inventively stupid in political matters. Neither of the two compared for political foresight with Ludwig of Bavaria, the patron of WAGNER. WAGNER would probably not have risen to the height he did but for Ludwig, whose musical and artistic criticism of the performances he insisted on enjoying alone, prepared WAGNER for the onslaught he later encountered.

Ludwig, in 1867, then at the height of his renown, courted at once by France, Prussia and the ultramontanes, highly esteemed as a discerning patron of art and music, met MOREL, whose keen eye saw the mental and physical stigmata of degeneracy, and who prophesied the coming catastrophe. Ludwig, by siding with Prussia, enraged the ultramontanes. All the material they had collected was (like that collected by the Prussian agrarian party against William II.) placed in the hands of the socialists. In 1884, the *Zurich Social Demokrat* detailed his mental and moral defects and paralleled them with those of Nero. By June, 1886, Prince Luitpold, the king's uncle, was pronounced regent, the immediate heir to the throne, Otho, Ludwig's brother, being a paranoiac with homicidal tendencies. June 12, 1886, Ludwig drowned Dr. GUDDEN and himself. Otho became king, but Luitpold remained regent.

LEGISLATION AGAINST DEGENERACY.

One of the results of the vulgarization of the Lombrosian theories of human degeneracy by such works as those of NORDAU and others, has been to give rise to a number of rather noteworthy propositions, some of which it has been proposed to realize by legislation. A bill is said to be now before the Texas legislature, prohibiting the marriage of those affected with any serious hereditary disease or taint; an act has, it is said, been passed in Connecticut forbidding the marriage of epileptics, and other similar legislation will probably be attempted in other quarters. The difficulty with all these propositions is not that they are not

good in themselves, at least in purpose, but that they are all more or less impracticable. Besides the difficulty of quelling or restricting the strongest animal impulses, that is met with everywhere in the endeavor to keep up and improve the moral standard and meet the needs of ordinary social morality, we have in this case an attempt to meet much less tangible conditions which can sometimes even altogether escape detection. Moreover, the public sense of justice would revolt sometimes against a strict construction and execution of laws that restrict natural rights in cases where there is, as there may easily be, a possible doubt of their applicability. In case of tuberculosis, for example, which is one of the diseases it is proposed to make a bar to marriage, we have learned to recognize, of late years more than ever before, that it is an almost universally disseminated infection from which few of us entirely escape and yet from which also the recoveries are much more numerous and complete than had hitherto been supposed. Epilepsy also is a symptom indicating cerebral instability, but it by no means invariably indicates an incurable organic defect. How is a law against the marriage of epileptics to be enforced strictly when we know that there are many individuals who have had perhaps only one or two fits in the course of a long life; or who have perhaps at some critical period had them frequently and none at any time thereafter? Nevertheless they can never be said to be absolutely free from the liability to the taint of epilepsy. As regards insanity, we yet know comparatively little of the real conditions underlying most types of mental disease, and there are very many cases where injustice might be done by the legal disability imposed by the proposed legislation.

The chief defect of all these proposals is that they are too vaguely stated and provide no method for the rational carrying out of the reforms they advocate. The difficulties in their way seem to be not fully appreciated and the legislation is in this respect inconsiderate. One of the most elaborate and complete of these projects is reported from France, where Dr. TOULOUSE, a well known writer on mental diseases, who has recently also been prominently before the public as the author of a rather sensational analysis of a noted French novelist, is the author. He proposes that epilepsy, mental weakness, cancer, syphilis, alcoholism, and tuberculosis should be made legal obstacles to marriage, and that persons intending to marry should declare these diseases before the marriage, and failure to do so shall be a legal ground for divorce or for fine in case a defective offspring results. If marriage is insisted upon in spite of and after declaration, the State shall have the right to interfere and prevent its consummation.

It is further proposed in Dr. TOULOUSE's plan that physicians shall be compelled by law to report to the authorities all cases of these disorders, so that a record

can be kept of every individual's disabilities. This will not be open to the public, but is intended to serve as a check upon the declarations made by the parties, so that the State can intervene and prevent dangerous alliances, for the public good.

Dr. TOULOUSE's plan is in some respects better considered than most of the others, but will be of interest to see how it is received in France where the question of population is at the present time an important one, and such a check on marriage and the consequent legitimate multiplication of citizens is hardly in the line of the reforms for which French economists are mostly concerned. It is for quantity rather than quality of population that they appear to be now most anxious, and the demands of modern European militarism will have to be first considered. Even were such plans perfectly satisfactory and practicable it is doubtful whether they could be adequately carried out so as to yield results that will show their utility, and this is true of the comparatively well considered proposition of the French alienist as well as of the cruder attempts of the Texas and Connecticut legislators. It is a question as open to differences of opinion as are any of the economic questions of the day, and it is hard to say whether after all a *laissez faire* policy is not the best. The prohibition of the marriage of idiots, imbeciles, and the actual or periodic insane may be a legitimate and practicable method of preventing the propagation of degeneracy, and the same may be said of the legal prohibition of consanguineous marriages, though this is to some yet an open question; but any such wholesale enactments as those proposed are questionable. Degeneracy is largely an incident of evolution, at least in some of its details, and according to the law of natural selection so far as it applies to men, carries with it its own cure. It is a direct result of human progress, a necessary concomitant of our civilization, and the increase of insanity and other evils just now so prominent and alarming are only incidents in the general line of human advance. They are partly, at least, only signs of the higher standards of philanthropy that now prevail, as compared with those of former periods, and the better statistical information of the present day. As yet our information as to the causes of human defectiveness is incomplete, and we do not know that it would greatly add to the sum of human happiness to interfere very radically with the ordinary course of events in these respects.

We will have, however, to expect more propositions of this kind in the future, as an inevitable result of the diffusion of information or misinformation on scientific or pseudo-scientific subjects, which always has as one of its first effects the starting up of reformers. But while we are unable to legally suppress sexual immorality the possible danger of such reforms is that they would only increase the number of illegiti-

mate degenerates. The only real safeguards against the propagation of degenerates are to be looked for in the higher moral education of the public, and the cultivation of higher practical moral standards.

RAILROAD RATES TO THE JUBILEE MEETING.

Advices have been received from the Traffic Association of a uniform rate of a fare and one-third for railways in the territory east of the Missouri River and west of Chicago, Peoria and St. Louis, on the certificate plan. This includes:

Atchison, Topeka & Santa Fe Railway; Burlington, Cedar Rapids & Northern Railway; Chicago & Alton Railroad; Chicago & Northwestern Railway; Chicago, Burlington & Northern Railroad; Chicago, Burlington & Quincy; Chicago Great Western Railway; Chicago, Milwaukee & St. Paul Railway; Chicago, Rock Island & Pacific Railway; Chicago, St. Paul, Minneapolis & Omaha Railway; Hannibal & St. Joseph Railroad; Illinois Central Railroad; Iowa Central Railway; Jacksonville & St. Louis Railway; Minneapolis & St. Louis Railroad Co.; Missouri Pacific Railway; Rock Island & Peoria Railway; St. Louis & San Francisco Railroad; Sioux City & Pacific Railroad; Wabash Railroad; Wisconsin Central Lines.

CORRESPONDENCE.

Railroad Rates.

RANKIN, ILL., April 12, 1897.

To the Editor:—Will you please inform me what rates can be secured for physicians and their wives for transportation to attend the meeting of the AMERICAN MEDICAL ASSOCIATION in June and oblige? Yours truly, J. R. LITTLE, M.D.

ANSWER.—One and one-third fare from all points for the round trip.

ASSOCIATION NEWS.

Dinner of the Section of the Practice of Medicine.—The dinner of the Section of the Practice of Medicine of the AMERICAN MEDICAL ASSOCIATION will take place at 7 o'clock on the evening of June 1, 1897. Gentlemen desiring to attend this dinner will please send in their names at once to Dr. J. H. Musser, 1927 Chestnut street, Philadelphia, Chairman of the Section. The subscription will be \$2.00 if one hundred attend, and \$3.00 if less than one hundred attend, so that it will be necessary for the subscription list to be filled as early as possible.

Section on Surgery and Anatomy.—Preliminary program.

1. Address of the Chairman. Reginald H. Sayre, New York, N. Y.
2. *a*, Ligation of the Common Carotid Artery for Trifacial Neuralgia, with Experiments and Observations on Dogs; *b*, Specimens and Charts of the Arterial and Nervous Systems, illustrating the paper. B. Merrill Ricketts, Cincinnati, Ohio.
3. The Nerve Element in Surgical Pathology. J. McF. Gaston, Atlanta, Ga.
4. Operative Procedure for the relief of Occlusion of the Jaws. I. Ewing Mears, Philadelphia, Pa.
5. Improvement of Brain Function by Surgical Interference. Ernest La Place, Philadelphia, Pa.
6. Demonstration on the Cadaver of a new Surgical Engine. M. H. Cryer, Philadelphia, Pa.
7. Hernia of the Cecum. J. H. Gibbon, Philadelphia, Pa.
8. One of the Rarer Forms of Hernia. Frank Stahl, Chicago, Ill.

9. Two hundred and fifty Bassini Operations for the Cure of Hernia without Mortality. W. B. Degarmo, New York, N. Y.
10. The Sac in Inguinal Hernia. D. W. Graham, Chicago, Ill.
11. Animal Suture, Its Preparation and Technique of Application. H. O. Marcy, Boston, Mass.
12. The Diagnosis of Minor Personal Injuries and their Relation to Accident and Insurance Associations (with illustrations). L. H. Montgomery, Chicago, Ill.
13. Appendicitis in its Relation to Life Insurance. D. W. Graham, Chicago, Ill.
14. Report of a Case of Cyst of the Appendix with Presentation of Specimen. E. E. Montgomery, Philadelphia, Pa.
15. Surgical Managements of Appendicitis. Joseph Price, Philadelphia, Pa.
16. Pelvic Surgery. Mordecai Price, Philadelphia, Pa.
17. The Differential Diagnosis of Surgical Lesions in the Right Half of the Abdomen and Pelvis. George R. Fowler, Brooklyn, N. Y.
18. Anchoring the Kidney. R. Harvey Reed, Columbus, Ohio.
19. Calculi in the Ureter. Weller Van Hook, Chicago, Ill.
20. The Comparative Merits of Different Operations for Stone in the Bladder. J. B. Deaver, Philadelphia, Pa.
21. Suprapubic Cystotomy, with a Report of Fifty Cases. John A. Wyeth, New York, N. Y.
22. Photography of the Bladder. W. K. Otis, New York, N. Y.
23. A Hypospadias Operation. R. T. Morris, New York, N. Y.
24. Ligation of the Dorsal Vein of the Penis for the Cure of Functional Impotence. J. A. Murray, Clearfield, Pa.
25. The Dangers of Clap. F. C. Valentine, New York, N. Y.
26. Stone in the Common Duct. W. E. B. Davis, Birmingham, Ala.
27. Demonstration of Technique of the Roentgen Rays, with the Practical Application to Surgery. Illustrated by Stereopticon Views. A. W. Goodspeed, Philadelphia, Pa.
28. The Treatment of Ununited Fractures. Edward Martin, Philadelphia, Pa.
29. Ichthyosis Papillaris Linguae, with Report of Case. Joseph Ransohoff, Cincinnati, Ohio.
30. Treatment of Abscess of the Lung. Carl Beck, New York, N. Y.
31. The Use of Dry Heat and a High Temperature for the Treatment of Chronic Joint Affections, with a Report of Cases. W. E. Wirt, Cleveland, Ohio.
32. Unnecessary Complications in Operative Surgery. John B. Roberts, Philadelphia, Pa.
33. The Present Status of the Injection Treatment of Hemorrhoids. L. H. Alder, Jr., Philadelphia, Pa.
34. Transperitoneal Ligation of the Iliac Artery, with Report of Cases. T. S. K. Morton, Philadelphia, Pa.
35. The Etiology and Classification of Tumors. S. H. Friend, Milwaukee, Wis.
36. Report of 200 Cases of Inoperable Sarcomata Treated by Injections of Mixed Toxins. W. B. Coley, New York, N. Y.
37. Serum Therapy in Acute Surgical Infectious Diseases. Howard Lilienthal, New York, N. Y.
38. Amputation in the Treatment of Malignant Disease. C. A. Wheaton, St. Paul, Minn.
39. The Technique of Pirogoff's Amputation. G. G. Davis, Philadelphia, Pa.
40. *a*, The Treatment of Colles Fracture; *b*, The Passing of Plaster. E. A. Tracy, Boston, Mass.
41. Morbus Coxarius, Exsection with Movable Joint; Case. J. B. Cokenover, Des Moines, Iowa.
42. Gangrene of the Foot due to Uterine Myoma. S. H. Weeks, Portland, Me.
43. Cicatricial Stenosis and Valve Formation as a Cause of Pyloric Obstruction, with Report of Five Cases Relieved by Operation. W. J. Mayo, Rochester, Minn.

SECTION DINNER, TUESDAY, JUNE 1; 7:30 P. M.

Price of tickets \$3, without wine. Those desiring to attend the dinner who have not already notified the Chairman will please send their names to Dr. Reginald H. Sayre, 285 Fifth Avenue, New York, N. Y.

Section on Obstetrics and Diseases of Women.—Preliminary program:

1. Address of Chairman. Milo B. Ward, Topeka, Kans.
2. A Consideration of Some of the Conditions Influencing the Results of the Surgical Treatment of Uterine Retroposition. Augustus P. Clarke, Cambridge, Mass.
3. Pathological and Surgical Complication in Abdominal and Pelvic Disease Requiring Supra-pubic Sections for their Removal. Joseph Price, Philadelphia, Pa.
4. The Technique of Vaginal Section, Exclusive or Hysterectomy, for Diseased Appendages and Small Pelvic Tumors. Augustin Goelet, New York City.

5. The Choice of Methods in the Operative Treatment of Fibroid Tumors of the Uterus. L. S. McMurtry, Louisville, Ky.

6. The Element of Diagnosis in Intra-Uterine Growths. Thomas B. Manley, New York City.

7. Hemato-salpinx with Congenital Uterine Atresia. Alex. Hugh Ferguson, Chicago, Ill.

8. The Treatment of Puerperal Sepsis. E. E. Montgomery, Philadelphia, Pa.

9. Tapping and Drainage of Tubal Abscess Instead of Removal of Same. J. W. Heddens, St. Joseph, Mo.

10. Obstetric Delivery by Abdominal Section. W. G. Macdonald, Albany, N. Y.

11. The Destiny of Vaginal Hysterectomy for Malignant Disease. Lester C. Hall, Kansas City, Mo.

12. The Treatment of Circumscribed Pelvic Hemorrhage. M. Rassenwasser, Cleveland, Ohio.

13. Rational Gynecology. J. H. Kellogg, Battle Creek, Mich.

14. Closure of the Abdominal Incision. Philander A. Harris, Paterson, N. J.

15. The Closure of Wounds of the Bladder by the Use of the Buried Tendon Suture; with Special Reference to a New Method for the Cure of Difficult Cases of Vesico-vaginal Fistula. Henry O. Marcy, Boston, Mass.

16. The Broad Coaptation Suture in the Radical Operation for Umbilical Hernia. G. M. Edebohls, New York City.

17. The Midwife Question in America. C. S. Bacon, Chicago, Ill.

18. Vaginal Puncture in Extra-Uterine Pregnancy, Lewis Schooler, Des Moines, Iowa.

19. Some Interesting Cases in Gynecological Practice. Henry P. Newnan, Chicago, Ill.

20. New Advances in the Treatment of Fibroid Uteri. Howard A. Kelly, Baltimore, Md.

21. Puerperal Infection. J. E. Cowles, Los Angeles, Cal.

22. Technique of Abdominal Hysterectomy. J. F. Baldwin, Columbus, Ohio.

23. Treatment of Retroversion of the Uterus. Franklin H. Martin, Chicago, Ill.

24. A Method for the Radical Cure of Gonorrhoeal Salpingitis. Robert T. Morris, New York City.

25. Relative Merits of the Cesarean and Porro's Operations. J. H. Carstens, Detroit, Mich.

26. Treatment of Pelvic Inflammations by Vaginal Incision. W. E. B. Davis, Birmingham, Ala.

27. The Anal Sphincter in Pelvic Surgery. Joseph Eastman, Indianapolis, Ind.

28. Some Methods of Suspending the Uterus. George H. Noble, Atlanta, Ga.

29. Fibroid Tumors of the Vagina with Report of a Case. J. M. Emmert, Atlantic, Iowa.

30. Is Gynecology a Narrow Specialty? Thomas Opie, Baltimore, Md.

31. Tubercular Peritonitis Surgically Considered. J. W. Felty, Abilene, Kans.

32. Electricity in the Treatment of Fibroid Tumors; its Ultimate Results and Comparative Value. G. Betton Massey, Philadelphia, Pa.

33. Toxicity of Urine in Pregnancy. Robert W. Stewart, Cincinnati, Ohio.

34. Studies in Gynecology from the Service of the Woman's Hospital of Philadelphia. Anna M. Fullerton, Philadelphia, Pa.

35. Some Reflex Disturbances Due to Pelvic Disease, with Report of Cases. J. M. Duff, Pittsburg, Pa.

36. The Conditions and Accidents of Curettage. W. W. Grant, Denver, Col.

37. How to Avoid Drainage in Pelvic Surgery. I. S. Stone, Washington, D. C.

38. Vagino-abdominal Section. Thomas H. Hawkins, Denver, Col.

39. The non-operative Treatment of Puerperal infections. Joseph B. De Lee, Chicago, Ill.

40. A Report of Three Cases of Ovarian Cyst with Appendicitis Resembling Torsion of Pedicle. X. O. Werder, Pittsburg, Pa.

41. Treatment of Pus Tubes and Pelvic Abscess per Vaginum. W. H. Wathen, Louisville, Ky.

42. A Synopsis of Plastic Surgery Now Practised. Joseph Price, Philadelphia, Pa.

43. One Hundred Cases of Atresia and Stenosis of Vagina in Labor with Thirteen Fatal Cases. J. J. E. Maher, New York City.

44. Which is the Preferable Operative Method of Holding the Uterus in Normal Position. C. C. Frederick, Buffalo, N. Y.

45. Antelexion of the Uterus. Russell G. Floyd, Eureka Springs, Ark.

SECTION DINNER.

Through the advice of the executive committee of the Section on Obstetrics and Diseases of Women, the chairman has arranged with the manager of the Hotel Walton, to give a Section dinner, Tuesday, June 1st, at 8 P.M. The price to be \$3 per plate; wines extra. In order to make this important feature of the ASSOCIATION a signal success, it will be necessary for each member of the Section who will be present, and desires to enjoy this social occasion, to signify his intention by promptly notifying the chairman, so that arrangements can be made to accommodate all. Please mail postal card to the undersigned as soon as you read this article, and state the number of plates for which you will be responsible. The dinner will be given in the Hotel Walton, and no member of the Section will be able to resist the pleasure when the time comes, but we must know how many will be present so that every detail may be previously arranged.

MILO B. WARD, Chairman.

707 Kansas Avenue, Topeka, Kan.

Section on Neurology and Medical Jurisprudence.—Members will please send in the titles of their papers to the Secretary of the Section promptly, that the permanent program may be arranged. The following is the preliminary announcement of papers already promised:

1. Aphasia. Charles K. Mills, Philadelphia. Discussion: F. X. Dercum, Hugh T. Patrick, William G. Spiller, Barney Sachs, J. J. Putnam and C. W. Burr.

2. French and Motor Aphasia in a Polyglot. Frederick Peterson, New York City.

3. Some States of Disturbed Consciousness. J. T. Eskridge, Denver, Colo.

4. The Status of the Present Treatment of Alcoholism. J. K. Baudy, St. Louis.

5. Meningo-mylitis with Special Reference to the Tubercular Form. William G. Spiller, Philadelphia.

6. The Medico-legal Aspect of Choreic Insanities. C. C. Hersman, Pittsburg.

7. Expertism. S. V. Clevenger, Chicago.

8. The Differential Diagnosis between Cerebral Syphilis and General Paresis. Hugh T. Patrick, Chicago.

9. Trunk Anesthesia in Locomotor Ataxia. Charles W. Burr, Philadelphia.

10. Habit Spasms of Children. Samuel J. Fort, Ellicott City, Md.

11. The Rest Cure. Landon Carter Gray, New York City. Discussion: E. S. Pettyjohn, C. H. Hughes, Chas. K. Mills.

12. Treatment of Graves' Disease. Harold N. Moyer, Chicago. Discussion: A. A. Eshner, Philadelphia, and C. H. Hughes, St. Louis.

13. Melancholia and Its Treatment. W. S. Watson, Fishkill-on-Hudson, N. Y.

14. The Subconscious Mind. Clark Bell, Esq., New York City.

15. Internal Cerebral Meningitis Chronica. E. S. Pettyjohn, Alma, Mich.

16. Stigmata in Young American Degenerates. Eugene S. Talbot, Chicago, Ill.

17. Pain Traumatism. Thos. H. Manley, New York.

18. A Synopsis of the Duestrow Case. E. Bremer, St. Louis.

19. Insanity and Pulmonary Consumption Among the Negro Population of the South Since the War. Thomas J. Mays, Philadelphia, Pa.

20. Inebriety and Tuberculosis as Allied Diseases. T. D. Crothers, Hartford, Conn.

21. Alcohol as a Causative Factor in Disease of the Central Nervous System. T. D. Crothers, Hartford, Conn.

22. On the Pathogenesis of Locomotor Ataxia. L. Harrison Mettler, Chicago, Ill.

23. The Use and Abuse of Electricity in the Treatment of the so-called Neuroses. L. Harrison Mettler, Chicago, Ill.

24. A Study of the Symptomatology of Neurasthenia in Women. Louis P. Bishop, New York City.

25. Clinical Evidences of Neurasthenia as an Abdominal Neurosis. G. Betton Massey, Philadelphia, Pa.

26. Hereditary Lateral Sclerosis. Augustus A. Eshner, Philadelphia, Pa.

27. History of the Section on Neurology and Medical Jurisprudence. J. G. Kiernan, Chicago, Ill.

28. Chairman's Address. W. J. Herdman, Ann Arbor, Mich.

29. History of American Neurology. C. H. Hughes, St. Louis.

30. Remarks on the Curability of Insanity. John Punton, Kansas City, Mo.

31. Bilateral Psychomotor Myo-synchrony. C. H. Hughes, St. Louis, Mo.

32. Rest and Northern Lake Air for Neurotics. E. S. Pettyjohn, Alma, Mich.

Papers have also been promised by the following: F. X. Dercum, Philadelphia; Henry W. Coe, Portland, Ore.; John K. Mitchell, Philadelphia, Pa.; A. O. J. Kelly, Philadelphia, Pa.

SECTION DINNER.

The Section on Neurology and Medical Jurisprudence will give a dinner on the evening of the first day. The price of tickets is three dollars per plate. Members of the Association wishing to attend will please sign the accompanying slip and mail it at once to the Secretary of the Section, Dr. C. H. Hughes, 3857 Olive Street, St. Louis, Mo., that proper arrangements can be made in accordance with the number to be present.

To the Secretary, Neurological Section, A. M. A. Sir:—I wish . . . plate placed for me at the dinner of the Section on Neurology and Medical Jurisprudence of the American Medical Association at Philadelphia, June 1, proximo.

Signed

Address C. H. HUGHES, Secretary.

Section on Dental and Oral Surgery.—Preliminary program:

1. Chairman's Address. R. R. Andrews, Cambridge, Mass.
2. Resection and Reproduction of the Maxilla. G. Lenox Curtis, New York City, N. Y.
3. Sterilized Roots of Beast's Teeth as Supports for Porcelain Crowns. W. E. Walker, Pass Christian, Miss.
4. Tumors of the Maxilla. Wm. Knight, Cincinnati, Ohio.
5. The Influence of Diseased Teeth upon the Adjacent Structures. J. Taft, Cincinnati, Ohio.
6. Etiology and Treatment of Inflammation of the Anterior Pillars of the Fauces. George T. Carpenter, Chicago, Ill.
7. Pathologic Conditions of the Throat and Contiguous Structures During Early Childhood. Prince.
8. Factors in the Causation of Irregularities of the Maxilla and Teeth. Wm. A. Mills, Baltimore, Md.
9. Dental Faculties in Medical Schools. Richard Grady, Baltimore, Md.
10. The Need of Dental Instruction in Medical Schools. Edward Branigan, Boston, Mass.
11. A Series of Clinical Cases. Vida A. Latham, Chicago, Ill.
12. Hyperkinesis of the Muscles of Mastication a Symptom and an Etiologic Factor in Nervous Affections, Particularly Neuralgia of the Trigemini and Diseases of the Jaws. G. V. I. Brown, Duluth, Minn.
13. The Relation of Dentistry to General Medicine. George F. Eames, Boston, Mass.
14. Cataphoresis, *i. e.*, The Use of Electricity Alone for the Obtunding Sensitive Dentine. W. A. G. Bonwill, Philadelphia.
15. Fraternity. A. C. McCurdy, Towson, Md.
16. Pyorrhea Alveolaris in Mercurial and Lead Poisoning and Scurvy. Paper No. 4. Eugene S. Talbot, Chicago, Ill.
R. R. ANDREWS, Chairman, Cambridge, Mass.
EUGENE S. TALBOT, Secretary, Chicago, Ill.

SOCIETY NEWS.

The French Congress of Alienists and Neurologists will be held in August at Toulouse. Questions to be discussed: Diagnosis of general paralysis; infantile hysteria; medical service in insane asylums.

International Medical Congress.—Germany has notified the Russian government that it will withdraw its representation unless all restrictions with regard to the passports of the Hebrew members of the German delegation are at once withdrawn. It is insisted that the Jewish members of the Congress shall receive from the Muscovite authorities identically the same treatment as their Christian colleagues.

International Congress of Forensic Medicine.—In connection with the Exposition at Brussels the local society announce an international medico-legal congress to meet August 2 to 7, to discuss the following questions: Internal factors in the putrefaction of cadavers; the medico-legal expert in cases of accidents caused by the ingestion of food; toxicology of acetylene; in-

toxication with carbonic oxid; the criminal insane; medical professional secrecy before the law; pulmonary docimasia; medico legal significance of subserous ecchymoses; responsibility, especially partial responsibility; hypnotism in relation to criminality. For further particulars address Dr. Dewez, Mons, Belgium.

Atlantic City Academy of Medicine.—The active regular physicians of Atlantic City, N. J., met April 9, and organized a permanent organization to be known as the Atlantic City Academy of Medicine, the objects of which shall be to encourage interchange of opinion upon medical and surgical cases; to consider all subjects bearing upon the health and sanitation of our "City-by-the-Sea;" and to promote a greater spirit of sociability among the fraternity. There are three classes of members, viz., first, active members who must be regular, registered, and practicing physicians in Atlantic City; second, contributing members, who must be legally qualified regular practitioners, druggists or dentists; third, honorary members, regular physicians or professors who have attained high honors in the profession or who have especially contributed to the valuable literature of the profession. The Academy was organized with a membership of twenty and will hold its regular meetings the second Friday of each month, with the exception of July and August, at 9 P.M. The following officers were elected to serve until January, 1898: President, William M. Pollard; vice-president, W. Blair Stewart; secretary, E. C. Chew; corresponding secretary, Joseph F. Edwards; treasurer, Walter Reynolds. Board of governors, the president, Boardman Reed and E. A. Reiley.

BOOK NOTICE.

Retinoscopy (or Shadow-test) in the Determination of Refraction at One Meter Distance with a Plane Mirror. By JAMES THORINGTON, M.D., Adjunct Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine, etc. Sixty-six pages and 24 illustrations. Price \$1.00. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut St., 1897.

The author of this well written little book has very satisfactorily described the most approved methods of retinoscopy. The work is especially valuable in that for a great part it details the results of personal investigation of such a well known authority on this subject as Dr. Thorington. Oculists accustomed to casually use retinoscopy as practiced in the old way with the concave mirror or with the ophthalmoscopic mirror, will be surprised to note the marked evolution of the modus operandi of this test as developed by Drs. Jackson and Thorington. With perfected instruments and strict attention to arrangement of light, distance, and other details, a surprising degree of proficiency and accuracy is possible. Any one pursuing the modern methods of retinoscopy will soon be convinced of its superiority over all other objective tests, and every worker in ophthalmology realizes the necessity of at least one reliable objective method of refraction.

Dr. Thorington has described in the plainest manner every important detail of the test, and has lucidly illustrated his text with diagrams and photographs (several of original instruments). His book will prove a welcome and useful addition to ophthalmologic literature. We are pleased to note the preference given to the term retinoscopy. The test is best known by this name, and since the publicity of the X rays, its common synonym skiascopy is liable to be confused with skiagraphy; besides skiascopy and the shadow-test are inappropriate terms, as it is the movement of the illumination rather than the shadow that is studied in the modern method with the plane mirror. We are somewhat surprised at the statement that satisfactory refraction without a cycloplegic "can be quickly and accurately obtained" by retinoscopy, in cases of myopia and mixed astigmatism in which the pupil is large, but we are glad to read that the author does not advise this as a routine procedure.

PUBLIC HEALTH.

The Utilization of Garbage.—New York city contracted last June with the New York Sanitary Utilization Company on a five year basis to receive the garbage delivered to it at Barren Island, the long established depot of animal cadavers. Brooklyn's garbage has the same destination. The garbage towed by the city's scows to the island is dumped into hoppers, from which it slides into the receiving tank, where it is cooked. The mass is then dropped into tanks and carried by elevator buckets to the presses which separate the grease and water. The grease, after partial purification, becomes a salable article to be made into soaps, lubricants, etc. The residue is changed into fertilizing products. Without the dead-animal contingent it would be difficult to make the garbage contract pay on the terms which the city allows. New York's garbage averages 800 tons a day, Brooklyn's is not nearly as great. The latter city has a contract with another company. The aim of both these cities is to dispense with sea dumpings, which prove such a serious impediment to navigation, as well as menace to the health of the shore dwellers. After years of lethargy the metropolitan center bestirs itself with a commendable activity.

For International Measures Against Leprosy.—Max Joseph (*Berliner klinische Wochenschrift*), considering the danger to the State, advises prophylactic measures, consisting in the duty for physicians to report every case, isolation of the patients, and international regulation for their internation. (*Janus.*) Professor Neumann (*Wiener medicinischen Wochenschrift*)—as the increase of leprosy, which, according to him, propagates itself as well by heredity as by direct contact, has been undoubted in Europe during the last decades—thinks that international measures of protection are necessary. The measures recommended by him are the following: 1. Strong control over all the cases, by compelling the physicians to report each case coming to their knowledge. 2. Isolation of the lepers in special asylums, like those of Norway. 3. Interdiction of marriages between them, and separation of the inmates of the asylums according to sex. 4. Appointment of special professionally educated physicians in the asylums. The latter being so arranged that they are not only places of nursing for the sick, but also seminaries for the scientific study of leprosy. (*Janus.*)

Entitled to Certificate to Practice Medicine.—A peremptory writ of mandamus, to compel the State Board of Health of Missouri to issue a certificate authorising one Charles E. Johnston to practice medicine and surgery in that State, was granted by the supreme court of Missouri, Dec. 23, 1896, in the case of State v. Lutz. Johnston was graduated at the Physio Medical College of Indiana, located at Indianapolis, Ind., March 18, 1896, when he received a diploma, which he presented to the State Board of Health of Missouri, in July, with his application for a certificate to practice in the latter State. This was refused on the ground, it was stated, that the college issuing the diploma was not, in the judgment of the board, a "medical institution in good standing," within the meaning of the statute; the grounds of this conclusion being that the board had, prior to the presentation of the diploma, passed a resolution, and mailed a copy of same to each medical college in the United States, requiring them to furnish the board, on or before Jan. 1, 1896, a list of their respective matriculates and the basis of their matriculation, and that the Physio-Medical College had not complied with this order; and also upon the further ground, that, upon announcing its refusal to grant the certificate, the board stated to the applicant that it would permit him to be examined, and, if found qualified, grant him a certificate. The weight of evidence was to the effect that the notice referred to was not sent to the college until June 23, 1896, and Johnston having theretofore graduated, the supreme court says, that he

was in no way affected by the failure of the college to comply with the rules in question. Moreover, as to the college being in good standing, the court says, was settled by the testimony of the president of the State Board of Health that he found its name of record in the list of colleges furnished by the Illinois State Board of Health, which he said was considered standard in the United States. Good standing, as used in the statute, the supreme court goes on to state, simply means good reputation, and must be proven in the same way. Had the certificate been refused upon the ground that the Physio-Medical College was not of good standing, as required by section 6872, of the Revised Statutes of Missouri of 1889, it was conceded that mandamus would not lie to compel the board to issue it, because that question is, under the statute, within the judgment and discretion of the board to determine. But it was refused upon entirely different grounds, which did not involve matters of discretion or of judgment. The board undertook to establish a rule of its own, by which such good standing should be shown; that is, by requiring all medical colleges to furnish to it a list of their respective matriculates and the basis of their matriculation. In this, the supreme court says that it went beyond the power conferred upon it by statute, from which it derives its origin, and by which its duties and authority are defined. While the members of the medical board are to be commended for their endeavors to elevate the standard of practitioners of medicine and surgery, in passing as a board upon the applications of such persons for certificates to practice their profession, and in prescribing rules and regulations to that end, the supreme court continues, they must keep within the limits of the statute creating it, and this they did not do in this instance. And as Johnston had a diploma from a medical college in good standing, the court holds, he was under no obligations to submit to an examination by the board, nor had it any authority to require him to do so, as a prerequisite to granting him a certificate to practice medicine in Missouri. Mr. Justice Barclay raises the only dissenting voice, and that only to the extent of suggesting that, as the validity of the rule of the board had not been called in question by Johnston, it seemed to him preferable not to express an opinion upon it.

An International Sanitary Code.—The Fourth International Sanitary Conference, held at Venice, after a session of five weeks, adjourned on March 19. Sixteen of the European powers concurred in the findings, which together with the conclusions arrived at by the Conferences of 1892, 1893 and 1894, held respectively at Venice, Dresden and Paris, will furnish the nucleus of a code for all civilized nations. The *Lancet*, March 29, states that while the action taken has not been officially promulgated, there has enough transpired to show that British sanitary ideas have triumphed. One British idea is to interfere in the least possible degree with commerce and thus discard the "antiquated" forms of quarantine detention. "It is altogether probable that the very eccentricities of sanitary administration which in a moment of panic were resorted to have had the effect of causing a marked change of opinion among some of the leading authorities of Europe in favor of the methods which have so long been adopted in England; some of these authorities have not failed to contrast the perfect quietude with which this country recently met not only an importation of a few cases of plague, but almost simultaneously the arrival of a batch of cholera cases at one of our southern ports, with the panic which was manifested in the Mediterranean—not because disease had been imported, but merely because it was thought such a thing might occur. It is, perhaps, due to this more than anything else that sound progress has been made in Venice, and as typical of this progress we may mention the fact that shipping from British India will no longer be detained at Suez merely on the chance that someone on board may sicken of plague, but will be at once allowed to

pass the canal under the care of guards, provided there is no plague on board. This in itself is a gain of the first magnitude, for the detention of ships at Suez, merely because that place is, as it has been termed, the neck of the bottle by which disease can be prevented from passing from the East into Europe, is a hinderance to British commerce and navigation of a serious character, and one which long years of experience have shown to be quite useless. India has been styled 'the home of cholera'; plague has, alas, been epidemic in Bombay for several months. But during all these years and months British shipping which passes from India to our ports in one unceasing line has always failed to convey disease to our populations, and this experience is at last telling on other nations beside ourselves. The protests which have been made by the leading medical advisers of the French Government, for example against the attitude of Marseilles, have been proved to be right. Marseilles is the main sufferer, for the shipping and merchandise which would otherwise have gone to that port have gone elsewhere and some of the inhabitants are now crying out for government support of those who have deprived themselves and their unhappy families of their means of existence. Another point of importance that has been gained at Venice relates to merchandise. No country is required to prohibit the importation of any article of merchandise, and yet the failure to impose such prohibition is in no way to bring about restrictions against any such country by reason of its free admission of merchandise. Before the Conference met we heard that nearly every conceivable article might convey the infection of plague and was therefore to be avoided. Thus corn, rice, cotton, skins, Eastern carpets and numberless other things were looked upon with suspicion and even with fear; but the Conference has not supported this view, and the result is that, while freedom of action within certain limits is allowed to each of the contracting governments, every one of the articles which had been regarded as dangerous may, under the Convention, be admitted into any country at the will of the country concerned. The governments which prefer to subject certain articles to disinfection before receiving them are free to do so; but in former Conventions there has always been a list of merchandise, produce, etc., which was either altogether prohibited or which could only be admitted after disinfection."

NECROLOGY.

CARL EISENLOHR, M.D., Hamburg, eminent neuropathologist and anatomist; author of "Spinal lesions in pernicious anemia"; "Pathologic anatomy of central paralysis of the larynx"; "Simulation of tabes by specific chronic meningitic affections of the spinal cord," etc. In the study of the pathologic anatomy of athetosis, he found in a case of congenital athetosis that there was no diffuse lesion of the cortex, no bilateral focus, no miliary encephalitis, but a chronic myelitis of the central gray matter with the bordering regions of the lateral columns and of certain zones of the posterior columns, which he asserts is the anatomic foundation of the disease. In another monograph he called attention to the peculiar forms of neuritis characterized by eruptions of herpes zoster and the development of circumscribed perineuritic swellings. A study of the physiologic importance of the thalami optici and of their significance to the mimetic functions, in 1890, was followed by a most comprehensive study of aphasia in which he added much to our knowledge of the localization of different forms of aphasia. The *Mitt. a. d. Hamburg. St.*, February, contains a detailed review of his works and an eulogy of his character. He died at the Madeiras of tuberculosis, in his 51st year.

CHARLES HAMMER, M.D., of Schenectady, N. Y., aged 65. He was born at Goslar in the duchy of Brunswick, Germany, Jan. 25, 1832, and was descended from a family whose

origin dates from the twelfth century and whose members were university men for generations. He served as volunteer in 1848 and was afterward exempted from military duty in Germany. He studied at Heidelberg University in 1852 and Goettingen in 1854. He then came to this country and lived for a time at Philadelphia, and for several years kept a drug store at Uniontown, Ala. He traveled extensively during the ten years prior to the civil war and spent a year in South America. At the outbreak of the war he was commissioned as surgeon of the First California Cavalry, with the rank of major, but did not see active service. He went to Schenectady in 1867 and has resided there ever since. He was a member of the Schenectady County Medical Society and the AMERICAN MEDICAL ASSOCIATION.

LEVERETT SILLIMAN KELSY, M.D., died at Mount Vernon, Ohio, April 9. He was born Sept. 4, 1854; was graduated at the Medical College of Ohio, 1879; was resident physician of the Hospital of the Good Samaritan until March, 1880. In 1882 he took a degree at the Bellevue Hospital Medical College, New York. Subsequently practiced medicine for fifteen years with great success at Richmond, Ind. He was loved by his friends, honored by his associates and respected by his profession.

F. C. L.

CHARLES R. WILEY, M.D., Jefferson Medical College, 1864, of Vineland, N. J., died of pneumonia April 2, aged about 53 years.

MISCELLANY.

Instance of Longevity.—"Uncle Josie" Field died April 1 in Middletown township, two miles from Red Bank, N. J. One of the incidents in his life was that he did not marry until he was 75 years of age, his wife being fifty years his junior. The couple had three children, who are still living. Mrs. Field is dead. Contrary to the theory that poverty is conducive to longevity he left considerable money and a farm of 4,000 acres.

A Cosmetic of Course.—The following is going the rounds of the secular press: "The oldest medical recipe is said by a French medical journal to be that of a hair tonic for an Egyptian queen. It is dated 400 B. C., and directs that dogs' paws and asses' hoofs be boiled with dates in oil." Perhaps it were well to investigate the chronology.

Medical Badges.—Russian doctors are hereafter to wear as a sign that they are legally qualified to practice, a little *zuak* or badge, a silver oval plate an inch and a half long by an inch wide, on which is a design of two intertwined serpents. The object is to increase the safety of the wearer in the less civilized parts of the country. This is according to the *N. Y. Sun*, and "must be so." Chicago physicians have had similar badges for about one year.

Urano-staphylorrhaphy.—Le Dentu reports 46 observations of congenital or cleft palate operated, and remarks that success is certain unless the chasm is of extraordinary width; 36 operations resulted in 31 complete successes, 3 satisfactory and 2 failures (acquired). In 11 cases of fistulas and acquired clefts, 8 were completely cured, 1 partially, and 2 proved unsuccessful. In each case of congenital cleft palate without complications, success was complete. He was also successful in all but 2 of 15 cases of congenital cleft palate with simple or double hare lip. In these 2 a slight communication persisted between the mouth and the nasal fossæ. He followed Trélat's instructions, with a special needle and scraper of his own design, and completed the operation at one sitting.—*Bulletin de l'Académie de Méd.*, March 9.

The Bubonic Plague in Literature.—"Chambers Encyclopedia," London, 1881, under the caption of "Black Death," beside mentioning Hecker's "Epidemics of the Middle Ages," refers to the "Decameron" of Boccaccio for a description of the

plague at Florence, "which for vividness and particularity of observation, almost equals Thucydides' account of the plague at Athens." In Bulwer's "Rienzi" an account of the plague will also be found. There seems to be no confusion of opinion regarding identities, but the meager resources of what little scientific language which abounded during the fourteenth century furnish appalling corroborations though really in a much mitigated form; to which may be added DeFoe's history of the London plague.

Effect of Fats on the Gastric Secretion.—Lobassow announces as the result of extensive experimentation with dogs, etc., that fat or grease coats the secreting surface of the stomach and diminishes the secreting power, and that it also coats the food taken into it and prevents the specific excitation of the mucosa, which normally favors secretion. He further states that this action of fat is not direct, but is due to a peculiar depressing influence exerted by the fats on the central nervous system. Aside from its theoretic interest, these conclusions may be found of practical value in controlling hypersecretion of the gastric juice by the administration of fats. Damaskin's experiments have confirmed Dolinski's assertion that fats stimulate the secretion of the pancreatic secretions.—*Ann. de la Soc. Méd.-Chir. de Liège*, February from *Wratsch*.

A Chilly Day for Willie.—The Reverend Dean Hole of Rochester, England, in his little book "A Little Town in America," says that he picked up the following bit of poesy in Cincinnati:

Little Willie from his mirror
Sucked the mercury all off,
Thinking, in his childish error,
It would cure his whooping-cough.
At the funeral Willie's mother
Smartly said to Mrs. Brown,
"Twas a chilly day for William
When the mercury went down."

Medico-legal Expert sued for Damages.—A woman was arrested March 18, 1896, on the accusation of infanticide. She was examined the 20th by Dr. Meloche in prison, who asserted that she presented every indication of a recent confinement. The day afterward she was delivered of a stillborn child. She instituted proceedings against the medical expert, and he has been condemned by the civil tribunal to pay her 1,000 francs damages, notwithstanding the contrary decision of the *ministère public*.—*Progrès Méd.*, March 6.

Action of Antitoxins.—Ehrlich has been experimenting to decide the question of the *modus operandi* of the antitoxins, whether they act by neutralizing directly the toxins or by stimulating the cells of the organism to action. He used for the purpose a vegetable toxalbumin, ricin, which possesses the property of producing, even in small amounts, coagulation of the blood. He found that antiricin—the serum of animals immunized against the effects of the ricin—possesses the power to suspend the coagulating property of the ricin *in vitro*. This result favors the theory that the antitoxins neutralize the toxins by direct chemic action.—*Therap. Woch.*, March 7, from *Fortsch. der M.*, January 15.

Cases of Carcinoma Under 20.—A writer in the *Mittheilungen aus der Hamburg. Staatskrankenanstalten*, the new periodical designed to supplement the year-book published by the Hamburg institutions, has been collecting the reports of carcinoma occurring under 20, as four of such cases had come under his observation, and finds the figures as follows:

	Carcinoma.	Under 20.
Gürtl's Statistics	4,769	10
Glasser: Erlangen University Statistics	527	1
Winiwarter: Billroth's Vienna Clinic	548	2
Fischer, Zurich	119	
Gusserow, Hough, Blau, Dittrich, Schröder:		
Carcinoma uteri	3,419	2
Hamburg Neues Alg. Hospital	524	4
Total	9,906	19

Cardiac Tracings in Basedow's Disease.—C. Ferrari has been studying the peculiar exaggeration and acceleration of the dirotic wave in nearly all of the cardiograms taken in this disease, which he ascribes to a modification in the nature of the cardiac contraction. The curve of the cardiac tetanus in Basedow's disease is not like that of the normal heart, which implies that the nerve impulses transmitted to the heart differ in some way from the normal, as in cases of stimulation of the pneumogastric. But there is also some special factor in the contraction of the myocardium in this disease; not only the rhythm but the form of the cardiac contraction is altered; instead of one single tetanic contraction in which the single beats succeed each other with an interval rather longer than usual, the second impulse follows so rapidly upon the first, that it seems to start even before the first has reached its extreme elevation. In his opinion this fact constitutes the significance of the cardiograms in this disease, and he asserts that we are not justified in assuming from the resemblance between these curves and those produced by stimulation of the pneumogastric, that the peculiarities are caused by modifications in the nervous mechanism. Too many important facts are arrayed against this assumption, among them the familiar fact that stimulating the pneumogastric *retards* the action of the heart.—*Gaz. degli Osp. e delle Clin.*, February 28.

Damage Suit for Syphilis Contagion.—Much adverse discussion has been caused by a recent judicial decision in France. An apparently healthy child was given to a healthy woman to nurse. In a few weeks the child developed hereditary syphilis, and the nurse contracted it, also her husband and child, with severe manifestations of the disease. She sued the parents for damages, but as neither of the parents showed the slightest trace of syphilitic lesions, past or present, no criminality could be fastened upon them and the plaintiff's claim for damages was refused. The case aroused much interest as the child of the nurse died and she committed suicide. The question has been raised whether nurses in future may not be tempted to sue the physician who countenances the introduction of such a child into their families. It behooves all to exercise extreme caution in such cases, and to refrain from countenancing them in any way when there is the slightest reason to fear possible syphilitic complications.

Amount of Iodin in Various Organs.—We notice the following table in an article on the various organ-preparations in the market (*Pharm. Ztg.*, No. 15, 1897).

Organ.	Average Weight.	Percentage of Iodin in organ.	Amount of Iodin in organ in grms.	Iodin soluble in physiologic salt solution.	Proportion of soluble Iodin to total Iodin.
Thyroid Gland.	10 grms	0.04	0.004	0.04	1:1
Spleen	1 kgm.	0.00152	0.015—0.020	0.00152	
	to	to	to	to	
	5 kgm.	0.00203	0.0225—0.080	0.00208	1:1
Pig's ovary	5 grms	0.000648	0.0000324	0.0002413	5:13
Cow's ovary	10 grms	0.000609	0.0000609	0.0000381	1:16
Suprarenal capsules	10 grms	0.0008048	0.00008048	0.0003048	1:1

—*Nouv. Remèdes*, March 8.

Death from Apoplexy Not Covered by Accident Policy.—An "accident policy" of insurance covenanted for the payment of an indemnity if death resulted from injuries through "external, violent and accidental means alone, independently of all other causes," and expressly stipulated that it should "not cover injuries of which there is no visible mark, nor death resulting wholly or partly, directly or indirectly, from disease or bodily infirmity." Death resulted from apoplexy, an attack of which followed certain work that required stooping and a run up a little hill. Under these circumstances, the United States

court of appeals holds, *Travelers' Insurance Co. v. Selden*, Feb. 2, 1897, that the case should have been taken from the jury and a verdict for the insurance company directed. It says that the sense in which the word "accident" was used in the policy, as shown by the context, and as expounded in similar cases, was as meaning "an event which proceeds from an unknown cause or as an unusual effect of a known cause, and therefore unexpected," something casual and fortuitous. Where an event occurs which can be readily explained as an operation of nature, working through natural, usual and ordinary laws, that, it declares, can not be called an accident. Consequently, the death in question must be attributed to disease, and not to "accident."

Leprosy Bacillus.—The presence of the lepra bacillus was reported in the medulla of a man 46 years old, who died of syringomyelia (Royal Bacteriological Institute, Lisbon, Dr. Canara Pestana and Dr. A. Beltencourt). At the necropsy there was found a gliomatous new formation of the medulla, which extended from the bulbous to the middle of the dorsal part, and showed strongest development in the neck region. The medulla was here strongly swollen, and presented a central cavity while the nerve substance was reduced to a thin bundle, formed mostly by degenerated anterior columns. In the substance which coated the medullary cavity inside, the authors found bacilli, which colored with carbol fuchsin, according to Ziehl, and also with aqueous fuchsin solution at 30 to 60 degrees, according to Gram, and which inoculated into the peritoneum of a guinea pig, produced no tuberculosis, and were, according to the opinion of the authors, undoubtedly lepra bacilli. We do not think, says Scheube in his review in *Janus*, this one essay at transmission to decide the question, whether the case was leprosy or tuberculosis, sufficient; whether the bacilli were isolated or aggregated, whether they were found in or between the cells is not indicated. In the nerves—the nerves examined were medianus and radiatus—no bacilli were found.

Restoration of the Vagina, Bladder, Urethra and Rectum.—Péan recently performed a successful anaplastic operation to relieve a woman who at her first confinement, age 28, had such a difficult delivery, the fetal head resting on the perineum four days, that part of the perineum and the recto-vaginal and vesico-vaginal septa were completely torn away. The urine, fecal matters and menstrual flow all issued uncontrolled from the cavern thus formed. The various steps of the operation are described with 10 cuts in the *Bulletin de l'Académie de Méd.* of March 9. The patient is now able to control her functions and lead a normal existence once more, although the menstrual flow issues through the same orifice as the urine. In case this produces trouble later, removal of the uterus and ovaries will put an end to the menstruation, as has been done in certain cases of vesico-vaginal fistulas.

Practical Radiography in Esophageal Surgery.—Péan, the Parisian surgeon, reports an interesting case in which the X rays were employed with great advantage to determine the exact position of a coin swallowed by a child. The following are the conclusions of Péan: 1. Foreign bodies up to 15 millimeters in diameter can be swallowed by infants with great facility. 2. Such bodies are generally arrested in the narrow part of the esophagus, of which the caliber in the adult does not exceed three-quarters of an inch, while in early life it is considerably less. 3. The difficulty of diagnosing the exact site of the foreign body is often very great, especially when the child can swallow liquids and does not complain of pain. 4. Radiography not only assists the surgeon by deciding the point as to whether the body has been swallowed or not, but also indicates the exact spot where it has lodged, and thus indicating where to operate. 5. Thanks to external manipulation, it is possible to cause a rounded and smooth object to travel from

below upward, until it can be extracted by the mouth. This mode of procedure is incontestably preferable to extraction through an incision in the tube. When once the exact position of a lodged coin has been determined in the esophagus, massage, in conjunction with position, might in some cases suffice for its removal, without recourse to the knife being necessary.—*The Scalpel*, February.

The Mission of the Microbe.—The history of science shows that a fact soon formulates itself into the dignity of a discovery, which in turn yields the palm to an explanation with the usual interdependencies of cause and effect. How easily at one time was said, "Eliminate the microbe, cure the disease;" how readily was the boon clutched after until Roux and Yersin proved the presence of the diphtheria bacillus in normal throats and Metschnikoff found the cholera bacillus widely spread in water. Then perhaps it began to dawn upon the intellect that Pythagoras once rushed naked from the bath to proclaim to the multitude an "eureka," which in his exhilaration he doubtless exalted into a panacea. Afterward the world discovered that he had promulgated a mode without establishing a principle. Now a virulent condition is made to do duty for an aggressive rod and health boards have begun to lose faith in their transferred cultures. Next antitoxic methods are in vogue to give way in turn to other theories, for such are these attempts to solve the biologic mystery still to be termed. Of course it were easy to offer the consolation to balked hopes that after the manner of certain transcendental philosophers "spirits may be bad as well as good—probabilities are to determine." Verily the equilibrium is hardly to be maintained when a dual life is concerned, the more especially when there is brought into the controversy the experiments of the Hygienic Institute of the Berlin University, which seem to convince that animals may live without depending at all upon the gratitude of parasites. "We might spend months in speaking of the beneficent ways of the products" says Dr. E. A. de Schweinitz in a recent Presidential address before the Chemical Society of Washington, "but these germs are only waiting man's bidding to become valuable subjects and to show that as has been instanced in the history of nations, conquered people often make the best and wisest citizens." After all what is really proven is that complex man has only a wider and busier field for his own particular warfare.

Walcher's Position in Parturition.—M. E. Fothergill of Edinburgh, in the *British Medical Journal* of October 31, says that Walcher's position—the *Walchersche Hängelege*—was first described by Walcher in 1889 in a short article in the *Centralblatt für Gynecologie (Therapeutic Gazette)*, February, 1897. By placing the parturient patient in the lithotomy posture, and then allowing the legs to hang freely down so that the feet do not touch the floor, the true conjugate is increased about one centimeter; this statement has been proved by numerous observers abroad, and the posture is now in use as a matter of routine in several German hospitals. It is employed in all high forceps operations, in extractions after turning, and after perforation of the head. Fothergill has found the posture extremely useful in several cases, which are briefly noted. In posing the patient, all that is necessary is to see that the buttocks are quite at the edge of the bed or table used, and high enough to allow of the feet hanging clear of the floor; pillows may be placed under the buttocks if the bed is low. There is a tendency to pull the patient off the bed; but she may be held by the anesthetist, or bands may be passed under the arms and fastened to the bed or table-legs so as to hold her in position. In this posture the axis of the pelvic brim presents downward at an angle of about 40 degrees; therefore, in order to exert traction in the proper direction with forceps, the operator must sit on a low stool, or on a cushion placed on the floor. In high forceps cases and after perforation, the position

saves, 1, the strength of the operator; 2, pressure on the head; 3, pressure on the symphysis; 4, pressure on the perineum by forceps. In cases of difficulty at the brim not needing forceps, and in breech cases, the position saves, 1, exertion to the uterus and abdominal muscles; 2, pressure on the head; 3, pressure on the pubic symphysis. In all cases, with or without forceps, where the perineum is in danger, extension of the legs at the hips is of advantage in relaxing the integument and subjacent structures at the vulvar orifice.

Inoculations of Erysipelas.—In order to determine the value of inoculations of erysipelas as a therapeutic measure in cases of carcinoma, Koch and Petruschky have been conducting a series of experiments, described in the *Ztschft. f. Hyg. u. Inf.*, Vol. 23, No. 3. Their conclusions are that the effect of the streptococcus varies very much with different persons. They found that streptococci, made very virulent by repeated passages through rabbits, has no effect on man, and that even human streptococci are not always efficient in producing erysipelas. Different kinds must be tried to ensure success. Erysipelas can be induced in man by cutaneous inoculation of streptococci derived from pure pus processes, such as peritonitis. The fact that one has had several light attacks of erysipelas does not confer immunity against further attacks; neither is it possible to induce positive immunity by previous treatment with anti-streptococcus serum. They conclude by stating that it is impossible to deny the therapeutic influence of several streptococcus infections on the course of a carcinoma, but that this is too slight in comparison with the consequent loss of vital strength, to allow us to cherish any hopes of securing the cure of carcinoma by this means.—*Cbl. f. Chir.*, March 6.

Radical Operation for Varicose Veins.—O'Connor (*Annals of Surgery*, April, 1897, p. 526) describes briefly the mode of procedure that he has followed during a year in the radical treatment of varicose veins. The limb having been shaved and disinfected from Poupart's ligament to the ankle, a two-inch incision is made over the saphenous opening and the internal saphenous trunk is doubly ligated and divided; if no varicosity is present above the knee, the wound is closed and dressed at once with iodoform gauze. If the femoral portion is affected, after ligation at the saphenous opening the vein is dissected up and its tributaries seized with pressure-forceps and ligated. In nearly all cases, if varices are present above the knee, there are also some below. Consequently the incision is prolonged downward directly over the vessel until the lowest limit of the disease is reached; the vein is then tied and divided below. In some cases an incision of eighteen or twenty inches is necessary. If the disease does not extend above the knee, after occluding the saphenous trunk in the manner described an incision is made over the affected portion, a ligature is applied above and below and the whole mass is removed by dissection. This maneuver, it is said, may be carried out with surprising ease and rapidity. All branches are caught up with pressure-forceps, and when the main channel is removed they are ligated. As frequently the external saphenous vein is also affected, its varicose portion is dealt with in a similar manner. While to one unaccustomed to an incision of eighteen or twenty inches this plan may seem formidable, it is pointed out that if the vessel is ligated above and below the varicose area there is not the slightest danger of embolism or pyemia, and the hemorrhage is insignificant. The method has also been employed in the removal of large thrombosed veins occurring in the first few months of pregnancy. Under these circumstances above all others it is particularly necessary, before manipulating the diseased portion, to occlude the main vein well above the seat of the disease, so that if thrombi are dislodged they can not pass into the general circulation. The time occupied in this procedure need not be greater than is required in other comparable operations. The wounds made heal just as kindly as do the short ones, and with ordi-

nary surgical cleanliness there is nothing to be feared. The insertion of a strand of iodoform gauze as a drain to every four inches of wound is a useful precaution, for it does away with the risk of any collections of blood. No bad results were observed to follow the employment of this method, and the patients treated are grateful for the results.

A Dwarf Race in Central Asia.—Two Danish explorers, Olufsen and Philippsen, have recently returned from a tour in little known territory lying to the north of the Himalaya ranges, which forms a part of the so-called Pamir plateau. High up on this tableland they found a unique race of men. Not only are they fire-worshippers, but they are also much smaller than the average human being. Of civilization, as we understand the word, they have apparently no conception, being in all respects as primitive as the most savage tribe. Traces of fire-worship may be observed throughout the entire orient and even in civilized Europe. Bonfires are still lit on St. John's eve, and this old custom is said to be a relic of fire-worship. It seems that in this strange country the animals, as well as the human beings, are ludicrously small. Thus, the donkeys, which are used as beasts of burden, are scarcely larger than dogs, and the oxen are never larger than ordinary foals. Scientists claim that the climate has dwarfed the four-footed animals, as well as the human beings, but the majority, while admitting that a rigorous climate may stunt men and women, deny that it can have the same effect on quadrupeds, since nature carefully provides them with adequate armor, even in the worst climate. That these little men and women are entirely uncivilized is shown by the fact that they have no money and carry on all their business by means of barter. It is also evident that the ceremony of marriage plays a very small part in their life, for we are told that the price of a woman is fifteen sheep or five or six cows. From what other travelers tell us it seems clear that the territory inhabited by the dwarfs is very limited. The entire Pamir region is not of any great extent, and we know that for nine and a half months of the year the Alai district is uninhabited owing to the extreme severity of the weather. A sturdy race, too, these dwarfs can hardly be, for more than one authority tells us that the people on this plateau suffer greatly from chills and rheumatism, and also from scorbutic affections, which are the result of their meager diet. In St. Petersburg the travelers have received a hearty welcome, and the opinion is freely expressed that their discoveries will prove to be of unusual interest and importance. They have brought back with them from Asia many curious objects collected during their travels, and these will probably be placed on exhibition in Denmark.

Not Proper Evidence or form of Action Against Office Physician.—Because it is an unsafe practice, in the admission of testimony, to allow witnesses to speak as experts unless the court is well satisfied that they possess the requisite qualifications, especially as the effect of such testimony is most difficult to estimate, from the fact that undue importance not infrequently attaches to it, and gives to it an influence upon the minds of a jury to which it is not fairly or reasonably entitled, the court of appeals of Maryland says that the rule allowing expert evidence will, in its opinion, be less objectionable, and more conducive to justice, if it be somewhat restricted, rather than relaxed. Accordingly, in the malpractice case, entitled *Dashiell v. Griffith*, wherein one George R. Griffith and his wife had obtained a judgment, it holds, Dec. 3, 1896, that a woman who had nursed twenty or thirty cases of "bone fellow" where opening or lancing had been resorted to, was not thereby qualified to say as an expert "that, in her opinion, the finger was not cut half way to the bone," because the wound did not "lay open," and "when an incision is deep, it always lays open." And the court takes pains to state that it has seldom, be it said to the credit of the profession, been required to pass upon question of

medical malpractice. But it thinks that the people are generally agreed upon the proposition that the amount of care, skill, and diligence required is not the highest or greatest, but only such as is ordinarily exercised by others in the profession generally. It also thinks that when a physician is employed to attend upon a sick person, his employment, as well as the relation of physician and patient, continues, in the absence of a stipulation to the contrary, as long as attention is required; and the physician or surgeon must exercise reasonable care in determining when the attendance may be properly, and safely discontinued. The same principles of law control the right of recovery for malpractice whether he goes to the home of the patient to bestow such attention, or renders his services at his own office. But if an office patient fails to come to the office of the physician or surgeon whom he employs, and from whom he has received careful and skilful treatment, and then fails to return to the office for further treatment, and in consequence thereof suffers injury, the court suggests that he is not entitled to maintain an action against the physician, because it is his own default and misfeasance. It further holds that if the defendant had, in his treatment of Mrs. Griffith's finger prior to a certain date, exercised reasonable care, skill, and diligence, and then, because of the illness of his father, had turned his patient over to another physician, a competent one, for the further treatment of her finger, and the woman refused to go to the latter for treatment, then the liability of the defendant ceased, and the patient assumed to herself the consequences of any injury resulting from the neglect of her finger. Aside from this, the court holds that no recovery could be had of damages for the failure of the defendant to be present at his office on and after the date above referred to, because the complaint stopped with the single allegation of "actual misfeasance, negligence, and want of skill" in the treatment of the finger, and no such further cause of action was laid therein. It also holds that the husband and wife could not sue jointly when the cause of action was the mere non-performance of a duty imposed by the contract of employment, which would be solely in right of the husband. For these reasons, the court grants a new trial.

Health of the British Army.—As the yellow-covered report for 1895 of Director General J. Jameson, Army Medical Department, to the Right Honorable the Secretary of State for War, is not to be found on every bookshelf, the following notes may prove of interest as showing how our Army medical statistics and sanitary conditions compare with those of Britain. The British troops serving at home and abroad, not including colonial corps, numbered 200,000 men, one-half of whom were on duty in the United Kingdom and the other in India and the Colonies. The number of cases admitted to sick report among the troops at the home station was equivalent to 702.8 per thousand of the strength, giving a constant sick rate of 41.76, with a death rate of 4.32 and a discharge rate for disability of 16.57. These rates, although somewhat larger than those of the previous year, are under the average of the last ten years. The rates of the U. S. Army compare favorably with these. Our admission rate is larger, because our medical officers are required to report as sick all men who are excused by them from the performance of any part of their military duties; but our rate of constant sickness in 1895 was only 33.89. The average duration of each case among the British troops was 20.64 days as compared with 11.1 in the U. S. Army; and the number of days lost by each British soldier on account of sickness (injuries included) was 21.03 days as compared with 12.4 days among our troops. Enteric fever was reported as the cause of admission in 137 cases, 35 of which were fatal. This number of deaths occurring in a strength of 100,000 men can not be considered large in view of the typhoid death rates that prevail in most of the cities of the United States. Venereal diseases occasioned 173.8 admissions and a constant sick-

ness of 15.28 per thousand of strength. The Channel Islands had the highest admission rate, 230.1; the garrison of Cork the lowest, 103.3. In this respect the United States soldier has a better record, for the admission rate was only 73.72 and the constant sickness only 5 per thousand men. Before discussing the medical statistics of the troops on foreign stations the report gives many interesting data concerning the 55,698 recruits examined in the United Kingdom during the year. In every thousand of these 411.43 were rejected as unfit, this rate being somewhat larger than that of the previous year. Deficient height, weight and chest measurement occasioned 191.66 rejections per thousand examined; defective vision 39.88; varicose veins and varicocele 28.13; heart disease 20.71 and hernia 6.68. Of the 32,782 found fit for service the ages varied from 18 to 25 years, very few being under or over these extremes. One-third of the whole number were between 18 and 19 years of age. In fact the average age was 19.4 years, the height 65.9 inches and the weight 125 pounds. The physique of the young recruits of the United States Army is greatly superior to this. During the year 3,286 native born whites between the ages of 20 and 25 (average 22) were enlisted, and the average height of these was 67.75 inches; weight 143.57 pounds.

The troops in Canada suffered less from sickness than any of the other commands serving abroad. Their rate of constant sickness was only 24.99, and the sick time to each soldier only 9.12 days. Speaking comparatively, the troops in Bermuda also had good rates: constant sickness 39.09 per thousand, with 14.27 days as the time lost through sickness by each soldier; but in all the other commands the rates were high. The rate of constant sickness in India was 93.61 with 14.31 dead, 12.01 discharged and 24.34 sent home as invalids out of every thousand men of the 68,331 serving with the flag in the Indian Empire. The highest admission rate, 2,844.9 per thousand, occurred in the Sind district, more than half of which was caused by malarial fevers. Of individual stations Karachi had the highest rate, 3,008.2, chiefly caused by malarial fevers and venereal diseases. The mortality was highest, 39.63 per thousand, at Barrackpore, nearly half of it due to dysentery. Enteric fever in India caused 322 deaths per 100,000 of strength, the percentage of mortality to attack being 24.8; but this rate of fatality is open to criticism when we find in a subsequent part of the report that 1,427 cases of simple continued fever, with 3 deaths, are recorded. The largest number of cases of enteric fever occurred at Lucknow, 128, with 35 deaths; and this notwithstanding the distribution of a new and pure water supply from the Lucknow waterworks. At Meerut, Umballa, Peshawar and several other stations where the prevalence of this fever was considerable, the benefit derived from boiling the water was by no means well defined. The medical officers in charge considered that the disease was contracted in the bazaars of the city, where ice creams and drinks of all sorts are sold and largely indulged in by the men. At several of the stations it was noted that no officer, married soldier, woman or child belonging to the garrison became affected, and it is remarked that had the milk or water supplies been infected, the women and children would have been among the first to suffer. Cholera touched the troops but slightly during the year, having caused only a total of 44 admissions and 32 deaths. Malarial diseases occasioned an admission rate of 342.2 per thousand, with 12.55 of constant sickness. Venereal diseases added 536.9 to the admission rate, or 127.6 more than the average. The constant sickness from this cause was 46.39, or considerably higher than the disability caused by all diseases and injuries in the army at the home stations. The highest admission rate was reported from Nowgong, 1,013.5; but Cawnpore furnished 967.6 and was followed by many others with rates nearly as high. "Lamentable as are the foregoing figures, they understate as regards secondary syphilis the amount of inefficiency due to that form of the disease, as in several stations

men were treated by hypodermic injections of mercury without admission to hospital." The disability due to injuries must be regarded as small, 99.7 cases with a death rate of 1.75 per thousand of strength. The sanitary condition of barracks and quarters appears from the report to have been excellent, and an occasional statement of primitive and unsatisfactory conditions serves merely to emphasize the excellence of the whole. Take, for instance, from the report on the Rangoon District: "At Meiktilla the water is taken from a lake by means of water carts drawn by bullocks; these are driven into the lake, and it is said that the *bheesties* frequently wash themselves and their bullocks before filling the water carts." In one instance (at Jubbulpore), the sand for the Macnamara filter was found to have been obtained "from a *nullah* contaminated by human excreta and washings from neighboring villages." The recommendations concerning water supplies made in the report are: "That in all stations not supplied with pipe-water from reservoirs certain wells be set apart for drinking water, and be put into thorough repair and covered in and fitted with pumps and reservoirs from which the water be laid on to barracks in pipes. That wherever reservoirs exist, the greatest care be taken to prevent the pollution of the water in the reservoir and during its distribution. That the Macnamara filters be replaced by the Pasteur-Chamberland filters in all stations." Concerning enteric fever and cholera the recommendations are: "That all drinking water and milk be boiled during the prevalence of these diseases in any station, and that the latrines be freely and regularly disinfected. That all wells used for drinking be disinfected with permanganate of potash." The rate of constant sickness in Egypt was 63.13 per thousand, chiefly due to fevers and venereal diseases. The presence of cholera in the country caused the strictest supervision to be maintained, and a set of instructions for guidance as to general sanitary and hygienic measures was issued. Pasteur-Chamberland filters were provided for many of the garrisons. The troops in China had a constant sickness of 73.39 per thousand, nearly half of it occasioned by venereal diseases. Only five cases of enteric fever were reported from this command of over 1,500 men, although "the insanitary condition of Victoria and the abominable stench in which it abounded probably lowered the standard of health, and if they did not actually cause, they at least predisposed to the occurrence of sickness. These stenches were in a great measure due to the absence of flushing of the drains and sewers, owing to the insufficiency of water—the rainfall for the year having been 35 inches below the average and 15 inches below the lowest recorded."

The Appendix to the Report contains a paper on the progress of hygiene during the year 1896, by the professor of sanitary hygiene at the Army Medical School, Surgeon-Colonel J. Lane Notter, with reports on cholera and enteric fever and a number of excellent papers on surgical cases. The most interesting paper, however, is probably Surgeon Major General W. Taylor's "Report on the Medical Transactions of the Ashanti Expeditionary Force," during the period from Dec. 14, 1895, to Feb. 7, 1896. A full account is given of the care exercised in the selection of the men, their clothing, food, water supplies and personal hygiene, and of the organization of the hospitals.

New York.

THE MANHATTAN STATE HOSPITAL FOR THE INSANE.—The damage done by the recent fire in the Manhattan State Hospital for the Insane, on Ward's Island, is greater than was at first estimated. The contemplated repairs will cost \$100,000. The patients placed temporarily in other institutions will remain subject to further disposal.

THE CENTENNIAL OF THE WESTCHESTER COUNTY MEDICAL SOCIETY.—Dr H. Ernst Schmid, of White Plains, N. Y., is to deliver during the coming month an historical address before this society, which will reflect the methods of practice and the manners of the period. He is reputed to be a philosophic and exhaustive writer.

THE HOSPITAL FOR THE RUPTURED AND CRIPPLED IN New York City, is to be enlarged. The present buildings at Lexington Avenue and 42d Street will be given up entirely for administration purposes. The exterior of the new structure will be of gray brick, with elevations of buff Indiana limestone. An architectural feature will be the semi-circular tower-like end at Lexington Avenue and 43d Street. About the only external ornamentation will be the scrollwork over the entrance doorway at Lexington Avenue and 43d Street. The main building will be five and a half stories in height. The

end flanking Lexington Avenue, a single story in height, will be used for the dispensary. Around the south end of the dispensary, a driveway is to lead from Lexington Avenue into a spacious court for receiving supplies. In the basements will be large workshops and sewing rooms, together with many appliances to enable the inmates to engage in light occupation. On the top floor will be the operating theater, with its adjuncts of necessary rooms. A large kitchen has been centrally arranged for the easy distribution of food to all the buildings.

THE BELLEVUE HOSPITAL MEDICAL COLLEGE and the University Medical Department have concluded to join forces. When the former school lost its dissecting room by fire, a few weeks ago, the latter tendered the use of its accommodations to the students. Growing out of that courtesy, harmony and consolidation have resulted, and the sanction of the State Board of Regents has been obtained for the union, under the title of the "New York University-Bellevue Hospital Medical College." As the lease of the Bellevue College site on the hospital grounds has not long to run, the trustees of that institution have recently obtained by purchase a valuable plot of ground on the southwest corner of 26th Street and 1st Avenue, which will probably be utilized as the site for additional laboratory accommodations.

Detroit.

THE STATE BOARD OF HEALTH meets in Detroit some time this month.

DETROIT has been having an epidemic of measles for some time. In a great many cases the type of the disease is very severe, bronchial and pulmonary inflammations being the most grave. Some deaths have been reported.

AT THE DETROIT MEDICAL AND LIBRARY ASSOCIATION, Monday evening April 5, Dr. John Flinterman read a paper entitled, "Carcinoma of the Duodenum, with Report of a Case." The doctor presented a specimen of the case reported, which showed a carcinomatous involvement of the descending portion of the duodenum with metastasis of the liver. The valvulæ conniventes were not closed. The hepatic duct was greatly hypertrophied. The ductus communis choledochus was considerably enlarged further down. Upon microscopic examination the hepatic cells were found to be atrophied; the liver itself atrophied; the stomach quite small. The doctor in his report stated that the patient suffered greatly from jaundice, and that the symptoms were unusual for cancer of the duodenum, which led him to rather suspect primary cancer of the liver. The writer also took the stand that cases of cancer of the duodenum give the same symptoms as those with cancer of the pylorus. The case under discussion was an exception to the rule and the doctor thought that it was due to the non-obstruction in the duodenum. The speaker took up the statistics on the subject showing how rarely carcinomas appear in this region, giving the records of the large hospital in Vienna, the Institute des Wiener Allgemeinen Krankenhauses as proof, where, during the last twenty-four years, 343 cases of cancer of the intestines were reported, and out of this number only three were of the duodenum.

THE WAYNE COUNTY MEDICAL SOCIETY had a very interesting meeting Thursday evening, April 1. Dr. David Inglis on the subject of, "Some Practical Points in Therapeutics" gave some very good suggestions, of which the following are the most important: In treating cases of inflammatory croup which are not diphtheritic, the administration of quinin in comparatively large and frequent doses is indicated. To a child of 5 years, 2 grains every hour for three to five times may be given. Should the physician be called early in the day, say at 1 P.M., the exhibition of 2 grains every two hours until 7 o'clock, and then every hour for a few times, will almost certainly insure a good night's rest for the child as well as for the doctor. On the following day the dose of 2 grains every three or four hours will almost certainly complete the cure. A very good way to administer quinin is by inunction, the quinin having been rubbed up with lanolin. This latter has been found to assist

the absorption of the remedy better than any other oily preparation. The treatment of chorea by sulphonal has been found to result satisfactorily. The author of the paper prefers trional to sulphonal for its hypnotic effect, as it produces more natural sleep and is more readily soluble. Acetanilid is preferable to the bromids for the treatment of epilepsy, as it has the same power to control the convulsions without the undesirable mental effects which the bromids produce. As to the objections which some raise to all coal-tar preparations, that collapse, cyanosis and excessive perspiration too often result from their use, the doctor believed that this was of no material consequence and never resulted disastrously. For burns, the use of castor oil and lime water, in place of linseed oil and lime water, has the advantage of a perfectly bland protective application which does not dry upon the surface as the "carron oil" is known to do. In the writer's experience no cathartic effect results from such use of the castor oil.

Washington.

QUARANTINE REGULATIONS.—The Secretary of the Treasury has added the following paragraph to the United States quarantine laws and regulations: "All bedding provided for steerage passengers must be destroyed or disinfected before being landed. Bedticking or other covering of mattresses and pillows used by passengers or crew shall not be landed unless disinfected at the quarantine station in accordance with these regulations, and tagged with the labels certifying to said disinfection."

MEDICAL AND SURGICAL SOCIETY.—At the April meeting of the Society Dr. P. C. Hunt read the paper of the evening, entitled the "Therapy of Phthisis." He said the only means of eradicating the disease was prophylaxis, and emphasized the fact that it is only through an early diagnosis that we may hope to accomplish a cure. He recommended the use of tuberculin as a means of early diagnosis in suspected cases of human tuberculosis. He mentioned a case where it had been so used as early as 1892. He does not believe in serotherapy in phthisis—though advises tuberculin in incipient cases, and creosote in small doses as a stomachic tonic. He does not believe this has any direct action on the bacilli in the body; has obtained the best results from strychnin in doses of 1-40 grain. He believes hygiene and alimentation one of more importance than drugs or climates, though each plays an important part in the treatment of the disease. The paper was discussed by Drs. Vincent, J. Eliot, Kober, Moran, Chamberlin, Mayfield and others. Dr. Chamberlin reported a case of nasal cystoma which he had successfully removed. He presented the specimen. An interesting discussion followed.

TO CHECK EXPECTORATION IN STREET CARS.—The Commissioners will shortly promulgate a police regulation prohibiting people from expectorating in or on any part of a street car. The new regulation will compel the railroad companies to keep posted notices of the regulation in each car, and will endeavor as far as possible to see to it that the regulation is faithfully observed. A fine of not less than \$10, and in default imprisonment in the workhouse not exceeding fifteen days, is provided.

FINE FOR VIOLATING THE MEDICAL PRACTICE ACT.—Simon Ford, colored, a so-called voodoo doctor, was fined \$50 and sentenced to ten days' imprisonment in jail in default for "practicing medicine" in the District without a license from the medical supervisors. The law will be pushed vigorously in the future, and it is hoped will soon rid the District of all "irregulars." The health officer has his eye on a number of such cases and will soon bring them into court.

STATED MEETING OF THE MEDICAL ASSOCIATION.—At a meeting of the Medical Association for the District of Columbia held on the 6th inst. the following officers for the ensuing year were elected, viz.: President, Dr. G. Wythe Cook; vice-presidents, Drs. Bowen and Ruffin; secretary, Dr. Wellington; treasurer, Dr. Deeble; councillors, Drs. McLain, Holden, Ober, Acker, Kober, Carr, T. R. Stone, H. L. E. Johnson and D. O. Leech; censors, Drs. Woodward, Frank Leech and Mayfield. Delegates to the meeting of the AMERICAN MEDICAL ASSOCIATION to be held in Philadelphia June 1 to 4 as follows: Drs. Cook, Barrie, Busey, Mayfield, L. Eliot, Deals, J. T. Johnson, H. L. E. Johnson, Ruffin, Barker, Acker, Hunt, Brown, Heiberger, Scott, S. S. Adams, Bovee, Nordhoff, Jung, Carr, I. S. Stone, McLaughlin, Glazebrook, Belt, F. Leech, Bogan, Wellington, D. O. Leech, Franzoni, Magruder, Tompkins, Sobon, Kleinschmidt, Moran, W. P. C. Hazen, Kober, Woodward, J. Eliot and Reyburn. The following new mem-

bers were elected: C. Neil Barry, Edmund Barry, Frank W. Braden, Durces Desmus Carter, Marion B. Carter, Edward Francis Cumiskey, Hub'd Gillette, Franz A. R. Jung, Robert L. Lynch, Bernard Francis McGrath, Robert Daniel Mayer, Frank A. Mazzei, Homer Sanford Medford, Thomas Miller, Leonard W. Munson, James Richard Tubman and William O. Wetmore.

THE EPISCOPAL EYE, EAR AND THROAT HOSPITAL.—The new hospital known as the Episcopal Eye, Ear and Throat Hospital was formally dedicated on the 7th inst. Addresses were made by Bishop Satterlee, D.D., Drs. N. H. Nicken and W. W. Johnston. The hospital will be open every day for the treatment of dispensary cases.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from April 3 to 9, 1897.

Capt. Eugene L. Swift, Asst. Surgeon, is relieved from duty at Ft. Yates, N. Dak., to take effect upon the expiration of his present sick leave, and ordered to Ft. Slocum, N. Y., for duty.

Capt. Edward R. Morris, Asst. Surgeon (Ft. Spokane, Washington), is granted leave of absence for six months, to take effect on or about May 18, 1897.

Capt. Henry S. T. Harris, Asst. Surgeon (Ft. Preble, Maine), leave of absence granted for seven days is extended twenty-three days.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for two weeks ending April 10, 1897.

Surgeon C. U. Grayatt, ordered to examination for promotion, Washington, D. C., April 5.

Asst. Surgeon J. C. Prior, ordered to the naval laboratory and department of instruction, New York, April 5.

Asst. Surgeon F. C. Cooke, ordered to examination for promotion, New York, April 5.

Asst. Surgeon G. D. Costigan, detached from the "Vermont" April 6 and ordered to the "Lancaster" per steamer of April 7.

Asst. Surgeon D. H. Morgan, detached from the naval laboratory, New York, April 6, and ordered to the naval academy April 8.

Surgeon C. U. Grayatt, when finished with examination for promotion April 5, detached from the Museum of Hygiene, ordered home and then hold himself in readiness for sea.

P. A. Surgeon J. A. Guthrie, detached from the "Katahdin" and ordered to the "Alliance."

Asst. Surgeon J. F. Leys, detached from the "Alliance" on relief and ordered to the "Vermont."

Medical Director T. N. Penrose, detached from the New York hospital June 5 and placed on waiting orders.

Medical Director G. W. Woods, detached from the Mare Island hospital May 10 and ordered to the New York hospital June 5.

Medical Inspector G. P. Bradley, ordered to the Mare Island hospital May 10.

P. A. Surgeon E. P. Stone, detached from the "Indiana" April 12 and ordered to the "Bennington."

Change of Address.

Ayres, S., from 247 Shady Av. to 826 Moorewood Av., Pittsburg, Pa.
Cresswell, G. H., from Chicago, Ill. to Awada, Wyo.; Clark, J. F., from 871 to 788 Jackson Boul., Chicago, Ill.

Deutsch, J., from 215 Main St. to 30 Monroe St., Memphis, Tenn.
Eckman, F. N., from 2223 Fairmount St. to 624 N. 22d St., Philadelphia.

Gambie, W. E., from 264 S. Halsted St. to Blue Island Av. and Harrison St., "New Era Building," Chicago, Ill.

Harlan, Herbert, new address, 516 Cathedral St., Baltimore, Md.;
Henkle, C. K., from Independence, Ore., to Julianna, Idaho.

Kent, J. L., from New York, N. Y., to Pulaski, Va.
Moody, H. A., from Mobile to Bailey Springs, Ala.

Norton, J. J., from Biloxi, Miss., to Monroe City, Mo.
Renn, T. H., from 227 Townsend St. to 1240 Milwaukee Av., Chicago, Ill.

Still, H. M., from Evanston, Ill. to Kirksville, Mo.; Silverberg, Geo. M., from 330 Blue Island Av. to 465 Marshfield Av., Chicago, Ill.

Thornbury, F. J., from 610 Main St. 401 Delaware Av., Buffalo, N. Y.
Withoua, R. A., from 303 W. 77th St. to 410 E. 26th St., New York, N. Y.;

Wilson, F. P., 922 A. Sutler Av. to 1101 Van Ness Av., San Francisco, Cal.

ORIGINAL ARTICLES.

THE OCCURRENCE OF SUGAR IN THE URINE; ITS CLASSIFICATION, ETIOLOGY AND PATHOLOGY.

NUMBER 1.

BY EDWARD L. MUNSON, M.A., M.D.

ASSISTANT SURGEON, U. S. ARMY, FORT ASSINNIBOINE, MONTANA.

The term diabetes mellitus is usually indiscriminately applied to a disease prominently characterized by an excess of sugar in the blood and by the occurrence of this body in the urine in varying amounts, this condition persisting over a greater or less length of time.

The occurrence of sugar in the urine may be primarily divided into the physiologic and the pathologic, the former being again separated into two classes: 1. That condition in which, as ordinarily found in health, the quantity of sugar present in the urine is too small to be detected by the usual clinical tests as by Fehling's solution, by fermentation, etc. That a certain amount is, however, normally present in health has been repeatedly demonstrated by the more delicate gravimetric method, so that the increased amount of sugar often found in a urine may be simply due to the increased activity of a perfectly physiologic process, which under certain abnormal conditions, may become pathologic. 2. Those cases, much more numerous than usually supposed, the urines of which will be found to contain sugar in such increased amounts as to be appreciable by the common clinical tests. This condition may extend over a considerable period, perhaps many years, the patient in the meanwhile continuing in perfect health and the katabolic processes, to which the term diabetes mellitus is only to be applied, never ensuing. In such a patient the ingestion of carbohydrates does not in the least affect the excretion of sugar. The pathologic division is also to be separated into two main classes, glycosuria and diabetes mellitus proper.

Glycosuria, by which is to be understood a temporary increase, as the result of certain abnormal conditions, in the quantity of sugar present in the urine; this sugar disappearing on the removal of the etiologic factors is to be classified as follows:

1. Nervous glycosuria, induced by prolonged and excessive emotions, by great nervous excitement or depression or by brain exhaustion. Thus it may be consequent to overstudy, excessive venery, fright, anxiety or grief. This condition has been well shown by Cohnheim in the lower animals by simply tying them down to a board, the terror and excitement being followed by the presence of sugar in the urine.

2. Febrile, as when sugar tests are obtained during or immediately following many pathologic processes, such as acute fevers or phthisis.

3. Traumatic.—Sugar is observed in urines passed soon after injuries affecting the cranium and its con-

tents, such as hemorrhages into the brain substance, fractures of the tables, blows producing unconsciousness, etc. It may continue during inflammatory conditions of the brain or its meninges. Experimentally, it may be shown by the well-known "puncture of the fourth ventricle." Glycosuria also frequently follows any severe traumatism even if it be unassociated with cranial injury. Its occurrence in such a case is probably due to similar influences to those which induce the condition recognized as "shock."

4. Toxic.—Glycosuria may be produced by the action of many chemical and medicinal bodies, as curare or phloridzin, by the administration of anesthetics, etc. It is probably caused by the depressing and paralyzing effect of the drugs upon the peripheral and central nervous system.

5. Dietetic glycosuria is induced in some individuals by excesses of diet, more especially by the inordinate use of carbohydrates but also by the use of alcohol particularly in the form of the dry wines. It is caused in the first instance, by the sudden entrance into the system of more sugar than the organism is able to burn or store up in a given time with the consequent appearance of the unburned portion in the urine. In the second case, the toxic action of the alcohol on the nervous system may be considered as the cause.

6. The glycosuria of lactation immediately precedes the secretion of milk in the puerperal woman. It disappears on the flow becoming established to again appear if the quantity of milk produced is in excess of its consumption. It is, without a doubt, due to a reabsorption of the milk-sugar.

Glycosuria, then, is a transient affection depending on the presence of certain exciting conditions, the removal of which is at once followed by a return to the normal. It has no more clinical importance than has a slight variation of temperature except as its presence may temporarily give rise to apprehensions of a true diabetes.

Diabetes mellitus proper is a disease depending upon deep-seated nervous processes which can not be traced to any known cause and which are not followed by any constant anatomic changes. It is to be considered purely as a neurosis and may be divided, clinically, under the following heads.

1. The mild form, in which the sugar excreted is consequent upon the ingestion of carbohydrates and in which, on a return to carbohydrates from a strictly proteid diet, the temporarily latent dyscrasia reasserts itself. An individual, therefore, under certain artificial conditions of diet may temporarily excrete no sugar without the abnormal systemic processes, to which alone the name diabetes should be applied, becoming cured. This stage is accompanied by comparatively little body waste and trivial nervous symptoms. Sooner or later it becomes the—

2. Severe form, in which, on a rigid proteid diet, a large sugar excretion persists as a result of the split-

ting off of the carbohydrate radical from the ingested and systemic albumins. In this stage there is great and progressive body waste with muscular weakness. There is also a great liability to coma, induced by the action of the toxic bodies resulting as by-products in the cleavage of the albumin molecule.

The cerebral and nervous symptoms are strongly marked, while the excessive tissue waste predisposes to a fatal termination by asthenia or by the inception of an intercurrent affection. It will be observed from the foregoing that it is believed that glycosuria and diabetes are two entirely distinct affections, having but a single symptom in common—and that symptom, as will be shown in a subsequent article, attributable to entirely different causes. The occurrence of sugar in the urines of both glycosuria and diabetes is no more presumptive evidence of the identity of the diseases than would the febrile movement in scarlatina and uremia prove them like affections. It is simply a prominent symptom common to both, but a symptom which in true diabetes is only of secondary clinical importance outside its value in diagnosis. The gravity of a diabetes can not be estimated in the percentage of glucose excreted as the sugar output may vary or even entirely disappear under artificial conditions without the true pathologic processes of diabetes being in the least influenced.

In its etiology, diabetes mellitus occurs so frequently in families having a general tendency toward neuroses of various types that its inception seems to be favored by an hereditary predisposition not necessarily to the diabetes itself but to other affections of the nervous system as neuralgia, hysteria and various psychoses.

Diabetes is much more liable to occur during the time of greatest nervous activity. This is to be explained by the greater mental strain of that period and by the higher development of the nervous system, which at the extremes of life, is undergoing evolution and involution. That diabetes is never caused by organic disease of the stomach and liver, will be agreed by nearly all modern pathologists. After death the quantity of glycogen present in the liver has been found to be normal, the production of glycogen not appearing to be greatly affected by the disease. According to Cohnheim, the amount of sugar excreted in certain cases appears far too large to be accounted for by liver glycogen alone. The glycogen stored up in other parts of the body, particularly the muscles, must therefore be called upon and it may perhaps be an intermediate product in the production of sugar in the decomposition of the albumins. The liver, however, plays but a minor role in the essential phenomena of diabetes. Even if the liver glycogen be referred to as the source of the excreted sugar, upon what basis is the excessive tissue waste and abnormal metabolism to be explained? The mere presence of sugar in the blood can not induce the marked clinical symptoms of diabetes, else the same effects would also occur in glycosuria, in which the excretion of sugar may for a time be larger than in a case of true diabetes. The cause should be sought deeper. Either there is such a condition of mal-nutrition induced that the processes of anabolism and katabolism no longer balance one another, or there is an abnormal breaking down of the body albumin. That this albumin decomposition occurs has been demonstrated by Voit and Pettenkofer by showing that the amount of urea excreted on a known diet, in diabetes, consider-

ably exceeds the quantity which could be produced from the nitrogen of the ingested foods. That the diabetic has, to a greater or less extent, lost the power of burning blood sugar is also true. Voit and Pettenkofer have shown that in this disease less oxygen is taken in than by the healthy system and that the quantity of CO₂ excreted is less than normal, in some cases being but a third that of health.

The importance of pancreatic disease in the occurrence of sugar in the urine has been strongly urged. Minkowski was able to produce diabetes in dogs by extirpation of the pancreas, but found that this disease did not ensue if a small portion of the gland was left *in situ* or transplanted to some other part of the body. This result has been confirmed by other observers. Unfortunately for the theory that diabetes is entirely dependent upon disease of the pancreas, only relatively few of the undoubted cases of diabetes examined *postmortem* show any pancreatic lesions whatever, while in many other instances in which the function of the gland was entirely destroyed by cancer or otherwise no diabetes ever ensued. He believes that a ferment produced by the gland is the great factor in the combustion of sugar, but what this ferment is he is unable to demonstrate. Lepine has also shown that a sugar solution on being treated with pancreatic juice loses a certain proportion of its sugar in the form of water and carbon dioxide. To offset this, in all idiopathic cases of diabetes, the administration of the pancreatic gland cooked or raw, fresh or in the form of various extracts, by stomach or subcutaneously, has so far been absolutely without influence either upon the sugar excretion or the progress of the disease itself. It is said, however, that in animals suffering with diabetes as a result of extirpation of the pancreas the administration of either the gland or its extracts will produce a temporary removal or amelioration of symptoms.

Cohnheim refers the excessive thirst to a morbid nervous condition manifesting itself especially in the nerve supply of the mouth, pharynx and alimentary tract and believes that the diabetic does not drink because he micturates but micturates because he drinks. He does not admit the polyuria to be due to the presence of sugar in the urine but attributes polyuria in diabetes mellitus to the same causes which prevail in diabetes insipidus. The disease may then be defined as follows.

Diabetes is a disease characterized by and dangerous on account of an excessive tissue-waste and systemic katabolism, excessive thirst, and the appearance of sugar in the urine being also diagnostic but of less clinical importance. In all its symptoms it is the result of a generally depressed nervous system acting through the inhibitory centers which normally control and retard these tissue changes. There are two causes which cooperate in diabetes to produce the presence of sugar in the urine in excessive amounts, an increased production and a diminished oxidation. Unlike glycosuria this disease is not dependent upon the constant presence of a certain irritant condition nor does it disappear under varying conditions of diet.

In its pathology it is agreed by nearly all authorities that there are no constant anatomic changes which can be observed in the diabetic organism after death. The liver, generally of a dusky hue, may be large, small or of normal size; anemic, hyperemic or of normal vascularity, the hepatic cells being fatty, atrophic or normal. Rarely an occlusion of the portal vein has been observed. Cirrhosis and phosphorus

poisoning do not cause and are not followed by diabetes even if carbohydrates in considerable amount are administered. The amount of glycogen may be either normal or slightly decreased. A diminution of fat in the liver, together with amyloid degeneration, has been observed in many cases. Abscesses may be present. The pancreas has so frequently been found affected that it has been claimed that nearly half of all cases of diabetes are associated with pancreatic disease. This is probably somewhat too high an estimate. The most frequent of the pathologic changes in the pancreas are carcinoma, generally secondary, and atrophy, accompanied by a fatty degeneration of the gland cells.

This degeneration may be induced by carcinoma, formation of calculi and by obstruction of the efferent ducts, leading to a cystic dilatation in the body of the gland. Sometimes the wasting of the gland has progressed so far that no remnants of the parenchyma can be discovered. The co-existence of diabetes and disease of the pancreas may depend upon lesions of the celiac plexus, especially since it has been experimentally shown that a diabetes can be readily produced in dogs by prolonged irritation of this plexus. In such a case a disease, such as cancer, starting from the pancreas may encroach upon and implicate the plexus to such a degree as to destroy the ganglia and so produce a diabetes, or, the plexus is first affected and in consequence the circulatory disturbances, which arise in the regions supplied by the celiac axis may result in the degeneration and atrophy of the pancreas. Diabetes complicated by pancreatic disease is thought to run an unusually rapid course.

The kidneys, which usually show slight pathologic changes, are generally very large and of soft consistency, a state of things which should be considered as a functional hypertrophy. A glycogenic or hyaline degeneration of the epithelial cells lining the loop tubules of Henle is said to be a constant change; and hyaline degeneration of the arterioles has been frequently observed. These changes are, however, probably secondary. There are rarely any changes in the spleen. It has been described as enlarged, firm and rich in blood. The stomach usually presents the appearance of a chronic catarrh, thickening of the muscular and mucous coats, slaty pigmentation and hemorrhagic erosions. The stomach contents possess a sweet, ethereal odor. Dysenteric ulcers are frequently observed in the intestines.

Changes in the central nervous system are often found. There may be tumors in, or pressing upon, the brain substance or there may be more or less marked sclerosis of the medulla and cerebellum. A lesion which has been claimed as constant is a dilatation of the arteries and perivascular spaces in various parts of the brain and spinal cord, especially in the medulla and pons. Small capillary hemorrhages of more or less recent occurrence and minute myelitic foci can often be observed. With regard to the spinal cord no satisfactory conclusions have been reached. Both softening and sclerosis may take place. A striking but rather infrequent change is a dilatation of the central canal in the lumbar and dorsal portions, accompanied by a great proliferation of the lining epithelium.

Changes are found in the sympathetic system, more especially in the abdominal plexuses. Thickening, induration, atrophy of the ganglion cells and great pigmentation have frequently been observed in the

celiac plexus. Tumors implicating the vagi have been found in several cases. Several observers have noticed that the blood during, or previous to, an attack of coma is much thicker and more viscid than normal. This is probably due to the withdrawal of the fluid constituents of the blood as a result of the increased functional activity of the kidneys. The blood of the diabetic often appears yellowish on account of the excessive amount of fats present. The presence of a body which yields or gives the reactions of acetone has been frequently demonstrated. Sugar appears to be present in nearly all organs, secretions and exudations. Glycogen has been found in the brain, inflamed pia mater, inflamed lung, testis and spleen. Since its presence in health, however, has also been satisfactorily demonstrated, only a quantitative determination would be of value, but this exact estimation would be practically impossible on account of the great rapidity with which glycogen is converted into sugar after death. The fact that glycogen is present in the diabetic liver in apparently normal amount shows that the power of manufacturing glycogen is not lost in diabetes.

In view, then, of the many and varied changes which may or may not be found postmortem in the diabetic, it will readily be admitted that both gross and microscopic pathology have utterly failed to furnish any anatomic basis upon which either the occurrence or phenomena of diabetes can be explained. As has already been stated, it must be considered as purely functional in character and classed among the neuroses.

SURGERY OF THE KIDNEY.

BEING A STUDY OF A SERIES OF CASES IN WHICH
METHODS OF DIAGNOSIS AND TREATMENT
ARE ILLUSTRATED.

BY BAYARD HOLMES, B.S., M.D.

PROFESSOR OF PRINCIPLES OF SURGERY IN THE COLLEGE OF PHYSICIANS
AND SURGEONS OF CHICAGO.

CONGENITAL ERRORS IN THE DEVELOPMENT OF THE
KIDNEYS AND THEIR ADNEXA.

There are many errors in the development of the kidneys which are of great surgical and pathologic interest. Most of these errors are easily explainable by the remarkable evolutions which attend the development of the urinary apparatus. If any one doubts the utility of a careful study of this subject, let him contemplate the feelings of the surgeon who has removed the only kidney a patient possessed, or of one who has explored the loin and found no kidney below the supra-renal capsule.

Congenital errors in the development of the kidney occur with about the same frequency as do malformations elsewhere in the body. In 13,478 autopsies, one kidney was entirely absent in 4 cases, and atrophic in 59 cases. Klebs places the ratio of the absence of the right kidney to that of the left as 7:2, while Beumer thinks there is no difference in frequency.

The malformations of the kidney which are macroscopic in kind are logically separated into *a*, anomalies in form or size and, *b*, anomalies of position. The normal size, form and position can be learned from any text-book of anatomy.

1. *Absence of both kidneys.*—Only in non-viable children are both kidneys absent. This malformation is usually accompanied by defects in the abdom-

inal wall, in the wall of the thorax or in the cranium and its contents. Acephalus and anencephalous monsters are often without kidneys. In some cases where the head and thorax are perfectly developed the pelvis and lower extremities are deformed and the kidneys entirely absent. Béclard considers the development of the kidneys related to the development of the lumbar vertebral segments and therefore to the development of the lumbar vertebræ and cord. Meyer of Bonn, describes the following stillborn child, which is a case illustrating this connection of development.

The lower extremities were contracted and the toes were rudimentary. The external genitals and the rectum were absent, and the anus opened into a small skin-covered sack. The intestine ended at the descending colon in a blind sack. The kidneys were both absent and the adrenals (supra-renal bodies) both twice the normal size. Both renal arteries were absent, as well as both ureters and the bladder and urethra. Near the adrenals were the small testicles and their epididymus. All the other abdominal and the thoracic organs were normally developed. The spinal cord ended at the twelfth dorsal vertebra. The coccyx and the lowest sacral vertebra were absent. The skull was unusually fattened from the forehead to the occiput. In the right eye there was a congenital cataract. The brain was much compressed and its cortex was almost as hard as cartilage.

A curious report was made by Moulon of Trieste, of a postmortem examination of a girl fourteen years old, who discharged her urine through an umbilicus just above the symphysis pubis. Moulon could find no kidney at all and he concluded that the urine was secreted by the umbilical vein! In commenting on this slovenly observation, Rayer concludes that it was a case of ectopy of the bladder in which the kidneys or kidney was overlooked.

Occasionally in unviable children both kidneys and the urinary bladder have been found but wholly unconnected on account of the complete absence of the two ureters. Such an observation was recently reported by Friderici.

2. *Complete absence of one kidney.*—The absence of one kidney arises either from the suppression of one kidney matrix or anlage, or by the coalescence of the two matrices with one another. Morris calls the former condition the unsymmetrical kidney and the latter the solitary kidney. He also makes another distinction when one kidney is represented by some remnant. This he calls the atrophied kidney. It would really seem better to call that kidney a solitary kidney which is formed from a single matrix and of normal proportion and parts, the other kidney being absent; and to call that kidney a coalesced kidney which is formed by the union of two matrices, having more than one artery or vein, or ureter. These anomalies are consistent with life.

The complete absence of one kidney is usually accompanied by the absence or defective development of the ureter, the seminal vesicles, the cord and the testicle on the same side or in women of corresponding sexual organs. The supra-renal body does not usually share in these defects, but is present and even enlarged where the kidney is absent. Morris found it absent in one out of ten cases where the kidney was absent. The solitary kidney (the unsymmetrical kidney of Morris) is usually hypertrophied, is larger and heavier than normal, and is sometimes supplied with

accessory arteries, veins or ureters; but occasionally the solitary kidney is smaller even than the normal. One such case at least has been reported by Wrisburg, in whose patient the skin took on the function of the kidney and the perspiration had a urinous odor (Haller's "Physiology").

We do not yet know just how radical the hypertrophy of the solitary kidney is. Some investigators hold that the absolute number of glomeruli is greatly increased, even doubled, while others have not been able to verify this observation.

We do not know yet whether the solitary kidney is more or less liable to disease than one of a pair of kidneys. It certainly would seem *a priori* that it is no advantage to a patient to have a solitary kidney.

The following interesting cases may be useful in getting an idea of this malformation:

Chaffrey, W. C.—Solitary kidney. (Transactions of the Pathological Society of London. Vol. 36, 1885.) In a boy five and a half years old, dead of tuberculosis, the normal left kidney was normally placed, but the right kidney was entirely absent. This kidney was $4\frac{3}{8}$ inches long, $1\frac{5}{8}$ inches broad and weighed $4\frac{3}{8}$ ounces. The ureter had a diameter of $\frac{3}{8}$ of an inch. It traversed the wall of the bladder less obliquely than usual and opened near the middle line by a slit-like aperture.

Prudden, T. Mitchell.—Congenital absence of left kidney, (N. Y. Medical Record, Vol. 29, p. 314.) The man died of tuberculosis of the lungs and tubercular meningitis. There had been no renal disease. At the postmortem, the left supra-renal gland was found in about its normal size and position, but there was no left kidney or ureter or renal artery to go with it. The right kidney was slightly larger than normal.

FIG. 1.—The left kidney in its fetal condition. (Kuster.)

Wood, J. W.—Absence of one kidney and carcinoma of the other. (N. Y. Medical Record, Vol. 29, p. 625.) A little girl three months old died after suppression of urine for five days. At the autopsy, the left kidney was absent, and the right was at large mass adherent to the intestines all about and cancerous. It was five inches long. The ureter was seven inches long and greatly dilated.

This might have been a case of epithelioma growing out of a matrix of supra-renal body left in the kidney (Grawitz).

3. *The incomplete development of one kidney.*—The growth of one kidney is sometimes arrested in early fetal life. Then the ureter leads to a small pelvis to which a few urinary canals open or none at all. The renal artery is either absent or very small. The opposite kidney is hypertrophied. The atrophic condition is sometimes confined to a part of the kidney. Sometimes two or more pyramids are normal and secrete normal urine (Morris) and sometimes only one pyramid (Birch-Hirschfeld). There are also anomalies in the formation of the calices which may result from the hypertrophy of existing pyramids or the coalescence of two or more pyramids.

A common arrest of development shows itself in the so-called "fetal kidney." The kidney is then of normal size and weight, but is divided into several lobules, 5-10, as in the fetus and in the cow. These kidneys have a normal function. The divisions are

not very deep and are held together by the fibrous tissue which forms the capsule. The divisions of the fetal kidney resembles somewhat scars left from destructive disease of the cortex. It is very possible that the fetal kidney is more liable to disease than the mature organ, especially to cystic atrophy through valve formation (Fenger). It has been noticed also that fetal kidneys are prone to tubercular disease (Küster).

Wolkowitsch (1895) describes an interesting case of rudimentary kidney in a surgical case. The patient was a man 49 years old with a pyuria six months after typhoid, for which the left kidney was examined by lumbar incision. There was an abscess

FIG. 2.—A typical horseshoe kidney viewed from before. From the Marburg collection. (Küster.)

in the lower end as large as an apple which was opened and drained. The abscess was thought to be tubercular. The upper pole of the kidney was also opened. The patient died of uremia on the twelfth day. At the autopsy the large left kidney was found full of small abscesses. The right kidney was rudimentary, 4 cm. long, cystic and suppurating. The right ureter was impervious except the last 2 cm., where it opened into the bladder. Both vasa deferentia ended 20 cm. from the bladder, blind behind the peritoneum. The right seminal vesicle was absent and the left small and empty. The right testicle was small.

FIG. 3.—An irregular horseshoe kidney from the Marburg collection. Notice the right ureter. (Küster.)

4. *Supernumerary kidneys.*—Such a thing as a supernumerary normally formed kidney is still a matter of tradition or speculation. Depage describes such a case. A tumor in the abdomen was removed and found to be a kidney. The two normal kidneys were found in the normal locations. The right one was so movable that it was sewed back in place. The older authors have reported similar cases, but no specimens are, so far as I know, at hand to support these observations. The possibility of a teratoma kidney-like in structure without function should not be forgotten in considering Depage's case.

5. *Coealesced kidneys or horse-shoe kidney.*—This is the most common of all congenital malformations of the kidneys. It occurs once in about 1,000 autopsies. It presents itself typically in a blending together of the lower poles of the two normally placed kidneys, making one large horse-shoe shaped organ. The accompanying drawing is from a specimen in the museum at Marburg.

Very rarely the union between the two kidneys takes place through the blending of the upper poles,

FIG. 4.—A sigmoid kidney. The right and left kidneys united by their lateral borders. (Brösike after Küster.)

making the kidney concave downward. The ureters are frequently more than two. The blood vessels are also more numerous than normal. The union of the two kidneys is sometimes only fibrous. Such a case

FIG. 5.—Congenital displacement of left kidney in left pelvis. (Rayer.) A, aorta; A.r.d., the double artery of the right kidney; R.d., the right kidney; u.r., the right ureter; V.r.s., the left renal vein; A.s.r., the left adrenal artery; A.r.s., the left renal artery; R.s., the left kidney; u.s., the short left ureter.

is to be found in Report of Guy's Hospital, 1880, and frequently elsewhere in the literature of medicine. The two kidneys are sometimes united into a long kidney lying on one side of the spine. *Ren sigmoides* or *ren elongatus simplex*. And again they are united into irregular masses. These peculiar combinations have received many descriptive names. *Ren scutaneus*, *ren informis*, etc.

Freund (*Arch. f. Gyn.*, Vol. 8, p. 538) found in an old woman with absence of the uterus, a tumor which he recognized through the vagina as a horse-shoe kidney. The diagnosis was made more certain by the

absence of the kidneys from their normal positions. The abdomen was so lax that they could have been easily felt. The hilus lay forward, which position is a rare one, remarks Freund. Out of twenty cases of horse-shoe kidneys only one lay with the hilus forward.

6. *Congenitally displaced kidneys.*—One or both normally formed kidneys are occasionally found congenitally displaced and so more frequently are malformed or coalesced, horse-shoe kidneys. The horse-shoe kidney is usually displaced, the united ends found in the pelvis, especially at its brim. It has a short ureter and also an unusual number of arteries coming from the adjoining trunks, the iliac, the hypogastric or the crural. In women such a displaced kidney may produce dystocia and in men it may give rise to errors of diagnosis. Runge (*Arch. f. Gyn.*, Vol. 41, p. 99) describes a case of congenitally displaced kidney which it is worth while to remember. A woman had given birth to seven children all living except the fifth which was stillborn, being a transverse presentation and artificially delivered. In the third or fourth month of the eighth pregnancy three tumors were found in the abdomen. The pregnant uterus, a tumor of the right ovary and the left kidney. The tumor of the ovary was removed by laparotomy. The kidney was found immovable on the pelvic wall,

FIG. 6.—Congenital cystic kidney of a newborn child. Two-thirds natural size. (Orth.)

the hilus upward. The child was delivered artificially with a fractured humerus. Two arteries could be felt in the kidney. Only three other cases like this are reported.

Strube, Georg.—“Ueber congenitale Lage- und Bildungs-anomalien der Nieren.” (*Archiv für pathologische Anatomie und Physiologie und für klinische Medicin*, 137, p. 227.) This case presented an absence of the right kidney with the left kidney in the pelvis. It was in a patient 32 years old, who died of an acute nephritis due to laparotomy, undertaken to remove a tumor, which proved to be the movable kidney. Both supra-renal capsules were found of their normal sizes and in their normal places, with a normal blood supply. The only kidney present lay between the fourth lumbar vertebra and the second vertebra of the sacrum. It was twelve centimeters long, eight centimeters wide and four and one-half centimeters thick. It lay in the pelvis especially toward the left side, so that it covered the left iliac vessels. Its highest point was at the bifurcation of the aorta; its lowest point rested deep in the pelvis. The kidney was lobulated. The pelvis of the kidney was made up of four calices, two of them small and two of them large. The ureter was eleven centimeters long and very much dilated. It passed behind the rectum on the left side of the vertebra into the bladder. On the right side of the kidney was a piece of tissue four centimeters long by two or three centimeters wide. It showed upon examination to contain a few glomerules with a colloid mass. From this passed a cord, evidently an obliterated ureter, toward the bladder, about its normal position. The kidney was supplied by two arteries and two veins. The supra-renal artery arose one and one-half centimeters from the bifurcation of the aorta and entered the right upper part of the kidney and distributed itself by means of two branches. The lower renal artery arose from the left

hypogastric and passed directly into the hilum. The renal vein emptied into the left common iliac vein.

Somewhat similar cases have been reported by Chapuis (*Lyon Médical*, 1895), Goullioud (*ibid.*), Fischel (*Prager med. Wochenschrift*, 1895), and the older authors referred to by them.

7. *Congenital cystic kidney.*—Congenital cysts of the kidney seem to be related to other malformations usually inconsistent with a viable child, so that only a few of these kidneys require surgical care. The blood supply of the cystic kidney is usually very small. The ureter remains patent, which easily distinguishes it from hydronephrosis. The cysts are sometimes of enormous size, in the fetus interfering with labor and after birth making respiration impossible or difficult. Many of these children with cystic kidney live a few days or a few weeks and then die of exhaustion; others live and come to surgical interference.

Sutton, J. Bland.—“Tumors, innocent and malignant.” Philadelphia, 1893, p. 253. Sutton copies a sketch from H. Morris which is reduced and presented here. It represents a congenital cystic kidney. Some of the cortical substance is left between the cysts. In typical cases like this, the kidney is converted into cystic masses, so that on section the appearance of a sponge is presented. The cysts vary greatly in size. Some of these project from the surface of the kidney. In early stages they have a covering of epithelium which is difficult to find in advanced cases. Sometimes the renal pelvis is easily recognized, but later it becomes filled with fatty matter. The ureter is usually extremely narrow, but always pervious throughout. The blood supply in the cystic kidney is always very small. Congenital cystic kidneys sometimes attain an

FIG. 7.—Cystic Kidney. (Morris.)

enormous size, so large indeed as to seriously impede labor, and necessitate the destruction of the fetus to enable delivery to be effected. Other congenital defects are usually associated with cystic kidney.

8. *Congenital malformation of the pelvis and ureter.*—One of the most common malformations of the kidney, and one consistent with life and the function of the kidney, is the double or treble pelvis or ureter. It is perfectly natural to expect, in cases of lobulated or fetal kidney, to find one lobule so separate from the other lobules as to require a separate pelvis. If this occurred early in kidney development, then the ureter also might be found double. As a matter of fact, the division of the pelvis and ureter has been found in every grade of division which theory would suggest, from simple division of the pelvis to complete double ureter and double pelvis on both sides of the body. The doubling of the ureter is by no means a rare malformation. It is said to be found, more or less complete, in one out of every thirty-five post-mortems. (Böstrom.) This frequency has not been sustained by other pathologists, perhaps because they have not been careful in examining the ureter. Malformations of the pelvis and ureters are certainly very dangerous to their bearers. Double ureters are apt to become obstructed and dilated and precipitate suppurative disease. They are much more apt than single ureters to be abnormally placed in the bladder and become obstructed by valve formation. They

stand also as a constant terror to the diagnostician who would discover the competency, the health or the disease of a kidney through the act of catheterizing the ureters.

9. *Malformations of the adrenals or supra-renal capsules.*—Complete absence of the adrenals is observed only in cases of unviable malformation, usu-

FIG. 8.—Showing a section of a kidney with a double pelvis and two ureters for a part of the way to the bladder. (Rayer.)

ally with defects in the head. Zander has observed absence or aplasia of the adrenals in connection with malformation of the genitals in nineteen out of fifty-six cases of this malformation. Enormous development of a supra-renal capsule has been observed with the complete absence of the corresponding kidney. The two adrenals are often united into one, especially in horseshoe kidney, and occasionally they are displaced with the kidney in the pelvis.

A remarkable error is found in remnants of the supra-renal body in the substance of the kidney itself. From this displaced tissue paratheliomas of the kidney are thought to grow (Grawitz). Such displaced fragments of the adrenals have been found in the broad ligament, the posterior abdominal wall, the spermatic

FIG. 9.—Double ureters complete on both sides. (Rayer.)

vessels (Marchand), and between the head of the epididymis and the testicle (Dagonet). All of these conditions are to be explained by the early association of the matrix of the spermatic apparatus with the adrenal matrix before the descent of the testicle into the scrotum. This is a subject of such clinical importance that it will be considered later at length.

THE PRESENT STATUS OF VAGINAL SECTION WITH RECORD OF PERSONAL EXPERIENCE.

BY HENRY T. BYFORD, M.D.
CHICAGO.

Much of the improvement in gynecology within the last few years has consisted in the development of vaginal section.

The pioneer in this direction is undoubtedly J. N. Sauter of Constance, Switzerland, who, according to a preconceived plan, similar to that employed at the present day, removed the carcinomatous uterus per vaginam, although K. M. Langenbeck performed the operation in 1813. Blundell did the same in 1828 and Recamier and Delpech in 1830. This ended the first act in the drama. The results were so bad that the operation was practically abandoned until revived by Czerny in 1879.

In 1872 Robert Battey, followed by J. Marion Sims and T. Gaillard Thomas, began removing ovaries and small ovarian tumors per vaginam, and was thus the pioneer in this country. Very soon, however, the success of Tait in performing abdominal section, drew the gynecological world after him, and vaginal section again fell into disfavor.

In 1886 I began removing ovaries and ovarian tumors in this way and for a long time was the only one doing it in this country. But as a result of the performance of vaginal hysterectomy for diseases of the appendages in France, and of anterior colpotomy in Germany, during the last four or five years, vaginal section for diseased uterine appendages has now become a permanently established procedure. The reports of the facility with which Péan cured, by vaginal hysterectomy, cases of pelvic inflammation that had been considered too complicated for operation by abdominal section, as well as of the battle that is still waging over the method, have reached us all. Duehrssen and Mackenrodt's operations for vaginal fixation of the uterus gave a new impetus to vaginal section for diseased appendages, for Mackenrodt and A. Martin soon began to remove the ovaries, tubes, and even the products of ectopic gestation by anterior colpotomy.

The old dictum that vaginal section is inferior in value to abdominal section for pelvic disease because the pelvic cavity is not as accessible, is only true for conditions located at the pelvic brim. To the parts below the pelvic brim vaginal section gives as good and often better access, and without disturbing the abdominal viscera. Its only disadvantage in treating conditions within the pelvic cavity is the danger of hemorrhage. But even this, the greatest danger, is no greater, in my experience, than in an abdominal section. In 161 cases of vaginal section I had difficulty from hemorrhage in two cases only, and these were cases for which vaginal section should not be employed, viz., a large uterine fibroid and a large uterine sarcoma.

The danger of infection is practically no greater than in abdominal section, for the vagina and shaved vulva can be scrubbed with green soap, alcohol and corrosive mercuric chlorid as effectively as the surface of the abdomen, and the uterus can be made clean by curettage. If septic infection takes place, the resulting inflammation is always localized, unless complicated by the rare occurrence of ileus from intestinal adhesions, or unless vaginal section be done for abdominal rather than pelvic conditions.

In illustration of the possibilities and limitations of the method and the possibility of seeing and knowing what one is doing, I will briefly state what procedures have so far been demonstrated to be practicable.

Through a vertical incision in the median line behind the cervix, half an inch long, one finger can be introduced into the peritoneal cavity and the pelvic organs be directly palpated. Through an incision from an inch to an inch and a half long in the same place, diseased uterine appendages and the products of early extrauterine pregnancy, as well as small ovarian tumors, omental tumors and small subserous fibroids on the posterior uterine walls can be removed. I have not removed a fibroid from the posterior uterine wall in this way, but have taken sutures in it for the arrest of hemorrhage due to adhesions, which practically amounts to the same thing. The cul-de-sac can be obliterated by tamponing the sutured vaginal wall against the opposite side of Douglas's pouch and retroversion often be cured. This was a frequent result in my earlier operations.

Through a transverse incision behind the cervix, beside all that which can be done through the vertical incision, the whole posterior pelvic cavity, the fundus uteri, and sometimes the appendix vermiformis can be exposed to view by long retractors that reach almost to the promontory of the sacrum. This has been repeatedly demonstrated by Prior. The sacro-uterine ligaments can be shortened by suture, or the cul-de-sac of Douglas be obliterated by excision of its peritoneal lining, or by packing it with gauze. Prior cures retroversion by the latter method. It is also possible, as I have demonstrated in one case, to extirpate the rectum considerably above the lower reflection of the peritoneum through this incision. By prolonging the incision laterally, or forward beside the uterus, moderate sized intraligamentous fibroids can be taken out either whole or by morcellement. The danger of wounding either the uterine artery or ureter can be avoided by ligaturing the former and placing a flexible bougie in the latter.

By an incision in the anterior vaginal fornix and separation of the bladder, fibroid tumors can be enucleated from the anterior uterine wall, as I have twice done; or by bisection of the anterior uterine wall they can be removed from the uterine cavity or posterior uterine wall and the uterine incision be sutured. Diseased appendages can be readily removed or drawn into the vagina, the ovaries resected, the closed tubes made pervious, and the parts be returned without bad results. The pubic peritoneum, normally lying above the collapsed bladder, can be drawn down into the vagina, and the stumps of removed appendages or the fundus uteri can be sutured to it. The round ligaments can be grasped and those portions near the internal inguinal rings can be drawn down in view and attached to the uterus, thus shortening them as much as is usually done in Alexander's operation. I have shortened the ligaments and attached the fundus or stumps over the bladder in twenty-four cases of retroversion, and have kept watch of most of them since. In but two cases that I know of has there been a return of the retroversion.

All this can be done without removing the uterus. If we remove the uterus the whole pelvic cavity is opened up to sight.

Intestinal and rectal tears can be successfully sutured. Medium sized adherent dermoid, papillary

and other pelvis-bound tumors can be removed, and the beds tamponed with greater safety than by abdominal section. Septic appendages, with adhesions that would make their removal by abdominal section almost unjustifiable, can be cured by vaginal section with but little risk.

Although so much can be done by vaginal section there is danger of extending its limits too far. Péan, Segond, Jacobs and others, in searching for these limits have, with consummate skill, made use of the method in cases for which it is not generally adapted and in which it can only succeed in the hand of such experts. Fibroids larger than a full term fetal head can be removed in this way, but the mortality will be greater than by abdominal section. The duration of the operation is apt to be too long and the loss of blood considerable. Fibro-sarcomas of the uterus of large size are still less suitable. Advanced carcinoma of the body of the uterus should be removed by abdominal section because metastatic deposits can be recognized and managed better. If I were to judge from a single experience, I should say that vaginal section is of but little value in tubercular peritonitis. I removed the tubercular tubes in a case connected with ascites and deposits of tubercles on the surface of the pelvic peritoneum. Although a large quantity of fluid was evacuated, the appendages completely extirpated and the cul-de-sac drained, the tubercular peritonitis increased steadily after the operation. The evacuation of the fluid had but little if any effect.

I have so far performed vaginal section 162 times, including two cases in which I opened the peritoneal cavity by mistake, and including none in which the cavity was not opened. Eighty of these sections were done without removal of the uterus. Of the latter all recovered from the immediate and remote effects of the operation.

I have performed vaginal hysterectomy eighty-one times, with four deaths, and resection of the rectum once, with one death. These represent results as they are, but not as they should have been. One of these deaths was in a case of sarcoma larger than a child's head; the other in the case of a large fibromyoma in an excessively anemic woman 53 years old; neither of them adapted to vaginal section. Had I operated by abdominal section, I should have recognized the futility of removing the first tumor, and would have been able safely to remove the second. If we eliminate these two cases, which ought not to have been operated upon in this way, and the excision of the rectum, which does not belong to the ordinary vaginal section, the mortality instead of being 3.05 per cent. would be 1.22 per cent.; a smaller percentage than I could have hoped for had I performed abdominal section for them. In fact a mortality of 3.05 per cent. in the first 162 cases (and which, including all, includes of course those upon which my experience was gained) is better than I could expect to do in a first series of 162 abdominal sections, and the series included more septic and complicated cases than is the rule in an equally extended series of abdominal sections.

The Roentgen Rays Innocuous.—Prof. Moritz Benedict in the *Medicinische Wochenschrift* ridicules the notion that the Roentgen rays are injurious to the hair or otherwise. He maintains that a few accidental cases have originated an unmerited notoriety.

PHOTOGRAPHY IN MEDICINE.

BY ELLERSLIE WALLACE, M.D.

PHILADELPHIA, PA.

To speak of the uses of photography in the healing art at the present day makes one immediately think of the great discovery of Roentgen.

This undoubtedly stands at the head of the list of useful achievements that photography can perform. But inasmuch as large pecuniary outlay, and much time and special study must be sacrificed to it, I shall not say anything about it here. My object is rather to refer to simpler things which the camera may be made to do, and to recommend the study of the art of photography to young members of the profession. After years spent in the comparative inaction of the lecture room, and the want of physical exercise, from which we all must suffer more or less, while our brains are absorbing useful knowledge, the active use of the camera will be a very salutary and welcome change. It will not be time lost, but will benefit both mind and body. Nor is it necessary to invest any considerable sum of money in elaborate apparatus; while the expensive forms of lenses and cameras are generally the best, a modest outfit may yet be made to yield excellent results.

Many students, particularly those who have a fondness for physiology, own a microscope. Let them add a photographic outfit for plates measuring five inches by four, get one of Carbutt's "*mulum in parvo*" dark-room lanterns, and they will then be in possession of an admirable apparatus for microscopic photography. I can not think of a more pleasurable and useful way of spending an evening than to make negatives of microscopic specimens, and then to print them on plates the right size for projection upon the screen by limelight, *i. e.*, $4\frac{1}{4} \times 3\frac{1}{4}$ inches.

Carbutt's lantern to which I allude is a most conveniently arranged affair for such work; it furnishes the red light in which the sensitive plate is unpacked and set in the holder. By a simple movement, the white light is admitted to the microscope (through a sub-stage condenser if required), and the exposure made. The ruby light is again turned on to develop by, and finally the finished plate is examined by still another kind of light just suited to the photographer's needs. All this is done without moving the lantern, and either kerosene oil or gas is used at pleasure. The camera (5×4) is set at the end of a board of say four feet in length, and the microscope turned over so as to bring the tube horizontal, pointing into the camera at one end and into the lantern at the other. A few bits of black velvet, two or three wooden blocks and some elastic bands complete the apparatus by which endless varieties of microscopic photography may be easily and cheaply done at night, after the toil of the day is over. It is hardly possible for one who has not handled this apparatus to imagine the extent of useful work it is capable of. I will not consume space by suggesting subjects—they are innumerable. I only wish to make it clear that the outfit will make either ordinary paper prints, or "lantern positives" on glass which will show splendidly on the lecture room wall to a class, no matter how large.

Objects not microscopic in size may also be studied in this way. Bones make excellent photographs. They should be carefully set in position on a board covered with black velveteen, and not taken in direct sunlight. A lens of rather long focus, say from six to eleven inches, should be employed, and a rather small stop

(diaphragm) put in, so as to bring all into sharp focus. If the negative is well made, there is nothing to prevent the enlargement of prints to even more than life size.

Greater difficulty will be experienced when photographing any of the soft tissues. Nevertheless, they can often be done successfully. Deformities of every kind, wounds and skin diseases, take well. Among the wonders of modern photography, we may call to mind the fact that some kinds of diseases accompanied by eruption, will show the eruption on the photograph *before* it is visible to the eye. Certainly this ought to be followed up and carefully studied. For instance, in the time of any mild epidemic, a suspected case in hospital should be photographed at regular intervals of time, say eight or twelve hours, in daylight, and the first appearance of the eruption noted. Comparisons could then be made when the eruption was fully developed. But the uses of the *orthochromatic* films and plates should not be overlooked in this connection. Such work as this can be done with the cheapest of apparatus, if only the operator understands how to "light the sitter." Now, in large places, like hospitals, it is seldom hard to find either a corner of the building where the light can be admitted to the sitter from two windows at right angles to each other, or else some position where the walls themselves are white and stand at such angles that the necessary reflection is made upon the shaded side of the sitter's face. Here is where the scientifically educated, amateur photographer is almost sure to fail. He is ignorant of just those elementary points in photography that any professional member of the calling, however poorly schooled otherwise, could teach him in a few moments. I have seen a great deal of just this sort of failure among medical men of superb acquirements. Should any commencing amateurs meet with this article, when they are in trouble, let me advise them, without loss of time, to secure some of the books written on the art of properly posing and lighting the sitter, and carefully study out the principles before wasting another plate. Such firms as Anthony & Co., 591 Broadway, New York, and the Photographic Times Publishing Association, 60 East 11th Street, in the same city, would promptly furnish the right sort of instructive material. Persons who take up photography seem to think, though perhaps they might not care to admit it, that the camera is a sort of machine to grind out "pictures" more or less bad. And the young graduates in medicine are just the ones who would be likely to indulge in quiet sarcasms at the necessity for any real study in such a thing as a "machine for taking likenesses." I will close this portion of my subject by merely hinting at the wonderful works in *monochrome* that all the great masters of art have given to the world, and by reminding the reader that very many such things can be done with the camera, if only its possessor have proper sympathy with artistic studies, and if he have not, his chances of success will be small.

The reports which almost all hospitals and asylums send out will be much more interesting and useful if illustrated with good photographs. This is just the work for young residents to occupy themselves with in their spare hours. A good idea of the perfection to which this can be brought may be had by observing the work in the annual reports of Dr. T. G. Morton, Chairman of the Committee on Lunacy of the State Board of Public Charities (Pennsylvania).

Much is being done every day in the interests of medico-legal matters. This is self-evident, and I need not enlarge upon it, except to remind the beginner that there is a fair possibility of getting presentable pictures of contusions and other marks of violence invisible to the eye, just like the eruptions previously spoken of. In the differential diagnosis of blood corpuscles, the microscope and camera together can be made to give evidence of the uttermost value and exactitude. And in returning for a moment to photomicroscopy, I wish to mention Dr. Woodbury's suggestion, that in diagnosing tumors or cancer in presence of the class, photomicrographs might be made in an adjoining laboratory from a small section taken from the patient, and the result projected on the screen at the close of the lecture by darkening the room for a few moments. Here we should see the diagnosis confirmed before our eyes—an admirable thing for both teacher and student. Pathology and histology will furnish us with plenty of material for such teaching, and this is the kind of instruction that is not apt to be forgotten.

The vitascope, or at all events the camera, for making the endless band of pictures to be afterward shown in this instrument, will some day take its place in medical institutions, just as the Roentgen apparatus is doing now. It seems very little use has thus far been made of ordinary instantaneous photography for the closer study of abnormal movements of every kind, but now that we can obtain exact reproductions of any phase of motion, surely we ought to have full sets of illustrations of chorea, locomotor ataxia and all other matters of the sort. We must not forget that the movement is reproduced with absolute fidelity.

Thus, the art of photography is by no means to be overlooked in teaching to large classes in large halls. But it is perhaps even more successful and fascinating to the solitary student, or to the pair of devotees, who can get a close look at their work. Two earnest men could work together at medical photography far better than either one alone, while even three would be too many. There is no end of work waiting for them. And of fresh matter, too. Why does nobody publish *stereoscopic* proofs of anatomic, pathologic or surgical subjects? How many who do use photography in medicine know how to increase or lessen the amount of relief in the stereoscopic slide? Pictures of operations could be made in this manner that would instantly supersede any other kind of illustration, even if colored. And it would only entail a little more expense to get *colored stereoscopic slides on glass* which would be, in many cases, as instructive as actual presence at the operation.

THE USE AND ABUSE OF EXPERT MEDICAL AND SURGICAL TESTIMONY AND SOME RECOMMENDATIONS FOR INCREASING THE VALUE OF SUCH TESTIMONY.

Read at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Sept. 23, 24 and 25, 1896.

BY ROBERT MATHER.

GENERAL ATTORNEY OF THE CHICAGO, ROCK ISLAND AND PACIFIC RAILWAY.
CHICAGO, ILL.

(Concluded from page 723.)

Thus far I have generalized, and what I have said is quite as applicable to many other kinds of expert evidence as to medical and surgical testimony. But a

railway lawyer, speaking to railway surgeons on such a topic as the present must be understood by his hearers as having in mind in everything he says the special class of cases in which both are so much and so often interested. While, therefore, my observations have been general in terms, they have, no doubt, come to your minds as having special and direct reference to personal injury cases. Certainly no other class of cases more frequently displays the abuse of expert medical and surgical testimony, or demonstrates more clearly the necessity for improving the method of procuring and presenting such testimony. No doubt it is within the repeated experience of each of you that ignorant or corrupt expert testimony has presented and upheld opinions that you knew were unsound and theories that you knew to be false. The obscurity of many of the injuries which give rise to these cases and the subjective nature of their symptoms render these achievements of the expert comparatively safe, while the sympathy that rests in the jury box for the subject of the injuries and the prejudice or indifference to the rights of the defendant which also there abide render them usually successful. Dishonesty and charlatanism among medical experts have won more cases without merit and magnified more verdicts where merit was slight, than character and learning have defeated in the one case, or diminished in the other. Nothing, more than the uniform and expected result in this class of cases, demonstrates the incapacity of our present system of presenting opinion evidence to lead the jury to a conclusion which speaks the truth. A nearer approximation to even and exact justice in the determination of causes arising out of personal injuries than is now possible under present methods of trial and existing rules of evidence would, I believe, be secured by the plan of selection and appointment of experts by the court.

The adoption of this plan would involve in this class of cases, a further step. The injured person should be compelled to submit himself to a personal examination by the court's experts. The right to require such an examination could not be denied to an officer of the court charged with the duty of ascertaining the truth. It would only furnish the opportunity for the performance of that duty. Indeed, some courts have held, even under the present system, that the power exists to compel such an examination by experts who are not official. *Schroeder v. Chicago, Rock Island & Pacific Railroad Company*, 47 Iowa, 375 (1877), was the pioneer case in that direction. The question was determined, without precedent or authority to guide the court, on lofty ground of principle. It was said: "Whoever is a party to an action in a court, whether a natural person or a corporation, has a right to demand therein the administration of exact justice. This right can only be secured and fully respected by obtaining the exact and full truth touching all matters in issue in the action. If truth be hidden injustice will be done. The right of the suitor, then, to demand the whole truth is unquestioned; it is the correlative of the right to exact justice. It is true, indeed, that on account of the imperfections incident to human nature perfect truth may not always be attained, and it is well understood that exact justice can not, because of the inability of courts to obtain truth in entire fulness, be always administered. We are often compelled to accept approximate justice as the best that courts can do in the administration of the law. But, while the law is

satisfied with approximate justice where exact justice can not be attained, the courts should recognize no rules which stop at the first when the second is in reach. Those rules, too, which lead nearer the first, should be adopted in preference to others which end at points more remote. This doctrine lies at the foundation of the rules of evidence, though it must be confessed that the superstructure does not always fully conform thereto."

Since this decision the right of a defendant in a personal injury case to demand, and the power of the court to compel a personal examination of the injured person has been much mooted, and the decisions of the courts have been not only diverse and contradictory, but wavering and inconsistent. Those States in which the power to compel an examination is admitted either absolutely or under conditions are:

Texas: *M. P. R. Co. v. Johnson*, 72 Texas, 95.

Georgia: *Richmond & Danville R. Co. v. Childress*, 82 Ga., 719.

Alabama: *Alabama Great Southern R. Co. v. Hill*, 90 Ala., 71.

Minnesota: *Hatfield v. St. P. & D. R. Co.*, 33 Minn., 130.

Wisconsin: *White v. Milwaukee City Ry. Co.*, 61 Wis., 536.

Nebraska: *S. C. & P. R. Co. v. Finlayson*, 16 Neb., 578; *Stuart v. Haven*, 17 Neb., 211.

Kansas: *A. T. & S. F. R. Co. v. Thul*, 29 Kas., 466.

Arkansas: *Sibley v. Smith*, 46 Ark., 276.

Ohio: *Miami & M. Turnpike Co. v. Bailey*, 37 Ohio St., 104.

Missouri: *Sidekum v. W. St. L. & P. R. R. Co.*, 93 Mo., 400; *Shepard v. M. P. R. Co.*, 85 Mo., 634; *Owens v. K. C., St. J. & C. B. R. Co.*, 95 Mo., 169.

Both the right of the defendant to demand and the power of the court to require such examination have been denied in Illinois: *Parker v. Enslow*, 102 Ill., 272; *C. & E. I. R. Co. v. Holland*, 122 Ill., 461, S. C., 18 Ill., App. 418; *St. Louis Bridge Co. v. Miller*, 138 Ill., 465, S. C., 39 Ill., App. 366; *Joliet Street Railway Co. v. Call*, 143 Ill., 177, S. C., 42 Ill., App. 41; *P. D. & E. R. Co. v. Rice*, 144 Ill., 227; *City of Galesburg v. Benedict*, 22 Ill., App. 111.

The same result was reached in Indiana: *T. H. & I. R. Co. v. Brunner*, 128 Ind., 542. And by the United States Supreme Court in *Union Pacific R. Co. v. Botsford*, 141 U. S. 250; though Justices Brewer and Brown, in a dissenting opinion by the former, gave their adherence to the doctrine of the Schroeder case in Iowa. An opinion by the Supreme Court of New York, rendered in 1868, but not published until after the Schroeder case was submitted in the Iowa Supreme Court, asserted the power to compel an examination. (*Walsh v. Sayre*, 52 How. Pr., 334.) This decision was afterward overruled at a general term of the Supreme Court (*Roberts v. Ogdensburg & Lake Champlain R. R. Co.*, 29 Hun. 154) and the question was finally put at rest in that State by a decision in 1891, denying the existence of the power. (*McQuigan v. D. L. & W. R. Co.*, 129 N. Y., 50.)

This vacillation in the courts of New York had its counterpart in the courts of Missouri, where the question as to the existence of the power was first decided in the negative and subsequently, as has been seen, in the affirmative.

The decision in the McQuigan case led to the adoption of a statute in the State of New York as follows:

"In every action to recover damages for personal

injuries, the court or judge, in granting an order for the examination of the plaintiff before trial may, if the defendant apply therefor, direct that the plaintiff submit to a physical examination by one or more physicians or surgeons to be designated by the court or judge, and such examination shall be had and made under such restrictions and directions as to the court or judge shall seem proper. In every action brought to recover damages for personal injuries, where the defendant shall present to the court or judge satisfactory evidence that he is ignorant of the nature and extent of the injuries complained of, the court or judge shall order that such physical examination be made."

This statute was enacted as an amendment to that section of the Code of Civil Procedure which provided for an examination of the plaintiff under oath. In construing the amendment, the court held (*Lyon v. Manhattan R. Co.*, 142 N. Y., 298) that the physical examination provided for thereby was designed to be a part of the examination of the plaintiff under the section as it stood before the amendment, and that an order would not issue for the physical examination of the plaintiff, except as a part of the taking of his testimony. In other words, the defendant, in order to obtain a physical examination of the plaintiff, must call him as a witness before a referee for the purpose of taking his testimony, and as a part of this process may compel a physical examination. It was said: "The statute has in terms provided that the physical examination shall be procured in the same way and as part of an examination of the party before trial, and in that way only and by conforming to the general provisions of law on the subject can the object and purpose of the amendment ever be attained. This construction gives effect to every word of the section as amended, and is in harmony with the other sections immediately preceding and following. Then the referee becomes something more than a mere spectator at an idle ceremony. He may take the plaintiff's testimony upon the issue and report to the court as upon an examination before trial. He has, of course, the power to administer an oath and to authenticate the proceedings, and the plaintiff is bound to appear before him and answer all proper questions with respect to the nature and extent of the injuries, whether framed by the medical experts from their own examination, or as a part of it, or by the counsel present. It becomes a fair struggle for truth and both parties may participate."

The "struggle for truth" provided for in this awkward enactment would seem to be an ordeal from which both sides would shrink. The defendant in the ordinary personal injury case would hesitate to make the plaintiff his own witness and, therefore, to be bound by his testimony, even if thereby he should secure the right, which otherwise he would not have, to a physical examination of the plaintiff and his injuries. On the other hand, if, as appears from the report of the case, the physical examination is to be part of an oral examination to be witnessed and participated in by a referee, experts and counsel on either side, it would seem that the plaintiff, especially if a woman, would rather bear the ill effects of her injuries entailed upon her than fly to a method of relief which contemplated such an inquisition. The more satisfactory and seemly way would seem to be to compel an examination of the plaintiff's person by the experts selected by the court under all the circumstances of privacy and of secrecy (except for the purpose of the giving of testimony by the experts at the trial) that would

surround a similar examination by the personal physician of the injured party. Such an examination, conducted for the sole purpose of ascertaining the truth by professional gentlemen of the highest standing, occupying the position of officers of the court, could neither wound the sensibilities of the most acute organism, nor excite alarm on the part of the most suspicious that the examination would be used for anything but the ascertainment and enforcement of even and exact justice.

The indictment here framed against the present abuses of expert testimony would be confessed by the defender of the existing system, if it had a defender. The remedy for the evil, substantially as I have outlined it, was long ago proposed and has been widely approved. The discussion of the mischief and its remedy furnishes a subjective intellectual pleasure to railway surgeons and lawyers on such occasions as this. But I doubt if practical accomplishment of the needed reform will spring from our discussion. We will be looked upon, I fear, too much in the light of special pleaders, advocating our and our client's advantage. Not that we *are*, but only that we *seem* to be to the prejudiced public interested in the question, except with a lively interest in the accomplishment of both abstract and concrete justice. All that has been said, however, of the use and abuse of expert medical and surgical testimony in personal injury cases, applies with as great or greater force to insanity cases and criminal trials. There the selfish and personal point of view is lost in the higher and broader considerations of public interest; for the abortions which the system there produces are not only crimes against justice but injure the health of the body politic. The ear of the public will eventually be caught by appeals for a change in the prevailing system, based on its evil manifestations in that direction, though our more or less selfish cry be not heard.

DISCUSSION.

Dr. R. HARVEY REED—This paper bears on a subject which, beyond all question, is of vital importance not only to the railway attorney and the railway surgeon, but to the railway company and the plaintiff. One thought brought out by the paper was that "the expert did not testify to what he knew, but what he thought." That in the abstract may be true—perhaps judging an expert from the standpoint that he is called in to tell what he thinks of certain facts when the facts are presented to him; yet I think you will bear me out that the average expert has knowledge of the facts as well. I know in the courts in Ohio it is a common occurrence for those who have been called to testify as experts to examine the case and then go before the courts and testify as to the facts in the case. For instance, we will suppose a man has prosecuted a company for injury to a limb; that it is short, or it is crooked, and he claims a certain amount of damages because of this. The experts are called to examine him to see how short or how crooked that limb is, how far it is from a normal condition, and to say whether or not this abnormal condition is an injury to that man, and to what extent it is an injury. Under these circumstances the expert is testifying on facts, and he acts as an expert in making an examination of the case to determine for himself what the facts are. Now it seems to me that the expert may not only tell what he thinks, but in many instances he tells what he knows. In the paper it was stated that an expert was called because of his peculiar or particular knowledge; then, if this is so, he must have knowledge or he wouldn't be called; if he has knowledge he speaks from what he knows, and forms his ideas from the facts in the case because he knows them to be facts.

I call attention to this because it seems to me from what little experience and observation I have had, that it is hardly fair to say that an expert only tells what he thinks.

If we discard the expert from the witness stand, then who shall give this knowledge? I will admit that as expert testimony is handled by our legal brethren and as expert witnesses act themselves of their own volition, expert testimony in a majority of cases is a farce. But because it has proved to be a farce, is that a reason why we should discard it? We must admit there is a value to be obtained from it if we put it in the right channel—if we handle it in the right manner—and I have for years been a strong advocate of calling the expert witness by neither the prosecution or defense. I think the moment you put the expert on the stand with the understanding that he is to testify for either the prosecution or the defense, you put him in a false position. He should be called, as the gentleman says in the paper, to testify to the facts and give his knowledge on those facts as they occurred to him and are presented to him. When medical experts are called on the stand it has been the custom of lawyers—and more by some than others—to commence by trying to show that the medical expert does not know anything, that he is a consummate fool, does not even know his anatomy because he could not tell some little muscle about the eye or nose that he would be supposed to know; and the attorneys have frequently made their cases a great deal worse in many instances by resorting to those little technicalities, if you want to call it, or catch-questions as the schoolboys call them, to give the impression that the expert did not know anything at all. That is wrong, and I think the attorneys on either side would take hold of the expert to find out what he knows about the case, place the questions fairly and squarely before him and get out of his head the idea that he is testifying for anybody, but that he is a sworn witness to tell the truth, the whole truth and nothing but the truth as it bears on the question; do not try to aggravate and entangle the witness by getting him off on a subject absolutely extraneous to the question in court, and then endeavor to make the jury believe that what he said is true or is not true, you would find the medical expert would be of more value than he is under the present system.

As to the pay of the expert, I think we are all agreed that he should be paid, but I most heartily agree with the paper that he should be paid and employed by the court. I do not think the prosecution or defense, either one, should employ him or have anything to do with paying him, except they should foot the general bill, which should come through the court entirely, making him a court official, as has been stated. This, I believe, a most valuable suggestion. I think we should advocate the idea—of course it is an embryonic cell and it needs to be developed into a fixed tissue cell, but it has given us thought that will perhaps help us to remedy this system which has been a detriment to the companies and a detriment to the courts.

Dr. R. S. HARNDEN—I concede the position which the paper takes. I believe we are in disrepute today as a profession—I do not think any physician here or elsewhere disputes that fact—but wherein lies the fault? The gentleman points out the remedy. It seems to me that he has simply quoted and reiterated what we ourselves have claimed for many years. I believe it is the voice of the medical profession as well as the legal profession that the expert witness should be employed by the court and paid by the State, so that his evidence should not be biased by the various attorneys. The gentleman has stated that as a matter of fact that might be the case—the attorney might employ the witness and bias his evidence. We all know that to be so. But I want to say in the defense of my profession, that I will not concede any one in the legal profession as being in advance of my own. I believe that while the legal profession is today studying Blackstone and the tenants' law of years since, that our profession is in advance of the current

of progress of thought throughout the world. (Applause.) I believe that our's is one hundred years or more in advance of the legal profession, and I say that not to their discredit, but I believe it is true. It seems to me, with our profession standing where it does today, that the courts and the legal profession must be far behind us if they can not obtain help for the procurement of justice from our profession. We have the experience, the ability, we have accomplished great ends in the past decade, and if the judge and the court can not receive the benefit of this improvement then where lies the fault? Now, it is my firm belief that, as able as a judge or a lawyer may be, he may be intensely ignorant on some things. The gentleman presented one point that attracted my attention. I do not remember the terms used, but he would not allow the court or the judge to make the selection, but simply to designate. I think that was a proper discrimination between the two terms, and I think I can state for our profession that we would favor the court's making the selection or designation, but I believe the main point, as has been stated by the gentleman, with some exception, is correct, that the litigant should not pay the expert witness. Now I do not believe that medical experts or medical men, as a rule, are biased to the extent that has been stated. I do not think my profession work for large fees. As a rule they do more for charity and honor than any other profession on the face of this earth, and it seems to me that it is a stigma upon us for the legal profession to point the finger of scorn at us simply because of their own ignorance and of the methods of obtaining the evidence which shall assist in the procurement of justice.

Dr. A. D. BEVAN—The statements as outlined in the paper I believe to be absolute facts. I could not see any attack upon the medical profession. I do not think it was so intended. Certainly expert testimony has been, since I have been a member of the profession and appeared as an expert, a farce. I have almost never testified in a trial without feeling that some of the experts were prostituting, not scientific knowledge, but the name of medicine in appearing in those trials—even men of wide reputation—by being the employed partisans on one side or other of the case. I know that personally I feel and always have felt that when a medico-legal case comes to me, when a man comes to me and is willing to pay fifty or a hundred dollars for my testimony, I can not get away from the fact that I am employed; I can not get away from the effort of making the very best of my employer's side of the case. I feel that and always feel it. I always fight against it and always say to myself, "Now I want to present this case and my opinion of it just as I would in a clinic if it were a medical case and I were describing it in class and not a court room," but the fact does remain that the medical expert testimony as it is today is a disgrace to the medical profession in the better sense of the word, or to medical science in any sense of the word. It is simply one of the evidences of human frailty, of bad machinery in bringing about justice. The same applies to any other profession—an engineer's, a real estate man's expert testimony. The same facts apply to all expert testimony and, as I understand the paper, it is not in any sense an attack upon medical progress or knowledge. It is simply a statement of facts as they are, and I believe them thoroughly stated. The remedy is, of course, the great problem. I think it lies more in the hands of the bench and bar than it does in the hands of the medical profession or any class of experts. I believe that they could start the machinery in motion that would bring about the necessary reforms better than we can, but that the fact does exist we can not get away from. I know that every one of the members of this Academy have felt when they have testified in various medical cases where some charlatan was introduced and made some absurd statement, that expert testimony was a disgrace to science and justice, and eventually we must find some means of curing this error. I have often

thought when I have heard this subject discussed, that someone must start the machinery in motion, someone must make an effort and bring about this reform. The Academy of Railway Surgeons can do very little, but I think we could do something, and whatever we can do I believe we should put ourselves definitely on record as doing. I would not submit a plan, but the end must be accomplished by the education and elevation of public opinion until it demands some definite, positive change in this matter.

Dr. MILTON JAY—I do not know of any subject that is more essential or of more interest to the physician than this one. Having been for many years connected with the railways of Chicago, I have been utterly disgusted with the testimony from experts, whether they are posted or not. It is an injury to the cause of railroads that we are surgeons of; it is not one time in ten that the injured individual gets justice, and it is never that the expert gets justice. Now I thoroughly believe what Mr. Mather has said on this subject. You go as an expert, you are the chief of local surgeons of the road and you are one of the experts. Dr. Reed says the lawyer tries to tear their evidence to pieces—the lawyer is not worth a cent if he does not. (Laughter.) What is he there for? How long do you suppose a man suing for an injury would employ a lawyer if he did not do his best to get all the damages he could? And the very fact that I am a railroad surgeon, although I undertake to tell what I honestly think is that man's condition, and has been, do you suppose a jury takes my evidence to be as honestly given as though it were given by a man outside the employ of the road? The jury can not do it, and the lawyer can make the impression that I am a little bit biased—and if I am not a little bit biased in its favor the railroad is not going to keep me. (Laughter.) I acknowledge that what Dr. Bevan says is absolutely true, and I do not like to go as an expert for my own company, while the companies tell us, as they do, "Tell what you believe is the condition of things, but if you have to be biased, try to be biased in our favor and get your witnesses to believe the same way." It is human nature and I do not think that is lying. These are the facts of the case. We do not get our dues and the expert does not get his. If he is employed by the plaintiff it is perfectly natural that he is going to help that plaintiff. I have talked within the last six months with the officers of our railroad from the President down, and said: "Can not we get together and get a petition to the legislature to remedy this evil?" Our attorney says, "You can not do that." I asked why. He said, "Because the legislators will say the railroads want it, and they have got to pay for it," and he said, "Good Lord, you would not expect to get anything through the legislature unless there was boodle in it? Have you got a hundred thousand dollars? If you have, I can get anything through." I do not believe we will ever get it by legislation, but if we could get at it in some way, either as Mr. Mather suggests, or in some other way, so that the judges or an association of judges, three or five, in this city should have a staff of disinterested surgeons or physicians, or whatever they might be called, so that out of them the judge should pick one, or two, or three, and that be the only testimony given, that would be disinterested. The point is to get disinterested evidence before the jury. The jury will not consider an employe as impartial as an outsider. I would rather never be an expert than what you have to be under the present circumstances. The Doctor here (Dr. Harnden), thinks he has got the grandest profession in the world, the medical profession. I have found some lawyers pretty well up in anatomy when they come to the cross-examination, and the doctor does not know anything like as much about legal science as the lawyer does about medical science. It is a subject as broad as the surgeon and the railroad and the lawyers that have to do with it, and I say, and have for years, there ought to be some kind of medical evidence, some way or rule adopted

by which the medical expert could be disinterested, not employed by either the defendant or prosecution.

Dr. W. A. WARD—I would like to have the gentleman in his closing remarks explain one thing that he broached in his paper. If this expert medical witness is made an officer of the court and these intricate medical problems are submitted for solution, and upon submitting that report, either verbally or in writing, as the court might dictate, I would like to know if he should be subjected to a cross-examination upon it. He simply does in that function, as I understand the idea, what the judge does in his charge to the jury. The judge elucidates, or attempts to elucidate the points of the law. Now let this commission, or whatever may be seen fit to call it, that is appointed from the medical profession elucidate the medical or surgical principles involved, and let that be as sacred as the judge's charge. If it were rightly conducted, and the proper rules employed, it would stand to the jury in the same relative position, or could be brought up to that position.

Dr. D. C. BRYANT—I want to state for the paper that the gentleman read, that I believe as he does, that the fault lies not alone with the medical or legal profession, but with the law itself. As the law now stands, we, if employed as experts, stand in the same relation to the plaintiff, or the one that employs us, that the lawyer does—the great difference being in the amount of fee received, the lawyer gets the money and we get very little. Out in the wild and woolly west the lawyer saves us from “prostituting our honor” by interviewing us beforehand; first the man who wishes to employ us holds a private interview with us, asking our opinion about the case; if it pleases him then he sends his lawyer the next evening, and the lawyer interviews us, and if we can answer his questions to his liking he employs us as experts; if not, we are turned down, which saves us from “prostituting our honor.” I do not know whether this is done in the East or not, but it is done in the West. I do not see any remedy except as suggested by the writer of the paper, that is, changing the law and have the expert employed and paid by the court and not by the parties.

Dr. L. E. LEMEN—There is one way in which this whole thing can be settled satisfactorily, and until that is done it never can be settled satisfactorily, and that is, to have the expert—let him be medical or any other department—be an officer of the court the same as the Judge. As long as humanity exists the expert will have a sympathy for the one who calls him; it is utterly impossible to be otherwise. A little further in the West, and perhaps a little woolier than where Dr. Bryant comes from, in Denver, when an attorney comes to see us as expert in any given case, he gives us a retainer and places the case before us, and if our testimony is such that it can benefit him we go on the stand; if not, he seeks some one whose conscience is more elastic.

Dr. C. B. KIBLER—I think it was Holmes who once said, “Strong is the blister that will draw upon the conscience of the man of law.” I believe the legal profession is as much at fault in the manner in which the expert medical testimony is looked upon today as is the expert himself. The attorney takes the expert in his hands and he assails him with the questions he has fortified himself with, and makes it appear that the expert does not understand the case; how does he do it? Simply by not allowing that expert to express his honest opinion. The charge can be laid at the door of the legal profession that the expert is such as he is.

Dr. C. K. COLE—The expert does not need to attempt to do this work unless he feels equipped, unless he feels competent. The expert should go upon the stand with the consciousness that he knows more about the subject than any one else, and he should know the law concerning the subject upon which his evidence is given. If he feels that he is not thus competent he should decline to give the testimony. I think we are agreed

that the writer of the paper has not undertaken to make an attack upon the medical profession. He has given us some plain truths and, as he himself terms it, his paper constitutes an indictment, an arraignment, and we can but acknowledge the truth in the main of what his paper says. I believe the medical profession has a crystallized sentiment upon this subject: we are agreed that our function as medical experts is to be non-partisan, to be absolutely fair, and I believe it is as possible for medical experts to be fair as for the judge on the bench to be impartial in his rulings. Professor Bevan speaks of the better side of the medical profession. There are two sides to the medical profession; the charlatan, the ignorant, who is ready to prostitute his position in the interest of the fee, may be compared to that class of lawyers who today in the butchering business, tomorrow elected justice of the peace and the next day are honored members of the bar; those are the lawyers who may be compared with the ignorant physicians who are incompetent and unworthy. I believe the solution of this question lies with the bar, with the better side of the legal profession, who must make sentiment for a better state of affairs and possibly carry out the suggestion in the address of the President, of a commission of experts appointed by the court, similar to the commission existing in France, which shall be prepared to give absolutely non-partisan testimony in cases of this character.

Mr. MATHER—Mr. President and gentlemen: I appreciate keenly all that has been said about my paper, and I accept it as heartily and welcome the criticism that has been urged against it. I think there will never be anything done to rectify the evils of this matter until the conscience of both professions are pricked by the deplorable situation and both impressed with the necessity for impartial expert testimony, and I think it is well both that I should have said some sharp things of the medical profession and as one of you said, that I should be compelled to take the medicine myself. I had supposed that the charge of prostitution that I brought against the medical profession had been so hedged by limitations that it struck those to whom it properly applied. Dr. Reed I think misconceived that portion of my paper in which I said the expert was called to testify to what he thinks and not what he knows. In a legal sense the expert occupies two positions. He is an ordinary witness as to the facts of which he is advised either through examination or treatment of the case; in so far as he testifies to the actual condition he stands on the apparent facts of the case; as for instance, the length of the limb or the extent of its crookedness, he becomes an ordinary witness; he is not an expert in the ordinary sense in which that is used in the courts until he comes to testify to the unseen and hidden things which the eye can not see and which the court, jury and lawyer know nothing about except as they have the opinion of the medical adviser on that point. So that when I said the expert is called to testify what he thinks and not what he knows, I had differentiated those two positions which he occupies. I do not think it is necessary for me to say that no attack on the medical profession was intended in my paper. I have already been ably and eloquently defended on that charge. With reference to the suggestion of an official staff of experts, it has occurred to me there is a great deal of practical difficulty in the way of working out the reform through that means. In Germany, as I understand, there is a complicated system of official experts that work up from the county physician, or what is called county physicians with us, to a sort of court of medical review which passes in the last instance on any medical question. I am hardly prepared to believe that our experiment with republican forms of government has demonstrated the entire feasibility of that sort of system here. I think the medical profession will agree that the character of medical men, the class of medical men either by election or selection of the executive to fill the offices of our public institutions that are

required to be filled by gentlemen of your profession, is of such character as to justify any considerable experimentation of that plan. In other words, I believe the influences which surround political selection for public office, either by ballot boxes or appointment of the executive, are such as would not get a high class of public experts, and therefore I am convinced that aside from the suggestion that I have made, that in each case there should be the designation by the court of the experts who should examine into that case and make a report, we ought not to go any further. (Applause.)

WHY ALL PHYSICIANS SHOULD BE PREPARED FOR SURGICAL EMERGENCIES.

Read before North Texas Medical Association, at Denison, Texas, Dec. 8, 1896.

BY J. E. GILCREEST, M.D.
GAINESVILLE, TEXAS.

It has long been a question of no small importance to me, why all physicians do not carefully prepare themselves for surgical emergencies; and especially does that query apply to men who practice in the remote villages, or in the country, where they will certainly be called to attend all accidents occurring in the immediate vicinity. For the older members, who have had the benefit of experience, there is no excuse. For the younger men who are just starting out, there may be possibly, but I doubt it, gentlemen, seriously doubt it. While we have many noble, conservative, earnest and capable young men in the profession, men who will shine in the scientific firmament, we still have two extremes: 1, the bold ones, who are over-anxious to wield the scalpel and thus roll up a large list of surgical operations, the results of which are more or less cautiously exposed; 2, the timid young men, who make a bad break in the very outset of their professional career, by quieting their consciences with the delusion that they will not be called upon to do any surgery, that they do not fancy it as a science, and consequently think it wholly unnecessary to go to any trouble or expense in preparation. The men comprising the first class are dangerous. With an eye single to reputation, they will rush blindly into an operation, without paying any attention to the minor details, so all-important in the successful treatment of recent wounds. They think more of the skilful use of the scalpel or saw, than of the preparation of those very useful instruments; study more about how nice they could do this amputation, or that resection, than how to dress and care for it properly, after its execution. They can very easily find occasion to operate, where the conservative surgeon could not possibly have done so. In short, if they do not curb their false ambition, these men will sacrifice many human lives in order to glorify themselves, and like a sky-rocket, will go on and up, until the explosion, in shape of some glaring blunder, comes, when their descent will be equally rapid, and remorse alone is all that is left to them.

And now we shall investigate those of the second class. The man who enters the ranks of professional life with an idea that he already knows enough for all practical purposes, would do well to commit suicide, for it will prevent him from doing murder indirectly. This class, if possible, is worse than the former, because people very naturally suppose that they at least understand the simpler details, and in consequence depend upon them to do the thing most necessary until more experienced help can, when required,

be summoned. What is the result? They are wholly unprepared. Their gray matter is a muddle and won't work. They get rattled. Everything they do only serves to make matters worse, and so hopelessly upset things generally, that it is sometimes impossible for the very best surgeon to correct the blunders which, taken with the original trouble, end seriously, if not fatally. Now, there is no excuse for all this. Any man can and should qualify himself to cleanse and dress wounds aseptically and antiseptically. The expense is nothing, really nothing, and the rules are easy to comprehend; true, they are strict, yet simple. Let us see what would be necessary for each physician to do, and have, to treat wounds successfully. First, he should spend a few hours in studying up the aseptic and antiseptic treatment of wounds from some recent text-book on surgery. If he has none, he should borrow one long enough for that. He will need in a small bag scalpel, scissors, dissecting and artery forceps and probe, ten yards bichlorid gauze in a sealed jar, bandages, absorbent cotton, antiseptic catgut and silk in bottles, a few needles, a box of green soap, brush and fountain syringe, some bichlorid solution or tablets. The cost of this need not be more than three or four dollars, and with it, it is possible to put nearly all recent wounds in an aseptic condition. But to return to our men. We would not expect a student of the fine arts, the first time he took up his brush or chisel, to execute a painting like the famous Raphael, or to design and execute a masterpiece in statuary like the immortal Angelo. But by careful study of the most minute details, he can and will master his work, if he keeps everlastingly at it. The same is true of surgery. It has its elementary rules, its fundamental principles, and to ever be successful, we must learn them as thoroughly as a child does its alphabet. The following language emanated, I think, from Sir Isaac Newton, just after the famous discovery which will carry his name in reverence among the learned of all future ages. "For I seemed to have been only a child playing on the seashore, diverting myself by now and then finding a smoother pebble or a prettier shell, while the great ocean of truth lay all undiscovered before me." Think of it! "Only a child." A man whose life entire had been given up to the study of science. The language is worthy the modesty of a great and learned philosopher. Such has been the experience of all men who have achieved either ordinary success, or eternal fame; all of them have been close adherents to the most minute details. Now, the first principles of surgery are those of aseptic and antiseptic preparation, dressing and treatment of wounds, recent or otherwise. Once we have this mastered, and can properly execute all points scientifically, we have then a solid foundation laid whereupon a substantial surgical edifice can be built, against which the storms of time or adversity can beat with all the relentless fury of enraged nature, and there stand, a lasting monument to the man who built as he went. We want no pyrotechnic displays, nothing but simple, earnest, honest, conscientious, hard work. We can not afford to either experiment, or treat with dalliance, the human family. Such is not our mission, and when we do so, we become not only professionally insincere and dishonest, but sin before the most high God of the universe, and to Him will be held responsible for any wrong done in cold-blooded experimental work, or from wilful ignorance; and most ignorance, in this nineteenth century, is little else than wilful.

Let us take the matter to our own rooftop. Suppose parent, wife or child should receive an injury, which of itself had it received proper care, amounted to nothing. One of these "don't-want-to-know" men is called, with his untrimmed finger nails, beneath which several generations of different bacteria have been allowed to thrive unmolested for many days. The wound we will presume to be nearly, if not quite, aseptic. How long do you suppose it will remain so under the following conditions? He very carefully gets a kitchen wash-pan, fills it from the tea-kettle, finds after cautiously inserting his dirty fingers therein, that it is too hot, slaps his hands against a pair of not over-cleaned pantaloons until the pain subsides, cools the water from an ordinary kitchen bucket, with great deliberation and care drops four minims of carbolic acid into the pan, and his antiseptic preparation is completed. He quietly tip-toes back to the injured one, looks very wise and the real trouble begins. He pays little or no attention to the broken and bruised pieces of flesh that, at best are of such low vitality as to offer no resistance whatever, but rather serve as an ideal pabulum for the bacteria. He gets a piece of cloth of doubtful origin, immerses it in his solution, squeezes a little water over the injured parts, pokes it once or twice with a dirty probe, binds it up with a piece of "nice soft old sheet" and his work is done. The wound is now thoroughly infected; it suppurates most beautifully; trouble follows; possibly death. Now this man may be called, and probably is, a thorough conscientious physician; but I maintain, that he is responsible for that death beyond any question. And while the law protects him, he is certainly guilty of an ignorance of those details which would have surely prevented all this, hence, is culpable, and ought to be punished. Here is a fact that is true beyond question. In medicine we often meet with indifferent results as to their action physiologically; but in wound treatment there is none of that uncertainty. Good work is always productive of good results. There are many lives lost annually from a lack of this knowledge, and no man is excusable, who has had time and opportunities to qualify himself for this work. The antiseptic method of wound treatment, has, like all good things, been the subject of ridicule by some men, but without cause. It has stood the test thus far, and will continue to do so. Last year Henle wrote a timely and important paper on the antiseptic treatment of recent wounds. He took up the laboratory study of streptococcus infection. The germs were obtained from erysipelas and phlegmons occurring in the human system and were inoculated in the ears of guinea pigs. In some cases they were rendered excessively virulent by a successive series of inoculation, the spleen pulp of animals dead of streptococcus infection being injected into another, the reënforcements being continued. The results showed that the application of bichlorid solution prevented the development of erysipelas. The ear which was not so treated but simply cleaned with water, after thirty or forty hours, became red, swollen and infiltrated, presenting all the symptoms of local erysipelas, while microscopic section showed wide diffusion of the germs. The disinfected ear remained normal, without reaction, saving that which comes from the healing of a clean wound. Microscopic section revealed a complete absence of germs. Beginning with disinfection carried out a few minutes after infection of the wound, and length-

ening the intervals, he found that if bichlorid be employed three hours after infection, even through the most virulent form of streptococcus be inoculated the wound remains reactionless. In some cases where cleansing was not attempted for eight hours, erysipelas did not develop, or if it did, was more mild and slow in its course. Microscopic section showed that the first four hours the germs remained strictly localized. After that, they begin to penetrate the lymph spaces, and were found at some distance from the surface of the wound, hence beyond the action of the most powerful disinfectants. The clinical application of these facts is very clear, as to the value of antiseptic treatment of recent wounds. It has been demonstrated by laboratory research; and to be effected, must be applied as early as possible after the infliction of the wound, and must penetrate to its deepest part; there should be no hesitancy in enlarging the wound when necessary to allow thorough applications to all its parts. But even if the wound be two, or three, or even four hours old, the surgeon by this treatment may hope to avoid suppuration. Now, gentlemen, if wounds that are septic from their manner of infliction and exposure, can be rendered aseptic, why can not all practitioners, by a few hours' study and preparation, cleanse and put a fresh wound in an aseptic condition? For my part, I can see no reasonable excuse. He can do so if he will; and after having rendered that valuable service, can if he does not care to close the wound or take any further surgical responsibility, dress the wound with plenty of moist bichlorid gauze, cover with rubber tissue, retain the whole by bandage, and keep the wound in good condition for any operation that may be necessary; but unless the work is carried out in every detail, it may as well not be done at all. I could mention a number of cases, that have come under my observation the past few years, where lives and limbs have been lost, that might have been saved by strict antiseptic treatment. Doubtless the majority of the association have had similar experiences, so I will not consume your valuable time by reporting them.

THE RADICAL CURE OF HYDROCELE BY A NEW AMBULATORY METHOD.

BY J. N. BARTHOLOMEW, B.S., M.D.

PROFESSOR OF SURGERY, WEST SIDE POST-GRADUATE SCHOOL AND POLI-CLINIC; PROFESSOR OF SURGICAL ANATOMY, COLLEGE OF PHYSICIANS AND SURGEONS; CONSULTING SURGEON TO THE WOMAN'S CHARITY HOSPITAL, CHICAGO.

The tendency of modern surgery is toward methods that shorten convalescence as much as is compatible with safety and toward ambulatory treatment when possible. As far as I have been able to ascertain no satisfactory ambulatory treatment of hydrocele by any radical method has been described. The nearest approach to it being the old method by injection, which in many instances is far from satisfactory. I wish here very briefly to detail a method of treatment that has been put to the test in a few cases with very gratifying results.

Before describing this method I wish to review briefly the operations that have been most used and are usually employed today; to point out some of the deficiencies of these methods and contrast them with the procedure I am about to describe. In speaking of hydrocele I refer to an abnormal accumulation of fluid in the tunica vaginalis testis, the pathology of which is so well known that it need not here be referred

to. The methods most in use at the present day are by injection and open incision. The injection method consists in withdrawing the fluid by means of a trocar or an aspirating needle and injecting some irritating fluid as tincture of iodine or carbolic acid with a view to setting up an adhesive inflammation that will result in the final obliteration of the cyst by adhesion of the apposing surfaces of the cyst wall. This method is successful in about 85 per cent. of cases, in which it is applicable if rightly carried out. It is almost always successful in children and in recent cases in adults. When this method fails the failure is probably due to one of three causes, either a badly selected case (and what is meant by that will be explained later) or too little irritating fluid being used; the amount should be at least one-fourth as much in volume as the amount of fluid withdrawn from the sac, or a failure in the aseptic technique.

There are several classes of cases in which the injection treatment is not applicable. This fact has long since been discovered and these cases have been classified by various authors as follows:

1. In those in which the vaginal process has not been obliterated or in the so-called congenital hydrocele.
2. In old long standing cases in which the walls of the sac are thickened or infiltrated with calcareous matter which prevents the complete collapse of the sac after the fluid has been withdrawn.
3. When the sac is very large.
4. In cases where the surgeon is desirous of examining the testicle by inspection or palpation.
5. In cases of hydrocele complicated with hernia.
6. In debilitated subjects in which the necessary rise of inflammation is dreaded.
7. In cases of multilocular cysts.

By the injection method the patient is usually confined to bed from one to two weeks and the cure is not complete for from four to six weeks, with uncertainty as to cure at the end of that time.

The injection is often extremely painful and after a few hours following the injection the scrotum has become as large or larger than before the sac was emptied. The inflammation does not entirely disappear before the end of six weeks.

Treatment by incision is of ancient date. It fell into disrepute on account of the resulting inflammation that invariably followed the operation before the days of antiseptics. After the antiseptic methods of surgery were introduced the treatment by incision was reintroduced by Volkmann and has since been variously modified by Von Bergmann, M. Julliard and others.

Volkmann's method briefly given is as follows: The hair having been shaved and the skin made aseptic an incision an inch and a half or two inches in length is made over the anterior and lower parts of the sac down to the tunica and all hemorrhage is checked; then the sac is opened and after the fluid has escaped the edges of the sac are stitched to the edges of the incision in the skin. A drainage tube is introduced, the sac is packed with gauze and allowed to heal by granulation, which it will do in five or six weeks. At least two weeks of this time the patient must remain in the recumbent posture with the scrotum elevated. The wound must be washed out at frequent intervals with an antiseptic solution. Von Bergmann modified the Volkmann method by removing all or a part of the parietal layer of the tunica, putting in a drainage tube and closing the incision.

M. Julliard modified this latter method by having a sufficient amount of the parietal layer of the tunica to stitch over the testicle, thus making a new tunica. Others remove only a portion of the parietal layer of the tunica and paint the remaining portion together with the visceral layer with carbolic acid or some other irritating agent with a view to getting an adhesive inflammation, then closing the wound with drainage. By any of these methods the patient is required to keep the recumbent posture for at least two weeks and a final result is not obtained in less than from four to six weeks.

My experiments have been upon the line of an ambulatory treatment with a view to accomplishing a radical cure. The author does not wish to convey the idea that he considers this the best plan to pursue in all cases. We believe that in many cases, especially in children, a cure can be brought about without resorting to the removal of the sac but we believe it is the best method to pursue in all cases in which the removal of the sac is indicated.

The treatment that has been adopted is as follows:

The skin of the entire scrotum having been shaven and rendered aseptic, an incision a quarter of an inch in length is made in the most dependent portion of the scrotum down to the tunica vaginalis, being careful not to open the sac. Then by means of some blunt instrument, as a grooved director, the sac is dissected from the overlying infundibuliform fascia. This is done by inserting the instrument at the point of incision into the cellular tissue space immediately outside of the tunica vaginalis. By sweeping the instrument around the sac through this cellular tissue space the sac is separated from the overlying structures speedily and with the greatest ease quite down to the epididymis on either side. After this has been accomplished the sac may be opened. After grasping a fold of the sac with a dressing forceps the sac is punctured and the contents allowed to escape. The empty sac walls may now be easily drawn through the small incision and divided close to the margin of the epididymis, although it is not essential to the success of the operation that the sac wall be all removed. In cases in which only half of the sac was removed recovery seemed to be as prompt as in those in which it was all removed. The sac having been disposed of, an examination of the testicle is made, if it is deemed necessary, by palpation and inspection. Any granulations or cartilaginous bodies found are removed.

The quarter of an inch incision will now be found to have contracted to less than half its former length, by contraction of the dartos and will require no attention. The incision being in the most dependent portion of the scrotum serves admirably the purpose of drainage.

An important part of this method of treatment is the dressing. The sac having been disposed of, the assistant grasps the testicle and draws it well down, while by means of adhesive strips three-quarters of an inch wide the testicle is strapped, beginning as high as the hydrocele extended and making circular turns around the testicle, each turn overlapping the former one about one-third of its width, until the entire testicle has been strapped, as in a case of epididymitis. No drainage is necessary, as no effusion or hemorrhage will take place; no swelling will or can occur. The patient may be allowed to go about at will and will experience very little pain. The strapping may be removed at the

end of the first week and a cure may be anticipated in two weeks.

The advantages of this method are: It is extremely simple and applicable in all cases. It does not confine the patient to the bed or to the house. In many cases an anesthetic is not required. The dangers of hemorrhage and sepsis are reduced to a minimum. A cure can be anticipated with almost absolute certainty.

THE BEST METHOD OF STERILIZING CATGUT.

BY I. S. STONE, M.D.
WASHINGTON, D. C.

The following method of preparing catgut has none of the disadvantages which have heretofore prevented the general use of this valuable suture material.

It is unnecessary to wash the gut in ether. The gut (Nos. 0 and 1) is cut in pieces eighteen to twenty-four inches in length, loosely coiled and placed in water for twelve hours at ordinary room temperature, to "swell it." This suggestion of my friend Dr. Kinyoun is a good one, for the obvious reason that the formalin solution will penetrate the more readily into the interior of the gut. I formerly wound the material on glass spools, but soon abandoned the idea, because it became so tightly and firmly contracted around the spool as to render it possible that the formalin solution could not penetrate to the deeper layers of the gut.

The gut is taken from the water and placed in a 5 per cent. solution of the ordinary 40 per cent. solution of formalin found in the shops, where it may remain twenty-four to thirty-six hours. It is then thrown into a jar containing absolute alcohol, where it may remain indefinitely.

The writer can positively confirm Dr. Senn's recent notice of formalin catgut, and can certify that it will be strong and reliable in every way after boiling for ten minutes in water. This simple method leaves nothing to be desired. Anyone can use it, and there is positively no longer any reason to rely upon such material as we find in the shops. Every surgeon can easily prepare his own material, and do so without loss of time. Catgut prepared in this way will be found to meet every requirement in surgery where absorbable material is required. There is rarely any need for catgut in abdominal operations until we are ready to close the abdomen, then the small size 0 or 00 for everything but the fascia. The No. 1 is best for that. In the skin the smaller size will become soft in ten days or two weeks. In the cervix and vagina the material thus prepared will be found eminently satisfactory. The small number is the proper one for most operations. In hernia the No. 1 is better and should be allowed to remain rather longer in the formalin solution. I have seen Dr. Edebohl's catgut made strong and sterile after his well known formula, but there is very much less trouble by the later method, and the formalin solution does away entirely with the necessity for bichromate of potash or chromic acid hardening. It is not absolutely necessary to boil the gut, as it gives perfect results without this precaution.

THE SERUM REACTION IN HOG CHOLERA.

BY JOHN E. CASHIN, M.D.

PROFESSOR OF BACTERIOLOGY, HOSPITAL COLLEGE OF MEDICINE; BACTERIOLOGIST TO STATE BOARD OF HEALTH OF KENTUCKY; PATHOLOGIST TO THE GRAY STREET INFIRMARY, LOUISVILLE, KY.

The success which has been obtained in the serum diagnosis of typhoid fever led me to try an experiment with this method as an aid to the diagnosis of hog cholera, an affection due to a motile bacillus, the lesions of which, in the chronic form of the disease, resemble somewhat typhoid fever of the human subject.

Dawson (*New York Medical Journal*, Feb., 7, 1897) reports having obtained the reaction with the blood of a rabbit after inoculation with a bullion culture of the hog cholera bacillus, the reaction appearing promptly after injection.

An opportunity presenting itself a few weeks ago, I isolated the bacillus from an acute case of hog cholera and tested the agglutinating power of the blood serum of different animals upon it with the following result: Human blood serum from the placenta and dried blood from the finger tip, no effect; horse serum, no effect; rabbit serum, no effect; ox serum agglutinated strongly. A trace of ox serum added to an actively motile culture of the hog cholera bacillus caused immobility before the microscope could be brought into focus. Clumping was noted in from one-half to three minutes.

The normal serum of the hog was found to be without effect. The reaction appeared in the blood of two pigs forty-eight hours after the subcutaneous injection of $\frac{3}{4}$ c.c. of a forty-eight hour old virulent bullion culture of the hog cholera bacillus. No signs of illness have appeared in these pigs, except in one case a small abscess at the site of the needle puncture. Nearly a month has elapsed since the inoculation and the reaction in their blood is as well marked as ever. It is still present in a pig which had a severe attack of cholera four months ago. As to the length of time the reaction persists after experimental infection or after an attack of cholera, I have not yet determined; but inasmuch as pigs are usually killed when ten or twelve months old, it would seem reasonable to suppose from what has been observed that it remains during the brief period of existence allowed to most pigs.

The technique in making the diagnosis of hog cholera does not differ from that used in other infectious diseases to which the method has been applied. An incision is made in the skin of the ear of the pig and a few drops of blood collected upon a glass slide or a piece of smooth stiff paper. The blood, if it has been allowed to dry, is moistened with a drop of water and some of it transferred to a cover glass on which has been placed the hog cholera bacillus, either from an agar tube or a bullion culture about forty-eight hours old. The liquids are mixed and the cover glass inverted over a hollow slide and examined with a magnification of 450 or 500 diameters. Fresh, virulent, highly motile cultures exhibit the reaction as well as more attenuated ones, and it appears to me better, when ox serum was used.

It seems this method will be a valuable one to veterinarians and others, enabling them to make a speedy and correct differentiation between cholera and swine plague, anthrax and other diseases of swine during the life of the animal; and that it will be of service in the study and differentiation of the various bacte-

ria which have been described in swine diseases in this country and abroad. One might be able in this way to determine quickly that a specimen of meat, if fresh, came from an animal with cholera.

The following cases illustrate some practical applications of the reaction which I have made in conjunction with Dr. F. T. Eisenman, V.S. A sick pig, belonging to a herd in which there had been two deaths from what was supposed to be cholera, was donated for study. The reaction was not present. Two days later the pig died. At the postmortem examination a fibrinous pericarditis was found, but no lesions of hog cholera. Cultures from the heart, pericardium and spleen showed the staphylococcus pyogenes albus alone. In another case which we examined, and in which the reaction was not found, diarrhea was the most prominent symptom. The pig recovered. This was probably an intestinal disorder brought about by improper feeding.

In four cases examined I have obtained the reaction during life and verified the existence of cholera by postmortem examination.

The clinical symptoms of hog cholera and other swine diseases are very uncertain, and as by early diagnosis often much can be done to prevent loss, this method should commend itself to veterinary practitioners, should further trial show it to be reliable.

ANTITOXIN—SOME MEDICO-LEGAL ASPECTS OF ITS USE.

BY JAMES L. TAYLOR, A.M., M.D.

WHEELERSBURG, OHIO.

In the issue of the JOURNAL of February 27, Dr. Chas. T. McClintock of Detroit discusses, in an admirable scientific paper, one of the most intensely interesting questions now before the medical profession, viz.: the cause of death in hypodermic serum medication. The doctor shows conclusively that the injection of air along with the serum is not an adequate explanation of the reported accidents. He also points out that carbolic acid or trikresol used as a preservative of the serum is still less likely to be causative of these mishaps, and that experiments seem to show that the serum *per se* is not responsible. What the true cause may be, the doctor believes to be at present unanswerable, and prefers to give definite form to our ignorance by calling it "shock."

The profession will certainly not remain satisfied with thus merely giving a name to our ignorance. The phenomena heretofore reported when accidents have occurred, and which so far as we know are liable to be repeated in any injection hereafter made, are too fearfully significant in their effects on both practitioner and patient, to be thus lightly put away.

No other agent now employed by the profession stands in the same category as antitoxin. It holds the unique distinction of occasionally causing sudden death, or an alarming condition of prolonged collapse, when administered to persons in perfect health. The anesthetics do not belong to this category, for they are not employed as therapeutic agents proper. They simply paralyze temporarily the centers of the nerves of sensation, and it is not strange that this paralyzing action should occasionally extend to other centers than those of sensation. The condition of anesthesia is recognized as one of profound danger and its effects are procured with a due sense of the risks involved. But antitoxin which is an alleged

remedy *per se* stands upon an entirely different footing. The recognized function of an anesthetic is to annul pain, which it invariably does, while the alleged function of the serum is to overcome disease, and its action in this role is in any case more or less problematical. The fact that its effects are not uniform is what gives us pause. When we can not be sure whether it will elevate the temperature of a patient or depress it, retard or accelerate the heart's action, develop albuminuria or erythema, or pustular inflammation at the site of the injection, or perhaps cause symptoms of temporary paralysis, and occasionally an alarming condition bordering on collapse and sometimes instant death, it is far from satisfactory to be told that the statistics of mortality tables are favorable to its use.

Moreover the physician is always believed by the laity to know what he is using, and what the effects of his treatment will be. He is employed and enjoys the confidence of his patrons because of his supposed expert knowledge. And when he employs an alleged remedy which may kill instead of curing without knowing why, can it be said that the confidence reposed in his expert knowledge is justified? Will it serve as an answer, if, in a given case, an accident should occur, to say that the general results of the remedy and the indorsement of the profession warrant its use? The fact being established that the use of the remedy is sometimes followed by unexpected consequences and even death, would such an answer exculpate the practitioner in case legal proceedings were instituted against him? Not long ago the daily papers reported the arrest of two physicians by a husband for causing the death of his wife by the administration of chloroform. Under proper precautions death in such cases is sometimes unavoidable, and in a sense therefore thought to be legitimate. Could an accident following the use of antitoxin be defended on the same grounds as a death from anesthetics? The medico-legal aspects of the question are of profound interest to every practitioner, and in the present state of our knowledge, no one who makes use of the anti-diphtheritic serum can know that he will not be confronted with its unexpected and untoward consequences.

From a scientific standpoint it is greatly to be regretted that where accidents have occurred, a portion of the serum used in that particular injection had not been subjected to a careful examination. A resulting accident is the only experimental proof that can be had of its toxicity in the human subject, and unfortunately, from obvious prudential motives, an examination in such cases is not likely to be made. Hence it is difficult to determine experimentally whether a given specimen of the serum possesses toxic properties or not. Obviously the general practitioner can not make tests of each specimen used for himself. He must rely on the guaranties of purity furnished by the manufacturer, and it is from the use of these guaranteed specimens that all the reported accidents have resulted.

Unfortunate results have been ascribed by some to a supposed idiosyncrasy on the part of the subject. This explanation is manifestly inadequate. As the term idiosyncrasy is ordinarily used and understood, it may account for variable physiologic manifestations, but another term is employed where the unexpected phenomena are associated with sudden death. Idiosyncrasy may be properly used to designate such minor constitutional

peculiarities as fainting at the sight of blood, or at the scratch of a vaccination, or a hypodermic injection. But these effects are as transient as they are sudden. Even where unexpected and unusual consequences are more prolonged, as when laudanum purges, or water-melon causes hoarseness and nausea, or green tea acts as a powerful diuretic, or mercury produces pytalism, there is in these cases no menace to life. But when an agent acts upon the nerve centers with the rapidity and energy of concentrated hydrocyanic acid, the term to be used here, we submit, is not idiosyncrasy. Such effects can be produced only by a virulent poison. Indeed the action of the serum in these cases more nearly resembles, than anything else, the effect produced by serpent venom in instantly overpowering the nerve centers when injected in relatively large quantities into the smaller animals.

It seems to me that a much more rational explanation of the ill effects of the serum may be deduced from the fact that it is an animal product, and like all other animal matter has a tendency to undergo change. Indeed the manufacturers of it admit that age changes its composition and diminishes its immunizing power. If it undergoes change therefore, in this respect, how may we know that it does not become profoundly altered also in other particulars? How are we to know that the carbolic acid or trikresol employed to preserve it has in every case done its perfect work, and that some portion of the fluid, even a minute quantity of it, may not have degenerated in the direction of putrefaction? Now it is quite conceivable that a change of this kind should produce exactly the ill effects heretofore noted. If a scratch at the dissecting table induces blood poisoning, what might we expect from the introduction of a quantity of effete matter directly into the blood current?

Whether the use of even a recently prepared serum would in no case be attended with ill consequences may be considered as yet unsettled. Observations as to the physiologic action of antitoxin are too conflicting to warrant conclusions. The fact that it does not neutralize the diphtheria toxin, but stimulates the cells of the body to more effective action, throws no light on those cases where pernicious effects have followed. Dr. McClintock is undoubtedly correct in holding that as to the real cause of these exceptional cases we are still in the dark. But when an agent so perfectly simulates a virulent poison as antitoxin sometimes does, are we not driven to the conclusion that the specimen responsible for that action is a poison? And if there is no means of detecting its toxic nature are we justified in recommending and using as a remedy an agent in which such danger lurks? This question is not raised here as an ethical conundrum or a speculative supposition. It is a problem of intense interest by reason of a horrifying accident having occurred within our cognizance as the readers of the JOURNAL know, and no physician using this remedy can be sure that the same misfortune may not overtake him.

There is another aspect of this question which would seem to merit more consideration than it has heretofore received. When the ill effects of the serum are exhibited in a fatal termination or in the sudden supervention of alarming symptoms, its injurious nature in those particular cases is sufficiently obvious. Now is it conceivable that these gross and pronounced manifestations are the only bad effects following the use of the remedy? Is it according to any analogy

with which we are familiar to suppose that a given therapeutic agent, where it does not kill, will be likely to cure? On the contrary is it not in a manner certain that in a lesser degree there may be any number of gradations in the less obvious ill effects following its administration? Whatever the toxic element may be, is it not reasonable to infer that there may be every degree of variability in the activity of the toxin between the innocuous preparation and that which acts with deadly effects? On what principle can it be assumed that in all cases where it does not endanger life, it of necessity acts in the opposite manner? The only answer that has been given to this question thus far is—statistics. No man can be absolutely sure that any given case of diphtheria where antitoxin has been used would not have recovered without it. For sometimes, as every physician knows, the most desperately malignant cases apparently, recover unexpectedly under the usual methods of treatment. While cases that do not seem so desperate often succumb notwithstanding its employment. So the question again recurs—are statistics a logical basis for determining upon a mode of treatment involving the use of an agent of acknowledged danger?

The serum treatment, as a theory, in view of its splendid possibilities, is one of the most captivating that has ever engaged the scientific mind. Medical men all over the world have watched its rise in almost breathless expectancy, feeling that such a magnificent generalization deserved to be true. And there is no right minded man but would rejoice if its highest claims could be substantiated. The reported casualties therefore attending the treatment have been received in the nature of a profound disappointment. The writer hereof has used the serum in a number of cases, at first with confidence begotten of the sanction extended to it by great names, but more recently with fear and trembling, and never without the expressed authorization of the legal custodians of the patient.

But for one to be thus driven, through motives of self-protection in case of accident, to refer the decision of so important a matter to a family necessarily without expert knowledge, is a unique and most unsatisfactory position to be occupied by the physician. Yet this is the attitude now invariably assumed by a number of physicians in this region, and no doubt by many others of the profession elsewhere. Hence an authoritative decision, if in the nature of the case one could be had, determining ones rights to employ antitoxin as a legitimate remedy, would be hailed as a desideratum. No doubt the matter will finally come up for adjudication, but in the mean time we are all hopeful that the occasion for it will not spring up out of the circumstances of our own practice.

THE AUSCULTOSCOPE OR PHONENDOSCOPE VS. THE BINAURAL STETHOSCOPE.

BY CHARLES DENISON, M.D.

DENVER, COLO.

I am asked my opinion of these new-fangled affairs I have tested them enough to know that they can never supersede the stethoscope, if the latter is properly constructed.

The auscultoscope bell gathers the sound from too large an area, as large as would the bell for stethoscopic percussion which belongs to my stethoscope, diameter three inches. The sounds are thereby con-

fused and not differentiated as they should be. To use the auscultoscope is too much like putting the whole side of your head against the chest wall. This confusion with an admitted exaggeration of impulse sounds, as are the heart sounds, is a positive hindrance to any one who has been used to getting definite information out of a stethoscope. I do not believe it is any credit to a physician to be or appear to be satisfied with any such uncertain and mixed-up results.

If the area of impingement of the bell against the chest wall were one-half or one-third this size, and then this bell were used in a nearly perfect transmitting instrument such as the last make of my stethoscope, by the Denver Surgical Instrument Company, then the exaggeration of sound would be in a degree corrected by definite transmission, which those little, long, soft-rubber tubes can never possess. Even then the sound will be perverted by the vibrations of the diaphragm of the phonendoscope. The kind of a sound needed is an accurate representation, clear and distinct, not some perversion which has to be dissected to get at the real thing. It calls in question the acoustic acuteness and diagnostic proficiency of many self-satisfied physicians to see the useless combination of little pipes and soft-rubber tubes which, under the name of "stethoscope," they carry in their coat-tail pockets. I feel like urging them to put their cheap affairs to the same test I put my own stethoscope several years ago, when comparing it with all those of English or any other make to be found at Down Brothers in London. It is this: Place a watch on a glass counter or any table and cover it with the palm of the hand, while with the other hand you press the bell of the stethoscope firmly on the dorsal surface. If the two bells of the instruments being compared can not be equally imbedded in the flesh so as to alike exclude the outside air, then put the back of the hand on the watch and press the bells in the palm while you listen to the watch ticks. The best results under such conditions—clearness, distinctness and naturalness of sounds—determine the best instrument for cardiac and lung examinations. There is here plenty of reverberation and exaggeration of the watch ticks to make this a very delicate test, especially with weak-ticking watches. At the same time the conditions, as to passing sound through bone and flesh, are very similar to the detection of valvular sounds and murmurs. It is a fair and delicate test by which any physician may gauge the accuracy of his own instrument. Measured by this test, the auscultoscope or the phonendoscope (practically the same thing), even with their too large area of impingement unaccounted for, are not "in it" with my stethoscope with the medium-sized bell. Whether the principle of the auscultoscope can be incorporated in a modified instrument, having a smaller bell and perfect transmitting arms, in a way that undue drum-like reverberation will be displaced by naturalness remains to be seen.

CERUMINOSIS OBTURANS.

BY LEWIS S. SOMERS, M.D.

PHILADELPHIA, PA.

The ceruminous glands of the external auditory canal secrete small quantities of a semi-solid, light yellow substance, called cerumen or wax. The secretion is produced in such small amounts as to be

unnoticed and by the action of the lower jaw is propelled toward the exterior of the canal, entangling small foreign substances and to a certain extent protecting the deeper and more delicate structures. If for any cause the secretion of cerumen is increased in amount or by osseous or other changes, the configuration of the canal become altered; this outward movement is restricted and the cerumen being retained, undergoes change producing the condition known as ceruminosis obturans, or more commonly called impacted cerumen or wax plug.

The size and density of the cerumen mass varies with the secretory activity of the glands and the length of time which it remains in the auditory canal. The increase in size is gradual, depending to some extent upon the location of the foreign body forming the nucleus, or the small amount of inspissated cerumen acting as such. If this foreign body irritates the glands by its immediate relation to them, there will be an increased secretion poured forth, rapidly augmenting the original body in size. The condition is seen most frequently in adults, especially after the age of twenty years. Sex does not seem to exert any influence as a causative agent, the cases seen being about evenly divided between the sexes, although the males slightly preponderate.

The pernicious habit of cleansing the ear with a small sponge or ear spoon is responsible for a large number of cases; the patient endeavoring to remove the small particles of offending material, only succeeds in pushing particles of wax beyond the isthmus of the canal, where it lies acting as a foreign body finally requiring skilful measures for its removal. Children are very apt to insert buttons, small pieces of paper and various other foreign bodies into the ears and forget all about them; probably ten or twenty years later sudden deafness will take place due to a cerumen plug with the foreign body as a nucleus. Some cases are undoubtedly neuro-trophic in source, due to excessive glandular secretion from a purely nervous origin. It has been claimed that the condition is most frequent in those liable to free perspiration, especially of the head; this seems doubtful, but may indirectly be an etiologic factor by associated trophic changes. Most frequently the condition has been seen in my experience, in those in which the entire glandular system was most active and especially in those of dark complexion.

On examination of the removed cerumen it will be found to contain scattered through the mass and especially over the surface, vegetable spores, epithelial cells derived from the canal walls, various kinds of debris and in many cases a foreign body forming a nucleus. The pressure of a large cerumen mass on the canal walls or membrana tympani may produce widely varying results. When the plug is very large in size and remains in situ for a long interval of time, inflammation and atrophy of the canal is apt to take place and finally chronic otitis occur, resulting in obliteration of the posterior wall and mastoid cells with a true osseous sclerosis, the bone becoming of ivory-like hardness. Or a desquamative inflammation may result with bony changes and large dilatation of the canal walls, especially the posterior. The membrana tympani may become inflamed from pressure and even perforated, resulting in morbid changes in the middle ear, which if infected and suppurative otitis results may occasion serious damage. Occasionally the cerumen will adhere in part to the

tympanic membrane, which during removal, unless great care is exercised, will be ruptured.

The symptoms depend upon the size and location of the plug and may conveniently be divided into local and reflex. A large concretion of cerumen may exist for years and produce no symptoms, while minute particles of wax adhering to the drum membrane may produce intolerable discomfort. As a general rule, the disease exists for a considerable period of time without the knowledge of the patient and may only be discovered accidentally, especially after swimming, or come on suddenly after washing the ears, the patient thinking from the sudden deafness or feeling of "stiffness" present that water has gotten into the ear. The usual local symptoms are partial or complete deafness in one or both ears, a feeling of "stiffness" referred to the auditory canal, tinnitus and rarely autophony and pain.

Occasionally there may be a feeling of tension in the head almost amounting to actual vertigo. The degree of impairment of hearing depends upon whether sound waves can pass through the canal or not, this varying with the size of the obstructing mass and degree of adherence to the auditory walls. Tinnitus seems to result from two causes, atmospheric pressure changes due to the obstruction to the free change of air in the external canal and secondly to the pressure exerted by the mass on the blood supply of this region. Autophony occurs when the cerumen plug is very large and entirely obstructs the canal, and is usually observed unilateral. The amount of pain will depend upon the degree of irritation exerted by the wax on the soft tissues of the wall; the pressure may be so great that from simple irritation and congestion we may even have ulceration, the morbid secretions being pent up increasing the discomfort of the patient.

Sudden onset of the symptoms may result from picking the ear or from a sudden jar or concussion, such as a blow over the auricle. In many cases the symptoms come on very gradually, the patient complaining only of a slowly increasing deafness for six months or a year. McBride has reported an interesting case in which there was gradually increasing impairment of hearing due to a cerumen plug, which when removed rendered the loss of hearing much worse; the mass acting as an artificial drum, the membrana tympani having been perforated.

The reflex symptomatology is varied in character and may be dismissed in a few words. As the canal is profusely supplied with nerve branches from the adjacent trunks the variability of the reflex phenomena may be readily explained. Among the more prominent reflex symptoms reported are neuralgia, numbness along the course of the nerves, cough peculiarly hard and spasmodic in character, varied mental disturbances, epileptiform attacks, sneezing, facial paralysis and blepharospasm. These reflex phenomena are comparatively rare, although cough is more or less frequently seen. Some cases where the cerumen obstruction is unilateral present changes in the well ear; these changes have not been thoroughly studied, but are usually due to over stimulation of the nerve apparatus of the well ear, this side doing a compensatory work becomes fatigued, as it were.

The diagnosis of the condition can only be made by a visual examination of the auditory canal. Under proper illumination the mass of cerumen will be seen lying in the canal or entirely filling it. If the con-

dition has existed for a limited time the cerumen will be seen as a brown sticky mass, and if of long duration will be hard and black, or grayish-black in color, the lighter gray color depending upon the amount of desquamated epithelial cells present.

Treatment consists in the removal of the cerumen and attention to any pathologic changes that may have taken place as the result of its presence. Removal may be effected immediately after the diagnosis has been made, or, if the cerumen is very hard, may be postponed until softening of the plug has been effected. The best policy is to remove as soon as possible, as there may be some morbid changes such as an acute or purulent otitis present, and if solutions are instilled into the canal to soften the mass, serious damage may result. About the only class of cases in which removal may be postponed are those where the wax is extremely hard, the patient nervous and an unsuccessful attempt made at removal. In these cases a solution of carbonate of soda in water, or glycerin, or a spoonful of warm water is dropped into the ear for several successive days, when removal can be easily accomplished.

In the majority of cases the mass may be readily removed by syringing. The stream of warm water is directed against the canal walls successively so as to effect dislodgement. If this method is not effectual, a dull curette or ear spoon may be used carefully, to remove small pieces of the cerumen until the canal is clean and free. Extreme care must be exercised in using any instrument in the ear, to avoid injuring the walls, and especially the membrana tympani. In using the dull curette the topography of the parts must be kept in mind, remembering that the upper and posterior parts of the tympanic membrane are nearer to the external meatus than the lower and anterior portions. Should middle ear disease be suspected, with perforation of the drum, mild antiseptic solutions, such as 1-10,000 bichlorid of mercury are indicated, instead of the ordinary fluids used in the syringe. If an external otitis exists, or the canal is unduly sensitive, the central portion of the plug should be taken away with the curette, avoiding the walls as far as possible. After this portion has been removed and a mere shell of cerumen remains adhering to the walls of the canal, gentle syringing will readily remove the rest of the material.

As rare results of the removal of large masses of the cerumen, have been reported rupture of some of the small vessels of the canal, with the formation of a hematoma; or long pressure, diminishing the tonicity of the vessel walls, transudation of serum into the middle ear has occurred. If efforts of removal are long continued, or traumatism inflicted on the canal, hyperemia, inflammation or even furunculosis may result.

After removal of the cerumen mass the membrana tympani will generally be slightly congested, especially over the area of the manubrial plexus. This will disappear in a few hours and need occasion no alarm. The after-treatment consists in inserting a pledget of cotton in the meatus and directing the patient to remove it in twenty-four hours. Should the canal wall be inflamed the case is then treated as one of external otitis.

A LEGACY TO A NEW YORK HOSPITAL.—The treasurer of the German Hospital, New York city, has received a bequest of \$10,645 from the John Roth estate. The executor added a personal gift of \$50 for a tablet in memory of Mr. Roth.

SOME AMUSING INSTANCES OF NASAL REFLEX.

Read before the American Laryngological, Rhinological and Otolological Association in New Orleans, March 3, 1897.

BY ARTHUR G. HOBBS, M.D.
ATLANTA, GA.

It was not without some misgivings that I thus christened this little paper, because some might regard it as a too flippant manner of approaching so scientific a subject as nerve reflexes; a subject fraught with such subtleties and as yet so suggestive of unknown quantities. Also because there may be others who can never look upon nature's phenomena as amusing, however, vagarious and unexpected they may at first appear.

While these instances of nerve reflex manifestations that I have dared to call amusing are no more wonderful than many others somewhat similar but more familiar to us all by reason of their frequent occurrence, nevertheless for this very reason, together with the particular organs involved, many of us at first can not avoid seeing the ludicrous side, however easy the scientific explanations, by analogy, may seem. Familiarity with frequent recurrences of nature's perversions does not breed contempt, but it does dull the sense of the ludicrous. Still, I have a feeling even now, that I should have said: "Some Interesting Instances of Nasal Reflex." If they are not *amusing*, I can hope that they may be at least in some degree, interesting.

I had never seen but one case of priapism, and that was in 1879 during my term in the New York Hospital, until by accident the second case came under my observation in 1888. A young cashier was driven from his rooms to my office in a close cab wearing an overcoat on an August day. He had been confined to his rooms more than two days with a painful attack of priapism for which he said he had run the gauntlet of all treatments, from hot and cold water locally to salines, opium and apomorphia internally, without any effect. He looked haggard and pale and in many ways the results of his great suffering were plainly shown. The object of his visit to me was to be relieved of an acute rhinitis accompanied with an almost complete nasal stenosis. I sprayed the nose slowly but persistently with a solution of cocain in albolene until the engorged turbinal tissues relaxed sufficiently, within about five minutes, to allow a comparatively free passage of the spray through both nares. About this time, with an expression of great joy, the young man exclaimed: "Doctor, not only is my nose free, and I am relieved there, but see! it has all gone down, and I am perfectly easy." His cocain exhilaration was scarcely perceptible, and indeed I would not have recognized any but for my anticipation that there might be some. As the nasal turgescence disappeared so did a complete relaxation in the principal organ of erectile tissue follow. How singular it was that a second case of priapism should have followed in the latter part of the same year, and yet in the nine years that since passed I have not seen or known of another case. This second case—a young man aged about 22—was in many respects similar to the first, except that he had suffered only intermittently, but during a longer period, five days. And yet his relief lasted only during a decided opium narcosis and pain gradually returned when the effect of the narcotic began to decline. His exposure to frequent applications of hot and cold water had probably

caused the acute aural catarrh, with a moist and stuffy nose, notwithstanding the large amount of opium he had taken. The subjective symptoms of pain and tinnitus together with the visibly retracted drum membrane suggested a nasal spraying with the same cocain solution in albolene, that I had used in the first case, before inflating. This young man had come to me for his aural and nasal troubles, and I was not aware of his priapism until after I had relieved it indirectly. His exclamation of delight was as prompt and no less decided than the cashier's. I saw both of these cases several times during the succeeding two or three days. There was no intimation of a return of a priapism in the first case, and in the second, only in a slight degree several times.

The soft tissue that covers the turbinal processes is not histologically dissimilar to the corpora cavernosa, hence the question: Was the distal effect by reflex, or through the direct systemic influence of the cocain on the arterial constrictors? Would cocain have produced the same result during its exhilarating stage had it been administered otherwise?

Although I have been using cocain constantly from the early eighties, indeed since I received a consignment of a part of the first half ounce imported from Koller's laboratory, I did not know as much of its potencies, nor did anyone else then, as the novice thinks he knows now. Yet will our present knowledge of the therapeutic properties of this drug explain how it effected these results?

I casually mentioned these two cases of priapism before the Atlanta Academy of Medicine about seven years ago, in a discussion on an allied subject, but do not remember that my remarks were ever published.

An unaccountable sneeze is produced in some persons merely by an erotic thought when accompanied by the desire and the anticipation of its fruition. All whom I have questioned upon this point say that the sneezing reflex passes off long before the usual and more important erectile area has been stimulated to its full limit of distention.

I do not doubt, from the accidental way in which some seven or eight such instances have come to my knowledge, that many more men are endowed with this faculty than we know of. From the descriptions it is characteristic and quite unlike the sneeze that first announces a cold.

A gentleman once described his own case to me more graphically than I can repeat it. While walking, he said, one evening arm in arm with a lady, his wife who was but a short distance in the rear was surprised at hearing a succession of sneezes that she first mistook for his characteristic sneeze, with which she thought she was quite familiar; but later on she was amused and no doubt delighted too, when she realized that what she had heard was only the ordinary commonplace bad cold sneeze (?) that any man might, unfortunately, contract at the wrong time. A young man has confided to me that he was constantly mortified and placed at his wits end in making excuses to his sweetheart on account of his susceptibility when with her, to drafts (?) that she could in no way discover.

Several men, with my encouragement, finally acknowledged that this little tell-tale reflex had been their principal cause for consulting me. A prominent physician very graphically described his own experience with these dual reflexes. It came to him so insidiously, he said, that he could scarcely realize it. Indeed his wife had become quite familiar with

the characteristics of his forerunner long before he would himself acknowledge it.

None of the means that are ordinarily resorted to can suppress this sneeze; it simply means to announce that "Barkis is willin'," or would like to be, at least, that such an idea exists in the brain of its victim whether or not it can be properly and effectually reflected.

In all of the cases without an exception it would appear that the effect on the sneezing area has come and gone before the mental reflex stimulus has had time to reach its usual result of erectile perfection. A sneeze is one of the most typical examples of a nerve reflex and while the neurologist can only construct a beautiful theory to explain its incentive and conductive factors, pathologists agree that the final result is brought about by the swelling of the erectile tissue covering the turbinal bones. The histologic similarity between the turbinal tissues and the corpora cavernosa is quite sufficient to cause no sense of wonder or surprise when a mental impression that excites one should also excite the other even within pathologic bounds, although we are accustomed to regard the one as an entirely physiologic function and the other as distinctly pathologic.

The instances just cited prove, however, that it is only the turbinal tissue that possesses the dual capacity of responding to either a physiologic or a pathologic stimulus, also that its response to a mental stimulus always precedes the more important effect below and is lost before the distention of the corpora cavernosa is complete. It may be answered that a priapism is a pathologic condition and yet its beginning is physiologic.

Is it not fortunate too, that every time we get our feet wet the reflex result on this lower and larger erectile area is not the same that is so often produced on the turbinal tissue by an over stimulus from an external source?

It has not been my intention to treat this subject lightly. It is too closely allied to one that men generally, I believe, do not disregard, "with but a single thought." But seriously, I do think the paper could be more appropriately read before a section on neurology, unless we can claim that rhinologists can be neurologists too, at least in some particular directions when they choose.

I would be glad to receive a short history from any one of any case apropos to this subject of reflexes, and will promise to give due credit to the writer in a future, and I hope more comprehensive paper.

P. S.—During the short interval since I read this paper I have been much gratified by receiving a number of letters from those who have seen its first epitomized report; many of these letters contain promises of short reports to me of cases either bearing directly on, or closely related to, the subject of *erectile tissue reflexes*. This subject is an evolution (so far as it has evolved) of the last six or eight years, and is not one of my choosing. Yet I confess a desire *now* to evolve it still further, if I can obtain sufficient data.

A METHOD OF PRESERVING UNBOUND LITERATURE WITH SUGGESTIONS REGARDING A SYSTEM OF CLASSIFICATION.

BY D. H. GALLOWAY, PH.G., M.D.
CHICAGO, ILL.

Probably the majority of physicians regard the unbound literature in their libraries as an unmitigated

nuisance. They may see much of interest in this literature when received but the likelihood of being able to find it again when wanted is so remote that it is generally consigned to the waste basket. Any plan which will rescue this material from the waste basket and make it useful ought to be received favorably by every one who has realized how difficult the subject is. The problem of preserving unbound literature, so that it is available for convenient reference, is so difficult of solution that few attempt it and those few usually get swamped before the amount of material becomes very great.

A system to be valuable, must conform to the following requirements:

1. The scheme must be so simple that it can easily be carried in the mind and it must require the minimum of labor to establish and to keep it up.

2. Each article or subject must be accessible without delay or inconvenience and without handling or interfering with any other material which is not wanted.

3. The different articles on any subject must come together so that everything on that subject can be obtained as easily as any portion of it.

4. It must be capable of unlimited expansion so that all new material falls naturally in place beside that already in hand on the same subject and so that new subjects may be introduced without interfering with the previous arrangements.

5. The arrangement must be compact; so that the library occupies no unused space. A hundred titles should occupy no more room when they constitute the entire library than they do when included in a library of 10,000 titles.

6. Every article or pamphlet should be a unit and capable of separate classification and of being moved independently of all others. The only exception to this being pamphlets or articles having exactly the same title.

Since the material is so easily damaged or destroyed everything in this library should be protected from injury and even wear, when not in actual use.

I have a system in use in my own library which, while not altogether unique, is entirely original with me. It conforms to all the requirements outlined above and as I know there are many who have felt the need of such a system, I have thought it worth while to publish mine. This system is applicable to any kind of literature and I carry it into all the realms of science included in my library. Unbound pamphlets of all kind are put into large envelopes and each envelope is treated as if it were a book. These envelopes may be sandwiched in with other books on the library shelves or they may be assigned to a section by themselves. I prefer the latter, thus drawing a sharp line between the bound and the unbound library. With this short statement of what I have done in my own library, I will go into the details of my work so that others wishing to do likewise may be saved the great amount of experimental work which I went through before the difficulties were overcome and the system made satisfactory. After many changes and much experimenting, I have selected an envelope $6\frac{1}{2}$ inches wide by $9\frac{1}{2}$ inches long, open on the side and made of manilla paper. The paper should be heavy enough to handle easily and should be tough, so that it will not tear readily; it should be as light as possible, consistent with these two requirements. I have been unable to buy, in the market,

envelopes that were entirely satisfactory, and recently had a lot made for me at an expense of \$3.75 per thousand, but when delivered, these envelopes were so irregular in size as to be unsatisfactory. In this great city of manufactures I feel sure that there is some one who can make them and make them right and I intend to keep looking until I find that person or firm.

The envelopes should have a flap, but be ungummed. I have bought and used gummed envelopes but after some experience with the flaps sticking in hot and damp weather, I took the trouble to wash the mucilage of the rest until I was able to get an envelope ungummed. Ready made envelopes are always gummed.

Now for the preparation of the material which is to go in the envelopes. The ideal form in which to have the literature for this method of classification is the "reprints" of articles which are obtained and distributed by many persons who write for medical journals. While these vary greatly in their value as contributions to medical knowledge and still more in their value to any particular individual, I carefully preserve every one which is sent to me. I also do another thing which is unusual and that is, acknowledge the receipt of them.

As a rule journals pay nothing for contributions from medical men, some give a few hundred reprints in lieu of other compensation and this would seem the least return any of them could make to the author. Since these reprints go only to the profession there can surely be no valid objection, from an ethical standpoint, to their distribution; for my part I would like to have in this form every article which interests me. Since however, not all articles of value are available in this form some other way must be devised for obtaining them. Of course a complete file of all the journals subscribed for, if bound and accompanied by a card index which has been very carefully made and conscientiously kept written up to date, will render available all that they contain. I prefer however the method I employ, which has many advantages and some disadvantages. The advantages will be obvious, the disadvantages I will point out as I proceed. When a journal comes in, I look through it reading all the articles that interest me and then put a check mark on it indicating that it has been read. When I have a little time to spare I take these up one at a time, take out the binding wires, and throw away the advertisements. Then selecting the first article which I wish to preserve. I tear out the leaves containing it and fasten them together at the back with two scraps of gummed label cut for the purpose, and used like a hinge, or instead of the label, small pieces of isinglass plaster. This keeps the leaves together and the articles may be piled up and handled without disturbing the order of the pages or losing any of the leaves. In this way all the original articles are disposed of.

There is one difficulty with the plan which immediately presents itself; one article will end and another begin on the same leaf. Usually one will not be wanted or the least desirable one will be sacrificed. If one of the articles begins a few lines from the bottom of the leaf, or the other ends a few lines from the top of the same leaf, I copy these few lines on the typewriter and thus save both. Or if there is too much to make that practicable and both are of value to me, I make a reference on the bottom of the page stating where the remainder of the article can be found.

This can not be done often, or much of the value of the system will be lost. If a large number of doctors should adopt this scheme there are some improvements in the journals which publishers might be prevailed upon to make which would obviate this objection. Paper is very cheap and postage is almost nothing, still I do not suppose they could be persuaded to leave a part of a leaf blank where one article ended and begin the next one on another leaf. There are some publishers who do this now, particularly in reports of scientific societies. There are in every journal a large number of small items which are of transient interest and they might be used to fill up the waste space; such an arrangement would improve the make-up of the journal. But until publishers are convinced that a large number of their subscribers desire such a change, we will probably be obliged to make the best of things as they are.

On every article, I write the name and date of the journal from which it was taken; this of course is unnecessary where that information is printed at the top of the page, as it is in some journals, and ought to be in all. The articles of a journal may thus be prepared for classification in less time than I have taken to write the description of it. If the journal is magazine size, the pages will be the proper size to go into the envelopes; some may need a little trimming. For this purpose I have a board a foot wide and two or three feet long, a shoe knife with a shoemaker's sandstone on which to sharpen it and a straight edge of wood. The latter may be a thin strip of hard-wood flooring about two feet long. I lay the leaves on the board and trim to the size of a card-board pattern $6\frac{1}{4}$ inches wide and $9\frac{1}{4}$ inches long, using the straight edge as a guide for the knife. Leaves from the double column journals of a larger size like the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION must be folded once.

There are many small items in the back part of all journals which are worth preserving; such as I want are cut out and classified in the same manner; these may be pasted on pieces of manilla paper and the paper folded the proper size to go in the envelopes, under the appropriate subject. Many will object to "destroying" their journals, and where complete files are kept, bound and indexed on cards, it may not be desirable to do so. This scheme is intended to supplement the ordinary library, not to displace it. There are many articles in the literary and scientific magazines which I wish to preserve and by doing it in this manner I have them all where I can lay my fingers on any of them at a moment's notice, and with bulk and weight reduced to a minimum. The pamphlets, articles and clippings being cut, folded or pasted on paper the right size, must be classified before they are ready to go into the envelopes. The decimal classification originated by Mr. Melville Dewey and published by the Library Bureau of Boston, is at once the simplest and most comprehensive system with which I am acquainted. This book costs \$5, and it is almost a necessity in any library. By this method all knowledge is divided into ten classes as follows:

0. General Works. 1. Philosophy. 2. Religion. 3. Sociology. 4. Philology. 5. Natural Science. 6. Useful Arts. 7. Fine Arts. 8. Literature. 9. History.

Each class is separated into ten divisions, each division into ten sections, and each section into ten subsections and so on, each subject being divided into ten to any limit desired. After the first three

figures the number is a decimal fraction. Medicine is classed with the useful arts, 600, and occupies the numbers 610 to 620, divided as shown in the following table.

610. Medicine. 611. Anatomy. 612. Physiology. 613. Personal Hygiene. 614. Public Health. 615. Materia Medica. Therapeutics. 616. Disease. Pathology. Treatment. 617. Surgery. Dentistry. 618. Gynecology. Obstetrics. 619. Comparative Medicine. Veterinary.

In classifying, one can see at a glance into which division an article goes, and with a lead pencil put on the appropriate number. All articles on medicine in general and not treating of any one division more than another are marked 610. In beginning such a classification with a large number of titles to work on, it is better to go through the whole lot, putting on the numbers thus far. Then sort them into ten piles, numbering from 0 to 9 according to the last figure. Tie up and put away all but one lot, take this lot, say Anatomy, 611, and go through it as before, this time putting a decimal point after the number already there and add a decimal number in the following manner:

- 611.1. Circulatory System.
- 611.2. Respiratory System.
- 611.3. Digestive System.
- 611.4. Glandular and Lymphatic System.
- 611.5. ———.
- 611.6. Genito-urinary System.
- 611.7. Motor and Integumentary System.
- 611.8. Nervous System. Sensory Apparatus.
- 611.9. Regional Anatomy.

Now separate this lot according to the last figure, wrap up and label all but one of the divisions (this is to prevent mixing when the work is to be done at odd moments) and classify this division still further. Each paper of this lot now has the number, say, 611.8 and is further classified as follows:

611.8. (Anatomy of the Nervous System. Sensory Apparatus).

- 611.81. Brain and Meninges.
- 611.82. Spinal Cord and its Meninges.
- 611.83. Nerves.
- 611.84. Sight.
- 611.85. Hearing.
- 611.86. Smell.
- 611.87. Taste.
- 611.88. Touch.
- 611.89. Ganglia.

Many subjects, even in a private library, will require a third decimal and in some cases even a fourth. The classification can be continued in this manner to any degree of fineness which individual taste may suggest but it is not advisable usually to go beyond three decimal places.

When no further classification is necessary or desirable, the papers are ready to be put in the envelopes. Now separate the lot as before into smaller lots to correspond with the last figure of the number, put all the papers having the same number into the one envelope and put that number on the outside of the envelope in the upper left hand corner. If there are too many papers to go in one envelope use as many envelopes as may be necessary. It is not necessary to put more than the number on the envelope, but if desired the names of the authors of the various articles it contains may be written on the outside. I lay the envelope on the desk before me, back up, with the open flap toward me, write the number in the

upper left hand corner, put in the material and tuck in the flap. The envelopes are then arranged on edge on the shelves in the book case, flap down and number to the right and in strict numerical order, the short way of the envelope vertical. All book cases are ten inches or more in depth and this allows the shelves to be placed seven or eight inches apart and the case will hold many more envelopes than it would if they stood on end. In arranging the envelopes on the shelves it is convenient to have some contrivance to prevent them from falling down. For this purpose I got a tinner to cut for me some pieces of galvanized iron ten inches long and three or four inches wide, and bend them in the middle to a right angle. One of these on a shelf with the end shoved under the envelopes will prevent their falling down until the shelf is full. An index is made of strips of card board an inch wide and an inch longer than the envelopes, shoved in between them and the appropriate number written on the projecting end; but few of these are necessary. The cataloguer meets with a number of difficulties which ought to be corrected. In the publication of articles which have been read before a society and discussed by the society, the paper and discussion appear in separate places; it would be better if the discussion should immediately follow the paper in the journal.

The authors' post-office address should be appended to the article. "Dr. Smith, N. Y.," is not enough. Authors should be careful to select such titles for their papers as will give some idea of their contents; one does not wish to read an article in order to find out the subject. It is difficult to index a paper with such titles as "Study of a few Suggestive Cases," "An Interesting Case," "A Surgical Fad."

All discoveries and improvements in medicine and surgery are first announced in the periodicals. Text-books are scarcely out of the press before they are "back numbers." Details of original investigations seldom appear anywhere but in the medical journals, and if a doctor would keep abreast of the profession he must read them and not books alone; the one who depends on books will always be several years behind.

The capacity of the average brain for detailed information is soon reached, while the extent of the knowledge a professional man needs to use at one time or another is almost limitless. Since at best no man can have at command in his brain all the knowledge he must use, the best education is the one which enables him to find any available information when he has use for it. Any one who makes a lumber gallery of his mind, trying to crowd into it everything he can pick up, will soon find that his brain is not the workshop it ought to be.

Comparatively few men know the capabilities of their own libraries, and fewer still have any idea how to avail themselves of the vast storehouses of knowledge placed at their disposal in the great libraries of the country. The man who will classify and index his own library will find that he has introduced into the workshop of his mind an instrument of great power, for that itself is an education. If he will preserve in some such manner as I have outlined, the unbound literature which comes to him for almost nothing, his library will be doubled and his ability to profit by its contents will be more than doubled. The fascination of the work is so great that when well begun there is little danger of its being abandoned, for it will be found a pleasure rather than a task.

For twelve years I have used the envelope system for preserving scraps of information on all sorts of subjects, particularly personal ones. A drawer in my desk is divided into four compartments and in these, standing on end, are more than a thousand envelopes (6½) containing all sorts of imaginable information, from teachers' certificates and college tickets to duplicates of ballots voted at various elections and clippings from newspapers and scientific periodicals. After filling some half-dozen scrap books, I found the material so inaccessible as to be next to useless. The envelope system is better than an index rerum for all things that will go into envelopes, for when the reference is found the material itself is at hand. I have kept a diary for over twenty-one years, and there is an entry for each and every day during that time. This record is a log-book rather than a diary, as that term is generally understood. In another book I have an accurate account of all earnings and expenses since I have earned and spent money; I have the name of every person who has paid me money since I began earning money. In one place I have listed all the trips I have made on the railroads during my whole life, with the distance in each case and the total number of miles. In one place the names of all my patients and the names of those to whom I have administered anesthetics.

With lifelong habits of keeping accurate accounts and much experience in all sorts of methods for making available information regarding persons and things, I have come to the conclusion that the envelope system is the most nearly perfect that has yet been devised.

200 Oakwood Boulevard.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

BY CARL H. VON KLEIN, A.M., M.D.

CHAPTER IV.—NOTICE ON HOSPITALS.

(Continued from page 738.)

In respect to the number of patients the Hôtel Dieu in Paris stood first, the General Hospital in Vienna second. The mortality was also greatest in the first mentioned hospital, so that, with the Berlin Charité, which held the second place; it had the reputation of a den of murder. One-third of all the mortality in Paris was in the hospitals, and one out of five patients in the Hôtel Dieu died. Trephining was no longer done there, for in forty years among a large number of operations, not one case had been successful. Tissot believed that without doubt fewer sick would die if they were allowed to lie under the blue sky and given only fresh water, since the hospital air alone could make every slight wound fatal. The mortality in the Vienna hospital was lower, as it was seldom more than half full. (Of the 30,764 patients received there in three years 24,900 were cared for without charge.) The best hospitals were the English, particularly those in Edinburgh and Manchester, because of their isolated situation and well ventilated buildings. The mortality there amounted to only 4 per cent. Of the surgical patients, concerning whom statistics are unfortunately very meager, in the Charité in Berlin, between 10 and 15 per cent. died. The following figures show the *extraordinarily small number of operations*. In the year 1801, in the Berlin

Charité, among 523 surgical patients there were 30 operations, and two years later among 793, only 23 operations. The facts were similar in Friedrich's Hospital in Copenhagen, where in the year 1783 of 593 surgical patients 34 were operated upon, and two years later of 639 only 30 were operated upon. Among the 34 operations the majority were trephining, 8, a fact very characteristic of that time. An overwhelmingly larger part of the hospitals of the last century were thoroughly bad. Built in unhealthy places, most of them had only small, low rooms, in which the patients, usually medical and surgical cases together, were as if buried. Dirt and stench abounded. The French especially lacked a sense of cleanliness, quite aside from their revolting custom of putting several patients in one bed. This custom was at that time so general that it is always especially mentioned in the descriptions of hospitals if each patient had his own bed. This nation has not to this day been able to free itself from the expensive and at the same time injurious custom of providing beds with curtains. As the directorships were often given by preferment, and to people without merit, who drew their money but left their business to inefficient assistants, abuses not only crowded into all departments, but science was quite extinguished. The cure of most diseases was very difficult, the simplest of them often assumed a malignant character. This was largely due to the neglect of the closets, sewers and ventilation. When one considers that even today a project is urged to alter our hospitals so as to admit fresh, pure air, that the question of ventilation is still everywhere felt to be one of the most important, one might suppose that our forefathers knew nothing of these things. However, this is not true. Even then they recognized in the infected air a source of great mortality, as well as the increasing danger in narrow rooms and the crowding of patients, but the majority of the physicians did little or nothing toward putting these ideas into practice.

One of the first to appreciate the value of *ventilation* and throw doors and windows wide open to admit fresh air, was the English military surgeon J. Pringle. His plans of improvement were originally made for field hospitals. Suffice it to say that his principle was as follows: We may lay it down as a rule that the more fresh air we let into hospitals, the less danger there is of breeding this distemper (hospital fever). The more fresh air, the less danger! He put so few patients in each room that one who did not understand the matter would think there was room for two or three times the number. A part of the boards were taken out of the floors in the field hospitals, and the garrets opened on to the roof. He knew in how incredibly short a time the air in narrow rooms was defiled, but recognized too the difficulty of remedying the evil when neither nurses nor patients could be convinced of the necessity of opening doors and windows. Those rooms were always the most healthful where the air entered through broken windows and other holes in the wall. (Written in the year 1752!) Pringle's contemporary, Stephen Hales, celebrated for his penetrating and accurate experimental researches, invented a ventilator in the form of a great mechanical bellows, in order to improve the air in prisons and ships. Pringle recommended this for the hospitals, and in winter fires in the fireplaces, which acted as ventilators. Only in cases where facilities for ventilation were lacking, would he purify the air with

frankincense, juniper or vinegar. Hales' apparatus was somewhat expensive, so the Prussian surgeon-general Theden devised another kind of ventilator, after he had observed that lockjaw did not readily come into wards with fresh, pure air. He had long wooden pipes, eight inches wide, laid through the wall near the floor, so that they projected on the outside; beside, he had a funnel put in a corner of the room in an opening in the wall. Both could be closed by a cap. Three times a day the caps were opened so that the pure air entered through the pipes, and forced the bad air out through the funnel. He, as well as Baldinger, saw much use made of this method of ventilation in the Seven Years' War, and the smoking out of rooms entirely discontinued, because the air was not improved in that way. For a long time the belief was current, based upon Duhamel's researches (1748), that the exhalations and impurities of the air rise and collect at the ceiling of the room, and therefore it would suffice to make openings there. Overhead the air was said to be so poisoned that a bird would instantly die in it, and fresh meat began to putrefy in a short time. Therefore the rooms in hospitals were built as high as possible, in order to remove the impure air from the patients, and the great hospital in Lyons was provided with a dome. For demonstration of these assertions Maret, in 1782, when the Hôtel Dieu in Paris was about to be rebuilt, had various birds in cages hung in one of the domes; after fourteen days they were entirely well. While a piece of fresh meat fastened there was not in the least spoiled after five days, another placed in a ward at the level of the beds, became putrid in twenty-four hours. He concluded from this that, contrary to the views of Duhamel, only the air about the patients became infected, while that overhead was not at all so, and therefore it was a mistake to build the wards very high. In a long, four-cornered room whose opposite sides had each a large window, the stream of air would flow only through the middle, while the air on both sides was stagnant, but the stream ought to go horizontally through the lower part of the room. On this account, he suggested that hospitals be built in the form of a long ellipse, extending from north to south, and with a vaulted ceiling. At both the truncated ends should be two doors, which would open the entire breadth and height of the hall; further, the walls should be perfectly smooth, and the beds stand in two long rows, two feet from the wall. Every morning, and as often as necessary, both doors should be opened to admit fresh air, the bedridden patients being well covered, while the rest left the room. These suggestions, to Frenchmen, died like voices in the desert; they could not appreciate the value of fresh air. That is shown not only by the pest-holes in the Hôtel Dieu, but also by the official regulations in their hospital order from the year 1781. The only thing which this accomplished in that respect was that the windows were opened on clear days; on the other days, the wards were smoked with juniper at least three times a day.

One at a time, other propositions were submitted to the hospitals. The Englishmen Aikin and Percival suggested (1771) that a hospital be built in an open and healthful locality, and that the builder follow the advice of the physicians' more than had heretofore been done, leaving as much vacant space as possible, instead of utilizing every inch. They did not favor a square structure, because this form made the neces-

sary ventilation difficult. The rooms should be small, but high, and the patients placed according to Pringle's principle. They recommended that beside the usual facilities for ventilation, apertures be made in the walls opposite the windows and fireplaces be put in all the rooms. The bandages for suppurating surfaces must be made just as they were needed for use, and the beds frequently made up with fresh linen. In large cities they would have several small hospitals rather than a single large one. A. G. Richter also agreed with this opinion, and when the building of the Vienna Hospital was projected he asserted that instead of combining the existing hospitals in one large one, they should divide them into still more small ones. The professor in Göttingen considered it advisable to provide the beds with castors and move all the patients daily from one room to another, cleaning the first, airing it, and then moving them back into it. He also demanded a separate room for the dying and for patients with bad suppurations, etc. In spite of all the good advice which the two Englishmen gave, they went to the other extreme when they refused admission to the hospital not only to all patients whose cure was not likely to be accomplished in a short time, but also to patients with contagious diseases and such as would contaminate the air of the hospital, and finally to all patients with lung diseases, for whom pure air would be especially necessary. The burning of one wing of the Hôtel Dieu gave the Frenchman A. Petit occasion to come forward with plans for improvement. He would have (1774) all the large hospitals outside of the city, where air and water were purer and where there was more space and less smoke. For accidents a house within the city could be maintained, in which the patients could stay until their removal to the hospital. For the sake of better drainage the structure should be located on high ground, and it should be protected as much as possible from the north wind; the spot should be dry, but in the neighborhood of flowing water. Instead of a square building, he recommended the form of a star, in which the wings with the wards radiate in points and unite in the center in a funnel-shaped dome. Here was to be the residence of the physicians, apothecaries, cooks, clergy, etc. This form facilitated the service very much, because no part of the hospital was far from the central point; the funnel-shaped dome served all the rooms as a ventilator, as they were all connected with it by pipes. He would have the beds stand in single alcoves provided with curtains, and in each alcove a window through which the excreta could be gotten rid of by means of pipes leading outward, without its being carried through the room. (There was invented at that time in France a so-called elastic bed, similar to our present air cushions; it was a mattress made of oiled linen sewed together, waxed over, and then filled with air by means of a valve (1779). Designs were also proposed by the Germans. Fauken made a plan for a general hospital (1784). He estimated 1,600 hospital patients to 200,000 inhabitants, and a daily expense of 24 kreuzer for each. The building must have only one story, but rooms enough to be used alternately and cleaned at least every three weeks. For each bed he allowed a space of five feet, and suggested that they be painted green with oil paint, to absorb the noxious exhalations. Lattices outside of the windows, which were provided with metal ventilators, should soften the rays of the sun without obstructing the passage

of air, and at least twice a year the rooms should be whitewashed. Extreme views were not lacking; as C. L. Hoffmann (1788) thought it necessary that each patient in the hospital should have a separate room.

We will not forget that our forefathers, in their efforts to improve the hospitals, did not entirely follow the empiric, but sought to solve certain questions by experiment. Among such were their *researches in putrefactions*. Lord Bacon had considered it extremely useful to search for a means whereby putrefaction could be prevented or arrested, and he believed such work to be of the utmost importance in medicine and surgery. Pringle made such experiments in antiseptics in 1750 and 1751, and published the results of forty-eight of them in the *Philosophical Transactions*. Contrary to the accepted theory, he believed that putrid matter was not alkaline, and that alkaline salts did not induce, but arrested putrefaction, and he made known various antiseptics. Likewise he showed that most animal putrefactions would cause fermentation in farinaceous matter, but that saliva, when well mixed with food in sufficient quantity, prevented fermentation in the first stages. Upon this were based experiments in the putrefaction of blood, and so on. A Scotch surgeon, W. Alexander, took up the same question (1771), and experimented with meat and with blood of men and cattle. No degree of heat would alone induce putrefaction, moisture was essential to the process; and also the vapors from dead men and cattle would cause contagious diseases only in hot regions not sufficiently swept by the wind. But the perspiration of a healthy man starts putrefaction, since a piece of meat rolled in drops of sweat putrefies very quickly. He denied that stagnant water breeds putrid fevers and diarrhea, although the vapors from it are dangerous. Similar researches were made by Macbride, Collin and Buchholz; Haller also experimented on animals concerning the action of putrefying matter.

In closing, a few words concerning the lying-in hospitals; as in Germany, obstetrics and surgery were usually taught by the same professor. France first introduced practical instruction for students and obstetricians, and to that end erected the first lying-in hospital, in Strassburg in 1728. It served as a model for all newly founded institutions, and attracted a crowd of foreigners. The largest was in the *Hôtel Dieu* in Paris, but at the beginning of the century students were not admitted there. The maternity cases were as closely crowded as all the other patients; indeed, four women in labor occupied one bed. The room was saturated with moisture and dampened the linen hung at the windows (1786). Lapeyronie founded two chairs in obstetrics, one for surgeons, the other for obstetricians (1743). Dublin had had a lying-in hospital since 1745, London since 1749; in the latter 2 per cent. died in 1771. In Germany, Berlin made a beginning, and opened the first obstetric school in the *Charité* under John Frederick Meckel. The chief surgeon treated the pregnant women, attended them at delivery, and instructed the pensionary surgeons and obstetricians in the maternity ward. For difficult cases and internal treatment, he was obliged to consult the physician of the *Charité*. Of greater value was the institution under Roederer, founded in Göttingen in 1751, modeled after the one in Strassburg. Roederer, who was called as obstetrician upon Haller's recommendation, wrote the first complete, systematic manual of obstet-

rics in Germany, which received much applause. Van Swieten first introduced public instruction in obstetrics in Austria. Dr. Crantz was sent to Paris for training, and then installed as first teacher of obstetrics in the University of Vienna, in 1752. Later, Steidele became professor of theoretic obstetrics in the Spanish Hospital. Joseph II. had a large maternity hospital connected with the newly founded General Hospital in Vienna. Here again, the humane sentiments which characterized the Austrian imperial house, were not renounced. The strictest privacy was maintained in the maternity hospital; no one was asked her name, much less the name of the father. Each patient, because of the possibility of her death, must write her name on a paper, seal it and mark it with the number of the bed and of the room, and keep it near her. At her discharge she took the paper with her unopened. Institutions for teaching obstetrics were founded in various German cities (Cassel, Marburg, Jena, Halle). Copenhagen had a large maternity hospital under Saxtorph, in which there were about 650 births in the year 1784.

(To be continued.)

SOCIETY PROCEEDINGS.

Chicago Ophthalmological and Otological Society.

Regular Meeting, held at the Victoria Hotel, March 9, 1897.

Dr. MONTGOMERY in the Chair.

There were eighteen members and visitors in attendance. The minutes of the last meeting were read and approved. The Secretary read the application of Dr. K. K. Wheelock of Fort Wayne, Ind., and it was referred to the Committee on Membership.

Dr. HALE showed a case of congenital cataract in a young man whose right eye had been needled four times and efforts made to extract the lens substance through a large cut in the cornea. There was still left considerable lens matter directly behind the pupil, which interfered greatly with vision. The cataract in the left eye had not been touched and was of a triangular form. Dr. Hale wanted the opinion of the Society as to the best method of procedure with the right eye.

Dr. GAMBLE showed a young lady with stellate congenital cataract in each eye. These had not been operated upon.

Dr. MONTGOMERY showed a case of gummata of the ciliary bodies. The patient was a young man who had had syphilis about a year ago, which was treated. In October, 1896, pain began in the right eye. This increased in severity, running into the temples and was accompanied by great injection. In November he was admitted to the Eye and Ear Infirmary with a severe iritis and great bulging at the sclero-corneal junction of the temporal side in the right eye. Apparently the iris had been drawn back into this bulging so that the pupillary edge was almost out of sight. The patient was put on calomel, 1-10 of a grain every two hours, but the symptoms increased in spite of this. Then the bulging and iritis began in the left eye. The treatment was changed to iodid of potash and increased to 45 grains three times a day, which was the saturation point. The symptoms rapidly disappeared and in two weeks the patient was without pain. The right eye, however, had a blocked pupil, and one week ago the doctor had done an iridectomy on this eye.

Dr. TILLEY showed a case of congenital paralysis of the third nerve with the exception of the fibers which supply the iris and ciliary muscle. This case was shown some ten years ago to the Chicago Medical Society, and since that time the only additional factor was a well determined history of syphilis in the parents. Both eyes turned strongly downward and outward, patient being obliged to throw back and turn his head to the side in order to see with either eye. There is some myopia in both eyes and the vision of the two is about the same. The only movement is a slight downward and outward one. Dr. Tilley thought there was probably a congenital absence either of the nerve or of the muscles. He was afraid to operate on the ptosis for fear that the patient could not close the eye sufficiently to cover the cornea.

Dr. HORTZ reported two cases of lamellar cataract:

Case 1, with almost normal acuity of vision and good accom-

moderation. The patient was a young man, 23 years old, who consulted the doctor April, 1896, because his eyes ached a good deal in continued near work. He was wearing concave spherocylinders prescribed three years previously. With these glasses the vision of the right eye was 20/100, of the left 20/40. Each eye showed a hazy condition of the lens, which, after the pupils were well dilated, presented the characteristic picture of lamellar cataract. In both eyes the opaque portion showed a circular outline from which, however, numerous very short but distinct dark lines were projected in such regular intervals that the whole looked very much like a fine cog-wheel of a watch. The diameter of the opaque portion was the same in both eyes, but the right was a little duller than the left. In the right eye the best vision obtainable was 20/70 with minus spherocylinders, while in the left eye 20/20 was obtained in the same way. With these glasses the patient could read Sn. 0.5, though he preferred the minus cylinders without the spheres.

Case 2, with an unusual occurrence after the needle operation. On April of last year Dr. Hotz operated on the eyes of a 4 year-old boy for lamellar cataract, the operation consisting in a small incision into the anterior capsule of the lens. No reaction followed; pupils kept well dilated by atropin and the cortex became gradually opaque. A week later in the right eye the entire central portion of the lens (that which had originally been enclosed in the opaque lamellæ) was found in the anterior chamber. This same thing happened a week later in the left eye. The lens nuclei looked like very small lenses, being circular in outline, and were absorbed in such a manner as to become gradually smaller, still preserving their shape and not breaking up. In June a needle operation was done on the capsule and left the eyes in very good condition, the fundus details being clear with a plus 8.

Dr. HOLMES had had a similar experience of lens nucleus falling into the anterior chamber, but it irritated so much that he had to do an iridectomy.

Dr. GRADLE had had a case in which the nucleus protruded through the wound in the capsule, but did not escape into the anterior chamber; it slowly absorbed in this position.

Dr. COLEMAN had recently had a case of a child, 6 months old, with marked congenital cataracts in both eyes. Six months ago he had told the father (who was a physician) that he thought it would be better to operate later, but in the meantime the cataracts had disappeared. Dr. Coleman would hesitate to remove any congenital cataract except by dissection.

Dr. COLBURN asked if anyone had ever seen the punch which he had seen described for the purpose of making a hole in an opaque capsule.

Dr. PINCKARD had seen the punch, but had never seen it used. He doubted the value of it in such cases.

Dr. HOTZ said that in Dr. Hale's case probably the 2-hook operation would be as good as any.

Dr. COLBURN had used a double needle.

Dr. McARTHUR stated that the 2-hook operation was still used very extensively in the London clinics.

Dr. HOTZ thought that it might be wise in Dr. Tilley's case to try to raise the eyes by advancement of the superior recti. He thought that any interference with the lateral muscles might produce a troublesome diplopia.

Dr. COLBURN had had a case similar to Dr. Tilley's in which after very extensive advancements and tenotomies he had finally succeeded in getting binocular vision. He had found no trouble in securing sufficient fibrous tissue to make the advancements, although there was no apparent muscle.

Dr. GRADLE stated that he had not succeeded in getting diplopia in cases of congenital paralysis and that the patients were never troubled with this symptom.

Dr. PINCKARD stated that he had had a similar experience, it being impossible to provoke double vision in most of these cases.

C. P. PINCKARD, M.D., Secretary.

SOCIETY NEWS.

Association of American Medical Colleges.

J. M. BODINE, M.D., President, Louisville, Ky.

BAYARD HOLMES, M.D., Secretary, Chicago, Ill.

The annual meeting of the Association of American Medical Colleges will be held at the Hotel Walton, Philadelphia, Monday, May 31, 1897, at 10 A.M. On account of the coincident meeting of the American Academy of Medicine and the Association of Examining Boards the Association will probably adjourn to meet at the College of Physicians at a later hour and probably on the following day.

THE ORDER OF BUSINESS.

1. Reading the minutes of the previous meeting.
2. Adjournment for ten minutes for the presentation of credentials by delegates who are not deans of the colleges they represent and for the payment of annual dues.
3. Roll call of colleges holding membership.
4. President's Address. By J. M. Bodine, of Louisville, Ky.
5. Report of
 1. Committee on course of study; a, Medicine, by Wm. Osler of Baltimore; b, Obstetrics, by — Williams of Baltimore; c, Surgery, by Bayard Holmes of Chicago.
 2. Committee on codifying the Constitution and By-laws, by the Secretary. The report is appended herewith.
6. Secretary-treasurer's report.
7. Report of Judicial Council.
8. Presentation of papers or essays.
9. New business.
10. Adjournment.

The following report from the Committee on Codifying the Constitution has been made to include all the recommendations which have been received from colleges in relation to constitutional amendments. No changes have been made in the spirit or requirements of the Constitution or By-laws, but their provisions have been made more exact and definite. On account of the establishment of examinations for entrance upon professional study in States other than the State of New York, the Committee recommends that the section relative to this matter be made general so as to apply to all States now giving medical students certificates, and to any State which may issue such certificates hereafter. The other changes in the Constitution were suggested at the Atlanta meeting and are for the most part of a similar character. The Committee recommends that this Constitution be adopted as a whole in the place of the existing Constitution.

BAYARD HOLMES, Secretary.

REPORT OF COMMITTEE ON CODIFYING THE CONSTITUTION.

ARTICLE I.

This organization shall be known as the ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

ARTICLE II.

SECTION 1. Any college conforming to the requirements of the Association, as expressed in this Constitution and in the By-laws of the Association, is eligible to *membership*.

SEC. 2. Any college desiring membership in this Association shall make *application* to the secretary and pay the annual dues of five dollars. This application shall be accompanied by evidence that the college applying is conforming to the requirements of this Association. The application and all evidence and information in relation to the college shall then be put in the hands of the Judicial Council, to be reported to the Association favorably or unfavorably at the next annual meeting, at which time the college shall be elected to membership if it receives the favorable recommendation of the Judicial Council and the favorable ballot of two-thirds the colleges represented in the meeting. The neglect of the Judicial Council to report on the application of a college shall not be a bar to election.

SEC. 3. Each college is entitled to one *representative* at all meetings of the Association and to one vote on all questions. The dean of the college will be its accredited representative in the absence of any other delegate.

SEC. 4. The dues are five dollars a year, payable in advance.

ARTICLE III.

SEC. 1. Each college holding membership in this Association shall require of each student *before admission* to its course of study an examination the minimum of which shall be as follows:

1. In *English*, a composition on some subject of general interest. This composition must be written by the student at the time of the examination and should contain at least two hundred words. It should be criticised in relation to thought, construction, punctuation, spelling and handwriting.
2. In *Arithmetic* such questions as will show a thorough knowledge of common and decimal fractions, compound numbers and ratio and proportion.
3. In *Algebra* such questions as will bring out the student's knowledge of the fundamental operations, factoring and simple quadratic equations.
4. In *Physics* such questions as will discover the student's

understanding of the elements of mechanics, hydrostatics, hydraulics, optics and acoustics.

5. In Latin an examination upon such elementary work as the student may offer showing a familiarity usually attained by one year of study; for example, the reading of the first fifteen chapters of Cæsar's Commentaries and the translation into Latin of easy English sentences involving the same vocabulary.

SEC. 2. In place of this examination or any part of it colleges, members of this Association, are at liberty to recognize the official *certificates of reputable* literary and scientific colleges, academies, high schools and normal schools covering the work of the foregoing entrance examination, and also the medical student's certificate issued by any State examining board.

SEC. 3. Colleges, members of this Association, may allow students *who fail in one or more branches* in this entrance examination the privilege of entering the first year course, but such students shall not be allowed to begin the second course until the entrance requirements are satisfied.

SEC. 4. Colleges, members of this Association, are free to honor official *credentials issued by medical colleges of equal requirements*, except in the branches of study embraced in the last year of their own curriculum.

SEC. 5. Candidates for the degree of Doctor of Medicine in the year 1899 and thereafter shall have attended at least *four courses* of medical instruction, each course of at least six months duration. No two courses shall be in the same calendar year.

SEC. 6. Colleges, members of this Association, are free to give to students who have met the entrance requirements of the Association additional *credit for time* on the four year course as follows: *a.* To students having the A.B., B.S. or equivalent *degrees* from reputable literary colleges, one year of time. *b.* To graduates and students of colleges of *homeopathic or eclectic* medicine, as many years as they attended those colleges. *c.* To graduates and students of reputable colleges of *dentistry, pharmacy and veterinary* medicine, as many years less one as they attended those institutions.

[SEC. 7. Colleges, members of this Association, may confer the degree of Doctor of Medicine during the year 1898 upon students who have attended *three courses* of six months duration each. Each course shall have been in a separate calendar year.]

ARTICLE IV.

SEC. 1. In addition to the representations of colleges in attendance at regular meetings, who are termed *active members*, there shall also be associate members and honorary members. *Associate members* shall consist of former representatives and representatives of post-graduate medical schools and members of State boards of medical examiners. Distinguished teachers in medicine and surgery may be elected to *honorary membership*.

SEC. 2. Only duly delegated and accredited active members in actual attendance whose annual dues are paid shall have *voting power*, but associate and honorary members may participate in all other proceedings and duties and may be elected to any office.

ARTICLE V.

SEC. 1. The *officers* of this Association shall be a President, Senior and Junior Vice-presidents, Secretary and Treasurer, and a Judicial Council of seven members; all of whom shall be elected annually by ballot and serve until the election of their successors.

SEC. 2. The *President*, or one of the Vice-presidents in the absence of the President, shall preside at all the meetings and perform such duties as parliamentary usage in deliberative assemblies and the By-laws of this Association may require. Of the seven members constituting the *Judicial Council*, the three whose names appear first on the list of those first elected shall serve three years. Of the remaining four, the two first named shall serve two years, and the two last named shall serve for one year. Vacancies by expiration of term to be filled at the annual election of officers. Vacancies by death or resignation may, if business of importance arise, be filled by the surviving members of the Association.

SEC. 3. The *Secretary and Treasurer* shall record the proceedings of the meetings, conduct the correspondence, receive dues and assessments from members, disburse the funds of the Association as provided by resolution, issue certificates of membership, and perform such other duties as the By-laws may require.

SEC. 4. The *Judicial Council* shall investigate and determine all questions of violation of the rules and regulations of this Association, and all matters of dispute between the members of this Association. All charges or complaints shall be

preferred formally in writing, and referred to the Council. The Council shall make written report at the next ensuing session of the Association upon all matters received for adjudication.

ARTICLE VI.

SEC. 1. The stated *meetings* of this Association shall occur annually on the Monday preceding the Tuesday on which the American Medical Association convenes.

SEC. 2. A majority of the active members whose dues are paid shall constitute a quorum.

ARTICLE VII.

This Constitution shall not be altered or amended, except by written notice to all members at least thirty days previous to a stated meeting, and by a vote of two-thirds of all the acting members present at such meeting.

(It is thought best to introduce for comparison the Constitution now in force.)

CONSTITUTION.

ARTICLE I.

This Association shall be known as the ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

ARTICLE II.

SEC. 1. Colleges adopting and observing the rules of this Association, as herein provided, shall be eligible to membership. Each college shall be entitled to one representative at all the meetings of the Association.

SEC. 2. Colleges desiring membership in this Association shall make written application to the Secretary, officially signed, and pay to the Treasurer of this Association the sum of five dollars (\$5.00) annually in advance.

ARTICLE III.

SEC. 1. Colleges, members of this Association, shall require of all matriculates an examination as follows: 1. An English composition in the handwriting of the applicant of not less than two hundred words, said composition to include construction, punctuation and spelling. 2. Arithmetic—fundamental rules, common and decimal fractions, and ratio and proportion. 3. Algebra—through quadratics. 4. Physics—elementary—(Gage) 5. Latin—an amount equal to one year's study as indicated in Harkness' Latin Reader.

SEC. 2. Graduates or matriculates of reputable colleges, or high schools of the first grade, or Normal schools established by State authority, or those who may have successfully passed the entrance examination provided by the statutes of the State of New York, may be exempted from the requirements enumerated in Section 1.

SEC. 3. Students conditioned in one or more of the branches enumerated as requirements for matriculation, shall have time until the beginning of the second year to make up such deficiencies; provided, however, that students who fail in any of the required branches in this second examination shall not be admitted to second course.

SEC. 4. College members of this Association are free to honor official credentials issued by colleges of equal requirements except in the case of branches embraced in the last year of their own curriculum.

SEC. 5. Candidates for the degree of Doctor of Medicine shall have attended three courses of graded instruction of not less than six months each, in three separate years.

SEC. 6. Students who have matriculated in any regular college prior to July 1st, 1892, shall be exempted from these requirements.

SEC. 7. Candidates for the degree of M.D., in 1899, or thereafter, shall have pursued the study of medicine for a period of four years, and attended at least four courses of lectures of not less than six months duration each. It is provided, however, that the following classes of students may apply for advanced standing:

a. Graduates of recognized colleges and universities that have completed the prescribed course in chemistry and biology therein.

b. Graduates and matriculates of colleges of homeopathy.

c. Graduates and matriculates of colleges of eclectic medicine.

d. Graduates and matriculates of colleges of dentistry requiring two or more courses of lectures before conferring the degree of D.D.S. or D.M.D.

e. Graduates and matriculates of colleges of pharmacy.

f. Graduates and matriculates of colleges of veterinary medicine.

All students shall be required to comply with the provisions of the entrance examination and prove their fitness to advanced professional standing by an individual examination upon each branch below the class he or she may desire to enter.

ARTICLE IV.—Membership.

SEC. 1. Membership in this Association shall be divided into

active, associate and honorary. The active membership shall consist of persons duly appointed to represent the college for the fiscal year. Associate membership shall consist of former delegates, representatives of post-graduate medical colleges and of State boards of medical examiners. Honorary membership, of distinguished teachers in medicine and surgery.

SEC. 2. Voting power shall be confined to active members in actual attendance. Associate and honorary members may participate in all other proceedings upon invitation of the presiding officer.

ARTICLE V.

Officers.

SEC. 1. The officers of this Association shall be a President, Senior and Junior Vice-presidents, Secretary and Treasurer, and a Judicial Council of seven members, all of whom shall be elected annually by ballot, and serve until the election of their successors.

SEC. 2. The President, or one of the Vice-presidents in his absence, shall preside at all the meetings and perform such duties as parliamentary usage in deliberative assemblies and the By-laws of this Association may require. Of the seven members constituting the Judicial Council, the three whose names appear first on the list of those first elected shall serve three years. Of the remaining four, the two first named shall serve two years and the two last named shall serve for one year. Vacancies by expiration of term to be filled at the annual election of officers. Vacancies by death or resignation may, if business of importance arise, be filled by the surviving members in the interval between the annual meetings of the Association.

SEC. 3. The Secretary and Treasurer shall record the proceedings of the meetings, conduct the correspondence, receive dues and assessments from members, disburse the funds of the Association as provided by resolution, issue certificates of membership, and perform such other duties as the By-laws may require.

SEC. 4. The Judicial Council shall investigate and determine all questions of violation of the rules and regulations of this Association, and all matters of dispute between the members of this Association. All charges or complaints shall be preferred formally in writing and referred to the Council. The Council shall make written report at the next ensuing session of the Association upon all matters received for adjudication.

ARTICLE VI.

SEC. 1. The stated meetings of this Association shall occur annually on the Monday preceding the Tuesday on which the American Medical Association convenes.

SEC. 2. A majority of the members shall constitute a quorum.

ARTICLE VII.

This Constitution shall not be altered or amended, except by written notice to all the members at least thirty days previous to a stated meeting, and by a vote of two-thirds of all the delegates present at such meeting.

BY-LAWS.

SEC. 1. The presiding officer shall, on calling meetings to order, call for the reading of the minutes of the previous session, which, when approved, shall be recorded in a book kept for that purpose, signed officially by the Secretary and approved by the President.

SEC. 2. After approval of the minutes, the Secretary shall announce the colleges represented at the meeting and an adjournment of ten minutes shall then follow to allow other representatives present to register and pay their dues.

SEC. 3. Order of business.

1. The reading of the minutes of the previous meeting.
2. Roll call of membership.
3. Reports of committees.
4. Secretary and Treasurer's report.
5. Report of Judicial Council.
6. Papers and essays.
7. New business.
8. Adjournment.

SEC. 4. These By-laws may be altered or amended at any time by unanimous consent of the members present, or by written proposition to so alter or amend, being read in open session and receiving the approval of a three-fourths vote of all the members present at an adjourned session of any stated meeting; provided, however, not more than twenty-four hours shall have elapsed between the time of the proposition to amend and the final vote thereon.

RULES OF THE JUDICIAL COUNCIL.

I. All complaints, charges and other questions must be submitted in writing through the Secretary of the Association, or directly through the Chairman of the Council.

II. All complaints of violations of rules and regulations must be in the form of written charges and specifications, signed by the complainant.

III. All charges and specifications must be presented to the accused for answer. In all cases the written answer must be filed with the Chairman of the Council within ten days from the receipt of the copy of charges by the accused.

IV. All counter charges must be submitted to the accused for answer, and pleadings in the same manner as the original charges, and the Council will take no notice of any evidence not submitted through its Chairman in regular form and order.

V. As the strictest formality is necessary to insure justice equally, all decisions of the Council must be rendered in writing, signed by each member taking part in the determination of any question.

VI. In the intervals between the annual meetings, the Council may act upon all matters submitted in due form by its Chairman, each member communicating his decision to the Chairman, who shall immediately, or within ten days from the date of any decision, file a certified copy with the Secretary, and notify all the parties interested.

VII. It will be the duty of the Chairman of the Council to file and preserve all original complaints, charges and other matter referred to the Council, and to deliver them to the Secretary on the first day of each annual meeting next ensuing the date of final decision.

THE FOLLOWING NAMED COLLEGES PAID THEIR DUES FOR THE YEAR ENDING MAY 30, 1897.

College of Physicians and Surgeons, Chicago.
 Detroit College of Medicine.
 Medical Department, Howard University, Washington.
 Western Pennsylvania Medical College, Pittsburg.
 Medical Department, Columbian University, Washington.
 Ohio Medical University, Columbus.
 Western Reserve Medical College, Cleveland.
 Rush Medical College, Chicago.
 Medical Department, University of Maryland, Baltimore.

American Academy of Medicine.

The twenty-second annual meeting of the American Academy of Medicine will be held in Parlor "C" of the Continental Hotel, Philadelphia, on Saturday and Monday, May 29 and 31, 1897.

The meeting will be called to order at 2 P.M., May 29, when the Academy will hold an executive session, open to its membership only. The order of business will be as follows: Reading of the minutes of the last annual meeting; report of the Council; election of Fellows; appointment of a Committee on Nominations; treasurer's report; action on the proposed amendments to the constitution; new business. At the conclusion of the executive session, approximately at 4 o'clock, an open session will be held for the reading of "Professional Program." Only those papers whose titles have been furnished are included in this list; several others have been partially promised and it is hoped that these will be added to the completed program to be presented at the meeting.

THE ASSOCIATED DUTIES OF THE PHYSICIAN.

1. "The True Principles on which the Medical Profession Should be Associated and the Character of the Resulting Organization." Leartus Connor of Detroit.

2. "Physicians' Mutual Aid Societies." John B. Roberts of Philadelphia.

3. "Quid pro Quo—Present and Future." C. C. Bombaugh of Baltimore, Md.

4. "The Relation of the Physician to the Public Press." Solomon Solis Cohen of Philadelphia.

5. "Some Relations of Author, Publisher, Editor and Profession." George M. Gould of Philadelphia.

6. "Medical Reviews." Walter L. Pyle of Philadelphia.

7. "The Influence of a Liberal Education with Reference to Medical Ethics." Elmer Lee of Chicago.

8. "Hospital Abuse." W. L. Estes, South Bethlehem, Pa.

9. "Result of a Year's Endeavor to Lessen the Dispensary Abuse in the Rhode Island Hospital, Providence, R. I." F. T. Rogers of Providence.

10. "Are Physicians up to Date? A Sociologic Inquiry." Charles McIntire of Easton, Pa.

The Academy will take a recess at about 6:00 and reconvene at 8:00 in open session.

11. The President's Address. J. C. Wilson of Philadelphia.

At the conclusion of the address, if it be the pleasure of the Academy, the papers not reached in the afternoon will be read.

Second day: executive session, 10 A.M.; reports of committees; election of Fellows; election of officers; unfinished business; new business. Open session, 11 A.M. Reading of papers resumed.

12. "The Relation of Alcohol to Preventive Medicine." J. W. Grosvenor of Buffalo.

13. "The Truth About Calomel." Everett Flood of Baldwinville, Mass.

14. "The Great Physician of the Revolution; A Doctor sans peur et sans reproche." A. L. Gihon, Medical Director, U. S. N., retired.

15. "Where Shall We Put Up the Bars? A Plea for Preliminary Education." A. L. Benedict of Buffalo.

DISCUSSION: "THE RELATION OF THE COLLEGE TO THE MEDICAL SCHOOL."

16. "The Side of the Medical School." Bayard Holmes, B.Sc., M.D., College of Physicians and Surgeons, Chicago, Secretary of the Association of American Medical Colleges.

17. "The Side of the College." Ethelbert D. Warfield, LL.D., President, Lafayette College, Easton, Pa.

18. "The Side of the University." William Pepper, M.D., LL.D., Ex-Provost, University of Pennsylvania, Philadelphia.

The Committee on Program will ask that thirty minutes be given to each of the speakers opening this discussion, and, at their conclusion, that visitors be invited to take part in the discussion, each speaker being limited to five minutes, according to the rule. The discussion will be assigned to the first place after the recess for lunch.

At the conclusion of this discussion the reading of any unread papers will be in order, after which there will be a short executive session.

Reports of committees; unfinished business; induction of President-elect; appointments for 1897-98; new business.

The reunion session will be held at the Continental Hotel on Monday, May 31, at 8 P.M. By a standing rule of the Academy, the price for the supper is limited to \$2 per plate. Fellows are at entire liberty to invite their friends to enjoy with them the Academy's annual social function. The meetings during the past years have been pleasant and the post-prandial pro-

gram of interest. It greatly aids the committee in every way to know in advance the probable attendance upon the reunion session. Those who may be thinking about attending are requested to send their names either to the chairman of the Committee of Arrangements, the President or the Secretary. The price for the ticket can be paid to either of them at any time. The time limit for papers read before the Academy is twenty minutes; discussion to five minutes for each speaker, excepting in closing, when ten minutes are given.

The Trunk Line Association, with their usual courtesy to the Academy, extend the time of the concession granted to the AMERICAN MEDICAL ASSOCIATION to include the earlier date of the Academy. Fellows desiring to avail themselves of this will please: 1. Pay full fare to Philadelphia and secure a certificate of that fact from the agent selling the ticket. 2. This certificate must be endorsed at Philadelphia by Dr. W. B. Atkinson, Secretary of the AMERICAN MEDICAL ASSOCIATION, and countersigned by an agent of the Trunk Line Association. 3. When so endorsed and countersigned the presentation of the certificate will secure you a return ticket by the same route at one-third fare. The Council will meet on Saturday morning, when the application for fellowship will be acted upon. Kindly forward any application you may have to the Secretary as soon as convenient.

SELECTIONS.

A Study in Air Embolism.—In the *Boston Medical and Surgical Journal*, February 26, Dr. Jay Perkins, a medical examiner for Rhode Island, has outlined a painstaking investigation, both clinical and experimental, on the above subject. The immediate cause of death in consequence of air in the blood-vessels is given by different authors as one of the three following ways: 1, paralysis of the heart from over-distention of the right ventricle; 2, air in vessels of the brain, causing ischemia; 3, obstruction of the pulmonary circulation by bubbles of air in the capillaries of the lung, causing death from asphyxia.

The symptoms of air in the veins depend upon the amount introduced, the rapidity and force with which it is introduced, and the relative strength of the heart into which it is introduced. A small amount can be taken care of by the blood without causing symptoms; a larger amount, but still not enough to kill, will cause immediate temporary irregularity of respiration and of the heart's action, a sensation of impending death, a cry, a convulsion, or simply a collapse. On listening over the heart a churning sound is heard. If the air enters more slowly, we may get air-embolism of the pulmonary vessels and death from asphyxia, or later from pneumonia. The plugging of the pulmonary vessels causes deeper inspirations, through the need of the system for more oxygen, and thus more air is drawn into the vessels. Air can, however, pass through the capillaries if only there is sufficient force behind it, as Professor Senn has shown by injecting air into the arteries of dogs. He found that by injecting air into the arteries he got "convulsions, coma, tetanic rigidity of the limbs and extensor muscles of the back. If the animal does not succumb to the primary effects of the air upon the brain and medulla oblongata, a series of symptoms succeed which announce the arrival of the blood in the veins and right side of the heart." Death takes place from asphyxia from the plugging of the pulmonary capillaries with frothy blood, the right side of the heart being less strong than the left. If a large amount of air enters the blood vessels at once, we have only momentary symptoms, the cry, deep respirations and death, the action being nearly or quite on the heart. Here the symptoms do not last long enough to be due to non-aeration of the blood and there are no brain symptoms unless, as occasionally occurs, we have a convulsion. If the chest is opened immediately after death, the right auricle will be found still contracting, the left auricle and both ventricles having ceased action. If, however, a puncture be made in the right side of the heart and the air let out, the heart will begin to contract again. In dogs dying from the spontaneous entry of air into the jugular vein death

is more prolonged and the heart continues to beat for some time after apparent death has taken place.

In a dog weighing about seventy-five pounds, ether was given while the vein was being secured and then removed. A large canula was introduced into the external jugular. Blood clotted in the canula, and but little air entered. An unknown amount of air was then blown into the canula, and the dog expired instantly. After a few moments the chest was opened; the auricles were still pulsating, the left slowly, the right seventy times per minute. Heart distended, right side more than the left. Air was present in both sides of the heart, more marked in the right side.

In a second dog a small amount of air was injected into the external jugular, producing labored breathing, a tumultuous action of the heart, and giving a slight churning or gurgling sound on listening over the heart. A larger amount of air was then forced into the vein, causing the arrest of any perceptible action of the heart after a brief space of time. Frothy blood came from the distal end of the jugular, and air was found in the femoral vein and cellular tissue of the thigh. The right side of the heart was distended, and contained air and considerable frothy blood. Some air and frothy blood were found in the left side of the heart.

Vaso-motor Poisoning in Accidents from Chloroform.—Dr. H. A. Hare, in the *Medical News*, March 6, appears in the editorial columns with a signed article, in support of the view that the dominant action of chloroform is to depress the vaso-motor center. The experiments of all, or nearly all, investigators have shown that this drug, as ordinarily given, produces a fall of pressure, although in the first moments of inhalation there may be a rise which is due to excitement. "Bowditch, Minot, Coutts, Wood, the Hyderabad commissioners, my own studies, with and without Thornton, and all teachings I have ever seen, prove this fact. This is the experimental evidence; the practical evidence lies in the fact that accidents from chloroform anesthesia result more frequently when the drug is given to a patient who is in the erect or semi-erect position than when lying prone. Inversion of the body of the patient under these circumstances, even in apparently hopeless cases, will often serve to resuscitate him by causing a portion of the blood to enter the feebly beating heart from the veins, and so reach the vital centers in the medulla, as well as filling the coronary arteries, an equally important matter. Again, accidents from the use of chloroform are exceedingly rare in parturient women, because the compression of the abdominal vessels cuts off a large vascular network and the pains stimulate the vaso-motor center. We know that if atropin, a valuable vaso-motor stimulant, is given before the administration of chloroform, the latter drug may be given with greater safety. Finally, I wish to mention an important clinical observation. On one occasion I gave chloroform to a feeble woman whose condition demanded an abdominal section. The face suddenly became pallid, the radial pulse disappeared and the heart sounds could not be heard. The operator immediately grasped the abdominal aorta to determine if the heart had ceased to beat, and as he compressed it, the pulse in the radial artery at once returned. The compression of the artery prevented what little blood the heart had to pump from flowing onward and stagnating, and, by restoring to a certain degree the normal pressure, produced a tonic cardiac influence; for the normal heart must have arterial resistance in order to perform its proper functions.

"My conclusions, therefore, are that chloroform generally kills by its vaso-motor poisoning effect, which deprives the heart and respiratory center of blood, and simultaneously the drug itself aids in the embarrassment of these parts. From these conclusions we may draw the following practical deductions: 1. In all cases when chloroform is to be given to a feeble patient, the extremities should be tightly bandaged. 2. Atropin should be given as a vaso motor stimulant. 3. A large

compress should be tightly bound over the abdomen if this is at all relaxed, or if an accident occurs. 4. The patient should be inverted, if syncope occurs. 5. Artificial respiration, performed by compressing the floating ribs and precordium, should be employed to aid in the circulation of the blood, to pump the chloroform vapor out of the lungs, and to aid the respiratory center in its functions. 6. During the use of chloroform the respirations should be watched for two reasons, because the depth and rapidity of the breathing is a gauge of the amount of chloroform inhaled (for the amount on the inhaler is not the dose), and because as the blood pressure falls, the respiratory center becomes disturbed in its function and the irregular breathing shows that the chloroform is disturbing it. Further, irregular breathing means irregular dosing, for twenty deep inspirations a minute means more chloroform inhaled than twenty shallow ones. The respiration is the dose gauge."

Successful Operation for Perforated Gastric Ulcer.—Clarke (*Lancet*, March 20, p. 806) adds another to the growing list of cases of perforated gastric ulcer successfully operated on. A domestic servant, 19 years old, was seized with severe epigastric pain and sickness two hours after her mid-day dinner of beef, potatoes and rice pudding. She had had some uneasiness about the stomach for two or three days previously and two years before she had suffered from hematemesis. Since this time she had often felt pain after food, with occasional sickness. In the course of four hours following the onset of the acute manifestations the patient was moderately collapsed, and the symptoms, together with her aspect, her attitude and her pallor, made it evident that abdominal exploration was urgently called for. Accordingly, a five-inch incision was made in the median line, from the xiphoid cartilage to near the umbilicus. The left rectus muscle was not divided. The falciform ligament of the liver was in the way and somewhat delayed the due opening of the peritoneum, but on getting through this membrane, odorless gas and turbid fluid escaped, and bits of potato and rice were seen scattered about. There were no adhesions. On drawing down the stomach a perforated ulcer perhaps an inch in diameter was found on the anterior surface near the cardiac extremity, through which more rice and potato was escaping. The edges of the ulcer were indurated and the base around for some distance was thickened. Considerable traction downward was necessary to bring the ulcer within due reach. The fluid and bits of food were, as far as possible, at once removed, sponges were adjusted around, and the stomach was washed out with two syringefuls of fairly hot water. The edges were too deep to admit of being trimmed; so the opening was closed by two rows of fine silk sutures by Lembert's method and fixed well beyond the ulcer, both above and below. The abdominal opening was then covered temporarily with hot sponges and a second median incision was made a little above the pubes, so as to explore Douglas' pouch. A good sized sponge passed into this cavity was found on withdrawal to be saturated with the same turbid fluid as had already been noticed. The abdominal cavity was now freely irrigated with hot water at a temperature of 105 degrees, several pints being used, and the various recesses especially were dealt with by means of the glass tube passed between the coils, above and under the liver and in the different regions, until all of the fluid returned clear. The surplus was then sponged away. A large drainage tube was then introduced into Douglas' pouch and the lower wound was closed. A similar piece of tube was inserted through the upper opening and reaching to the site of the ulcer. The operation lasted an hour and a quarter and was well borne by the patient. Three hours later a hypodermic injection of morphin was given to relieve pain. Sickness occurred once in the night. Nutrient enemata were administered regularly. On the second day improvement was noticed. Thirst was relieved by hot water enemata each day and the drainage-tube was soon removed and replaced by plugs of iodoform gauze. On the sixth day a small discharge of pus took place from the epigastric wound, which otherwise was doing well. Rectal feeding was continued until the eighth day, when

the patient began to take liquids by the mouth. The wounds gradually closed and convalescence was uninterrupted. The patient was dismissed two months after the operation, having gained seven pounds in weight.

PRAGTICAL NOTES.

Radiographic Test After Osteotomy.—At the New York Post-graduate Hospital Dr. Samuel Lloyd recently gave an interesting demonstration of the surgical utility of ray work. One case was that of a young girl whose thigh bones were crossed, thus preventing her from the use of her limbs. She was taken into the hospital nine weeks ago, when the surgeon performed the operation of osteotomy. Both thigh bones were broken and placed in position for a normal reunion. The bones were subjected to a ten-minute exposure of the ray, and by the use of the fluoroscope Dr. Lloyd was able to announce a perfect union of the bones, so that the girl would be able to walk. The successful application of the X rays to this part of the body was more difficult than to any other part a representative of Mr. Edison explained, but the healing bones could be seen as readily by placing the Crookes tube under the operating table and holding the fluoroscope above the thigh bones. Other experiments, equally successful, were made with fractured bones of the knee and elbow and with diseased bones of the hands.

Vaginal Atresia and Its Cause.—Meyer has published a very complete monograph on this subject, with no fewer than 216 cases carefully tabulated. He does not confirm Kussmaul's doctrine that ill-development of the lower part of the genital tract with atresia is due to fetal inflammation. It is in infancy and childhood that these inflammations occur, such as vulvitis and local lesions in general infectious disorders. The vagina closes, the tissues heal and look healthy after a time, and it is not till puberty that the damage becomes manifest. Then it is easy to understand how the disease might be wrongly considered congenital. Unilateral hematosalpinx, with inflammatory closure of the vagina, is very often observed, and Meyer holds that there is closure of the tube at the ostium from the same inflammation, due to some infective agent. As the agent can cause septic changes in the blood in the tube, the ultimate rupture of the hematosalpinx into the peritoneum or into some visceral cavity puts the patient to great peril. This explains the high mortality of atresia vaginæ with unilateral hematosalpinx.—*American Practitioner and News*, March 20.

Prodromal Eruptions in Measles.—Robet has collected a number of observations showing that measles may have a premonitory rash as is the case with variola and varicella. These eruptions vary in character, being scarlatiniform, morbilliform and erysipelatos. They may even resemble red miliaria, showing small vesicles filled with a clear fluid surrounded by a pink areola, and accompanied by itching. The erythemata generally appear about the second day of the period of invasion, and disappear before the measles eruption, and they do not seem to affect in any way the invasion period of the disease, and the temperature course in no wise differs from the cases in which there is no premonitory rash, nor does the subsequent condition of the patient show the least difference; moreover, there does not seem to be any serious constitutional effect similar to that following the erythematous eruptions met with in diphtheria, enteric and some other diseases. The author admits that the number of cases sufficiently recorded is as yet too small to warrant any statistics being drawn, but he thinks that these premonitory rashes are much more frequent in measles than is generally supposed.—*British Medical Journal*.

Identity of Scborrhea and Alopecia.—It is announced from the Pasteur Institute that M. Sabouraud has established the fact of the identity of the microbe in these two affections, which

he has successfully isolated and with which he has produced the characteristic alopecia patches on sheep, guinea pigs and rabbits. Inoculations with the seborrheic microbe are not quite so convincing, and hence he only asserts in the case of seborrhea that the microbacillus is the constant microbial expression of the affection, without being able to demonstrate that it is the cause of the lesions. His article in the *Annales de l'Institut Pasteur*, February 25, is an able presentation of the clinical picture, elementary lesions and the microbe of the two affections reveal the connection between them, and proves the facts that acute alopecia is an acute local seborrhea, and alopecia decalvans a generalized chronic seborrhea. The same parasite produces two distinct diseases; why they differ is still a problem. The bacillus can only be cultivated on very acid media. The growth of the coccus albus interferes with its cultivation, unless "vaccinated gelose" is used, in which the coccus albus has already been cultivated. The same effect of abundant and isolated cultures can be secured by slow pasteurization; ten minutes at 65 degrees C. kills the coccus, but does not affect the bacillus. Further details are quoted in the *Presse Méd.* of March 20.

Serum Diagnosis of Typhoid Fever in Norway.—The *Tidsskrift for den Norske Lægeforening* of March 1, contains Dr. P. Aaser's report of the results of this method of diagnosis at the Ullevold Hospital during the epidemic of typhoid that has prevailed at Christiania since last October. Positive results were obtained in 98.9 per cent. of the 91 cases of unmistakable typhoid, and in 5 out of 59 cases in which clinical examination had failed to disclose it. He found that the intensity of the reaction does not depend upon the severity of the disease, some of the lighter cases producing the effect with greater intensity than the graver cases. The length of time required varied also from five to twenty minutes. He stated that the more the culture can be attenuated, without losing its agglutinating and paralyzing power, the more certain the diagnosis with it. He even succeeded with 1 part serum to 1,000 parts culture. Contrary to the experience of some others, he found the reaction continue with the same intensity two to three months after the commencement of the disease, and in the case of a nurse who had passed through an attack of typhoid over a year previously, the reaction was rapid and distinct. He obtained the reaction the third day in 2 cases; the fourth day in 4; the fifth day in 2; the sixth day in 3, and the seventh day in 4; the second week in 24; the third week in 10; the fifth week in 8; the sixth week in 19; the seventh week in 8; the ninth week in 6. Dr. Aaser refers constantly to the article on the subject in this *JOURNAL*, Feb. 6, 1897, by Appel and Thornbury, and concludes with the generally accepted opinion that while the serum test is not infallible, yet in connection with the syndrome, etc., it is of great practical value.

Perforation of Gastric Ulcer Following Anesthetization.—At the Berlin Society of Obstetrics and Gynecology, a report of which appears in the *Centralblatt für Gynäkologie* for December 5, Kiefer showed a specimen of perforation of the stomach by an ulcer after anesthetization. Four weeks after parturition the patient had been subjected to a secondary suturing operation, presumably on the perineum. Previous to the anesthetization she had been in excellent condition, but she vomited immoderately after it. On the following day she was manifestly in a state of collapse, short-breathed, and complaining of a stabbing pain in the right side. The abdomen was tympanitic, but not very tender on pressure. The pulse was about 120, and there was no elevation of the temperature. She died in about thirty-six hours after the operation. In her last hours she had vomiting of bile, and seems to have gone to sleep quietly after that. As there were no significant abdominal symptoms, embolism suggested itself at first. When the abdomen was opened postmortem the protruding coils of intestine were

accompanied by an abundant escape of liquid that was of a cloudy, yellow appearance and smelled aromatic and alcoholic. The peritoneum, including the serous coat of the intestine, showed recent hyperemia, and was partly covered with lymph. There was a decided hour-glass shape to the stomach, owing to firm adhesions of the cicatricially contracted lesser curvature to the left lobe of the liver in consequence of an old ulcer of the stomach. At the pylorus there was a transverse laceration about two-thirds of an inch long through which the mucous membrane was prolapsed; the neighboring portion of the organ was infiltrated with bile, and there was a recent ulcer of the pylorus. The perforation had not given rise to the hemorrhage. The account leaves it to be inferred that the perforation was due directly to the excessive vomiting that followed the anesthesia. What anesthetic was used is not stated. We must probably include ulcer of the stomach among the morbid conditions that render the vomiting incidental to general surgical anesthesia dangerous. In this instance the ulcer does not seem to have been diagnosed.—*New York Medical Journal*.

Chlorosis.—As the result of a study of thirty-one cases of chlorosis, with especial reference to the etiology and the dietetic treatment, Simon (*American Journal of the Medical Sciences*, April, 1897, p. 399) has arrived at the conclusion that an anatomic basis for the disease has not yet been satisfactorily made out. Perversion of the appetite, as manifested by excessive consumption of starches and sugars, has been noted as a common symptom of chlorosis. The development of the disease is attributed to an insufficient consumption of animal proteids. The affection is thought to be more common than is generally supposed, and occurs in both sexes and at almost all ages. The diagnosis should be based solely on the results of examination of the blood. It is further recommended that the designation, simple anemia, should be substituted for that of chlorosis. Iron is not believed to be a specific in the treatment of chlorosis. In the treatment especial attention should be given primarily to the diet. In cases in which iron fails to yield good results resort should be had to a suitable diet, of which animal proteids, bone-marrow and dark beer are important constituents. The beneficial effects of bone-marrow are not ascribable to the amount of iron it contains.

Acetanilid in Minor Surgery.—The general practitioner is, at more or less frequent intervals, called upon to do minor surgical work in his office, and an antiseptic dressing that is convenient of application and at the same time reliable is a special need. Many antiseptics, of alleged great germicidal powers, are offered by the manufacturers, but most of them are proprietary articles and high priced. For some time acetanilid has been recognized as one of the best dressings in minor surgery, though it still left something to be desired in the attempts to prevent suppuration. In the *Medical News* of February 6, Dr. W. A. Fallas, Horton, Mich., makes the following suggestions with regard to acetanilid as a dressing. In place of the pure drug, he uses a compound that seems based on good ground, and is said to overcome the weak points of the single substance. He recommends, acetanilid 48 per cent., boric acid, powdered, 15 per cent., starch powdered and finely sifted, 35 per cent., carbolic acid, liquid, 2 per cent. This makes a mixture that is slightly moist, but is practically a dry dressing, and at the same time has stronger powers of absorption than pure acetanilid. Its special advantages are its powerful bactericidal action, freedom from odor, painlessness and cheapness. This latter advantage is one not to be lost sight of, for by reason of this cheapness it may be applied quite profusely, especially to sutured wounds, and in locations generally where absorption into the blood is not to be feared.

Treatment of Prostatic Hypertrophy—Cauterization through the Rectum.—Negretto records four cases of prostatic retention

treated with much success by the above method. After thoroughly emptying the rectum, the patient is anesthetized and the rectal speculum passed, the upper part of the bowel is plugged with gauze, and then, under the guidance of the finger, a specially devised hook with graduated stems is passed into the prostate to steady it. The prostate is then cauterized with a Paquelin or galvano-caustic over the extent required. The operation only lasts two minutes. The bowels are kept confined for a few days, and a catheter kept permanently in the bladder for some time. On the sixth or seventh day a purge is given, at the end of ten or twelve days the catheter is removed, and the patient can urinate by himself. The patients were 56, 62, 74 and 78 respectively, and had suffered from prostatic disease from three to five years on an average. In each case cauterization per rectum not only speedily relieved the congestion, but caused a notable diminution in the size of the prostate. The author believes this method to be superior both in its immediate and remote effects to castration or excision of the vas deferens.—*British Medical Journal*.

Veratrum Viride in Eclampsia.—Dr. W. H. Thayer claims that in puerperal convulsions he has found a condition of the nervous system that begets a peculiar tolerance of certain drugs, especially of veratrum viride, so that the officinal dose has no effect. But large doses quiet the nervous erethism, producing a decided effect in a short time—sometimes in fifteen minutes, but almost certainly within an hour—and keeping the nervous system under control for several hours. The administration is followed by cooling of the surface, great lowering of the pulse in rate but not in strength, and along with this complete arrest of the convulsions. The state of the pulse is the guide in treatment. From a high rate, which rules in the disease, it is reduced to the normal standard or below it; and while it is kept below 60 there need be no fear of a recurrence of the paroxysms. When this effect has been once produced, it will continue several hours, and a single dose will do it; if not apparent within an hour or less, the medicine must be repeated in smaller doses; and it can be safely repeated at intervals until the pulse begins to fall. With the pulse for a guide, no untoward symptoms need occur from its use; the pulse may be brought to 50 without any general depression; if carried so far as to produce vomiting we may find great prostration produced by the nausea, which is overcome within thirty or forty minutes by opium or any diffusible stimulant, perhaps in less time by a solution of morphia hypodermically. The employment of veratrum viride in large doses in puerperal convulsions was first reported to the Kings County Medical Society by Dr. Herbert Fearn of Brooklyn, in 1869, substantiated by cases in which he had used dram doses of the tincture, sometimes required to be many times repeated, with favorable results. Since 1869, when Dr. Fearn's paper was read, the treatment of puerperal convulsions with veratrum viride has been slowly gaining favor, of which we have evidence in many communications to various societies and medical journals. Bartholow, in his *Materia Medica and Therapeutics* (1888) says: "Dr. Sullivan of San Francisco informs me that veratrum viride (half a dram of the fluid extract every fifteen minutes, until nausea or vomiting ensues) is invaluable in puerperal convulsions. Barker, in his 'Puerperal Diseases,' had already called attention to its utility, and Boyd confirms the previous observations. Increasing experience adds to the testimony regarding its exceptional value in relief of this formidable malady." "The experience of one general practitioner in puerperal convulsions is not very great; but in the convulsions of children I have regularly employed veratrum viride for twenty years past with excellent effect, and as a prophylactic in ephemeral fever in children who are subject to convulsions. I believe the use of veratrum viride in puerperal convulsions originated in Brooklyn, where its value is now generally recognized. It has gained ground elsewhere, as rapidly as could be expected of the management of an affection so infrequent, and promises in time to supersede all other methods of treatment."—*Boston Medical and Surgical Journal*, April 1.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, APRIL 24, 1897.

THE MEDICAL SIDE OF THE DEPARTMENT OF
AGRICULTURE.

Since no one disputes the beneficent act of the man who makes two blades of grass grow where one grew before, it is evident upon slight reflection that wisdom and propriety can not go far astray in attributing to agriculture and all pertaining thereto, the greatest meed of praise for acts and motives so highly commendable. The empirical methods of farmers, gardeners, stock-raisers and others who supply our food either directly or indirectly, are now giving way to the more rational investigation and experiment of skilled biologists, the result of whose work and induction the Government is endeavoring to spread and diffuse gratuitously where it will do the most good. With a view to carry out this purpose a number of properly qualified experts in microscopy, bio-chemistry and veterinary medicine have been for some time quietly at work on various problems of a bucolic nature and with gratifying results. In the well equipped laboratories for pursuing this form of medical industry one finds all appliances for conducting the necessary experimentation, in addition to card catalogues of the literature bearing on the subject, with collections of specimens surpassed by a few only in Germany.

Among the various bulletins, more or less medical, issued by the Department in the last few years those relating to food products deserve more than passing notice. With a more varied and abundant food sup-

ply than that of any other country, we find in the United States not only the worst prepared food, but a greater waste and neglect of nutrient material that might be utilized in the interests of frugality. Take, for instance, the edible mushrooms and other allied fungi so rich in quantity and variety both North and South, no less than 111 species being indigenous to North Carolina alone, and in almost every section and climate of the Union are to be found the species common to Continental Europe. During the Arctic cruise of the U. S. Steamer *Courier*, mushrooms might have been gathered by the cart load in the vicinity of Point Barrow, Alaska, but not knowing how to distinguish the comestible from the poisonous species, no one dared eat them, although it is safe to say that all were edible, for as a rule nothing is poisonous in the far north.

Varieties of truffle, edible boletus and puff-ball from great antiquity have been articles of large consumption, and at present are widely cultivated in Europe; but according to a late authority, in the most prosperous and progressive of all countries, with a population of nearly seventy million of people alert to every profitable legitimate business, mushroom-growing, one of the simplest and most remunerative of industries, is almost unknown. As a matter of fact, from an economic point of view the mushroom industry is so profitable when intelligently conducted as to bring in more money than eggs and poultry and with less trouble. Moreover, it is stated that the food value of many species of mushrooms entitles them to a place beside meat as sources of nitrogenous nutriment, and their analysis seems to bear out the statement, being rich in protein, potassium salts and phosphoric acid, fatty matter and a considerable quantity of sugar. As compared with other foods, mushrooms are said to surpass in nitrogenous value bread, oatmeal, barley bread, leguminous fruits and potatoes. In France the popular belief in truffles as an aphrodisiac is as widely prevalent as the use of mushrooms among the peasantry and the working classes in towns, among whom this esculent often takes the place of meat. Indeed, an exclusive diet of mushrooms is so compatible with the preservation of excellent health that a number of investigators report never having enjoyed better health than when living for weeks and months upon mushrooms, and the case of a centenarian is cited who lived upon mushrooms and nothing else for thirty years. So much is to be said upon the alimentary value of mushrooms and their use as a delicate condiment, we wonder why fungiculture is not more in vogue. To the gourmet what more dainty addition to an otherwise prosaic breakfast than that of mushrooms to bacon? And who that has spent much time in Southern France does not recall with dreamy delight the gastronomic ecstasy of eating an omelet with mushrooms, such as a French cook only can prepare? Here

then is an alimentary substance almost equal to meat, which general ignorance of its distinguishing characteristics allows to rot and waste in enormous quantity in our fields and woods. There is also in our country a popular but unfortunate prejudice concerning the use of mushrooms similar to the appendicitis craze in the use of grapes, which time and intelligent instruction only can eradicate. The purpose of the food bulletins is therefore to promote the mushroom industry; to place on the table of the middle classes a wholesome delicacy which before had been restricted to the wealthy; and to give some clear and trustworthy criteria by which to make the essential distinction between the edible species of mushrooms and those that are poisonous. Unhappily this distinction is less easy than might be wished. The old test of the silver spoon, the onion, and milk are not fixed and certain, since some of the most poisonous species are without action upon silver or an onion, or upon new milk. The authorities are that in general all mushrooms should be regarded as suspicious whose flesh changes to blue or greenish color on contact with air; also those having a disagreeable, nauseating or bad odor; or of which the taste is acrid and biting, or the flesh soft, deliquescent, spongy, hard or corky. The flesh of edible mushrooms is usually firm, but tender, exhaling an aromatic odor suggesting freshly ground meal. But these characteristics alone are more or less faulty as diagnostic methods. To avoid error the generic and specific features of the parasite must be studied. It is only by taking into account as much as possible the botanic character, organoleptic properties, and other specific traits that distinguish the species of the mycologic world that we may hope to formulate therefrom practical directions for distinguishing the innocent and edible mushrooms. Happily, muscarin poisoning is not common, though it has been observed; only a few of the species are toxic; some of these are rendered inert by cooking, and their digestibility, like that of other articles of real alimentary value, varies with individuals, temperaments and morbid states.

Equally bearing upon the subject of bromatology is the study of the animal parasites, most of which are enigmas for the biologist and yet a problem for the hygienist. Through the efforts of the medical men connected with the department much light has been thrown upon the history of these strange beings; their organization has been described, their activities revealed and a classification made. One of the latest bulletins on this subject deals with the tapeworms of poultry. To the practical man who asks the use of all this, we have only to mention the valuable aid that such work affords in the inspection of food supplies, the stamping out of disease among domestic animals, the enforcement of cattle quarantine, and the like. As an instance bearing on this point we may cite a path-

ologic specimen from a sheep erroneously supposed to be infected with tubercle, which caused the whole flock to be condemned and slaughtered. Had the inspector known enough to recognize the existence of a common entozoön the mistake would not have occurred. Again, the subject of trichinous meat much affects our trade relations with Germany. History shows, however, that the disease first occurred in that country in 1875, and a record of all the instances of this disease occurring in the last four years shows that 50 per cent. of them originated in German pigs.

To the average farmer and stock-raiser the subject of parasites in domestic animals is a matter of no little interest. Our old friend the horse, whose sphere of usefulness is being daily lessened by the bicycle, the electric car and the automobile carriage, comes in for a fair share of treatment in the "Special Report on the Diseases of the Horse," which is intended to be distributed to farmers as a safe and scientific guide. It is doubtful, however, whether the mass of farmers, many of whom do not know the "canon bone from the paxwax," care to be told anything about the prehistoric hipparion; or that the horse is a monogastric mammifer, non-ruminating, gyrencephalic perissodactyl ungulate, having three sesamoid bones in the flexor tendon of the foot, no clavicles or gall-bladder, and is unable to vomit. It is also doubtful whether the chapter on disease of the nervous system of the horse will be of much use to the ordinary farmer; since neurology is the most difficult and recondite branch of medicine, and neurologists now doubt the existence of hydrophobia, which the report in question admits is the subject of much controversy and may be mistaken for tetanus.

Since the Saxon days of the *Horsthegn*, government officers have interested themselves in perfecting the breed of horses and other stock; so that now we find the stoutest blood on the turf in animals perfected by fresh strains and full of go and quality. The perfecting of stock being an index that points to a higher state of civilization everything therefore that conduces to that end is praiseworthy, whether it comes from the farmer or the man of science.

European critics accuse our cattle inspectors of being over confident, and one foreign minister in Washington quotes to that effect an outbreak of Texas fever on board a foreign-bound ship in which the cattle that died overnight became dismembered on attempting to hoist them from the hold, so advanced was the decomposition.

As a matter of fact, judicial fairness prompts no very serious criticism in the considerations of the fore-mentioned bulletins. Perhaps a little less zeal is to be commended among the followers of PASTEUR, who make unsound deductions from laboratory diseases with which they have no clinical acquaintance. However, the writers have reported their work with

considerable accuracy of anatomic and morphologic description couched in the special and new terms of mycologic, helminthologic and veterinary language, which we regret to say is such unpopular reading to the average congressional constituent that the leaves of these really valuable publications will come ultimately to such base uses as did the noble dust of ALEXANDER, or find their last resting place as wrapping paper in the corner grocery.

SEWAGE DISPOSAL AND WATER PROTECTION.

The disposal of sewage is the important sanitary problem of the present time and of the immediate future for the people of this country, for, outside of seacoast communities, the condition of natural water supplies will be dependent on the manner in which it is worked out. The rapid growth of our cities, and the increasing volume of their excreta discharged into the water courses, lead the sanitary authorities of every community which pumps up river water for use to give serious consideration to the method of sewage disposal of their neighbors up stream. The consoling reflection that the running stream becomes purified during its flow, is not now available. Aeration, sedimentation, dilution and nitrification have long been recognized by chemists as unreliable purifying agencies in the flow of a stream from city to city; and the typhoid death rates of the down stream settlements tell the same story to the etiologic investigator. England has been at work on this problem for half a century, and it is yet far from being satisfactorily solved. When the Health of Towns Commission, over fifty years ago, aroused public attention to the existing filthy conditions and the want of facilities for even the removal of human excrement, not to speak of its disposal, local authorities vied with each other in the construction of sewerage systems. The cities become cleaner, but at the expense of the streams. Legislation had then to be directed to the protection of the latter, that they might cease to be nuisances in their character of open sewers. Sedimentation or precipitation of the sludge with purification of the liquid was successfully carried out in some instances, but failed in so many others that the attention of sanitary engineers became directed to irrigation and filtration as yielding better results. Many cities with suitable lands in their vicinity succeeded in disposing of their sewage in this way; but the efforts made to improve existing methods, or to discover better methods, indicate that the success achieved does not satisfy the British sanitary authorities. At the present time an experiment is being conducted in Essex, in which the sewage is retained in an underground "septic tank," excluded from light and air to give the anaerobic bacteria opportunity of breaking up the organic matter of the sewage prior to treatment by intermittent filtration (*Lancet*, Dec. 5, 1896); and a somewhat similar

method is on trial by the Sutton Urban Council (*Sanitary Record*, Dec. 11, 1896).

We are encouraged to hope that great impetus will be given to progress in the disposal of sewage in this country by the report of the Passaic Valley Sewerage Commission. This Commission, consisting of Dr. ELIAS J. MARSH, Dr. H. C. H. HERROLD and Mr. WILLIAM T. HUNT, was appointed in accordance with an Act of the Legislature of New Jersey, approved Feb., 26, 1896, to consider the subject of the pollution of the Passaic river and of a general system of sewage disposal for the relief of the valley of the Passaic river. The daily discharge of 70,000,000 gallons of sewage into the river below the Great Falls at Paterson, with the deposit of foul-smelling sewage sludge on the shores, is recognized by the Commission as a public nuisance, an injury to health, and an increasing menace to property interests in the valley. The river has lost its former attractiveness for pleasure purposes such as boating, bathing, etc.; its fisheries have been destroyed, and its waters have become unfit for many manufacturing purposes. As a means of relief the Commissioners propose a system of trunk sewers leading from the falls of Paterson to the meadows below Newark, collecting the sewage but not the storm water from the towns and villages of the valley, and discharging near the southern end of Newark bay where the volume of water is great owing to the junction of the Hackensack with the Passaic. The soil of the valley is unfavorable for filtration or irrigation, and chemie disposal works for the various communities would be likely to result in the deterioration of some of them into local nuisances. The estimated cost of the proposed trunk system constructed to meet the wants of a population of 1,500,000, which is represented as the limit of probable increase in 1930, is \$6,500,000. To provide for the needful expenditure the Commissioners present a draught of a general enactment calculated to meet the necessities of other drainage districts in the State, as well as that of the Passaic river. Their scheme of action proposes that the water-sheds of the State be recognized as drainage districts, and be treated for legislation as such; that where pollution of the rivers exists of a nature to constitute a public nuisance or to be detrimental to public health, the Governor shall have power to take proceedings under the Act, upon report to the Legislature of a commission especially appointed to consider the subject; and that he shall then appoint three commissioners to take the work of purification and protection in charge. These river commissioners, having defined the territory requiring sewage disposal, would then proceed with the construction of the necessary works. The funds would be obtained by the issue of bonds, the payment of which, with interest, would be provided by assessment upon the communities and the individuals benefited.

The commissioners deserve credit for the able manner in which they have done their work, and for pointing out the necessity for the protection of other drainage areas than that of the Passaic, and the means by which their protection may be effected. The difficulties encountered by them in devising a method for the disposal of sewage, and the protection of a single river within the limits of their own State are suggestive of those that would be encountered, in the absence of National legislation on the subject, in the case where two or more States are concerned. In progress of time we may have a Department of Public Health.

THE PHILADELPHIA SEMI-CENTENNIAL MEETING.

The semi-centennial meeting of the AMERICAN MEDICAL ASSOCIATION, which will be held in Philadelphia June 1, 2, 3 and 4, 1897, bids fair to surpass in the character of the entertainment, the scientific papers and the number in attendance any meeting which has heretofore been held. The committee in charge have been able to obtain large and roomy places of meeting for the general and the Section meetings, all within a single block, and within a very short walking distance or immediately adjacent to the largest and most comfortable of the Philadelphia hotels.

The general meetings of the AMERICAN MEDICAL ASSOCIATION will be held in the Academy of Music, which is an opera house capable of seating nearly three thousand persons, the acoustic properties of which are so excellent that a speaker on the stage can be heard in any part of the house. Immediately across the street from the general meeting place is situated the Hotel Walton, which will be the ASSOCIATION headquarters and which contains no less than five large meeting halls, in which several of the more important Sections will hold their meetings. In this hotel, too, will be given most of the receptions and dinners held by the Sections or private individuals. Immediately to the south of it in the same block is the South Broad Street theater, with a capacity for about fifteen hundred persons, which will be given over to one of the larger Sections, and adjoining this is the Hotel Stenton, in which three Sections will hold their meetings. Immediately south of the Academy of Music, and in the same block on the opposite side of the street from the South Broad Street theater, is situated Horticultural Hall, a building recently erected at a cost of about half a million of dollars and which is supposed to be one of the handsomest and the best hall for acoustic properties in the United States. The main hall of this building will be devoted to the exhibits, and it is interesting to note that nearly all the space in this hall has already been taken by prospective exhibitors. Two or three important Sections of the ASSOCIATION will hold their daily meet-

ings in the large meeting rooms in this building.

It will be seen from this description that the exhibition hall and all the meeting places are situated on both sides of the street within one block, and in this way physicians desiring to hear different papers in different Sections can readily pass from one meeting to another during the course of the morning or afternoon hours. All of the hotels are so large and commodious that they will amply accommodate the 3,000 members which the Committee of Arrangements hope to have in attendance, and nearly all the large hotels, a list of which has already been published in the JOURNAL for April 3, are within five blocks of the meeting places, and several of them not more than a few hundred feet away.

Nor has the Committee been content with arranging for a complete and useful scientific meeting. Efforts have been carried to a successful termination looking toward the entertainment during the hours between the morning and afternoon sessions, and in the evenings, of all the delegates and their wives and daughters, and it has been found possible to so group together these entertainments that only short distances will be traversed from one entertainment to another.

With the reputation which Philadelphia has for hospitality and for the study of scientific medicine, we feel that we can urge our readers most enthusiastically to make every effort to attend this meeting, which bids fair to be an historic occasion in the history of the ASSOCIATION.

BIO-CHEMISTRY AS A RECOGNIZED MEDICAL SPECIALTY.

In the *American Naturalist* for April, Mr. ALBERT MATTHEWS makes a plea for the recognition of bio-chemistry as a special branch of science and for the establishment and endowment of professorships and laboratories for research in this particular line. He shows that the chemistry of living matter, or the chemistry of metabolism, has problems of its own quite apart from those that engage the attention of the specialist in ordinary organic chemistry. The fully qualified bio-chemist should also have his own special qualifications; he should be to some extent a zoologist and a botanist as well as a physiologist, and while he widens his range of knowledge in this way he can best work by restricting his field to the study of the chemical problems of life and the substance of living beings. His specialty is in its way one of the widest, but it is even yet wider when to his duties are added those of the general chemist working on the ordinary problems of analysis and synthesis of organic and inorganic compounds, as is the case with the majority of the professors of chemistry in our colleges and universities. Medical chemistry includes the whole range of inorganic and organic chemistry in the usual curriculum, and its biologic relations are only treated

as side issues to be cultivated as a later post-graduate study, if at all. Yet these are practically and almost exclusively the chemical problems that engage the attention of the practicing physician, and their practical applications are every year becoming more and more extended. Even the most ordinarily qualified doctor has to make use of bio-chemic tests of the secretions and excretions for purposes of diagnosis, and the use of these is constantly increasing. The phenomena of digestion, secretion, reproduction, all require for their understanding, to say nothing of their study, a knowledge of these relations, and the fuller and more accurate this can be the better for the physician and his patrons. Bio-chemistry has, moreover, within the last few years entered the field of therapeutics as well as those of physiology and pathology; the rational use of organic extracts and serum therapy generally depend upon it. It is a necessary adjunct to bacteriology, for it is the toxins the microbes elaborate, not the organisms themselves, that are deadly, and medical chemistry gives us the knowledge of these, and often that of the methods by which we can successfully counteract them. In a word, bio-chemistry is the one thing that bids fair to make therapeutics a system of scientific and rational procedures, instead of being, as it has largely been, only an empirical and unsystematic experimentation upon the complex and too little understood human mechanism.

The propriety, therefore, of making it a special branch in our medical colleges is sufficiently evident. In the post-graduate schools it should be a necessity even now, and the time is probably coming, with the advancing requirements of medical education, when the knowledge of the general principles of inorganic and organic chemistry will be a preliminary requisite for admission to our medical colleges, and their courses of clinical instruction will be confined to the special physiologic and pathologic relations and reactions of chemical substances and compounds. That this field is wide enough for any medical course is sufficiently evident, and it is widening every year.

There is a sort of unworthy satisfaction that we may feel from the fact that according to Mr. MATTHEWS' showing America is not so far behind Europe in her inadequate recognition of this important specialty. In only a few of the great European universities, it appears, are there special chairs of bio-chemistry, and these few are chiefly those of Austria and Russia. In Germany, where so much work is done in this department, it is mostly by professors filling chairs of physiology and pharmacology, bio-chemistry by itself being there as yet a generally unrecognized specialty. The same is true of England and France and this country, though excellent work is done in each in this special line. There are, moreover, few special journals in this department, though

certain physiologic journals are largely filled with articles on bio-chemic research, notably the *Zeitschrift f. Physiologische Chemie* and *f. Biologie*, *Pflüger's Archiv* and the *Archiv für Experimentelle Pathologie und Pharmacie*, the *British Journal of Physiology*, the *Journal of Experimental Medicine*, and a few others. It is needless to enumerate the important works that treat of this specialty or some one of its departments; their titles should be familiar to any well-informed physician.

Another feature which will undoubtedly come to be considered as a medical necessity is the establishment in our large centers of bio-chemic laboratories for practical purposes, where the more elaborate analyses and examinations which are now coming to be often exacted for diagnostic and other purposes, can be made. These are for the most part impracticable for the average physician, who can go on as heretofore using the simpler tests, but who will be compelled to call in skilled assistance for the more complicated analyses and examinations. Such laboratories already exist in some cities, like Chicago, for example, where one is in profitable operation under Dr. WESENER, and they have long been recognized as essentials to the health departments of our great centers. Their multiplication will be a great advantage to medical research, as well as of practical use to the profession.

Specialties in medicine are, it may be said, numerous enough already, but the truth is they do not exist or prosper except as they meet a need. They are generally practiced before they are actually professed, and that is the case at present with that of bio-chemistry. The time has apparently come for its full recognition by the profession and in our medical instruction.

THE JOURNEY TO MOSCOW.

An arrangement has been made with Thos. Cook & Son, tourist agents, for a round trip to Moscow in August. The party will leave New York on Saturday, July 3, by the North German Lloyd Steamer *Werra*. The steamer calls at Gibraltar July 12 and on July 15 arrives at Naples, where three days will be spent; on July 19 the party will travel to Rome, where four days will be spent; on July 24 travel to Florence, where two days will be spent. Various towns in Italy will be visited; Switzerland will be traversed, thence to Vienna, Warsaw, Moscow, St. Petersburg, Stockholm, Christiania, Hamburg, Bremen, etc., whence they return by the same line to New York, where they expect to arrive September 24. The cost of membership in this party has been fixed at \$560. Such well known physicians as the following are among the signers of the circular: Nicholas Senn, Casey A. Wood, Harold N. Moyer, Eugene S. Talbot, D. R. Brower, J. B. Murphy, D. A. K. Steele, B. T. Whitmore.

Let us have a Department of Public Health!

CORRESPONDENCE.

White Glossy Paper Injurious to the Eye.

SAN JOSE, CAL., April 20, 1897.

To the Editor:—It is not often that one will complain of receiving something that is too good, but I do wish to thus complain at present. While the matter and make up, generally, of the JOURNAL OF THE ASSOCIATION have improved to a high point of excellence, the paper-maker has been endeavoring not to be left in the rear; and he has brought up the excellence of the paper on which the JOURNAL is printed to a degree of perfection altogether too high to be acceptable to many readers of the JOURNAL.

As sanitarians and hygienists we ought to practice what we preach. There is not a medical man who will not say at once, when his attention is called to it, that printed matter intended to be read by human eyes—and it is mostly thus intended—should not be impressed on paper of high glossy finish or of glossy finish at all. Some other color than white might be suggested as more comforting to the human eye, but inasmuch as white is the color of paper generally used for printed matter it ought to be a dead white with slightly yellowish tinge. Any white surface reflects light, but when it has the gloss of a looking-glass it does so in high degree. The reflections from glossy paper cause greater contractions of the pupil than would occur if the paper were dead white. And further such reflections dim the letters, relatively, on the same principle that we can not see the stars when the sun is shining. Not only should the JOURNAL be printed on paper of proper texture and finish but we, as conservators of public health, should insist that all books be printed on paper the most pleasing to the eye and the most preservative of human vision. Most respectfully,

A. C. SIMONTON, M.D.

ANSWER: We have several times asked leading members of the Section on Ophthalmology to discuss the question of the paper on which our JOURNAL should be printed, its quality, color and finish, but nothing has been done. This year it is hoped that the Section will give their opinion. The Ophthalmology Section is one of the strongest in the ASSOCIATION, and its deliberate judgment will be generally acquiesced in.

Medical Instruction of the Laity in the Lay Press.

GALESBURG, ILL., April 13, 1897.

To the Editor:—It is certainly unwise for physicians to attempt professional instruction of the laity in the lay press by means of signed articles. In the first place, such articles blur the distinctions between their writers and advertising charlatans; in the second place, the tendency in such articles is to say the brilliant rather than the true.

Yet, after all, should not the laity be instructed medically in the lay press? By all means. The instruction in physiology and hygiene presented in the common schools is distinctly inadequate and is, moreover, imparted to the learner at a time of his life when he can not by any possibility correctly estimate its importance and therefore the necessity of remembering it far on into later years. Besides, in the common schools practically nothing is said of disease. It might be urged that the less the laity learns of disease, the better for the laity. But notions of disease, superficial though they necessarily are, the laity will have, and if it does not get them from doctors, it will get them from almanacs, fences, barns and billboards.

To anyone practicing medicine it would seem unnecessary to urge the immense amount of harm that comes from widespread medical misinformation. The worry and depression in cases of disease that are either slight or non-existent; the difficulty on the part of physicians to secure intelligent coöperation, especially in the country; the enormous amount of injury

from the use of patent medicines; the large number of lives lost that might have been saved had the patients had in time the slightest inkling of the real nature of their maladies; these are a few of the considerations which to any thinking physician present themselves at once.

How should the matter be gone about? The plan, it would seem, should be this. Let a competent staff be chosen yearly from among the members of the AMERICAN MEDICAL ASSOCIATION, whose duty it should be to furnish a very large proportion of the lay press (as literary syndicates furnish stories, poems and the like, but without cost to the press) a considerable number of unsigned articles (simple, clear and honest) on such subjects as would seem to the staff as a whole to be proper and important for the general public to consider. Plenty of competent writers would lend themselves to the purpose.

Let it be borne in mind that the subject chosen should be such as seems to the staff as a whole proper and important for the general public to consider. There is no doubt that a staff chosen from among the members of the AMERICAN MEDICAL ASSOCIATION could be altogether trusted to make a wise choice of subjects. Some of the possible themes that suggest themselves to the present writer are these: Why Promiscuous Spitting should be Prohibited. Why Legitimate Physicians do not Advertise. What not to do while waiting for the Doctor. The Truth about Catarrh. Some of the Swindling Methods of "Traveling Physicians." Pain in the Back no sign of Bright's Disease. Old and Discarded Methods of Treatment Revived under new names by Quacks. On these and a multitude of other topics, the laity is sadly in need of information.

It might, of course, be contended that the masses simply will not learn. But it is certainly true that the masses do learn, only they learn the wrong things; and may not a partial explanation of that fact be found in the further fact that the right things are so seldom, indeed almost never, presented to them? Then, again, all people are not blockheads, and there are no doubt in existence a number of persons who might, good sooth, have comprehended some medical matters, but who merely happen never to have studied medicine. Finally, to present to the laity the truth about matters concerning which the laity is already in possession of the error, certainly could do no harm.

THOS. H. SHASTID, M.D.

Weak Cylindric Lenses.

BOSTON, April 12, 1897.

To the Editor:—I notice in an editorial in the JOURNAL of April 10, on page 709, "Oculist Taylor who cured all sorts of diseases by operations and manipulations on eyes, after the cylinder quackery of today." Several years ago the Editor of the JOURNAL appeared in an editorial in which he expressed disbelief in the efficiency of cylindric lenses of as low degree as one-half a dioptre, in relieving symptoms of an asthenopic or reflex nature. At that time he was answered by ophthalmologists from various parts of the country, testifying as to the efficiency of weak cylindric lenses, but this does not seem to have convinced our editor, and so the continuation of his remarks about the "cylinder quackery of today." If the unanimous opinion of ophthalmologists at that time did nothing to convince him, it would seem as if something stronger was required; and it would be well for him to refer to the writings of Dr. S. W. Mitchell of Philadelphia on the subject of reflex disturbances in relation to eye diseases; as it has often been said that by him, more than by any one else, has the attention of the profession been called to this matter. WM. E. BAXTER, M.D.

ANSWER: The original editorial to which our valued correspondent takes exception was written by a distinguished member of the Ophthalmology Section and of many of the ophthalmic societies of the country. The last editorial was written against quack practices, not against any one engaged in honest work.

Physician's Duty to Husband and Syphilitic Wife.

KEARNEY, NEB., April 14, 1897.

To the Editor:—Will you please enlighten me as to my duty in the following matter. About three months since, a married lady came to this city to visit her parents. She and her husband had been living in a distant State. A few weeks after her arrival here, she called upon me for advice concerning a rash which practically occupied the entire cutaneous surface. Her mother accompanied her at the first call. Each of them insisted on knowing my diagnosis. In the presence of her mother I stated that she had a papular eczema of which she could be relieved within the course of a month. Within a few days the patient called alone, when I told her she had syphilis, and this papular eruption was one of its constitutional manifestations. She did not manifest any surprise and thanked me for my discretion before her mother. Within a month I received a letter from her husband demanding my diagnosis in the case of his wife. I could easily see between the lines that his suspicions were aroused. I did not disclose her malady to the husband. He writes again insisting on my diagnosis. What is my duty?

H. S. B., M.D.

ANSWER: Refer him to his wife; she alone in this case has the right to disclose the nature of her illness.

ASSOCIATION NEWS.

Special Exercises at the Jubilee Meeting.—The Committee of Arrangements has set aside an hour on the second day of the meeting for exercises to commemorate the founding of the ASSOCIATION in Philadelphia in 1847. The founders of the ASSOCIATION believed that it would raise the standard of medical education and combine the medical profession of the United States in one body. Dr. Davis, who is recognized by all as the moving spirit in the enterprise, will read a short paper, giving an account of the origin of the ASSOCIATION and how the objects for which it was founded have been attained. The committee has taken steps to secure the attendance at the meeting of the presidents of the State Medical Societies and the presidents of the State Boards of Medical Examiners as an illustration of the success attained through the instrumentality of the ASSOCIATION.

In addition to the address of Dr. Davis, there will be two or three other short addresses to add to the interest of the occasion. It is desired that the presidents of all State Boards of Medical Examiners and of all State Medical Societies meet Dr. Davis a few minutes before his address, in order that they may escort him to the stage. In the event of the president of any one of these organizations not being able to attend the meeting, he is requested to send as an alternate one of the ex-presidents, in order that every State society and every examining board may be represented upon this notable occasion.

Of the original members of the ASSOCIATION there are still living, Dr. N. S. Davis of Chicago, Dr. Alfred Stillé of Philadelphia, Dr. John B. Johnson of St. Louis and Dr. David F. Atwater of Springfield, Mass. The committee hopes that these gentlemen will all be present to take part in the meeting.

JOHN B. ROBERTS, M.D.,

Chairman Committee on Anniversary Exercises.

Section on Dermatology and Syphilography.—Preliminary program:

TUESDAY, JUNE 1ST—AFTERNOON SESSION.

Address of the Chairman. A. Ravogli, Cincinnati, Ohio.
Report of the Secretary. T. C. Gilchrist, Baltimore, Md.
Report of the Executive Committee. L. D. Bulkley, New York; A. H. Ohmann-Dumesnil, St. Louis, Mo.; A. E. Regensburger, San Francisco, Cal.
Miscellaneous Business.
1. An Attempt to Classify the Clinical Varieties of Eczema,

with special Reference to their relative Frequency and Importance. Edward Preble, Cleveland, Ohio.

2. Report on Carrasquilla's Serum Cure of Leprosy. Albert S. Ashmead, New York.

3. The Treatment of Skin Cancer. John V. Shoemaker, Philadelphia.

4. Electricity in Dermatology. Robert B. Morison, Baltimore, Md.

5. Appointment of Nominating Committee.

DINNER OF THE SECTION—8 P.M.

WEDNESDAY, JUNE 2D—MORNING SESSION.

6. Neurotic Eczema. L. Duncan Bulkley, New York.

7. A Localized Epidemic of Impetigo Contagiosa. A. H. Ohmann-Dumesnil, St. Louis, Mo.

8. Ulerythema Sycosiforme, with Report of a Case. J. Abbott Cantrell and Jay F. Schamberg, Philadelphia.

9. Lantern Slide Exhibition of Clinical Cases and Pathologic Conditions in Dermatology. J. A. Fordyce, New York.

WEDNESDAY, JUNE 2D—AFTERNOON SESSION.

Report of Nominating Committee.

Election of Officers of Section.

10. The Successful Management of a Case of Psoriasis Colossus by Hydrialin Treatment. Elmer Lee, Chicago, Ill.

11. The Tongue as it Interests the Dermatologist. Charles W. Allen, New York.

12. The Use and Abuse of the Iodids in the Treatment of Syphilis. C. Travis Drennen, Hot Springs, Ark.

13. On Various Forms of Cutaneous Tuberculosis. A. Ravogli, Cincinnati, Ohio.

THURSDAY, JUNE 3D—MORNING SESSION.

Clinical demonstrations.

14. The Effect of Erysipelas and its Toxins upon certain Diseases of the Skin. B. Foster, St. Paul, Minn.

15. Remarks on the Symptoms and Nature of Erythema Multiforme. Louis A. Duhring, Philadelphia.

16. Mycosis Fungoides, with Report of a Case. John V. Shoemaker, Philadelphia.

17. Some Remarks Concerning Acne Vulgaris. T. C. Gilchrist, Baltimore, Md.

THURSDAY, JUNE 3D—AFTERNOON SESSION.

18. On a New Method of Pictorial Representation of Diseases of the Skin. Wm. S. Gottheil, New York.

19. Three Cases of Tuberculosis Cutis Verrucosa. M. B. Hartzell, Philadelphia, Pa.

20. Demonstration of Clinical Printings and Photographs of Diseases of the Skin. J. A. Fordyce, New York.

21. Syphilis in Reference to Marriage. Discussion opened by L. Duncan Bulkley, New York, and discussed by Joseph Ransohoff and A. Ravogli, Cincinnati, and Charles W. Allen, New York.

PUBLIC HEALTH.

The Smoke Nuisance at Cleveland.—Partisan politics in the management of municipal health is as damaging as la grippe to the human organism. This trite observation is suggested by the situation of affairs in our own city. A few months since a smoke ordinance was passed by the council, which was guaranteed to be legal, and the administration announced with blare of trumpets that the smoke nuisance had to go. Not only has the smoke not gone—that was not to be expected—but complaints entered at the health office against specific chimneys, which are and have long been doing definite damage to adjoining property, are met with empty promises and the sly hint that after the coming spring campaign for city offices it may be more convenient to enforce the law. In other words, the laws are used to aid the cause of candidates and parties, and the officers who swore to enforce the laws do so only when it suits the convenience of themselves and their political cohorts. It is a disgrace to the city that the enforcement of the laws must abide the sweet pleasure of our ward politicians. —*Cleveland Journal of Medicine*, March.

Mortality by Influenza in New York State.—The *Bulletin* of that Board states that in February there was a mortality by la grippe estimated at 300 deaths; or 200 less than in the same month in 1896. In March, there were 700 deaths estimated by the same

cause. At the same time the general death rate of the State in February mounted up to 19.0 per 1,000 as compared with 17.25, the rate for January, 1897; the average for February, for the past ten years, was 18.35 per 1,000. The totals by acute respiratory diseases were 254 higher in February, 1897, than in January, the same year. The infantile mortality was relatively small, 28 per cent., as is usual in the times of influenzal prevalence. We notice in a recent New York city official bulletin that no less than seventeen deaths occurred by influenza in a single week out of a total death-toll of 839; only one other zymotic cause, namely diphtheria, showing a higher total. When we consider the slowness with which some practitioners accept influenza (or any other of the newer causes) as death-causes, we think we are not mistaken in assuming that la grippe is capable of making very serious ravages; a position that we have not always found it easy to accept.

School Admissions in 1896.—Questions likely to be put to a child on application for admission to school, in 1896:

Teacher—Young man, have you a certificate of vaccination against smallpox? Pupil—Yes, sir.

Teacher—Have you been inoculated against croup? Pupil—Yes, sir.

Teacher—Have you been treated with antidiphtheritic serum? Pupil—Yes, sir.

Teacher—Have you a written guaranty of immunity against whooping cough, measles, mumps and scarlet fever? Pupil—Yes, sir.

Teacher—Have you an individual drinking cup? Pupil—Yes, sir.

Teacher—Do you promise never to exchange pens with your neighbors? Pupil—Yes, sir.

Teacher—You are supposed to be convinced of the necessity of disinfecting, at least once a week, with sulphur vapors, and of sprinkling your clothing with chlorid of lime? Pupil—Yes, sir.

Teacher—Then you possess all that modern hygienists require of a pupil; you may pass up these steps, be seated upon your separate aluminum bench, and begin to write your p's and q's.—*Deut. Med. Zeitung.*

Limit of Power of State Board of Health as to Vaccination.—A very important decision, but one which has been misstated in some early press reports, was handed down by the supreme court of Wisconsin, Feb. 23, 1897, in the case of *State v. Burdge*. The court particularly disclaimed expressing any opinion on the question of legislation making vaccination of children attending school compulsory. At the same time, it rather gives one the impression that it would uphold a statute of that character. What it did decide had reference to the power of the State board of health to make a rule that no child should be allowed to attend any public or private school in the State, without first presenting the certificate of a reputable physician as to having been successfully vaccinated. There is no statute in Wisconsin authorizing compulsory vaccination, or requiring vaccination as one of the conditions of attending the public schools. In the absence of any such statute, the supreme court holds that it can not be maintained that such a rule as the foregoing is a valid exercise of the powers of the State board of health. It says that the State board of health is a creation of the statute and has only such power as the statute confers. It has no common-law powers. In Wisconsin it is given "a general supervision throughout the State of the interests of the health and life of citizens," and is authorized "to make such rules and regulations and to take such measures as may, in its judgment, be necessary for the protection of the people from Asiatic cholera, or other dangerous contagious disease," the term "dangerous and contagious diseases," to be "construed and understood to mean such diseases as the State board of health shall designate as contagious and dangerous to the public health." But its powers, though quite general in terms, the court holds, must be held to be limited to the enforcement of some statute relating to some particular condition or emergency in respect to the public health. It has no "legislative power," and none can be delegated to it. Consequently, so far as the statute just quoted delegates legislative power over the subject involved, rather than provides for the administering and carrying into

effect of some substantive provision, it is unconstitutional, and furnishes no authority for anything like legislation on the part of the State board of health. The rule which the latter promulgated is also pronounced unreasonable, and therefore void.

New York Quarantine Laboratory.—Drs. Doty and Fitzgerald, at the Swinburn Island laboratory of the New York Quarantine Station, have been hard at work since the middle of February in initiating the production of an American anti-pest serum. The first horse was inoculated with a culture of plague bacilli on February 26. This was repeated on March 4, and again on March 9. For the purpose of determining how early the serum might have acquired antitoxic qualities, about one pint of blood was drawn from the horse on March 15 for experimental purposes, and from this one-half pint of serum was obtained. One cubic centimeter of this was injected into each of a number of white mice. After thirteen hours they were inoculated with a culture of the plague bacilli. These mice did not die, but several mice into which the serum had not been injected died, thus showing the efficacy of the serum in the cases of those that lived. Tests were also made to ascertain the curative power of the serum, but they did not prove satisfactory, although in most cases they prolonged life, and in one case a cure was effected. These tests were made by inoculating mice with the deadly dose referred to, which killed in twenty-four hours, but within three to twelve hours after the first injection they were treated with one cubic centimeter of the serum. These tests indicate that the serum in the horse is surely both preventive and curative. Other tests with blood from the same horse will be made. According to the investigations made by Dr. Doty, to Dr. Yersin of the Pasteur Institute in Paris, is due the credit of the discovery of the bacillus of the bubonic plague; although it must be admitted that Kitasato is a close competitor, one writer claiming that there was not more than three weeks' difference between the two and that that difference is in favor of Kitasato. Now then, let the interesting question be looked into: By whom and at what date did either of them place their discovery upon the printed page. Dr. Doty is proceeding cautiously and slowly, bearing in mind the experience and teaching of Yersin that the proper development of an anti-pest serum demands much time and prolonged treatment of the animals under the toxins. After the discovery was made a bacteriologic laboratory was founded on the Annam coast, in China, about one year and a half ago, for the study of the serum treatment of the plague. The opportunity to test the serum came when the plague broke out in China. Out of twenty-five cases treated by Dr. Yersin, twenty-three recovered. In the course of his experiments Dr. Yersin found that mice, rats and pigs were stricken before human beings. He decided that these animals possessed special receptivity for the plague, and that they would be serviceable to him on that account in his experimental work. Dr. Yersin placed healthy animals in contact with those inoculated and found that the latter died first, but in a few days the sound animals died one after the other, the plague bacilli being found in their organs at postmortem. They had therefore taken the plague by simple propinquity. These facts proved that the plague is a contagious disease that can be inoculated.

NECROLOGY.

FREDERICK W. WHITEMORE, M.D., Harvard, 1878, died at his home in Cambridge, Mass., April 14.

THOMAS SPENCER DAWES, M.D., Albany, N. Y., 1848, died at his home in Saugertres, N. Y., April 11, aged 76 years. He was born in Cummington, Mass., of which State his brother Henry L. Dawes served as senator.

THOMAS S. BAHAN, M.D., New York University Medical College, 1856, died at his country home in Douglaston, Long Island, N. Y., April 6, from cerebral softening. He was born in St. Johns, New Brunswick, came to New York in 1853, and began his professional career in what was then Greenwich village. He served as surgeon in charge of the Park Barracks throughout the war, was long attending physician to the Northern Dispensary and had identified himself with most of

the medical societies. As a family physician he won an enviable reputation for skill and culture. A few years ago he lost a promising son, who was drowned while asleep in the Doctor's yacht, as the result of a collision, for which the pilot of a tug-boat was imprisoned for criminal carelessness. A widow and two sons survive him.

NEW INSTRUMENTS.

A PRESBYOPIC TRIAL FRAME.

ALBERT B. HALE, M.D.
CHICAGO.

A few weeks ago I had occasion to ask a patient to sit in my office for some time, for the purpose of testing the efficacy of glasses at the reading distance before I finally prescribed them. On measuring the pupillary distance, however, I was annoyed to discover that I had nothing at all suitable to her case, for the greatest distance I dared allow was 55 mm., while the smallest frame I had was not under 60 mm., and as it was a decentration I wished to avoid, I was obliged to postpone the trial till another day. Meanwhile, I investigated frames, but could find nothing in a small, light presbyopic frame that was adjustable, and I am sure that it is not at present to be found.

After explaining my idea, I finally had Mr. Allen (Edward Allen & Co., 80 Dearborn Street, Chicago) make the frame, of which this illustration is the best description. (The cost is three dollars.) It explains itself. By means of traction the button connecting the two sides by a mild spring, yields, so that the pupillary distance is modified without changing the symmetry of the frame itself. The frame is as light as any other, and causes no inconvenience to a patient. It allows of a pupillary distance of from 54 mm. to 65 mm., certainly suitable to any but an extraordinary head, and by its use the adjustment can be so accurate that the usual cause of dislike to the trial frame (decentration) is well avoided. The frame can be made, at a small increase in cost, to hold two lenses on each side, if so desired.

Columbus Memorial Building.

FOR THE APPLICATION OF COCAIN TO THE UVULA.

HENRY W. WANDLESS, M.D.
Chief Surgeon Dallas Charitable Eye, Ear, Nose and Throat Infirmary;
Consulting Oculist and Aurist M. K. & T. Ry.
DALLAS, TEX.

There is always more or less difficulty to anesthetize the uvula with cocain by making application with cotton on a carrier. I had for several years used cotton on a toothpick, with very little satisfaction, and seldom getting the uvula insensible.

The first attempt usually produces reflex spasms of the soft palate and faucial muscles. Rubbing the uvula with cotton keeps up this effect until the mucous membrane of the uvula is insensible to the touch. This is very disagreeable to the patient; besides, the cocain by contact spreads over the base of the tongue, the pharyngeal wall and the larynx. This often produces nausea and discomfort.

I have devised a little instrument, shown in the cut, which has none of the objectionable features of the cotton probe method; besides, it does its work thoroughly and is no trouble at all. Its general contour is that of a spoon, its bowl being deeper and more uniform. The handle is curved so as not to obstruct the light, and is seven inches in length; flat, so as to

prevent rotation in the fingers emptying its contents into the mouth. Its bowl is three-fourths of an inch long, five-eighths broad and five-sixteenths deep.
