This was the title of a paper by Dr. ROBERT H. BABCOCK of Chicago, in which he reported the following instructive case: During the past winter a lady of 50 was placed under his charge with a history of having been treated for years for a weak heart. Upon one occasion last fall, while shopping, she had succumbed to an attack thought to be heart failure, dyspnea, cyanosis, etc. His examination revealed a slight enlargement of the heart transversely with rather feeble sounds, but no murmur. The pulse was regular, slightly accelerated and moderately tense. The patient was somewhat corpulent and the abdomen was flabby and pendulous. She gave no symptoms of abdominal or pelvic disorder. Urinalysis was negative; blood examination showed a mild chlorosis, hemoglobin 72 per cent. After careful consideration of the history, symptoms and result of examination, Dr. Babcock decided that this was a case in which the heart required no direct treatment, but that efforts should be directed to improving the general health and lessening the work put upon the heart. Consequently he sent her to a rest cure where she was given forced feeding, massage and rest in bed. After two weeks her pulse became intermittent and she complained of vague precordial discomfort. Examination of the heart disclosed no cause for the condition, but there was infra mammary tenderness in the areas shown by Head to indicate gastric disturbance, and analysis of the urine showed uric acid crystals in abundance. The colon was flushed two or three times, the patient ordered to drink large quantities of water, and a few drops of tincture of digitalis twice or thrice a day were given in the hope of regulating the pulse. This failed, however, and was discontinued after a few days. With this exception the patient received no heart tonics. After three weeks of treatment, examination of the blood showed an improvement in the hemoglobin of only 3 per cent., and treatment was continued for two weeks longer. At this time her pulse was still somewhat irregular, but she felt well. Although no symptoms of pelvic disease had ever been acknowledged further than great weariness upon walking, exploration of the pelvic viscera was considered advisable in the expectation of its throwing some light on the patient's condition. Accordingly, a gynecologist reported perineal and cervical laceration with subinvolution of the uterus, and advised a reparative operation. This was done without delay, and since her convalescence from the operation the patient's condition has been highly satisfactory so far as the heart is concerned. Without any further treatment, she is now able to ascend stairs and enjoy long walks without dyspnea or other discomfort.

Here was a patient who, without very positive evidences of cardiac disease, suffered from symptoms of weak heart, and for years had supposed that was her only complaint. Yet without therapeutic measures directed to this organ, except physical rest and the small amount of digitalis previously stated, the pulse lost its irregularity and the heart its potential weakness so soon as relieved from the reflex disturbance proceeding from the pelvis. Without wishing to ignore the influence of rest in this case, the author yet believes the reinstatement of cardiac vigor must be attributed in large measure, if not wholly, to the surgical interference.

Finally, when a diseased heart which has hitherto performed its work satisfactorily, suddenly displays vagaries of action, it should not be taken unreservedly for a sign of failing compensation. Efforts should be made to discover the cause, since the correction of injurious habits, or the removal of reflex disturbances, may set the heart to rights before serious damage ensues. Should the derangement of the cardiac action threaten to produce or actually cause dilatation, then digitalis and strychnia are indicated, but so long as compensation is intact, digitalis and allied remedies should be withheld.

DISCUSSION.

Dr. D. R. BROWER of Chicago said arterio sclerosis was a very common affection, and, speaking from personal experience, it was a condition very frequently overlooked, it being the foundation of many nervous diseases. As to its etiology, when it occurs in persons under 40 years of age, it is probably due to one of three factors—alcohol, interstitial nephritis or syphilis. He believes that in persons under the age mentioned, syphilis is the most important etiologic factor of arterial degeneration, par-

ticularly in the absence of evidence of interstitial nephritis and alcoholism. Relative to the treatment, he endorsed the suggestions of Dr. Favill as to food, and freedom from care and over-exercise. While calomel was a great alterative, the chlorid of gold and sodium was in his opinion much better, in that it had a greater effect not only upon interstitial degeneration in arteries, but elsewhere throughout the body.

Dr. ARTHUR R. EDWARDS of Chicago directed attention to the frequent confusion of the results of changes in the coronary arteries with cerebral disease. Especially was this true when the cases were seen in the last stages of the disease. Many cases are stricken down where a diagnosis of apoplexy is made, and in private practice the practitioner is frequently unable to either confirm or refute the diagnosis. Furthermore, the changes in the arteries of the heart muscle may produce insufficiency of the muscle and clinically a relaxation or dilatation of the left ventricle. With this relaxation of the left heart there is frequently found associated with it a systolic murmur. These cases coming under observation are frequently diagnosed as valvular diseases, are called cases of mitral insufficiency, and yet, when followed out on postmortem the lesion is found not to be due to any valvular disease *per se*, but due to a lesion existing solely in the heart muscle.

With reference to treatment; diligent search must be made to ascertain the cause of the disease, as no treatment could be based on rational grounds that did not inquire into the cause and remove it when found.

Dr. J. B. MAXWELL of Mt. Carmel commended the remarks of Dr. Babcock relative to the indirect treatment of heart disease, in that they coincided with the speaker's experience. Physicians ought to be exceedingly careful in telling patients that they have serious heart trouble when they are consulted by them.

Dr. C. B. HORRELL of Colchester reported a case that he saw a few months ago in consultation. The patient had an extremely purple face with conjunctivitis. There was some blurring of vision. On examination he found a severe case of tachycardia with arterio-sclerosis. The patient was put upon a course of treatment similar to that indicated in the papers, and following it the patient began to complain of pain in the lower extremities, which at first simulated articular rheumatism, and finally multiple neuritis. He was satisfied that in this case the cord was involved rather than the cerebrum as a result of the sclerosis. Notwithstanding dietary measures and the administration of such remedies as had been mentioned, the patient gradually grows worse, and the prognosis is unfavorable.

Dr. HUGH T. PATRICK of Chicago said that cerebral hemorrhage practically never occurs, except by the rupture of a miliary aneurysm. Of course, there are exceptions to all rules, but this was a rule with few exceptions. Another point: Before the artery reaches the stage at which miliary aneurysm forms, there has been a thickening of the coats, a loss of elasticity and a diminution in the caliber of the artery; consequently many of the symptoms of cerebral trouble due to arterio-sclerosis are attributable more to the effect upon the entire artery than to miliary aneurysm.

In the treatment of arterio-sclerosis, Dr. Patrick recommended very highly tetra-nitrate of erythrol, which he says dilates the arterioles equally as well as nitroglycerin, and its effects were more lasting.

Dr. A. R. COLE of Kewanee said it has been his special privilege to see a number of cases of heart trouble in an apparently dying condition that rapidly recovered under the use of the old remedy—calomel. He especially recommended its use to the younger members of the profession.

Dr. JAMES B. HERRICK of Chicago spoke of venesection as a method of treatment in cases of myocarditis where there is extreme dilatation. This was brought forcibly home to him within the last year by seeing three cases that came into the Cook County Hospital with extreme dyspnea, amounting to orthopnea, with edema of the lungs, feeble pulse, marked cyanosis and the physical signs of extreme dilatation of the heart, without the findings that would convince one there was valvular disease. From the sclerotic condition of the radial arteries, the cases were looked upon as cases of fibrous myocarditis consequent upon arterio-sclerosis, where the musculature of the heart had become insufficient and extreme dilatation had occurred. It was considered more rational to relieve the extreme work of the heart than to stimulate the organ, and in these cases the greatest benefit was derived from abstracting from the veins from 8 to 16 ounces of blood. The rapid improvement that was apparent not only to the patient, but to the physicians who witnessed the operation, would convince any one that in some cases of dilatation of the heart venesection is of benefit. Dr. Herrick mentioned this in connection with the

subject of arterio-sclerosis, as perhaps there was nowadays a tendency to discard venesection where in certain cases, at least, it is of benefit.

The discussion was then closed by the various essayists.

FIRST DAY—AFTERNOON SESSION.

Dr. ARTHUR R. EDWARDS of Chicago read a paper on
THE DIAGNOSIS OF MALARIA.

The diagnosis and the pathogenesis of malaria have a scientific life of scarcely two decades. In this time extreme views have been held by the profession. The skepticism greeting Laveran's discovery has given way to equally great credulity.

1. *Diagnosis of the existence of malaria.*—a. Positive blood findings establish the existence of malaria, the disease being always caused by the parasite, the parasite being practically always found in malaria and in malaria only. It must not be forgotten that malaria may occur simultaneously with other diseases, *e. g.*, ulcerative endocarditis, pulmonary tuberculosis, chronic nephritis, but never with typhoid. Atypical fevers, associated with chills and sweatings, which have few or dubious local findings and are hence difficult of diagnosis, can at least be differentiated from malaria, *e. g.*, anomalous typhoid fever, septic-pyemia occulta, generalized miliary tuberculosis, febrile gastritis, ulcerative endocarditis, suppurative cholecystitis, central pneumonia, deep-seated sarcomatosis, etc. b. Negative blood findings are not definitive from one examination. While suggestive, a single negative finding is far from conclusive. The parasites may be indistinguishable in the first few days of the disease; in certain forms and stages they swarm in internal organs only, and lastly, in recurrent and chronic types they are found with great difficulty only. c. Fallacies. Deformities in the red blood discs are often mistaken for plasmodia, *e. g.*, crenations, poikilocytosis, vacuole formation, plastic conditions of the hemocyte, which are more frequent than is usually recognized, melaniferous leucocytes, blood plaques, the small bodies, microcytes, frequently seen in anemia, etc.

2. *Diagnostic technique.*—Direct examination of the freshly drawn unstained blood is best, using forceps to avoid corpuscular alteration by the finger's heat and moisture, and only touching the drop of blood lest pressure cause precipitate drying of the preparation. Eosin staining, with methylene blue, is the best stain. Fresh preparations are best, since the dye stain blood plaques and various artefacts, act as protoplasmic poisons, abolish the ameboid movement and pigment vibration.

3. Not only the fact but the type of malaria can be diagnosed. Determination of species not merely establishes the diagnosis, but declares the prognosis, as in pernicious types, and designates the treatment, as arsenic in tropical malaria. Crescents augur relapse. Segmentation forms predict an imminent or incipient paroxysm, etc. The various forms are distinguished from each other by differences in mobility, pigment, size, sporulation, changes in the red blood discs, protoplasm of the parasite by crescent formation and flagella.

4. *Diagnosis of individual malarial symptoms.*—The symptoms are not only immediate sequences of the malarial infection, but are beautifully explained by the life cycle, life activity and metabolism of the parasite, *e. g.*, the fever, melanemia, splenic tumor, hemorrhages, etc. The anemia is more rapidly induced than in any other disease. The triad of symptoms, fever, chills, sweating, are a "protozoan sepsis."

5. *The diagnosis juvantibus.*—Simulating diseases may recover under quinin or without it. Malaria exhibits great tendencies toward spontaneous recovery, *e. g.*, by phagocytosis, action of the fever, etc. Quinin cures certain malaria with rapidity and certainty. Hence a diagnosis (at least of benign tertian malaria, our sole endogenous form) of malaria is disproven by failure of treatment.

Dr. C. W. HALL of Kewanee, read a paper entitled
THE SEQUELÆ OF TYPHOID FEVER.

He had learned the frequency of such sequelæ and their importance from a medico-legal aspect. The physician should always be on the alert for sequelæ and when he suspects the presence of one he should enlighten the family, ask for counsel and transfer the responsibility from his shoulders to theirs, and thus save trouble, if nothing else.

Dr. DANIEL R. BROWER of Chicago then read a paper entitled
AUTO-INFECTION IN ITS RELATIONS TO DISEASES OF THE
NERVOUS SYSTEM,

in which he drew the following conclusions:

1. Some of the nervous diseases are the product of auto-intoxication.
2. That this autotoxis produces a parenchymatous degeneration of the nervous system, acute or chronic, that may result in the destructions of the structure and function of the nerve cells. (Van Gieson and Andriezen.)

3. The peculiar arrangement of the lymph channels in the nervous system makes auto-intoxication of the brain possible by the blocking of these channels.

4. The principal factors in this autotoxis are a disordered gastro-intestinal tract.

5. Gastrectasis, intestinal dyspepsia and coprostasis are ordinary conditions producing gastro-intestinal intoxication.

6. The diagnosis is to be made by *a*, regional examination; *b*, by examination of the gastric juice and contents, and *c*, by examination of the urine.

7. The urines will show increased amount of indican, diminished total sulphates, but an increase in the amount of ethereal or conjugate sulphates.

8. There will also be found usually in consequence of this autotoxis a diminished hemoglobin record and a diminished number of red blood corpuscles.

9. The treatment should consist of lavage, enteroclysis, gastric and intestinal antiseptics, laxatives and hematinics.

Dr. HUGH T. PATRICK of Chicago read a paper entitled

REMARKS ON SPINAL IRRITATION.

He said that the term spinal irritation should be irrevocably banished from medical nomenclature. The pain and tenderness along the spine, generally known by this name, have nothing to do with the spinal cord or membranes or vertebrae or any other structure in this vicinity. He showed first that a normal person is unable to locate accurately a spot on the back previously touched, and secondly, that tender spots in so-called spinal irritation are located with the same inaccuracy; that is, the examiner having found where the tender spot is, five or ten minutes later it will have shifted one to two inches. From this the following conclusions were drawn: 1, in so-called spinal irritation, there are always tender points along the spine; 2, these may be definitely located; 3, they may be shown to absolutely shift in position within five or ten minutes; 4, such rapid shifting demonstrates that the tender points are the result of purely functional disease, which disease is located not lower than the cerebral cortex.

(To be continued.)

Chicago Pathological Society.

Regular meeting, Feb. 8, 1897.

Dr. JAMES B. HERRICK, President, in the chair.

Drs. M. L. HARRIS AND MAXIMILIAN HERZOG presented a paper on

SOLID MESENTERIC TUMORS, WITH A REPORT OF A CASE.

The new case reported is that of a boy 5 years old, who came under the treatment of one of the reporters (Dr. Harris) in April, 1896. A large tumor, easily palpable, was found to fill the greater portion of the abdominal cavity; its surface was smooth, though somewhat irregular, the entire mass was as movable as the closely fitting abdominal walls would permit. From the relation of the tumor to the abdominal organs, especially to the colon, and from other data, a clinical diagnosis of solid tumor of the mesentery was made and an operation performed on April 13, 1896. The tumor was found as expected; it appeared to have started in the mesentery; a loop of intestine (jejunum) passing over it was attached to it and had to be removed with it (about 51 cm. long). The ends of the divided intestine were united end to end by the operator's (Harris') method. The patient's condition when removed from the table was quite critical, but he rallied and made an uninterrupted recovery. Ten months after the operation he was in excellent health and without any signs of recurrence.

The tumor, the pathology of which was studied by one of the reporters of the case (Herzog), is egg-shaped in its general outlines, the periphery of its longest axis measuring 57 cm. Histologically the growth proved to be a lympho sarcoma with extensive colloid degeneration. A remarkable histologic feature was the presence of colloid material found in the lumen of blood vessels. Sections of the growth had been embedded in celloidin as well as in paraffin, and had been stained with hematoxylin and eosin, orcein, and according to Van Gieson's methods.

DISCUSSION.

Dr. EMIL RIES—I wish to ask Dr. Herzog one or two questions. Were these specimens imbedded in celloidin?

Dr. HERZOG—Some.

Dr. RIES—Have sections been made from the fresh material?

Dr. HERZOG—No.

Dr. RIES—When I looked at the specimens just now, it struck me as remarkable that colloid masses formed in the arteries. The reason why I asked the question, whether sections were made from fresh material, was because I could not distinguish in the microscopic specimen the colloid mass from the celloidin.

With regard to the observation of vacuoles in colloid masses I wish to state that vacuoles can be found in celloidin. When the ether evaporates from the solution of celloidin unequally under different degrees of heat, the formation of vacuoles occurs. I do not doubt the presence of colloid masses in the cells and in other parts, but just this one mass in an artery is remarkable. I would like to ask Dr. Herzog how he thinks the mass got into an otherwise normal artery?

With regard to the case itself, I wish to add a few words concerning an observation of my own which belongs to this class of cases, although it is not a primary tumor of the mesentery. I observed a case of large sarcoma of the uterus, for which abdominal hysterectomy was made. Some thirteen tumors of various sizes were found in the mesentery besides the uterine tumor. Microscopic examination showed that it was a fibrosarcoma. In a few of the tumors of the mesentery remnants of mesenteric glands could be found, so that the glands could be recognized as the seat of the metastatic tumors. The patient made a good recovery, but returned about eight months after the operation with a recurrence from which she died. I understand the patient of Dr. Harris is still alive, and I wish to congratulate him on the result.

Dr. MAXIMILIAN HERZOG—You may see exhibited under the microscope some specimens containing vessels, the middle coat of which shows signs of a homogeneous degeneration; you can not see any nuclei, nor are the fibers themselves distinct in their outlines. Concerning the histology of the tumor under discussion, I reported to you what I found; among other things, I found in some of the vessels a homogeneous material, exactly like the material found elsewhere in the tumor. I have called this material colloid because it answers, as far as I can see, in every detail to the description of colloid material. How this material was formed in the vessels or how it got there, I am not prepared to explain in detail today. That the masses in the vessels are not thrombi is evident.

Dr. HEKTOEN—I think some further microchemic tests ought to be made before we are justified in speaking of this material as colloid, that is, if we use the term as we apply it, for instance, to the material found in the thyroid and other epithelial structures. If we use the term colloid as meaning any homogeneous material, then there is colloid material in these arteries and elsewhere. I have observed such substances in the vessels of tissues hardened in Müller's fluid, and I have thought that such colloid-like material might be a pure artefact.

Dr. HERZOG—There is a good deal of controversy today as to the limitation of the term, "colloid." Virchow discards the term entirely, and calls certain materials, which others call colloid, "gallertig." Recklinghausen classes what others call colloid with "hyaline degeneration." Ziegler and others describe as colloid, a degeneration which seemed to me to answer to the degeneration which I found in the tumor of the mesentery exhibited here tonight.

FOCAL OR INSULAR NECROSES PRODUCED BY THE BACILLUS OF TUBERCULOSIS.

Dr. E. R. LECOUNT read a paper with above title, of which the following is an abstract.

Focal necroses have been observed in consequence of various causes and in various organs. The substances abrin and ricin the former from the jequirity bean, the latter from the castor bean, the toxins produced by the diphtheria bacillus, the micrococcus lanceolatus, the typhoid bacillus or its toxins and the bacillus malleus, all may cause necroses as their initial lesions. They have also been observed in consequence of the injection of the blood serum of dogs into rabbits and in puerperal eclampsia.

These necroses occur mainly in the spleen, lymph glands and liver, but also in the intestinal epithelium, the peritoneum and in other viscera. Most instances of focal necroses as produced by the substances mentioned, are caused by the action of some harmful material circulating in the body fluids; less frequently they are caused by bacteria acting *in loco*.

These lesions are as a rule minute and frequently only to be found in the course of a routine microscopic examination. They are characterized by a degeneration of the fixed cells of the organ or tissue in which they occur and then affect as a rule mainly the essential cells. In some instances simply loss of staining capacities (karyolysis), is found to form the only change in the nuclei of the cells, in other instances karyorhexis fragmentation of the nucleus results, and again these are frequently found associated in the same area of necrosis.

With these changes in the nuclei, fibrin is frequently formed as the result, in part at least, of exudation (coagulation necrosis). In certain instances the necrotic area is invaded by polymorphonuclear leucocytes as in the so-called lymphoid nodules seen in the liver in typhoid fever.

Nuclear fragmentation results in the accumulation of numerous ball like granules of chromatin which stain intensely with nuclear dyes. Necroses of this variety have been observed by R. Kockel in experimental tuberculosis of guinea-pigs, but the areas observed by this author in the liver were ascribed by him to ischemia. Pilliet also described necroses in the liver in tuberculosis in animals, but did not believe them to be due in any respect to the direct action of the bacillus of tuberculosis. Leredde in an article upon acute and subacute human tuberculosis, has depicted visceral necroses which have apparently resulted from venous hyperemia, which resulted from interference with the pulmonic circulation.

Case 1.—A case of chronic ulcerative tuberculosis of the lungs, showed in the spleen and liver, areas visible only with the microscope which corresponded in all respects histologically, to other forms of focal necrosis observed in diphtheria, a brin poisoning, etc. They were on an average, the size of a normal glomerulus in the kidney of an adult, and were made up of necrotic cells, nuclear fragments and fibrin and in them the bacillus of tuberculosis was invariably present in small numbers. No leucocytic invasion had occurred into the area, no giant cells were present, no other bacteria could be demonstrated nor were any changes present in the adjacent small arterioles or capillaries, such as thrombosis. Consequently these areas differed histologically from tubercles.

Case 2.—A case of chronic peritoneal tuberculosis in which exactly similar areas were found in the spleen. In the liver, however, typical microscopic tubercles were present.

Case 3.—A case of tuberculosis of the retroperitoneal lymph glands which anatomically simulated the enlarged lymph glands seen in lymphatic leukemia. No caseation was visible to the naked eye, but microscopically irregular confluent areas of necrosis were found present, mainly affecting the peripheral parts of the gland and these also contained the tubercle bacilli. From the resemblance of the areas of focal necrosis in these three cases to all other described instances of focal necrosis and the fact that they contained within them the bacillus of tuberculosis and no other bacteria, it was concluded that the action of the bacillus of tuberculosis upon the tissues is not such as to invariably produce that combination of proliferative and exudative changes which is called a tubercle. The absence of proliferative changes which are by most authorities accepted as phenomena of tissue resistance or reaction was in direct accord with the marasmus present in all three cases.

DISCUSSION.

PROFESSOR KLEBS—These necrotic processes in cases of tuberculosis are interesting, and I am quite familiar with them in guinea pigs. Necrotic areas occur in the liver and form cirrhosis of the liver. I have not seen these necrotic processes so frequently in man. I remember to have seen cases in which there were necrotic areas in the spinal cord, the brain and the kidneys. I have almost always found that necrotic processes in tuberculosis were not caused primarily by the toxins of tuberculosis, but by obstruction of the vessels. There is a great difference between the toxins of tubercle bacilli and those of other diseases. Large necrotic areas are observed in bacterial processes. These necrotic processes develop in the kidney sometimes in a comparatively short time, and we have an enormous quantity of the toxins thrown out by the diphtheria bacilli, the cholera vibrio, etc. The most extensive toxic necrosis I have described in the kidneys of Asiatic cholera. As to the distribution of the toxins in bacteria, there are very great differences. In typhoid bacilli there are considerable quantities of toxic substance contained in the bodies of the microbes, but not so in tuberculosis.

I have done considerable work toward finding out the composition of the tubercle bacilli and I have tried to prepare toxins from their bodies but I have not had any results. All the toxins are in storage in the fluid culture; there they are to be considered as secretion products. The quantity of the toxins in the bodies of the tubercle bacilli is not quite a fourth of that in the whole culture formed by four to five grains of dry tubercle bacilli in five or six weeks. So the quantity of toxin formed in a few tubercle bacilli must be very small. From this cause I do not think they are formed in such quantity that the necrosis is produced directly by them in the same way as it is in diphtheria or cholera. I have always held the opinion that necrosis in tuberculosis was formed by obstruction of vessels. Wherever tubercle bacilli are deposited, there we first observe obstruction of vessels, also in dissemination of the tubercle bacilli in the blood, particularly in cases of miliary tuberculosis. It is shown by Roux and Yersin and myself that by injecting living tubercle bacilli in the blood, the greatest part of them is killed in the blood. Otherwise obstruction of vessels is an important factor

in the formation of necrotic masses. I would remark also that this necrosis, if I understood Dr. Le Count rightly, is found mostly in the spleen, and, secondly, in the liver. Those are the organs in which obstruction of vessels is of frequent occurrence. In the spleen we have very extensive capillary circulation, the blood current is slow, and obstruction likely to occur. In tuberculosis of the spleen wedge-shaped, yellow infiltrations occur as well as in the liver of guinea pigs. I have frequently found in tuberculosis of the kidneys, occurring in older persons, very small atrophic spots on the surface of the organ, which were perhaps the consequence of necrotic processes. I have seen similar atrophies in the brain and spinal cord.

I think the fibrinous matter that is found in the necrotic parts points toward obstruction of the vessel. It is not necessary that this obstruction should be caused by thrombi. It may be due to stasis in the vessels as it is found in the diphtheritic mucous membranes. We can have obstruction of the vessels by other substances than thrombi; as if the vessels are enormously dilated and filled up with red blood corpuscles compressed against one another, or there are formed thrombi of blood plates—after the injection of Koch's tuberculin. The presence of the fibrinous matter in the necrotic parts would favor the opinion of obstruction in the vessels.

DR. LE COUNT—The idea that these areas of necrosis might be due to obstruction to the circulation was not neglected; a careful search was made for thrombotic processes in the vessels and at the same time the relation the areas bore to the vessels was thoroughly examined by means of serial sections. Any reasons for ascribing the necrosis to interference with the circulation could not be found; nor were thrombosed capillaries found. The additional facts that tubercle bacilli were invariably present in the areas of necrosis, that these lesions were present in cases of well marked cachexia and that in the spleen they were diffusely scattered throughout, not located near the capsule as areas of ischemic necrosis are liable to do, seem to support the position taken.

We likewise can not overlook the researches of Abtl, who injected tubercle bacilli into the trachea of rabbits and found twenty-four later small whitish isolated areas in the bronchi and lung alveoli which proved microscopically to be areas of necrosis, in which proliferative changes occurred two days later. Concerning the action of toxins which Professor Klebs refers to, there is a marked difference between the lesions at present described in the literature as "focal necrosis" and the changes produced in the kidney either by diphtheria or cholera toxins, in that the latter do not occur in foci, indeed the necroses produced in diphtheria and described under the term focal do not include those which are found in the kidney.

In conclusion I wish to state that it is my firm belief that the bacillus of tuberculosis in exceptional instances can produce necrosis as a primary effect upon the tissues, as seems to be demonstrated in these specimens, but that in the majority of instances the effect as Baumgarten has stated is to cause primarily proliferative and exudative phenomena.

SPECIMENS.

DR. E. R. LE COUNT—I have here two specimens which were removed today from the same body. They are not without interest and also show well on account of their fresh condition. The first is a calculus imbedded in the substance of the kidney. As you can see, it is L-shaped, half as large as the little finger, and lies apparently in a dilated calyx.

The second is a mesentery for the gall bladder, forming a pendulous gall bladder. The "mesentery" measures one inch in breadth at its widest portion and gradually narrows as the cystic duct is approached. One and one-half inches of the cystic duct are also suspended in the "mesentery." There is entire absence of the furrow for the gall bladder, so that the lobus quadratus is directly continuous on the right side with the right lobe of the liver. There is also absence of the notch which occasionally forms the termination of the groove for the gall bladder. Both of these specimens came from the body of an old man who died of empyema and purulent bronchitis.

DR. JAMES B. HERRICK—I present a specimen of *ancurysm* of the right auricular appendix. I am indebted to Dr. Hektoen for the privilege of exhibiting it. There is nothing known of the clinical history, the heart having been obtained by the coroner's physician.

The pericardium shows no change. The heart is rather large in size and shows left and right ventricular hypertrophy. The coronaries are sclerotic. The valves of the heart show slight thickening, but nothing can be proven to have resulted in a clinical valvular lesion. The aorta shows some calcareous plaques. The point of interest is that at the tip of the right auricular appendix there is a sac-like projection,

the long diameter of which is about 2 cm. and the walls of which are perfectly translucent, and which is wholly made up of endocardium and epicardium. We have, therefore, an aneurysm of the right auricle. A similar one, though smaller, is found in the left auricle. There is no evidence of inflammation of the pericardium, endocardium or auricular myocardium. We can scarcely look upon this as an aneurysm the result of myocarditis, which is the common cause of aneurysm. It would rather seem to be due to a separation of the muscular fibers in the auricle, either through congenital or acquired weakness, and a hernial protrusion of the endocardium. It can readily be seen that this point of weakness is also a point of danger, and that a rupture of such a hernia of the endocardium would be followed by the most serious consequence in the shape of hemorrhage. The auricle itself is comparatively rarely the seat of an aneurysm; the commonest place being the left ventricle, particularly near the apex; the septum, particularly near the membranous portion; the right ventricle, and lastly the auricle.

Dr. KARL F. M. SANDBERG—This specimen of *extra-uterine pregnancy* was removed this morning from a woman who has had three children and one abortion. She menstruated the last time on November 12. On December 29 she had a spasmodic pain in the lower part of the pelvis, and during January of this year she had a repetition of the same pain three or four times. There was an irregular loss of blood through the vagina at different times. She consulted her family physician, Dr. A. B. Oyen, who promptly made the diagnosis and referred the case to me. The specimen shows a pregnancy in the distal two-thirds of the right tube with the ovary located posteriorly, the fimbriated extremity of the tube attached to the same. The specimen was removed entire without having been ruptured or opened. It was located in the cul-de-sac of Douglas and universally adherent with the exception of about one square inch of the top part. The lowest portion is apparently the softest part, the easiest to rupture, and in this case a rupture would not have occurred into the broad ligament, but into the peritoneal cavity, remaining separated from the general peritoneal cavity by the adhesions. The pregnancy after rupture would very likely have gone on, the adhesions gradually moving up higher and higher, and the fetus developing in the cul-de-sac of Douglas, gradually pressing higher up, and in this way the woman might have had a good chance of going to full term. I will pass the specimen around without opening it.

The Medical Society of the County of New York.

*Report to the Medical Society of the County of New York of
its Committee on the Abuse of Medical Charity.*
Transmitted May 24, 1897.

Mr. President and Gentlemen:—In accordance with a resolution acted upon at a meeting of this Society held in October last a committee of eleven members was appointed to devise means for the control or correction of the abuse of medical charity now existing in this city. This committee was made up as follows: J. H. Burtenshaw (Chairman), A. B. Ball, Hermann J. Boldt, E. S. Bullock, Henry D. Chapin, Carter S. Cole, Alexander Hadden, William M. Polk, W. Washburn, W. H. Weston, and F. H. Wiggin.

At the first meeting of this committee two steps were decided upon: 1, to ascertain the sentiment of the governing boards of the different dispensaries regarding the proposed effort to check indiscriminate dispensing of medical aid, and 2, to communicate with the Charity Organization Society of the City of New York with the object of ascertaining if a system might be devised whereby the worthiness of applicants for dispensary treatment might be investigated and reported, and if its coöperation might be relied upon to this end.

As a result of the last named resolution the fact was made known that the Charity Organization Society would willingly coöperate with this Society along the lines proposed, and that it would place its general offices and staff of assistants at the service of the County Medical Society free of cost, provided the extra expense attendant upon the proposed investigations was met by contributions from other sources.

In order to determine to what extent the coöperation of the dispensaries might be relied upon a copy of the following letter was sent to the president, secretary or physician in charge of each of the ninety-five dispensaries located in this city.

[COPY.]

NEW YORK, Feb. 13, 1897.

Dear Sir:—The committee recently appointed by the Medical Society of the County of New York to devise means to correct the abuses of medical charity now existing in this city, respectfully asks for answers from you, in your official capacity as an officer of one of the free medical dispensaries, to the subjoined questions:

1. Does the governing board of the Dispensary approve of the movement to abolish or regulate the abuse of medical charity?

2. Will the governing board coöperate with the committee of the Medical Society of the County of New York and endeavor to dispense free medical treatment only to those applicants that are deserving and unable to pay a physician for such services?

3. Will the governing board agree, at such time as called upon, to display in conspicuous places in the Dispensary a placard reading somewhat as follows: "On and after [date] the case of every patient applying for free medical treatment at this Dispensary will be investigated, to determine if the applicant is deserving of free medical service," provided such agreement is not to be construed as binding the Dispensary to make such investigations on its own account?.

[Signed] On behalf of _____ Dispensary.

Replies to this letter have been received from seventy-six dispensaries. Of the nineteen dispensaries ignoring the first circular letter, and a duplicate sent out on the April 1, five are homeopathic, two are under the supervision of the Department of Charities, and the remaining five are either private or church institutions at which but a small number of patients living in the immediate vicinity are treated. These replies were affirmative, or conditionally affirmative, to all three questions, with the exception of those received from the Dispensary of St. Mary's Free Hospital for Children, located at 435 and 437 Ninth Avenue, and the Out-Patient Department of the New York Hospital, 21 West 15th Street.

The Dispensary of St. Mary's Free Hospital for Children treated 7,101 patients during the year 1896, and during the same time the Out-Patient Department of the New York Hospital treated 9,803 new patients, who made 45,838 visits to the dispensary, a majority, it is understood, being required to pay one dollar per month for the treatment received regardless of financial condition.

At a succeeding meeting of your committee it was made known that a committee having in view the same object as its own had been appointed by the County Medical Association, and that an organization known as the New York Medical Society for the advancement of the Practice of Medicine had been formed and on March 22 had caused to be introduced in the Legislature of the State a bill embodying certain reforms in the management of dispensaries in this city. It was the opinion of your committee that certain features of this bill were of too radical a nature to allow of its becoming a law at the present time; that any enactment designed for the control of dispensaries should apply to the entire State rather than to the City of New York alone; that, in the former case, the supervision and control of dispensaries should be placed in the hands of the State Board of Charities; and finally, that as far as practicable, the efforts of the different committees formed for the same purpose should be directed along the same lines. Your committee feels that great credit is due the members of the New York Society for the Advancement of the Practice of Medicine and the members of the committee of the County Medical Association for their efforts toward the control of the charity abuse and thanks for their hearty coöperations with your committee toward this end.

The bill introduced in the Legislature by the first named organization was ultimately amended so that its provisions read as follows:

SECTION 1. By this act a dispensary is defined to be any institution, agency or place, society or association whose actual or alleged purpose it is to furnish gratuitously or at a nominal price to indigent, needy or other persons not resident therein, medical or surgical relief, advice or treatment, medicine or orthopedic or other appliances.

SEC. 2. On or after the first day of October, 1897, it shall not be lawful for any one to establish, conduct or manage at any place in this State a dispensary not duly incorporated as such under the laws of this State, or not connected with another corporation and licensed by the laws of the State Board of Charities.

SEC. 3. In no case shall a dispensary be established, carried on or conducted in any place in this State commonly known as a drug store, nor in any place or building in the

State defined by law or by an ordinance of a board of health as a tenement house.

SEC. 4. It shall not be lawful for any person or persons to display the word "dispensary" or to cause the same to be published in any form or in any manner in order to attract any indigent, needy or other person to any dispensary not duly incorporated or licensed as provided in Section 2 of this act.

SEC. 5. Any person who shall by means of any wilful false representation on his or her part obtain at any dispensary medical or surgical relief, advice or treatment, medicines or orthopedic or other appliances, or any person who shall wilfully violate any of the provisions of this act shall be guilty of a misdemeanor, and upon conviction shall be required to pay a fine of not less than \$50 nor more than \$250.

SEC. 6. The State Board of Charities is hereby empowered to make rules and regulations and to alter and amend the same when in its opinion necessary, in accordance with which indigent, needy or other persons shall be given medical or surgical relief, advice or treatment, medicines and orthopedic or other like appliances by such duly incorporated or licensed dispensaries, and the said Board is empowered, a chance for a hearing having been given, to annul the corporation or suspend the operations or to revoke the license of any dispensary for wilful neglect or failure on the part of its managers, trustees, officers or employes to comply with the rules and regulations so established by said Board, but nothing in this act contained shall be considered to mean that said Board shall have power to determine the particular school of medicine under which the dispensary shall be conducted.

SEC. 7. All acts or parts of acts inconsistent with the provisions of this act are hereby repealed.

SEC. 8. This act shall take effect on the first day of October, 1897.

This bill has passed without a dissenting vote by both Senate and Assembly on April 14, last, but up to the present time has not received the signature of the Governor. This fact is peculiarly unfortunate as, according to the law of the State, all bills that do not receive the approval of the Governor within thirty days of the adjournment of the Legislature, lapse and become void, and in the present instance this time limit expires at twelve o'clock tonight. This failure on the part of the Governor to approve the bill can perhaps be attributed only to the pressure of official business, as at the date of adjournment of the Legislature on April 24, there were more than 700 enactments awaiting his signature.

The president of this society, your committee, the president of the County Medical Association and the members of its committee and the members of the Society for the Advancement of the Practice of Medicine have thoroughly appreciated the importance of this bill and the necessity of its becoming a law, and every influence at their command has been brought to bear toward this end. As no opposition was made to the passage of the bill in either branch of the Legislature, and as the profession, not only in this city but throughout the State, is practically unanimous in commending its main features, the sense of disappointment is the more keen at the failure of the Governor to stamp the measure with the seal of his approval.

In anticipation of the bill being signed, the State Board of Charities, at a meeting held April 14, last, appointed a committee of three of its members to hold public meetings immediately after the bill became a law for the purpose of receiving suggestions regarding the promulgation of rules for the management of dispensaries, and it was the intention of your committee to ask for authority from this Society to represent it before that body. In view of the failure of the Dispensaries Bill to become a law, your committee is in a position only to recommend that the Committee on the Abuse of Medical Charity be continued indefinitely, and that it be empowered to take such steps as may appear to it advisable toward obtaining future legislation in the direction of correcting or controlling the medical charity abuse.

* * * * *

In conclusion, your committee expresses the conviction that there is no species of charity so beneficent, so far-reaching or so generously bestowed as true medical charity, and that nothing could be further removed from its wish than that it should be curtailed or kept from the reach of the deserving poor; but it has been so conclusively demonstrated that there exists such gross and unpardonable abuse of that charity on the part of those who are not entitled to it that it has become imperative to adopt radical measures for the suppression of that abuse and at once.

Respectfully submitted,

[Signed] JAMES HAWLEY BURTENSHAW, Chairman.

EARL SPRAGUE BULLOCK, Secretary.

Committee: H. J. Boldt, Henry D. Chapin, F. H. Wiggin, A. B. Ball, W. M. Polk, Alexander Hadden, Carter S. Cole, W. Washburn, W. H. Weston.

PRACTICAL NOTES.

Uterine Fibroma.—It is a familiar fact that fibrous tumors of the uterus sometimes grow in size during pregnancy and then decrease, afterward undergoing an involution similar to that of the uterus, especially if the woman nurses her child a long while. Howitz of Copenhagen draws the conclusion that pregnancy and prolonged nursing should be recommended to patients suffering with fibromas of the uterus. As pregnancy under these circumstances, however, is not devoid of danger, he proposes to substitute artificial stimulation of the mammary secretion by aspirations of the nipples morning and night, for five to ten minutes. Three cases thus treated have found the fibroma diminish in volume, in others there has not been any perceptible change, but the period of treatment has been too brief to be conclusive. Milk appeared in abundance in one case, and in four others after one or two months of the aspirations. He states that he has seen more than once a flow of milk, even in a virgin, the day after interuterine injections, which shows the close connection between the uterus and the mammary glands.—*Ann. de Policl. de Toulouse*, February.

Treatment of Fractures with Massage Exclusively.—Woolsey's prognostications of the future of this method of treatment (see the *JOURNAL*, May 1) are strikingly confirmed by the remarkable results obtained by Lucas-Championnière in fractures of the clavicle treated exclusively with massage, as shown by four men he exhibited recently at the Académie de Médecine (*Bulletin*, April 6), who could move their arms in every direction without pain, on the eighteenth, nineteenth and thirtieth days respectively. All were serious fractures from falling from a bicycle going at full speed, etc. A light sling had been used to rest the arm for a few days. One, a mechanic, had been able almost from the very first to resume his work. The pain disappears very rapidly with the massage, and the bone is solid at a period when no one would venture to look for solidification with the usual treatment. The formation of the callous is at least as rapid, if not more so, than with an immobilized bone. The perfect suppleness of the region, the normal play of all the muscles of the arm and shoulder, and the final absence of riding, important in the rare female cases, leads him to recommend the method to all. He has now an experience of thirty-one fractures of the clavicle thus treated, and states that even before the solidification is complete, the patient can wait upon himself and continue his daily occupation to a certain extent without difficulty.

Sympathetic Amblyopia.—Besides iridocyclitis and optic neuritis, there is another sympathetic complication of injuries to one eye, which may possess legal importance and yet be mistaken by many practitioners. Professor Nuel has observed sixteen cases of it in his practice in an industrial town where injuries from flying scraps of metal are frequent. It is a severe affection, tending to blindness, but has always yielded readily to appropriate treatment. The noticeable points are its tardy manifestation and the absence of ophthalmoscopic signs. It may not appear until six months or a year, or even two, after the original accident. The sight varies from good to bad, at intervals; there is sometimes frontal or temporal pain, and a heavy feeling in the head, while the visual acuity is reduced. After a while these symptoms pass away and the sight seems normal, but the improvement is only transient and the amblyopia continues its progress. Slowly the sight is decreased to 5-36 or 5-60 by the end of a year or so; sometimes the patient can only count fingers at a meter or less. The maximal restriction of the field of vision was 10 to 15 degrees in his cases, and he has never seen amaurosis ensue. By the end of two years the optic nerve is more or less atrophied and sclerosed, but the ophthalmoscopic degenerations are very secondary and tardy. Mercurial frictions and smoked glasses, with functional rest, produce great improvement, but the industrial capacity of the patient is diminished and possibly abolished. The sight may still be good, but close application may bring on absolute blindness. The possibility of this affection should therefore be borne in mind by the medical adviser, as the damages from the primary accident may have long been settled before it appears.—*Ann. de la Soc. Méd. Chir. de Liège*, January.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the Association living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JUNE 5, 1897.

MEDICAL EDUCATION.

A strong impression exists among many persons that medical teaching and education today is most faulty and imperfect; also that the great universities of this country and Europe have reached a degree of perfection that would make them models for all educators.

Many persons are convinced that only a classic training in the university colleges can properly fit a man for the study of medicine. Now we are told by the deans of some of these colleges, that their system of training is very imperfect and crude in its methods; also that they are anxiously looking around for improvements and trying to break away from the prestige and old-time forms of teaching.

There is something very refreshing in this awakening of educators in the higher centers of learning. The dogmatic egotism which has centered around some of the great universities of this country is lifting and we begin to realize that educational methods in its highest forms are still very crude. While medical training and the standards of medical colleges are very far from the ideals which have been marked out, there is a restless movement and struggle upward which promises much for the future.

The literary colleges and great universities still more are apathetic and the same studies are taught in the same way as half a century ago. Science schools and new departments of learning must of course go on

without prestige and follow new lines of presentation, but even here the obvious imperfections of teaching methods are clearly recognized. The medical men who urge so strenuously that a classic training in a literary college is an absolute essential as a foundation for a medical training are very often good examples of the folly of such training. Men with literary degrees from the best colleges are very often poor, weak medical men. The prize and honor men of the great literary colleges are rarely heard of in after-life in any department of human activity. Literally the high classic training demanded as a requisite to enter upon the study of medicine is often a most serious obstacle to all future success. This is clear in the fatal egotism of the college graduate, who has been taught that his studies of the languages has raised him above the level of others and made success a greater certainty in any direction. Where this follows, in all after-life he is crippled and fails to attain the level of a student and original worker.

The fault is in the college methods, they have literally unfitted the man for close, hard work and broad reasoning. They have cultivated a strong personal bias in his capacity and superiority that is fatal to good work afterward.

Fortunately this does not occur in all cases. Many college graduates rise above the narrowness of so-called culture and make a culture and acquire an independent knowledge for themselves.

We do not wish to discourage a thorough preliminary training before entering upon the study of medicine; but the idea that a degree from any college is evidence of such training is not true in many cases. While the medical colleges are extending their courses and requiring more thorough preparation before entering, they can not reach the end sought for in a thoroughly educated profession by accepting the diplomas of colleges without question or examination. While we all recognize that graduates of the leading medical colleges may be very scantily equipped for the practice of medicine, it is a notorious fact that men with diplomas from the most famous institutions in this country are often very weak and uncultured. This is true the world over, the English or German student who has spent ten or more years at the great seats of learning may not have acquired the first principles of culture.

Evidently a great revolution is beginning in this direction, from the common school up to the highest universities and technical colleges. Men must be trained up to do the work along the lines of natural adaptability and not trained down opposed by constitutional and physiologic conditions of the organism. A leading college president said, "We are constantly making the mistake of training men out of their natural capacities, teaching them facts that are useless rubbish in all after life." The idea can not be repeated

too often, that no training can make a medical man who has not some constitutional adaptability and tact for the work. No colleges can graduate educated, cultivated men by the present indiscriminate methods applied to all, without regard to ability or personality. What will be required in the future will be some test of the character and capacity of the student for the life-work he would engage in; then training becomes exact and development and culture positive and certain.

IDIOT SAVANTS, ARTISTS AND MUSICIANS.

One of the prominent features of the co-eval discussion of the relation of genius to degeneracy is the discovery of idiot savants, artists and musicians. These result from the phenomenon of degeneracy removing that check on expression of ideas which results from timidity and also checks which have existed on the expression of "unconsciously assimilated" ideas. In ordinary life, as well as to a less extent among the idiots and insane, much is unconsciously assimilated by the mind, but remains without association with the daily life of the assimilator. Dr. LANGDON DOWN (*Alienist and Neurologist*, Vol. viii) applies the term "idiot savants" to children who, while feeble-minded, exhibit special faculties which are capable of being cultivated to a very great extent. One youth was under DOWN's care who could build exquisite model ships from drawings, and carve with a great deal of skill, yet could not understand a sentence, had to have his food cut up for him and when writing to his mother, copied verbatim a letter from "The Life of Captain HEDLEY VICARS," by Miss MARSH, although it had not the slightest appropriateness in word or sentiment. Another under his care could draw in crayons with marvelous skill and feeling but in whom nevertheless there was a comparative blank in all the higher faculties of mind. Extraordinary memory is often met with, associated with very great defect of reasoning power. A boy came under DOWN's observation who, having once read a book, could evermore remember it. He would recite all the answers in "Magnall's Questions" without an error, giving in detail the numbers in the astronomical divisions with the greatest accuracy. This, however, was simply a process of verbal adhesion. DOWN once gave him GIBBON'S "Rise and Fall of the Roman Empire," to read. This he did, but on reading the third page he skipped a line, found out his mistake and retraced his steps. Ever after, when reciting from memory the stately periods of GIBBON, he would on coming to the third page, skip the line, go back and correct the error with as much regularity as if it had been part of the regular text. Later on, his memory for recent reading became less tenacious but his recollection of his earlier readings never failed him. Another boy told the tune, words and number of nearly every hymn in

"Hymns Ancient and Modern." Often memory takes the form of remembering dates and past events. Several children under DOWN's observation have had this faculty in an extraordinary degree. One boy never failed to be able to tell the name and address of every confectioner's shop that he had visited in London, and they had been numerous, and could readily tell the date of each visit. Another could tell the time of arrival of all children at the institution, and could supply accurate records in relation to it if needed. Another knew the home address of every resident who came under his observation and they were by no means few. The faculty of number is usually slightly developed with feeble-minded children, while memory is fairly well developed. There are cases where the power of mental arithmetic existed to an astonishing extent. One boy about twelve years of age who could multiply any three figures by three figures with perfect accuracy, and as quickly as DOWN could write the six figures on paper, yet so low mentally was he that although having been for two and a half years in the almost daily habit of seeing and talking to DOWN he could not tell his name. Another boy under DOWN's observation could multiply two figures by two figures and a short time since could multiply three figures by three figures, but, since an epileptiform attack, has lost this faculty to some extent. None of them can explain how they do it. When by rare chances they have made a mistake and some hesitation has arisen the plan has been to clear off the multiplication of the higher figures, first.

Improvisation is an occasional faculty. A boy under DOWN's care who could take up a book, pretending to read, an art he had not acquired, and improvise stories of all kinds with a great deal of skill and in variety to suit the supposed tastes of his author. Memory of tune is a very common faculty among the feeble minded; they readily acquire simple airs and rarely forget them. One boy if he went to an opera would carry away a recollection of all the airs and would hum or sing them correctly. In none of his cases of "idiot savants" has DOWN been able to trace any history of a like faculty in the parents or in the brothers and sisters. He has had an opportunity of making a necropsy only in one instance. This was in the case of a boy who had a very unusual faculty, the perfect appreciation of past or passing time. He was 17 years of age, and although not understanding, could gather the use of a clock face, could tell the time to a minute at any part of the day and in any situation. Although DOWN tried him on numberless occasions he always answered with an amount of precision truly remarkable. Gradually his response became less ready. His health became enfeebled and the faculty departed. On necropsy DOWN found that there was no difference in the cerebrum from an ordinary brain except that he had two well-marked and

distinct soft commissures. All these cases of "idiot savants" were males. DOWN has never met with a female. The most remarkable instance of the idiot musician in the United States is that of "Blind Tom," who is now about 60 years of age and who, like the cases mentioned by LANGDON DOWN, could play from memory any tune or modification of a tune which he had once heard. After making thousands of dollars for the master who once owned him, he was placed under a conservator, the daughter-in-law of his owner. When placed under her charge he was practically penniless, despite the hundreds of thousands of dollars he had earned in a quarter of a century's musical work for his master. In a few years after being placed under guardianship, sufficient money was obtained to warrant the temporary withdrawal of "Blind Tom" from the amusement world, so that he might recuperate his health and at the same time familiarize himself with modern musical composition.

Tom enjoys his long rest after so many years of incessant travel and work. He does very little visiting among his neighbors and receives few callers at his cottage. He passes hours at a time at the piano playing his old pieces and practicing new ones. Occasionally he attempts improvisation, but even then the imitative faculty predominates, as the notes he picks out are usually the reproduction of sounds that he has heard.

When not at the piano, Tom amuses himself by imitating the small talk of ladies and other visitors, to which he is a silent listener. He holds imaginary receptions at which the weather, new styles in dresses and like topics are discussed by the imaginary visitors, as imitated by Tom, in a way that is very comical. This he will not do if he knows there is any one listening to him. In spite of his advanced years and his reserved, formal demeanor in company, Tom is merely an overgrown child and has to be carefully watched by the male nurse especially hired for that purpose. He has all the selfishness of a spoiled child and is jealous of any attention paid to any one else in his presence. He has little natural affection and cares only for those around him who minister directly to his wants. He is willing that his mother should be taken care of out of the money he has earned, but he does not wish to have her or his brothers and sisters near him, for fear that they may annoy him or prevent his being the sole object of attention to those around him. With the exception of this child-like selfishness, "Blind Tom" is extremely religious in his habits and disposition. He never eats without first offering prayer, and on Sundays will play only church music on his piano. Soon after Tom was placed under guardianship, his mother met him for the first time since his infancy, but after the novelty of the reunion had passed away, it was evident that their tastes and temperaments were so utterly antagonistic

that there was little hope of their living happily together.

Art and music were very early acquirements of the race, hence it is not astonishing that atavistic returns to soundness in the idiot, imbecile, paranoiac and degenerate should take these particular directions.

THE CRIMINAL RESPONSIBILITY OF THE INSANE.

The legal standard of responsibility given in the famous answer of the judges to the House of Lords in connection with the celebrated MCNAUGHTON case which still stands in the laws of England and many at least of its dependencies, and which has been to a certain extent adopted in this country, has always from the first had the disapproval of competent alienists, those who of all men, are best qualified to estimate the responsibility of the mentally defective. They have used every argument against it, have proved that it is a false criterion in almost every possible way, have shown clinically and pathologically its incorrectness, but have not as yet been able to thoroughly eradicate the belief in its validity from the legal mind. Even in this country where we are in no way bound legally by this utterance, given out at a time of great popular excitement comparable to that which existed while the GUILTEAU trial was in progress, judges still charge juries and juries convict lunatics on the ground that knowing the nature of their acts they are responsible and fit subjects for the fullest punishment the law allows for their crimes. That this is not done universally in England, that judges often evade the doctrine, and where they do not do this juries sometimes "take the bit in their teeth," as an English magistrate has expressed it, and acquit a lunatic against the judicial charge and interpretation of the law, is a sign that the world does move in spite of legal conservatism. It is not an equally good indication that the English doctrine should have here the weight it so often seems to have, and that this irrational barbarism, in spite of many better precedents still enters to any extent whatever into our judge-made laws.

In Canada, where the principle of the answer of the judges is incorporated into the criminal code, they are worse off than we, and judicial murders would seem to be legally necessitated in a large proportion of the cases where lunatics are tried for capital offenses. In view of this condition of affairs, and seeing the hopelessness of ordinary argument or theoretical demonstrations in amending the situation, one of the leading asylum superintendents, Dr. R. M. BUCKE, in his late annual report, gives the result of a careful canvass of the capacity for moral judgments of the inmates of a large asylum, with special reference to their legal responsibility under the Canadian law. He finds, and there is no reason to doubt his ability to correctly estimate their capacity for moral judgments, that out

of a total number of 1,034 inmates of the London Asylum no less than 763 were perfectly capable of realizing and appreciating such an act as homicide in its moral and legal relations. Of the remaining 271 inmates 121 were intellectually able to express an opinion but were apparently morally obtuse and disclaimed any repulsion to the act or knowledge of its wrongfulness. Only 150 out of the whole number were unable on account of their mental condition to intelligently answer the questions or give any index to their moral perceptions.

In other words, nearly three-quarters of all the inmates of the asylum were responsible and fit subjects for capital punishment under the criminal law as it exists today in Canada. At the same time, as asylum inmates they were civilly incapacitated from making the most unimportant valid contract, criminally responsible and civilly irresponsible, a paradox that seems to give no solicitude to Canadian lawmakers and lawyers. It is true as, Dr. BUCKE admits, that the fact itself of their being inmates of an insane asylum would be taken as *prima facie* evidence of their irresponsibility and that an asylum inmate would not suffer the penalties of the law for criminal acts committed as such, whatever might be his status under the strict wording of the code. But he points out the fact that there are many just as insane outside of the public institutions, and that the mere fact of having been thus sequestered or otherwise, does not morally and should not legally affect the question when insanity actually exists. As an instance of the working of the Canadian law, Dr. BUCKE refers to a recent case where the prisoner was not merely proven insane, but was a recognized imbecile, but the fact that he was capable of appreciating the wrongfulness of the act he had done according to the judgment of the court and jury insured his conviction and sentence. As a similar instance in this country, and a very prominent one, the conviction and execution of the imbecile paranoiac, PRENDERGAST, may be cited; but in his case, as in that of GUITEAU, the popular excitement and temper must be held largely responsible for the result, not the requirements of the law. In Canada, it would appear, three-quarters of the acknowledged lunatics are legally capable of suffering capital punishment and are liable to it, at least when not actually asylum inmates.

It is a curious fact, and one that shows the irrational nature of the distinctions made by the English judges that according to it the morally insane, the most dubious and dangerous of all lunatics, could legally escape the penalties of the law, in being incapable of appreciating moral distinctions and therefore unable to apply any moral judgments whatever as to the nature of their acts. The nearer the lunatic is assimilated to the criminal, by this rule, the less is his criminal responsibility, his pathologic normal obtuseness is his salvation from the law.

Dr. BUCKE has done a real service by his statistical contribution to the question of the moral capacity and responsibility of the insane. His facts, of course, are not novel to alienists, but, as stated they have the advantage of a direct object lesson that ought to have weight and influence with those to whom the only conception of a lunatic is that of a raving maniac or an absolute dement. Without any doubt similar findings could be obtained by a like inquiry by competent observers in any large asylum or hospital for the insane, and considering the need of enlightenment on the part of the public and the legal profession it might be well if such researches were multiplied and published. It would be a good thing also to do away with the legal fiction that there is any real difference between a lunatic in an asylum and one as yet uncommitted, as regards their real responsibility for criminal acts, and might be a step toward the greatly needed recognition of the many dangerous lunatics at large.

THE CORPUS DELICTI IN MEDICAL JURISPRUDENCE.

The LUETGERT case recently under investigation in Chicago has once more raised the question of the absolute necessity of proof of commission of a homicide or of finding of a dead body ere conviction of murder should occur. Even two centuries ago so many judicial murders had been committed because of neglect of precautions on the part of the prosecution as to evidence of a homicide or as to the existence of a dead body obviously the victim of homicide, that Chief Justice HALE (2 Hale P. C. 290) remarked that he "would never convict any person of murder or manslaughter unless the fact were proved to be done or at least the body found dead." Two very striking cases of this kind have occurred in the United States, one in Vermont and the other in Illinois. In the last, ABRAHAM LINCOLN was the attorney for the defense. The Vermont case was as follows (WHARTON and STILLÉ, "Medical Jurisprudence" Vol. I., p. 79 a): Two brothers, named BOORN, had an altercation with a brother-in-law, named COLVIN, an errand lunatic. He fled to New Jersey. Several years afterward suspicion was excited by a dream of an uncle of the supposed murderers. In this dream he was told that COLVIN had been murdered and that his remains would be found in a spot that was pointed out. The dream was repeated three times, until at last the place was searched and some articles of clothing were found which were identified as COLVIN'S. Then a spaniel, connected in some way with the COLVIN family, was seen snuffing uneasily about the spot close by, calling attention to it by his importunities. It, too, was examined, and a cluster of bones were drawn up by the dog's paw. That these were COLVIN'S and that these almost miraculous interpositions were designed to bring the murder out, there were none in the com-

munity who doubted. Other circumstances led to the arrest of the BOORNS. They were conscious of guilt, and it is no wonder that these prosecutors, who after so long an interval had united by means so extraordinary to ferret out their guilt should have impressed them with the belief that it was vain to fight against what seemed to be divine vengeance. So one of them confessed an assault, and went on further to state how in order to evade detection, the body had been partially burned and the clothes destroyed. The first part of the story was true; the last was a fabrication, the result either of delusion, or of desperation, or of that impulse to complete a story with which the imagination is sometimes seized. That the actual death was indeed false was shown by the subsequent appearance of COLVIN himself in time to intercept the execution of at least one of his supposed murderers. In this case prosecution and "expert" evidence played a part. The bones were examined by irregular "physicians" who declared them human. One physician, however, thought otherwise and was able to demonstrate his position. The bones were in a degree pulverized, but some pieces were in a tolerable state of preservation. Suspicions were excited that the body was burned and some parts not consumed cast into the stump, and other bones put among them for deception. Some time after the departure of COLVIN a barn belonging to Mr. BARNA BOORN was accidentally consumed by fire. It was conjectured that the body was taken up and concealed under the barn and mostly consumed. About that time a log-heap was burned by the BOORNS, near the place where the body was supposed to be deposited; it was thought by some that it was consumed there.

Of the Illinois case LINCOLN gives a decidedly humorous account in a letter to SPEED (LAMONT'S Life of ABRAHAM LINCOLN). The case occurred in 1841. Three brothers named TRAILOR were arrested on the charge of murdering a man named FISHER, who, when last seen, had been in their company. Strong circumstantial evidence was adduced, inclusive of the testimony of an "expert," as to human hair cut from whiskers in a struggle, at a spot where other evidences were found and where the crime was alleged to have been committed. The case was fortified (WHARTON and STILLÉ) by expressions alleged to have been subsequently used by one of the brothers as to his having become a legatee of the deceased. The examination had scarcely been finished before one of the defendants made a confession detailing circumstantially the whole transaction showing the previous combination and ending with a direct statement under oath of the homicide. The defense produced Dr. MERRYMAN, who swore that he had treated the victim of the homicide for insanity due to traumatism, that he was given to wandering tendencies consequent on this insanity and that he had been under observation two

days subsequent to the date of the alleged homicide and that he would shortly be produced before the investigating justice. To the astonishment of the whole country, however, the "deceased" made his appearance in just time enough to intercept a conviction. The only way of accounting for the confession which had been produced was, that the party who made it, in the desperation of impending conviction, took this method of cutting short suspense. In view of the practically unanimous testimony of the medical experts for both prosecution and defense in the CRONIN case it seems a little absurd at this date to claim that from the casual observation of a few hairs and a few stains that human blood and human hair can be identified beyond a doubt. The elements of error in such investigations were so thoroughly outlined by the medical experts on both sides that it would only be a simple precaution for the prosecution to avoid them at the outset of a criminal case, lest criminals evade justice through the difficulty of proving unjustifiably strong counts in an indictment. Such counts endanger on the one hand the innocent, while in the resulting reaction they tend to protect the guilty. In view of the admittedly large number of judicial murders due to the absence of a dead body or corpus delicti the greatest possible use of the fundamental legal principle of the presumption of innocence (which requires that all circumstances which can be interpreted in accordance with innocence should be so interpreted) should be made. The function of the medical expert here is not to play the detective, but, as elsewhere, to determine scientific truth. This is his duty both as a physician and as a law-abiding citizen.

CORRESPONDENCE.

Foreign Patented Articles.

NEW YORK, May 25, 1897.

To the Editor:—Our attention was recently called to a letter, which appeared in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of March 13, 1897, signed "An American Manufacturer." Since the writer of that letter relates to foreign products which are protected by United States patent, and of which we, ourselves, control a few, we would state that the notice is not only misleading but also an offence to respectable firms. We can not believe that any of the large chemical houses of Germany act in the manner stated in your journal, i.e., "make their own statements and attribute them to some doctor with a foreign name." As far as patents are concerned, would say that comparatively very few chemical products are patentable, since a distinct new result must be shown, and this is not an easy matter. Of all the so-called patent medicines, very few are really patented, but they are supposed to be, and mostly are of unknown and secret composition. The manufacturer who wrote the article in question is evidently preparing mechanical mixtures and is unable to produce scientific chemical compounds. Protection by patenting involves disclosure of their composition and this is the last thing their proprietors would think of. It is such secrecy that is opposed to every fundamental principle of medical ethics. Every scientific chemical product that is patented is protected only for seventeen

years and after the elapse of that time any one can prepare it, since in the patent a plain and reliable method of making the products must be given, or else the patent is worthless. In this connection, we would state that we have introduced many years ago salicylic acid and chloral hydrate, the patents of which have expired, and now every one has the right to make the same, but these articles are at the present time so much reduced in price that it would not pay any one to start a new factory for the same.

You will see from the above that the term patent is grossly misapplied in the case of anything secret. A thing patented is a thing divulged.

Many of the American manufacturers of pharmaceuticals, etc., coin a new word for their preparation, and if they do not have it registered as a trade mark, they know that they are protected under the common law forever, hence a trade mark really affords much longer protection than a patent.

In a leading article entitled, "The Ethics and Economics of Proprietary Preparations," published in the *New York Medical Journal* of May 22, 1897, the views of Dr. Charles Rice, member of the committee of revision of the United States Pharmacopoeia, are clearly defined, respecting patents for scientific chemical products and secret nostrums. Dr. Rice says:

"A patent not only does away with all secrecy, which is usually considered the objectionable feature of a proprietary article, but it commonly acts also as a sort of guarantee of the uniformity of the product in composition, strength and purity." All of our chemicals are of known composition and properties, hence there is no secret whatever about them.

We remain, yours truly, SCHERING & GLATZ.

Some Untoward Effects from Trional.

MEMPHIS, TENN., May 24, 1897.

To the Editor:—Some months ago a patient of mine took a dose of 20 grains of trional at 10 P.M., for insomnia with peculiar results cited below.

Shortly after having taken it he went to sleep and did not awaken until he was aroused the next morning for breakfast. Not feeling very well, he had a cup of coffee brought to his bed. After a short while he arose and went to his office, but feeling very bad he returned home about 10:30 A.M. and again lay down and went to sleep. On being aroused for dinner by the servant, his wife being away, he responded that he would be down in a few minutes, but instead he went to his club for dinner.

While at the club he must have felt ill as he went into the lounging room and slept until 7:30 P.M., when he was awakened by a porter.

He felt completely dazed and as if he had awakened from a horrible dream. It was some time before he could collect himself and realize that he was at the club. He was very much surprised to find himself there, as he had absolutely no recollection of having gone there, or eaten dinner or slept there. His mind was a blank from the time he returned from his office in the morning at 10:30 A.M. until 7:30 P.M., having remembered nothing he had done during that time and reporting this effect from hearsay. During this time he met several friends who say he talked and acted rationally, but complained of a severe headache.

I report this case, as it was of much interest to me, inasmuch as I have always held that many of these hypnotics are given too freely and that there is a certain amount of danger connected with all of them.

K. B. HERMAN, M.D.

PUBLIC HEALTH.

Progress of the Bubonic Plague.—A report from Paris, May 10, is to the effect that the Tonkin officials on the Chinese frontier

and just within the boundaries of the colony, have discovered several cases of the plague. Special precautions have been taken.

Rations for Shipwrecked Mariners, Etc.—Langlois, chief of the Phys. Lab. of the Paris Faculté de Méd., comments on the terrible sufferings and insanity of the shipwrecked crew of the *Saint Nazaire* (who had six hours for their preparations before abandoning the ship), by urging a reform in the boats carried on board ship. Something is radically wrong, he states, when these boats are swamped and destroyed the moment they touch the water, as so often happens. He suggests the following ration for such cases, combining the maximum of calories utilized with the minimum of bulk: Dutch cheese (100 grams = 350 calories utilized); sugar (60 grams = 200 c.u.); crackers (600 grams = 1000 c.u.); meat and fish pastes (300 grams = 600 c.u.) with sardines, etc., as convenient, and especially condensed milk (100 grams = 350 calories utilized), which makes a very nutritious and palatable drink diluted with sea water, as salt improves it for most persons. Two pounds apiece of this ration, or a total of half a ton for twenty-five men, would be ample to sustain life and enable the crew to resist cold and exposure for ten days, with a half ton of water. The boats should be built to carry this amount and protect it from the elements. He disapproves theoretically of alcohol, but adds that the moral effect of a little wine or diluted brandy should not be ignored.—*Presse Méd.*, April 17.

SOCIETY NEWS.

Twelfth International Medical Congress.—The following is the program of the proceedings of Section on Laryngeal and Nasal Diseases:

1. Suppurations of the Nasal Accessory Sinuses (except the maxillary), their diagnosis and treatment, Dr. E. Moure, Bordeaux; Dr. M. Hajek, Vienna.
2. Cancer of the Larynx, its diagnosis and treatment, Prof. O. Chiari, Vienna; Dr. G. Catti, Fiume.
3. The Causes and Treatment of Loss of Voice in Singers, Prof. H. Krause, Berlin; Dr. M. Lermoyez, Paris.
4. The Progress Made in the Treatment of Laryngeal Tuberculosis since the Last International Congress, Dr. Ruault, Paris; Dr. J. W. Gleitsmann, New York.
5. Laryngo-Stroboscopy, Prof. Simanowsky, St. Petersburg.
6. The Use of the X-rays in Laryngo-Rhinology, Dr. I. Macintyre, Glasgow; Dr. Mount-Bleyer, New York.
7. Esophagoscopy, Prof. V. Hacker, Innsbruck.
8. The Adaptation of Photography to Laryngology, Dr. I. R. French, Brooklyn; Dr. Flatau, Berlin.

Besides the above it is proposed to arrange a joint meeting with the other Sections on the question of Serum Treatment of Diphtheria.

The committee ventures to hope that you will consent to communicate the results of your observations and investigations as regards the subjects mentioned above as well as any other subjects pertaining to our special branch.

We beg you to furnish us, not later than June 1 (No. 8) with the titles of your intended communications with a detailed résumé of their contents, in order that both may be got out of the printer's hands in good time.

We remain, sir, yours respectfully,

E. STEPANOFF.

A. BELAYEFF.

Congress of the Surgeons of Germany.—The twenty-sixth annual congress was held at Berlin in April. The first address was from the standpoint of internal medicine—a delicate compliment from the surgeon to the physician—v. Leube spoke from an experience of over a thousand cases in the last ten years on the "Surgical Treatment of Ulcer of the Stomach." His treatment is absolute repose for ten days, with cataplasms on the epigastric region, as hot as possible, renewed every ten to fifteen minutes and replaced at night and after the first ten days with Priesnitz compresses. He first covers the skin with a compress of boricated vaselin to prevent blistering, over which the cataplasms are applied. They are continued until five days have passed without pain. A quarter of a

liter of tepid Carlsbad water is given at the same time, not hot, with some effervescent mineral water as a beverage. He rejects opium and prescribes nothing but small doses of sodium bicarbonate, especially at first. Milk, concentrated bouillon and a few crackers are all the food he allows during the first ten days. After this, relative repose, with eggs and a gradual return to the usual diet by the ninth week. He reports with this treatment of 556 cases, 75 per cent. completely cured, marked improvement in 21 per cent. and a mortality of 2.2 per cent., or 12 deaths in all, six of which were the result of perforation, and the others of hemorrhage. Surgical treatment is demanded when internal medication fails, and the patient's life is in danger, especially when there is constantly recurring slight hemorrhage, which leads almost certainly to anemia and death. Violent hemorrhage is a relative indication, as in some cases it seems to be the precursor of recovery, while in others death ensues before an operation is possible. In locating the ulcer for an operation the pain is very deceptive. Violent pains and persistent vomiting he ascribes to an imperfectly healed ulcer, and instead of an operation advises recommencing the course of medical treatment, with rectal alimentation if necessary. If this fails he recommends gastro-enterostomy. Perigastritis is the third indication for operating, but he ascribes these adherences and scattered abscesses to a still persisting ulcer, which should be cured if possible before resorting to an operation. Perforation, subdiaphragmatic abscess and the presence of a tumor formed by the thickened gastric wall and its adherences to the abdominal wall, are all indications for immediate operation, which statistics show is successful in 25 per cent. of the cases.

Mikulicz, the "corapporteur," mentioned that the average mortality from gastric ulcer is from 13 to 50 per cent., much higher than Leube's figures. He stated that the results obtained in Billroth's clinic, Czerny's and his own, with resection of the stomach, gastro-enterostomy and pyloroplasty were before 1891, a mortality of 39.3 per cent. with the first; 43.5 per cent. with the second, and 23.8 per cent. with the third. Since 1891 the mortality with resection has been 27.8 per cent., with gastro-enterostomy, 16 per cent.; and with pyloroplasty, 13.2 per cent. These figures should encourage surgeons to operate cases that resist medical treatment. His own observations have convinced him that gastric ulcers can be cured by restoring the permeability of the pylorus, whether the stenosis of the pyloric stenosis is of a cicatricial or spasmodic character. He is even tempted to accept the theory that the pathologic syndrome of simple ulcer of the stomach is due solely to the stricture of the pylorus. Circular resection should be reserved exclusively for cancer. He used to prefer gastro-enterostomy to pyloro-plasty, but now he prefers the latter, unless it is counter-indicated by adherences or much thickening of the gastric wall. If gastro-enterostomy is selected, it should be completed with an entero-anastomosis between the two ends of the intestinal loop, in contact with the gastric wall, in every case when there is reason to fear regurgitation of the contents of the intestines from atony of the walls of the stomach. In operating, the shock should be reduced as much as possible by using the Schleich method of anesthesia, instead of general. Perigastritis requires prompt intervention. He added that epigastric hernia simulates all the symptoms of gastric ulcer, and warned against the deceptive gastralgias of neurasthenic subjects.

Alsberg related a case of ulcer adherent also to the liver, impossible to extirpate, which he enclosed with deep sutures, and a sero-serosa suture with the complete recovery of the patient. Braun also described one case in which the stomach wall was so friable that he could not suture it, but completed the operation successfully by suturing a piece of the omentum over the stomach wall.

Israel, Sonnenburg and König proclaimed the advantages of

large openings into the abdomen, and Lennander stated that if the operating table is warmed, with intravenous injections of salt solution, and ether alone used, there is no need to fear operative shock, while rapid elimination of the noxious matters after perforation is the best means of combatting it. Heidenhahn has abandoned the use of wet compresses around the intestines drawn out during the course of an operation, having found that they caused a decided loss of heat, and now uses dry sterilized compresses exclusively. He always evacuates the fecal matters in such a case through a small incision, and administers a dose of castor oil at once after the operation. He reports 14 recoveries in 30 cases of intestinal occlusion for various causes.

The statistics of anesthetics for the last seven years are 134 deaths in 327,599 narcoses, or 1 in 2,444. With chloroform, 1 death in 2,039; with Billroth's mixed anesthesia (morphin, chloroform and alcohol), 1 in 3,807; with ether, 1 in 5,090; with ethyl bromid, 1 in 5,228; with chloroform and ether combined, 1 in 7,594.

Helferich's address was on, "Surgical Treatment of Hypertrophied Prostate." He stated that in four-fifths of the cases treated with castration, the gland was diminished in size and the subjective symptoms usually disappeared. These results are about the same as the statistics in regard to section of the vas deferens collected by Köhler. He considers these operations indicated in serious cases when catheterism is insufficient, with preference for the latter as more simple and benign, while fully as efficacious. Both he and Socin, who followed his address, consider the hypertrophy of the prostate merely one symptom of a more general affection of the entire genito-urinary system, due possibly to arterio-sclerosis, which should be carefully studied and treated as indicated, before resorting to surgical intervention. Socin classifies these patients as: 1, those without cystitis, with good functions of the bladder. These should have the bladder systematically catheterized and the diet regulated, which frequently puts an end to all the urinary troubles for years; 2, those with a median lobe to the prostate, which requires extirpation by epicystotomy, and 3, those with serious lesions of the bladder. Regular catheterism should be tried first, and if this is not enough, perineal prostaticotomy. While he does not deny that castration or section of the vas deferens can be employed in these cases, he still thinks that the same results can be obtained without operating. Even after these interventions, the bladder is never completely emptied. The prostate grows smaller immediately after the operation, which proves that merely deturgescence of the organ and not atrophy has been attained, and this could have been secured just as well by mere massage of the prostate.

NECROLOGY.

LYMAN MOORE TUTTLE, M.D., Albany, N. Y., 1859, of Holyoke, Mass., died there April 26. He was an assistant surgeon of the 6th Vermont Infantry and served as such until Dec. 26, 1862. As one of the founders of the City Hospital he gave liberally of his time and means until his death. His age was 60 years.

WILLIAM CLINTON THOMPSON, M.D., Ohio Medical College, 1839, and one of the founders of the Indiana State Medical Society, died April 19 in Indianapolis, Iowa, where he had been in practice since 1847.

JOHN F. KIMBLEY, M.D., Jefferson, 1849, died May 24, from apoplexy, at his home in Owensborough, Ky. During the war he served as surgeon of the 11th Kentucky Infantry, U. S. V., for the period of three years, and afterward became a surgeon-general of his residential State.

JOHN J. LOBAUGH, M.D., Farmington, Ill., May 18, aged 68 years.—J. C. Jordan, M.D., Richmond, Va., May 21, aged 61

years.—W. W. Virdin, M.D., Lapidum, Md., May 20, aged 68 years.—Walter A. Boor, M.D., New Castle, Ind., May 24, aged 48 years, at one time a member of the State Medical Society and the AMERICAN MEDICAL ASSOCIATION.—W. S. Schultze, M.D., Louisville, Ky., May 24, aged 35 years.—Anthony Eugene Stoker, M.D., May 23, Philadelphia, aged 76 years. During the civil war he was surgeon on General Meade's staff, and after the close of the war was, for many years, surgeon at the Pennsylvania Hospital, and the Blind Asylum.—L. M. Lochman, M.D., York, Pa., May 21, aged 68 years.—Patrick O'Riley, M.D., Greenville, Pa., May 21, aged 58 years.—F. G. Coffin, M.D., Brockwayville, Pa., May 23, aged 43 years.—George R. Taylor, M.D., Waupaca, Wis., May 26, aged 75 years.—W. T. Aikins, M.D. Toronto, Canada, May 26.

MISCELLANY.

President George M. Sternberg.—As we go to press we are advised of the election of Surgeon-General GEORGE M. STERNBERG, U. S. A., to the presidency of the AMERICAN MEDICAL ASSOCIATION. His record as a surgeon on the battlefield, his rank as a sanitarian and his eminence in bacteriologic investigation, make this selection an admirable one and adds crowning luster to the Golden Jubilee.

The Journal Special Train.—A large number of members of the ASSOCIATION availed themselves of the opportunity to go to the meeting on this train. The officials of the company surpassed all former efforts to provide for the comfort of the travelers, and as a result the equipment was the finest ever run under the auspices of the JOURNAL.

The number was augmented at various points along the line and the trip was made without a hitch. The party arrived in Philadelphia half an hour ahead of the schedule time.

Among those present from Chicago and the northwest were: Frederick Menge, Hugh T. Patrick, T. J. Murray, Christian Jonsson, J. P. Lord and wife, W. C. Wendell, F. C. Greene, J. V. R. Lyman, Wm. H. Mackey, J. W. Chamberlin, E. J. Radcliffe, R. W. Petty, J. F. Fulton, W. S. Cossar, *Chicago Times-Herald*, J. Takamine, J. W. Cokenhour, Wm. Eastman, E. J. Brown and wife, W. A. Jayne, E. S. Antisdale, Liston H. Montgomery and wife, J. W. Freeman, John B. Hamilton, E. J. Senn, C. C. Gratiot, G. E. J. Brown, J. H. Martindale, Wm. H. Harsha, C. S. Bacon, B. F. Whitmore, E. W. Lee, F. C. Hotz, Casey A. Wood, H. V. Würdemann, W. K. Jaques, W. A. Batchellor, G. W. Cox, Chas. Denison, W. VanWerden, William E. Quine, H. Ash, W. H. Palmer, C. H. Ludor and wife, J. T. Priestley, A. B. Spach, J. A. Gates, Frank Allport, A. R. Reynolds, H. Cradle, W. R. Fringer, C. M. Hobby, A. E. Prince, G. E. Crawford, H. S. Patrick, J. S. Love.

Diplomas Non-valid.—In a recent decision (May 27) Judge Neelan, Milwaukee, rules that physicians practicing medicine in that city, under diplomas granted by the Eclectic Medical College, are doing so without authority of law.

A New Publication.—The *X-Ray Journal*, Vol. I., No. 1, May 1897, has appeared. The purpose of this new monthly is "to give a faithful résumé of all X-ray work done in any portion of the globe." The subscription price is \$1 per year; the editor, Dr. Heber Robarts, St. Louis, Mo.

Prevention of the Rusting of Instruments.—After an experimental investigation as to the rusting of instruments, it has been found that the process is due to carbonic acid contained in water, and that it is not absolutely prevented by the addition of carbonate of soda, as recommended by some. It was, however, found that rusting can be greatly lessened by first boiling the water before placing instruments in it, since thus the greater part of the carbonic acid is expelled. The most efficient means is to add to the boiled water 0.25 per cent. of sodium hydrate, pure, containing no sulphur. During an operation the instrument should lie in the solution thus prepared. Sharp knives placed

in this preparation do not lose their edge in the faintest degree.—*American Practitioner and News.*

A Check Needed.—Governor Black of New York, who seems to be a man of mettle, has given out his decision that the expenditure of the State after the next legislative session will be still further reduced without the aid of a graduated inheritance tax. This measure failed to become a law. So far he has cut out \$950,145.92 from the bills on which he has just acted, \$789,195 from miscellaneous measures, \$138,720.92 from the supply bill and \$22,230 from the supplemental supply bill. "There ought to be," says the Governor, "some check applied, and applied at once, on the scale of expenditures for the State's charitable and penal institutions."

Chronic Cocainism from Catarrh Snuff.—A woman was received recently at a Montreal hospital with the trembling hands, staggering gait, insomnia, dyspepsia, loss of appetite, etc., of alcoholism, also visual hallucinations, dilatation of the pupils, mental dullness and pronounced moral depravity. She had always been a person of quiet, modest tastes, and her husband asserted that she never took liquor. Asked whether she took any drug, he went home to investigate and returned with a bottle of Agnew's catarrh powder, a patent remedy which she had been using as a snuff for four or five months, consuming three bottles a week. The bottle held 80 grains and contained 1.75 per cent. cocain. The therapeutic dose is $\frac{1}{4}$ to 1 grain.—*Un. Méd. du Canada*, April.

Constitutionality of Law Regulating Sale of Opium.—Section 3874 of the Revised Statutes of Missouri of 1889 provides that every person who shall set up, maintain, open, or keep any house, room or place to be used for the purpose of smoking opium, hashesh or any other deadly drug, shall be deemed the keeper of an opium den, and, on conviction, be adjudged guilty of a misdemeanor and fined not less than \$100 and not exceeding \$1,000. This law, the supreme court of Missouri holds, in *State v. Lee*, Jan. 19, 1897, constitutional, and declares can not be considered class legislation, because prohibiting the keeping of an opium den comes within the police power of the State, under which the legislature has the power to regulate or prohibit such occupation in the advancement of public morals, health and the safety of its citizens. It is true, continues the court, that opium is often used as a medicine. So is whisky, but the right of the State, under its police powers, to prevent its sale altogether, except for medicinal purpose, is indisputable. Nor is the foregoing law in restraint of trade. It does not prohibit the disposition of opium as a commercial agent, but prohibits its use as a kind of intoxicant. And it does not deny to any person equal protection with other citizens, is not unreasonable or oppressive; nor does it, concludes the court, in any way infringe upon any rights guaranteed by the constitution.

The Starch Habit.—Dr. L. Kahn of Leadville, in the *American Therapist*, May, reports a case of so-called starch-eating habit. A female, aged 20, unmarried, had been in invalid condition for ten years subsequent to an attack by enteric fever, with slow convalescence. Suffered greatly with rheumatism, which probably caused a severe cystic inflammation which she had at the same time. Considerable heart trouble, which she could not fully describe but which caused her to faint on slightest excitement without any premonition. She stated she had fainted five or six times in twenty-four hours. The history for the past eighteen months was particularly interesting. She started her peculiar habit by taking lumps or pieces of starch from the box as she passed it three or four times daily; this gradually increased till she was using it regularly every few hours with a teaspoon. Her mother noticed the disappearance of the starch and watched for the cause; discovering her daughter's habit, she stopped the supply. The starch habit lasted about six months. Now that the starch was no longer obtainable, she started on flour, first using a teaspoonful twice

or thrice daily, gradually increasing till she used two teaspoonfuls every hour when awake. Condition: weight, 92 pounds; very anemic and pale; eyes dull, patient loth to move, heart sounds normal but beats intermittent, pulse about 120, respiration, 25; lungs normal; skin, very dry and harsh; urine, sp. gr. 1030; no albumin or sugar, but excess of phosphates; tongue coated whitish-yellow; bowels constipated; nights sleepless; absolutely no appetite. Treatment: Externally, liberal use of didactic English in reference to the habit. Internally, strychnia in doses of the one-sixtieth of a grain ferruginous tonic and laxative. The results were favorable and progressive; patient's weight is twenty pounds more than two years ago, and the functions are in normal operation.

Lime Water as a Disinfectant for Linen and Cotton Fabrics.—Beyer has tested different methods employed for the disinfection of bed linen and underclothing. The ordinary methods by boiling are not suited to these articles, as the presence of blood, pus and feces causes an ineradicable stain if a high temperature is used. Soaking the garments in solutions of various soaps for one or two days failed in every instance to kill cholera, typhoid and pyogenic organisms which were mixed with the feces with which the garments were smeared. In some cases the germs were killed when the solution containing the linen was kept at 50 degrees C. for a few hours. With lime water the results were much better. Sample garments which were soaked in this solution for twenty-four hours were found to be sterilized. An equally good result was obtained in a hospital where about one-half a cubic meter of soiled linen was soaked in lime water for forty-eight hours, or for twenty-four hours if the clothing was first rinsed with lime water and then placed in a fresh solution. The lime water does not injure linen or cotton goods, but shrinks woolen to such an extent as to prevent its use.—*Fortschritte der Medicin.*

Intermedial Types.—The European edition of the New York *Herald* of late date states that an experiment in catacombs near the Jardin des Plantes of Paris has been instituted for the purpose of reproducing the intermediary types of cave dwellers. The underground passages employed were discovered only last year and are of Roman build. A number of steps lead down to a curious round chamber overtopped by a roof supported in the center by an enormous column of stone. Here bats, pigs, and all kinds of fish are to be kept in darkness for the minute study of transformations—the atrophy of certain senses and the hypertrophy of others. It has long been claimed that the eye under such conditions has been replaced by antennæ or feelers. Already the subjects of the present experiments are frightened by the dim light of the candles and scurry into the obscure corners. Only very occasionally will an official descend into these underground passages with a red lamp to take food for the animals, and more rarely still will M. Armand Viré and his colleagues visit the laboratory.

Liability for Maliciously Filing Information Charging Insanity.—The supreme court of Iowa affirms, in the case of *Comfort v. Young*, Jan. 22, 1897, a judgment of \$750 for the plaintiff, who sued to recover damages for an alleged libelous publication that consisted of an information, filed by the defendant with the board of insane commissioners, charging that the plaintiff was insane and a fit subject for custody and treatment in the insane hospital of the State. The defense was made that the information was a privileged communication. Persons have the undoubted right, says the supreme court, to file such informations as the one in question, when made in good faith and in the honest belief that the statements therein made are true. But one can not use such instrumentalities for the express purpose of gratifying his malice or indulging his passions without making himself answerable to the law. It is for the trial judge to determine whether the publication complained of was privileged or not, and, if privileged, whether absolute or condi-

tional; but it is for the jury to find whether the proceeding was instituted through malice.

Undulation of the Nervous System.—Broco and Richet have demonstrated the existence of rhythmic undulations in the nervous system, obeying the general laws of synchronization of oscillating bodies, with a negative period and rhythmic responses to one in two, and one in four stimuli. They have experimented with electric excitation of the brain, and also, more recently, with the hyperexcitability to the reflexes produced by chloralose, and found the "refractory" or negative period the same in both forms of excitation, and also in normal and choreic dogs. They conclude that these facts signify that all these stimuli, electric, reflex or pathologic, can be substituted for each other, and that all have one property in common, viz., the undulation proper of the nervous system.—*Semaine Méd.*, March 31.

Aseptic Traumatic Fever.—Pillon ascribes this condition to the absorption of pyretogenic substances evolved: 1, in the traumatic effusion; 2, in the products of necrobiosis of the mechanically injured cells; 3, products evolved by the anatomic elements disturbed in their vitality; 4, products secreted by the migrating white corpuscles. He obtained a constant and progressive hyperthermia in guinea pigs by injections of salt solutions holding living white corpuscles in suspension. His experiments are described in the *Presse Méd.*, of March 27 and demonstrate that the secretions of living or necrobiotic migrating cells play an active part in the genesis of hyperthermia; but it is still unknown whether this is due to the fibrin ferment, uric acid or nucléin. (Ewald, Schnitzler.) He adds that a certain proportion of the elevation of the temperature is due to the sensitive nervous element.

Resection of the Liver to Remove a Multilocular Hydatid Cyst.—This is the first case of the kind on record in which the abdominal cavity was closed after the tumor was removed. The patient had complained of a dull pain in the hepatic region and a tumor was palpated, moving with the liver in respiration. Through an incision parallel with the right costal arch, P. Bruns resected the tumor, the size of a man's fist, after liberating the adherent gall bladder. The hemorrhage was slight, requiring only the ligation of two arteries. The lips of the wound in the hepatic tissue were united with a deep suture of strong catgut and a superficial suture with fine catgut. The abdominal wound was sutured by layers. The wound healed rapidly and the patient left the hospital in three weeks.—From *Beiträge z. Klin. Chir.*, xvii, 1, in the *Sem. Méd.*, January 27.

New Method of Making a Permanent Pancreatic Fistula.—The *Cbl. f. Phys.*, of February 20, refers to Fodera's new method as "deserving of the greatest attention." It accomplishes the purpose completely, while the pancreas remains macroscopically and microscopically sound, and its normal secretions can be thoroughly studied. The duodenum and the pancreas are left intact and the arrangement of the intestines undisturbed. The pancreatic duct is located through an incision in the line of the umbilicus, and a small opening made into it, 3 or 4 millimeters from the duodenum. An ingeniously contrived arrangement of small silver tubes connects with one that communicates with the outer world as it projects from the wound, or it can be tucked into the hypochondrium. The outer end is closed at first, but in 8 or 10 days the receptacle is attached. The tubes heal into the tissues rapidly and thoroughly. For complete details see *Moleschott's Untersuchungen zur Naturlehre*, xvi.

Glycogenesis in Neoplasms.—The histologic resemblance in certain respects, between the tissues of the embryo and tumors, and the known presence of glycogen in the former, suggested to Dr. A. Brault the query whether glycogen could not also be found in neoplasms. He now announces as the result of his investigations that glycogenesis is an important

factor in the evolution of neoplasms, intimately connected with their nutrition and growth. Glycogen is fixed and stored in the cells of an invading tumor, in direct proportion to its rate of development, and hence his discovery is of great importance in determining the prognosis of neoplasms, and confirming the diagnosis. The location of the tumor does not seem to affect the glycogenesis, which depends solely upon the energy of its growth. The older, indurated zones of the tumor contain little or no glycogen; it is accumulated in the cells of the new invading zones, which show a glycogenesis surpassing that of the liver itself. Tested with iodine, the glycogen shows as small irregular mahogany brown drops, always inside the cells, never between them. It is especially interesting to observe the glycogenesis in neoplasms of the liver, contrasted side by side with the glycogenesis of the normal hepatic tissue.—*Presse Méd.*, April 3 from *Arch. des Sc. Méd.*, pp. 232, 301 and 419, 1896.

Another Medical Poet.—The production of a volume of Dr. Frederick Petersen's verses in the court room where the author was giving expert testimony in a recent murder trial, was an interesting incident of a highly melodramatic case. Whenever a medical man writes poetry it is viewed with some suspicion; the example of Dr. Oliver Wendell Holmes to the contrary notwithstanding. But Dr. Petersen, like Dr. Weir Mitchell, has wooed the muse to some purpose, and his verses are distinctly good. The volume in question was the second he had produced, each of them containing a number of charming lyrics and some clever translations from the Swedish. The author is about 36 years old, and already a distinguished alienist. His volume of verses, "In the Shade of Ygdrasil," was published by the Putnams.—*Leslie's Weekly*.

Dr. Rizal, the Revolutionist of the Philippines.—Jose Rizal Mercado y Alonzo is spoken of as a wealthy doctor of medicine and a man of remarkable ability. He is said to be a doctor of law, as well as of medicine, holding German degrees as well as Spanish, and he has also attended post-graduate instruction at the Paris University. He is an author of note in Spain, two of his books which treat of political and social subjects in a novel and uncompromising manner having long since procured him the attention of the Philippine government and his banishment and imprisonment in a distant island, where it was thought his seclusion would be perfect. Yet he managed to keep in constant touch, during his banishment, with the other leaders of the revolutionary party and directed the successive developments of their propaganda as well as if he were free. Rizal ordered the adoption of the *pacto sanguinis*, or bond of blood, by which the members of the *catapuin* were bound together, well knowing that the Malay race could only be successfully aroused to fanaticism by an appeal of this kind. The influence of nearly four centuries of Christianity has largely changed the outward seeming of the people, but at heart they are the same, as Rizal well knew; hence his suggestion of surviving the bloody compact among the brotherhood of the revolution, who have been largely held together by this bond, made with the most impressive rites. He is above the average height and has the characteristic snake-like expression of so many men of Philippine birth, but mixed Mongolian and Malay blood. It is a very repulsive face, immobile, yellow, passive, showing no change or sign of the thoughts passing through the brain, except for an occasional very unpleasant, half-closed, sidelong glance of the narrow eyes, when the owner steals a rapid and furtive glance at any object.

Longevity at a Higher Rate in Temperate Climates.—The official figures of a recent census report show that climate determines longevity; that is to say that within the temperate zone, the duration of life is higher than in warmer or semi-tropical countries. To quote conclusions: The average number of persons over 60 years old in 1,000 inhabitants in the United Kingdom is 77, and in the German empire, the climate of which is similar,

it is the same. In Holland it is also 77; in Denmark 84; in Sweden 88, and in Norway 90. In Russia the longevity of the inhabitants is greatest in the northern provinces and lowest in the southern ones. The average of European countries in the north temperate zones, England, Germany and Holland—77 a thousand—falls to 71 in Austria and in Portugal. In Spain, where the climate is generally milder than in Portugal, the number of persons over 60 years of age in a thousand is 58 only, and in Greece it is 56. In the East Indies, as far as there are any authentic figures, the average is only 40 in a thousand inhabitants. In South America the average is about 50, though there are, of course, many exceptional cases. During 1896 the death of 188 persons over 90 years—14 of whom were actually over 100—was recorded in Great Britain—the average longevity rating in the following order, Ireland, Scotland, England. Of a thousand persons, men, women and children, resident in England, the average number over 60 years of age is 72, or somewhat more than 7 per cent. In Scotland the proportion over 60 years of age is 7.7 per cent. and in Ireland it is 10.5 per cent. Ireland follows after France as regards respective age, the proportion of adults over 60 years being 127 out of each 1,000 inhabitants. The United States do not stand very high in the scale of the elderly, the law seeming to be that life is longer in old than in new countries. Unexpectedly this census reveals the fact that the birth rate is the greatest in England and the least in Ireland.

Appendicitis; Hysterical, Lithiasic, Primary or Secondary.—The clinical picture of acute appendicitis has been observed in several cases of hysteria lately, and the special symptoms were relieved by ablation of the appendix, although it was found only slightly affected. It is evident that a comparatively insignificant appendicular congestion, in a hysterical subject, may simulate a severe appendicitis or peritonitis. Talamon, Hayem, Rendu and Brissaud relate deceptive cases of apparent acute appendicitis and peritonitis, the only means of differentiation the non-exact location of McBurney's point and the presence of hysterical stigmata. Debove has seen hysterical phantom tumors simulating an appendicular abscess disappear under the influence of chloroform. Much discussion has been elicited by the acceptance of "intestinal lithiasis" as a common occurrence and cause of appendicitis. Reclus and Lucas-Championnière consider appendicitis usually the consequence of muco-membranous enterocolitis, and seldom a primary affection. Dieulafoy disputes this, and has collected 800 observations of chronic muco-membranous or lithiasic enterocolitis without one being accompanied by appendicitis. The former reply that most of the observations date from pre-appendicitis days, and are therefore unreliable. Dieulafoy advocates the term, entero-typhlo-colitis, as more exact, and others go still further and suggest entero-typhlo-appendico-colitis. Bacteriologic examination of the purulent exudation in 20 recent cases resulted in finding the coli bacillus alone in 7 cases; associated with the streptococcus in 5; with the pneumococcus in 5; with the staphyl. alb. in 1; with the strept. and staphyl. in 1; with various saprophytes in 2; streptococcus and aerogen. bac. in 1; staphyl. aur. in 1; undetermined bacillus in 1.—*Presse Méd.*, March 27.

The Bacillus of Syphilis.—Van Niessen replies at some length to the critics of his book on the syphilis bacillus, and adduces further evidence in support of his views. His later work has been carried on mainly in two directions: 1, the comparison of microorganisms stained in syphilitic tissues with those observed in pure cultures; and 2, the cultivation of the specific bacillus from the affected tissues. He has especially investigated syphilitic lesions of the brain and spinal cord. Sections of these were stained by Gram's method or cultivations made by imbedding little pieces in gelatin, so that one surface was left exposed to the light. On this numerous colonies soon devel-

oped, which were employed in further researches. The author claims to have infected eight rabbits in various ways, so as to produce secondary syphilitic lesions, but he has not yet succeeded in inducing the primary lesion upon the genitals. Owing to the great difficulty of excluding other causes, such as infection by tubercle and coccidia, his researches in these directions are not yet ripe for publication. He has, however, been able to demonstrate the "syphilococcus" in an excised primary sore of the prepuce, and also to cultivate it in gelatin mixed with the blood taken from the wound produced by the excision. The cocci were present throughout the tissues removed, but were particularly abundant, often forming emboli, in the deeper layers. Van Niessen is therefore convinced of the diagnostic value of the organism in primary affections, and although the result with later syphilitic lesions of the central nervous system are not as yet equally consistent, he is convinced that further improvements in investigation will render them equally available for diagnosis. His inoculation experiments are very striking. A pure culture of the organism, from the primary sore above mentioned, on veal broth was injected two months later into three rabbits, a goat, a guinea-pig and a pigeon. In several of the animals typical hard sores developed, which in the pigeon took on a phagedenic course, while in the goat and one of the rabbits gummata developed. The syphilis thus produced in animals was characterized by slow and protracted symptoms, by a marked tendency to cell proliferation in the form of a tumor with necrotic centers, and by involvement of the capillaries and lymphatics. The author claims to have proved that his syphilococcus when injected in pure culture into animals will produce both the typical primary affection and gummatus tumors.—*British Medical Journal*.

Insanity and Evidence.—Only a little more than a year ago, the *JOURNAL* called attention to a very important decision rendered by the supreme court of the United States in the case of Davis v. United States, on the "Burden of Proof as to Sanity." (Vol. xxvi, page 343.) After a second trial and sentence to hanging, appeal was again taken to the same court, which handed down its second decision, Feb. 15, 1897, affirming the judgment of the circuit court, and reiterating its opinion that, while it is true that every man is presumed to be sane, yet whenever, by the testimony, the question of insanity is raised, then the fact of sanity, as any other essential fact in the case, must be established to the satisfaction of the jury beyond a reasonable doubt. Here the supreme court also approves, as under the circumstances, in no degree prejudicial to the rights of the accused, the charge given the jury that "the term 'insanity,' as used in this defense, means such a perverted and deranged condition of the mental and moral faculties as to render a person incapable of distinguishing between right and wrong, or unconscious at the time of the nature of the act he is committing, or where, though unconscious of it, and able to distinguish between right and wrong, and know that the act is wrong, yet his will—by which I mean the governing power of his mind—has been otherwise than voluntarily so completely destroyed that his actions are not subject to it, but are beyond his control." After a witness has once qualified himself as an expert, and given his own professional opinion in reference to that which he has seen or heard, or upon hypothetical questions, the court further holds that then it is ordinarily opening the door to too wide an inquiry to interrogate him as to what other scientific men have said upon such matters, or in respect to the general teachings of science thereon, or to permit books of science to be offered in evidence. At any rate, it insists, the trial court must have some discretion as to the limit to be placed in any given case upon the extent to which the expert testimony may be carried; and when, upon direct examination, the opinion of the witness is fully disclosed, it can not be said that the court erred in declining to permit on the same direct examination an inquiry into what is in some aspects both collateral and hearsay. Again, the supreme court holds that it was clearly within the proper limits of cross-examination to ask a medical expert: "You think, from your conversation with him, that he killed the man because he threatened his life?" and to receive the answer: "Well, in part; and because he thought his own life was in danger, and because he thought he had the right to destroy this menace to his own life."

New York.

GOVERNOR BLACK'S VETOES.—Governor Black has refused to sanction an expenditure of \$200,000 for the Eastern Reformatory. He states that this institution "was put in about the most inaccessible part of Ulster County, and then a plan for its construction was adopted which it will take \$1,000,000 out of the State to execute. There are to be accommodations for 500 boys or young men, who are to be reformed, if possible. Think of it! One million dollars for the housing of 500 persons!" He further claims that it would be more economical to entirely abandon this building and erect another for about \$300,000. "Convicts should not be housed in luxurious hotels, for the support of which farmers and working men are to pay taxes." Among the bills carrying appropriations which the Governor vetoed were the following: An act to provide for the construction of certain buildings on Swinburne Island for the use of the quarantine establishment, \$75,000; appropriating money for the construction of additional buildings for the New York State Woman's Relief Corps Home, \$30,000; and many others which he suspected of having a flavor of special legislation. It is evident that the bills which failed to receive executive approval would have entailed on the State an expenditure far in excess of \$1,000,000. Thus the Governor's failure to sign instead of vetoing a bill to discipline the hospitals and dispensaries is hardly to be regarded as a snub of the profession.

Washington.

DR. FORD APPOINTED ASSISTANT.—The vacancy of assistant to the superintendent of Garfield Memorial Hospital, recently caused by Dr. Heller's resignation, has been filled by the appointment thereto of Dr. J. H. Ford. Dr. Ford graduated a few weeks ago from Columbian Medical School, taking the honors in the practice of medicine and surgery. He has been associated with the hospital for several months past, and his promotion is accepted as one of the evidences of appreciation of his work in the institution.

ENFORCING QUARANTINE REGULATIONS.—Passed Assistant Surgeon M. J. Roseman of the Marine Hospital Service has been assigned to duty as quarantine officer at the port of San Francisco to enforce the national regulations for preventing the introduction of infectious and contagious diseases.

NEW HEALTH REGULATION IN THE DISTRICT.—It will now cost \$10 to spit in a street car or a public building under the control of the District Government.

CONGRESS PROPOUNDS QUESTIONS.—The congressional joint select committee to investigate charities and reformatory institutions in the District of Columbia has addressed a letter to the mayors of about seventy-five principal cities throughout the country requesting answers to the following series of questions: 1. Whether any charitable institution in the city of which you are mayor receives the whole or a part of its maintenance from municipal or State moneys? 2. Are any public moneys appropriated to aid charitable institutions under the care or control of any religious denomination? 3. Are any public moneys appropriated to aid charitable institutions controlled by private corporations, whether sectarian or unsectarian? 4. In case public moneys are appropriated, please give the names of the institutions and the amounts of the annual appropriations.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—At the 246th meeting of the Society, held on the 21st ult., Dr. G. Wythe read a very valuable paper on "Membranous Dysmenorrhea." A case was reported with several casts from the uterus and a full report on the same by Dr. Reed, U. S. A., and Dr. Gray. The paper brought out a very full and valuable discussion.

Colleges.

WOMAN'S MEDICAL COLLEGE.—The twenty-ninth commencement of the Woman's Medical College of the New York Infirmary for Women and Children, was held May 27. Sixteen

received their degrees, of whom eleven were from New York State. The college building, totally ruined by fire on April 22, is soon to be replaced by a structure better adapted for "the growing needs." This year the college registry shows 106 students.

THE FACULTY APPOINTMENTS OF THE CONSOLIDATED COLLEGES.—The New York University Council with eighteen members present held a special meeting May 25 and elected to full professorships in the University-Bellevue Hospital College Dr. E. G. Janeway and Dr. Frederick S. Dennis. Dr. Austin Flint, Jr., was made adjunct professor of obstetrics, and Dr. G. B. Stewart, adjunct professor of anatomy. The roll of the governing faculty now numbers twenty-one members, while the clinical, emeritus and assistant professors are twenty-five.

PARK RICHTER, M.D., has been appointed Dean of the Medical Department of the Minnesota State University. The library of the late Dean Millard is to become the property of the College of Medicine.

THE commencement of Rush Medical College, Chicago, was held May 26. The graduating class numbered about two hundred and sixty.

THE commencement at the Johns Hopkins Medical School, will be held June 15. The graduating class numbers seventeen and is the first class to graduate from the Medical School, which is now four years old. Among the graduates is one woman.

Hospitals.

OAKLAND, California, is to receive \$600,000 for the establishment of a hospital. The bequest is one made by Mrs. Catherine Garcelon, who died December, 1891, litigation having prevented its utilization until a recent decision of the United States Supreme Court ruled in favor of Oakland.—A recent report from the Toledo (Ohio) State Hospital shows 1,266 patients, April 10, 1897, as compared with 1,223 April 10, 1896.—The Hospital of the Insane, Middletown, Conn., is to have some new buildings this summer.

Societies.

THE PHYSICIANS of the counties of Knox, Davies, Pike and Gibson, Indiana, met at Vincennes, and organized a society to be known as the White River District Society. They will meet biennially. The following officers were elected: President, W. W. Blair, Princeton; vice-president, J. L. Moore, Washington; secretary, J. T. Smith, Petersburg; treasurer, L. M. Becker, Vincennes. It was in Vincennes, several years ago, that what is now known as the Mississippi Valley Medical Association was organized, and the future of this new society is equally as promising.—The forty-eighth annual meeting of the Indiana State Medical Society was held at Terre Haute, May 20.—William H. Humiston, M.D., Cleveland, has been chosen president of the Ohio State Medical Society, and J. Geiger, M.D., of St. Joseph, president of the Missouri State Medical Society.—The new president of the Pennsylvania State Medical Society is W. Murray Weidman, M.D., of Reading, Pa.—The State Medical Society of New Hampshire, met at Concord, May 24.—The New York State Medical Association meets at Norwich, June 8.—Other gatherings noted are: Windham County Medical Society, Hartford, Conn., May 26-27; Georges Creek Medical Association, Frostburg, Md., May 20; Baltimore County Medical Society, Towson, Md., May 20; White River Medical Society, White River Junction, Vt., May 18; West Virginia State Medical Society, Wheeling, May 20; Newport Medical Society, Newport, R. I., May 19; American Academy of Medicine, Philadelphia, May 29 and 31.—The Queens County Medical Society held their ninety-first semi-annual meeting at Mineola, L. I., May 25.—The physicians of Temple, Texas, organized the Temple Medical Association, May 22.—The fourteenth semi-annual session of the East Tennessee Medical Society, was held at Newport, Tenn., May 28-29.—The Lincoln (Neb.) Medical Society met May 25.—The Scandinavian physicians of the Northwest, especially of the States of Minnesota, Iowa, Wisconsin, North and South Dakota, have formed an organization. The officers are:

President, Dr. Chr. Hirsch of New Ulm, Minn.; secretary, Dr. J. E. Engstad, Grand Forks, N. D.; treasurer, Dr. Olaf Hegge, Austin, Minn.; vice-presidents Drs. Oscar A. Fliesburg, Minneapolis; F. Foss Mohn, Decorah, Iowa, and John J. Ecklund, Duluth. The next annual meeting will be held in May, 1898, in St. Paul.—The North Dakota Medical Association convened at Grand Forks, May 26.

A Washington Physician has forwarded his dues in currency to the treasurer, Dr. H. P. Newman, Chicago, without a letter of transmittal, thus making it impossible to properly credit him on the books, or to send a receipt.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from May 22 to 28, 1897.

First Lieut. William F. Lewis, Asst. Surgeon (Ft. Apache, Ariz.), is granted leave of absence for one month.

Major Henry McElderry, Surgeon (Ft. Leavenworth, Kan.), is granted leave of absence for one month, to take effect on or about June 24, 1897.

Major Edwin F. Gardner, Surgeon (Ft. Grant, Ariz.), is granted leave of absence for three months, to take effect on or about June 15, 1897.

Capt. Isaac P. Ware, Asst. Surgeon, is relieved from duty at Madison Bks., N. Y., and ordered to Ft. Grant, Ariz., for duty.

Capt. Champe C. McCulloch, Jr., Asst. Surgeon (Army and Navy General Hospital, Hot Springs, Ark.), is granted leave of absence for three months, to take effect on or about June 1, 1897.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending May 22, 1897.

Surgeon H. G. Beyer, ordered to the Naval Museum of Hygiene for temporary duty in connection with the preparation of new microscopic outfits for ships and hospitals.

CHANGE OF ADDRESS.

Barber, W. M., from West Sunbury, Pa., to Birmingham, Ohio.
Burch, L. A. W., from Chicago to Morrison, Ill.
Beller, O. B., from Chicago to Vinton, Iowa.
Barrett, Fred, from Chicago to Tower, Minn.
Carroll, C. C., from New York city to Liberty, Sullivan Co., N. Y.
Chesire, M. N., from Chicago to Anamosa, Iowa.
Cox, F. P., from Chicago to Kenney, Ill.
Clark, J. F., from Chicago to Angola, Ind.
Demaree, T. E., from Chicago to Rossville, Ill.
Devine, G. C., from Chicago to Oregon, Wis.
Evans, W. A., from 433 Calumet Av. to 116 43d St., Chicago.
Frick, Lewis, from Chicago to Hilbert Junction, Wis.
Grove, W. W., from Chicago to Ligonier, Pa.
Hoelcher, J. H., from 298 Webster Av. to 284 Belden Av., Chicago.
Johnson, J. E., from Chicago to Marion, Ind.
Klempner, J. C., from Cerro Gordo, Ill., to Union, Ohio.
Llencrantz, A., from San Francisco to 359 Telegraph Av., Oakland Cal.
Lensean, C. T., from Chicago to Mt. Ayr, Iowa.
Lehan, J. W., from Chicago to Dunlap, Iowa.
Proctor, C. M., from Chicago to Harvard, Ill.
Roler, A. H., from 2330 to 2843 Indiana Av., Chicago.
Riley, E. A., from Chicago to Huron, Kan.
Smith, F. F., from St. Augustine, Fla., to Bar Harbor, Mich.
Shaw, Carl A., from Chicago to South McAlister, Ind. Ter.
Scott, R. G., from Chicago to Sandwich, Ill.
Sweet, H. L., from Chicago to Mt. Etna, Iowa.
Synon, G. C., from 12th St. and Sawyer Av. to 900 W. 12th St., Chicago.
Schjelderup, N. H., from Chicago to Granite Falls, Minn.
Schulze, W. C., from Chicago to Lonura, Wis.
Schultz, E. F., from Chicago to Reedsburg, Wis.
Van Nuys, J. C., from Chicago to Franklin, Texas.

LETTERS RECEIVED.

No. 24

ADDRESSES.

STERCORIN AND CHOLESTEREMIA.

Address on Medicine delivered at the Semi-centennial Anniversary of the American Medical Association, at Philadelphia, June 2, 1897.

BY AUSTIN FLINT, M.D., LL.D.

PROFESSOR OF PHYSIOLOGY IN THE RELLEVUE HOSPITAL MEDICAL COLLEGE OF THE CITY OF NEW YORK.

Looking far into the future, it seems possible that our successors may fix upon the month of May, 1946, as the true centennial of the AMERICAN MEDICAL ASSOCIATION, dating the origin of this body from May, 1846, when a convention of representatives of our profession, held in New York, proposed the formation of a National association, which was formally organized in 1847. If your orator of today finds it impossible to do justice to this occasion, how much more difficult will it be to present, in a single address, an adequate picture of a full century of medical progress! The year 1946 will be the centennial of the application of anesthesia to surgery. It will be the third jubilee of the crowning glory of the eighteenth century, the completion of the discovery of vaccination, when the terrible scourge, smallpox, which had been more destructive to human life than war or famine, was virtually subdued. At the Jenner Centenary, held in Berlin in May, 1894, Virchow stated, as an ethnologic fact, that "all peoples that had not been reached by vaccination, or that had not accepted it, had disappeared from the face of the earth, destroyed by smallpox." Will the orator of 1947 be able to point to a triumph of American medicine equal to the application of anesthesia a hundred years before or to the beginning of an era in preventive medicine, like that inaugurated by the immortal Jenner? Looking into the future, it is possible that in fifty years smallpox will have disappeared from the face of the earth, like the peoples it has destroyed. But who can say, in the light of what has been accomplished within our own recollection, what may not be done within the next half century! In the single line of preventive medicine, is it not possible that we may be able to secure immunity from tuberculosis, typhus and typhoid fevers, scarlatina, diphtheria and other infectious maladies, and that these diseases may disappear? As it is now, even with a not inconsiderable popular prejudice against vaccination, many successive years have passed in the city of New York without a single case of smallpox; and medical knowledge is becoming daily more progressive and more generally accepted by the laity.

It is not too much to say that the Convention of May, 1846, marked an era in the history of medical organization in the United States. It had become necessary that the medical profession should be unified and separated from those practicing under sectarian designations, particularly as at least one sect was beginning to secure the confidence of men other-

wise intelligent, and assumed to practice medicine on a scientific basis. Nearly coincident with the organization of this ASSOCIATION was the discovery to which I have already alluded, which marked a grand epoch in the history of American medicine. On Oct. 17, 1846, practically the first surgical operation was performed under the influence of an anesthetic administered by inhalation. Its semi-centennial has recently been most impressively celebrated at the Massachusetts General Hospital in Boston. There are few who remember the horrors of severe surgical operations and the agonies of difficult childbirth before anesthesia, as there are few remaining who participated in the convention which organized what is now the AMERICAN MEDICAL ASSOCIATION; but all can realize what surgery would be without artificial insensibility to pain, and what the medical profession would be without a National association.

The status of medicine forty years ago is quite within my recollection. Medicine is not, never was and never will be an exact science; but it always has been progressive, and never more so than at the present time. Fifty years ago, perhaps medicine merited the reproach of being the least exact of all sciences; but its progress within the last fifteen years has been so prodigious that it is now in advance of them all. The Abbé illuminating apparatus made the study of bacteria possible; and this, with the wonderful apochromatic lenses, as it now appears to us, have rendered nearly perfect our technical means of histologic and bacteriologic research. We no longer differentiate and separate structures by the coarse methods of actual dissection alone, but with the delicate and precise instruments used in cutting thin sections and by staining, we have come to an exact knowledge of physiologic and pathologic histology, which, fifty years ago seemed unattainable. Without staining fluids, the physiologic and pathologic histology of the present day would be impossible. Fifty years ago skill in the diagnosis of certain diseases was acquired only by long practice and large experience. With our present methods, properly employed, it is impossible to make an error in the diagnosis of many of the diseases which formerly presented difficulties, such as typhoid fever, tuberculosis, diphtheria, cholera and most of the neoplasms. To say that pathology has been revolutionized within the last ten or fifteen years is not enough—a new pathology has been created, and with it has come an intelligent hygiene, prevention and therapeutics, based upon exact scientific knowledge.

Eleven years ago the great physician whose name I bear, and who still lives in the memory of this ASSOCIATION, wrote an address which was to have been delivered before the British Medical Association, entitled "Medicine of the Future." This classic legacy to the profession he so loved and adorned, embodied recollections of a half century of medical observation,

with a prophetic view of the possibilities of medicine within the succeeding half century. It was difficult for this wise physician to restrain his predictions within the bounds of reasonable enthusiasm. The epoch-making discovery of the bacillus tuberculosis, announced by Koch in 1882 and graphically described by Dr. Belfield before this ASSOCIATION at the meeting of 1883, made a most profound impression upon his mind and imagination, which found expression in an elaborate paper on the subject read in January, 1884. His predictions of possibilities in medicine before 1936 are now more than verified. It was predicted "that before the lapse of another half century there will be another era in organic chemistry, and that light will penetrate dark recesses which histology can not reach." If "light" be taken in its literal sense, is this not more than realized by Roentgen's marvelous discovery, in which a hitherto unknown light is made to penetrate opaque matter and disclose the invisible? In 1886, he wrote: "Moreover, there are present intimations of important discoveries respecting inoculation with attenuated viruses and contagia in order to forestall the development of infectious diseases. Here open up to the imagination the future triumphs of preventive medicine in respect to all classes of disease." Now, little more than ten years later, serum therapy has taken a permanent place in practice, and we stand on the threshold of a full knowledge of immunity, natural and acquired.

As no human imagination fifty years ago could have pictured the condition of the medicine of today, so it today seems impossible to imagine the process of another half century. Never, since medicine became a science, has medical history been made so fast as now. Between the time of writing and delivering this address, scientific labor may give birth to a discovery destined to revolutionize some department, as Pasteur, Koch and their followers have revolutionized therapeutics, and as Lister has created a new surgery.

The reasonable limits of an anniversary address do not permit even an enumeration of the greatest of the advances in the science of medicine since the organization of this ASSOCIATION, much less their discussion. Your orator on surgery will find it impossible adequately to describe the progress of the last half century in a single address; your orator on State medicine can hardly compass the wonderful advances made even in the single line of prevention of disease; and I certainly can not hope to be more successful.

It is a matter of congratulation that the name of this body was early changed from National to AMERICAN MEDICAL ASSOCIATION. We have good reason to be proud of American medicine, and our great representative association may properly claim a distinctive title. When one is able to call up at random the discoveries in gastric digestion, anesthesia in surgery and obstetrics, the successful deligation of the arteria innominata, the operation for vesico-vaginal fistula, ovariectomy, and intestinal anastomosis, to say nothing of minor advances in medicine and surgery, can we not claim a distinctive place for American medicine? It is in the United States that advances in the science of medicine find the most ready acceptance and appreciation. The American physician is the most intelligent and judicious therapist; and in the United States is the best and safest surgery and gynecology.

I hope to see, beginning with the second half century of the AMERICAN MEDICAL ASSOCIATION, a more complete unity of the profession, through its author-

ity and influence. In the matter of general professional welfare, there seems to me nothing more important than uniformity in medical legislation, and, so far as possible, in educational requirements preliminary to the study of medicine and for license to practice after graduation. Admitting the proposition that the profession is crowded, it is evident that this condition is most serious in the large cities; but overcrowding can not be prevented by legislative enactment, except in so far as unqualified men are excluded. Uniformity of legal qualifications to practice medicine in the different States can best be secured by making every State society actually, as well as nominally, a branch of the AMERICAN MEDICAL ASSOCIATION, with permanent committees from each State organization together to constitute a central legislative body. The object of this central body should be to secure uniform medical laws in all the States, making any State license valid for all, and a matriculation certificate for one State good for matriculation in all schools represented in the Association of American Medical Colleges. A certain kind of medical instruction must be concentrated in large cities, where clinical material is abundant; and absolute uniformity of curriculum can not exist in all colleges; but certainly the legal requirements for practice, as determined by examination by State boards, can be made practically identical for all the States. While this would not prevent ambitious young men from trying their fortunes in large cities, it would distribute well-qualified physicians more equally in the country at large and tend to raise the standard of qualifications and usefulness of the average country doctor.

It is the prerogative of the presiding officer of this ASSOCIATION to make recommendations, and this is not the province of one appointed simply to give an anniversary discourse. At the jubilee meeting to be held later in the session, it is hoped that the four surviving members of the Convention of 1846 will be present. From at least one of these you may expect a more accurate and complete account of the past work of the ASSOCIATION and a more intelligent view of its probable future than I am able to give. What I have had the honor to present I well know is entirely inadequate to the occasion, and it has been given merely as an introduction to addresses by others which will be much more suitable and interesting. The remainder of the time that has been placed at my disposal I shall venture to occupy with a subject which I hope may not prove entirely unworthy of your attention.

Stercorin and cholesteremia.—While the presentation, on this occasion, of researches made thirty-five years ago—viewing the question from a physiologic standpoint—calls for an explanation and perhaps an apology, none is required if their great importance in relation to the pathology of the liver be considered, especially as cholesteremia is by no means accepted as a distinct pathologic condition. Were it not that stercorin has just been rediscovered in Germany by two eminent physiologic chemists, who make no mention of its full description in 1862, and have even called it by another name, I probably should not have repeated and extended my original observations. As it is, however, I feel that I may properly, as an American investigator, make my reclamation before the AMERICAN MEDICAL ASSOCIATION. Although my paper, published in the *American Journal of the Medical Sciences* in October, 1862, received an "honorable men-

tion" and substantial recognition from the Institute of France, and my observations have been verified and extended by French and German investigators, many writers on physiology and pathology, even the most recent, fail to recognize such a substance as stercorin and, in treating of cholesterol, speak of its functions as obscure or unknown.¹ In "An American Text-book of Physiology," Philadelphia, 1896, cholesterol is described as a constant constituent of the bile, very widely distributed in the body, and eliminated by the liver cells from the blood. "That it is an excretion is indicated by the fact that it is eliminated unchanged in the feces." Stercorin is not mentioned. As a matter of fact, cholesterol does not occur in the human feces in health, and its presence in this situation is exceptional.

In Hoppe-Seyler's *Zeitschrift für Physiologische Chemie*, Strassburg, 1896, is a paper by Bondzynski and Humnicki entitled "The Destination of Cholesterol in the Animal Organism." The authors claim to have discovered a new constituent of the human feces, which they call "koprosterin." This substance is identical with stercorin, fully described in 1862. The reading of this article led me to repeat the original researches of 1862, carrying them out by the methods then employed, at the same time repeating the observations of Bondzynski and Humnicki with the methods and appliances used in their work. It is mainly an account of these new observations that I now give. The chemic manipulations were done by Dr. H. A. Haubold, assistant to the chair of physiology in the Bellevue Hospital Medical College, and J. A. Mandel, assistant in the department of chemistry in the College of the City of New York and to the chair of chemistry in the Bellevue Hospital Medical College. To these two skilful assistants I am indebted for most painstaking and accurate work extending over a period of several months.

The original stercorin, of which specimens obtained in 1862 are in my possession, was extracted from the human feces by the following process: The dried and pulverized feces were extracted with ether. The ethereal extract was passed through animal charcoal and afterward evaporated. The residue was then extracted with boiling alcohol. The alcoholic extract was treated with potassium hydrate solution at a temperature near the boiling point of water, in order to remove the fats by saponification, which were washed out with water until the filtrate was neutral and perfectly clear. The filter was dried, extracted with ether, and the ethereal extract evaporated to dryness and extracted with boiling alcohol. The stercorin was obtained from the alcoholic extract by repeated crystallization.

This process was exactly repeated in our recent observations, and, at the same time, stercorin was extracted by the process described by Bondzynski and Humnicki. Normal human feces were obtained to the amount of about fifty pounds. After drying, the feces were divided. Two analyses each were made by Haubold and Mandel, each one extracting stercorin in one portion by the original method, and in the other by the new method. All the extracts obtained were identical in their composition, reactions and the form of crystals. It was fortunate that I had for comparison a fairly large specimen of stercorin extracted in 1862, and a microscopic slide bearing the date of June, 1862, in which the crystals were perfect. The

product obtained by my process was a little more abundant and crystallized rather more readily than that obtained by the later method.

In the process employed by Bondzynski and Humnicki, the dried feces were extracted with ether, using Soxhlet's extraction apparatus. The fats were saponified with sodium alcoholate. No animal charcoal was used. The substance was purified by repeated crystallizations. These variations from the original method are unimportant, except in so far as they expedite the process of extraction. The form of the crystals and the reactions were identical with those which I obtained for stercorin in 1862. Analyses of the products obtained by us, full details of which are given in a paper sent to *Hoppe-Seyler's Zeitschrift*, gave, for stercorin, the formula, $C_{27}H_{48}O$, the formula found for cholesterol being $C_{27}H_{46}O$. The change of cholesterol into stercorin is effected by the addition to the former of two atoms of hydrogen. A close comparison of the results of our ultimate analyses with those obtained by Bondzynski and Humnicki shows conclusively that "koprosterin" and stercorin are identical, and that stercorin is not an impure cholesterol, as is held by some eminent investigators, as Hoppe-Seyler, K. B. Hofmann and others. Stercorin crystallizes in long, fine needles which radiate from a center forming tufts, and which can not be confounded with the characteristic crystals of cholesterol. In a chloroform solution, stercorin gives, with an equal volume of concentrated sulphuric acid, first a yellow color and then a gradual change to orange, red and finally dark red. Treated in the same way, cholesterol promptly gives a blood-red reaction without these intermediate tints.

The opinion expressed by Hoppe-Seyler, Hofmann and indeed many others, that stercorin simply is impure cholesterol, can not have been based upon a practical knowledge of this substance. Stercorin has a well-defined formula— $C_{27}H_{48}O$ —which has been calculated and verified by the formation of esters. Its crystals are quite different from crystals of cholesterol and are invariable in form, arrangement and color. It was extracted by methods practically the same as those used in the extraction of cholesterol. In view of these facts, to assume that stercorin is an impure substance one must deny a positive scientific basis to organic chemistry.

In the recent, as well as in the original observations, it was clearly shown that cholesterol is changed into stercorin in passing down the intestinal canal. I found that this change involved processes incidental to intestinal digestion. Cholesterol and no stercorin was found in the feces of fasting animals and in the meconium. Bondzynski and Humnicki found an increased proportion of "koprosterin" in human feces after the ingestion of a certain quantity of cholesterol. They also showed that cholesterol unites readily with bromin, while "koprosterin" forms no such combination; and, indeed, by the use of bromin, these two substances may be separated when they exist together. They confirmed the empirical formula for their product by the formation of a number of esters.

In 1862, I wrote: "What the discovery of the function of urea has done for diseases which now come under the head of uremia, the discovery of the function of cholesterol may do for the obscure diseases which may hereafter be classed under the head of cholesteremia."

It is now generally admitted that the bile in addi-

tion to its function connected with digestion, contains one or more excrementitious matters. Taking into consideration the various ingredients of the bile, there seems to be but one which can logically be compared to urea. Cholesterin is found in many of the tissues and organs of the body and exists in the blood. Likening it to urea, it becomes a question whether it is formed in the liver and discharged in the bile or is merely separated from the blood by the liver and excreted. As it is constantly found in notable quantity in the nervous tissue, in the proportion of eight to twelve parts per thousand, it occurred to examine the blood of the internal jugular and compare the proportion of cholesterin with that found in arterial blood. In one experiment on a dog, the blood being taken without using an anesthetic, I found an increase in the jugular over the carotid of nearly sixty per cent. In an etherized animal the increase was only about three and a half per cent. In another dog, not etherized, the increase was about twenty-three per cent. There was also an increase of from four to six per cent. in the blood of the femoral vein over arterial blood. In three cases of hemiplegia, the blood from the arm of the sound side contained about the normal proportion of cholesterin, while blood from the affected side contained no cholesterin.

In an experiment on a dog it was found that the arterial blood lost about twenty-three per cent. and the portal blood about four and a half per cent. in passing through the liver, comparing these two kinds of blood with blood taken from the hepatic vein.

These experiments led to an examination of the feces to determine the quantity of cholesterin discharged; but in a number of careful examinations of many different specimens of feces I was unable to find cholesterin. I found, however, what appeared to be a non-saponifiable fatty substance in considerable quantity. Examining this substance daily with the microscope, after five or six days I saw crystals beginning to form, which finally presented the appearances I have already described as characteristic of stercorin. I found the daily discharge of stercorin to be 0.7 gram, about equal to the estimated quantity of cholesterin discharged into the intestine in the bile in the twenty-four hours. In but one examination of feces of the dog did I find cholesterin, and this was in a fasting animal, a small quantity of cholesterin being found with stercorin. In a specimen of meconium, I found a hundred and sixty parts per thousand of cholesterin and no stercorin. In clay-colored feces from a patient with jaundice from obstruction, neither cholesterin nor stercorin was found. In the feces of the same patient, which were normal in color and obtained fifteen days after the first examination, stercorin was found and no cholesterin. These experimental facts seemed to show that the stercorin of the feces is derived from the cholesterin of the bile, and that the change of cholesterin into stercorin is incidental to the processes of intestinal digestion. In no case was I able to detect in the feces any trace of the biliary salts.

Passing from these observations to the pathologic relations of cholesterin, after examining three specimens of normal blood and finding the proportion of cholesterin from 0.445 to 0.751 of a part per thousand, examinations were made of the blood of patients with simple jaundice and those with what is called icterus gravis, the cases terminating fatally with grave nervous symptoms. In a case of simple jaun-

dice, terminating in recovery at the end of about four weeks, the blood contained 0.508 of a part per thousand, well within the limits in normal blood. In case of jaundice with cirrhosis, terminating fatally with serious nervous disturbance, the blood taken six days before death contained 1.850 part per thousand of cholesterin, an immense increase over the normal proportion. In this case, on postmortem, the liver was found contracted, and the gall bladder was shrunken, containing about seven cubic centimeters of bile.

The question of cholesteremia has been much discussed since 1862, for the most part with scant approval or without acceptance. However, Picot,² in 1872, reported a fatal case of "grave jaundice" in which he determined a grave increase in the proportion of cholesterin in the blood, 1.804 part per thousand. Many attempts have been made, also, to produce toxic effects by injecting cholesterin into the blood, but most of them have been unsuccessful on account of mechanical obstruction of the blood vessels. In 1873, however, Koloman Müller³ succeeded by injecting cholesterin rubbed with glycerin and mixed with soap and water. In five experiments on dogs, injecting in each 0.045 gram of cholesterin, he produced a complete representation of the phenomena of "grave jaundice."

In repeating the original researches of 1862, the observations, as regards analysis of feces, etc., were somewhat extended. With modern apparatus, the manipulations may be freed from many disagreeable features which heretofore, probably, have interfered with this line of investigation. In extracting stercorin, various volatile fatty acids and other substances were removed, the constitution and relations of which are unknown. We studied, in this connection, some of the products of bacterial action, obtaining, by the action of fecal bacteria on proteids, skatol and indol, both substances containing nitrogen. It is well known that phenol and cresol also exist in the feces. These nitrogenized matters are putrefactive products; nothing is known of their physiologic or pathologic relations, and up to this time stercorin is the only excrementitious matter yet found in the feces, the origin and relations of which are at all understood. Our knowledge, indeed, of the physiologic chemistry of the feces is only just begun; and we may look to future investigations for much that will be most important as well as interesting. The same may be said, in a measure, of the bile and of the true pathology of certain functional and structural diseases of the liver. How long shall we continue to speak of biliousness, congestion or torpor of the liver, the classic "liver complaint" *et id genus omne*, using terms which have no scientific meaning? Undoubtedly there are general disturbances, dependent upon some disorder in the functions of the liver, which occur without jaundice, and this fact has long been recognized. In a cirrhosis with considerable constitutional disturbance but no jaundice, the blood was found to contain an excess of cholesterin, 0.922 of a part per thousand. In what is termed acholia, there may be grave nervous symptoms without jaundice, and the pathology of such cases is unknown. The biliary salts are not found in the blood, and the symptoms can not be accounted for by disturbances in digestion. It is possible that light will be shed upon their pathology if it be admitted that there is a condi-

² Journal de l'anatomie, Paris, 1872, tome VIII, p. 216 et seq.

³ Ueber Cholesterämie. Archiv für experimentelle Pathologie und Pharmakologie, Leipzig, 1873, Bd. I, S. 218 et seq.

tion called cholesteremia. As yet this is but speculation; but if the theory of cholesteremia be accepted, a wide field of inquiry is opened in this direction, and ere long we may speak of "biliousness" and "liver complaint" with some definite ideas of their pathology.

It must be remembered that the liver is by far the largest gland in the body; that it secretes a fluid which is known to have a double function, one connected with digestion and the other with the elimination of cholesterin; that the blood from the digestive tract all passes through this organ, where it undergoes certain changes; that it probably stores up the products of amyolytic digestion in the form of glyco-gen; that it arrests certain poisons, and that it is the chief organ concerned in the production of urea, which is discharged by the kidneys. It may have other uses in what is now called internal secretion, in addition to that of destruction of blood corpuscles and the change of hemoglobin into bilirubin. With all these varied uses of the liver, however, the pathology of hepatic diseases is most obscure. We do not know even the cause and mechanism of the formation of gallstones, which are often composed almost entirely of cholesterin.

The term, acholia, as used in pathology, now means very little and conveys no distinct idea of the causes of the nervous symptoms which attend this condition. The term cholemia is generally regarded as almost synonymous with jaundice. If cholesteremia be recognized as a distinct pathologic condition, with symptoms due either to the accumulation of cholesterin in the blood, acting as a toxic substance, or to imperfect separation of cholesterin from the nervous tissue, a positive advance will be made in our knowledge of the pathology of many obscure liver disorders.

The quantitative estimation of cholesterin in the blood is not difficult, and it does not require more than from four to six or eight grams of blood. The only tedious manipulations are the drying, saponification and weighing; and these are readily done in a well-appointed laboratory. Some process may be devised which will expedite this extraction. If examinations of the blood were to be made in cases of obscure nervous disturbance, in epilepsy and other disorders of this nature, it is possible that cholesterin may be found to play an important part in their pathology. The fact that bromin readily combines with cholesterin, taken in connection with the wide use of the bromids in diseases of the nervous system, is very suggestive. May not the bromids promote the elimination of cholesterin, a substance which is so insoluble and which forms few combinations? These points seem well worthy of the consideration of pathologists and therapeutists. Certainly the physiologic and pathologic relations of cholesterin offer a wide and perhaps fruitful field for further observation.

With this paper I present photographs of cholesterin, stercorin extracted by the original method and stercorin extracted by the method of Bondzynski and Humnicki, all in 1897, with a photograph of crystals obtained in 1897 from a specimen of stercorin extracted in 1862.

I have added, for comparison with the recent crystallization from the specimen of 1862, a photograph from a slide marked June, 1862. These crystals, which are from the same specimen of 1862, have been mounted for thirty-five years and are much more abundant and beautiful than those obtained by recrystallization in 1897.

ADDRESS IN SURGERY.

Delivered at the Semi-Centennial Meeting of the American Medical Association at Philadelphia, Pa., June 3, 1897.

BY W. W. KEEN, M.D., LL.D.

PROFESSOR OF THE PRINCIPLES OF SURGERY AND OF CLINICAL SURGERY, JEFFERSON MEDICAL COLLEGE, PHILADELPHIA, PA.

Mr. President and Gentlemen of the American Medical Association:—It is always proper to acknowledge an honor, but when it comes unsolicited from so large and distinguished a body of men, representative of the entire profession in the United States, and on an exceptional occasion, I feel it a double honor to have been chosen to deliver the semi-centennial address in surgery. I beg to return you my very hearty thanks for your extreme kindness.

As we celebrate on this occasion the semi-centennial of the organization of the AMERICAN MEDICAL ASSOCIATION, in this city, in 1847, it is very natural and proper, that the Address in Surgery should be a review of the work done in the last fifty years, and by contrasting the state of surgery and of surgical teaching in 1847 with that which exists in 1897, to see what progress has been made. To recount what has been achieved in these "fifty years of science" far better than a "cycle of Cathay" is not only a pleasure, but it is an immense incentive, since by the progress made in the last fifty years we can in some measure anticipate the enormous, and probably even still greater progress, that will be made in the next half century.

The time, also, is opportune. Last year was celebrated the centennial of vaccination and the semi-centennial of the first public administration of ether. Sydney Smith's bitter query in 1820, "In the four quarters of the globe, who reads an American book, what does the world yet owe to American physicians or surgeons?" was answered a quarter of a century later and made all these "four quarters of the globe," our grateful and everlasting debtors for the gift of anesthesia. The discovery of an American dentist; first used by an American surgeon; christened by an American physician and litterateur; the recent celebration awakened throughout the world the interest not only of the profession, but also of the entire public; and the strains of our still living poet, novelist, physiologist and, as we all best love to remember him, neurologist, Dr. S. Weir Mitchell—*nihil tetigit quod non ornavit*—as he sung of the "Birth and Death of Pain," have scarce died away before we begin anew our round of celebrations in the anniversary of this now almost venerable ASSOCIATION.

A most important factor in the improvement not only in surgery but also in all departments of medicine, has been the immense advance made in medical teaching. The educational plane of the profession has been steadily elevated. If the teachers of fifty years ago were to revisit the scenes of their early labors they would scarcely recognize the medical colleges, in which, in their day and generation, and with the meagre appliances then at their command, they did what we must still recognize as yeoman's work in education. Apparently, at that time, the entire instruction consisted in lectures, no text-books even being advised. In reply to a letter addressed to the deans of the Jefferson Medical College and of the Medical Departments of the University of Pennsylvania, Harvard University and Columbia University,

1 The names of American surgeons are printed in italics, to point out more distinctly some of those Americans who have aided in the development of surgery. The limits of the address only allowed me to name a few, and I must apologize for all the necessary omissions.

I am told that no lists of text-books whatever appear on the catalogues of fifty years ago. In the "catalogue" of the Jefferson, for 1857—a mere catalogue of names of the faculty and students, instead of the present elaborate "Announcement"—for the first time appears a list of "Books of Reference," and the Dean of Harvard, states that there, "the first mention whatever made of text-books appears in the announcement of the summer session, beginning March 12, 1866," four years after I graduated! At first the text-books generally recommended on surgery were Drewitt and Erichsen; Malgaigne and *Pancoast*, on "Operative Surgery," and, for collateral reading, Bordie and Holmes.

The course of didactic lectures then began on the second Monday of October and ended soon after the middle of February, and if we take out the holidays, and remember that not a few made up for coming late by leaving early, it was quite a possibility for a man to receive his authorization to practice, a diploma which alleged him to be "*Virum probum in arte medica, aeque ac chirurgica . . . dignum amplissimis honoribus academicis,*" after practically only two sessions of three months each! The examination was a farce and the diploma a falsehood. Even so late as 1860, when I began the study of medicine, there were no laboratories, except that of anatomy—the dissecting room. I doubt whether of the two hundred and odd men who graduated with me in 1862, 10 per cent. had ever looked through a microscope or handled a test-tube, palpated a tumor or auscultated a chest. There were no recitations; neither were there ward classes nor other means for actual contact of the student with disease. We can but wonder that any of us who graduated in the first twenty years of the half century we are celebrating ever learned enough to prevent some from being rivals to Saul, who had slain his thousands, and the more nimble from rivalling David, who slew his ten thousands. That we have become respectable practitioners, or possibly more than respectable, is due not so much to our early opportunities as to later incessant midnight labors.

Now we may congratulate ourselves that the majority of the Medical Schools of the country have a graded course of four years, each covering not less than six, and often eight months; not only lectures, but in many instances constant and searching recitations; almost a score of laboratories in which each student actually does the work of observation and experiment; ward classes in which every man is obliged to train his eyes, his ears, his fingers and his judgment, in the examination of patients in every department of medicine; to ferret out the history of the cases brought before him, ascertain symptoms, seek for physical signs, reach a diagnosis, determine the treatment, and often actually to prescribe and to assist at operations.

Not only, however, is the advance marked in our medical schools, whose diploma now really means, almost what it says, but also all over the land since 1847 there have been established, partly from philanthropic motives and partly for the purpose of medical teaching, an enormous number of hospitals, in which a very large proportion of the young men, after receiving their diplomas, spend a year or more in the actual practice of their profession, under the eye of accomplished teachers. It is impossible to describe the immense benefit thus obtained by large numbers of nascent practitioners, from such familiarity with all the phases of disease which they will

meet in their after lives. Not a few of them also, by being brought in contact with energetic, enthusiastic, and wise teachers, receive their first stimulus, both literary and scientific, a stimulus which will influence their entire future course, and is of far more value than any amount of mere scientific knowledge they may acquire.

What untold good these hospitals do, not only to the patients who are cured and the internes who are taught, but equally to the older medical staff who are still further trained and educated by them! Not only in great metropolitan centers, but in small towns, and sometimes even in rural communities, this growth of hospitals has been within the last twenty years one of the striking features of our civilization. It is not too much to say, that every city or town establishing a hospital, is repaid a hundred fold in the immediate improvement of its medical men, from these opportunities for experience and exact study. No one can visit a modern hospital without being struck by the immense improvements of the last few years. The noisome hotbeds of contagion, of fever, of suppuration, of erysipelas, of blood poisoning and of "hospital" gangrene—could irony wield a sharper weapon than such a name?—have given way to neat and trim wards, the home of cleanliness itself with iron bedsteads, glass topped tables, cement or marble, tiled or tessellated floors and walls, with trained nurses whose jaunty caps and pretty uniforms and often winsome faces almost make one half wish to be sick, and when one is sick half loth to be well.

I mentioned a moment ago the text-books in use forty years ago. Except *Pancoast's* "Operative Surgery," every one of them it will be observed was the work of a European. *Gross's* "System of Surgery," which has probably had a wider influence in educating the profession than any other general surgical text-book issued up to the present time—a monument of surgical knowledge and indefatigable labor—was first published in 1859. This was far in advance of most of the surgical text-books then in use. The literary labors of American surgeons consisted chiefly in translating foreign surgeries, or in annotating American editions of English text-books.

Within the last two decades, and especially the last, we all know, without my undertaking the invidious task of naming them, how many distinctly American surgeries have been written, and we may say without undue national vanity that they are the equals of any similar European works. This literary and scientific activity, however, has not been limited to text-books or systems of surgery alone, but our forward strides in education have been marked by the appearance of not a few monographs of original research which do credit not only to their authors but to all American surgeons.

On more than one occasion I have had to call attention to the difference between American surgery and that of Europe. While in the department of the practice of surgery, after a full acquaintance and observation with European men and methods, I can state my deliberate conclusion that the best American surgeons are the peers of the best European surgeons; yet in the department of original research and especially of laboratory work, we must confess our very evident shortcomings. I do not say that we should be ashamed of them, for we must remember that we are but little more than a century old as a nation; that the practical needs of everyday life must first be met; that oppor-

tunities must be created by the construction and endowment of laboratories, and especially by the growth of that literary and scientific spirit which only develops in any community or profession in the course of long years and with accumulated wealth, and which has had little opportunity for growth in this country until within the last twenty years. The genius of our institutions is such that we can never look for government or State endowments of such laboratories, but must depend on the far sighted and broad minded liberality of our wealthy fellow-citizens for the establishment of such laboratories and the consequent opportunities for investigation and discovery. Nor do I believe in the long run we shall suffer by reason of this difference. As a people we are not apt to be left behind in the race, and the stimulus of a somewhat exceptional distinction in science or literature will meet with a responsive chord in the breast of many a young man now beginning his studies.

To attempt to impress upon the members of the AMERICAN MEDICAL ASSOCIATION the need for such original research in this country is a work of supererogation, but I may with propriety urge you with all the ardent and intense conviction I feel, that as we leave this festal meeting and go to our homes, every one of us as occasion offers will urge upon our wealthy liberal-minded fellow-citizens the duty and also the privilege of founding in connection with every medical school laboratories of research, the good influence and beneficent results of which can never be estimated in paltry dollars and cents. Yet tried even by this commercial standard science pays. The early recognition of the germs of cholera at the port of New York some years ago by preventing the entrance of such a commerce-destroying epidemic, leaving wholly out of consideration the saving of human life, saved to the citizens of the metropolis more millions of dollars than are represented many times over by the cost of all the laboratories now existing in this country. Our merchants should be made to understand, therefore, that even from a financial point of view, to say nothing of the humanitarian standpoint, the cheapest means of preventing the enormous business losses which occur from epidemics is by such scientific and hygienic measures as the laboratory makes possible.

Allied to medical teaching and the most important adjunct to medical literature is the establishment of extensive medical libraries. In this, as an American, I am proud of my own country. No foreign nation can point with equal pride to any such medical libraries as the last thirty years have developed in this country. Foremost, not only among American libraries, but in the world, is that of the Surgeon-General's Office of the United States Army in Washington. Not only has it gathered thousands of medical books and eleven hundred medical journals (the estimate of Dr. Fletcher) from all over the world, but the entire library is managed with a liberality which makes it the admiration and the envy of foreigners. Its treasures are freely at the service of the entire profession of the country, and the publication (under the editorship of Dr. John S. Billings) of its magnificent "Index Catalogue," has made the whole world debtors to America. We trust that a more liberal congress may see that if even the small amounts thus far given to it have made it of such immense value, still larger and more generous appropriations would keep it ever in the van.

In addition to this, the libraries of the College of Physicians of Philadelphia, of the New York Academy of Medicine, and of the Boston Medical Library Association are only surpassed by those of the faculties of medicine in Paris, of the Royal College of Surgeons of London, and of the Military Medical Institute of St. Petersburg; while those of the Newberry Library in Chicago (thanks to our honored and liberal president), of the New York Hospital, and of the Pennsylvania Hospital rank well with the best European libraries. With such literary opportunities, therefore, if we had equally good scientific laboratories the possibilities of American medicine and surgery would be almost unbounded.

The scientific progress of this half-century of surgery has separated us from the past as by a great gulf. Great theologians, such as a Calvin or a Jonathan Edwards, were they recalled to life, could discourse as learnedly as ever of Predestination and Free Will; great preachers, as a Beecher or a Spurgeon, could stir our souls and warm our hearts as of old; great jurists, as a Justinian or a Marshall, could expound the same principles of law which hold good for all time; great forensic orators, as a Burke or a Webster, could convince us by the same arguments and arouse us by the same invectives or the same eloquence that made our fathers willing captives to their silver tongues. But today, so rapid has been our surgical progress, a Velpeau, a Sir William Ferguson, or a *Pancoast*, all of whom have died within the last thirty years, could not teach modern surgical principles nor perform a modern surgical operation. Even our every-day surgical vocabulary—staphylococcus, streptococcus, infection, immunity, antiseptics and asepis, toxin and antitoxin—would be unintelligible jargon to him; and our modern operations on the brain, the chest, the abdomen and the pelvis would make him wonder whether we had not lost our senses, until seeing the almost uniform and almost painless recoveries, he would thank God for the magnificent progress of the last half-century, which had vouchsafed such magical, nay such almost divine power to the modern surgeon.

The splendid Index Catalogue of the library of the Surgeon-General's office teaches another lesson. In law, the jurist or attorney deals with statutes and precedents, and to some extent with principles which are for the most part local. An American lawyer could not plead a case in Germany, nor a German lawyer in Russia, nor a Russian lawyer in Italy. Laws and customs differ from country to country. An American or an English divine would be an alien in language and religion in Hindostan; a Hindoo, equally an alien in China; a Chinaman, in Africa. But surgery is one and the same the world over. Whether in the frozen north or under the equator, in civilized America or barbaric Africa, be the patient white Caucasian, swarthy Negro, red Indian or yellow Malay, the same accidents and diseases assail him, the same remedies save him, identical operations cure him: a new remedy discovered in Japan is equally efficacious in Philadelphia; a new operation devised in America is equally applicable in Egypt. The Index Catalogue, which is a catalogue not for one country, but for all nations and all tongues, contains them all. This, with our noble stand as a profession against patenting any instrument, any operation or any method of treatment, makes every sick or injured man my brother, and makes me his keeper, under every sky, and clothed in any skin. Heaven bless such a divine profession,

such a noble array of generous men battling for the life and health of all mankind, the world over, in one serried phalanx of unselfish heroes!

The development of modern surgery, apart from surgical teaching, libraries and laboratories, is dependent on several noteworthy factors. These have to do partly with the discovery and development of surgical principles, and partly with the development of surgical practice. Now the one and now the other is in advance. Each is the handmaid of the other. In Listerism we see surgical practice outstripping surgical principles, for of Lister it might truly be said, that by the "scientific use of the imagination" he saw the germs, "when as yet there were none of them." His surgical insight convinced him of the existence of the germs of suppuration years before Ogston's and Rosenbaum's discovery of the pyogenic organisms. On the other hand, the moment that the scientist discovered these germs, the laboratory enabled him to discover many others, and the discovery of the bacillus of tetanus, of the tubercle bacillus, of the streptococcus of erysipelas, of the gonococcus, of the bacillus of malignant edema, the bacillus mallei, etc., illustrate the converse—science forging ahead of practice, and pointing the way to new achievements in the healing art.

Foremost among the important studies which the past fifty years have seen established on a firm foundation, is that of *Pathology and Pathological Anatomy*. It is not a little credit to America that the first pathology written in the English language was written by a young American doctor, in a then small western town, as early as 1839. In spite of Gross's book, however, pathology and pathological anatomy were almost unknown sciences in 1847. The Pathological Society of Dublin was founded in 1839, that of New York in 1844, that of London in 1846 and that of Philadelphia in 1857. The microscope, and especially microscopical methods of staining, section cutting and the like were in their infancy, or may indeed be said scarcely to have existed. No accurate views of pathology could be entertained without these aids. What is now the heritage of every first year student was beyond the possibilities of the most advanced teacher of fifty years ago.

Second. — *Allied sciences* have been put under tribute to surgery. In physics the discovery of the *Röntgen rays* is so recent as to require only mention. This discovery, as well as the enormous advances of *Electricity*, as seen in the electric head-light, the cystoscope, the gastroduaphanoscope, and other means of diagnosis, engenders the hope that other forces and other means of investigation quite as surprising and quite as marvelous, are certainly to be expected within the next fifty years.

It is due, however, especially to the development of *Embryology and Comparative Anatomy*, in combination with pathology, that our views of the nature of disease have become so much more accurate. Perhaps the book which influenced surgical views and surgical practice more than any other, was Chelius's "Surgery," of which a translation by South was republished in Philadelphia in 1847. It had passed through six editions, and had appeared in eight languages. It may be taken, therefore, as the type of the most advanced continental surgery of that day. How curiously vague his ideas of pathology were, may be seen in his classifying together false joints, old rupture of the female perineum, harelip and cleft palate,

as "old" in contradistinction to "recent," "solutions of continuity which do not suppurate." Though he speaks of the last two as "original vices," yet so far as concerned embryology, which has shown the cause for hare-lip and cleft palate, he is absolutely silent. Stenosis of the esophagus, of the rectum, of the prepuce, urethra and vagina, were all classed together under "diseases of unnatural adhesions of parts." The existence of neoplasms as a cause of the stenosis, was not clearly differentiated from other causes. All his ideas as to tumors were vague, and, as we now know, wholly unscientific. There is no chapter on tumors in the modern sense, though there is one on "diseases which consist in the degeneration of organic parts, or in the production of new structures;" but even in this, enlarged clitoris, goitre, warts, bunions, fungus of the dura mater, fatty swellings, encysted swellings and loose bodies in the joints are grouped with polyps, sarcoma, cancer, and other new growths. Ranula, retention of urine, and retention of the fetus are classed together as "Foreign Bodies formed in our organism by the retention of natural products," and hernia cerebri is treated in connection with all other forms of hernia. Greater disregard of their pathology or etiology, of their origin and significance, can hardly be imagined.

Though John Hunter had dissected over five hundred varieties of animals a half century before the AMERICAN MEDICAL ASSOCIATION was organized, yet the solidarity of the animal kingdom from man down to the lowest form of life was not recognized. Evolution and, therefore, reversion to animal types, was not recognized, and hence not used to explain many abnormal developments. For instance, abnormalities in the arch of the aorta and its branches, which we now recognize as variations of a general plan running through the entire animal kingdom, were then mere curiosities of structure without any meaning.

Third.—The year before the AMERICAN MEDICAL ASSOCIATION was organized the world was startled and surgery revolutionized by the introduction of *Anesthesia*; first of ether, in America, in the year 1846; and of chloroform, in Edinburgh, in the following year. What this has done for the amelioration of the horrors of pre-anesthetic surgery, very few now living can appreciate. Instead of shrieks, and cries, and groans, and a needful celerity which sometimes became dangerous haste, everything now proceeds with that quiet and leisure which is essential to the performance of many, if not most, of our modern, elaborate and prolonged surgical operations. Now "the fierce extremity of suffering has been steeped in the waters of oblivion, and the deepest furrow in the knotted brow of agony has been smoothed away forever." (Holmes.) Who could possibly endure the tortures of an operation lasting for one, two, or it may be even three hours, when every minute seemed an eternity of agony? I would rather be the discoverer of anesthesia than have won an Austerlitz or a Waterloo.

The old motto, "*tuto cito et jucunde*," is now changed by the omission of "*cito*." In fact, as has been pointed out by Cheever and a few others, the leisurely performance of operations which is made possible by ether is in danger of leading us to a dilatory method of operating which has its own dangers. Some of our most successful modern surgeons owe not a little of their lessened mortality, I am sure, to their swiftness.

The ideal anesthetic has not yet been obtained. No one who reads the journals from week to week, and

sees the sad headings "Death from Anesthetics," and especially "Death from Chloroform," can fail to see that both ether and chloroform, and also a few others which occasionally replace them, have very real dangers. The ideal anesthetic will not be one which will abolish pain without abolishing consciousness. To have the patient aware of surgical emergencies which test even a veteran operator's skill and resources to the utmost, would frequently invite death by the terror which it might occasion. The ideal anesthetic will abolish pain by the abolition of consciousness, *but without danger to life*. That it will be found, is as certain, as that experiment and progress are our watchwords.

Besides general anesthesia, several forms of local anesthesia have been devised, within the last few years, by freezing with salt and ice, rhigolin or chlorid of ethyl, by cocain, eucaïn, Schleich's infiltration method, etc., methods which have a distinct sphere of usefulness, especially in minor operations.

Fourth. *Antiseptic surgery*.—While the exact date of the revolution in surgery due to anesthesia can be fixed, a later revolution in our surgical methods came in so gradually that one can not name any special day, or even year, when it was introduced. But, while the day or year can not be given, the one man to whom this great revolution in modern surgery is due is well known. The name of Lister, *primus inter pares*, is honored throughout the entire surgical world, and his recent distinction, as the first medical peer of the United Kingdom, is an honor conferred not upon Lord Lister alone, but upon the entire Profession, and worthily marks a new departure in the recognition of medical science by the queen.

So far as this country is concerned, the introduction of antiseptic surgery may be said to date from the visit of Mr. Lister to this same city of Brotherly Love, at the Centennial International Congress of 1876. Derided at first as a "fad" or as "nothing more than surgical cleanliness," it has now won its way over the whole world. A few laggards in the surgical army there are who even yet do not practice modern antiseptic or aseptic surgery, but the overwhelming majority of the profession recognize that the world owes a debt to Lord Lister, which no honors can pay. His service to humanity will never be forgotten, and probably never will be surpassed, in its wide-reaching beneficent influence. Anesthesia abolished pain; antiseptics has almost abolished suppuration, erysipelas, tetanus and the various forms of blood poisoning; in other words, nine-tenths of the dangers of surgical operations. Malgaigne, from 1836 to 1840, lost 126 amputations of the thigh, out of 201, a mortality of nearly 63 per cent. (Mütter's Liston, p 425). Erdman (*Annals of Surgery*, xxii, 1895, p. 358) has shown, that in nine New York hospitals, from 1882 to 1894, the mortality in 223 amputations of the thigh was 21.5 per cent. Heimann (*Arch. klin. Chir.*, 1897, liv, 223) reports in Germany, in 1894, 475 cases with a mortality of 21.7 per cent. Page (*Lancet*, 1894, i, 1439) of Newcastle-upon-Tyne has shown that, from 1876 to 1893, of 230 amputations of the thigh, the mortality was only 11.3 per cent., and Estes (*N. Y. Med. Rec.*, Nov. 3, 1894) of 77 such amputations lost only 8, a mortality of but 10.4 per cent.

Without anesthesia and antiseptics, modern surgery would be an impossibility. It is to me an inspiring and encouraging thought that the world owes the three greatest discoveries of modern medicine—Vaccination,

Anesthesia and Antiseptics—to England and America. Long may they be joined in such scientific brotherhood! Never may they be sundered by fratricidal strife!

Fifth.—As an outgrowth from the practical development of antiseptic surgery has arisen a wholly new science, and a wholly new method of practice, which bid fair to revolutionize our modern therapeutics—*Bacteriology and Orrhotherapy*. Like the antiseptic method, they have been a gradual outgrowth. Modern laboratory research has verified the crude suspicions and shrewd guesses of thirty years ago, and transformed them into the certainties of modern science. The discovery of the anthrax bacillus by Pötlender, in 1855; the epoch-making discovery of the pyogenic organisms, in 1881, by Ögston and Rosenbaum; of the tubercle bacillus by Koch, in 1882; of the tetanus bacillus by Nicolaier, in 1887, will illustrate how recent is this scientific knowledge. The splendid results which have been achieved in medicine, by the use of Behring's and Roux's diphtheritic antitoxin, seem to promise that some form of anti-streptococcic serum will do as much for surgery, and that your orator fifty years from now will be able to trace the history of the probably soon to be realized method of battling with infection, of which at present we have only a premonition. Bacteriology and orrhotherapy are so recent that it is dangerous to prophesy what may occur, but it is not venturing far to predict that fifty years from now we shall be able not only to easily convert infected into non-infected wounds, but also, by some means as yet undiscovered, we shall be able successfully to combat the infection, and prevent the dire ravages of tuberculosis, of syphilis, of cancer, of sarcoma, and possibly even the occurrence of benign tumors. That will be indeed the surgical "Golden Age," when surgery will be robbed of nearly all its terrors, when a peaceful victory will abolish our present instruments and the majority of our present operations.

Sixth.—*Animal experimentation* has had also a very large share in the development of modern surgery. The whole question of the introduction of animal ligatures was begun in America by *Physick*, who used buckskin; his follower, *Dorsey*, who used kid, and cut both ends short; *Hartshorne*, who used parchment, and *Bellenger* and *Eve*, the tendon of the deer; and this has been solved principally by experiments upon animals, in order to determine accurately the behavior of such ligatures in the tissues. Only professional readers can appreciate what a boon to humanity this single achievement has been. Modern cerebral surgery also owes its exactness and success almost wholly to cerebral localization and antiseptics, both of which were first studied by experiment upon animals, and later by the application of the knowledge so gained to man. *Bacteriology would not now exist as a science, nor would accurate modern surgery and a large part of modern medicine be possible, had experiments upon animals been prohibited, as some zoöphilous men and women who love dogs better than men and women, and even little children, desire.*

Seventh.—The developments of modern surgery has naturally been on two lines: First. That of *scientific* progress based especially on pathology, bacteriology, embryology and comparative anatomy. Our present views of tumors, of malformations, of the theory of immunity, of septicemia and pyemia, of thrombosis and embolism, have been the result of the studies by physi-

ologists and pathologists, which have most profoundly helped our practice and influenced our results. Secondly. Within the last twenty-five years, especially, there has come what might be called preëminently the era of the *operative surgeon*, due more especially to the introduction of anesthesia and later of antiseptics. By making it possible to perform an operation without pain, and almost without danger, organ after organ of the body has been made accessible to the modern surgeon with almost invariable success. Scarcely twenty years ago even Erichsen, in a public address, declared that surgery had nearly reached its final limits, and that the brain, the heart and the lungs must ever remain inaccessible to the surgeon's knife! But now these organs are so constantly operated on and even removed that I have about reached the conclusion that, with the exception perhaps of the heart, all of our internal organs are strictly to be classed as luxuries—and we even know some heartless people. From this safety and painlessness there has been born an audacity unknown to the men of a former generation. Diseases then thought to be incurable are now vanquished every day in our clinics, and organs thought to be inaccessible are attacked with an impunity which is perfectly marvelous. Indeed, the danger is not slight, that we may go to the other extreme and we may well heed the warning of *Weir Mitchell*, that, perhaps, "surgery has lost much of that keen sense of responsibility which grew out of the larger mortality of other days."

Modern instruments of precision, such as the clinical thermometer, the cystoscope, the ophthalmoscope, the laryngoscope, the otoscope, the proctoscope, the aspirator, etc., without which accurate diagnosis and proper treatment are often impossible; instruments accessory to operation, such as retractors, hemostatic forceps, transfusion apparatus, etc., without which the modern surgeon would be hampered and hindered beyond measure, were wholly unknown thirty years ago.

Time will not permit me to trace chronologically the introduction of one operation after another. We can best, perhaps, obtain a notion of the difference between the surgery of 1847 and that of 1897, by noting what operations were performed at the former date and contrasting them with present possibilities. Among the operations performed a half century ago may be included—

- Amputations;
- The ligation of the most important arteries;
- Occasionally excision of joints;
- The removal of tumors;
- Lithotomy;
- Lithotripsy;
- Colostomy;
- Herniotomy;
- Tracheotomy;

Tenotomy (the subcutaneous performance of which, together with the difference in the danger of open and closed fractures, long before the day of Lister, should have pointed out the road to antiseptic surgery); and

Trephining, which, though formerly very frequent, had almost fallen into desuetude. South says in 1847, "the less done as regards fractures of the skull the better. They should never be interfered with except compression be present." The barbarous *écraseur* and the equally barbarous *Jarvis's adjuster*, were then in frequent use.

Ovariectomy was more than looked at askance. In

1846, *Mütter*, in commending Liston (*Mütter's Liston*, p. 442) for protesting against ovariectomy says: "It is certainly hazarding but little to assert that in a very few years the measure will be assigned to the oblivion it so richly merits," and so late as 1862, the year that I graduated, I heard the then professor of obstetrics (*Meigs*) in the Jefferson College, in his last course of lectures, declare with a warmth which did more credit to his humanity than to his science, "that the men who go about the country ripping open women's bellies should be indicted for murder." The first ovariectomy in England was performed in 1836; the first in France in 1844; but for Europe ovariectomy "was not fully established as a surgical procedure until after 1858, when Wells took it up" (*Heath's Hunterian Oration*, 1897); and in this country, where it had originated in 1809, at about the same date when the brothers *Atlee* suffered, one may say even persecution, because of their adherence to their belief that ovariectomy was a justifiable operation. Now, a number of surgeons can each count more than one thousand ovariectomies, perhaps some even two thousand, with a mortality in their later results as low as 3 per cent. In his first thousand ovariectomies, on the basis of the annuity tables of life insurance companies after deducting the years lost by the fatal cases, it was estimated that Sir Spencer Wells alone had added twenty thousand years of happy useful life. With our modern antiseptic methods it would be no exaggeration to say that a thousand similar cases today would add thirty or possibly even thirty-five thousand years of human life. What that means to the hundreds of homes, to the hundreds of husbands and thousands of children in those homes, who can say?

It is impossible in the time allotted me, to do more than make a very brief survey of the surgery of 1897, as contrasted with that of 1847, but even a hasty glance will give us some idea of how far we have gone on the road of progress.

One of the most striking departments in which progress has been made is in that of the nervous system. In this *Mitchell*, though not a surgeon, has suggested many surgical advances. I have already quoted South's dictum as to fractures of the skull—a dictum which is now violated with the happiest results by almost every surgeon in the land. In addition to this, a very large number of tumors of the brain have been successfully removed, tumors which before 1854 were considered as wholly outside the domain of surgery. To our English brethren, *Godlee*, *Horsley* and *Macewen*, above all others, is due the credit of establishing cerebral surgery on a firm basis of right principles and successful technique.

In abscess of the brain we have a lesion, which is still more amenable to treatment, and the number of recoveries now mounts even into the hundreds. We have recognized that these abscesses very frequently arise from chronic disease of the middle ear, and, thanks to the otologist, we can now, by proper treatment, in many cases do better than operate on these abscesses—we can prevent them. The papers of *Arbuthnot Lane*, *Ballance* and *Macewen* have taught us that even so formidable a disease as thrombosis of the sinuses, especially of the sigmoid sinus, can be dealt with successfully. Even the ventricles of the brain have been successfully invaded, drained, packed with gauze and washed out from side to side.

Tumors of the spine, since *Mr. Horsley's* brilliant paper, in 1888, have been proved accessible to the

modern surgeon. Though *Abbe's* division of the posterior nerve roots, in cases of intractable neuralgia, has not been followed by all the success we could wish, it has proved that the operation is a practicable one. While, in the words of the hymn, we have not yet "stretched every nerve," we have almost realized that pious exhortation. Section of nerves by accident or deliberately, in the removal of tumors, was formerly followed by permanent paralysis, but now nerve suture has rescued many a poor sufferer and restored the junction of the divided nerve, even after months of separation. Facial neuralgia, once the bane of the surgeon and the sufferer, has now been cured in a number of cases, not only by the removal of the rebellious nerve, but as was suggested by *Mears* in 1884 (*Trs. Amer. Surg. Assoc.*, 1884, p. 482-3), even the Gasserian ganglion itself has been removed in more than a hundred cases. In this department the names of our American brethren, *Carnochan*, *Pan-coast* and *Hartley* stand preëminent.

In disease of the organs of locomotion—the bones and the muscles—the expansion of modern surgical technique has been very marked. The plastic surgery of the bones seems scarcely to have any limit. Osteotomy is so safe that in 1884 *Macewen* reported 1,267 operations, on 704 patients, with only 5 deaths, and they were chiefly due to other causes than the operation. Tenotomy and transplantation of tendons have assumed a new field of usefulness undreamed of a few years ago. In fractures and dislocations the progress has been equally extraordinary. *Jarvis's* adjuster has given way to the method of manipulation first introduced by *Reid*, and reduced to a science by *Bigelow* and *Allis*, for the hip, and *Kocher*, for the shoulder, and in a combination of fracture with dislocation, the ingenious hook of *McBurney* has enabled the surgeon, in many cases, to accomplish that which manipulation alone could not have done. The splints of *Nathan R. Smith* and *Hodgen*, and the introduction of adhesive plaster by *Gross*, and the subsequent application by this means of the weight and pulley by *Buck*, have supplanted the clumsy splint of *Desault*. Even so simple a means of treatment as that by plaster of Paris, together with the thorough disinfection of compound fractures, has enabled us to obtain results, either by the recumbent or the ambulatory treatment, which, but a few years ago, were impossible. Compound fractures, then among the most serious accidents of the human frame, with a mortality of about two out of every three, have so lost all their dangers that the mortality is hardly more than two out of every hundred.

Tumors, once too formidable either by reason of their size, their location, their adhesions, or the hemorrhage which attended their removal, have been made wholly amenable to treatment. We have been taught largely by the labors of the younger *Gross* and *Halssted* that even cancer no longer necessarily entails death by recurrence, but that if we remove the growth early and thoroughly, we can obtain a cure, which in the hands of *Mr. Cheyne* (*Lancet*, 1896, 1, p. 397) has recently reached the extraordinary result of 57 per cent. of permanent cure in cancer of the breast.

Not only has the exterior of the chest been invaded, but the ribs and the sternum are now resected, and when necessary the entire chest wall, over a large area, is removed with impunity.

Few of us, excepting the older living members of the profession, can remember the immense advance

which paracentesis of the chest made, by reason of the persistent and fruitful researches of *Bowditch* and *Wyman*, about 1850, out of which have grown *Estlander's* and *Schede's* heroic and successful operations. Not only have accumulations within the pleura been evacuated, but *Roberts* was among the pioneers in the operation of paracentesis pericardii, while the surgery of the lung is now only taking its first tentative steps. The pericardium has also been sutured, and even the heart itself has twice been sutured, with one complete recovery (*Farina*, *Rev. de Chir.*, 1897, 335—*Rehn*, *Lancet*, 1897, 1, 1306).

We were taught by the younger *Gross* that the great veins could be successfully tied, and recently they have been successfully sutured—even the lateral sinus. The recent researches of *Abbe* (*N. Y. Med. Rec.*, Jan. 13, 1894, 39), and *Murphy* (*N. Y. Med. Rec.*, Jan. 16, 1897, 73), may open a new chapter in the surgery of the arteries by substituting suture with preservation of their lumen for occlusion by the ligature.

Quite as fruitful has been the surgery of the digestive tract. Foreign bodies in the esophagus which were very inefficiently dealt with fifty years ago, thanks to the Roentgen rays and modern surgical methods, are now in the large majority of cases successfully removed. In non-malignant stricture of the esophagus, *Abbe's* bowstring method has been a credit to American surgery.

I can do scarcely more than allude to the surgery of the stomach; to the value of gastroenterostomy, to pylorotomy, to pyloroplasty, to dilated stomach in which a tuck has been taken both by European and American surgeons, or hour-glass contraction of the stomach, which *Weir* and *Watson* have successfully remedied by operative procedures, to gastrotomy in stricture of the esophagus or *Richardson's* gastrotomy for the extraction of foreign bodies in the esophagus. In the surgery of the entire intestinal tract, America, it can be safely said, has led the world. To no one laborer in this field is more credit due than to the distinguished President of the AMERICAN MEDICAL ASSOCIATION (*Senn*), to whose irrepressible labor, genius and skill we owe most of our means and methods of dealing with such diseases. He first showed us the most successful methods of making intestinal anastomosis, from which have arisen all of our modern methods of treatment of cancer of the large and small intestines, and many allied conditions. From these fruitful labors also have arisen our modern methods of the treatment of intestinal and fecal fistulæ, even in some cases reaching so far as the total exclusion of a considerable portion of the bowel. The modern, wonderfully successful treatment of wounds, whether stab wounds, gunshot wounds or others of the stomach, intestine or bladder, owe their success largely to the labors of the elder *Gross*, *Parkes*, *Senn*, *Bull*, *Murphy* and other Americans.

Cancer of the rectum, which, until about ten years ago, was almost inoperable, has now taken its place among the formal and justifiable operations of modern surgery, so that as much as twelve inches of the rectum have been resected by *Kraske's* method. The mortality has been reduced to 20 per cent., and permanent cure of such a formerly fatal disease has been attained in over one-third of the cases which recovered. (*Therap. Gaz.*, April and May, 1897.)

The other accessory organs in the abdomen have been conquered by the modern surgeon. Fifty-seven

tumors of the liver have been removed with a mortality as low as 13.5 per cent. (Transactions Pennsylvania State Med. Soc., 1897.) The world owes to America the operation of cholecystotomy, since it was first done by *Bobbs* in 1867, and was popularized by the powerful influence of *Sims* in 1870. Pancreatic cysts, chiefly through the labors of *Senn*, are now amenable to treatment, while the spleen has been extirpated many times.

The appendix, that meagre but most troublesome ancestral vestige, which with the bicycle has been the faithful friend of the surgeon through the past few years of commercial depression, has been recognized within the last few years as the real origin of the so frequent abscess in the right iliac fossa. Beginning with *Willard Parker's* paper, in 1867 (*N. Y. Med. Rec.*, 1867, ii, 25), and *Fitz's* memorable paper, in 1886 (*Trans. Assoc. Amer. Phys.*), the treatment of appendicitis, and even its much abused name, are distinctly of American origin, and an immense credit to American surgery.

Until *Simon's* classical experiments on dogs, in 1870 (*Deutsche Klinik*, xxii, 137) the kidney was a practically inaccessible organ, but now, when it wanders, we secure it by sutures; when there is a stone in it, we open it fearlessly and remove the stone; when it is distended with pus or urine we drain it, and if it is past hope of recovery we extirpate it, all with most remarkable success. Even stones in a ureter or a divided ureter, *Cabot*, *Fenger*, *Kelly* and *Van Hook* have shown us, can be successfully dealt with.

The treatment of stone in the bladder has undergone an extraordinary revolution since the introduction of *Bigelow's* litholapaxy. Its introduction as a surgical procedure was dependent on the prior researches of *Otis* and other Americans, who showed us that the caliber of the urethra was much greater than we had supposed, and permitted, therefore, the introduction of instruments of much larger diameter than before had been deemed allowable. The reintroduction of supra-pubic cystotomy, due largely to *Dulles's* paper, in 1875 (*Am. Jour. Med. Sci.*, lxx, 39), has permitted us to deal not only with large stones, but also with ulcers and tumors of the bladder; even large portions of the wall of the bladder have been removed successfully. The enlarged prostate is now, though always a serious danger, far less a menace to comfort and life since the introduction of *McGill's* and other methods of prostatectomy, and of *White's* operation of orchidectomy or the resection of the vas deferens.

The surgery of the pelvic organs has, one may say, been created since 1847, but its triumphs are so many that time allows only a word. *Sims's* treatment of vesico-vaginal fistula and his introduction of silver wire in 1852 was distinctly an American triumph, while the labors of the *Allees*, *Kimball*, *Peasley*, *Goodell*, *Thomas*, *Emmett*, *Balfey*, *Kelly*, household names to all of us, have made pelvic surgery so successful that the danger is that it may be overdone. Many an ovary or womb, in the words of the witty toast, "absent from the body but present in the spirit," would far better have been left in possession of their owner.

The radical cure of hernia has been the product of the last twenty years, and the operations of *Halsted*, *Bassini* and *Macewen*, not to mention the many others, have taken a permanent place in the practice of the profession within the last ten years. When we

can report, as *Coley* has recently done (*Annals of Surg.*, March, 1897, 270), 360 cases, with only one death and seven recurrences, or as *Degarmo* has reported at this very meeting, 250 cases unmarred by a single death, the question of the propriety of operating for the radical cure of hernia even in children, is settled once for all.

Goiter fifty years ago was simply allowed to run its course, since hemorrhage destroyed nearly all those operated on; but two years ago *Kocher* (*Beilage z. Centralbl. f. Chir.*, 1895, 66) reported a series of a thousand operations, with a mortality of but 1 per cent., in non-malignant cases.

Extirpation of the larynx for malignant growths has taken its place among the justifiable and formal operative procedures. Acute intestinal obstruction, whether from bands, volvulus, intussusception or other conditions, is now dealt with as it ought to be, surgically, and, if promptly done, with the happiest results.

A hasty and very imperfect review, such as has been above given of the improvements in surgery within the last fifty years, does much more than show us the adroitness, audacity and success, of the modern surgeon. That is the thing which strikes us most as surgeons, but we must regard all this progress also from the standpoint of the patient and the community, and see what it means. It means a prolongation of life by operations, which, while not without pain and suffering during recovery, have been robbed of all their primary terrors by anesthesia, and most of their subsequent pain and suffering and danger by antiseptics; it means that patients who in 1847 were hopelessly consigned to the grave after weeks and months of suffering, are now, in the vast majority of cases, rescued from death; it means that families formerly bereft of husband and wife, parent or child, and left to spend years of sorrow, of suffering and, in many cases, of poverty, because the breadwinners were taken away, have now restored to them, their loved ones, in health and strength and usefulness; it means that the hecatombs of a *Cæsar*, an *Alexander*, a *Napoleon*, are offset by the beneficent labors of a *Morton*, a *Warren*, a *Lister*, who are, and for all time will be, blessed by many a poor patient, who never heard of them, instead of being cursed as the destroyers of nations and of homes innumerable; it means that man's inhumanity to man shall be replaced by a scientific and Christian altruism, which sheds blessings and benefits on the whole human race, seeing in the patient, whether saint or sinner, only a human being who is suffering from accident or disease, whom it is the province of the surgeon, in imitation of Him who went about doing good, to restore to health and happiness. Even where life can not be prolonged, the agonies of death itself can be soothed by his gentle hand and his fruitful skill.

What the future has in store for us we can only dream. Two diametrically opposing tendencies are prominent in modern surgery; radical interference with disease so that there is now scarcely a single organ or portion of the body, not within our reach; yet on the other hand a remarkably conservative tendency in cultivating remedial rather than radical surgery. Joints so diseased as once to require amputation, are now treated conservatively with the best results; ovaries, a portion of which can be preserved, are kept in the abdomen; kidneys once doomed to extirpation are now partially removed, and bones so destroyed that

they formerly required amputation, are now excised and the limb preserved. Experiments upon animals have recently given us wholly new views of infection and of the origin of many diseases, and also the little knowledge that we yet have as to either natural or acquired immunity, and to a consequent orrhoterapy.

It is, I believe, on these lines that our more immediate future triumphs will be achieved. We have discovered the actual cause of tetanus, tuberculosis, erysipelas, suppuration, and a host of other diseases and conditions, of the cause of which we were wholly ignorant a few years ago. The causes of many other disorders, both medical and surgical, still remain hidden from our view. We know almost nothing of the origin of benign tumors, and are groping to discover the origin of cancer, sarcoma and other malignant growths. When we have discovered the cause, we are nearly half way, or at least a long way, on the road to the discovery of the cure, and I think it not unlikely that in 1947, your then orator will be able to point to the time, when a definite knowledge of the causes of these diseases was attained, and probably to a time when their cure was first instituted.

That will be a surgical Paradise, when we can lay aside the knife, and by means of suitable toxins or anti-toxins, drugs or other methods of treatment, control inflammation, arrest suppuration, stay the ravages of tuberculosis and syphilis, abort or disperse tumors, cure cancer, and it may be, so prolong human life that all of his then audience will die either of accident or of old age. Would that you and I could be alive in 1947 to join in the glorious surgical *Te Deum!*

THE PREVENTION OF TUBERCULOSIS.

The Address in State Medicine at the Semi-Centennial Meeting of the American Medical Association at Philadelphia, June, 1897.

BY JOHN B. HAMILTON, M.D., LL.D.

PROFESSOR OF THE PRINCIPLES OF SURGERY AND CLINICAL SURGERY IN RUSH MEDICAL COLLEGE; CONSULTING HYGIENIST TO THE CITY OF CHICAGO, ETC., ETC.
CHICAGO, ILL.

Mr. President and Colleagues:

I stand here today by appointment in the place of the late Dr. Jerome Cochran of Montgomery, Alabama, whose preëminence in the science of preventive medicine easily singled him out from among his fellows, as peculiarly fitted to deliver the annual oration in State Medicine. His vast erudition, extended experience, and long public service made him *facile princeps* in all matters relating to sanitary work. Few have spoken with better right, or with greater authority.

This is not the proper place to pronounce the eulogy of Jerome Cochran; that was done in this hall yesterday, but the world knows of his life and his work. The laws of Alabama which furnish us today the best model for Medical Legislation in other States, were largely the handiwork of Dr. Cochran, and the medical profession of that State is under enduring obligations to his memory. It was my good fortune to have known him well, and to have served by his side in trying times; and in all matters relating to the public health of the State in which he was so long State Health Officer, it is safe to say that Dr. Jerome Cochran, whether engaged in investigation of an epidemic, inspection of quarantine, or in the daily routine of office work, was master of the occasion. No weakness! No concessions! No trimming! Faithful to his trust always, loyal to his State and industrious beyond the habit

of most men, he has gone to his rest, full of years, full of honors worthily won, with the love and admiration of his immediate colleagues, and the respect of all his professional brethren throughout our country wherever located. His knowledge was encyclopedic and there are few by-paths in sanitary science which he had not explored.

In person and manner he seemed at times austere, but those that knew him knew that under that rugged exterior there dwelt a soul as full of sentiment as a woman's and a heart as tender as a child's.

Blow softly, sweet South wind, over his resting place, and disturb not this laurel leaf, we gently lay upon his tomb.

Naturally this is the occasion for reminiscence, a place to recite the triumphs of Preventive Medicine under the auspices of our famous ASSOCIATION. It is true that while the musty records of the past are gilded with the recital of the glories of the Goddess Hygeia, yet so far as records are concerned a thousand years of history are as but a day, compared with the greater progress of this restless but successful age, compressed within the period of the life of this ASSOCIATION. The formation of Boards of Health, of Cattle Commissions and Sanitary Bureaus, and the organization of official forces against epidemics and the spread of infectious diseases, belong to our time, and in this country is largely the result of the educational work of this ASSOCIATION. Until yesterday, I had thought there was such a thing as the practice of hygiene, the prevention of disease by the application of the known rules of the art, but when I listened to the matchless eloquence of our colleague, whose oration was justly the topic of praise from every tongue, I too joined in the applause we were giving Surgery through its learned and able advocate and came to the conclusion that it was *Surgery*—the handicraft of CHIRON, the Centaur; and not Hygeia and her gentler methods that year by year reduces the mortality rate.

But however attractive the field and gratifying the glimpse that might be afforded of the various reforms brought out by the influence of the ASSOCIATION, let us reflect that after all the *present* has many claims to our attention, and I shall therefore hope for your indulgence if I touch upon an important topic of today rather than recite ancient history.

Prevention of tuberculosis—Statistics.—The topic which I have selected is that of the Prevention of Tuberculosis. No more important subject could possibly be discussed, for this disease causes about one death in every seven that are recorded in the United States; about one death in every eight is caused by tuberculosis of the lungs alone. It is now known that no tissue of the body is exempt from the invasion of tubercle bacilli, and that the clinical appearances vary so much according to location, that tuberculosis is better entitled to be called the "protean" malady than syphilis, unless indeed, we shall sometimes find a closer relation between syphilis and tuberculosis than has hitherto seemed probable.

Pulmonary tuberculosis alone took 345,963 lives in the five years 1850, 1860, 1870, 1880 and 1890. These were the years in which the U. S. census was compiled.

"In the 28 largest cities of the German empire the number of deaths from consumption per 100,000 of the aggregate population during the year 1890 was 299, ranging from 453 in Nuremberg, 367 in Dortmund,

357 in Frankfort on the Main, 388 in Crefeld and 353 in Elberfeld to 236 in Königsberg, 249 in Strasburg, 239 in Halle and 247 in Chemnitz.

"The average annual number of deaths from consumption per 100,000 of inhabitants for the 10 years 1881 to 1890 was, for Paris, 463; Nuremberg 457; Dortmund, 417; Barmen, 381; Aachen, 377; Frankfort-on-the-Main, 373; Crefeld, 373; Breinen, 392 and London 206. The death rates from consumption in most of the large cities diminished during the 10 years 1881 to 1890. The differences in the mortality from consumption in the large cities of the United States depend largely upon differences in the proportion of different races in the several cities, and also, to some extent, upon the age distribution and density of population, on the depth of the level of subsoil water, and on the dryness and uniformity of temperature of the climate. As a rule, the death rate from this cause in large cities is greater than it is in the small towns and rural districts."

The following table from the ninth U. S. census shows for the 28 cities and for their aggregate the number of deaths from consumption during the census year, in the aggregate and for 3 age groups, per 100,000 of corresponding population, the cities being arranged in the order of magnitude of the aggregate death rates from this cause.

Cities.	All Ages.
Total	268.81
New York	387.45
San Francisco	378.26
Boston	375.72
Washington	358.95
New Orleans	343.75
Newark	326.68
Providence	303.45
Baltimore	293.02
Brooklyn	288.34
Indianapolis	283.58
Louisville	281.14
Cincinnati	280.22
Philadelphia	279.57
Jersey City	271.77
Denver ¹	240.83
Rochester	213.60
Buffalo	186.18
St. Louis	184.61
Milwaukee	183.89
Kansas City	179.33
Chicago	175.93
Detroit	162.23
Cleveland	158.79
Minneapolis	152.97
Pittsburg	149.19
Allegheny	147.22
St. Paul	125.42
Omaha	67.64

If we add to this enormous mortality the record of the deaths from other forms of tuberculosis we shall find that tuberculosis rolls up a frightful death record. In my opinion, excluding injuries by mechanical violence, it is safe to say that localized tuberculosis causes nearly one-third of the surgical diseases for which operation is required, and that of those crippled for life by spinal and joint diseases tuberculosis causes seven-eighths of them.

General measures of relief.—The humanitarian turns to science for relief from this "great white plague," so destructive, so elusive and so calamitous, and it is now the province of State Medicine alone to

point out the methods by which we may put this plague "upon a basis of gradual extinction."

The prevention of tuberculosis can not be accomplished in a day, but its ravages may be made less by such prompt measures on the part of our boards of health as may easily be taken, provided the laity are taken into confidence. The public must be fully educated to an understanding of the causes and method of propagation.

The demonstration that the bacillus tuberculosis is the principal cause of pulmonary consumption and the sole cause of bone tuberculosis is a fact which must be kept before agriculturists, dairymen, stock-breeders and butchers, until the coöperation between them and the health officer is complete. Let the public understand that since the discovery of the bacillus tuberculosis the disease has been added to the list of diseases that are preventable by attainable means. Let the public schoolmaster understand that he may render his healthy boys and girls immune by gymnastics and calisthenics which increase their vital resistance, for while the object of hygienic regulations is the prevention of the propagation and spread of the tubercle bacilli, yet we know that the healthy tissue cell has a demonstrable power of resistance, so by increasing vital force we may build up a nearly impenetrable barrier against bacillary invasion. Let the consumptive fully understand that he has no right to allow himself to become a center of infection by carelessness, or to marry while the subject of the disease.

Heredity.—The heredity of the disease has been established by "Baraud and Rénon, who reported to the Société de Biologie of Paris, in June 1895, that they had investigated the question of the direct transmissibility of the bacillus through the placenta to the human fetus. In five cases they took a quantity of blood from the umbilical veins, and injected it under the skin of the abdomen of guinea pigs, immediately after the birth of the child. In three of the cases the guinea pigs did not become tuberculous, while in two they did. In the first case the mother was in the third stage of phthisis, the sputa containing bacilli. There were no lesions of the placenta present, apparently. The guinea pig which was injected developed a chancreous ulcer at the point of inoculation and died with tuberculosis of the liver and spleen at the end of two months. The bacilli were found in the spleen, pulp, and in the caseous masses of the chancreous ulcer. An autopsy performed on the still-born infant gave negative results. Three guinea pigs were injected with the juice of the pulp of the lung and liver and peritoneal serum, and two of them died. In the second case, the mother had pulmonary cavities, but no examination of the sputa was made. The child died of broncho-pneumonia on the fortieth day. The placenta presented a normal appearance. At the moment of birth, blood from the umbilical vein was injected into two guinea pigs; one pig died of generalized tuberculosis, the other lived."

Solly of Colorado holds that a connection between phthisis in an individual and phthisis in the family may be exercised in one of three ways, viz.: By inheritance of bacilli, by inheritance of susceptibility, or by contagion.³

Lehman has reported a case of congenital tuberculosis where a mother died three days after the birth of the child, of tuberculous meningitis. The child

¹ The deaths upon which death rates from consumption for Denver are computed do not include 133 deaths of non-residents dying of this disease in that city during the census year. (From Ninth U. S. Census, Vital Statistics, Part 2.)

² Health, Oct. 17, 1896.

³ Gould: The American Year Book of Medicine and Surgery, p. 92.

lived but twenty-four hours. In its spleen, lungs and liver were found nodules resembling tubercles and containing tubercle bacilli in large numbers.⁴

Hahn has collected and reviewed some cases of tuberculosis where they were undoubtedly congenital. The semen may also become infected and thus transmit the disease to the fetus. Gärtner caused tuberculosis in young mice by injecting the mother with tubercle, either into the peritoneal cavity or into the blood stream.⁵

Baumgarten detected the tubercle bacillus in the ovum of a female rabbit which he artificially fecundated with tuberculous semen.⁶

Infection by milk.—There is no longer any question of the possibility of infecting the lower animals by the injection of tuberculous milk, but direct evidence of transmission of tuberculosis by milk in man by ingestion is not yet positive, except in cases of udder tuberculosis.

In cows with tubercular disease of the udder, the Royal Commission found that the milk was in every case infective and the experiments made by inoculation in every case gave positive results. As regards feeding, 27 animals were fed with varying quantities of milk from cows with tubercular udders. Of these 27 animals, 19 developed tuberculosis. The brunt of the disease in these cases fell on the abdominal organs, showing the alimentary origin, but in some cases also there was a more generalized infection. The glands about the mouth and angle of the jaw were also found sometimes tubercular. Dr. Martin, in speaking of these experiments says:

"The milk of cows with tuberculosis of the udder possesses a virulence which can only be described as extraordinary. In those cows where the tubercle bacilli were found in the milk, the feeding experiments were uniformly positive as well as the inoculation experiments. It is noticeable too, that a small dose of the milk diluted four times gave tuberculosis to all the animals fed, and that a dose of even 0.05 to 0.1 c.c. diluted with non-infective milk was sufficient to produce tuberculosis."—(T. P. C. Kirkpatrick, "The spread of Tuberculosis by the Milk Supply," *Dublin Jour. Med. Sci.*, May, 1897.)

It is well known that many cattle are affected with tuberculosis in this country, that the milk goes into the general supply and that tubercle bacilli may be found in the milk in cases of udder tuberculosis, and that rabbits inoculated with infected milk or fed upon infected milk become tuberculous. Dilution with non-infected milk attenuate the bacilli and the dishonest practice of watering is therefore not without its compensation.⁷

Dr. Gehrman, of the Chicago Health Department, after testing the milk from tuberculous cows, writes:⁸ In only one specimen of milk was it possible to demonstrate the presence of the tubercle bacillus microscopically, but in thirty-eight injections of the milk in animals we had the transmission of tuberculosis demonstrated six times.

Infection by tuberculous meat.—Tubercle bacilli have been found in the flesh of horses, cattle and swine. Birds and fowls also become infected, and when dogs and cats become infected it is said that

they become so by reason of eating flesh of tuberculous animals, but this lacks corroboration by extended experiment.

"In 1890," says Crookshank, "a Royal Commission was appointed to investigate the subject and the report was issued in 1895. Martin, on behalf of the Commission, tested the flesh of twenty-one tuberculous cows. In two cases only was evidence obtained of the presence of the bacillus by inoculation of guinea pigs. The flesh of eight cows affected with mild tuberculosis produced tubercle in one instance by inoculation, but the ingestion experiments were negative. The flesh of five cows severely affected with tubercle gave the disease in four cases, either by feeding or inoculation, but only one gave the disease both ways. Martin thought that some of the results were due to the butcher infecting the meat in the process of dressing the carcass, either by his hands or knives. Woodhead made a series of experiments to test the effects of roasting and boiling on tubercular virus in meat. It was found that in boiling and roasting experiments as ordinarily carried out in the kitchen, the temperature, however high it may be on the surface, seldom reaches 60 degrees C. in the center, except in the case of joints less than about six pounds in weight. Boiling and roasting were found insufficient to destroy tubercular virus enveloped in rolls of meat.

The committee having enumerated many obvious preventive measures, made the following suggestions regarding the extirpation of the disease: "We are of opinion that it should be included in the contagious diseases (animals) acts for the purpose of certain sections of those acts, so as to provide: *a.* For the slaughter of diseased animals, when found diseased on the owner's premises. *b.* For the payment of compensation for the slaughter of such animals. *c.* For the seizure and slaughter of diseased animals exposed in fairs, markets, etc., and during transit. *d.* For the seizure and slaughter of diseased foreign animals at the place of landing in this country."

In the tuberculin tests made in various sections of the country an enormous number of cattle have been found to be tuberculous. According to Wood and Fitz, in Massachusetts, of 4,093 cattle 1,081 reacted positively, and on being slaughtered all but two were found tubercular. In Copenhagen, of 132,294 cattle slaughtered 17.7 per cent. were found tuberculous; of 142,872 slaughtered in Berlin, 15.1 per cent. were tubercular.⁹

The review of the recent reports on this branch of the subject corroborates the former view that careful cooking of meat and boiling of milk before eating or drinking these articles will prevent them from doing positive harm, but few would relish food if it were known to be tuberculous, even if cooked by a Lucullus. An act passed this year, by the Maine Legislature, to prevent the use of diseased meat for food purposes, provides that all diseased animals killed shall have injected into the carotid artery of each animal kerosene oil in sufficient quantity to thoroughly permeate and penetrate the fleshy parts of the animal, and every carcass thus treated shall be buried within twenty-four hours thereafter to a depth of at least four feet, or within forty-eight hours be reduced by the process of manufacturing the same for fertilizers.

Sources of danger.—Our danger from tuberculous meat is not very great in comparison with the dangers that confront us in daily contact with consumptives,

⁹ The Practice of medicine, by H. C. Wood and R. H. Fitz, 1897.

notwithstanding the fact that it is not the patient himself, but his expired air and sputum that are dangerous. Bergey of Philadelphia, however, in a paper read before the American Climatological Association in 1896, asserted that numerous experiments with the collected moisture of consumptives' breath, even those with extensive cavity formations, gave negative results. The great danger is in the dried sputum. Kruger showed that the dust of a hospital ward in which patients with pulmonary consumption expectorated occasionally, contained tubercle bacilli (Sternberg). This he proved by wiping up the dust on a sterilized sponge, washing this sponge in bouillon which was subsequently injected into guinea pigs. Two of the pigs became tuberculous. More conclusive experiments were made originally by Cornet. The experiments of G. Cornet showed the absence of infectivity in the dust of rooms and hospital wards where precautions were taken against the drying of the sputa, and also proved the rapidly fatal action of sunlight on the bacilli. On the other hand, he demonstrated the insignificance of so-called predisposition compared with the influence of over-crowding, dirt, darkness, and damp, and he demonstrated the necessity of prolonged and close association with tuberculous patients for the direct infection of healthy persons. (*London Lancet*, April 3, 1897.)

These experiments were repeated by Hance (Gould, Year Book, page 32), who collected the dust from the floors and walls of the various buildings at the sanitarium for consumptives, suspending it in sterilized water and inoculating a number of guinea pigs. Of eighty-one animals used, five developed tuberculosis, being half of the number injected with the dust from a cottage in which a patient had been reported for carelessness. Four of the pigs died of other infectious diseases, while the remainder remained healthy.

To sum up it appears that the greatest danger is from the dried sputum and that other causes, while they exist, are of much less importance. The local infections that are found in the bones and internal viscera are produced by invasion through the circulation, while the infection of lymphatic glands doubtless takes place by direct absorption through the lymph channels. Every surgeon has noticed without doubt that tuberculous glands become successively affected; it is the exception to find a whole chain of glands simultaneously affected. When the tubercular lesion is found in the skin the point of invasion is an abrasion; or a center beginning in the hair follicle.

The means of prevention of the spread of tuberculosis is then sufficiently apparent after we have taken our observations on the methods of infection. The factors in successful prophylaxis are: 1. The guarding against infectious food or drink being issued to the people anywhere. 2. The prompt destruction of cattle proved to be tuberculous. 3. Proper notification to the sanitary officer of the occurrence of cases of tuberculosis, especially walking cases of pulmonary consumption, in order that the officer may in conjunction with the attending physician make sure that proper precautions shall be taken to secure thorough disinfection of sputum and bedding.

Early diagnosis.—Not only as a means of prevention, but as a curative procedure is it important to make an early diagnosis. Physical signs are not always pronounced, and the bacilli may escape observation. The tuberculin test is therefore not less valuable in man than in animals, but the dose must be carefully graduated.

There has been much discussion over a recent requirement of some of our municipal boards, by which notification of cases of pulmonary tuberculosis are made compulsory. We must admit that consumption is slowly decreasing throughout the civilized world; but that decrease is only such as results from the improved hygiene of the day, and is not so great as the present state of knowledge warrants, for modern sanitation will only be satisfied by the extirpation of the disease.

To make extirpation possible we must adopt no half-way measures; prompt notification should be the rule, whether any specific measures are to be taken by the Health Department or not. That body can at least send printed information regarding the sanitary care of the patient and his apartments. No better justification of the recent order of the New York City Board of Health can be found than in the frightful records of mortality, from a disease which as already stated, in its various forms causes one-seventh of all the deaths.

The following is the amendment to the sanitary code of New York city adopted Jan. 19, 1897:

Section 225. That pulmonary tuberculosis is hereby declared to be an infectious and communicable disease, dangerous to the public health. It shall be the duty of every physician in this city to report to the Sanitary Bureau in writing the name, age, sex, occupation and address of every person having such disease who has been attended or who has come under the observation of such physician for the first time within one week of such time.

It shall also be the duty of the commissioners or managers or the principal, superintendent or physician of each and every public or private institution or dispensary in this city to report to the Sanitary Bureau in writing, or to cause such report to be made by some proper and competent person, the name, age, sex, occupation and last address of every person afflicted with this disease who is in their care or who has come under their observation within one week of such time. It shall be the duty of every person sick with this disease and of every person in attendance upon any one sick with this disease, and of the authorities of public and private institutions or dispensaries to observe and enforce all the sanitary rules and regulations of the Board of Health for preventing the spread of pulmonary tuberculosis.

The new law renders physicians and laymen alike liable to punishment for misdemeanor when any part of the section is violated. This order is the result of a report presented to the board by Dr. Hermann M. Biggs, pathologist of the department and director of the bacteriological laboratories; Commissioner George B. Fowler and Dr. T. Mitchell Prudden, consulting pathologist. The report showed that in twelve years the mortality from tuberculosis had decreased 30 per cent. owing to the steps taken by the department to prevent its spread. It was argued that more radical measures would produce even a greater reduction of the disease, and the amendment to the code was recommended.

A feature of the new law is the isolation of patients in aggravated cases.

The next step will undoubtedly be the erection and establishment of suitable sanitariums for the reception and care of those unable to be suitably cared for at their homes. Careful observation of the general principles of hospital construction as now understood will make it comparatively easy to construct special buildings with abundance of fresh air, plenty of sunlight and capable of being kept scrupulously clean. Then with proper regulations for the government of the inmates no one of them can possibly communicate the disease to others; beside that his condition can be made infinitely more comfortable. Patients able to avail themselves of a prolonged residence in Arizona

or New Mexico, or other approved climates, if not too far advanced, may reasonably expect a cure. The most rigid observance of sanitary regulations is necessary everywhere to prevent the sanitarium itself from becoming a center of infection. Daily sponging of the walls, floors and furniture, daily changes of bed linen, daily changes of patient's body-clothing and its frequent disinfection or exposure to the sun, careful regulation of temperature of the ward or room in which the patient is kept, besides the usual therapeutic measures are the indications that should be met. These special hospitals have been doing excellent work in England, where it is asserted that the general mortality has been greatly reduced since their establishment. The same is reported as true in France and Germany. Our own are few but have done excellent service.

Should the States take up the matter of location of sanitariums it is obvious that the location should be convenient of access and not too remote from the great centers of population.

In regard to the doubt often expressed that large sanitariums often become dangerous to the neighborhood, Dr. Knopf¹⁰ has well laid that doubt at rest by citing the case of the sanitariums at Goerbersdorf and Falkenstein, the two largest in Germany where "the mortality from tuberculosis has actually decreased among the village people, being now one-third less than before the establishment of those institutions."

We should be on our guard against the frightful treatment of consumptives that prevailed a couple of centuries ago, by which patients were feared and subjected to every hardship, and shunned as if they had smallpox or cholera.

The formation of colonies for consumptives.—The climatic conditions of the different parts of each State should be thoroughly investigated by disinterested parties, and the report published in one volume under the auspices of the State Medical Society, and then with the procurement of these data colonies may be formed to the best advantage.

What shall be done with the large class of tubercular patients that can not or will not go to a sanitarium? Clearly the same rules must be applied so far as possible, the patient must not expectorate in public places if he goes out and he should burn the sputum at home, which he can easily do if he uses paper receptacles for his sputum. For bedridden patients the physician in attendance will be the best authority, and his intelligent supervision will prevent the patient from becoming a nuisance.

Marriage of Tuberculous should be opposed.—The law prevents marriage within certain degrees of consanguinity; no account is taken of the physical state of the contracting parties, although in many States, several physical causes are especially named as sufficient cause for divorce. If chronic and incurable disease be sufficient ground for separation, how much more reason is there for the prohibition of the marriage rite. The insane and incurable diseased should not be allowed to propagate their species, unless we confine our sympathy to the individual instead of the whole people. The heredity of the disease has at last been fairly proved by scientific investigation. Public opinion should now do the rest. I am fully convinced that even now matters are so well understood, that little effort will be needed. Great delicacy

is needed in the practical handling of this means of prevention, for as love laughs at locksmiths, so it does at sanitary regulations if they happen to be restrictive.

The discovery of the bacillus tuberculosis has thus resulted in making clear the means of its prevention, and able experimenters by the hundred are patiently working out a cure; some seem to have it almost within their grasp; some proclaim that they already have it, but the great body of the profession are waiting. There are too many cures on the market for us to conclude rashly that the certain specific has been found; I am aware that the subject of therapeutics of tuberculosis is not properly under discussion in this address, but as silence may be misconstrued, permit me to say that modern treatment by open air, by climate properly chosen, by education, by pulmonary gymnastics, by hydrotherapy, by mental diversions, by serum therapy and proper medication have done much to make the consumptive's life more endurable, less likely to infect his fellows and in many instances have effected a cure.

According to Dr. Rooney of California, mountain air laden with balsams and terebinths, sea-shore air and sea air, all have their importance in different cases. Hypertrophic cases do best in mountain air, especially where hereditary, chronic pneumonia and pleurisy, apyrexia, emphysema, spinal and cerebral complications, lesions in the blood vessels and heart, liver and kidneys are found as complications. Cases in which cavities have developed with hemorrhages and general debility are benefited most by sea voyages, or prolonged residence on the sea shore. All these points should be thoroughly investigated before sending a patient to any locality, or establishing tuberculous colonies. (*Pacific Med. Jour.*, May, 1897.)

The English Royal Commission on Tuberculosis visited Germany investigating this question, in May, and afterward Denmark, whence I understand they will return to London. Professor Bang, with the sanction of the Danish government, is now conducting experiments on a large scale and we may soon have the benefit of the published results.

I have the utmost faith in the ultimate success of the great efforts now being made by sanitarians throughout the world to eradicate the tuberculosis pest—and after all, the efforts themselves are worth something and have their effect.

Richardson's "City of Hygeia," that "beautiful fabric of a vision," as one of our countrymen has said, "was blown away by the winds, but they blew it all over the earth." So the wide dissemination of correct knowledge concerning the cause and propagation of tuberculosis can not but tend to still further restrict its ravages and thus add to the sum of human happiness and the prolongation of human life.

Erb's Paralysis.—The lack of anatomic lesions in Erb's paralysis has always been a mystery. Widal and Marinesco have recently discovered marked chromatolysis in the nerve centers of the hypoglossus, motor oculi, anterior cervical gray matter, etc., from the necropsy of a typical and acute case terminating fatally in sixteen days from its first appearance. There was no trace of vascular or perivascular alteration nor of interstitial inflammatory reaction, nor were any histologic lesions to be discovered by the ordinary methods. But with Nissl's and Marchi's tests, more or less pronounced disintegration was discovered in the chromatophilous elements of the cells of the nerve centers of the region involved. The chromatolysis is described in detail, with numerous illustrations, in the *Bull. de la Soc. Méd. des Hop.*, April 15, and also in the *Presse Méd.* of April 14.

A BRIEF HISTORY OF THE ORIGIN OF
THE AMERICAN MEDICAL
ASSOCIATION.

THE PRINCIPLES ON WHICH IT WAS ORGANIZED; THE
OBJECTS IT WAS DESIGNED TO ACCOMPLISH; AND
HOW FAR THEY HAVE BEEN ATTAINED
DURING THE HALF-CENTURY
OF ITS EXISTENCE.

Read in the Semi-Centennial Meeting of the American Medical Association in Philadelphia, June 1, 1897.

BY N. S. DAVIS, A.M., M.D., LL.D.
CHICAGO.

The AMERICAN MEDICAL ASSOCIATION, to the semi-centennial celebration of which we devote the present passing hour, was the first truly National organization of the medical profession, deliberately planned to represent the profession of an entire country and to promote all its general interests, together with the sanitary interests of the whole people, of which we have any knowledge.¹

The circumstances that prompted the primary steps for the organization of this AMERICAN MEDICAL ASSOCIATION were National in their scope, and pointed unerringly to the necessity for National conference and coöperation. In devising a permanent constitutional government for the union of the several States that had achieved their independence of the mother country, one of the important problems that taxed the wisdom of the statesmen of that period, was to determine what interests and institutions should be controlled by the general government and what should be left to the individual States. Strongly imbued as they were with the broad principle that only such topics as related to the regulation of commerce and intercourse with other nations and between the several States, and the common defense of the whole, should be placed under the exclusive control of the general government, they decided to leave the important subject of education and educational institutions to the regulation of individual States. Consequently the people of each State, through their State legislative bodies, established such systems of primary education, and granted charters for such academic and collegiate institutions for literary, scientific and professional education, as appeared to them most appropriate. Our educational history as an independent people commenced thus, during the last half of the last quarter of the eighteenth century, in a new and sparsely populated country, extending from Maine to Florida, with only four medical schools organized, all as departments of literary colleges or universities, and all attracting annually attendance of less than three hundred students, of whom not more than fifteen annually received the degree of Doctor of Medicine, and no two of them controlled by the laws of the same

¹ It is true that the British Medical Association dates its origin back to July 19, 1832, when in response to the invitation of Dr. Charles Hastings of Worcester, Eng., between fifty and sixty medical men, all from the provincial towns and cities in the south part of England, assembled in Worcester and formed a strictly "Provincial Medical and Surgical Association," which was to meet annually in some one of the provincial towns, for mutual intercourse, support and professional improvement. The membership at the end of the first year numbered only 140; but under the guidance of its founder, Dr. (afterward) Sir Charles Hastings, its membership annually increased and its annual meetings were invited to cities farther north, meeting in York in 1841. It was not, however, until 1856, twenty four years after its organization, and nearly ten years after the organization of the American Association, that it began to claim national attributes by changing its provincial name for that of British Medical Association. And it did not hold its first meeting in the metropolitan city of London until 1862, during the first great International Exhibition.

State. And it must be noted also, that a very large majority of those who entered upon the practice of medicine at that time gained their education in the office of some established practitioner, and were licensed by the censors of medical societies, the judges of courts, or even by the certificates of their preceptor, without ever having spent a day in a medical college. But the rapid increase of population, and consequent building of new cities, and the addition of new States, that took place during the next fifty years, developed a correspondingly rapid increase in the number of medical schools. So true is this statement, that at the time of the organization of this ASSOCIATION, 1846-1847, the number of medical colleges in the United States was more than thirty, with an annual attendance of more than 3,500 students, of whom not less than 1,000 annually received the degree of Doctor of Medicine; thereby showing that the education of medical students had been transferred with equal rapidity from the preceptor's office to the medical schools. Unfortunately, this rapid evolution of collegiate medical education took place under no general supervision, nor in accordance with any uniform system of laws. On the contrary, the legislatures of the several States freely granted charters for medical schools, with authority to grant diplomas, which were accepted as a sufficient license to practice medicine, but left them all without pecuniary endowment, and therefore directly dependent upon the fees received from students for their support. This necessarily led to a most active rivalry for numbers of students. Had this rivalry been limited to efforts to see which school or college faculty would give the most complete and reliable instruction in the various branches of medicine, only good could have resulted therefrom. The making the diploma a sufficient authority to enter upon the practice of medicine, however, changed the ruling question in the minds of three-fourths of the students from, "in which medical school can I obtain the most thorough medical education," to, "in which school can I obtain the degree of Doctor of Medicine for the least expenditure of time and money?" And so potential was the latter question on the several medical schools, that although the three medical schools originally organized in Philadelphia, New York and Boston had been founded substantially on the same basis or curriculum as the University of Edinburgh, requiring a good academic education as a preliminary for entering the medical course, then from three to five years of medical study, with annual college terms of not less than six months, long before the number of our medical schools had reached thirty, all preliminary requirements had been abandoned, the term of medical study limited to a nominal three years, and the medical college instruction to two annual repetitional courses of from twelve to sixteen weeks each. Under this inadequate and unsystematic medical education, it really cost less in time and money to obtain the degree of Doctor of Medicine than it had previously cost to serve an apprenticeship in the office of a respectable practitioner and obtain a license from the censors of a local medical society. Of course, it elicited severe criticism by some of the most eminent teachers connected with the medical schools, by contributors to the medical press, and in discussions in many of the medical societies. And the one great fact that no adequate improvement could be made without either actual concert of action between the medical schools of all

the States, or the establishing of independent boards for examining and licensing candidates for the practice of medicine in each State, became apparent to every enlightened member of the profession. The earliest attempt to procure concerted action was among the medical schools of the New England States. In 1835 the faculty of the Medical College of Georgia urged through the medical press and by correspondence with other college faculties, the holding of a National convention of delegates; and in February, 1840, the Medical Society of the State of New York adopted a preamble and resolution, offered by Dr. John McCall of Utica, recommending the holding of a convention of delegates from all the medical societies and colleges in this country in Philadelphia in May of the same year.

The sole object of all these propositions was to procure concert of action in elevating the standard of medical education in the United States; and though they failed to get even the semblance of a convention, the discussions to which they gave rise did aid in demonstrating more fully the necessity of accomplishing the grand object just stated. At the annual meeting of the Medical Society of the State of New York, in Albany, February, 1844, Dr. N. S. Davis, then a young delegate from the Broome County Medical Society, offered a series of resolutions declaring in favor of the adoption of a fair standard of general education for students before commencing the study of medicine; of lengthening the annual courses of medical college instruction to at least six months, and the grading of the curriculum of studies; and have all examinations for license to practice medicine conducted by State boards, independent of the colleges. After a brief but earnest discussion, the resolutions were laid on the table until the next annual meeting, and the committee on correspondence directed to bring them to the attention of the several county societies in that State. At the next annual meeting of the State Society, February, 1845, the resolutions were taken from the table, the committee on correspondence reported favorable action by several of the county medical societies and the whole subject was freely discussed. It was admitted by all parties that the standard of medical education was too low, but at the same time it was claimed that the standard was as high in New York as in any of the other States, and if her medical schools were compelled to elevate the standard, it would have no other effect than to turn the students from them to the schools of Pennsylvania and of the New England States. Consequently, the author of the original series of resolutions closed the discussion by offering the following preamble and resolutions:

WHEREAS, it is believed that a National Convention would be conducive to the elevation of the standard of medical education in the United States; and

WHEREAS, there is no mode of accomplishing so desirable an object without concert of action on the part of the medical societies, colleges, and institutions of all the States; therefore,

Resolved, That the New York State Medical Society earnestly recommends a National Convention of delegates from medical societies and colleges in the whole Union, to convene in the city of New York on the first Tuesday in May, 1846, for the purpose of adopting some concerted action on the subject set forth in the foregoing preamble.

Resolved, That a committee of three be appointed to carry the foregoing resolution into effect.

The preamble and resolutions were adopted, and the mover, Dr. N. S. Davis, then of Binghamton, and Drs. James McNaughton and Peter Van Buren of

Albany, N. Y., were appointed the committee to further promote the object in view. This committee, through its chairman, prosecuted an active correspondence with the officers of all the regular medical societies and medical schools in the United States, and with influential members of the profession in which no medical societies existed. Commendatory notices appeared in most of the medical periodicals; and in the *New York Journal of Medicine and Collateral Sciences*, letters were published from the chairman of the committee, and from Dr. Luther Ticknor, then President of the Connecticut State Medical Society, discussing at considerable length the advantages of making the proposed convention the occasion for organizing a permanent National Medical Association. As the result of all these influences there assembled on the morning of May 5, 1846, in the hall of the Medical Department of the New York University, about one hundred delegates representing medical societies and institutions of sixteen of the twenty-six States then constituting the United States of America.

A complete organization was effected by the election of the following officers: For President, Dr. Jonathan Knight of New Haven, Conn. For Vice-Presidents, Dr. John Bell of Philadelphia, and Dr. Edward Delafield of New York City. For Secretaries, Dr. Richard D. Arnold of Savannah, Ga., and Dr. Alfred Stillé of Philadelphia, Pa.

On motion of Dr. N. S. Davis a business committee of nine was appointed "to bring the subject of medical education before the convention, in the form of distinct propositions suitable for discussion and action." This committee reported the four following propositions with the recommendation that a committee of seven members be appointed on each subject whose duty it should be to report at a meeting to be held in Philadelphia, on the first Wednesday in May, 1847:

1. "That it is expedient for the medical profession of the United States to institute a '*National Medical Association*.'"

2. "That it is desirable that a uniform and elevated standard of requirements for the degree of M.D. should be adopted by all the medical schools in the United States."

3. "That it is desirable that young men, before being received as students of medicine, should have acquired a suitable preliminary education."

4. "That it is expedient that the medical profession in the United States should be governed by the same Code of Medical Ethics."

After a free and friendly interchange of opinions, the report of the committee was adopted, and committees of seven were appointed for the full consideration of each subject, and directed to report at another convention to be held in Philadelphia, May 5, 1847.

Two other committees of seven were appointed to report at the same place and time, viz.: One on the proposition that all licenses to practice medicine should be conferred by a single board of medical examiners in each State; and the other on the necessity of efficient laws for effecting the registration of births, marriages and deaths in all of the States, and for a nomenclature of diseases. After spending two days in thus planning the preliminary work and having filled the six committees with men of known ability and influence, a seventh committee was

appointed with the President, Dr. Jonathan Knight, as chairman, with instructions "to prepare and issue an address to the different regularly organized medical societies, and chartered medical schools in the United States, setting forth the objects of the National Medical Association, and inviting them to send delegates to the convention to be held in Philadelphia, in May, 1847. The address of this committee was soon issued and with the proceedings of the convention were published with commendatory notices in all the medical periodicals, and elicited favorable action on the part of nearly all the States and local medical societies throughout the country.

The result was, that on May 5, 1847, there assembled in the hall of the Academy of Natural Sciences in Philadelphia, Pa., about two hundred and fifty delegates, representing not less than forty medical societies and twenty-eight medical schools, constituting the organized medical institutions of twenty-two of the twenty-six States then constituting the United States.

The convention was organized by the re-election of Dr. Jonathan Knight of New Haven, Conn., for President; Drs. Alexander H. Stevens of New York, George B. Wood of Philadelphia, A. N. Buchanan of Nashville, and John Harrison of New Orleans, Vice-Presidents; and for Secretaries: Drs. Richard D. Arnold of Savannah, Alfred Stillé of Philadelphia, and F. Campbell Stewart of New York.

The first business in order was the hearing of the reports of the several committees appointed at the previous convention. A full and able report was made by each committee, which may be found in the first volume of Transactions of the ASSOCIATION. These several reports were deliberately considered and their recommendations adopted with a near approach to unanimity by the convention. The committee on a Code of Medical Ethics for the whole profession reported through its chairman, Dr. John Bell, aided by Dr. Isaac Hays, both of Philadelphia, the full and admirable code which still remains as the best exposition of medical ethics in the English language.

The committee appointed in 1846 to report a plan of organization for a permanent National Medical Association was composed of Drs. John Watson, John Stearns, F. Campbell Stewart and N. S. Davis of New York; Alfred Stillé of Philadelphia; W. H. Cogwell of New London, Conn., and E. D. Fenner of New Orleans.

This committee adopted as the basis of a National Association the county or district and State medical societies in the several States and territories, and the faculties of the medical schools; allowing to each regularly organized medical society one delegate to every ten of its members, and each medical college faculty two delegates; and limiting the privilege of voting on all questions to the delegates in attendance at the regular meetings. By adopting such a basis, it was expected to greatly increase the number and efficiency of the local or county and State societies in every part of the country, and thereby constitute the National Association a true representative body, entitled to express the wishes and guard the interests of the whole profession. To retain the interest of delegates after their office of delegate had expired, the committee made provision for them to remain as permanent members, attend all regular meetings, and participate in all work of the ASSOCIATION except the

privilege of voting, so long as they paid the annual dues and remained in good standing in the societies from which they were sent as delegates. Guided by these principles the committee reported a constitution and by-laws, prefaced by the declaration that the purposes of the ASSOCIATION are "for cultivating and advancing medical knowledge; for elevating the standard of medical education; for promoting the usefulness, honor and interests of the medical profession; for enlightening and directing public opinion in regard to the duties, responsibilities, and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession; and for facilitating and fostering friendly intercourse between those engaged in it." The several sections of the Constitution were considered in detail and some amendments were offered but were rejected, and the report of the committee without amendment was adopted by a large majority vote. Having thus adopted a complete Constitution, By-laws and Code of Ethics, the convention resolved itself into the AMERICAN MEDICAL ASSOCIATION, and appointed a committee of one member from each State represented, to nominate officers for the ensuing year.

The committee soon reported, recommending the election of the following, viz.: For president, Dr. Nathaniel Chapman of Philadelphia, Pa.; for vice-presidents, Dr. Jonathan Knight of New Haven, Conn., Dr. Alexander H. Stevens of New York City, Dr. James Moultrie of Charleston, S. C., and Dr. A. H. Buchanan of Nashville, Tenn. For secretaries, Dr. Alfred Stillé of Philadelphia, and Dr. J. R. W. Dunbar of Baltimore. For treasurer, Dr. Isaac Hays of Philadelphia. The recommendations of the committee were unanimously adopted. After filling the several standing committees required by the constitution and agreeing to hold the next annual meeting in Baltimore, Md., on the first Tuesday in May, 1848, the ASSOCIATION adjourned. Such is a brief history of the *origin, objects and organization* of the AMERICAN MEDICAL ASSOCIATION, which, with the exception of the first two years of the great war for the preservation of the Union of these States, has held its regular annual meetings in all the important parts of our widely extending country, still adhering tenaciously to the fundamental principles on which it was founded. And I am most happy to add, that every leading object sought to be accomplished by its founders has been substantially obtained: That is, universal free and friendly social and professional intercourse has been established; the advancement of medical science and literature in all their relations has been promoted; and the long agitated subject of medical education has reached the solid basis of a fair academic education as preparatory, four years of medical study, attendance on four annual courses of graded medical college instruction of from six to nine months each, and licenses to practice to be granted only by State Boards of Medical Examiners. The grand citadel of our noble profession has thus been constructed on its legitimate foundations, and it only remains for those who come after us to perfect its several parts, and make them more and more efficient in preventing human suffering and prolonging human life.

The Bicyclers' Sanitary Crusade.—The bicycle clubs of France have combined and inaugurated a crusade to secure more hygienic sanitary accommodations throughout the country.

LIST OF MEMBERS OF THE

American Medical Association,

As returned by H. P. NEWMAN, M.D., Treasurer.

ASSOCIATION NEWS.

AMERICAN MEDICAL ASSOCIATION.

Official Report of the General Sessions of the Forty-eighth Annual Meeting, held in Philadelphia, Pa., June 1, 2, 3 and 4, 1897.

JUNE 1—FIRST GENERAL SESSION.

The Association met in the Academy of Music, Broad and Locust Streets, and was called to order at 10 A.M. by the President, Dr. NICHOLAS SENN of Chicago, Ill.

On the platform were Vice-presidents Dr. GEORGE M. STERNBERG of Washington, D. C.; Dr. EDMOND SOUCHON of New Orleans, La.; the Permanent Secretary, Dr. WILLIAM B. ATKINSON of Philadelphia, Pa.; the Assistant Secretary, Dr. T. B. SCHNEIDEMAN of Philadelphia, Pa., and the Treasurer, Dr. HENRY P. NEWMAN of Chicago, Ill.

Divine blessing was invoked by the Rev. L. Bradley, D.D.

President SENN then introduced the Hon. C. F. WARWICK, Mayor of Philadelphia, who delivered the following

ADDRESS OF WELCOME.

Mr. President and Members of the American Medical Association: I do not know that I have ever extended a welcome on behalf of the city in the presence of so many doctors before in my life. Philadelphia is the home of medicine, as you all know, and here Gross, Pancoast, Leidy and Agnew made for themselves reputations not only local, but national and international. It is my pleasure today to welcome and greet you.

A doctor is about the last man on earth we want to send for, but I wish to say without reservation that we are glad to have you in our midst today as a body of physicians. I have great respect for doctors. I have heard men in health condemn both God and doctor, and I know it is always these men who call for both most hurriedly when they fall sick. I have a welcome to give in another part of the city, so I am afraid to utter all the pleasure I have in greeting you, or to show you how much I think of all doctors, especially female doctors. (Laughter.) But if I could find a full opportunity to tell all I think and feel, you would see that it would be impossible for anyone to find a heartier or more sincere welcome than this I give you now. I hope your discussions and deliberations will result in great good to the human race.

The other day I addressed a class of trained nurses—graduates, and I said at that time that after a while nursing would be made such an art that it would be worth one's while to get sick occasionally in order that he might be nursed. (Laughter.)

I welcome you to this city with all the hospitality of her people and with the warmest welcome from my heart in representing them as their Mayor. (Applause.)

It was intended to have had Governor Hastings address the members of this Association, but he found it impossible to be present, and in his stead President Senn introduced the Hon. CHARLES EMORY SMITH, ex-Minister to Russia, who welcomed the Association in behalf of the State of Pennsylvania.

Mr. Smith was warmly received. He said:

Mr. President, Ladies and Gentlemen: I regret very much that the Governor of the State is unable to be present on this most interesting occasion; but I am sure you will excuse him when you understand the cause which detained him. He is holding a very important clinic at Harrisburg. He has a patient on his hands—I will not say sick, but considerably diseased. (Laughter.) Unlike your cases, it is his duty not to save but to kill the patient. He can only do this by the most drastic treatment, and so he is detained at Harrisburg in the

artistic work of amputating gangrene legislation. (Applause.) He is using the scalpel with great industry and considerable skill, and I am sure we shall all wish him greater power to his elbow in the operation.

In his absence I am not merely a substitute, but a substitute drafted at the last moment, and I can only say in a very few words what he would if he were here, namely, that the State of Pennsylvania, as well as the city of Philadelphia, cordially and heartily welcomes you within her borders. The banners which I see before me, bearing the names of the States, tell me that this is a National Convention. You have delegates here from every State and I suppose from almost every Territory in the United States. You are the distinguished representatives of that profession which comes closest to the hearts and the homes of the people, and the great State of Pennsylvania welcomes you for what you have done in the work in which you are engaged. I congratulate you that you have approached the semi-centennial of the American Medical Association. I am sure that your meeting here will mark an epoch in the history of medicine. I congratulate you on the auspices under which you assemble, and again, in the name of the Governor, I bid you a hearty welcome to the State of Pennsylvania. (Loud applause.)

Dr. H. A. HARE of Philadelphia, Chairman of the Committee of Arrangements, reported the following

RECEPTIONS AND ENTERTAINMENTS.

TUESDAY, JUNE 1.

Luncheon, 1 p. m.

Philadelphia County Medical Society, Hotel Walton, Broad and Locust Streets.

Philadelphia Polyclinic, Lombard Street, between 18th and 19th Streets.

Laryngological, Rhinological and Otological Section, Howard Hospital, Broad and Catharine Streets.

Section Dinners, 7 p. m.

Practice of Medicine, Hotel Aldine, 1914 Chestnut Street.

Surgery and Anatomy, Hotel Bellevue, Broad and Walnut Sts.

Obstetrics and Diseases of Women, Hotel Walton.

Ophthalmology, Hotel Walton.

Laryngology and Otology, Hotel Stenton.

Materia Medica and Pharmacy, Willow Grove Park.

Diseases of Children, The Bourse.

Neurology and Medical Jurisprudence, Aldine.

Dermatology and Syphilography, Hotel Walton.

State Medicine, Aldine.

Dental and Oral Surgery, Aldine.

WEDNESDAY, JUNE 2.

Luncheon, 1 p. m.

J. B. Lippincott Company, Union League, Broad near Walnut Street.

University of Pennsylvania, Houston Hall, 34th and Spruce Streets.

Jefferson Medical College, Academy of Fine Arts, Broad and Cherry Streets.

University of Pennsylvania, Union League.

Medico-Chirurgical College, 1723 Cherry Street.

Woman's Medical College of Pennsylvania, 21st Street and N. College Ave.

Dr. J. V. Shocmaker, 1519 Walnut Street.

THURSDAY, JUNE 3.

Luncheon, 1 p. m.

Dr. W. W. Keen, to Section on Surgery and Anatomy, Hotel Walton.

Philadelphia Obstetrical Society and Gynecological Section College of Physicians to Section on Obstetrics and Diseases of Women, Hotel Stenton.

Philadelphia Neurological Society to the Section on Neurology and Medical Jurisprudence, University Club, 1316 Walnut Street.

Dr. J. H. Musser, to Section on Practice of Medicine, Houston Hall, 34th and Spruce Streets.

Dr. L. Webster Fox, to Section on Ophthalmology, Hotel Bellevue, Broad and Walnut Streets.

Provost C. C. Harrison, a tea from 6 to 7 p.m., on the Campus of the University.

Theater Party, 8 p.m.

Lea Brothers & Company to the Association, South Broad Street Theater.

FRIDAY, JUNE 4.

Luncheon, 1 p.m.

Philadelphia Medical Club, Hotel Aldine, 1914 Chestnut Street.

Medico-Chirurgical College, 18th and Cherry Streets.

The following clubs extend the courtesy of open doors to the members of the Association:

Art Club, Broad Street below Walnut.

Columbia Club, Broad and Oxford Streets.

Manufacturers' Club.

Athletic Club of the Schuylkill Navy.

At this juncture, the First Vice-President, Dr. George M. Sternberg, took the Chair, and President SENN then delivered his Annual Address. He selected for his subject "The American Medical Association, Its Past, Present and Future." (See THE JOURNAL, June 5, 1897, page 1049.)

At the conclusion of the Address, Dr. E. D. FERGUSON, of Troy, N. Y., moved that the thanks of the Association be extended to Dr. Senn for his admirable and instructive address, and that the recommendations contained therein be referred to a committee of three, to be appointed by the Chair, to report thereon. Seconded by Dr. Humiston.

It was moved as an amendment that the recommendations in the President's Address be referred to the Business Committee. Seconded.

Dr. Ferguson accepted the amendment.

The motion as amended was carried.

Dr. Hare presented Dr. Senn with the insignia of his office as a token of the high esteem in which he was held, not only by the profession of Philadelphia, but by the profession of the United States of America.

Dr. Senn accepted the badge with a few words of acknowledgement.

On motion of Dr. I. N. Quimby of New Jersey, several visitors were made members by invitation.

Dr. Albert L. Gihen, U. S. Navy, then read the report of the Rush Monument Fund. (To be published later.)

The following is the Report of the Treasurer of the Rush Monument Committee:

SYKESVILLE, MD., June 1, 1897.

To the Rush Monument Committee:

I have the honor to submit the following report of the condition of the Rush Monument Fund:

On hand May 1, 1896 and reported to the American Medical Association at the Atlanta Meeting. \$3,787.64

Received from May 1, 1896 to June 1, 1897, inclusive of subscriptions, interest on deposits and investments 324.80

Total on hand June 1, 1897 4,112.44

Collections to Oct. 31, 1896, have been reported in THE JOURNAL of the American Medical Association. Collections since the above date are as follows:

Interest	120.80

Very respectfully your obedient servant,

GEORGE H. ROHE,

Secretary and Treasurer Rush Monument Fund.

THE FIRST VICE-PRESIDENT—What disposition will you make of these reports? They must be disposed of in some way. □

Dr. J. A. CUTTER of New York—I move that the Association place annually in the hands of the Treasurer of this Committee \$1,000, to be contributed toward the Rush Monument. Let me say, Mr. President, that if the homeopaths should erect a monument costing \$1,000,000 it would not be as good a monument as that of Dr. Benjamin Rusk. Nevertheless we must build this monument, and I believe this Association can stand \$1,000 yearly until the amount is raised. Seconded.

Dr. J. A. GRAHAM of Colorado—I move to amend the gentleman's motion, that this Association proceed at once to raise \$100,000 for the Rush Monument Fund, and in doing so I will pledge for the State of Colorado one-fiftieth of that amount, namely, \$2,000.

Seconded by Dr. Love.

Dr. WM. H. HUMISTON of Ohio—I agree with Dr. Graham in reference to raising these funds. If the motion of the gentleman from New York were to pass it would take us years to raise the amount necessary and we would get very tired of it. As President of the Ohio State Medical Society, I will pledge myself to raise \$2,000 promptly.

Dr. I. N. LOVE of St. Louis—I want to say, Mr. President, it is not creditable to this Association for us to go on year after year and not do the work we started out to do. The suggestion that \$1,000 be appropriated each year by the Association is not a practical one. It drags the thing along in a very undesirable way. I am in favor of the amendment of Dr. Graham of Colorado, and on behalf of the Missouri delegation and the State I will pledge myself to raise \$2,000.

Dr. E. D. FERGUSON of Troy, N. Y.—I am thoroughly in sympathy with the remarks of the last speaker, and the amount should be raised now, if possible. Each State may not be able to pledge itself to the extent of \$2,000, but as individuals we can pledge definite amounts. I will start the subscription from New York State with \$100 for myself.

Here a motion was made that not less than \$2,000 be accepted from each State, but it was not seconded.

Dr. CUTTER withdrew his motion.

Dr. H. D. DIDAMA pledged himself for \$100.

Dr. A. C. CORR of Carlville, Ill., ex-President of the Illinois State Medical Society, said the profession of his State would pledge itself for \$2,000.

Dr. JAMES T. JELKS of Hot Springs, Ark., contributed \$100. Dr. E. J. RUSS of Pennsylvania pledged himself for \$100; while Dr. WEIDMAN pledged \$2,000 for Pennsylvania.

Dr. JAMES H. HERRICK of Cleveland, Ohio, subscribed \$100, and expressed the hope that the audience would not disperse until the entire amount was raised.

Dr. WM. L. BAUM of Chicago pledged \$100 for the Chicago Post-Graduate Medical School.

A member from the State of Alabama said that Alabama would do its duty toward contributing its share to the Rush Monument Fund.

Here Dr. LOVE suggested that the States be called in alphabetical order.

The Secretary then called the States in the following order: Alabama. Contribution promised.

Arkansas. Dr. JAMES T. JELKS—After consultation with the Arkansas delegates, we want to say we will give all we can. Every member of the profession of our State will be appealed to for a contribution. I think we will be able to raise \$2,000; I am going to try to do it.

Arizona. No response.

California. A delegate from this State said that California would do its share.

Colorado pledged \$2,000.

Connecticut. Dr. LINDSLEY—Connecticut is in hearty sympathy with this matter. Not having been instructed to contribute to this fund I do not feel authorized to pledge \$2,000 at present. The members of our State will make earnest efforts to raise an adequate sum toward the accomplishment of this object. We can only pledge ourselves to that extent at present.

District of Columbia could not guarantee \$2,000, but \$250.

Delaware. A delegate from this State said that the matter would be brought before the State Society at the next meeting to see what it would give.

Florida. A gentleman responding for this State said he did not feel authorized to guarantee \$2,000, but the members of the profession would do the best they could.

Georgia. Dr. F. W. McRAE—There are only a few members from my State present, and I do not feel that we can pledge \$2,000. Personally, I will pledge the sum of \$100. I will also go before the medical societies of Atlanta and make an appeal for contributions to this fund. Georgia always does her duty.

Illinois. Already heard from.

Indiana. It was said that a special committee had been appointed by the State Medical Society to solicit subscriptions for the Rush Monument, but that said committee had not as yet made its report.

Iowa. A member from this State said that the profession had not been canvassed on the subject. The Iowa members did not come authorized to make a pledge, but Iowa would give as much in proportion to her population as the great States of New York, Pennsylvania or Illinois.

Idaho. No response.

Kansas. Dr. DAVIS—I am not able to make a pledge for Kansas. Kansas will do her part in contributing to this fund. Personally I pledge \$100.

Kentucky. Dr. MATHEWS—Like the other gentlemen, I do not feel authorized to make a contribution; but as President of the Kentucky State Medical Society, I shall have a special committee appointed to raise as much as it can. Kentucky is not usually behind.

Louisiana. Dr. SOUCHON—Louisiana will do her duty in this matter.

Maine. Dr. GARCELON—I am not prepared to give any pledge for the State of Maine. I can only say that if my life be spared, I can reasonably pledge for my State a sum equivalent to our proportional part, as compared with New York and Pennsylvania in point of population. Further than that, I can not pledge myself.

Maryland. A delegate from this State said that at the next meeting of the Medico-surgical Faculty of Maryland steps would be taken to appoint a committee to solicit contributions for this fund.

Massachusetts. Dr. HENRY O. MARCY—Massachusetts State Medical Society has appointed a special committee for this purpose that will report at the next meeting, which occurs in a few days.

Michigan. Dr. DONALD MACLEAN—I have no authority to speak for Michigan further than to say this, that so far as I know, Michigan has never been found wanting in the matter of liberality or appreciation toward the interests of the profession,

and I think I can safely promise you that Michigan will do her full share. Personally, I will pledge you that a special effort will be made to arouse interest in this matter in Michigan.

Minnesota. The Minnesota delegation talked the matter over, and like others did not feel like pledging themselves to contribute a definite amount.

Missouri. Already pledged.

Mississippi. No response.

Montana. No response.

North Carolina. Not authorized to give any amount.

North Dakota. No response.

Ohio. Already pledged.

Oregon. No response.

Pennsylvania. Pledges \$1,000.

Rhode Island. A delegate from this State said that the members of the profession would contribute their share *per capita* to the fund.

Nebraska. A member from this State said that Nebraska always did its duty, but she did not feel warranted in guaranteeing as much as the great State of Pennsylvania or of New York.

New Jersey. A delegate stated that its Society would consider the matter of subscribing to the Rush Monument Fund, and he extended to Dr. Gihon an invitation to be present at the next meeting to solicit subscriptions. New Jersey would not be found wanting.

Tennessee. Dr. HAPPEL—Tennessee is notorious for shouldering its part of work. It can not undertake to do more than its proportion, according to its population and the wealth of the people. I promise that when we go home we will organize ourselves and go to work earnestly to canvass the profession of the State and endeavor to secure more than our proportion of this burden. I am unwilling at this time to give a specified amount.

Texas. A representative from this State said that the profession would organize and endeavor to do its duty.

Vermont. Dr. HOLTON—Vermont is a small State, but the Green Mountain boys will be found to the front.

Virginia. Dr. JOHNSTON—We are not prepared to pledge any specified amount, and I merely wish to say that the proper amount from our State will be forthcoming.

Washington. A member from this State said he had no doubt the profession would contribute its share.

West Virginia. The members of this State pledged themselves to do all they could in subscribing their share to the monument fund.

Wisconsin. A member stated that the profession of this State would do all they possibly could toward contributing to this fund.

South Carolina. Dr. KOLLOCK—South Carolina has generally taken a part in all scrimages which have excited this country and does not wish to be left out. I am not prepared to say that my State will give \$2,000, but I think I can safely promise you that we will give just as much as we can afford to give, and more than that I can not say.

Dr. Cutter having withdrawn his original motion, the motion of Dr. Graham was then put by the First Vice-President and unanimously carried.

On motion, the Editor of the JOURNAL of the Association was requested to keep a standing appeal in the JOURNAL until the amount of money was raised.

Dr. I. N. Love moved that the Secretary be instructed to communicate with the presidents of the various medical societies and request them to appoint special committees with a view to coöperating with the Rush Monument Committee to the fullest extent in the raising of this money.

Seconded and carried.

Dr. Gihon said that he was delighted at the prospect of so much money being forthcoming, and he promised the Association that he would live to see the fulfilment of this work.

Dr. Henry P. Newman of Chicago read his report as Treasurer, as follows:

REPORT OF THE TREASURER, DR. HENRY P. NEWMAN, FOR 1897.

In presenting this my third annual report to the Association, I desire to call your attention to some encouragements in our work. The fact of prime importance to us as an organization is the steady growth manifested and the increase in our receipts from year to year. Notwithstanding the hard times of the past three years, our increase in membership has been constant and substantial during this time.

The growth of the Association can be estimated somewhat from the following figures: In 1894 our receipts from members amounted to \$12,695.58; in 1895, \$16,665 and in 1896, \$26,075.

There is also a large decrease in our delinquent list, namely,

from nearly 2,500 in 1894 to less than 1,000 the present year. While our expenditures are necessarily large, our balance continues on the right side of the ledger, it being, prior to this meeting, May 1, 1897, \$6,931.29, and with the \$3,000 invested by the Board of Trustees as a sinking fund added, \$9,931.29, a larger balance than any previous year.

H. P. NEWMAN, A.M., M.D., Treasurer, in account with the American Medical Association.

RECEIPTS.

Total			\$56,182.48	

Respectfully submitted, H. P. NEWMAN, Treasurer.

On motion, the report was accepted and referred to the Committee on General Business.

Under the head of "Proposed Amendments," the following were taken up:

Offered by I. N. LOVE:

ARTICLE IV.—Officers. Amend to read, "Each officer shall hold his appointment for one year, and until another is elected to succeed him."

Dr. Ferguson moved that this amendment be indefinitely postponed. Seconded.

Dr. I. N. LOVE—Mr. President; I rise to a question of personal privilege. At the Baltimore meeting of this Association, I introduced the amendment to the Constitution that has just been read. It did not properly appear in the minutes for the next meeting, and therefore was not read. I did not again introduce it, and it appears on the program this year through an error of the Secretary. Therefore the amendment is not before the house. (Applause).

The Secretary then read the following amendment offered by the Executive Committee:

That there be made an Executive Council of five consisting of the three officers of the Executive Committee and two officers chosen by election. Of this Council of five, one must belong to the Section on Practice of Medicine, and one to the Section on Surgery and Anatomy. To this Executive Council shall be delegated all the duties of the Executive Committee during the interval between the meetings.

Dr. L. D. BULKLEY—I am instructed by the Executive Committee to say that there is an error in the wording of the amendment as read by the Secretary, and I will read the amendment as proposed.

Resolved, That there be made an Executive Council of five, consisting of the three officers of the Executive Committee and two other members of the Committee to be elected annually. Of this Council one must belong to the Section of Practice of Medicine, and one to the Section of Surgery and Anatomy. To this Executive Council there shall be delegated all the duties of the Executive Committee during the interval between the annual sessions of the Association.

Dr. Bulkley moved the adoption of the amendment. Seconded.

Dr. JOHN B. HAMILTON asked how many meetings a year the Executive Committee would be likely to hold, as the matter of expense in attending these meetings was one of importance.

Dr. BULKLEY replied that it was not expected any meetings would be held prior to or between the meetings of the Association. The Council had never had occasion to meet at intervals between meetings, most of the work being done by correspondence.

The motion to adopt was then put and carried.

The Secretary read the following amendment, which was offered by H. B. Ellis:

ARTICLE IX.—Conditions for further representation. "Any State or local medical society, or other organized institution whose rules, regulations and Code of Ethics agree in principle with those of this Association may be entitled to representation on the advice or agreement of the Judicial Council."

On motion of Dr. James F. Hibberd, of Indiana, this amendment was indefinitely postponed.

The Secretary read the following amendment offered by L. D. Bulkley:

To change the name of the Section on Dermatology and Syphilography to that of "Cutaneous Medicine and Surgery."

On motion, the amendment was adopted.

On motion, the Association adjourned until Wednesday 10 A.M.

JUNE 2—SECOND GENERAL SESSION.

The Association met at 10 A.M., and was called to order by the President.

The Secretary began to read the minutes, when on motion of Dr. Hare, further reading of them was postponed till later in the session.

COMMITTEE ON NOMINATIONS.

The Secretary announced the Committee on Nominations as follows:

Alabama, J. C. Le Grand; Arkansas, J. H. Southall; California, H. B. Ellis; Colorado, J. W. Graham; Connecticut, R. Robinson; District of Columbia, H. L. E. Johnson; Delaware, R. G. Ellegood; Florida, T. S. Anderson; Georgia, F. W. McRae; Illinois, Norval H. Pierce; Indiana, J. V. Woollen; Iowa, J. M. Emmert; Kansas, F. M. Dailey; Kentucky, J. B. Marvin; Louisiana, Edmond Souchon; Maine, C. W. Foster; Maryland, C. M. Ellis; Massachusetts, A. H. Tuttle; Michigan, H. O. Walker; Mississippi, W. S. Greene; Minnesota, John Fulton; Missouri, C. Lester Hall; Montana, T. J. Murray; New Mexico, W. R. Nathran (?); New Hampshire, G. P. Conn; New Jersey, Alex. Marcy, Jr.; New York, J. E. Jannvrin; North Carolina, H. B. Weaver; Ohio, C. A. L. Reed; Pennsylvania, E. E. Montgomery; Rhode Island, J. T. Farrell; Tennessee, W. K. Shedd; Texas, J. W. Coble; Vermont, E. R. Campbell; Virginia, J. R. Gildersleeve; Washington, T. L. Catterson; West Virginia, R. W. Hall; Wisconsin, H. V.

Würdemann; U. S. Army, W. N. Norwood; U. S. Navy, W. K. Scofield; U. S. Marine Hospital Service, G. W. Stoner.

It was announced that the Committee would meet at 4 P.M., at the Hotel Walton.

Dr. AUSTIN FLINT then delivered the Address in Medicine. His subject was "Stercorin and Cholesteremia." (See page 1097.)

On motion of Dr. Holton of Vermont, the thanks of the Association were tendered to Dr. Flint for his able, interesting and instructive address.

Vice-President SOUCHON now took the Chair.

Dr. L. D. BULKLEY of New York, reported on behalf of the Executive Committee as follows:

The Executive Committee beg leave to report to the Association as follows: Full meetings have been held on Monday and Tuesday afternoons, and many matters of importance have been discussed.

In order that the Committee may keep fully informed and better able to perform its work, it was

Resolved, That the permanent Secretary of the Association furnish to the Executive Committee a completed copy of the Constitution and By-laws of the Association, and send in writing to the Secretary of the Committee a copy of each amendment as soon as passed by this Association; also a written copy of all rules and regulations immediately on adoption.

In order to better fulfil one of the objects for which it was created, the Executive Committee has undertaken to secure a daily report, through the different members of the attendance at each of the sessions of each Section, and would report that about nine hundred and fifty person were counted in the nine sections from which report was obtained on Monday. The Committee have taken further action relating to the better work of the Sections.

The Committee is not ready as yet to report upon the President's Address, or on the report of the Treasurer.

After very full and long discussion, the Committee unanimously recommend the following preamble and resolution for adoption by the Association:

WHEREAS, It is important for the welfare of the Association that the dues for membership be paid as promptly as possible, and

WHEREAS, Conducing to this end it is desirable that a uniform method of registration be adopted, year after year, with which members may become familiar, and thus facilitate the payment of dues; therefore be it

Resolved, That the Treasurer of the Association be constituted, *ex officio*, the Committee on Registration, and that in such capacity he shall proceed to the place of meeting at least three days before the time of meeting to establish the Registration Bureau, and that the sum of \$100 be annually appropriated as his compensation for this extra service.

Dr. Bulkley moved the adoption of the resolution.

Dr. W. H. DALY, Pittsburg—I desire to second the resolution and hope it will pass. This resolution must not be considered a reflection upon the magnificent work of the Committee of Arrangements here. The resolution simply states that the object is to establish uniformity and facility and place this work in the hands of the proper officer year after year.

Carried.

The Secretary read communications from cities inviting the Association to hold its next meeting at Tampa, Fla.; Denver, Colo.; Milwaukee, Wis.; Columbus, Ohio; and Chicago, Ill.

Dr. JOHN B. HAMILTON of Chicago moved that the various invitations be referred to the Committee on Nominations. Seconded.

Dr. JOSEPH T. COULBOURN, Birmingham, Ala.—Mr. President: The place of meeting is one of the most important things that this Association has to deal with, because we want to hold our meeting in a place where we can have the largest membership and the largest attendance; and, Mr. President, I want to make a motion that the selection of the place of meeting be left at some future date for the Judicial Council or Nominating Committee to decide. My reasons for doing this are, that we want a larger attendance from the Southern and Western States. Many of us who come from away down South and the distant West have had to go deep down into our pockets in order to attend this meeting. The railroads ought to give us half rates. It is an outrage. Many of us have come to this meeting and have had to pay full fare, and it is on this account that many physicians who are not present would otherwise have been here to accept and partake of the hospitalities and courtesies extended by the profession and citizens of this beautiful city, which has thrown open its doors and its finest institutions. Many physicians have not been able to take advantage of this meeting on account of railroad rates. Mr. President, we demand rates. We should insist that the railroads treat us with the consideration due our numbers and importance. (Applause.) We want an opportunity to examine and study all the magnificent institutions that cities like Philadelphia offer us to visit. It may not be in order, but my motion is that the place of meeting be left to the Judicial Council, so

that we can "dicker" with the railroads and compel them to give us half rates. Seconded.

Dr. SHEDDAN, Tennessee—I move that the last motion be laid on table. Seconded.

The President put the motion to table, but it was lost.

Dr. REYBURN, Washington D. C.—This motion is out of order, for the reason that the place of meeting should be referred to the Nominating Committee.

Dr. I. N. LOVE, St. Louis—The matter of deciding the place of meeting has always been left to the Nominating Committee, and I am sure this Committee will properly attend to the matter.

Dr. E. D. FERGUSON—I am fully in sympathy with the mover of the resolution and with the object sought to be accomplished, but I rise to ask of the Secretary whether this matter must not be left to the Nominating Committee, to report on the morning of the fourth day.

Dr. I. N. QUIMBY—The object of the mover of the resolution is one of great importance. The railroads do not grant to the American Medical Association the same privileges they do political bodies, synods, Christian Endeavor Unions, etc. Now, Mr. President, let it be understood by this audience that there is no body of men who spend so much time for the benefit of railroads as the medical profession. (Applause.) Let it be distinctly understood that there is no class of men who more quickly appeal to the medical profession for assistance than railroad men when they have a lawsuit on hand. (Applause.) It should be thoroughly understood that it is the sense of this Association that the railroads be respectfully requested to give us half rates, the same as they do political bodies and trade organizations, whom they have hitherto respected more than the medical profession.

Dr. I. N. LOVE—I would offer, as a substitute, that the matter of deciding the place of meeting be left to the Nominating Committee, and each State representative on the Committee be requested to confer with the railroad companies of his respective State, with a view to giving us the same consideration and generosity as are given to other conventions of the United States, such as Christian Endeavor societies, Grand Army men, etc. Seconded.

THE SECRETARY—I wish to say that since last December I have been begging of the railroads for half rates to this city for our members. I have had a voluminous correspondence with what is called the Trunk Line Association, which has had this matter in charge, and they positively refuse to give us a better rate than a fare and a third, although it is known that they give Christian Endeavor societies, baseball men, and other organizations half rates. I also asked the railroad officials to extend the railroad certificates to at least three days after adjournment, and the reply was that they could not do better than they had done. I assure the Association that I have done my best toward securing rates for the members.

At this juncture President Senn rapped for order and announced that President McKinley had arrived.

A moment or two later President McKinley came in arm in arm with Dr. Senn, who had returned to the rear of the stage to perform the office of escort, immediately after quieting down the Association. Dr. Hare preceded Dr. Senn and President McKinley; Mayor Warwick and Governor Hastings and Dr. Pepper and the others of the party attending President McKinley, came after. The Association rose and cheered heartily for a minute or two. Quiet being restored, Dr. Senn presented President McKinley, who addressed the Association as follows:

REMARKS BY PRESIDENT MCKINLEY.

Mr. President, Ladies and Gentlemen: Although summoned to this city for another purpose, I deem myself most fortunate to find this honorable Association in its semi-centennial meeting on the same day, and I can not refrain from taking a moment from the busy program mapped out for me by Dr. Pepper, whose assurance I had before coming here that it should be a day of rest. I can not refrain from pausing a moment that I might come into this brilliant presence to meet the learned gentlemen here assembled, and to pay my respectful homage to the noble profession which you so worthily represent. You have my best wishes, and I am sure the best wishes of our countrymen, for the highest results of your profession, and my warm and hearty congratulations upon this, your fiftieth anniversary. (Loud applause.)

The applause having subsided there were loud cries for Hastings! Hastings!

Governor HASTINGS advanced to the footlights and was very warmly received.

REMARKS BY GOVERNOR HASTINGS.

Mr. President, Ladies and Gentlemen: It was with great

regret that I was compelled to be absent from your initial meeting yesterday morning. I am here twenty-four hours late, but I give you just as warm and as cordial a welcome as if I had met you upon the borders of our city to welcome you here and to our commonwealth. Philadelphia and the State of Pennsylvania are greatly honored with the presence of this distinguished Association, and although our people here are very much occupied in matters tending to the development and upbuilding of the city and State and United States, yet there is always room for such a splendid American organization as this. (Applause.) Two weeks ago there was unveiled in this city the grandest monument that was ever erected to perpetuate the memory of Washington; and only a few days ago another statue was unveiled to perpetuate the memory of Philadelphia's, of Pennsylvania's greatest philanthropist, Stephen Girard, and today the chief executive of this nation comes here, first of all to pay his respects to this great national organization, and secondly to attend the inaugural of the Philadelphia Commercial Museum, which, in my judgment, is the initial movement in an enterprise that will grow until it shall not only be a Pan-American institution, but one which shall take in all the commercial nations of the earth. President McKinley is here today to give his official seal of approval. It is not a new thought to him, because these ideas of reciprocity and mutual trade relations with the nations of the western hemisphere were agitated by him, by Harrison and by Blaine, and are grafted into our fundamental law. (Applause.)

Of course, I am only a layman. Looking into the faces of distinguished representatives of medicine from all over this country it puzzles me, and I can only stand on the side-board and look at the procession of medicine as it goes by. (Laughter.) I will give you some impression of what the common, everyday people of the country think of you, who are subject to the ills which you cure. There is a code of honor in the medical profession in this country that is worthy of the highest emulation. (Applause.) The lawyer's contention is in the forum where he has an antagonist worthy of his steel, and it is before courts of justice, educated and trained, that he pleads for the rights of people and of corporations. The work of the Christian teacher is done in the full glare of the sunlight of the people; while with the physician it is different. He is judge, jury and opposing counsel—and, sometimes, executioner. (Laughter.) From his court there is no appeal in this world. Sickness and the fear of death make cowards of us all in the sick room, and the physician is the autocrat whose voice, direction, instruction and prescriptions are taken generally with the simplicity and the confidence that a babe takes its food from its mother. In that forum, in those sacred precincts the American medical profession have determined that there is no room for the quack or the mountebank. (Loud applause.)

We have all seen the ideal physician, whose presence in the sick room is as welcome as the morning sunshine; his voice is a benediction, his touch an inspiration and his presence an emblem of security. To him children turn, and the marks of pain are changed into the expression of love and confidence. The aged reveal to him the secrets of their lives and their hopes of the life hereafter; mothers forget their vigils of the night in loving anticipation for the restoration of their revered or dear ones, or perhaps in the contemplation of the inevitable that the pathway to the tomb shall be strewn with roses in the confidence of a Redeemer's love. (Applause.)

There are a great many doctors in this country. A gentleman told me a short time ago that there was one doctor for about every four hundred and fifty of our population.

You have county, city, State and National societies that are the means of wielding great power; they are a constant factor in every community, just as constant as the postoffice, the grocery store, the tavern or the sepulcher. (Laughter.)

The development of medicine from a layman's point of view has been greater than that of any other science during the last one hundred years. There was left a hiatus for a long period of time, when medicine appeared to be nothing but an empiric art. It is very, very different now. I was speaking to you a moment ago about the erection of statues or monuments to our great philanthropists, great soldiers, etc., and allow me to say that I think it is absolutely wrong and decidedly un-American that we do not erect monuments and statues to the great masters of medical science in this country. (Loud and prolonged applause.) Then, too, I have been puzzled at the number of new diseases you have discovered. I read in a history of the fourteenth century by Horner something about diseases of the skin, in which he said there were three diseases of the skin. One was a disease which could be cured by the use of sulphur, a second disease of the skin could be cured by the use of mercury, and the other was a disease of the skin which the devil himself could not cure. (Laughter and applause.)

I am beginning to think there is a better feeling existing among the different schools of medicine in this country than there used to be. I think there is great room for it. (Laughter.) I read that in ancient times one of the great physicians—I think his name is Galen—went to another physician and notified him that he had cured numbers of people by a method of his own discovery, and that he wanted to burn the books that were written by Hippocrates; that a new science of medicine had been discovered. The great physician (Galen) had a conversation with him, and after he had consulted with Hippocrates a few moments he ordered his servants to throw him out of the window, and history tells us that he broke his neck in the fall. That kind of peaceful and pleasant consultation has been going on in the medical profession ever since. (Laughter.) Nevertheless, if I had my way, I would build monuments to the great medical teachers, to the discoverer of anesthesia, to the discoverer of the science of bacteriology, to the men who first told us about antitoxin, the spectroscope, the stethoscope and other valuable inventions. What new discoveries medicine may make; what advancement may come to the American Medical Association under your leadership; what a proud position American medicine may take among the nations of the earth as one generation passeth away and another generation cometh! The true physician follows the true teacher of medicine, He who was the first healer of humanity, the lowly Nazarene, in whose footsteps every true physician will follow. (Loud and prolonged applause.)

At the conclusion of Governor Hastings' remarks, the debate on railroad rates was resumed.

Dr. C. A. L. REED, Cincinnati, Ohio—In pursuance of the regular order, which I believe is the motion of Dr. Love, I beg the indulgence of the Chair for a moment. That motion is one of extreme importance to this Association. The question of transportation is a serious one, and one for which this organization has labored and suffered. The transportation companies of this country have discriminated against this Association. It is absolutely impossible for us by any organized effort to bring the railroads to task this year, for the reason that the time is too short, and it will necessitate considerable communication to carry it out, and the only thing that is left is to select the place of meeting, and then make arrangements with the railroads for rates afterward.

After further discussion the place of meeting was referred to the Nominating Committee for its decision.

Under the head of miscellaneous business, Dr. H. C. WOOD of Philadelphia, offered the following resolution, presenting it with a brief speech:

WHEREAS, Senate Bill 1063 (formerly Senate Bill 1552) has been reported favorably to the United States Senate; and

WHEREAS, We believe that its passage would seriously interfere with the progress of practical medicine and therefore be a public calamity; therefore, be it

Resolved, That the American Medical Association, with a full knowledge of the contents of Senate Bill 1063, most earnestly protest against its enactment.

Dr. HOLTON moved the adoption of the resolution, which was seconded by Dr. QUMBY and unanimously carried.

On motion of Dr. GIBON, the Secretary was instructed to forward a resolution of thanks to both President McKinley and Governor Hastings for attending the meeting and addressing the Association.

Seconded and unanimously carried.

On motion, the Association adjourned until Thursday at 10 o'clock.

JUNE 3—THIRD GENERAL SESSION.

The Association was called to order at 10 A.M. by President SENN.

The Secretary read the minutes of the previous session, which were approved.

Announcements were made by the Chairman of the Committee of Arrangements, Dr. HARE, relative to entertainments and receptions.

President SENN called for the report of the Board of Trustees, which was read by Dr. E. E. MONTGOMERY, as follows:

REPORT OF BOARD OF TRUSTEES.

The Trustees would present the following report for the year ending Dec. 31, 1896:

RECEIPTS.	
On hand January 1.	\$ 1,009.04
Advertisements.	14,502.02
Subscriptions.	3,398.97
Reprints.	1,251.53
Press work.	927.98
Rebate on insurance.	80.29
Sales.	197.96
Bank collections.	1,837.85
From Treasurer.	20,800.00
	\$43,505.66

EXPENSES.	
Pay roll	\$14,387.03
Paper	6,394.01
Office salaries	7,185.88
Editorial staff	3,555.06
Rent	1,500.00
Postage	2,923.15
Membership transfers	280.00
Miscellaneous	1,051.19
Electrotypes	425.71
Commissions	920.87
Reporting	619.59
Binding	308.84
Ink	308.50
Moving	337.00
Express	227.82
Press clippings	120.00
Repairs to machinery	187.64
Electric power	261.89
Carpenter	72.10
Office fixtures	68.75
Telephone	87.50
Freight on folder	22.75
Stationery	19.70
Press work	56.55
Bindery supplies	16.98
Journal Index	150.00
Type	89.09
Insurance	85.00
Taxes	105.99
Gas fixtures	63.10
Agent's traveling expenses	55.85
	\$41,811.14
Balance on hand December 31	\$1,694.52
Balance in Treasury (See Treasurer's report)	5,465.86
Total	\$7,160.18

It will be seen that the balance on hand is some \$3,000 less than in the report of last year. It should be remembered, however, that this is about equal to the amount which has been invested in the building fund, as was authorized by the Association at its last meeting.

In our last report it was estimated that the policy of the Association would reduce the amount of money received from advertisements some \$3,000. The actual experience has been nearer \$4,000, as advertisers who have withdrawn from the Association make a total for advertising of \$3,815.40. The reason assigned for withdrawal of an advertisement has been that the continued publication of a formula gives every druggist an opportunity to enter into competition with the manufacturer of such specialties. It has been suggested that one publication of the formula should be considered as complying with the requirement, but upon consideration the Board has decided it could not so interpret the decision of the Association without its express permission, and the Board would now ask an expression from the Association as to its willingness to make any change in the manner and standard of advertising.

While there has been a severe cutting off in the advertisements, the Board is able to report a marked increase in the circulation. In our last report the issue of the JOURNAL was 6,548. The issue for Dec. 26, 1896, was 9,000, making a difference of nearly 2,500. The weekly average for 1896 was 7,742, while the regular issue in 1894 was 4,876, showing the JOURNAL has nearly doubled its circulation in less than three years.

The vote authorized by the Association to determine the choice of its members as to a permanent home for the JOURNAL was largely in favor of Chicago, although the report does not demonstrate that anything like a majority of its members cast a ballot.

In obedience to the action of the Association, \$3,000 has been invested in a first mortgage on real estate in the city of Indianapolis, at less than half its value. As neither the Association nor the Board of Trustees was a chartered or legal corporation, this investment had to be made in the name of one of the Board, as trustee for the Association.

The Treasurer's report will show that owing to a bank failure a large amount of the funds of the Association were placed in peril. A portion of this has been paid and from the present indications the entire amount will be repaid, although at present the funds are locked up and unavailable. This failure and the beginning of investments have impressed the Board with the importance of securing a legal position, not only for its protection, but for the protection of the Association and its funds, as under the want of legal organization no one has any authority to proceed against a defaulter or protect the interests of the organization. For this reason, the Board at its last meeting authorized that a charter should be secured for the Board of Trustees, which would give it the right to sue and be sued for the interest of the organization, and this has been done.

The increase in the circulation of the JOURNAL is largely due to the untiring efforts of the Editor, as medical organizations all over the country have had brought to their notice the Association JOURNAL, and the methods by which they could become subscribers to the JOURNAL and members of the Association.

The Board feels confident that the Association will agree with it that the JOURNAL is increasing in value as well as in importance and gives promise of being an exceedingly important factor in developing the best interests of the profession of this country.

In conclusion, the Board would express its appreciation of the untiring efforts of the Editor and of the JOURNAL employees.

Respectfully submitted,
A. GARCELON,
D. W. GRAHAM,
CHARLES A. L. REED,
G. C. SAVAGE.

On motion of Dr. W. T. BISHOP of Harrisburg, Pa., the report was accepted and the action of the Board in securing incorporation concurred in.

Dr. FREDERICK HORNER, Chairman of the Committee on Mutual Aid Section for Physicians, presented the following report:

REPORT OF MEDICAL AID SECTION.

In 1876 it was suggested by the success of the Medical Aid Societies of Boston, Louisville, New York and Philadelphia, and that of the British Medical Association founded in 1836, to raise funds for the relief of disabled physicians and their families, to try a like experiment in this Association; the late Prof. S. W. Gross and the father of this Association, Prof. Nathan S. Davis, gave their cordial approval to such a plan to be carried out with the cooperation of the State Medical Societies and that of the District of Columbia.

In such behalf the Chairman of your Committee of a Medical Aid Association published from time to time in the columns of the *Medical and Surgical Reporter* and the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION a series of articles, viz.: "A Plea of an American Medical Brotherhood for a Medical Aid Association."

"A Medical Aid Fund."

"A Proposed American Medical Benevolent Fund."

"A Section of Benevolence Urged at the Association Meeting in Baltimore."

"An Appeal to the Fellows of the American Medical Association in behalf of the Disabled Physicians, and Widows and Orphans of Physicians Members of the Association, presented at the Meeting in Atlanta, Ga."

With no exception, such a plan has been endorsed by thirteen of the Presidents of this Association, and one of these distinguished physicians, Dr. Hooper, at Minneapolis, made the subject well nigh the theme of his address on that occasion. During the past year your reporter in correspondence with all the secretaries or presidents of our forty-eight State Medical Societies and the District of Columbia, received encouragement to be present at this semi-centennial gathering, where the first Medical University was founded under the inspiration of Benjamin Rush. Can you, my medical brethren, marvel that I should urge upon you to emphasize and make glorious this semi-centennial meeting by raising a fund for the relief of disabled physicians and the widows and orphans of our members? Have the members of it forgotten or have they failed to make any provision for their disabled medical brethren, or their destitute families? Some of our medical brethren may be stricken down by insanity or in time of financial distress, and in the midst of a life of self-sacrifice for others, are cut off and their families left destitute. Dr. Taliadro of Virginia was drowned as he in vain sought to visit his patient, and Dr. Payne, a professor of the Medical College of Atlanta, Ga., both physicians of talent and learning, presented examples of the kind; unlike the mechanical and operative classes, surely the American medical profession as represented by its National Association will not permit the exit of the nineteenth century to close without providing for the destitute of their household. "Allowing the ratio of deaths per 1,000 to be 15 per cent. per annum of the 4,000 or more," Fellows of the Association, we have by such estimate, sixty widows with perhaps orphan children to care for; may we not assume that of such one-fourth have but limited means to subsist upon and on which to be educated? And of this class there can be no question according to human experience and confirmed by Holy Writ, that both widow and orphan are sometimes dependent and imposed upon by selfish and covetous individuals. The strongest reason which can be urged for the Fellows of this Association to raise an *American Medical Benevolent Fund* is that, while the mechanical, the operative and the clerical and military and naval organizations have long ago had such a fund for their needy ones, we have permitted a half century to elapse without making any provision at all. The Mutual Aid Association of the Philadelphia County Medical Society founded in 1876, and which has 665 enrolled members, has at present a fund of \$12,000. It is said of the late Mr. Charles Parrish, President of the Lehigh and Wilkesbarre Coal Company, that he

prevailed upon his employes to allow the entire wages of one day in each year to be retained for the purpose of raising a fund for the relief of disabled miners and their families. In this way a yearly charity of \$15,000 is amassed, from which may be said, in honor of the memory of Mr. Parrish: "Many wants have been provided for and much suffering relieved." The Irish Medical Benevolent Fund, according to its report for 1896, expended £1,413, 4s. to eighty applicants, five of whom were physicians, nine widows and sixty-six orphans. The Birmingham Medical Benevolent Society, founded in 1821, has distributed £16,510. At the end of last year there were 353 members. The Medical Assurance Society of London, founded 1884, has steadily prospered. The medical fraternity in America, equally potent, ought not to continue longer ignoring the claims of the disabled and be deaf or indifferent to the appeal to them from widows and orphans of physicians of this Association, while your lives and property may be covered by secure investments. Forbid that Fellows of this Association should any longer practically leave a disabled, sick-stricken brother physician to suffer because of failure on their part to raise an *American Medical Benevolent Fund* at this meeting of the semi-centennial year of our existence, and we say to them: "Depart in peace, be ye warmed and filled." How many are practically deaf to the wail of the widow and orphan, while among the latter class there may perchance be some bright and talented boy who recalls no favor shown by medical *confrères* to his disabled father, and none to his impoverished and widowed mother. No marvel such a boy has no desire to buckle on the armor and to don a shield with neither spot nor stain upon its surface and upon which Spartan-like the father he had seen borne by strangers' hands to the silent tomb, with not a single brother physician present to do the faithful hero honor; can you wonder over that boy's decision, rather than belong to the medical fraternity, deciding, let me choose to be "a hewer of wood," any calling other than the medical. During this semi-centennial anniversary year, the occasion could not be more gloriously emphasized than for the 4,000 or more Fellows, representing perhaps forty-eight States of the Union, with forty-eight or more State Medical Societies, learned faculties of richly endowed colleges and universities, medical editorial corps, boards of health and surgeons to the U. S. army and navy, all of whom enjoy liberal incomes, and with their lives and properties, perhaps, insured, for them, who are able, to come to the sacred resolve to give annually at least two or five dollars as the American Medical Benevolent Fund. Various State medical societies might then be invited to cooperate in this good work, this labor of love for our medical brethren less favored; the secretaries of such societies receiving the honorary appointments by the Association in their several States, cities and communities, as the authorized legal representatives of that section of benevolence. When organized, the British Medical Association undertook a like experiment as long ago as 1836, "for the relief," as the late reports state, "of medical men in temporary distress and for their widows and orphans, and also, for granting annuities to those who are quite incapable of providing for themselves," after sixty years' trial have carried out a plan of this kind with marvelous success and blessing to the recipients. We believe that the members of the Medical Aid Societies in Massachusetts, in Kentucky, in New York, in Philadelphia and friends in Virginia will come forward at this meeting and will help us to organize as to officials, and will now, not tomorrow, take from their pockets the stipend of a few dollars only to start such a fund, and that each of us will cheerfully do this every year hereafter. President Senn, one of your honored predecessors, gave a cordial approval to this undertaking, and others were Presidents Drs. S. W. Gross, N. S. Davis, L. A. Sayre, J. T. Hogden, H. O. Marcy, Donald Maclean, W. T. Briggs, R. Beverly Cole and Hooper. Mr. President, I pray the Association will now not accept mere words written or spoken as things of course in behalf of a Medical Aid Section, but that the Association will organize now or in the near future the Section and elect its officers, and doctors become members and contribute funds to make a practical, legal working Section, as stated, seeking the support and cooperation also of the forty-eight or more State medical and municipal societies of our country. Sir, when the Savior of mankind hang in agony on the cross He provided for His widowed mother when He said: "Behold thy mother," and it was He who commended the good Samaritan who took pity on a disabled brother, helpless by the wayside.

Dr. HENRY O. MARCY of Boston offered the following in connection with Dr. Horner's report, which was unanimously adopted:

Resolved, That the suggestion of Dr. F. Horner, that steps be taken to organize a relief association for disabled physicians and the widows and orphans of deceased members, be approved;

Resolved, That a committee, consisting of a member from each of the several State medical societies, be appointed by the Chair to formulate a scheme for the organization of such a beneficial association within the American Medical Association, and that this committee report in detail at the next annual meeting;

Resolved, That the President add to the committee the names of the secretaries of State medical societies.

Dr. W. W. KEEN of Philadelphia then delivered the "Address in Surgery." (See page 1102.)

The Address was punctuated with applause throughout its delivery.

Dr. G. LANE TANEYHILL—I move that a vote of thanks be extended to Professor Keen for his incomparable address, and that that part of it which is a strong and incomparable argument in favor of the justification of animal experimentation be added to the resolution of Dr. Wood relative to the Anti-vivisection Bill, and that the resolution be transmitted to the Senate Committee of the District of Columbia.

Seconded by several members and unanimously carried.

JUBILEE EXERCISES. FIFTIETH ANNIVERSARY OF THE FOUNDING OF THE AMERICAN MEDICAL ASSOCIATION.

The Jubilee Exercises being in order, Dr. N. S. Davis of Chicago, the founder of the Association, appeared upon the stage, escorted by the Presidents of the State Medical Societies and the Presidents of the State Boards of Medical Examiners.

Dr. Davis was presented to President Senn by Dr. JOHN B. ROBERTS, Chairman of the Committee on Anniversary Exercises, who said:

"Some fifty-two years ago, at a meeting of the New York State Medical Society, there appeared for the first time a young delegate from Broome County. Observation during his collegiate course had opened his eyes to the fact that there were radical defects in the methods of medical education. To remedy these evils and to organize the profession of the United States into a professional brotherhood with a common purpose, a common dignity, a common ethical standard and a common humanity, he determined to use all the vigor which he possessed. It was his desire to separate medical teaching from medical licensing and to organize the profession in connection with a central medical body. That his labors, despite much opposition, have been crowned with success, is shown by the existence of a Medical Examining Board in nearly every State in the Union and State Medical Societies in all parts of the country. The presence of these gentlemen who accompany him today and the registration of 2,000 delegates and members attest the approval given to the efforts of the ever young man whom I now present to you." (Applause.)

At the conclusion of Dr. Roberts' remarks, Dr. Davis arose and was greeted with round after round of applause, which continued for fully three minutes. As soon as quiet was restored, President SENN said:

"Dr. Davis, in the name of the nine thousand members of the Association I greet you, and congratulate you that you have been permitted to live long enough to witness the commemorative exercises of your life work, the fiftieth anniversary of your favorite child—the American Medical Association. May you live long, and when the inevitable comes find a peaceful end and an ample reward in the life to come." (Applause.)

Dr. DAVIS then delivered his Address, selecting for his subject "A Brief History of the Origin of the American Medical Association, the Principles on which it was organized, the Objects it was designed to accomplish, and how far they have been Attained during the Half Century of its Existence." (See page 1115.)

Dr. JOHN B. ROBERTS, Chairman of the Committee on Anniversary Exercises, informed the Association that diligent search had shown that there were surviving only four of the original members of the Association. Dr. Alfred Stillé of Philadelphia, an ex-President of the Association; Dr. John B. Johnson of St. Louis, an ex-Vice-President; Dr. David F. Atwater of Springfield, Mass., and Dr. N. S. Davis of Chicago, an ex-President. Dr. Roberts stated that the Committee regretted that Dr. Stillé was not present, and read the following letters to the Association from Drs. Atwater and Johnson. Dr. Davis had made his presence known by the excellent address on the history of the Association, which had just been heard.

Letter from Dr. D. F. ATWATER of Springfield, Mass.:

"While it would give me much pleasure to be with you on this interesting occasion, I feel that I must deny myself the privilege. The Association is to be congratulated on having with it Dr. N. S. Davis, a representative specimen of a Doctor of the Old School. The first meeting of the Association was held under very different conditions and circumstances from the present one, and it is interesting to note the contrast between then and now.

"I can not be supposed to intimate any deficiency in the

knowledge of medicine and surgery at that day, but we were, comparatively speaking, pioneers in a new country, where there was much clearing to be done and roads to be made, with but the rudest implements at command. Disease was then combated with arms and ammunition quite different from those in use at the present day. The lancet was our inseparable companion and bleeding was practiced freely. Calomel, ipecac, squills, tartar emetic, castor oil and senna were familiar words in every household.

"When room was needed in the medical department of the library at the University of Edinburgh the custodian, it is rumored, was once told to remove all books over ten years old and put them in the basement. What do you think should be done with doctors whose medical degrees are now over fifty years old? We had, however, some compensations as an offset to our limited means. Appendicitis, diphtheria, la grippe, heart failure and the deadly pneumonia were not as frequent as at the present day. We could not summon to our aid, unfortunately, many remedies of recent date, nor the thermometer, microscope or chemic analysis. The profession has sought and discovered where the germs of disease are to be found, where the bacilli have their hiding place, whence come typhoid fever and other diseases arising from impurity and uncleanness; the laws of health have been investigated, and the prevention of disease now claims quite as much of the doctor's attention as its cure.

"That the Association, so powerful for good in the past in the promotion of medical science and the elevation of the profession, may maintain its reputation in the future, so that the close of another half century may find here those pursuing their profession with equal zeal, and that at last one and all of its members may hear the welcome summons, 'Come ye blessed of my Father, for I was sick and ye visited me,' is the earnest wish of

DAVID F. ATWATER."

Letter of Dr. JOHN B. JOHNSON, St. Louis, Mo.

"I regret that I can not accept the kind invitation to be present at the Semi-Centennial meeting of the American Medical Association. I have been suffering from the past three months from an attack of articular rheumatism which has not only unfitted me for professional duty, but has greatly interfered with my powers of locomotion. Much as I should enjoy a reunion with the few original members now remaining, who fifty years ago in Philadelphia founded the Association, I would even more rejoice in witnessing the increasing evidence of its prosperity and usefulness.

JOHN B. JOHNSON."

Dr. GEORGE BEN JOHNSTON, President of the Medical Society of Virginia, told the Association "What State Medical Societies have Done for the People," saying:

The enactment of such laws as now exist was, it is fair to claim, procured through the efforts of the State societies acting independently of each other. There was never any well-directed attempt at coöperation, hence the dissimilar character of the statutes and the varying nature of the prescribed machinery for executing them. Yet in every case the object was the same—to furnish the people with only properly equipped practitioners. This called into existence many State Examining Boards, whose function was to select qualified men. It was soon made apparent that even many of those holding diplomas were not qualified. Careless and inferior schools saw their graduates excluded from the privileges of practice and their classes diminished, because young men contemplating the study of medicine began to choose their schools with discrimination, having in view the purpose of properly fitting themselves to meet the requirements of the Examining Boards. The effect of all this was to elevate the standard of medical education. New subjects were added to the college curriculums, practical work was required, the time of study lengthened, and more rigid examinations exacted.

It became obvious that these legislative measures to secure higher medical education usually styled "Laws regulating the Practice of Medicine and Surgery," they would be more accurately described as "Laws for the Protection of the People," had taken root and had come to stay. National bodies have taken them up and are rapidly centralizing the work accomplished in a desultory but partially effective way by the State societies. On Monday of this week we witnessed in this city the seventh annual meeting of the "National Confederation of State Medical Examining and Licensing Boards." This Association is the legitimate and natural outgrowth of the efforts of the individual societies which have for so many years patiently but unconsciously worked for its formation and development. Although as yet it is scarcely more than embryonic, its function is well defined, and it must become the leader in further efforts to secure appropriate and uniform laws regulating the practice of medicine, and State societies ought to earnestly

coöperate with it in order that it may be strengthened and its usefulness increased. But the results obtained in another department of legislation are not less striking.

In most of the States in which State Boards of Health have been established these bodies have been brought into existence through the suggestion and instrumentality of the State Medical Societies. These Boards have been of inestimable value to the public in the way of promulgating the laws of hygiene, in the prevention of epidemics, the suppression of those already existing, and the conduct of commerce in times of public fear.

If then, as I believe, the State societies were the main instruments in calling into existence the State Boards of Medical Examiners and Licensers, and the State and other Boards of Health, may we not justly claim for them the title of public benefactors? They fallowed the field and sowed the seed; the community is reaping the harvest. And how are their labors made manifest?

By the improvement in the material from which medical men are formed. By the better preliminary education of medical students. By the higher technical education of doctors. By the binding together of the best medical colleges in a league, the sole object of which is to elevate the standard of medical education. By the enactment of laws which admit only properly equipped men to enter the practice of medicine. By the rapid disappearance of the pretender and the ignorant quack. By the presence in every village or hamlet of a medical man whose character and attainments entitle him to rank with the best of his community; whose professional acumen and honesty fit him to discharge the duties of his high calling with confidence, skill and success, and whose trained faculties constitute him the guardian of the public health. All these beneficent results may be traced to the working of your State societies.

Dr. William Perry Watson, President of the New Jersey State Board of Medical Examiners, who had a paper entitled "State Boards of Medical Examiners—What They Have Done, How They Should be Made up, and What They Should Do," was unexpectedly called home.

The following was offered by Dr. W. LEMOYNE WILLS of Los Angeles, Cal., which was referred to the Executive Committee with the request that it report at this meeting, if possible:

At the last annual meeting of the Medical Society of the State of California, held in San Francisco, April 20-24, 1897, the following resolution, introduced by Dr. Wm. LeMoyné Wills, was unanimously adopted:

Resolved, That it is the sense of this Society that the American Medical Association take such action on the subject of medical legislation as will bring this matter to the attention of Congress and the President, and request the passage of such laws as will regulate by National examining boards the right to practice medicine in the United States; and, furthermore, we would urge that the delegates to the American Medical Association be instructed to make it their purpose to secure the adoption of such action by the American Medical Association.

Dr. W. H. SANDERS of Alabama, offered the following resolutions relative to the death of Dr. Jerome Cochran:

1. *Resolved*, That in the death of Dr. Jerome Cochran, late State Health Officer of Alabama, this Association has lost one of its most loyal and useful members, the science of medicine one of its most devoted followers, and the great cause of sanitation one of its foremost pioneers and ablest expounders.

2. *Resolved*, That the career of Dr. Cochran was signally marked by unrivaled achievements in the cause of medical organization, and by illustrious services in the field of preventive medicine.

3. *Resolved*, That the death of such a man is nothing less than a public calamity, and so regarding it, we bow in sad submission to the immutable decree that deprives the human race of his wise counsels, his fruitful labors, and his sublimely unselfish devotion to its broadest, deepest and most far-reaching interests.

After the reading of the above resolutions, Dr. GEORGE M. STERNBERG arose and said: I desire to second the resolutions offered by Dr. Sanders. I knew Dr. Cochran well. I have met him under trying circumstances. We all appreciated his loyalty to the profession, his good judgment and his earnest work, especially in the Department of State Medicine, and I wish briefly to mention one circumstance under which I saw him to the best advantage. It was during the yellow fever epidemic at Decatur, and I asked permission of the President of the United States to go there for the purpose of continuing my yellow-fever investigations. Among the first men I met was Dr. Cochran, who had been on the ground from the first. He stood by the local physicians during the epidemic from first to last. He visited my laboratory daily and took the utmost interest in the researches I was conducting. There is one incident that I would like to mention in this connection. An old practitioner of that town, who came to visit me within a day or two after my arrival at the laboratory, said he was ready to do anything he could for me. He died within a week and left instructions that I could have his body. This is the kind of

men we had there on that occasion, and Dr. Cochran was the leader among them.

Dr. HENRY D. HOLTON—In rising to further second the resolutions, I can not forbear to speak of the long acquaintance, of the love and respect which arose from that acquaintance with Dr. Cochran. We know that his whole heart and soul were in the progress of medical science, of sanitation, of doing good to his fellow men. His life was so gentle and the elements so mixed up in him that all nature could stand up and say, "Here is a man." Mr. President, time is too far spent for any lengthy eulogy, but those of us who remember Dr. Cochran can not do better than to try and follow his noble example. He directed all his efforts to increase the efficiency of medical education; he directed his efforts in sanitary science to relieve suffering, to prolong life, and like a seed planted which shall grow to a goodly tree, it shall shed its fruit when time shall have flown down the gulf of eternity. I move sir, the adoption of the resolutions.

Dr. W. H. SANDERS—I am aware that the patience of the Association has already been greatly taxed, and I would not impose upon it further, but Dr. Cochran in his life work and good judgment instilled some of the fundamental principles underlying the organization of the medical profession of my State, which principles I believe would be useful if announced to this body. But your time has been already too much taxed, and I fear it would consume too much of it to undertake to point out these principles now, but I hope I may have an opportunity of doing so some time in the future.

Dr. LISTON H. MONTGOMERY—In further honoring the memory of Dr. Cochran, I move, as an amendment, that these resolutions be adopted by a rising vote.

The motion as amended was then unanimously adopted.

Dr. BULKLEY read the following

REPORT OF THE EXECUTIVE COMMITTEE.

The Executive Committee report as follows upon the recommendations contained in the Address of the President:

1. The recommendation of the President in favor of restoring the former policy of the Association in offering a gold medal to its members for meritorious work be and is hereby endorsed, and it is recommended that the project be referred back to the Committee for the elaboration of details.

2. That the public addresses delivered before the entire Association be hereafter designated as "orations," to distinguish them from the addresses of the Chairmen of Sections, and that the speakers on such occasions be designated as orators, provided that the proposed changes in nomenclature do not conflict with anything in the By-laws.

3. That the third evening of each meeting be devoted to an illustrated lecture on some medical topic, microscopic or other, the topic and the lecturer to be decided upon by the Executive Committee.

On motion, the recommendations as reported by the Executive Committee were adopted.

Dr. T. J. HAPPEL, and Dr. T. K. POWELL of Tennessee, offered the following:

WHEREAS, The discussion of the question of railroad rates to meeting of the American Medical Association has revealed much dissatisfaction in regard to the actions of the roads in these matters; therefore, be it

Resolved, That the President for the next ensuing meeting of this Association appoint a special committee of seven, to be known as a Committee on Transportation, whose duty it shall be to report to the Committee on Nominations at the next meeting the railroad rates offered by different places put in nomination as a place of meeting for 1899, and that the Committee in selecting such a place of meeting for 1899 be directed to consider such rates in connection with the selection of such place of meeting.

Resolved, Further, that the President be instructed to appoint this Committee within the next thirty days, and that the Secretary notify at once each member when appointed.

On motion, these resolutions were referred to the Executive Committee.

Dr. I. N. QUIMBY offered a resolution which was referred to the Executive Committee.

The report of the Judicial Council was read by the Secretary, as follows:

REPORT OF THE JUDICIAL COUNCIL.

Your Judicial Council would report that the charges against the Cleveland Medical Society were dismissed for want of jurisdiction, on account of said Cleveland Medical Society having become affiliated with the Ohio State Medical Society.

In the matter of protest and charges against C. G. Cannady, M.D., your Council has referred the matter to the State Medical Society of Virginia for adjudication.

In regard to the protest and appeal of William F. Barclay, M.D., Pennsylvania, your Council has instructed its Secretary to transmit the same to the State Medical Society of Pennsyl-

vania, and instructed him to inquire as to the status of this case, and why there has been so much delay in its adjudication.

NATHAN S. DAVIS, President.

X. C. SCOTT, Secretary.

On motion, the report was accepted.

On motion, the Association adjourned until Friday, 10 o'clock.

(To be continued.)

SOCIETY PROCEEDINGS.

Illinois State Medical Society.

Abstract of the Proceedings of the Forty-seventh annual meeting, held at East St. Louis, May 18, 19 and 20, 1897.

SECTION ONE—FIRST DAY.

(Afternoon Session Continued.)

Dr. C. C. HUNT of Dixon reported a very instructive case of
ATROPHIC CIRRHOSIS OF THE RIGHT LOBE OF THE LIVER, WITH
COMPENSATORY HYPERTROPHY OF THE LEFT LOBE, ASCITES,
RESTORATION TO HEALTH OF THE PATIENT AFTER THE
REMOVAL OF 1,440 POUNDS OF LIQUID.

The following is a report of a case: On Oct. 1, 1894, J. E. T. presented the following history: Age 32, adjustor for fire insurance company; parents both living and in good health; never had venereal disease; had acquired the habit of drinking largely of alcoholic beverages, but never lost his legs nor his head. Soon after the habit was fixed he began to grow corpulent. This corpulency increased month by month until his legs and body assumed vast dimensions. So large did his abdomen become that he could not crawl through the ordinary trap-doors leading to the roofs of buildings, which his duties frequently required him to do. His bowels were regular, unretained naturally, had a fair appetite and good digestion, but for some months his locomotion had been growing more and more impeded. Some "doctor" had told him he had "five large tumors in his belly." Abdominal enlargement came on before swelling of legs. So much subjectively. Objectively, Dr. Hunt found: Emaciation great, lips pale ashy color, ears translucent, skin pale yellow, dry, no icterus. Pain on pressure all over regions occupied by stomach and liver, but more marked in right epigastrium; marked edema of skin and subcutaneous tissues from toes to umbilicus, from which it gradually lessened upward until at the level of the xyphoid termination of the breastbone none was appreciable. Adipose tissue of thorax, neck, face and upper extremities had about all disappeared. Abdomen immensely enlarged. All these gave a figure to the individual most singular and impressive. Physical exploration revealed the presence of liquid filling the abdominal cavity, crowding the intestines as far as possible into the vault, and at the same time causing a large loop to protrude through the umbilicus. So great was the distension that when patient was placed on back there was scarcely any appreciable flattening of the abdomen; it presented more the appearance of a cystic growth within than that of ascites. Neither palpation nor percussion afforded any evidence as to condition of liver or spleen owing to the large accumulation of liquid. No evidence of organic changes in lungs or in walls or valves of heart; urine contained neither sugar nor casts, but a considerable quantity of albumin; specific gravity 1028. Contents of stomach not examined; no blood-count made.

The next day (Oct. 2, 1894), assisted by Dr. Sheffield, he punctured the abdominal wall midway between umbilicus and pubes with a large aspirator needle and removed 54 pounds of viscid, greenish-yellow liquid, specific gravity 1017, leaving undrawn a considerable residue. The walls fell into loose folds. The skin and linea alba aponurosis between umbilicus and xyphoid cartilage had become so attenuated that the hand, covered as it were by a thin membranous mitten, could enter the upper abdominal cavity between the widely separated recti muscles, and the lower edge of liver could be felt between thumb and fingers. The left lobe markedly hypertrophied, of apparently normal consistency and smooth surface. The right lobe characteristically "hob-nailed," and of firm consistency. The area of dulness over right lobe but little greater than that of a normal adult heart; over left lobe it extended almost to left thoracic wall. Spleen not appreciably enlarged. The xyphoid appendix was curved forward and upward like a hook. Umbilical hernia disappeared upon removal of the liquid. There was no collapse following the operation. Patient sat in an armed chair until needle was removed and then walked a few steps and took his bed. Hastening to catch a train he did not seal up the wound with as much care as he should have done, and when he called the next day he found the dressings, bed clothes and mattress soaked with the liquid

which had discharged through the opening made by the needle, and the excess was dropping into a receptacle underneath the bed. The edema rapidly disappeared. The abdomen re-filled so rapidly that he tapped him again ten days later removing 34 pounds of liquid. Eleven days after this, 24 pounds. Nine days later 32 pounds. One week later 18½, and again one week later 15 pounds. Then every two weeks removing 19, 11½ and 16 pounds respectively. This ends the three months of 1894, with a total of 224 pounds. During the year 1895 he tapped patient every two weeks, February 3 withdrawing the minimum 14 pounds and September 22 maximum 42.55 pounds, a total for the year of 696.01 pounds. Tappings were continued every two weeks until September 6, when the minimum was reached of 8.62 pounds. Maximum April 5, 40.83 pounds. From September 6 to October 25, a period of seven weeks, patient gained rapidly in muscle, fat and strength, so that his weight had increased from 123 to 145 pounds, with only a residue of liquid (less than one-half pound) remaining. This the doctor aspirated and since then patient has been in first-class health. Without taking into account the unmeasured amount of liquid which escaped just after the first tapping, as before noted (presumably about ten pounds), we have a total of 1,440 pounds, or including that lost, a grand total of 1,450 pounds removed in twenty-three months. The specific gravity was taken of the liquid withdrawn at various times after the first tapping. It varied but little from 1015. Extremes of temperature, any undue excitement or exposure to cold or moisture were followed by increase in the quantity of the deposit. At no time was there hemorrhage from any source. The stools were usually of yellowish or yellowish-brown color. Temperature ranged from normal to 102 F. Infiltration of skin never reappeared after the first tapping. Edema of lower extremities would always disappear within twelve hours after tapping and would not reappear until liquid reached a point above umbilicus, or when withdrawn it measured about thirty pounds.

Patient abruptly ceased the use of his beverage when he came under my care.

Dr. Hunt omitted to state that the superficial veins coursing over abdomen were somewhat enlarged, but so-called "caput medusae" not well represented, nor was "muddy yellow color under the eyes" a prominent feature, as noted by Dr. Edwards of Chicago.

Dr. OTTO L. SCHMIDT of Chicago, made some interesting remarks on

SKIAGRAPHY IN INTERNAL MEDICINE,

and showed numerous skiagraphs. Among the pictures exhibited was a skiagraph of the heart, showing a bullet on the left side; a post-syphilitic clavicle; a picture showing hypertrophy of the heart from an advanced case of insufficiency of the aortic valve, with the presence of an enormous hypertrophy of the left ventricle. The next picture was one showing infiltration of the lungs in which case there was a systolic murmur at the pulmonary valve, with distinct hypertrophy of the right side of the heart, which was not as well marked as on the left.

Speaking of the photography of the blood vessels, the author stated that blood vessels may be seen (in favorable cases by the fluoroscope) pulsating, while in other instances the blood vessels may be skiagraphed. The next was a skiagraph of a large aneurysm of the ascending and transverse portion of the aorta. He said it had been suggested that in the diagnosis of obscure conditions in the thorax by means of the fluoroscope, while noticing the pulsation of the tumor, differentiation could be made between aneurysm and a simple tumor.

Several other skiagraphs were shown.

Dr. GEORGE H. WEAVER of Chicago read a paper entitled

A CONTRIBUTION TO THE SUBJECT OF THE SERUM TEST IN THE DIAGNOSIS OF TYPHOID FEVER.

The paper was a report of the use of the test in 71 cases; 9 being persons in good health, 30 cases of disease other than typhoid fever, and 32 cases of typhoid. In the tests non-virulent cultures were used. The examinations were made by placing a drop of emulsion of typhoid bacilli in a drop of undiluted serum and keeping the hanging drop so prepared for 16 to 20 hours at 37 C. The drop was then examined and the result considered positive if the bacilli had entirely lost their motion; doubtful if lessened motion and some clumping occurred; and negative in the absence of any effect upon the motion and no considerable clumping.

Positive reactions were obtained in all the typhoids except three, in which doubtful results occurred. Positive results were not obtained in any other disease or in health. He concluded that the presence of such a positive reaction was strongly in favor of typhoid fever, but its absence did not necessarily exclude such a diagnosis. Parallel observations made with

virulent and non-virulent cultures showed the non-virulent culture to reach more quickly and perfectly. Dry blood did not give as satisfactory results as fresh serum. He obtained doubtful reactions in two cases of typhoid fever and tuberculosis as a mixed infection, both coming to autopsy. In order that the reports of examinations may be of the most value, each writer must tell what he considers a positive reaction, what is the age of the culture employed. Only by careful testing of the effects of the serum of healthy persons and those with other diseases upon a given culture is it possible to draw definite conclusions as to how it will be differently affected by the serum of persons with typhoid fever.

FIRST DAY—EVENING SESSION.

A joint meeting with the Missouri State Medical Society was held at the McCasland Opera House, at East St. Louis. The meeting was called to order by the first vice-president, Dr. Carter of Waukegan, who introduced Dr. J. H. Duncan, the president of the Missouri State Medical Association, who in a brief speech welcomed the Illinois State Medical Society on behalf of the Missouri State Medical Association.

President DUNCAN then, by request, introduced Dr. A. C. CORR, of Carlinville, as the President of the Illinois State Medical Society.

President CORR delivered his ANNUAL ADDRESS, in which he forcibly brought before the Society medical legislation. The necessity for a committee on medical legislation he said seemed to be a development not yet perfected, and he thinks the history of its growth will bear out such a conclusion. By scanning the 23 volumes of transactions, the first legislative work of the Society was done in accordance with a motion made by Dr. J. H. Hollister in 1874, for the appointment of a committee by the President to memorialize the legislature for an appropriation to establish an institution in the State for the better and more humane care of the feeble-minded children. Those appointed were Drs. L. P. Pierce, E. P. Cook, and J. L. White. As to the ultimate success of the work of the committee the magnificent institution at Lincoln for that purpose makes further comment unnecessary. Recent events suggest the necessity of a still further perfection of the committee's duties on legislation by the addition of preventive legislation. The attitude of the so-called osteopathic bill in the present legislature suggested this most emphatically, which should make it as potent a factor to prevent pernicious as to procure and encourage useful legislation. He most emphatically suggested that in the future this be a tantamount part of the work of the legislative committee. The committee needs numerical influence and financial backing. The expense of legislation, either aggressive, conservative or preventive, to some extent depends upon the magnitude of the legislation desired. The process of legislation is very tedious and devious, and the committee pursuing it must be at every turn, for verily is safety the only reward of vigilance.

If we would procure needed reformatory legislation for sanitary purposes, for the better protection of the health and well-being of the people of the State, we must have a greater number of members, and thereby greater numerical influence and financial backing; or we must levy a tax or an assessment, or we must create a voluntary legislative fund. President CORR thinks if the membership of the Society could be increased say to 2,000 or more, with the annual dues as now, \$3.00, it would afford ample funds from which to make a sufficient legislative appropriation; otherwise voluntary contributions to a legislative fund might be solicited; and if funds can be made available he would suggest the employment of a legislative attorney, who could better watch the mutations of a bill to be passed or defeated.

The Address of Section One was delivered by Dr. WELLER VAN HOOK of Chicago, who selected for his subject

THE PRESENT RELATIONS OF SURGERY TO INTERNAL MEDICINE.

Dr. VAN HOOK expressed his especial gratification in having opportunity, as a surgeon, to address the Medical Section of the Society upon the topics of common interest to the specialties represented.

The differentiation of internal medicine as a distinct specialty was regarded as a distinct gain and the hope expressed that it might meet with still more recognition in America.

The decline of surgery as a well marked special ground, seemed, however, unfortunate. At no time in history has surgery been so little regarded as a distinct and separate field as at present, when antiseptic and aseptic methods put a large number of operations in the hands of the general practitioner. It is not the enlargement of the bounds of minor surgery which is to be deplored—on the contrary, every one must rejoice that the general worker, often remote from the specialist, is able to

extend relief to the suffering in a thousand cases we would have thought, but a short time ago beyond the reach of any but the most skilful. But the attempts to include in minor surgery the more complex conditions met with in the great cavities of the body, and the consequent operating upon cases which legitimately belong only to those especially prepared, is much to be regretted.

After briefly reviewing the recent progress in some of the subjects in which medicine and surgery are both equally interested, the speaker concluded as follows:

"While we see that surgery and internal medicine are thus working side by side to the common end of increasing one's store of knowledge and of reaching the goal of relief for our patients, we must acknowledge that a sort of friendly rivalry exists between the two specialties, not to see which can acquire the greatest amount of pathologic territory for itself, but rather to determine which can bring quickest, safest and surest relief to the sufferer. And it must be admitted that surgery has been of late years oftener the victor. Surgery has wrested from medicine the treatment of a host of diseases and morbid conditions, in addition to those in which only the so-called "expectant" treatment was practiced. The heart has been sutured after injury; its covering, the pericardium, has been tapped and even drained for purulent pericarditis. We invade the brain and even open its ventricles with impunity. We have long since opened the spinal canal and corrected morbid conditions within. Surgery must return upon herself; must now perfect her methods within the territory already conquered; must perforce leave off the search for new organs to invade and for new diseases amenable to surgical therapeutics, and will be obliged to devote herself to diminishing the risks attendant upon surgical operations and to the improvement of functional as well as anatomic results.

Our knowledge of regeneration of organs has been enriched by the labors of Ponpick, Padwyssosky, and others in a wonderful way. Ponpick has shown that three-fourths of a rabbit's liver may be removed, a part at a time, without the death of the animal. Regeneration of the lobules of liver substance takes place and the organ continues to perform its functions. The compensatory growth of the paired organs when one of them is lost requires no comment.

The spleen when removed is functionally replaced by other lymphatic structures.

Gluck of Berlin, has shown us how we may cultivate or grow certain tissues to our advantage. He has shown us how we may substitute silk or catgut strands for tendons, making connective tissue growth about them. He has shown how small bones may be replaced by pieces of ivory of proper form and size. Bardenheuer has gone a step further in the same direction and has lately made new phalanges and metacarpals by splitting and transplanting parts of similar bones, not injured or diseased. He has even taken a piece of a scapula to make good a partial loss of the humerus.

The Marmorek serum for streptococcus infection is still on trial.

The immediate great advances in internal medicine seem to lie in the direction of a development of the doctrine of immunity and the therapeutic corollaries justly dependent upon a demonstration of the problem. It seems probable that at least some of the wound infectious diseases may be successfully attacked by the method so brilliantly developed by Behring for diphtheria. Tuberculosis, the cure of which has been for fifteen years the subject of investigation with the aid of a knowledge of its specific cause, seems likely to yield before many years.

Even the malignant growths are being subject to a serum treatment invented by the enthusiasts, Emmerich and Schall. Some reports would already indicate that adherents of the method are being found.

The great surgeon, Kocher, in reporting a thousand operations for goiter, expressed his gratification that the technique had been so far improved as to give a surprisingly low death rate even in severe cases. But at the same time, he expressed the hope that prophylaxis might show how to diminish the frequency of the disease or to stamp it out entirely from its endemic haunts.

In conclusion, it must be said that at no time in the history of our common art have the difficulties in our way been more accurately appreciated or more heroically attacked. Never has our profession been so united in its efforts to overcome disease, never have the personal sacrifices of its members been so great for the common good; never have internationalists and surgeons so readily and freely and trustingly appealed to one another for aid and counsel and in deed, and never have we called upon another with greater assurance of receiving that aid we sought. For the future we can only ask that these

relations continue, that they become more intimate, and that these warmer relations between surgery and internal medicine may redound to the credit and advancement of our common art.

Dr. Van Hook was followed by Dr. E. P. Cook of Mendota, who delivered the Address of Section Two, selecting for his subject "The Relation of Surgery and Surgical Specialties to Medicine."

Dr. JOHN B. HAMILTON of Chicago, followed with the Address of Section Three, which by request was upon the subject of "Medical Legislation, and How to Obtain it." [See page 1005 of the JOURNAL, May 29].

SECOND DAY—MORNING SESSION.

SECTION TWO.

Chairman, Dr. HENRY P. NEWMAN, Chicago.

Secretary, Dr. E. W. WEIS, Ottawa.

The Section was called to order by the Chairman.

INTESTINAL ANASTOMOSIS

was the title of a paper by Dr. JACOB FRANK of Chicago, in which he stated that in 1892 Murphy had surprised the surgical world with his metallic button, which reduced the length of time required to perform an intestinal anastomosis to about thirty minutes. If Murphy's button was soluble we could wish for nothing better, but since it is not it will always create a certain degree of fear in the minds of surgeons who are about to introduce the same.

Dr. Frank then quoted from Dr. Murphy's article his claims for the button: 1, reducing the duration of the operation to at least one-half of its former length; 2, extreme simplicity of technique; 3, automatic retention of position; 4, entire independence of sutures; 5, it produces a pressure atrophy and adhesion of surfaces at the line of atrophy; 6, it insures perfect apposition and therefore obviates the danger of displacement; 7, its applicability to the lateral as well as to the end to end approximation; 8, it produces a linear cicatrix, thereby insuring a minimum of contraction; 9, edge to edge union of same intestinal coats.

Dr. Frank claims for his contrivance all of the above good qualities, with one exception and a few additions. He claims for his contrivance lightness, which is of great importance as the intestines can float it, and this obviates a possible bend or spur. Another point is the partial solubility of the apparatus, leaving but a small piece of soft rubber tubing to pass away, which is not apt to cause obstruction nor is it apt to ulcerate through the bowel.

Since the last publication on this subject, he has had the pleasure of receiving the news of a successful gastro-enterostomy with the aid of his decalcified coupler, performed March 16, 1897, by Dr. McCandless, of St. Louis. The rubber tube passed on the thirteenth day. The patient left the hospital on the twenty-fourth day after the operation.

He also reported a successful case of end to end anastomosis with the coupler, for strangulated hernia, eight inches of gangrenous bowel being resected. The operation was performed by Dr. Kramps, April 13, 1897, at the St. Elizabeth Hospital. The rubber tube passed after twenty-four hours, and the patient, who is 49 years of age, is well and now attending to her household duties.

Dr. JOHN E. OWENS of Chicago read a paper on

THE USE OF TOXINS IN THE TREATMENT OF SARCOMA, PARTICULARLY IN OPERABLE CASES.

He said the beneficial results of the treatment of inoperable sarcomatous tumors with toxins of erysipelas and the bacillus prodigiosus are so striking that the subject seems to the author most worthy of consideration.

Experiments in this direction were undertaken by Dr. William B. Coley of the Cancer Hospital, New York, in April, 1891, and the interest excited by the antagonistic and gratifying action of accidental erysipelas in a case of recurrent inoperable round-celled sarcoma led to the formation of this method of treatment. In the case referred to, the patient was known to be healthy and well seven years after the attack of accidental erysipelas. The first case treated by Dr. Coley was a recurrent sarcoma of the neck and tonsil in a male 37 years old. The patient had been twice operated upon. After the second operation a portion of the tumor of the tonsil, involving the deep structures, remained. It grew rapidly and filled the pharynx to such an extent that only liquid food could be taken, and this was frequently regurgitated. The patient was greatly emaciated. Dr. Coley began by giving injections of bouillon cultures of erysipelas, one or two weeks old, directly into the tumor of the neck. The cultures were of little virulence, and the reactions following the injections slight. There was, however, some improvement, and whenever the injections were

discontinued the patient grew worse. Having obtained a virulent culture, inoculation was followed by a very severe attack of erysipelas. The tumor of the neck broke down in part and in part was absorbed, while the tonsil tumor diminished in size, but did not entirely disappear. The general health of the patient rapidly improved without further treatment, and he was known to be healthy and well two and three-quarter years after the last inoculation.

Dr. Owens then reported a case of sarcoma of the leg which was treated successfully with the toxins of erysipelas and the bacillus prodigiosus. From April 10 to July 10, 1896, sixty-three injections were employed, the smallest dose being $\frac{1}{2}$ m., the largest 7 m., the latter without reaction. After this date the treatment ceased. The highest temperature was, on one occasion only, 105 degrees, and the maximum pulse 132. In another successful case of sarcoma of the leg below the knee, published in the *Chicago Medical Recorder*, February, 1895, by the author, sixty-six injections were used between Sept. 28 and Dec. 7, 1894, the minimum dose was 2 m., the maximum 10 m. Elevation of temperature was not a marked feature, consisting mostly of a fraction of a degree, 101.8 degrees being the maximum. During the treatment, pain, frequency of urination, nausea, occasional vomiting and muscular soreness was experienced. Improvement was noticed on the eighth day. This patient was found in good health in all respects Sunday, May 16. In this case the diagnosis was verified by microscopic examination. In such case a leg was saved and probably the life of each patient.

Dr. J. A. BAUGHMAN of Neoga reported a very interesting case of gastrectomy, and exhibited the patient.

Dr. WELLER VAN HOOK of Chicago reported a case of excision of the testes, prostate, and vesiculae seminales for tuberculosis in a man 26 years of age, whose health was apparently good, with the exception of a local trouble located in the right epididymis. There were no evidences of tuberculosis anywhere excepting in this epididymis. There was no fistula, no breaking down of tissue and the epididymis was hard.

At the first examination the rectum, prostate gland, and vesiculae seminales were found intact. When first attacked, the patient was informed that in all probability the disease of the epididymis and testes was tubercular, and in view of the possibility of the extension of the disease, he readily consented to have the testes removed. This was done, the testes being removed as carefully as possible by the method described by Dr. Van Hook.

Dr. HAROLD N. MOYER of Chicago read a paper on

THE NERVOUS AND MENTAL PHENOMENA FOLLOWING SURGICAL OPERATIONS,

in which he said that it seemed to him that too little attention was paid to the nervous states which predisposed to shock. Of late years studies of the heart and kidneys had been made, but the nervous system did not seem to have been included in that careful scrutiny which should precede every surgical operation. It had been known for years that patients sometimes died very suddenly during the most trivial operations, such as a hypodermic injection, slight incision or the extraction of a tooth, but only during the past year had a series of these cases been investigated. In all of them an enlarged condition of the thymus gland was found, to which condition the term *constitutio lymphatica* had been given. We know of no means of recognizing this condition during life. Perhaps if cases were studied in reference to this state, clinical data might be accumulated by which it could be recognized, and thus some of the most deplorable accidents in surgical practice might be averted.

It, too, would seem advisable to study the general nervous system, especially with reference to the pupils, muscular tonus as shown by the tendon-jerks, the superficial reflexes, coördination, etc.

It is now generally believed that the length of an operation, the quantity of anesthetic, the part involved, the amount of hemorrhage, are the chief causes which determine the degree of shock. While it is conceded that shock is largely physical, yet the mental condition of the patient plays a most important rôle. A confident feeling on the part of the patient in the operator and the result of the operation is one of the most important factors in lessening shock and preventing the unpleasant nervous sequelæ which follow.

The question of local anesthesia by the Schleich method was one that was bound to be of great importance in lessening general anesthesia and consequently shock. The nervous phenomena which follow operations, often had their foundation in the preoperative period, and no intelligent discussion of their treatment could be had which did not include the entire care of a patient before and after operation.

The forms of insanity following operations were almost always included under the terms confusional, which is the most frequent; melancholia, less frequent; hypochondriasis, simple mania and sometimes paranoia. As a rule, the chronic degenerative psychoses did not have their initiation in a surgical operation. The treatment of these various conditions was not different when caused in this way from what it is when occurring in non-surgical cases.

Dr. D. W. GRAHAM of Chicago read a paper entitled

PILO-NIDAL SINUS.

The author stated that there occurs not infrequently in the sacro-coccygeal region a form of suppurative inflammation whose peculiarities were first correctly described by Dr. R. B. Hodges in the *Boston Medical and Surgical Journal*, November, 1880, and aptly named by him "Pilo-nidal Sinus." Dr. Graham finds this affection referred to only in two works on surgery, in one of which the writer places it under the head of "Diseases of the Spine," and the other classes it with "Diseases of the Rectum."

In the middle line of this region there is found in some persons one or more blind follicles or pits in the skin which will admit the end of a small probe for a quarter of an inch, more or less. These infundibula may be situated either over the coccyx, below it toward the anus, or more often, according to the author's observation, above it. There is also not infrequently found a shallow but larger depression directly over the coccyx, which has been called the coccygeal or post-anal dimple, and by the French, the posterior umbilicus.

Accumulations of dirt and débris within any of these pits or dimples may give rise to abrasion, infection and the ordinary circumscribed cutaneous or subcutaneous abscess for which the practitioner is often consulted. But when loose stiff hairs from the skin of contiguous regions in hirsute individuals find lodgment, either alone or as part of other accumulations; they are liable to burrow in any direction in the subcutaneous areolar tissue, and remaining, they cause a persistent suppurating sinus. The condition when first seen by the surgeon is almost always a chronic one, having existed for months or years. Dr. Graham then cited an illustrative case.

The author says that pilo-nidal sinus must be clinically differentiated from tuberculosis, from ordinary fistulae of the rectum and anus, and from dermoid cysts. The fact that almost all the cases occur in adult males with coarse hairy development will be an aid to diagnosis. The hair found in the sinus itself is the best witness in any case as to whether we have a dermoid or the acquired hair sinus. The speaker believes that the hair found in external dermoids is, without exception, short, fine, curly and devoid of pigment; while that found in the hair sinus will always correspond in size and color found on the contiguous regions of the patient. The object of the paper was to insist on the recognition of pilo-nidal sinus as an affection distinct from dermoid proper.

Dr. J. B. MURPHY of Chicago reported some experimental work in arterial surgery. Recently he said he had made a number of experiments to establish the idea that the arteries could be united and the blood current conducted through them as before, the same as a mechanical tube may be united for conducting water or other fluids. The technique of arterial suturing is extremely difficult. We have here a tube with a wall that is strong and resisting, with but little regenerative power, which is the greatest difficulty of treating arteries with suture. He had succeeded in overcoming this difficulty in the dog as well as in the patient. He exhibited drawings illustrating the method of overcoming the feeble reproductive power of the artery by replacing it in such a position that it is kept in apposition, and the connective tissue reproduction around the artery suffices to retain it while the current continues to flow through the artery. The difficulties to be overcome are to prevent closure of the artery by manipulation; to prevent immediate thrombosis within the artery; to prevent primary and secondary hemorrhage.

Dr. Murphy reported two cases, one of which had previously been placed on record. The other case was a bullet wound of the femoral artery in which he made a resection and end-to-end approximation. There was a feeble pulsation in the artery before the operation, which was increased after operation, but the circulation in the limb was at no time disturbed by the operation. There was an enormous aneurysm produced around the femoral artery from the bleeding beneath the connective tissue, and by removing the clot he exposed the vessel. End-to-end union was performed in six minutes. The patient is now perfectly well.

Dr. ALEX C. WIENER of Chicago made some remarks on the ambulatory treatment of fractures of the lower extremities, and exhibited the apparatus which he uses.

Dr. TRUMAN W. BROPHY of Chicago followed with a paper on the "Surgical Treatment of Cleft Palate," and exhibited two patients upon whom he had operated, showing closure of the cleft in each case.

The following resolution was unanimously adopted:

Resolved, That it is the opinion of the Illinois State Medical Society in convention assembled that the laws governing medical practice in the State of Illinois should apply with equal force to all persons engaged in the healing art, and no discrimination should be made in favor of any school of practice. Furthermore, we wish particularly to enter our emphatic protest against the enactment of Senate Bill No. 297 (the osteopathic bill).

SECOND DAY—AFTERNOON SESSION.

Dr. C. S. BACON of Chicago read a paper on

THE USES OF HYPODERMATIC INJECTIONS OF NORMAL SALINE SOLUTIONS IN OBSTETRIC PRACTICE,

and showed a simple apparatus for making the injections. Three indications for the use of saline solutions were given, namely, hemorrhage, eclampsia and puerperal infection. Hemorrhages were divided into three classes. Those of the first degree included the cases where less than one-fourth of the blood was lost, *i. e.*, in women of medium size weighing 130 pounds, where less than 2.5 pounds were lost. Here the blood pressure did not change greatly because of the contraction of the vessels, and if the shock was not great the results were not serious. In hemorrhages of the second degree, where one-fourth to one-half of the blood was lost, *i. e.*, from 2.5 to 5 pounds, the most serious symptoms were due to the fact that the quantity of blood was too small to fill the vessels and the heart had nothing to contract on. Hemorrhages of the third degree, where more than one-half of the blood was lost, were generally fatal. It was in the second class, which comprised most of the serious obstetric cases, where the saline solution was most useful. Transfusion of blood and intravenous injections of defibrinated blood had been rejected on account of their dangers. Intravenous injections of saline solutions as well as intraperitoneal injections were more dangerous and scarcely better than hypodermatic injections.

In eclampsia the salt solution diluted the poisonous blood serum, especially when combined with venesection, and likewise stimulated the excretory organs. The same was the mode of action of the solution of puerperal infection.

For the solution sodium chlorid in the proportion of 8 parts in 1,000 parts of water was employed. A sufficiently accurate approximation was obtained by taking one level teaspoonful of fine table salt to a pint of water. The solution was first made and then boiled and afterward cooled by letting cold water flow over the containing vessel. The proper temperature was determined by turning a few drops on to the back of the hand. The injection apparatus consisted of a bottle or enameled-ware can holding about a pint, which had a spout from the side at the bottom, to which was attached a rubber tube about three feet long. Into this tube was inserted the stem of a glass Y, to whose branches were attached smaller tubes carrying needles. The apparatus was sterilized by running an antiseptic solution through it, followed by sterile water or by boiling. It was then filled with the salt solution; the needles were inserted into convenient locations, generally the inside of the thighs, and the solution caused to flow by raising the reservoir. Constant massage assisted the absorption of the solution. A quart at a time might be introduced in a case of hemorrhage, in from ten to fifteen minutes. In eclampsia a quart might be injected with or without the withdrawal of a pint of blood.

Dr. ALBERT GOLDSPOHN of Chicago followed with a paper on

INTRAPELVIC RETRO-VAGINAL PERINEORRHAPHY WITHOUT LOSS OF TISSUE.

Being convinced of the superficiality and relative uselessness of many operations that are performed upon the perineum, the author briefly called attention to some anatomic facts and several fundamental principles which underlie the plastic surgery of the perineum.

Accepting the wholesome reformatory views advanced by Schatz, and profiting by the suggestion of flap-splitting by Lawson Tait, the author has developed a method of operating for these lesions of the female pelvic floor, which he has employed with satisfaction for about five years. With the sharp point of a scissors passed under the skin, a rounded incision, resembling an arc of one-quarter to one-half of a circle, is made through the skin on the skin side of the mucocutaneous junction, terminating at the posterior ends of the nymphæ or at the posterior remnants of the hymen. This flap is dissected up in the beginning and wherever cicatricial tissue

must be severed, with careful clipping of connective tissue bands in small parts with a scissors that has rounded ends and is always directed against the tactile surface of a finger of the left hand placed on the upper side of the flap within the vagina, while the fingers of the other hand are elevating the flap. By thus constantly estimating the thickness of the flap we can take the usually scant muscular structure beneath the mucous membrane, along with that membrane, without injuring the rectum and without passing a finger into it. In rectoceles with a very thin septum the latter precaution is advisable, although the author has done so very rarely. Beyond the cicatrized portions the dissection is readily done with the end of a finger covered with gauze. This flap composed of the posterior vaginal wall is temporarily elevated to an extent of six or nine cm. inward from the plane of the hymen and the detachment is carried well up on the sides, higher on the side where the edge of the levator ani and pelvic fascia have retracted most, until the inner edges of the two lateral portions of these structures are recognized by the finger. Usually the otherwise easy detachment of the vagina becomes arrested where the borders of the fascia and levator are reached and it need not be continued further. If the venous hemorrhage is very marked, compression of the wound through the flap may be made for a few minutes, or hot water used in the irrigation. Next a full curved needle not over six cm. in total length, with a round catgut eye and armed with a round and strong catgut thread, which has been prepared to hold two weeks, is grasped with a good needle-holder that does not permit it to roll and is carried with its point at the tip of the left index finger to the bottom and left side of the wound. The levator is not often felt at that depth; so the needle is, from the front backward, made to take a liberal grasp of the soft parts and is brought out closely upon or near the rectum upon the nail of the index finger which at that moment is depressing the rectum. This finger is then turned to guide the point of the needle into the needle-holder. After it has been drawn out its point is passed by the same finger into the bottom of the wound upon the right side, the rectum depressed with the finger first, and then the point of the needle passed from the finger nail outward and forward, taking a likewise liberal grasp of soft parts. A second round of sutures is next made with the needle precisely as before, grasping deeper where the first ones caught possibly less or more yielding structures, and then the suture is drawn up tightly and tied in the bottom of the wound, when the bleeding becomes mostly checked. Then a continuous suture of three to five more rounds is placed in the same manner, by means of which the wound cavity becomes reduced to only about two cm. in depth. In the sides of the portion of the wound which is closed by this suture, the edges of the levator are usually discernible readily and should be caught in every stitch that the needle makes. Likewise every turn of this suture should seize a bit of the connective tissue from the bottom of the wound posteriorly and from the under surface of the vaginal flap anteriorly, so as to hold these surfaces against the bridge that is being constructed by the approximation of the lateral parts, but not to draw them in between the latter. The remaining superficial wound upon the outer aspect of the perineum is closed, as the cosmetic part of the operation, by interrupted silk-worm gut sutures passed from side to side successively from behind forward until the new posterior commissure of the vulva is developed. At this point a slight tip of the former vaginal flap is frequently redundant and projects. This it is best to cut off, and then this cut edge can be gathered into the final silk-worm gut suture. In case of complete rupture into the rectum, he denudes its edges and the ends of the sphincter ani and closes the wall of the bowel and the anus by interrupted sutures tied within the gut as an intermediate step between the two parts of the other operation. Placing a finger into the vagina, after this work, is like introducing it into a uniform tube seven to eight cm. in length and not merely like sticking it into an auger hole in a board two cm. thick, which resembles the usual product of most of the purely external plastic, like that of Tait, whose chief merit is frequently of a cosmetic nature only.

Dr. FRANKLIN H. MARTIN of Chicago followed with a paper on "Treatment of Fibroid Tumors of the Uterus." and Dr. J. W. M. CATTO of Decatur read a paper on "Uterine Hyperplasia."

Etiology of Yellow Fever.—Dr. Havelburg announces that the microbe which he considers the specific cause of yellow fever is found only in the stomach and intestines, but is cultivated by injecting it subcutaneously into guinea pigs. He finds that a previous injection of blood from a yellow fever convalescent renders an animal immune to an otherwise fatal dose of injection of the cultivated microbe.—*O Brazil Medico*, April.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JUNE 12, 1897.

THE JUBILEE MEETING.

It was a common remark at the meeting that few if any present, would ever see such a meeting of the ASSOCIATION again. It not only surpassed all previous meetings in number of members present, but in *tout ensemble*. The papers were many of them of the highest class, and the average quality was superior. The attendance on Section sessions showed great interest, and the general sessions were crowded. The citizens of Philadelphia met fully all expectations. The places of meeting of the Sections were as a rule convenient, and selected with an intelligent estimate of the needs of each.

The general sessions were opened on the exact minute by President SENN, whose skill as a presiding officer was manifest from the first hour. He made graceful recognition of the four Vice-Presidents by requesting them to preside in turn, after the address of the day, so that the ASSOCIATION had an opportunity to see them in official position. Without exception they showed themselves fully capable of keeping the sessions under control and down to business. The meeting was unmarred by any disagreeable incident such as has sometimes characterized the sessions when "miscellaneous business" was under consideration.

The proposed amendments, with two exceptions, were indefinitely postponed; one was offered by Dr. BULKLEY of New York, to change the name of the Dermatology Section to that of Cutaneous Medicine

and Surgery, by which it will hereafter be known. The amendment of Dr. LOVE to amend Article IV in regard to officers, was withdrawn by the author, but subsequently renewed by another member, so that it will come up again next year.

Action in regard to the Rush Monument resulted in the appointment of a committeeman for each State, who will raise all funds possible in his State. The JOURNAL will also receive money on this account and pay it over to the Treasurer. Several of the States were pledged to raise \$2,000, and many individual contributions were subscribed without conditions. The state of the Rush Monument fund was thus much improved in a few minutes, and Commodore GIBON, the chairman of the committee, made very happy. The members should, however, remember that pledges, unless accompanied by proper collateral, are not negotiable paper. What the committee wants is *cash*.

The resumption of prize essays, as recommended by President SENN, is a wise measure, and will undoubtedly help the ASSOCIATION, and indirectly the whole profession, by stimulating original experiments; and here we may venture to record an expression of regret that steps were not taken to form a standing committee on legislation, so that the resolutions passed against Senate Bill 1063 (which prevents vivisection, and practically animal experimentation) might be made more effective. The report of Dr. FREDERICK HORNER on a benevolent aid association was well received, and a committee was appointed to formulate a plan, and report the details at the next meeting.

Dr. U. O. B. WINGATE, from the Committee on a Department of Public Health, made an elaborate report, and formulated a Bill, the result of much correspondence, which seems to meet the desire of the ASSOCIATION, as it was adopted without dissent or opposition. The Bill provides for a commissioner of health who shall be the head of the new department, which if the Bill becomes a law, will establish the Health Department on a broad and enduring foundation. This bill, as finally perfected and agreed to by the ASSOCIATION, will be urged until it shall be finally passed. No action of the ASSOCIATION was more important than this and none has been more carefully prepared, or has more skilfully harmonized opposing interests.

The jubilee exercises were impressive. The venerable founder of the ASSOCIATION, Professor NATHAN S. DAVIS, accompanied by his colleague, Professor ALFRED STILLÉ, was escorted to the stage between a double line of ex-presidents of the ASSOCIATION, who were standing in open order. The escort consisted of the Presidents of State Medical Societies and Presidents of State Boards of Examiners.

President SENN then welcomed him in a few well-chosen words, the delegates in the hall rose and cheered until they were stilled, when Professor DAVIS

delivered the historical reminiscences which we elsewhere publish. No one present will ever forget it. The orator read with his old-time earnestness, and with a clear voice that time has scarcely impaired; and the pride and affection that the ASSOCIATION has for our venerable colleague was manifested again, when he closed, by vehement and enthusiastic applause.

Another noteworthy incident was the appearance and pleasant words of congratulation by the President of the United States, the Hon. WILLIAM MCKINLEY. His presence was the signal for prolonged applause, and his speech, which is printed in the minutes, was exactly in the right vein to be appreciated and enjoyed.

The witty speech of the Governor of Pennsylvania, the Hon. DANIEL H. HASTINGS (p. 1143) was much appreciated for its bright and telling points, and it lost nothing in its effect by the excellent voice and style of delivery. The Governor was so pronounced in favor of the regular profession, and in his denunciation of quackery, that several of the members expressed the wish that Pennsylvania's Governor might infuse some of his correct ideas into the minds of some other governors—alas, gone wrong on these questions.

Taken all in all, the jubilee meeting was a perfect and pronounced success.

THE CUMULATIVE ACTION OF DIGITALIS.

There is scarcely a text-book on therapeutics and but few works upon practice of medicine, which are carefully written in the portions of them which are devoted to therapeutics which do not warn the student and young practitioner of the fact that digitalis is capable of producing a cumulative action, and it is unfortunate that in a large number of the books which we have mentioned the author does not clearly state what he means by this term. Further than this there seems to be some difference of opinion among many members of the profession as to what is intended by the word "cumulative" and so much confusion has existed in regard to this matter that some eminent clinicians have gone so far as to state that no such thing as a cumulative effect of digitalis is ever met with. From a careful consideration of the statements which have been made in various medical journals and text-books we think it may be concluded that where the so-called cumulative action of digitalis is denied an existence the person making a denial has not a very clear idea of what is meant when such a condition is described, and with a few exceptions we think it will be found that those who have denied its existence are usually careless in studying the effects which are produced by the administration of their remedies. Our confidence in the belief that there exists a cumulative action of digitalis has been considerably sustained by an original article on this subject which was read by HARE before the Association of American Physicians

at the recent Congress in Washington and which has been published in the *Therapeutic Gazette* for May. In this paper the author after describing what was meant by the so-called cumulative action of digitalis, gives the replies which he has received from a large number of prominent practitioners and teachers of medicine throughout the United States and Great Britain as to what they mean by this term, and it is an interesting fact to note that with a few exceptions those men having the largest experience and ability for therapeutic study are firm believers in the statement that digitalis is a drug which possesses peculiar properties in this respect. The cumulative action of digitalis differs from what might be called the cumulative or poisonous effects of other drugs in that the symptoms associated with the over-action of the remedy usually come on suddenly and are alarming in character. They are associated as a rule with great gastric disturbance and with mild nervous symptoms, but it is the circulatory disorder which is most distressing to the patient and alarming to the physician. This usually consists in a sudden change from the slow, full pulse, which is so characteristic of the full influence of digitalis, to the irregular, hobbling pulse produced by a disturbance of what might be called the "cardiac balance." When sudden in its onset it is generally produced by the patient changing his position as by quickly sitting up in bed, or attempting to stand erect by the bedside, when, from the disordered function of the vaso-motor system and the heart and its supplying nerves, the circulation suddenly fails and the patient suffers either from cardiac distress or a dangerous syncope.

It has been stated by those who are opposed to the view that digitalis produces a cumulative effect that any remedy given in over-dose for too long a period produces a cumulative effect and that digitalis is therefore no more peculiar in this particular than is strychnin or morphin. This, however, is not correct. Digitalis produces its cumulative effect as a rule because it is so slowly eliminated from the body and the effects of one dose are maintained for so long a time that ordinary frequency of dosage rapidly carries the patient beyond the point of tolerance, and if it is desired we can use the term "poisoning from medicinal doses of digitalis" to cover the same symptoms as some practitioners are wont to cover by the term cumulative.

As a rule the cumulative symptoms develop because the physician who is administering the drug ignores the rules which have been laid down ever since WITHINGTON, one hundred years ago, first introduced this remedy into therapeutics, namely, they give it in large doses and give it frequently and continue these large and frequent doses over long periods of time. That this is an incorrect way of administering the drug is recognized more thoroughly in France than it is in the United States. SOULLIER, a distinguished French

therapeutist, directs that the so-called cumulative effect of digitalis is to be avoided by the suspension of the remedy for eight days after it has been given for eight days, and quotes LEPINE as never using it on consecutive days. Another reason why digitalis is more apt to produce a so-called cumulative influence than are other drugs which are more powerful but whose influence is more fleeting, is that its physiologic action tends to retain it in the body, for, as BRUNTON points out, digitalin when taken for several days causes a decrease in the flow of urine through the spasm which it produces in the renal blood vessels and this decrease of urinary flow probably diminishes the elimination of the drug. One of the most noteworthy replies which was received by HARE in his collective investigation was received from JANEWAY of New York, whose large clinical experience certainly qualifies him to speak authoritatively in this matter. This observer states that he found the chief manifestation of this state to be sudden death on exertion and he adds that he has on several occasions made post-mortem examinations of persons who had been under treatment in the hospital with digitalis, the death being due in his opinion to the continuance and excessive administration of this remedy.

H. C. WOOD also recorded a case in which digitalis was administered for a number of days without effect, until suddenly the patient's pulse, which had been running about at 90, fell to 75; the drug was immediately discontinued, but the next day the pulse was 60, the next day 50, and the next day 40, and the patient had all the symptoms of the over-action of digitalis.

In the discussion which followed the paper that we have quoted we learn from the report made in *The Medical News* that OSLER expressed an entire disbelief in the possibility of the development of the cumulative action of digitalis and attempted to explain the changes in the pulse rate mentioned by Dr. WOOD as due to the inability on the part of the clinician observing the case to accurately count the pulse without paying attention to the cardiac pulsation in the precordium. He stated that it was frequently his experience when exhibiting digitalis to a patient to find that the apex beat of the heart to occur eighty times a minute, although the pulse at the wrist could only be counted forty times a minute, the forty lost beats being due to the fact that the heart produced an abortive systole which could be felt in the precordium, but which did not have enough power to produce a pulsation in the radial artery. It seems to us that this denial of the existence of the cumulative action of digitalis is on its face a proof of its existence. Any patient who has received this drug in such large doses over a considerable period of time, as to develop such an irregular action of the heart as we have described, is certainly suffering from a cumulative or

poisonous effect of this drug, notwithstanding the fact that Dr. OSLER believed his doses to be medicinal and not poisonous, and it is pointed out by the author of the paper quoted, in closing the discussion, that this statement proves exactly what its maker is attempting to disprove. In our opinion the proper administration of digitalis consists in giving it in such doses for the first day or two as to stimulate the heart and circulation to a point as nearly normal as possible, and then the physician, remembering how persistent the action of this drug is, and how slowly it is eliminated from the body, should cut the dose down to a comparatively small amount which though minute in comparison with the original dose, is still large enough to maintain the physiologic action of the drug. Or, if he fails to do this, he should at least stop giving the remedy for a few days at the end of each week in order that the system may rid itself of the drug which the physician has been administering in excess of its needs.

THE OSTEOPATHY BILL.

The bill allowing a certain class of practitioners, styling themselves osteopaths, extraordinary and special privileges has recently passed both houses of the Illinois Legislature and is now in the hands of the Governor—let us trust for slaughter.¹ It is incredible that a bill which confers special privilege on masseurs or chiropodists can receive sanction. Regular, "homoeopathic" and "eclectic" under the existing law must come to practice under the medical practice act, but these persons are to be exempted from any restrictions whatever. This is probably unconstitutional, as it is certainly class legislation. Under the provisions of the proposed bill all the irregular advertising mountebanks that masquerade under the name of "doctor" will become osteopaths and practice without let or hindrance. The act to regulate the practice of medicine in the State of Illinois was passed for the protection of the people of the State against the quacks. This bill renders the act of no use, and practically annuls, for it would be monstrous to require an educated physician to pass under restrictions which do not exist for the so-called osteopath, this term being simply used as a cloak for ignorance and deceit. The profession in Illinois are justly aroused, but too late to have made an impression on the Legislature, where the bill was kept very quiet. They now depend on the well-known good sense of the Governor to return this piece of half-baked legislation without his approval.

THE JOURNAL TRAIN.

The JOURNAL Special train went to Philadelphia exactly on time. Its appointments were perfect, and its accommodations ample for the 140 persons who availed themselves of them. Thanks are due the

¹ As we go to press we learn that this bill has been vetoed.

management of the Pennsylvania Company for the perfectly satisfactory manner in which the train was equipped.

BOOK NOTICES.

Registration of Births, Marriages and Deaths in the Province of Ontario, for the year 1895. Pp. 354. Toronto: Warwick Bros. and Rutter. 1897.

The report presents, with other data concerning vital statistics, notes on the several Registration Acts of Ontario; the Act of 1896, in full; and replete tables summarizing births, marriages and deaths. These tables present their data by counties, by towns and by cities; with tabulations of causes of deaths, number of births and marriages by order of months, and proportion of male to female births. The twelve highest causes of deaths were phthisis, prenatal period, old age, pneumonia, diphtheria, cholera infantum, valvular diseases, paralysis, typhoid fever, convulsions, bronchitis, wounds and accidents.

Transactions of the American Microscopical Society, at its nineteenth annual meeting, held at Carnegie Library, Pittsburg, Pa., Aug. 18, 19 and 20, 1896. Vol. xviii. Paper, pp. 420. A. T. Brown Printing House, Buffalo, N. Y. 1897.

Many of the papers presented are of marked value to medical men, while all are a credit to the Society. Among others, we note: "Diphtheria, its Bacteriology," by Charles F. Craig, M.D. "A Study of the Cellular Pathology of Carcinoma," by C. W. Kellogg, M.D.; "The Red Blood Corpuscle in Legal Medicine," by M. C. White, M.D.; "The Requisites of a Pure Water Supply," by W. C. Krauss, M.D.; "The Increasing Pollution of our Municipal Water Supplies," by F. J. Thornbury, M.D., and "Public Water Supply for Small Towns," by M. A. Veeder, M.D.

NECROLOGY.

GEORGE THOMAS, M.D., born in Maryland thirty-eight years ago, died in Baltimore of pneumonia, June 3. He was graduated in 1882, from the College of Physicians and Surgeons, Baltimore. Four years ago he became Secretary of that College and was also a member of the Maryland Medical and Surgical Association, the Clinical Society and the American Laryngological Society.

ANTHONY EUGENE STOCKER, M.D. University Pennsylvania, 1840, for many years on the surgical staff of the Pennsylvania Hospital, died May 23, in Philadelphia, aged 78 years.—Jeremiah B. Selby, M.D., May 31, aged 75 years. In point of residence, the oldest physician in Milwaukee.—A. L. Knight, M.D., West Columbia, W. Va., May 27, aged 74 years.—Henry A. Dubois, M.D., San Rafael, Colo., formerly in charge of the U. S. Medical Laboratory, Philadelphia.—B. F. Sherwood, M.D., Ogdensburg, N. Y., May 30, aged 80 years, at one time president of the New York State Medical Society.—B. H. Benham, M.D., Honeoye Falls, N. Y., May 31, age 68 years.—John Westgate Ladd, M.D., Newport, R. I., May 29.—Alphonso Xavier Illinski, M.D., East St. Louis, May 29, aged 90 years. Dr. Illinski belonged to the nobility of Poland but was exiled during political disturbances of 1836, coming to America in 1837. He introduced the use of antisepsis, the hypodermic syringe and the fever thermometer, into the Mississippi Valley.

MISCELLANY.

Injection of Chloroformed Guaiacol in Severe Neuralgia.—Subcutaneous injections of 15 to 60 drops of a solution of chloroform, 10 grams, and guaiacol, 6 grams, always soothes the pain,

improves the neuralgia often and occasionally cures it. The bottle should be sheltered from the light and kept in an opaque paper. The injection should be made as close as possible to the nerve trunk, once a day, or once in two or three days. These injections have also been found effective in small surgical operations as an analgesic.—*Presse Méd.*, April 24.

Mirror Writing.—Professor Laveran has remarked that if a pencil is taken in each hand, and one then commences to write with both, the left hand will write reversed, from right to left, unless the attention is concentrated upon it. The two hands will soon be far apart, writing in opposite directions, as any one can corroborate for himself. He ascribes the reversed writing in certain cases of hemiplegia to the fact that the act of writing becomes then purely automatic, and the reversed direction of the writing proves that the individual was naturally left handed, although this might have been unsuspected by those around him, and possibly by himself. He mentions the fact that the Arabs and Jews of antiquity wrote with the left hand, and from right to left. He suggests writing down the incomprehensible speech in aphasia, when possibly some clue to it may be discovered.—*Nord Méd.*, April 1.

Early Diagnosis and Treatment of Malignant Deciduoma. The predominant symptom is the copious and repeated metrorrhagia resisting all the usual methods of treatment. The uterus is voluminous, the cervix soft and gaping. The pre-existence of a mole pregnancy, an actual or suspected abortion, pregnancy, all assume great importance, as a deciduoma does not develop without some product of true or false conception in the uterus. The condition of the general health is also very important, especially if there is debility more than can be ascribed to the recognized lesions. Certainty can only be obtained by curetting the uterus, when the presence of cells in the scraps of mucosa, with the characteristics of decidual tumors, decides the question. Immediate vaginal hysterectomy is the only treatment. Monod and Chabry thus recently operated on a young woman presenting the above clinical picture. The neoplasm was found penetrating the muscular interstices and lymphatic vessels, in a way that proclaimed its malignant character at a glance, although it had been ablated at such an early stage.—*Rev. de Gyn. et de Chir. Abdom.*, February 10.

The Spectroscope in investigating the Blood.—Professor Lewin urges all to master the simple details of using the spectroscope in examining specimens of blood, calling attention to its great importance in medico-legal questions and also its clinical significance in infective and metabolic diseases. The urine, for instance, in some cases shows no macroscopic nor microscopic traces of blood, but with the spectroscope it is distinguished at once. The discovery of carbonic oxid in the blood is conclusive evidence that it was inhaled during life. The presence of sulpho-hemoglobin is also important in cases of poisoning from sewer gas, emanations in industrial establishments, etc., but it can only be discovered with a thick layer of blood, and a very narrow slit for the entrance of the light. Methemoglobin is the first product of the decomposition of oxyhemoglobin. If present in large quantities, the blood becomes thick and dark brown, and it imparts a grayish-violet color to the skin, often mistaken for cyanosis from the usual causes. The poisons that generate methemoglobin in the blood during life are sodium and potassium chlorate, arsenious oxid, the inorganic nitrates and nitrites, and also all the nitro-compounds of the fat and aromatic series, such as ethyl nitrite, amyl nitrite, nitroglycerin, nitro-benzol; also the amido-compounds, like anilin, amido-toluene, paramidophenol, nitro-anilin, hydroxyl-amine; most of the hydrazins, chinolin, *helvella esculenta* and others. The indications of methemoglobin are the bands in the red, but still more characteristic is the disappearance of these bands, with reduction, and the appearance of the hemoglobin

bands. Old yellow ammonium sulphid (Schwefelammonium) is a reliable and sensitive test for hematin; its diagnostic value is evident. Hematoporphyrin is an extremely sensitive test for blood, and if old, dried, putrefied or otherwise altered blood is mixed with sulphuric acid, the compound contains hematoporphyrin, and the resulting spectrum is unmistakable. Lewin gives many other important suggestions with a carefully compiled table of the most frequently encountered blood spectra in the *Deutsche med. Woch.* of April 1, adding that a most important part of the procedure is to identify and interpret the bands after they are distinguished. The Browning pocket spectroscope is all that is required, with the blood in a test tube or flat-sided bottle. The bands in the red and orange portion of the spectrum must be examined first, before the blood is diluted, as even experts might fail to distinguish them after the bands in the blue become visible.

Denial of the Usefulness of Bianchi's Phonendoscope.—Egger, after a careful study of the practical usefulness of Bianchi's phonendoscope, obtained results that do not fully accord with those claimed by the inventor of that instrument. He objects to the instrument, in the first place, on the ground that even the slightest shaking of the rubber conducting-tubes produced very distinct accessory sounds that were conducted to the ear, thus tending to obscure the heart or lung sounds. On the other hand, the very slightest manipulation of the metal rod that rests on the surface of the body causes a noise in the ears so intense as to be painful. Bianchi held that with the use of the phonendoscope all sounds, normal or adventitious, when they reached the ear, had the same intensity and quality which they possessed at their point of origin. Egger believes this to be untrue in many cases. In a tuberculous patient with lung cavities, an examination by direct application of the ear to the chest or by the use of the ordinary stethoscope showed pure amphoric breathing and exquisite metallic râles. On using the phonendoscope the amphoric character of the breathing and the metallic character of the râles were entirely lost, and only bronchial breathing could be made out. He convinced himself that high-pitched notes were much more poorly conducted than with the naked ear or with the ordinary stethoscope. Low-toned notes, on the other hand, were much better conducted. Bianchi claimed that the notes obtained while rubbing the skin slightly during auscultation over an air-containing organ is different from that obtained over an organ not containing air. He was thus able to map out the outlines of the heart and liver. Egger is doubtful whether results thus obtained can be fully relied on, as he was able to get marked variations in the note while auscultating over various parts of the thigh. He does not believe that the phonendoscope will displace the stethoscope in the clinical work.—*Münchener medicinische Wochenschrift*.

Complete Crossed Hemiatrophy of Neuritic Origin.—Lunz (*Deutsche Med. Woch.*, March 18, 1897, p. 185) has reported the case of a married woman, 26 years old, who presenting wasting of the left half of the face and of the right upper and lower extremities and of the right half of the trunk including the breast. Prior to her marriage she had been employed as a weaver and had always been perfectly well. Subsequently she worked in the fields and was often exposed to cold and wet. Soon after this change in her mode of life she became troubled with pain in the right thigh, particularly upon its posterior aspect and extending to the sole of the foot. After the lapse of several years the pain became more aggravated, and it was now noticed that the right lower extremity was wasted. Shortly before this, while nursing her first child, the patient had observed the right breast to be smaller than the left, and that the former secreted less milk than the latter. For a period of four years her friends had noticed that the left side of her face was smaller than the right side, and the former was at times the

seat of slight pain. For a year there had been complaint of pain in the upper extremities. The atrophy involved, so far as could be determined, only the soft parts. Motility, however, was in nowise impaired, except for a marked insufficiency of both ocular internal recti. Sensibility was unchanged in its several forms and there were no tender points or lines. In some muscles in the affected areas faradic and galvanic irritability was increased, probably from diminished resistance to the passage of the currents. The cutaneous reflexes were normal. The knee-jerks were slightly increased, particularly upon the right side. Tinnitus aurium recurred frequently, in association with vertigo and feelings of heat in the head. At the same time the face became reddened and there was free perspiration. There was a sense of coldness in the lower extremities, which were livid and cyanotic. Careful studies of the local temperature showed this to be depressed in those situations in which the manifestations were active and the blood vessels contracted and relatively elevated where the activity of the manifestations had largely subsided (and the tone of the blood vessels was diminished or lost). Control observations showed considerable variations between symmetric parts of healthy persons, though not so pronounced as in the case of the patient under consideration. The conclusion is expressed that the case is one of wandering interstitial neuritis, with vaso-motor manifestations resulting in atrophy from constriction of the blood vessels.

Test of the Permeability of the Kidneys.—Methylene blue injected subcutaneously after urinating appears in the urine normally in half an hour, attaining its maximum of intensity in three to four hours. But if the kidneys are affected, the blue appears much more slowly, and in seventy-seven observations this test confirmed in every case the diagnosis of renal disturbances. Achard and Castaigne also found several cases in which there were no clinical evidences of renal trouble, but investigation in each case disclosed early troubles. They consider the test a valuable confirmation of other evidence as the function of the organ is alone involved. The average dose injected was 0.050 gram.—*Bulletin de la Soc. Méd. des Hôpitaux*, May.

Intermittent Drainage of the Pleura.—R. Macias has secured brilliant results in eight cases of purulent pleurisy by this means and recommends it for the serous form also. A rubber tube is inserted into the pleural cavity and left permanently, but the free end is closed with a clamp or tied in a knot, and only opened for a while every two hours at first and once a day later. Infection and the entrance of air must be scrupulously prevented, the latter by keeping the free end when open in a vessel containing a weak solution of bichlorid of mercury. If the tube becomes obstructed, the clot can be manipulated from without and forced along.—*Revista Med.* March 14.

Acute Edema of the Lung.—A recent session of the Paris Académie de Méd. was devoted to this subject, Huchard ascribing it to aortitis, or periaortitis, shown by the diminished blood pressure. The treatment therefore should be based on the pulmonary hypertension, the disturbances in the pulmonary innervation, and the renal impermeability, as it frequently accompanies interstitial nephritis. The heart must be strengthened and its work lessened, which can best be accomplished by a large general or local venesection. With this injection of caffeine and camphorated oil should be made, and strychnin administered internally or in subcutaneous injections. Morphine is strictly contraindicated owing to its depressing effect. Iodin medication should be immediately suppressed. Death ensues in a few minutes in the violent form, but there may be several attacks before the fatal ones in the subacute form. It should be distinguished from syncope, stenocardia, alimentary toxic dyspnea, asystolia, uremia and asthenia.—*Bulletin*, April 27.

Colleges.

THE COMMENCEMENT exercises of the Woman's Medical Col-

lege, Baltimore, were held May 31.—Jenner Medical College, Chicago, held its annual commencement June 3.

Hospitals.

THE fifteenth annual report of Garfield Memorial Hospital, Washington, D. C., is out. In 1896, the patients numbered 1,268. Among these were thirty-eight cases of typhoid fever, as compared with seventy cases in 1895 while the mortality rate, in 1896, was 10.5 per cent., and in 1895, 17.14 per cent. There were also (1896) sixty-five cases of malarial disease, forty-six of alcoholism, thirty-seven of pulmonary consumption, and thirty of neurasthenia, while 329 operations were performed in the surgical and gynecological departments; and forty-six in the Department of Diseases of the Eye. The dispensary work covered 1,426 cases.—The Jewish Hospital, Philadelphia, treated 648 patients during the past year, besides 12,450 dispensary cases.—The eighteenth annual report of the Binghamton (N. Y.) State Hospital, shows the average population of the institution to have been 1,249 during the past year.

Societies.

THE ANNUAL MEETING of the State Medical Society closed at Grand Forks, N. D., May 27, with the election of the following officers: President, August Eggers, Grand Forks; first vice-president, F. R. Smythe, Bismarck; second vice-president, George F. Bates, Hillsboro; treasurer, J. A. Rankin, Jamestown; secretary, R. D. Campbell, Grand Forks; board of censors, J. P. Ayles and T. Thames, three years; J. D. Wendell and Alex. Stewart, two years; George A. Carpenter and F. B. Smythe, one year. The next meeting of the association will be held at Jamestown, May, 1898.—At the seventy-seventh annual meeting of the Monroe County (N. Y.) Medical Society, the library committee reported that \$1,500 worth of books had been collected during the few years' existence of the library. The library is a branch of the Reynolds library, Rochester, and open to the public. The Reynolds library not only cares for it free of expense, but donates \$250 annually.—The Missouri Valley Medical Association convened at Omaha June 1.—The annual meeting of the Somersworth and Berwick Medical Society (N. H.) was held May 27.—The Wayne County (Mich.) Medical Society convened May 27.—The physicians of Trumbull County, Ohio, have organized the Trumbull County Medical Society.—The Ramsey County Medical Society (Minn.) met at St. Paul May 31. Plans were formulated for starting a library.

Washington.

A COMMITTEE ON TRANSPORTATION.—The action of the AMERICAN MEDICAL ASSOCIATION in creating a permanent committee on transportation will do much toward securing suitable reduction in transportation rates for their delegates and prominent members attending future meetings. The wisdom of concentrated action by the ASSOCIATION can not be overestimated. Heretofore the different States and cities have left this important matter in the hands of local committees who have never been able to secure a satisfactory reduction in rates. The temper of the medical profession was clearly demonstrated at the public meetings of the ASSOCIATION at Philadelphia, when the roads, particularly the trunk lines of the East, were severely criticised for what the medical men characterized unjust discrimination against them in matters of transportation rates. The future Transportation Committee of the ASSOCIATION, consisting of Drs. H. L. E. Johnson of Washington, D. C., chairman, Charles A. L. Reed of Cincinnati, and Henry D. Holton of Vermont, will have charge of transportation matters and report to the ASSOCIATION. The committee have decided to take action at once in the matter of reduced rates, and report to the profession at short intervals through the JOURNAL.

MEDICAL SOCIETY.—At the meeting of the society, held on the 2d instant, Dr. J. Ford Thompson made a valuable contribution to surgery in an essay entitled, "The Treatment of Open Fracture." Dr. Hasbrouck reported a case of chloroform narcosis.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—At the 265th meeting of the Society, held on the 4th inst., Dr. Samuel S. Adams read a valuable paper entitled "Tetany in Infants." He presented the literature of all the cases (forty-six) reported in North America, in children under 2 years of age. These were all cases of tetany and did not include trismus nascentium. He included three cases which occurred in his own practice, one in a rachitic, one from trauma and one from erysipelas. A full and interesting discussion followed.

THE ANTIVIVISECTION BILL.—Senator Cockrell has presented a memorial from the representatives of medical and scientific societies of Washington, D. C., and elsewhere, protesting against the passage of Senate Bill 1063, for the further prevention of cruelty to animals in the District of Columbia. It is Senate Document 107, 55th Congress, 1st session, and can be obtained free on application to the U. S. Senate. It is a very valuable seventy-one page report.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from May 28 to June 4, 1897.

Major Joseph K. Corson, Surgeon (Ft. D. A. Russell, Wyo.), is granted leave of absence for one month, to take effect on or about June 15, 1897.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending June 7, 1897.

Medical Director T. N. Penrose, retired from June 6.

CHANGE OF ADDRESS.

Brown, H. M., from 2362 S. Elm St. to 1219 McMillan St., W. H., Cincinnati, Ohio.

Brown, R. L., from 1211 Van Buren St. to 1217 Jackson Blvd., Chicago, Ill.

Billmeyer, G. M., from Chicago to Waukegan, Ill.

Butler, T. L., from 2101 Floyd St. to 1511 4th Av., Louisville, Ky.

Derwent, A. E., from Chicago to Peconic, Ill.

Faber, C. A., from Chicago, Ill., to Room 41 and 42 Merrill Bldg., Milwaukee, Wis.

Hartman, F. T., from Chicago, Ill., to Anamosa, Iowa.

Hammond, Wm. A., from Washington, D. C., to Hotel Madison, 42d and Madison Av., New York, N. Y.

Jegl, H. A., from Arcadia to Galesville, Wis.

Miller, De Laskie, from Virginia Hotel to 56 Astor St., Chicago, Ill.

McDougall, G. T., from Hotel Phister Drug Store to 70 Farwell Av., Milwaukee, Wis.

Otis, N. M., from Chicago to Fairbury, Ill.

Owen, D. W. C., from 1961 Arsenal St. to 3864 Park Av., St. Louis, Mo.

Phelps, A. M., from 40 West to 62 East 34th St., New York, N. Y.

Roseberry, B. S., from Catekill, N. M., to Florence, Colo.

Steele, D. C., from Cocato, Minn., to Kindred, N. D.

Trout, E. H., from 1278 Adams St. to 1025 Warren Av., Chicago, Ill.

Traver, W. H., from 203 High St. to 5 Stewart St., Providence, R. I.

ORIGINAL ARTICLES.

THE LATEST METHODS OF TREATING CARCINOMA BY HYPODERMIC INJECTION.

BY EDMUND ANDREWS, M.D., LL.D.

PROFESSOR OF CLINICAL SURGERY IN THE MEDICAL SCHOOL OF THE NORTH-WESTERN UNIVERSITY, AND SENIOR SURGEON OF MERCY HOSPITAL, CHICAGO.

The partial success of Professor Coley's treatment of sarcoma by the injection of the toxins of erysipelas and of the bacillus prodigiosus has aroused interest, and induced surgeons both sides of the ocean to experiment with other articles.

One of these is the extract of *chelidonium majus*. This is the ancient semi-domestic remedy calledcelandine. It is an acrid irritant having such energy that applied to the skin it causes inflammation and blisters, and applied to warts is said to destroy them by acting like a caustic.

Dr. Denicenco of Russia (*Wratsch, St. Petersburg*) experimented with it first in epithelioma of the lip, and having produced cures (by sloughing) he was led to use it in inoperable cancers of various parts of the body. He gives it internally by the mouth, applies it on the surface, and injects it into the tumor itself. Probably the whole effect comes from the injections, but of that I am not certain. By the mouth he gives from one and a half up to five grams of the extract dissolved in peppermint water in twenty-four hours. On the ulcerated surfaces of the cancer he paints twice a day a mixture of two parts of the extract of *chelidonium* and one of glycerin. For injection into the substance of the tumor he prepares a solution of extr. of *chelidonium*, glycerin and water in equal parts, and adds half of 1 per cent. of chloroform to prevent decomposition. One ordinary hypodermic syringe full is injected daily. Denicenco says that it causes pain, a severe chill, and a high temperature lasting until the next day. This series of symptoms does not always follow. I know of at least one case of cancer of the rectum in which there was no pain, chills, nor fever, and yet the patient derived great benefit from the treatment.

Denicenco describes the local effect as follows: "On the first days of the treatment the tumor softens and seems to melt; in three to five days fistulas appear at the places of the punctures; around these fistulas the neoplasm seems to be dissolved; in fifteen to twenty days the tumor separates from the healthy tissues and is expelled" (*i.e.*, it becomes gangrenous and sloughs out). "The enlarged lymphatic glands become normal." This latter statement is very important, if true, because it implies that the effect goes beyond the mere caustic destruction of the primary tumor, and cures the infected lymphatics, or in other words the glandular secondary tumors. If I understand him rightly, he does not claim that the secondary tumors are

sloughed out like the primary, but that they are changed in character and "become normal." This opinion needs confirmation. The author asserts that he examined all the primary tumors microscopically, and was sure of their malignant structure.

Dr. Hunt of Dixon, Ill., sent a patient to me for examination and opinion. I found a malignant tumor of the rectum surrounding the entire gut about 2½ inches above the anus, and causing a stricture which amounted to an almost total obstruction of the bowel. The growth was firmly adherent to the walls of the pelvis and evidently inoperable. On consultation we agreed that it was best to try the *chelidonium*. Dr. Hunt and Dr. Grim arranged to carry out the injections, using a mixture of equal parts of extr. *chelidonium*, alcohol and glycerin. After three weeks trial, there was no softening. They then increased the strength to nearly pure extract (Parke, Davis & Co.'s). The tumor now softened, and soon sloughed away so extensively as to completely relieve the obstruction of the intestine and the distress of the patient, and causing a decided improvement of his health as well as of his comfort. One pretty severe hemorrhage occurred during the sloughing, but it was not exhausting. The parts being internal, it is impossible to say whether the whole primary tumor is destroyed, nor whether the infected lymphatics have improved in their condition, as was claimed by Denicenco.

This is a new treatment, and needs further testing, but I incline to think it will be found valuable in certain cases which are now considered hopeless because inaccessible to operative measures.

INTERSTITIAL INJECTIONS OF ALCOHOL.

Hassel of Nordhausen, Prussia, claims remarkable effects and even cures by injecting a solution of alcohol having a strength of 30 to 50 per cent. He says there is some pain at the moment of injection, but great relief from the pain of the disease. In tumors of the breast, he does not inject the tumor itself, but the connective tissue under and around it are liberally infiltrated with the alcoholic fluid by means of a syringe with a long pipe. The tumor shrinks and in many cases seems permanently cured.

Hassel of Germany, says the same thing substantially (*Therap. Woch.*, Oct. 11 and 25, 1896). He puts in from 5 to 20 cubic centimeters at once. The injections are made twice a week at first, and later once in two or three weeks. In fifteen out of eighteen cases of carcinoma of the breast the growth "dwindled gradually away until in a year there was nothing left of it but the connective tissue stroma, and there has been no return." The pains disappear and the general health improves in a remarkable manner. In five cases of carcinoma of the cervix uteri similar success was obtained.

Dr. Edwin J. Kuh of Chicago, reports one case. He deviated from the plan of Hassel by using absolute

alcohol, instead of a dilution. The patient could only tolerate three minims at first on account of the pain, but later endured with difficulty 30 minims. Dr. Kuh thinks the diluted form might have been better. The tumor was a carcinoma seated in the naso-pharynx. The reduction in size began after the seventh injection, and was apparently cured after the twenty-fifth. After four months there was no sign of return. He put the fluid into the tumor itself.

I have recommended the alcohol injections in consultation in several cases; but there has not been time enough yet to judge of the permanency of the cure, nor of the effects on the infected lymphatic glands. At present I advise it only in inoperable cases.

Dr. Young of Bloomfield, Iowa, uses the pure alcohol and puts it into all parts of the tumor itself. He claims some cures.

Hu  of France, injects a solution of arsenic and cocain at intervals of two or three days, and later at longer periods. He claims good results and some cures, with freedom from pain.

Alexandro and others have injected methyl blue, and report the pains relieved and the tumors made to shrink and disappear.

Dr. C. M. Fenn of California, reports the injection of saturated solution of citric acid. He says it brings "instant relief" and some cures.

This whole investigation is yet in a crude and unfinished state, but it will go on to more definite results. If some injection can be found which, while curing the primary tumor, will have such a controlling power over the inaccessible secondary ones, as is claimed for the chelidonium, it will be of immense value. If this power over the infected glands is not finally proven, it will still be of great importance in many individual cases to atrophy the primary tumor and to relieve the distressing pains.

3912 Lake Avenue.

SURGICAL SHOCK.

Read before the Chicago Academy of Medicine April 9, 1897.

BY FENTON B. TURCK, M.D.
CHICAGO.

The experiments on animals for inducing shock were reported before the AMERICAN MEDICAL ASSOCIATION, May, 1896. In these experiments the color changes in the abdominal viscera were noted, the blood pressure in both arteries and veins in the peripheral circulation as well as the central. I will give a brief r sum  of some of these experiments.

Experiment No. 1 showed that after exposure of the stomach and intestines to draught of air from an open window, temperature 58, profound shock resulted. The gastric veins within half an hour were all congested. Respiration shallow; pulsations weak. The chloroform was pushed to the extreme; animals stopped breathing. Withdrawal of chloroform and artificial respiration did not excite respiratory movements. The intragastric resuscitator¹ was introduced into the stomach, and hot water 130 F. As soon as the water returned from the other side of the double tube, and more hot water introduced the animal began to breathe. In twenty minutes there was a remarkable change in the color of the stomach. Instead of the blue dull color it became a bright red. In forty minutes the surface of the body became warm. The mouth showed a bright red color, in place of the pale

livid hue. Pulsation became strong, showing increased arterial tension and the respirations became deep and uniform. This was repeated during the same period, and the second time the same phenomena were again presented. When the restoration of the circulation seemed assured, the abdominal wound was closed, leaving a permanent gastric fistula. The animal recovered and was exhibited in my lectures given at Jefferson Medical College, Philadelphia, February, 1896.

Experiment No. 2 was of a similar character. The pressure in the veins and the arteries was studied with a manometer to indicate the changes in blood pressure. During shock the veins and the viscera show increased pressure while the arteries a decrease. After the introduction of the intragastric resuscitator this condition is reversed.

Experiments 3 and 4 similar to 1 and 2.

Experiment 5 was a study of changes that occur by the observation of color of the viscera. The shades from the normal to profound shock, showing eight different stages; also standard changes of shades observed after the introduction of the intragastric resuscitator. Referring to the chart, No. 1 is the normal, No. 2 the first changes observed after shock, No. 3 and so forth up to 8. It is found that within three minutes after exposure shade No. 2 was observed, in eight minutes No. 3; ten minutes No. 4; fifteen minutes No. 5; half an hour No. 6. It required an hour and a half for No. 8 to appear. There was a marked difference in the shades of the intestine and the stomach; when the stomach showed shade No. 5 the intestines appeared shade No. 6 (after the introduction of the intragastric resuscitator). After thirty minutes the shade in the stomach showed No. 4, intestines showed No. 5. In forty-five minutes all the larger veins were apparently empty. In one hour the stomach showed shade No. 3, while intestines remained shade No. 4. (Exhibition of color chart.)

SHOCK BY THE INTRODUCTION OF TOXINS.

Experiment No. 5. Method. Stomach contents drawn off, from a patient suffering with dilatation of the stomach. One hundred cu. cm. injected into a dog weighing 15 kg. This is repeated in one hour. Evidence of shock observed. In one hour the surface was cold, the mouth and gums pale, and on opening the abdomen a deep injection of all the viscera was apparent. The animal was in shock. Introduction of the intragastric resuscitator, reduction of the shock is produced. The animal recovered. While a control under the circumstances carried out on a dog weighing 16½ kg. the animal died.

Experiment No. 7. Shock produced by operation on abdominal viscera. Long incision from xiphoid appendix to symphysis pubis. Operation for gastrostomy (Turck's valve operation). Operation for the Heincke-Mukilitz pyloroplasty. Also Martell's operation for gastro-enterostomy. Within one hour the entire stomach and intestines showed a bluish color with all the veins congested. Respiration shallow; pulse 130; evidence of collapse. Hot water bag placed inside the stomach. Temperature of 125 raised to 135, in a moment there was a change in both the pulse and respiration, the high heat having an instantaneous reflex action. The color changes within two minutes. In fifteen minutes the veins grew smaller in size and the surface appeared more of a rosy color. Respirations not so shallow, pulse strong, show-

¹ For description of the instrument see Journal, Jan. 11, 1896, p. 79.

ing increased tension. Twenty minutes intestines began to change in color similar to the effect observed in the circulation of the stomach. The general effect was pronounced upon all the mesenteric vessels. Thirty minutes the congestion was reduced and arterial circulation restored. Water introduced had to be changed every five minutes and absorption of heat was very great. Water introduced at 125 and 130 returned at 110 and 105. The viscera was exposed for three hours. The animal made a good recovery.

Experiment No. 9. To determine the rapidity with which color changes take place in the abdominal viscera. Exposed to the cold draught No. 1 on opening the abdomen. Color No. 2 in five minutes; No. 3 in ten minutes; 4 in fifteen minutes; 5 in thirty minutes; 6 in forty-five minutes. Hot water bag introduced in ten minutes from the time shade No. 2 was evident. In other areas No. 3 shade was observed.

Experiment No. 10, April 7, 1896; assisted by Captain Appell, Assistant Surgeon U. S. A. The animal was placed on a hot water bed. The abdomen was opened to a draught of air; operation was made for valvular gastrotomy. In forty-five minutes profound congestion of abdominal viscera was apparent; congestion of all the viscera, gastric vessels, gastric epiploica, and senestra, and gradually became filled and the tortuous veins stood out in dark relief upon the livid background. The stomach, though congested, was cold to the touch and intestines likewise. All evidence of shock was present. Reflexes absent though the animal was not under the influence of chloroform at this time, or ether. Shallow and rapid breathing. Rapid weak pulse, surface of the body cold, gums and tongue pale; collapse was imminent. The intragastric resuscitator was introduced and water of 130 degrees. In three minutes the water was withdrawn at 110 degrees F. The effect of the hot water was instantaneous. A continuous stream was allowed to play through for ten minutes; breathing and pulse improved at once and the circulatory changes were manifest, probably due to the stimulation of the solar plexus, cardiac plexus. The veins diminished in size right under the eye, the red bluish shade taking place instead of the sluggish blue. In twenty minutes the animal breathed steadily, pulse "came up," and arterial tension was increased. The body grew warm; tongue and gums showed a natural color. It was evident to all present that the animal was out of shock in half an hour.

REPORT OF CASES AND METHOD OF TREATMENT.

The following cases are selected from a large number to illustrate the symptoms and physical condition found in shock, also the effects of the treatment by the intragastric resuscitator.

Case 1 was that of a woman 40 years of age, suffering from impaction in which she was found in an unconscious condition, surface of the body cold, pale, lips bluish. The intragastric resuscitator was immediately introduced into the stomach. Within fifteen minutes reaction was complete, consciousness was restored and in thirty minutes the surface of the body, hands and feet were warm and the patient out of shock. Following this the usual treatment was inaugurated to reduce the impaction of the bowel.

Case 2.—Mrs. K., age 36, was found in shock, resulting from acute gastro-enteritis. There was a cold sweat upon the surface, a feeling of impending

death and anesthesia of the surface, pale and livid. The intragastric resuscitator was introduced into the stomach; within ten minutes the pulse became fuller, stronger and less rapid. The color began to change in the lips from a bluish to a reddish. Within half an hour the surface became rosy in color, hands and feet warm, and instead of the heat increasing perspiration, skin became more dry while under shock.

Case 3, operation on a case of carcinoma of the pylorus. The operation was a gastro-enterotomy. Murphy button anastomosis. On opening the abdomen on exposure to the air a red shade of the stomach was observed, and after manipulation of the viscera there were great adhesions, shade No. 3 was observed. In thirty minutes shade No. 4 was observed. At the same time breathing became very laborious, pulse diminished, the lips became pale and there were other evidences of shock. The intragastric resuscitator was introduced into the stomach and the immediate effects could be observed under the eye. The change of the color of the viscera was apparent; with the reduction of the venous congestion, surface grew warm, the perspiration which stood out like beads upon the forehead, disappeared. All signs showed the reduction of shock within fifteen minutes.

Case 4.—A young football player in Lincoln Park was struck in the epigastrium. At the same time sustained a Colle's fracture. Was brought into the office insensible and after a moment recovered, calling for water; his eyes were leaden; slow respiration; surface cold; great anxiety. I introduced the intragastric resuscitator and the effect was immediate. The breathing became even, the pulse that was weak became strong, fuller, the color returned to the surface; the eyes bright. The effect of this was very evidently due to the use of the intragastric resuscitator.

Case 5.—Mrs. McG., age 45, case hemorrhage from the bowels; estimated loss of blood was over one quart. All the signs of shock were present including anesthesia, disturbance of vision, thirst, cold surface, lips blue, anxious expression; patient experiences the feeling of impending death. The intragastric resuscitator was introduced into the stomach and within twenty minutes the symptoms disappeared with the exception that the hands and feet were still cold, but within forty-five minutes the hands and feet also were warm. No other treatment for the reduction of shock was used. This was again repeated the next day and the patient felt so well after treatment that she requested a daily treatment, which was instituted for one week. Recovery complete.

Case 6.—Mrs. F., Presbyterian Hospital, called by Dr. Etheridge; been in shock two days and a half. The patient was moribund, mottled blue surface, could not speak, and impending death was apparent. The intragastric resuscitator was introduced in the usual manner and temperature at 130; observations made by the attending and house physician as well as myself. It was observed that the stimulation was immediate. The pulse that was before imperceptible could now be felt. Breathing improved and patient could speak. The physicians and attendants thought that there might be some hope for her recovery, but as the patient was already moribund, the blood having passed largely into the veins, and extravasation had occurred and the whole surface was mottled. When in this condition it seemed that nothing could restore her. The improvement in this case kept up for three

hours, when the patient gradually sank and died. It was instructive in this case, however, to observe in the extreme the profound effect that the hot water had upon the nervous centers and upon the circulation, including respiration and return of intelligence.

The seventh, eighth and ninth cases were cases of laparotomy upon the pelvic viscera. Shock was imminent in each case and in Case 9 the shock occurred also the following day, when the intragastric resuscitator was introduced again with the usual prompt results.

The last case that I report here tonight is one for an exploratory incision in which was found large adhesions, due to a pancreatitis, parapancreatitis hemorrhagica. The case was operated upon by Dr. Ferguson. The patient was found in shock; face was blue, especially marked about the lips; breathing became very labored, large beads of perspiration were found all over the face and was regarded as a case of shock. The intragastric resuscitator was introduced into the stomach and immediately the effect was manifest to all present. Within five minutes the color had changed from the bluish to the rosy tint. The perspiration disappeared from the face, breathing was again deep and regular, pulse restored. It was evident that the respiration of this condition was brought about promptly by the use of the intragastric resuscitator.

DISCUSSION.

Dr. JAMES G. KIERNAN—I can hardly agree with Dr. Turck that stimulation of the ano-genital center is comparable with that of the gastric centers. It has been shown by experiments on conditions of collapse resulting after anesthesia, and also on the conditions of coma resultant on opium poisoning, that the ano-genital center is one of the last centers in the body whose reflex action is destroyed, and is the quickest to react to excitants in the restoration of consciousness. For example, sixteen years ago I was called to a case of opium poisoning. The patient, a prohibition Congressman, went on a tremendous spree, as a consequence of which he had incipient symptoms of delirium tremens, and sent out for laudanum and took an ounce of it. All the usual methods to counteract poisoning from opium were employed without avail. The case was turned over to me with the benevolent intention of having me sign the death certificate, inasmuch as he had passed into the condition of opium collapse. I poured three drams of tincture of capsicum up his rectum. I have never seen anything act as quickly as that did. Since that case a large number of others have been reported independently, and my observations have confirmed with regard to the quickness with which this center reacts. Not only that, but a large number of observers have pointed out that this center is the quicker to be excited in failures after anesthesia than almost any other. This has been demonstrably the case with Dr. R. A. Murray in New York and a number of others who have followed his researches. I do not doubt, from the surrounding innervation of the stomach, but what Dr. Turck would get undeniably rapid and beneficial effects from this procedure. At the same time, I doubt very much whether if the shock had passed beyond a certain point, he would get quite as rapid and efficacious results from this procedure as from a similar one applied to the rectum.

Dr. WILLIAM L. BAUM—I have had no experience with the apparatus of Dr. Turck, but I have been making some experiments during the last few months at the Cook County Hospital on cases of erysipelas. In a number of cases in which there was present nephritis with scanty urine, where the patients were in a condition practically of uremic coma, with slow and labored respiration and very irregular pulse, particularly in old individuals, for want of any other therapeutic measure I could think of at the time, advised in one case hot injections of normal salt solution of the strength of six-tenths of 1 per cent., using a quart every two hours. This was kept up night and day for eight days, the patient receiving the injections every two hours. He passed not only large quantities of urine, but the casts diminished rapidly in number, and the patient was discharged as cured. Since that time I have had four other cases in which I have resorted to similar treatment, all of which have recovered and have been discharged as cured.

Another case in which hot water injections have been very efficacious was one that I was called to see in connection with Dr. Fütterer. It was a case of vesical hemorrhage. The hemorrhage was continuous for some forty-eight hours; there was also present hydronephrosis. The patient had at some time ulcerative endocarditis with marked symptoms of recent endocarditis. He was given hot rectal injections of the normal salt solution, as well as subcutaneous injections of one quart of normal salt solution on each side of the abdomen. In this case, as in the other cases, within almost half an hour the respiration became more regular, and the pulse also became more regular, full and strong. Whether in the latter case the marked improvement was due to the hot solution injected subcutaneously, I am not at present prepared to say. We have benefit from large quantities of hot water taken up by the mesenteric glands and the intestines, and we have rapid elimination through the kidneys. In the erysipelas cases the heat may have had a marked beneficial effect, because the change took place in an extremely short period of time.

Dr. D. W. ROGERS—I was very much interested in the remarks of Drs. Kiernan and Turck with regard to surgical shock, and consider the method of Dr. Turck especially commendable. The heat supplied by the hot water which is poured into the stomach is rapidly taken up by the tissues. In addition there is a nervous stimulus, but the heat which the body must have in order to carry on its functions is supplied by this hot water, for this simple nervous stimulus would in my opinion not be sufficient to resuscitate a case suffering from severe surgical shock.

Dr. W. X. SUDBUTH—The remarks of the last speaker bring up the point as to the causes of temperature. The old idea that temperature is entirely the result of chemic changes in the body has to be modified to a considerable extent according to recent observations. You may take an iron bar and pound it to a red heat without any chemic change taking place. It is then a matter of vibration, and so we find in the body that vibration is the principal cause of the development and maintenance of temperature in the body, and that temperature is to a very great extent, to be controlled through mental processes. We have unquestionably much that is to be commended in the method of Dr. Turck by raising bodily temperature by the immediate contact of the hot water, which may be accounted for on the same ground, because we know vibration is much higher in hot than it is in cold water. Whether this vibration is carried and taken up by the body directly, as Dr. Turck has mentioned, in the passage of the blood through the different portions of the body and marking its course, or whether it is simply through association, raising the temperature in that way, is an open question. Undoubtedly, we have a nervous stimulation which is more effectual in the raising of the temperature and the resuscitation of the patient than we have in its mechanical effect. We have, then, the temperature raised by reason of the increased rate of nervous vibration, and the strength or the ability to maintain that vibration is the result of the increased temperature which is induced by the hot water.

The old theory of oxidization being the principal cause of temperature is pretty generally accepted, but I think we have evident reason for attributing many of the changes in temperature to mental processes. Let us take fevers, for instance, where we have a temperature of 104 degrees, by purely passifying methods, by suggestion, the temperature can be dropped from 3 to 4 in from fifteen to twenty minutes without the use of any drug or the induction of any chemic change, that we know of, in the body. Even so where we have a subnormal temperature, by working on the emotions, we can raise the bodily temperature a number of degrees in a few moments. While suggestion is not an important part in the treatment used by Dr. Turck, yet we can not eliminate it from any process on the living human body, even where the patient is apparently unconscious. The facts are there is no such thing as unconsciousness short of death. I have proved that, in my experiments in the administration of anesthetics, I was able to get a response from patients under the most profound anesthesia, simply by keeping in touch with them when they were going into the anesthetic state. So Dr. Turck's remarks and conduct with the patient must have a direct effect in the resuscitation.

Dr. JAMES G. KIERNAN—I do not want unduly to swell the neurologic trend of the discussion at the present time, yet I can not but take issue with the position that local tissue change irrespective of nerve action underlies the results, as Dr. Turck has claimed. This seems to be turning back the page of pathology to the days of Broussais when such a doctrine led to an abuse of venesection because fever was regarded as a result of such local change. Fever, as the researches of

Ott of Pennsylvania, have shown, is primarily set up by an increase of heat production beyond that of heat dissipation. An agent from within or from without deranges the harmony of the thermotaxic, thermogenetic and thermolytic apparatus by which in the initial stage the metabolism of the tissues are usually increased temporarily, this increment being greater than that generated upon the restricted amount of nutriment. Once established, the fever continues not from excessive production but from an altered relation between heat production and heat dissipation. Fever is not a fire kept up by an excessive oxidation of the constituents of the economy. Thus heat production may really be subnormal, yet the bodily temperature may be at high fever heat. The thermotaxic centers of the brain maintain the balance between heat production and heat dissipation so as to keep the temperature at 98.4 degrees F. In fever these thermotaxic centers are disordered; it is mainly the basal thermotaxic which are so affected that disturbance of the relation between heat production and heat dissipation produces a higher temperature. Since the peripheral terminations of the sensory nerves influence a thermolytic center by reflex action they constitute important factors in heat regulations. It seems to me, therefore, from the description given by Dr. Turck, that the comparative rapidity with which this treatment acts would imply such a reflex action on certain vaso-motor centers and on certain heat-regulating centers, because the condition of surgical shock is essentially one of extreme heat inhibition. To reverse that condition excitation would be physiologically indicated along the line stated by Dr. Turck. He could thus excite a large number of centers quickly through the stomach. It would seem that a reverse physiologic process would be desirable, and if there be need to stimulate the thermo-excitatory centers, it can be done better by a method of this kind than by a procedure implying merely local thermic excitation, which is very slow. As to the ultimate origin of this stimulation, in all probability, like all nerve force, it is allied to vibration. But be that as it may, to refer it simply to a local chemic action would be going a long way to accomplish a small result. Furthermore, transmission of heat must be more or less through the nervous system, and not direct.

Dr. WILLIAM A. PUSEY—In the interest of orthodox physiology and physics, I would ask Dr. Sudduth and Dr. Kiernan if they mean to maintain that the heat of the body is not the result of metabolic changes of exactly the same character as those that produce by oxidation the heat in an ordinary fire? I may have misunderstood Dr. Sudduth, but my understanding of his remarks was that the nervous system not only regulated heat, but was of great importance in the production of it; that the production of heat in the body was not, at all time, simply a question of the transformation of physical energy. Am I right?

Dr. SUDDUTH—You are correct.

Dr. PUSEY—The position is so contrary to the accepted doctrines of physics that it seems to me it should not be allowed to pass unnoticed. I accept all that Dr. Sudduth and Dr. Kiernan say with regard to the influence of the nervous system in regulating temperature and know that we may have all sorts of aberration of temperature when the heat center is interfered with. I accept the statement that the heat of the body is merely a form of energy—that is the point I am maintaining—but to assume that the nervous system can produce heat without a material foundation for it, can evolve *de novo* and from nothing material, is a position that it seems to me should not be allowed to pass unchallenged in this Academy.

Dr. KIERNAN—I would ask Dr. Pusey, without attacking his position, whether he believes in such a doctrine as correlation and conservation of energy.

Dr. PUSEY—I certainly do. It is because the positions enunciated are in conflict with this universally accepted law of the conservation of energy, that I take exception to them. I will gladly agree with the proposition that the nervous system is the thermostat, but that it is anything more than a very significant part of the human furnace is a proposition which is so contrary to the accepted laws of physics and physiology that with the shades of Michael Foster staring me in the face I can but protest against it.

Dr. D. W. ROGERS—Exactly what Dr. Pusey has said is something that came into my mind. No one will deny from the experiments that have been made during the last twenty-five or fifty years, that heat is a form of vibration, and that by pounding a piece of iron we can get it red hot. As Dr. Pusey has said, the heat generated in our body comes from the food which we take into it. The idea of calling the nervous system a thermostat is an excellent one. We might consider the body an automatic furnace, regulated and controlled by electric devices. Regarding the experiments of Dr. Turck, the hot

water which he pours into the stomach supplies the place of heat made in a normal condition of the body by the chemic processes controlled by the nervous system, and this heat is not taken up by the body simply through an increased stimulus to the nervous system, but by the transmission of vibrations from the hot water to the tissues of the body itself. Mental processes, it is true, have much to do with the production of heat, inasmuch as these processes control the nervous system, control the impulses going to various parts of the body, and if a heat inhibitory center is excited (we are supposing, for instance, we have a heat inhibitory center) the metabolic processes in various parts of the body would be checked, and the heat would be lessened.

Dr. WILLIAM L. BALLENGER—I have seen neurasthenic cases with cold skin, feet and hands, and I have seen them come out of this condition of shock or collapse by simply following deep breathing exercises for a few minutes. Undoubtedly others have seen the same thing. I narrate the above as suggestive. It is one of the ways in which the temperature of the body may be regulated. Dr. Turck's experiments upon animals are very instructive, showing the physical changes which take place in the blood in conditions of shock, and the changes which occur under the influence of heat applied to the stomach. His work is deserving of praise and commendation.

Dr. TURCK (closing the discussion)—I have presented these experiments and clinical observations just as they appeared, and it is impossible at present to explain the phenomena completely. But there are facts here that can not be disputed. First, the congestion of the abdominal viscera in shock, and this congestion is apparently commensurate with the loss of temperature and also with the lack of tone of the nervous system. To completely analyze these phenomena would require more knowledge than we have at the present time; but the facts are stubborn, that we can not apparently experimentally produce a profound shock without the occurrence of congestion and that the reduction of such shock does not occur until we reduce the congestion and distribute blood over the surface. The blood that is being distributed over the surface is warm blood. Energy is transmitted and as this energy is carried on we see the effect upon the arterioles. I could not recite all the experiments here, because I have previously published some and others are to follow. Let us take the simple introduction of water into the colon; we often produce a condition of congestion rather than of reduction. The patient feels the shock of such a procedure. He is momentarily stimulated, but soon relaxes into a state of congestion, the hands and feet become cold, and the patient will feel weak. Whereas, if we use water of high temperature the reverse condition is produced. We have a vasomotor stimulation. Inasmuch as water at a high temperature, introduced directly into the viscera is contraindicated, we use this method of introducing it through a tube, and if I may use another term, the absorption of that heat is constant. I have presented these facts as possibly opening up further investigation in determining the exact cause of the phenomena of shock and also the *rationale* of the reduction of shock.

INTESTINAL ANASTOMOSIS.

Read before the Illinois State Medical Society, May, 1897.

BY JACOB FRANK, M.D.

SURGEON TO THE ST. ELIZABETH AND GERMAN HOSPITALS,
CHICAGO, ILL.

The subject which I am about to touch upon is an ever interesting one. I would like to relate the early history of our instructors in surgery, in the line of intestinal anastomosis, but were I to attempt such a task I would be called a monopolist of time. Suffice it for me to state, that they, even 150 years ago, realized the necessity of some speedy and safe method for dealing with this most important branch of surgery. They were evidently not satisfied with the suture method, as is manifest by their numerous attempts to call unto their aid mechanical means, such as steel rings, rawhide, turnips, bone, catgut, rings, gelatin, etc. Denan, in an article in "Receuil de la Société Royale de Médecine de Marseille," l'an 1826, described his device for intestinal anastomosis, consisting of steel rings connected with a spring, and laid stress upon the pressure necrosis to be obtained from

the spring. To accuse our predecessors of futility of effort, even though their labors seemed apparently in vain, would be doing them a great injustice, for had we not the results of their trials we would probably travel over the same course, and, after all, our present and most modern contrivances are simply improved and newly evolved measures.

Permit me to carry you into a more modern era, a period of time which is fresh in the mind of every surgeon, *i. e.*, 1888, when Senn, with his decalcified bone plates, opened the path for the exit of the Czerny-Lembert suture. The plates, although used quite generally for a time, were not deemed applicable in all cases, and served the purpose of stimulating us to further improvements.

In 1892, Murphy surprised the surgical world with his metallic button, which reduced the length of time required to perform an intestinal anastomosis to about thirty minutes. I believe I will be upheld by all present in the statement which I am about to make, and that is, were Murphy's button soluble we could wish for nothing better. But since it is not it will always create a certain degree of fear in the minds of surgeons who are about to introduce the same, this said fear being substantiated by the reports which come in every now and then, of an obstruction following its use; less often, an ulceration through the bowel into the peritoneal cavity. That contrivance which will answer all the essential purposes of the button and which has added to it the great advantage of at least partial solubility, will sooner or later displace it. I beg to quote from Dr. Murphy's article his claims for this contrivance. They are:

- 1, Time, reducing the duration of the operation to at least half its former length;
- 2, extreme simplicity of technique;
- 3, automatic retention of position;
- 4, entire independence of sutures;
- 5, it produces a pressure necrosis and adhesion of surfaces at the line of necrosis;
- 6, it insures perfect apposition and therefore obviates the danger of displacement;
- 7, its applicability to the lateral as well as to the end-to-end approximation;
- 8, it produces a linear cicatrix, thereby insuring a minimum of contraction;
- 9, edge-to-edge union of same intestinal coats.

I claim for my contrivance all the above good qualities, with but one exception and a few additions. The first difference is, that while the claim, "entire independence of sutures" could be maintained, it is not, as it has been strongly impressed upon me during my series of experiments, that a few Lemberts never do any harm, and the good that follows their use more than compensates for the two or three minutes required to insert them. Besides, I have on several occasions found it necessary to use a few Lembert sutures with Murphy's button. I also claim for my contrivance, lightness, which is of great importance, as the intestines can float it, and this obviates a possible bend or spur, and last but not least, is the partial solubility of the apparatus, leaving but a small piece of soft rubber tubing (the rubber tube can be split in two longitudinally if required) to pass away, which is not apt to cause obstruction nor ulcerate through the bowel.

Since the last publication on this subject I have had the pleasure of receiving the good news of a successful gastro-enterostomy with the aid of the decalcified coupler, performed March 16, 1897, by Dr. McCandless of St. Louis. The rubber tube passed

on the thirteenth day. The patient left the hospital on the twenty-fourth day after the operation.

I wish also to add a successful case of end-to-end anastomosis, with the coupler, for strangulated hernia, eight inches of gangrenous bowel being resected. The operation was performed by Dr. Kramps April 13, 1897, at St. Elizabeth's Hospital, in the presence of Drs. Hall, Wallace and Leland. The rubber passed after forty-eight hours and the lady, who is 49 years of age, is well and attending to her household duties.

FIG. 1.—Decalcified bone collar. A, inside view; B, outside view; natural experimental size.

Up to three months ago the contrivance had not, to my knowledge, been used upon the human subject. It is more gratifying to me to have others attain good results with the coupler than were I to obtain them myself. I have been called upon to operate for strangulated hernia seven times in the past eleven weeks, but was unfortunate in always getting at the operation before strangulation had gone on sufficiently to demand resection of the bowel, and as all the cases made an uneventful recovery I have nothing to regret.

FIG. 2.—Bone collar sewed to rubber tubing.

FIG. 3.—Inside view of collar with rubber tubing sewed on.

The apparatus consists of two decalcified bone collars (Fig. 1) with six needle hole perforations at the apex or shoulder of each collar, and one piece of ordinary pure gum rubber tubing, seven-eighths of an inch in length and five-sixteenths of an inch in diameter, the kind used for drainage. It is prepared for use in the following manner: A collar is slipped over a piece of rubber tubing of the dimensions stated, until the apex is brought to a level with the end of the rubber tubing, when an ordinary medium-sized curved needle, threaded with No. 8 braided silk, is carried through each opening and tied; this, as can readily be seen fastens the collar to the tube; the other collar is next fitted snugly to the one already

FIG. 4.—Decalcified bone collars sewed to rubber tubing ready for use.

fastened, and is then in like manner sewed to the other end of the tube and placed in absolute alcohol until they are to be used. The rubber tubing to which the collars have been sewed, being hollow, serves subsequently for the passage of the intestinal contents after being placed *in situ*. (Fig. 4.)

It will be observed that the bases of the collars, which are formed into a broadened rim, are being held firmly in apposition throughout their entire circumference. Now the intestinal ends are brought over each collar and crowded within the line of junction

of the two; of necessity the latter are forced apart, and the rubber tube is put upon the stretch, thus affording pressure of adequate amount to cause a necrosis of interposed intestines. The collars dissolve in due course of time, but a small piece of rubber tubing is left in the intestinal canal to pass off with the feces (Fig. 10).

FIG. 5.—Longitudinal section. AA, collar; BB, rubber tubing, 10 mm. in diameter; C, cavity in collar; 7 MM, inside diameter of rubber tubing; 20 MM, length and width of collar.

The collars are carved out of sound, very compact bone, which is obtained from the lower hind legs of 4-year-old oxen. The collars are now subjected to the decalcifying fluid, which consists of a 10 per cent. solution of absolute hydrochloric acid, and are removed from this fluid in six hours and placed under a stream of cold water for half an hour to remove the salts which have formed. They are then placed in a fresh decalcifying fluid of the same strength, and the process is repeated until they are completely deprived of their calcareous constituents, when they are washed with cold distilled water, so that all traces of acids and phosphates are removed and the collars have acquired an almost transparent appearance. Then they are practically dehydrated by treatment with pure cologne spirits, and finally, immersed in absolute alcohol, which renders them sufficiently tenacious for their purpose.

Having described the apparatus, its mode of preparation and construction, the experimental work upon dogs is next to be explained. As nearly as possible the same aseptic and antiseptic precautions were

FIG. 6.—Murphy's running thread.

observed with regard to the hands, instruments, field of operation and dressings as modern surgery teaches us to observe in a laparotomy upon the human subject. The dogs that were fed upon fluids prior to the operation gave less trouble at the time and thereafter than dogs otherwise fed. A dose of castor oil given the evening before the operation always

cleanses the intestinal tract, and the dogs seem to do better after this.

The general technique.—A median incision from three to four inches in length is made either above or below the umbilicus, the small intestine is drawn out through the wound and the part to be excised is gently freed of its contents by drawing it between the

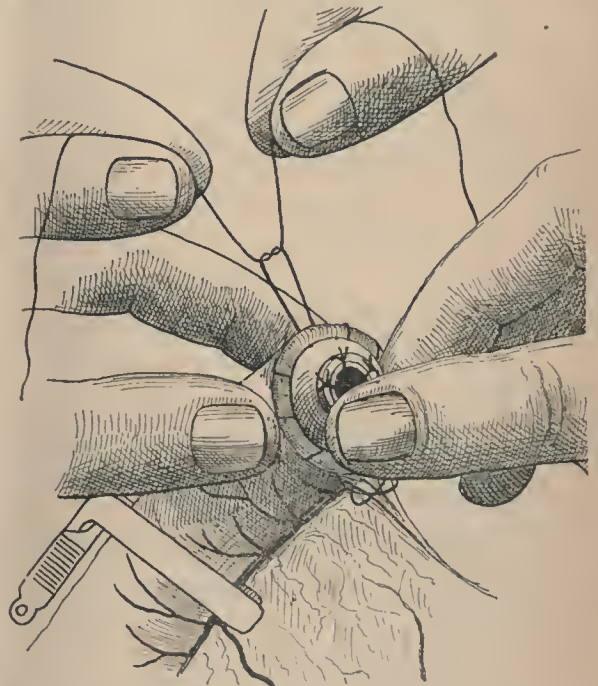

FIG. 7.—Manner of introducing collars.

thumb and index finger, when an intestinal clamp is placed at each end of the portion to be cut away, care being taken not to cut too close to the clasp, for if this is done there will not be enough gut to bring over the collars, which will necessitate the removal of the clamp farther back. The main mesenteric branch supplying the excised portion is first ligated with a No. 9 silk. From two to five inches of gut may be resected, according to the fancy of the operator.

Upon severing the intestine, it will be observed that

FIG. 8.—Showing collar in place in one end, the running suture in the other.

there is an eversion of the edge of the bowel, and also a contraction, producing a circular constriction at the end of the intestine; this can be easily overcome by inserting a finger into the lumen of the gut and retaining it there for a minute or two, thus producing temporary paralysis, and allowing a much easier manipulation of the parts; this stretching of the gut must

be gently performed, otherwise the peritoneal covering will split longitudinally. The everted mucosa should be curetted away for the following reasons: 1. I have satisfied myself that it plays no part in the healing process. 2. The running thread of Murphy (Fig. 6) is more easily applied, and the danger of merely taking up the mucosa and not the other coats is done away with. 3. It permits of nicer coaptation, as, without curetting, the mucosa pops out between the couplers as a pulpy mass. A straight or curved needle threaded with No. 6 silk is used for inserting the puckering string (a description of which can be found in the *New York Medical Record*, Vol. xlii, p. 673, 1892) to fasten the intestine about the rubber tube after the

FIG. 9.—Anastomosis completed, showing Lemberg suture.

former has slipped over the collars. The puckering string is similarly inserted into the other intestinal end, and the coupler, having been previously prepared as described, is taken out of the absolute alcohol in which it was placed. The operator slips an intestinal end over one of the collars, to the line of junction, at the same time gently spreading the collars apart to facilitate the easy access of the gut. An assistant takes charge of the ends of the puckering string, and when the gut has been brought over the collar he makes one knot, and draws down until his puckering ligature strikes the rubber tubing, which he will perceive by the resistance offered; the tube

FIG. 10.—Rubber tubing showing puckering thread in center and sutures at ends after bone collars had dissolved. Experiment No. 4.

will not generally permit a too tight drawing of the puckering ligature on account of its resiliency, but to make absolutely sure that the tube is patulous, the end of a forceps or sterilized nail may be passed through the lumen; if this is found pervious the assistant finishes the tying of the puckering string. The other intestinal end is then slipped over the other collar and also tied. Of course, at this stage nothing can be inserted by which to determine that the tube is not shut off, but, after having tied one side, the assistant will know positively when he strikes the tube. The ligature is cut off short and the clamps are immediately removed, when the operated portion of the

bowel will be slowly distended with gas. An interrupted or continuous Lemberg suture should be taken around the border, with an intestinal needle threaded with a No. 2 silk, to make the work more secure. (Fig. 9).

The rent in the mesentery may or may not be sewed. In those cases that were sewed, catgut was used; any bleeding vessels should be tied with catgut. The intestine is returned into the abdominal cavity as nearly as possible in a straight line, the site covered with omentum, and the abdominal wound closed in the ordinary manner. The wound is powdered with iodoform and a collodion dressing applied; gauze and cotton are placed over this, and then the bandage.

In the *Journal of Medicine*, January, 1897, will be found a detailed report of the experimental work. 17 Lincoln Avenue.

THE CAUSES OF DEATH IN ABDOMINAL SURGERY AND THEIR TREATMENT.

BY J. WESLEY BOVÉE, M.D.

PROFESSOR CLINICAL GYNECOLOGY COLUMBIAN UNIVERSITY, GYNECOLOGIST TO COLUMBIA AND PROVIDENCE HOSPITALS AND VISITING SURGEON TO WASHINGTON ASYLUM HOSPITAL. WASHINGTON, D.C.

Great advances have been made in abdominal surgery during the past two decades and the mortality rate has been very materially reduced. As a fair illustration of this progress hysterectomy might be mentioned and may be said to have changed from an unjustifiable operation with a mortality rate varying from 80 to 90 per cent., to one of the most common of abdominal operations having a fatality of about 5 per cent. It is not necessary to state that this wonderful change is the result of the peculiar special attention devoted to this line of work. But contentment should not exist with a death rate following operation in this region, slightly less than that of unoperated cases. So far as it is directly due to surgical operations we should endeavor to reduce it to zero, and not until then will we be able to rest contented. The complete abolition of the mortality rate of abdominal operations will probably be encumbered with more difficulty than besets the arctic explorer in his attempts to reach the north pole.

We can hope to approach perfect results only by carefully studying causes of death in the individual cases and striving to apply the knowledge thus acquired.

Many deaths may be directly attributed to lack of skill on the part of the operator and assistants and it is to be hoped that with the constantly increasing advantages at the command of the younger element of the profession, together with the decided tendency of the age to specialism, that untrained, pragmatic operators, if they exist, will not invade the domain of abdominal surgery. But the most experienced and skilful have a considerable death rate, very low, it is true, but higher than they themselves desire; yet it is from this class of workers we must expect the methods for still greater success. Of course a small percentage of deaths after these operations has been due to intercurrent diseases, but it can not be denied that some of these sufferers yielded to the disease more readily or perhaps directly because of the operation. There is little doubt that ether will cause pneumonia when administered for surgical purposes and I have seen cases of phthisis that closely followed abdominal or pelvic disease and operation. This I

have noticed in a number of cases of hysterectomy for uterine fibroids and in cases where there was considerable shock, hemorrhage, sepsis or other complication, that for a time severely taxed the recuperative power of the patient. Whether there was any relation between the disease for which the operation was done and the subsequent lung involvement can not now be stated. I am inclined to blame the operation rather than the disease for the appearance of the tubercular infection, but as yet we are not warranted in absolutely tracing this cause and effect.

Whenever possible, and usually it is, a careful study of the condition of patients before subjecting them to such an ordeal as an abdominal operation, is imperative.

Systematic autopsies on fatal cases will furnish valuable information for future use. In this way we can find why we failed to save our patient and thus be fore-armed for another case nearly similar. We have had occasion to note this in cases of chronic suppurations of the adnexa and of the vermiform appendix. Occasionally we will find an extra collection of pus behind the liver or even over by the spleen in appendicitis and oftentimes collections of pus exist in the liver and kidney in puerperal sepsis.

The causes of death from these operations may be conveniently divided into five classes, viz.: 1, operation and complications; 2, bad condition of the patient before operation; 3, intercurrent diseases; 4, bad after-treatment, and 5, accidents.

Many operations are done at a time when death seems imminent from sudden severe hemorrhage, as in ruptured ectopic pregnancy or severe gun-shot wounds of the abdomen, or from bowel obstruction or pressure from large tumors, or even, from prolonged suppuration or acute sepsis. Many different injuries may demand immediate section and these cases will necessarily increase the mortality rate of laparotomies. In these cases very little time is at the disposal of the operator for investigation of the condition of the patient before operation, other than a very superficial one that determines his decision to operate without loss of time, and usually during it haste is one of the most important features of his work.

Many times the abdominal condition is not the only one threatening life and in many cases the risk from anesthesia is greater than from the presence of an abdominal tumor. Oftentimes, too, uranalysis may reveal the presence of kidney suppuration at the same time as pyosalpinx or other form of pelvic or abdominal suppuration. Again a large abdominal tumor may have caused prolonged and strong pressure on the lungs, heart, abdominal blood vessels and other portions of the body and have caused a considerable relaxation or atonicity of those structures. If this be the condition and the tumor removed, then there exists great danger of engorgement of the veins thus relieved from pressure and of resulting death from heart exhaustion. We have previously referred to this more in detail in a paper published in *The Virginia Medical Monthly*, 1892, xix, 101.

Concerning the operation nearly everything devolves upon the operator, and the manner in which he performs the operation will usually govern the result. The principal complications of intra-peritoneal operations are shock, severe hemorrhage and sepsis. It is usually one of these three that causes the fatal issue in the unsuccessful cases and its work is generally not long delayed. Death from shock usually occurs some time within the first 72 hours.

Severe primary hemorrhage may prove fatal during the operation or within a few hours afterward and secondary loss of blood may occur at any time during the convalescence and be sufficiently severe to cause death. Fatal cases of secondary hemorrhage as late as from twenty to forty days after operation have been reported. Sepsis resulting from infection during operation may prove fatal after the first day or may be introduced in wound dressings some days later and then hasten the patient's death.

Other conditions produce fatal results, though less frequently, and generally at a time more remote from the operation. Of these mention might be made here of bowel adhesions producing obstruction, injuries to the various viscera, as liver causing hemorrhage not noticed at time of operation, kidney or ureter causing either hemorrhage or urinary extravasation with subsequent infection, or perforations of the intestine that through negligence or necessary haste, have been overlooked. I have been surprised in practicing experimental surgery on the ureter in dogs by the severe hemorrhage that often follows section of this duct and its nutrient vessels.

While separating adhesions of tumors to bowel it is easy to injure that tube and if the wall be friable, as often is its condition when attached to suppurative masses, necrosis may later produce an opening through the bowel wall, even though sutures have been employed for reinforcement. Small openings accidentally made in the omentum during operation may admit and strangulate a loop of small intestine, thus terminating life. A considerable number of autopsies have demonstrated this as the cause of death. Urinary and fecal fistula may cause death by exhaustion. We had a death from fecal fistula three weeks after operation and recall one case, not our own, in which death was produced a few weeks after operation, by a fistula in the lower end of the abdominal wound discharging fecal matter and urine. In incarcerated hernia there is great danger of exhaustion following diarrhea that sometimes attends the liberation of the bowel. We had one case in which there was obstruction of the bowel before operation and immediately after it was finished the bowels began to move, twenty-three movements occurring within the next six hours and during the remaining hours of life, a constant discharge from the bowel continued in spite of vigorous treatment to check it. It also terminated a case of volvulus for us in 1891, on the day following operation. Ventral hernia in the line of incision of the abdominal wall caused death in a case not long since in the practice of a surgeon of this city, about the fifth day after operation. She was thought to be suffering from la grippe and the hernia was never suspected, but the autopsy readily revealed the cause of death. Shock is produced in some degree, in every surgical operation, but many causes contribute to it. Anesthesia alone in prolonged operations may be sufficient to produce a fatal degree of shock. Hemorrhage, already mentioned, though slight, may have a like effect. Mutilation of vital organs is a frequent cause and removal of large tumors, by taking a large amount of blood from the circulation in some cases, as well as by bleeding the patient into her own veins as a result of removal of the pressure from large abdominal veins, and from heart, lungs and other viscera, has a similar tendency.

One of the most potent causes is slowness of decision and execution on the part of the surgeon. The

very slow surgeon will probably not have nearly as good results in severe cases as does the quick-thinking and rapid-working one. Exposure of viscera during operation is a frequent cause of fatal shock and this is, of course, very materially aggravated if temperature of the operating room be low. I have repeatedly seen abdominal surgery done in rooms having a temperature of scarcely 60 degrees F. The danger of this is certainly very apparent to all.

The ureters have been injured during operations followed by urinary extravasation and discovered only at the autopsy. These canals have often been unconsciously ligated as in hysterectomy or the removal of a large intra-ligamentous cyst. The peritoneum has often been badly injured and bowel adhesions occurred often causing obstinate obstruction that was relieved by secondary operation, but more often has resulted fatally. The author has lost one case in this manner after secondary operation and Marcy, of Boston, has reported very unpleasant experiences of this kind. The absorption of ptomain, following this impairment of bowel movement, often results in death. An irritable stomach may prevent the taking by the mouth of sufficient nourishment and these cases are not the best for bowel feeding, consequently gradually increasing exhaustion ends the drama. Some patients are panic-stricken soon after operation and can not well be controlled, gradually wearing themselves out. Others may be attacked with insanity in some form that may or may not terminate fatally. These conditions always render recovery doubtful. The effect of ether on the kidneys or lungs often leads to a fatal termination by producing defective respiration, pneumonia and by urinary suppression. Chloroform, aside from its action on the heart and lungs, may also produce anuria.

If the preparation of a patient for operation be neglected we may here have furnished a fertile cause of death a few hours or days after operation. Insufficient or extreme purgation are not a part of the proper preparation of patients for operations of this kind. In one of the author's cases that is now recalled, operation was compulsorily postponed, as within a few hours immediately preceding the time set for the operation eighteen bowel movements resulted from over-purgation, and the patient, though usually strong, fainted on rising from the bed. One week later the operation was successfully done. So also must the after-treatment not be improper. Fatal bowel adhesions may result from the long postponement of the use of purgatives, especially if severe pelvic or abdominal adhesions existed before operation. Injudicious diet has caused no small number of deaths weeks after operation.

Enough has been said earlier in this paper concerning the influence of intercurrent disease as a factor in the production of a fatal result to abdominal surgery, but we must ever be alert for organic diseases intercurrent or concurrent with this work. It is easy to overlook the possibility of such an occurrence until death has placed its hand on our patient. It is not to be understood that they necessarily prohibit such important surgery, but that they are always to be given sufficient consideration.

The accidents always besetting the abdominal surgeon are varied and numerous, and serve to keep him constantly on guard. They are by no means unavoidable in many instances. They will always complicate the work of the inexperienced and careless surgeon

far more than one careful, wide-awake and experienced. In fact, a very large proportion of accidents in this line of surgery are the direct result of improper surgery. A very common one is secondary hemorrhage. This often follows removal of the spleen, kidney or a uterine appendage. I must acknowledge having lost a case in this manner in spite of a second opening of the abdomen. The cause of this accident is, of course, improper ligation of the blood vessels severed in the operation, or too much freedom of movement allowed to the patient after the operation. Too much tissue, besides the blood vessels, is included in the ligature, followed by shrinkage of the stump. This allows the ligature to slip off or, by the lessened pressure on the vessels, the blood to be forced out through their cut ends. Both these results are facilitated by a restless patient moving suddenly and vigorously about the bed, and perchance getting out of bed when the eye of the nurse is directed elsewhere.

After this quite casual recital of the principal causes of the mortality incident to abdominal surgery, it may not be out of place to point out some of the procedures that will assist in lessening the proportion of cases that do not survive operation. In doing so I regret I can offer no new suggestions that have been found worthy of note. It may be the principle of some surgeons to refuse operation to some cases that do not appear to have much chance to survive it, even though they are in a practically hopeless condition if left without surgical treatment. They, no doubt, believe they are doing more for the reputation of surgery in pursuing this course. While not agreeing with men of that opinion, I am not prepared to say I am right and they are wrong. Certainly, their mortality rate should be much better than that of the operator who will do for any living person all his skill and experience will permit. As many times death has resulted from insufficient knowledge of the real condition of the patient at the time of the operation, it follows that to be very familiar with the physical condition of a patient before operation is an essential feature of abdominal surgery. The principal organs of the body should be studied, both as to their function and organic condition. In the vast majority of cases, the operator has an abundance of time for careful study before operation. The detection of the localized tumor or other abnormality is not sufficient, but careful exploration should be made of all the principal organs of the body. The condition of the kidneys, heart, lungs, liver and gastro-intestinal canal are particularly important, and when possible, the function of these organs and their accessory structures should be normal or nearly so, before an operation is performed. This will assist in the after-treatment, as well as lessen the susceptibility to shock. A healthy, vigorous organ or system of the body is less easily influenced by shock, ptomain absorption, etc., than is one that is sluggish, incompetent or impaired. Urinalysis is a very important matter in this work. We have learned that an examination of the urine that tells of the presence or absence of albumin, the specific gravity and reaction of a specimen voided by the patient, is of no earthly consequence. We must know the amount of solids passed by the kidneys in twenty-four hours, the presence or absence of renal casts, and whether any abnormal ingredients are present. The urine must be drawn by catheter to prevent its being contaminated by extraneous matters, and we must know how much these points are modified by insignificant conditions. Urin-

alysis is a perfect index of the kidney function, and oftentimes will tell us much about other organs that might not be noticed by any other kind of examination.

After we have carefully studied the condition of the patient we turn our attention to the operation, upon which depends greatly the result. We should always know when to stop, and not to place upon the patient a greater load of shock and other handicaps than she can stand and recover under. Preparations should be made in every instance for rapid and proper operation. As very few are competent to administer anesthetics, special attention should be given to the selection of the anesthetizer. Many deaths are directly due to the anesthetic, and therefore we should carefully study the action of the anesthetic upon the patient. The most intelligent and best informed assistant should be the one to give the anesthetic; trusting this part of the operation to nearly any one that can be procured is extremely reprehensible.

The author has found the admixture of oxygen with chloroform to be very satisfactory. The amount of time consumed in giving the anesthetic is important and, of course, the rapidity of the operator will to a great extent control this. Careful and clean surgery should always be done, but no time should be used during an operation for study. The operator should be quick to appreciate the work before him in any case, and to do it in the shortest possible time consistent with good work. In cases in which we have reason to expect much shock it is very important to do everything to prevent it. The heating of the operating table by hot applications in the way of hot water pipes or hot water bags is of untold value. The temperature of the room should be about 85 degrees F., and every assistant well trained to the work. In this way only is rapid work possible. Some of the principal points to be remembered by the surgeon are to do as much of the work as possible by sight, to expose no viscera not to be removed, either to contamination with discharges in the field of operation or to the outside air. Drainage is oftentimes necessary, and probably if more drainage was practiced more permanent cures would be secured. Close all peritoneal tears if possible, and thus remove danger of intestinal adhesions; endeavor to leave no bleeding surface. It is not necessary to wait until the patient has been removed from the operating table to begin the use of stimulants. Very frequently a liter or less of normal salt solution run under the breast of a woman during operation will turn the course of her condition toward recovery. I am firmly convinced that I have seen a great many women saved by the prompt use of this agent on the operating table. I have seen bad cases recover in which artificial respiration was necessary throughout nearly the whole operation. If clean surgery has been done, when shock lessens convalescence begins and continues steadily. If intestinal tears be made during operation they should be isolated completely, that the peritoneal cavity will not be infected, and repaired as soon as possible. If the bowels are kept moving by cathartics adhesions are not so apt to occur. Over-feeding and under-feeding are bad for these cases, though the latter is the less harmful. We must not feel that our patients are out of danger when the bowels have been moved once, for many cases of bowel obstruction have been noticed as late as the second or third week, when all seemed serene, and rapidly proved fatal. Fecal fistula following operation is, to say the least, a very disagreeable complication

at all times, and if large and connected with the small intestine, will perhaps kill the patient. We very vividly remember a fistula connecting the ileum with the vagina that proved fatal about three weeks after operation.

Ureteral and kidney fistulæ may cause death by infection of these organs. Those connecting with the bladder will usually close spontaneously if that viscus be properly drained.

Sepsis is a very difficult condition to contend with. Many of the operations are for this cause, and a good many die from it that were infected during or following operations for other causes. As bacteriology is making such praiseworthy progress in sero-therapy, we can with reason hope for the successful treatment of this condition in some such manner as is being applied to puerperal sepsis.

But at present we are almost powerless against it, and the patient who has already undergone the ordeal of an abdominal operation has very little chance against it. Fortunately, we have it to contend with far less often than formerly. We must not allow this opportunity to pass for saying a good word for the infusion of normal salt solution in these cases of sepsis. It is certain we have had cases in which it acted almost magically both in reducing temperature and improving the condition of the pulse. We need say nothing more concerning accidents, except that good judgment is required, and that in ligating blood vessels in the abdominal cavity it is advisable to include in ligatures as little of the tissues about vessels as possible, thus preventing the tendency to secondary hemorrhage.

DISEASES OF RAILWAY MEN CAUSED BY THEIR OCCUPATION.

Read by title at the Thlrd Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 23, 24, 25, 1896.

BY J. F. PRITCHARD, M.D.

DISTRICT SURGEON ON THE CHICAGO AND NORTHWESTERN RAILWAY.
MANITOWOC, WIS.

All occupations nearly, affect the human economy in some peculiar manner. Where there arises a strain of the physical system we find diseases affecting the muscles, joints, bones, etc., and when the strain is mental the nervous system is found involved. These facts are so common that they are truisms and need no demonstration.

We would expect to find among railroad men a complication of diseases from the very nature of the occupation. There is no doubt of intense mental strain at times, and the general muscular system is subject to a degree of fatigue almost past endurance, which must produce its effect; but I find upon investigation that but little attention has been paid to the subject, and my only hope now is to direct your attention in this direction in order, if possible, to reach some clear conclusion regarding the effect of occupation on railway men, and its ultimate effect in case of injury.

The following, quoted from a stray medical publication, shows evidently that others have been giving this subject attention.

"Neurologists are watching with great interest a new expression of nervous malady which has appeared since the introduction of the Broadway Cable cars and the Brooklyn trolley system. With the exception of Chicago there are no cities having so much street traffic as New York and where these methods of trans-

portation are in operation. A nervous state unlike that which is excited by great noise or sudden danger has developed in several gripmen employed on the Broadway road and among the motormen of the Brooklyn trolley lines.

The constant lookout for collisions in the overcrowded district below Canal Street in Broadway keeps the gripman in a state of extreme nervous tension from the hour he goes on his car until he goes off duty. Besides keeping an eye open for visible trouble his mind dwells on possibilities that are under his feet. He does not know when there is to be a pooling of interests between the grip and a broken strand in the cable which will whisk him along the street into trucks, smashing wagons, frightening people, and exasperating the city fathers. This nervous strain results first in wakefulness, then in loss of appetite and extreme irritability; after this a tremor in the facial muscles. At the end of a week, says the medical examiner, all of these symptoms disappear and do not come back for ten days, but afterward the intervals are regular, about a week apart. Seven days in a state of nervous terror and seven days in a healthy state apparently. These symptoms apply only to men of nervous, nervo-sanguine or bilious temperaments. While present in other temperaments they are not pronounced."

I am informed that on some English railways where very fast trains are being run, only young men as engineers are employed. After running for a length of time they can not make the schedule, and as there is a fine for delay of mail at the rate of one pound (\$5) per minute it seems to be important that the train reach its terminus on time. Why are experienced men unable to do this? Is it not from some depressing effect on their nervous system?

I have three notable examples of the influence of their occupation as engineers.

The first was an engineer on passenger trains. He never had an accident but developed severe neuralgic pains in various parts of his body, notably his head and back; was troubled with chronic cough also, and finally was pensioned on light duty on account of his disability until the road was sold, when he returned to duty on a branch line, but suffered at once from severe girdle pain and great lassitude, which finally developed into an epilepsy with gradual softening of the brain. He is now at times unable to walk, has regional paralysis, is unable to talk at all, and can live but a short time. This man is a pensioner, was discharged from the army for disability affecting the lungs, but recovered and to my personal knowledge had charge of an engine for nearly twenty years. I am satisfied that his present condition is largely due to his occupation and the nervous strain attending it.

In the second, also a passenger engineer, and one of the best, he had the misfortune to run into a washout without injuring any one except some few slight scratches, although the train was very badly wrecked. After a month or more he was set to work as a conductor, but made a failure of that as he seemed to be unable to comprehend the time-card. He could not stay on an engine when running as he seemed to become paralyzed with fear. He was given a position in a round-house and shop, which position he now fills, but he can not run an engine because of a return of his nervous symptoms, although fifteen years have passed since the accident referred to. In every other respect he is in perfect health.

In case third, also an engineer of the first-class, while running a passenger train on a branch line collided with some cattle and his engine was thrown off the rails, but no damage done. He has never since been able to run on any fast train, and is now pensioned on a short branch line where he does effective work. He informs me that he becomes nervous and unstrung when running fast or on the main line, and in deference to his wishes he has been kept on easy work since his accident, now nearly sixteen years.

I will refer to but one or two more of this class as showing in my opinion the effect of mental strain due to occupation. A case reported by Charles S. Potts, M.D. Mr. A. R., age 28 years, a railroad engineer, was perfectly well until three weeks previous to coming to the hospital. At that time while attempting to save a man from being run over he had a narrow escape himself. Since this he has been very nervous and excitable. He complains of restlessness at night, frequently walking in his sleep, palpitation of the heart, headache, and of being confused mentally. There were also dyspeptic symptoms which he says did not exist before.

The *Brit. Med. Jour.*, says that there is reason to believe that at all times there are men on the line who are working very near the breaking strain. We may in regard to this mention three well-known instances which at the least show the tension under which work is carried on. A station master seeing a man run over on the line, himself fell down dead upon the platform. Here was a shock which permanently made his heart stand still; and how many times had not that man's heart stood still before? We may feel perfectly certain that if the major shock could kill, the minor daily shocks of a railway life must have greatly damaged a heart under the influence of the nervous system.

Two trains collided at a junction. It was either the fault of the drivers or the rails, certainly not the signalman. The signals were right; yet when the box was entered the signal-man was found to have gone mad and had to be taken to an asylum, where he remained for long. He was broken utterly by the horror of the dilemma. But what shall we say about the smaller dilemmas which every hour of his working life he had to solve? Did they not also have an effect, although a lesser one, on the brain?

A few years ago it was found that the sickness rate among signal-men of certain lines was becoming excessive, and it was determined to do away with the system of leaving to one man the whole responsibility of taking charge of a signal-box. At great expense every box along the line was supplied with two men. Great evils were prophesied. It was thought the men would talk and lark and neglect their duties. This did not happen but the sickness stopped. Under the shared responsibility they no longer broke down. If then, as seems to be indubitable, railway strain can have definitely injurious effects upon the nervous system it becomes an important question for inquiry whether this nervous derangement at all frequently has the effect of impairing the nutrition of the heart. Upon this special point we do not at present possess sufficient information to warrant the expression of a definite opinion.

Now, while these cases are extreme and well marked, as a matter of convenience and for a basis from which to make deductions, I think we can fairly say that they are all due to occupation. And while all railway men of this class may not have similar experiences yet

they all have similar mental strain from constant watching to avoid teams on grade crossings in country and town, more particularly with fast trains where time must be made regardless of every other consideration, and also to avoid crushing track-walkers. By these I mean trespassers on the track. Have you ever ridden on an engine when ahead you see a man walking in the middle of the track as unconcernedly as though on a promenade in the park? He is going your way. The engineer puts his hand on the air valve, watching the man intently, but not slackening speed, waiting to see him leave the track. He next blows an alarm with the whistle but does not apparently attract attention. He is now so close that he can not stop, but he makes the effort, reverses his engine, puts on the emergency brake and, when he is just on the man, turns his head away to avoid the sight, but the man steps off. Yet the mental and nervous strain is just as great as though he had killed this individual. If the trespasser happens to be a child or an intoxicated man, usually he is a subject for an inquest with all of the usual senseless blame and criticism. Every engineer has more or less of this to bear, and as a consequence there must of necessity be nervous disturbances of varying degrees of severity in this class of railway men, although I am not aware that they have been made a separate study up to the present time.

I find a great deal of complaint of backache among all classes of railway men. I think it is mostly muscular, from the mere muscular strain of maintaining equilibrium from rapid movement of the trains. Especially is this true of freight train crews and where men are obliged to be on their feet in the various duties of their work. I have not been able thus far, however, to note any unusual number of kidney diseases, but this may be modified by more extended observation. Certainly they complain of a frequent desire for micturition, an indication pointing to congestion of the kidneys, but it is so difficult to keep any considerable number of men under continuous observation, more particularly on western roads, that I at least am not prepared to say that their occupation may not be a potent cause of kidney disease.

From the very nature of the occupation we would expect digestive difficulties of all kinds with attendant diseases. Twenty minutes for a meal is the limit of time allowed in any case. The train men always have some duty to perform after the train stops or before starting which cuts out five minutes or more. They rush in, bolt their food, rarely knowing what or how much they eat. All aboard, the train starts, the men are intensely occupied with their work, and food remains either fermenting in the stomach or digesting but slowly with the subsequent troubles. I can conceive hardly of a human stomach that could digest food under such circumstances, yet many of these men appear to become accustomed to this method. Still I am sure from my contact with them that many of them suffer in this manner. In this connection I note two serious and finally fatal cases of stomach disease among very many minor ones. These two men give somewhat similar histories and required constant attention, yet they both finally died from exhaustion at about 40 years. I am well aware that digestive diseases are very common among all classes of people, but do not find such diseases prevalent among young men in any other occupation.

The second part of this paper, referring to the in-

juries to railway men and their prompt recovery or otherwise, could be easily answered if we can admit the first, viz., that railway men as a class are more subject to neurasthenia and some other serious diseases than men of similar ages in other occupations. It is very positive that men under constant nervous tension bear injuries badly; and my observation is that their prompt recovery is in proportion to their length of service. This rule, if we may so call it, admits of exceptions, but I think by investigation you will find it to be a fact.

This brings up a question in legal medicine which is important, viz., traumatic neurosis. Can we say positively that a railway man suffering from any of the forms of traumatic neurosis, that his disease was caused by the injury, or was it not in existence and the injury merely brought it to light? Is it not more probable that under nervous strain for years his nervous system was diseased and that this shock merely called the attention of his physician to it? I am strongly of the opinion that if we can carefully investigate individual cases, eliminating all pseudo cases, we will find this to be the case.

One writer in summing up a paper on traumatic neurosis says, "It can not be denied that neurasthenia when produced by overwork, exhausting disease, or any of the many recognized causes for such a condition, may cause great suffering and disability when only subjective symptoms are present, and these cases would seem to prove that traumatism should be placed among the causes." I would reverse this method and say, that the disease was existent previous to the traumatism and that the injury merely called attention to it. The symptoms of this neurosis are merely accentuated by the traumatism but not caused by it. How many cases are noted in which the symptoms are out of all proportion to the injury, and in what other manner can they be explained? Many cases of so called railway spine, and in fact all forms of neurosis, can be easily understood on this basis of reasoning.

I had only hoped in this paper to call the attention of the society to this line of study, and hope it may be a means of originating a collective investigation that may make this whole question clear. I would suggest that it be made a line of study for this learned society as I know of no better means by which to settle it.

FRACTURES OF THE FEMUR.

Read at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Sept. 23, 24 and 25, 1896.

BY E. M. DOOLEY, M.D.

SURGEON TO THE NEW YORK, LAKE ERIE AND WESTERN RAILWAY.
BUFFALO, N. Y.

The subject we have before us may justly be considered a trite one. It is one with which we are all apt to have experience of one kind or another. Some we may call fortunate, others unfortunate experiences.

With the advent of the penetrating X rays it behooves all surgeons to make a special effort in the diagnosis and treatment of fractures of the long bones.

My object in bringing this subject before you today is not with the idea that anything new or startling may be shown in the diagnosis and treatment of fractures of the femur. But my experience as regards injury to this particular bone has been more or less extensive, and I have a few observations to make which may be of interest to all. Surrounded as the femur is, especially at the upper extremity, by large

and powerful muscles, there are times when it requires the utmost care and precaution on the part of the surgeon to determine definitely the existence or non-existence of a fracture. Under such circumstances we can not be too careful in our examinations if we would assure ourselves of a correct diagnosis, and a correct diagnosis is the only means by which an intelligent prognosis can be given. I believe in all cases where it is difficult to observe after careful examination any definite sign of fracture, and the latter is suspected, we should insist on the administration of an anesthetic. With spasm relaxed we are often enabled to locate crepitus and in cases of impaction our measurements can more accurately be made. I have seen some very grave mistakes made by men who justly bear reputations as surgeons, which I am confident would not have occurred had their patients been examined under anesthesia. As regards fracture of the neck of the femur, I think that in most cases where such are suspected, an anesthetic should be given and the examination be thoroughly made. Due care should be used, however, to guard against the possibility of breaking up an impaction.

I have had unfortunately within the short space of a month in my own practice two cases which a careful examination without anesthesia failed to reveal what ultimately proved to be a fracture.

In one case I had in consultation with me one of the best surgeons in my neighborhood, and together we measured the patient carefully and could detect no shortening. The position of the limb was normal, rotating and flexing, although it gave more or less pain to the patient and failed to give any definite sign of fracture. Our diagnosis was contusion, and we told the patient he would be well in about ten days. This occurred about two years ago and the patient still uses crutches and has about two and one-half inches shortening on the injured side. The second case passed from my hands to the hospital, where under anesthesia a fracture was discovered.

No bone in the skeleton is more influenced by the action of the muscles and yet it is surprising often to see how little attention is paid to the importance of muscular contractions. In saying this I do not intend to convey the impression that surgeons of today treat fractures of the femur without in some manner or other extending the limb for the purpose of overcoming muscular contraction. But it has been evident from some of the results we have seen that an effort has not been made to overcome muscular contraction in a scientific manner. Our efforts to overcome muscular contraction by extension should be directed against those contractions as they are liable to occur. Several muscles whose combined action tends toward one direction displace the fragment. It may or may not be possible to use extension sufficient to overcome these contractions. We have besides the situation of the fragment, another factor in the peculiarity of the patient. This latter in my opinion is more important than is usually conceded. We see some with the proverbial muscles of iron, the degree of contraction necessarily being in proportion to their tonicity. It is quite reasonable to understand, therefore, that a fragment of bone likely to be displaced by an ordinary muscle is likely to be more displaced by one exhibiting stronger powers of contraction.

We use extension to overcome the contraction of the long, powerful muscles of the thigh, or in other words, to overcome the muscles displacing the lower

fragment. We elevate in the hope that we may bring the lower fragment in apposition with the upper.

Before we would enter into an intelligent discussion of the treatment of fractures of the femur, it becomes of utmost importance to review the pathology as it generally occurs. I think that fracture of the shaft at the upper one-third offers the most advantageous means of applying our knowledge for the bettering of the patient; and for that reason principally, and also in order not to infringe on the time of others here, I will confine my remarks on the pathology to this particular form of fracture.

Recall for a moment the anatomy of the upper one-third of the femur and we find an abundance of muscular attachments so that at first thought it would seem difficult to determine the exact direction the upper fragment is most liable to take in complete fracture just below the lesser trochanter. By dividing the muscles into two groups, one set being posterior, the other anterior to the great trochanter, we have a simple and exact method of determining the position of the upper fragment. We find, however, that the action of the posterior set of muscles is not in proportion to offset the action of the anterior, partly due to the nature of the muscles themselves, the larger ones acting as a cushion to the bony parts, rather than as a powerfully contracting tissue to assist in the movements of that portion of the body, and partly also due to the relative points of insertion. The fragments being acted upon as a lever of the second class, naturally the muscles inserted at the lower point exert a more powerful influence on the movement of the fragment. When a complete fracture occurs just below the lesser trochanter, the contraction of the psoas magnus and iliacus are exerted to such a degree as to almost entirely overcome the action of the glutei and remaining posterior set of muscles. The usual result is the tilting upward and rotating outward of the upper fragment. The lower fragment naturally slips behind and the contraction of quadriceps, extensor, adductor, gracilis, biceps, etc., causes the lower fragment to draw upward, the result being shortening of the entire limb.

To illustrate this I have with me an excellent pathologic specimen. It represents a fracture at the upper one-third of the shaft just below the lesser trochanter. This specimen emphasizes the necessity for elevation and extension if we would have the fracture unite on a straight line and not have a result of two and one-half inches of shortening.

I have no history of this case, but it is quite apparent from the result shown here that the fracture was treated without elevation or extension.

It is quite evident that the upper fragment was drawn forward by the psoas magnus and iliacus, and that the lower fragment was drawn upward by the long powerful muscles of the thigh. As this was a complete fracture and directly transverse, I see no reason why it could not have been properly reduced under complete anesthesia. With muscles relaxed and elevation and extension applied, it might have resulted in a perfect union of the fragments without shortening.

One question as regards the treatment of fracture of the upper one-third of the shaft of the femur, has, I must confess, often puzzled me, and that is, what is the proper amount of elevation to use in order to have the lower fragment in apposition with the upper, or at least to have the shaft of the lower fragment take the same direction as the shaft of the upper fragment.

We know that in the case of children good results have followed the raising of the entire limb to a vertical position or at a right angle to the direction of the body. Fairly good results in adult cases have followed the use of the double incline plane with Buck's extension where we have a much greater angle, and I have seen good results follow the use of the Volkman slide.

I think it is a well known fact that the best results have been obtained in young patients; various reasons are given, but to my mind the increased amount of elevation is one of the most important factors.

I do not think it essential or advisable in the case of adults to elevate the limb so as to place it in a vertical position or at right angles to the body, but I do claim from the pathology of the fracture that in the great majority of cases more elevation is required than is generally given.

One object we have in making extension and that is, not that the entire limb may be as long as before, but that it may not be shorter than its fellow. I recall a case in particular which aptly illustrates my meaning. A young man, age 19, acting as a brakeman on a freight train, was brought to the hospital with fracture of the shaft of the left femur, and who had at the same time a fracture of the acetabulum of the right hip. We were confronted with an irreducible dislocation of the head of the right femur and an oblique fracture of the shaft of the left. An attempt to make sufficient extension on the left side to reduce the amount of shortening to a minimum would, without doubt, have resulted in a longer limb for the left than for the right. Hence, although our results might have been more perfect as regards the union of the fracture, yet it would have been less acceptable to the patient.

By simply steadying the right side by means of sand bags so arranged as to keep the line as near like the original as possible, and by using a double incline plane without extension for the left side, we obtained ultimately a good result. For although the patient was perhaps a little more than two and one-half inches shorter in stature than before, yet he was finally enabled to walk with scarcely any appreciable limp.

In my hospital service I noticed that nearly every patient treated with the Volkman extension apparatus complained constantly of pain in the heel. I tried every imaginable way to relieve the pain and have the extension continued, without success. This was particularly the case with the small boys who invariably tried to reach the foot of the bed, and thereby defeat the purpose of extension. Having had occasion since then to treat several boys for fracture of the femur, I succeeded very nicely with a modification of the Volkman slide.

First, I removed the metallic splint and foot rest, I had the little patient's stocking and shoe put onto his foot. The stocking was cut off at the shoe top, so as to leave the leg bare. Then with some adhesive plaster I strapped the shoe and leg as high as the knee, then a screw was inserted into the heel of the shoe to which was also attached a transverse piece of wood to slide along the board beneath, and to assist in keeping the foot upright. A cord was tied to the screw and extension weights attached. All of those treated in this manner never once complained of pain in the heel. In this way I was able to use more extension weights without distress to the patient. The results, I am happy to say, were very gratifying.

One word I wish to say in regard to fracture of the femur occurring in elderly people. I think it is our duty to have these patients able to leave their beds as soon as possible, and to this end I do not think there is a more serviceable appliance than a spica made of plaster of Paris, always carefully padded with cotton.

In the treatment of compound fractures, I think that, wherever it is possible, they should be converted into simple fractures by thoroughly cleansing the opening, closing with sutures if need be, and healing with an antiseptic dressing. I have seen some excellent results follow this method of procedure, and am heartily in favor of it wherever it can be done.

DISCUSSION.

Dr. M. GARDNER—It has been my fortune to see a number of ununited simple fractures in the right limb, and I do not know whether other surgeons and employes of the companies have met with these cases; we have had three on our system in two years; they have been in the hands of good surgeons, men competent to attend to business, but union did not take place, and the result has been we have been obliged to make a compound fracture and wire it.

Dr. COLE—I have had three cases of ununited fracture of the femur, two of them I wired without satisfactory result, and I would like to know—because that is a mooted question in the profession—the experience of those who have had these cases as to the results obtained in wiring ununited fractures of the femur.

Dr. GALBRAITH—I call to mind a very interesting case: A conductor sustained a simple fracture of the thigh, I forget which leg now; he was placed in a hospital and treated by a very good man; the usual methods were employed, but he failed to get union. He cut down and wired it and put it in a plaster-of-paris dressing and it remained some ten or twelve weeks; there was no tendency to repair, the splint was replaced and remained about six weeks I think, and after removing the splint on examination it was found there was a false union; it was a railroad case, and the surgeon wrote me concerning the man's condition, and a little later, probably two weeks, I visited his hospital and advised cutting down and sawing off the bones and using Wyeth's device in the usual method; the limb was put into a plaster-of-paris cast, at the end of ten weeks the dressing was removed and we had succeeded in getting an excellent result; and I believe invariably the use of this in the thigh, and more especially in the leg, is much better than the wires or any other strong suture; I think better results will be obtained by its use than by any other method; it certainly holds the bone in better position and maintains better apposition and rest to the parts. The great difficulty in those cases where wire has been used, is that the regenerative process that goes on is so violent as to be continuous and resolution does not take place till so late that the callus becomes softened.

Dr. LEMEN—I have had varied experience with the cases that I have used wiring. I must say that it has never been very satisfactory to me. I find that where you have to cut down and wire in ununited fractures, it requires at least twelve weeks of immobilization before you can expect union; the patient becomes impatient and the surgeon becomes impatient; in a case that I have had recently I kept it up for thirteen weeks and there was as much of an artificial joint at the end of that time where I used my wire as when I began. I had another case in which there was a compound comminuted fracture of the femur; the laceration of the soft parts was very extensive, and one portion of the bone was split off from the other two between three and a half and four inches long. I did not have to do much cutting in that case because the external wound exposed the interior wound completely. After washing it out thoroughly instead of using wire I simply took silkworm gut and put it around in three or four places, binding very much as the old farmer binds his sheaves of wheat, and I never had a better result in any case. I believe instead of using the silver wire, unless the fracture is almost transverse, and it is a very rare occurrence in my experience to have an ununited fracture of the femur where it is almost or completely transverse, if the first cardinal principle which should be regarded in the treatment of the fracture, is observed, simple apposition, the muscles themselves retain it in position; an oblique fracture gives the most trouble and is the one most likely to be ununited. In any oblique fracture of the femur where it is necessary to use wire you can use the silkworm gut; I put it entirely around the bone, periosteum or anything else,

bring it as tight as I can, tie it in three or four knots, dress with aseptic dressing, immobilize it. The great reason that we have ununited fracture in most of the cases is that we do not immobilize our fractures, and as I have stated to our Society for two or three years, the treatment of fractures of all kinds is the simplest thing; there are three cardinal principles that should be observed and we will rarely have bad results; the first is, diagnosing—make out the fracture and the condition of affairs; the second is apposition; the third the retaining in apposition—and your results should be perfect.

Dr. REED—I want to add one more cardinal principle which is highly important in the repair of fractures, and that is we must have in addition to apposition and holding in position, the disposition on the part of the economy to repair. I remember a case which was injured on the Baltimore & Ohio railway some twelve years ago in which there was a transverse fracture which I knew was properly adjusted and held in apposition because it was placed in the hands of one of the best surgeons in that section of the country, in which there was no repair whatever, that was operated on, and still no union, the subject of which sued the company for damages; and the company had to pay a good many thousand dollars in that case. I began to feel that something had been left undone, something that I ought to have done. After experience has taught me that in those cases where there is non-union it is nine times out of ten the result of the failure on the part of the economy to repair the bone, except in those cases where there has been a portion of the connective tissue or muscles interposed between the ends of the bone. I have operated on quite a number of cases for non-union and in, I will say at a rough guess, perhaps 50 per cent. of those cases there has been an interposition of connective or muscle tissue in between the end of the bone, and when that is there there can not be union; but on the other hand when there is no foreign substance between the ends of the bone it is due to a lack on the part of the economy to replace new bone, and when that is the case I do not care whether you wire the bone or whether you hold it together with silkworm sutures or what you do, it will not repair. In a number of these cases in which we have made careful union, in which we have sutured the bones together with various sutures, we have had no repair whatever, no disposition to repair. One case I recall: The fracture had been immobilized for ten or eleven weeks, and in cutting down we found no disposition to repair whatever; it was like an entirely new fracture, not even absorption of the end of the bones; it is not the fault of the surgeon, but the fault of the economy or the tendency to repair in the person who is injured, which should be taken into consideration; and I believe in a large majority of these cases where there is non-union it is often the fault of the persons themselves, not what they do, but a constitutional condition which prevents the repair of the bone.

Dr. HERNDEN—The remarks of Dr. Reed call up a point in my mind and that is the failure on the part of nature to provide for the repairs. I believe myself, from some experience in that direction, that is true, and I would like to speak of a case in particular which will help the author of the paper. We all feel sympathy and admiration for the fellow who owns up to the corn. I wish to speak of this case because I fully agree with him? It was a peculiar case. A wealthy man in our vicinity, and in fact about the only one we have around there, was visiting in Minneapolis, and fell through a skylight in the hotel, the skylight to the library, struck on the steam radiator; he was severely shocked and it was thought he would not live—and I think the condition of shock is a barrier in the process of repair in a fracture wherever received; he received a compound comminuted fracture of the forearm; he also received a fracture of the thigh or femur. Dr. Hague of Minneapolis, an eminent physician, and a professor in one of the colleges there, were called and diagnosed an intra-capsular fracture of the hip, and put him under treatment, carrying out immobilizing of the hip joint and the whole body for about a little over two months and then declared that there was a repair of the fracture. Dr. Hague wrote to me subsequently that the case was one of those unusual cases where recovery had been achieved where the fracture had occurred within the capsule. The man got homesick and came home on a bed. The doctor had taken off the immobilizing appliance but had a weight and pulley still attached to the limb, because he wanted to maintain his glorious result—the doctor wrote he had achieved a result that was remarkable, he felt proud of it, and wanted that I should keep up the extension so there should be no shortening—and there was no shortening that I ascertained on examining the man. I took off the weight and pulley, threw the weight over the bed and told him, "You never

had any fracture of the capsule, Dr. Hague to the contrary." On examination the joint was soft, weak and exhausted, the fracture in the arm had not healed nor the bones united; this delayed the fracture of the arm, and the fracture existed in the thigh, not the hip. I speak of this to emphasize this point that the processes of repair may be delayed by shock or other systemic condition. On examination I found no shortening, but I found a splitting fracture of the thigh, commencing at the trochanter extending down eight inches. I could pass my fingers—he was thin—between the fragments and push out the lower end of one fragment. Not being content to let the diagnosis remain with myself pitted against Dr. Hague and the professor, I called in three prominent and competent surgeons. They agreed with me. I made an appliance holding the fragments in apposition and got a good result under heroic systemic treatment. I wrote to Dr. Hague and gave him what I thought was the history of the case from the beginning. I said, "You have not achieved a grand result, you have achieved a grand sort of ignorance." He sent me the affidavit of the Professor stating that there was crepitus, no doubt about the fracture being in the capsule, I was a foolish man to speak of the splitting fracture, I was simply stating something that did not exist. We had some more correspondence about it; I wrote him that the surgeons that examined it were eminent, and the four of us concurred, no question about it, and each of us passed our fingers under the fragment of bone. I said, "That is where you got your capsule—it never was an intra-capsular fracture." I have brought up the case to emphasize the point made by Dr. Reed and to help our Dr. Dooley as to the diagnosis in such cases. I have myself been very much bothered sometimes, and I think Dr. Hague and his friend must have been bothered when they made that diagnosis.

Dr. MAYO—In reply to Dr. Cole's inquiry in regard to wiring fractures I would say that in one case of ununited fracture the result was unsatisfactory. In a number of instances I have wired compound fractures, or at a secondary operation wired for the relief of deformity due to improper union. One fault in wiring is that while you can hold the ends of the bone in position, muscular action has a great tendency to cause angling or bowing, which is hard to prevent. About a year ago I saw a silver bone splint in Baltimore, used both by Tiffany of the University of Maryland and Halsted of Hopkins Hospital. This splint is composed of silver, is about three-fifths of an inch wide with screw holes at frequent intervals. A piece of this splint can be broken off the right length, laid so as to cover the seat of fracture, and on the sound bone each side, and with silver screws firmly anchored in position. It is claimed that this can be sealed and left permanently. A recent case is reported in the *Annals of Surgery* where this was done successfully in a case of ununited fracture which had been previously operated upon several times, with failure. I have used this on one case with great satisfaction; the case was a septic one and I packed with iodoform gauze and eventually removed the splint. I was surprised on removal to see how tightly the screws were held in the bone at the end of a number of weeks.

Dr. SCOTT—I wish to say a word on Dr. Reed's remarks relative to the nutritive influence in connection with fractures, especially in fractures of the femur. I think a great deal more attention should be paid to that especial point by the railroad physician than is usually given. Recently, upon my recommendation, the general manager of my road has taken steps for the purpose of employing a better class of labor on our road. We have heretofore had no examinations made scarcely, and while we have had some examinations made in the transportation department, we have not had any in the road department, and have had a great many fractures from that department; our general manager has given instructions that the foreman or the road master should employ none but comparatively young, able-bodied men. While that seems to be an injustice to the old class of laborers, yet it is nothing but justice and is a protection to our company to employ such laborers. I believe that on account of this step we will be saved some of this trouble and it may save the company thousands of dollars at the same time.

Prof. RIDLON—When the general surgeon treats a case of fracture and fails to get union, and wires it and fails to get union, he sometimes comes to the orthopedist for help. That leads me to feel I have some right to take a part in this discussion. There is one point omitted in the question of treatment for repair of fracture. As I understood Dr. Reed's point of defective nutrition, he means defective generally and not local. I should take exception if it were defective locally.

Dr. REED—It may be either or both.

Prof. RIDLON—I will cite two cases: Henry D. Sands of New York; treated for fracture of the tibia, non-union; he was wired, non-union; then afterward it was operated on by

Dr. Frank Hartley of New York, and failure to get union; he was sent to me. I took off the splint and in six weeks there was good union. The other case was treated by William T. Bull of New York City; there was a local defect, not general; after wiring and getting no union, the case came to me. I took off the splint and treated it and in four weeks there was a good solid union. The point I would make is this: These cases, and all the cases I have happened to see, have been treated by plaster splints. I would not say that plaster splint makes non-union, but I say in many cases of non-union the effect is due to constriction of the fractured region. When the constriction was removed, when the local congestion was reduced at the point of fracture, union took place. I believe a fracture should not be constricted.

Dr. GALBRAITH—In view of the fact that our discussion is placed on record, I wish to take some exception to Dr. Lemen's remarks; possibly I did not understand his meaning. If my memory serves me right, he cited the fact that all there was to do was to secure and maintain apposition and that in all cases you would secure a perfect result. Now I may be in error in this; if I am I will go no further. If I am correct I should like to say something concerning his treatment.

Dr. LEMEN—I think you understand me correctly; my statement was this: Diagnose your fracture, place it in position, retain it in position, trust to nature, your results are perfect.

Dr. GALBRAITH—I will cite a case and I will be much obliged if the gentleman will advise me regarding the treatment. A lady, 18 years old—she is under my care at the present time—met with an accident in a railroad collision, receiving a fracture of the right clavicle near the shoulder joint, a fracture of the left clavicle near the middle, a fracture of the scapula, a simple fracture of the middle portion of the humerus and a compound fracture of the elbow joint. Repair has taken place at all seats but the third of the simple fractures; there was a rupture of the muscle and I have some deformity of the clavicle and scapula and a non-union at the point described. And I would like to know in a case of this kind, how any man can apply a dressing, how he can secure a perfect apposition and maintain it by any surgical dressing or surgical appliance? The great difficulty in making positive statements of this character is that we may in a short time be confronted, as oftentimes happens when a railroad is sued, with the statements especially of an able man like Dr. Lemen; he is an able surgeon and inasmuch as he has taken this positive stand how can we avoid conflict when we are not having the best results in practice?

Dr. LEMEN—There is just one remark that I would make in addition—and yet I doubt the propriety of making it a matter of record—but I have always looked first upon science and results to be the first consideration, the first duty in the position that I have always occupied, and I do not feel that I should have my views, honest convictions restricted for the mere fear that perhaps it might not suit the railroads or the selfishness of the other corporations that I might work for. I believe we should rise above these things; we should stand upon a higher plane than to allow for one moment the position that we occupy toward a corporation to prevent us from righting ourselves in regard to scientific facts. I perhaps am a little more outspoken than the most of men, but it is due to my bringing up and I perhaps can not help it—built that way.

Dr. GALBRAITH I do not think the Doctor understood the gist of what I wanted to convey. It was not for the protection of the corporation nor the individual, it was the protection of the surgeon himself. I have a deformity in this case and a non-union, and I do not know how anybody could overcome the difficulty and secure better results than I did; certainly could not apply any dressing, could not secure apposition, on account of the serious complications and multiple combination of the fractures. It was not for the purpose of protecting any corporation—it was simply the individual. I do not feel I am responsible for the result I have got in this case. While the deformity is slight, there is some.

Dr. LEMEN—I believe that it is true in our profession as well as others, there is an exception to all rules and the exception very often proves the rule. But I was speaking about general results.

A Doctor's Button.—A badge as an international insignia for physicians has been recently proposed. It is a button in the form of a circular shield, in the center of which is a modified form of a Maltese cross, opposite the arms of which are the letters "M. S. O. H.," meaning medicine, surgery, obstetrics and hygiene. The button is of gold, and the cross is of red. This may be unnecessary, as the profession is "of the people, for the people and by the people."

COMPOUND COMMUNUTED FRACTURE AT THE KNEE—REPORT OF A CASE.

Read at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Sept. 23, 24, and 25, 1896.

BY W. A. WARD, M.D.

SURGEON TO THE NEW YORK, CHICAGO AND ST. LOUIS RAILWAY,
CONNEAUT, OHIO.

Compound injuries of the knee have at all times been considered most serious in character, more especially when complicated with fracture; in the latter the knife and saw have been considered indispensable, their absence fatal to the life of the patient.

Thus Erichsen (System of Surgery) in speaking of this class of injuries of joints, says: "This is more especially the case when the knee is the articulation injured; extensive laceration of this joint, more particularly complicated with dislocation or comminution of the bones, being cases for early amputation." Later Dr. Ashurst (International Encyclopedia of Surgery) in discussing "Conditions calling for Amputation" places it more mildly by the remark, "Compound fractures into the knee joint may be considered a cause for amputation," yet when taken in connection with the text may almost be considered imperative.

Since the days of antiseptics, which may not inaptly be termed the New Surgical Dispensation, surgeons have become bolder and conservative treatment has in a measure supplanted the more radical, with varying degrees of success. Each successful case undoubtedly carries with it one or more practical points; and, if the report of the following accomplishes that purpose, the object of this paper will be fulfilled.

S. M., aged 38, Finn, laborer, married. On March 13, 1896, while at work at the base of an ore pile on the P. & C. docks at Conneaut Harbor, about 2:30 P.M., was injured by a mass of frozen ore which rolled down the side of the pyramid and caught his left knee between it and an ore bucket. He was at once conveyed to his home about half a mile distant, and surgical aid summoned. On arrival found Drs. Baker and Tower present. Told them I had been requested by an official of the company to take charge of the case. Had been telephoned for and word returned I could not come, which was a mistake and accounted for my tardiness, as I had only a few moments before received word. Patient was under chloroform, and the doctors assured me that "the head of the tibia was comminuted and the joint open, that finger could be readily passed into the joint through the external wound and fracture plainly felt; that they had adjusted fragments and sutured external wound." By palpation the diagnosis of comminuted fracture was readily confirmed, the head of tibia being broken into at least three pieces; also dislocation of head of fibula with transverse fracture of shaft about an inch below. Inspection also revealed a wound on extero-posterior surface, along lower border condyle of femur, some three inches in length. After explaining to friends the serious character of injury, that amputation might be required, etc., was willing to make an attempt to save the limb, and so decided. The wound was dressed with iodoform gauze, limb placed on a double incline plane well padded with sublimated gauze, and a padded Levis splint anteriorly, bandaged, and patient conveyed to bed. Morph. gr. $\frac{1}{4}$, to repeat as necessary. Corrosive sublimate solution was freely used from first to last.

8 P.M. Knee and limb swelling, making bandages tight, considerable pain. On removing bandages blood welled freely from wound, which was gaping and stitches tense. Hemorrhage was readily arrested, parts cleansed and redressed. Ice bag applied over knee, which was protected by a folded towel placed underneath bag.

14th, 9 A.M. Still oozing, swelling increasing, limb inclined to roll inward, pain severe notwithstanding morphia. Complains bitterly from slightest motion of the body, evidently splint not meeting requirements and some other device loudly called for. Redressed wound and adjusted as well as possible, ice bag continued.

2 P.M. Assisted by Drs. Tower and Baker, removed double incline plane, bathed limb thoroughly, cor. sub. sol. not forgotten, and placed in a Smith's anterior wire splint with a foot piece; adhesive strips applied to sides of leg and fastened to

foot piece in the ordinary way for extension, splint extending over fully two-thirds of thigh, limb being supported by a continuous series of strips of a common roller bandage 2½ inches wide, whole length of splint, fastened upon either side by pins and then suspended in a Salters cradle. Sutures removed and wound drained by iodoform gauze crowded well into joint, over which was placed iodoform gauze and sublimated cotton, held in position by the strips of bandage supporting limb. Ice bag replaced and morphia as necessary.

15th, 10 A.M. Very little pain since yesterday P.M. Pulse 90, temperature 99.6, tongue coated, bowels inactive, enjoys his pipe, had a fair night. Wound oozing, dressings soiled. Comp. cathar. granules (Whitbeck's) ii, repeat in evening if necessary.

16th, 9:30 A.M. Pulse 90, temperature 99, no action of bowels. Comp. cathartic pills ii every six hours until bowels move.

17th, 9:30 A.M. Pulse 90, temperature 99.6, a costive movement of bowels. Soda et potass. tart. a tablespoonful once in four hours until proper action secured.

18th, 10 A.M. Pulse 90, temperature 99.

19th, 9:30 A.M. Pulse 90, temperature 98.6.

20th, 10:30 A.M. Pulse 90, temperature 98.4. Outer dressing to wound unsoiled for first time.

21st, 10:30 A.M. Very comfortable. Ice bag discontinued.

22d. In redressing wound omitted drainage.

23d. Very little swelling of knee.

25th. For past two days had had a severe pain in middle third of leg, commencing about 5 P.M. and continuing into the night. Pulse 80, temperature 98.4, tongue coated, hydrarg. chlo. mit. gr. ss. once in three hours for three doses (from which bowels moved thoroughly), quinia sul. gr. ii every three hours. Quinia continued for two days with complete relief.

Fig. 1.—Appliance for support of fractured knee.

April 15. Wound closed.

20th. Osseous union fair, motion of joint more than expected, flexed and extended knee quite a number of degrees. Limb heretofore kept slightly flexed, readily straightened. Bathed thoroughly and placed in plaster Paris cast. On the next day (21st) to my surprise found patient dressed, sitting in a chair. He at once commenced getting about on crutches and progressed rapidly.

May 3. Complained of pain in lower third of leg, inner side. Cut off cast, and union appearing good, omitted splint of any kind, simply a cotton compress and bandage. Motion from extreme extension to very near right angle.

The pain continued, sometimes in leg, at others in foot, or in both, of a very severe character, notwithstanding treatment, which was both general and local; among the latter liniments, blisters, cupping, massage, etc., until July 2, when an interrupted galvanic current was used with marked relief, repeated on the 5th, and no complaint since, although it was again used on the 13th. At latter date motion was nearly complete, and used only a light cane in walking.

There is a little deformity on outer side, owing to excessive callus formation and undue prominence of head of fibula, otherwise the result is as complete as could be wished.

In reviewing the management it is unnecessary to comment on the strict antisepsis which was maintained, the drainage or antiphlogistic of cold as applied by the ice bag. To do so would only be to repeat what has oft been reiterated heretofore; but to the mechanical device, which, to my mind, proved a strong link in the chain leading to the result, I wish to call special attention, not that there is anything in it new or original, for there is not.

The Smith wire splint, with the attached strips of bandage as applied, afforded a bed and support to the limb, held it firmly and secured perfect rest and repose for the injured parts. The facility or ease by which the wound could be reached was also important, to accomplish which we had only to loosen a couple of the strips upon that side, turn them back underneath, or if soiled remove entirely and replace with new, take away the dressings, which were then entirely free, bathe, or do whatever necessary, apply fresh dressings and readjust the strips, all without any handling or moving of the limb whatever; a great convenience, as it was deemed advisable to redress at each visit for some ten days, on account of oozing, and at longer intervals thereafter until healed. Pus was not at any time visible. Strips were carefully examined each

Fig. 2.—Support for fracture of knee. Bandages loosened for dressing wound.

day, to see that each remained properly adjusted, or all bearing equally. When we desired to inspect the sides or posterior surface at any point, we loosened one or even two strips on one side; if more desired, readjusted ones already loosened, and proceeded as before. For the anterior surface, simply lifted the covering which had been folded and loosely laid thereon.

By the Salters cradle, in which it was suspended, extension was maintained by the heft of the limb and the pitch of the incline, and thus kept uniform. If the patient moved up in bed (he could readily do so himself unassisted), or if from any cause slid down, the pulley automatically rolled up or down the incline, creating no disturbance. When the patient was moved to the right or left, the position was immediately accommodated by the swivel by which the cross bar was attached to the pulley, thereby affording quite a range, or even allowing the bolstering of the patient without the least inconvenience.

By the cord and hook in the ceiling, or a gallows placed by the side of the bed, the extension is main-

tained by the obliquity of the cord. If increased, then extension is increased; if lessened, extension lessened, until at the perpendicular it becomes null, and if perchance it passes beyond, then we have a crowding; therefore, to have uniformity of extension by this means, it is necessary to secure your patient against any sliding up or down, a very uncomfortable thing for him, but not required by the cradle, hence its advantages. The cradle I have found of inestimable value in severe injuries of the leg necessitating confinement to the bed, no matter what kind of splint was used.

It will be noticed that with the exception of April 20, when passive motion was made simply as a test, the joint was kept in perfect quietude until the removal of the plaster splint, May 3, after which patient was instructed to gently exercise it each day—another refutation of the idea of motion, either passive or otherwise, being essential against ankylosis.

DISCUSSION.

Dr. SCOTT—I happen to be one among the number who believe it is all right to use chlorid of mercury in the joints. While that practice is condemned by some of the leading surgeons, I believe it is justified under certain circumstances, and I believe as a railway surgeon in using chlorid of mercury in the joints. I have used it in the cranium and I believe it can be used in the joints. When we consider the fact that a majority of the wounds which we have to treat in joints are infected when we are first called to see them, full of dirt and various foreign substances, and owing to the fact that we may have some difficulty in removing all foreign substances, all sources of infection, it is justifiable to use an antiseptic for the purpose of destroying those germs that remain. I believe it is good principle and good practice all the way through, and as I said a moment ago, I presume the Doctor's treatment was successful largely on account of the fact that he used drainage and the wound was fortunately situated for the purpose of getting good drainage. In a similar case of my own, a young physician—a young homeopath, by the way—who was afflicted with pulmonary tuberculosis in an advanced stage, but continued the practice of medicine, while whipping his horse one day was kicked on the knee, and the result was a compound comminuted fracture of the tibia which went through the skin and the synovial membrane about an inch and a half long; the lower half of the patella was simply pulverized. I was called to see the man in a short time after the accident. On examination I found the injury I have described, also a lot of dirt on the wound; found some bits of underclothing in the wound, and having gotten him in proper place, I made the opening larger and irrigated the wound thoroughly; and by the way, I believe we can not clean a wound of this character without the use of water in a stream; I do not believe we can clean it by sponging or dropping or anything of that kind, but it needs a good strong stream of water to flow into the cavity in order to flush. I used the bichlorid of mercury, just as the Doctor has stated; after I got through I was not satisfied with the opening that existed in the joint, I stitched up part of it because it would not be of service to me, but I made two openings on either side near the lower part of the joint as far back as I could go, put on the drainage, left a piece of iodoform gauze to the front, placed the limb in an inclined plane, gave the patient a little medicine, I forget what; although he was a homeopath, I think I treated him by the usual methods—he did not ask any question about what he should have—and left him alone; changed the dressing every three or four days, but the result was something surprising, because I was afraid his pulmonary trouble would have some influence on the result. The patient, however, seemed to get no worse during the time he was laid up with this injured joint, and finally made a good recovery, got excellent motion, hardly a bit of sepsis connected with the case. I think the good result in my case was due chiefly to the openings referred to, the excellent drainage and perfect cleanliness and antiseptics combined.

Dr. REED—I was very much pleased with the Doctor's paper and also very much interested in the remarks of Dr. Scott, but I must take some exceptions in reference to one point which each of them recommend, both in the paper and in the remarks on the paper, and that is in reference to drainage. I most fully concur with them that a sepsis or antiseptics is one of the secrets of success in the treatment of joint injuries, as well as other

injuries, but as to the use of drainage it is a question in my mind and one which I seriously question, except when you have something to drain. I do not believe drainage adds one particle to the recovery of an injury to a joint or to any other traumatism unless you have absolutely something that you want to drain. If you have supuration of a joint, I should undoubtedly use drainage. But my experience is that the use of drainage in joint injuries is absolutely useless unless you have something to drain. I used to use drainage in almost every injury, whether of the joint or any other part of the economy, but during the last three or four years I have almost entirely discarded drainage, except when I have had a reason for it. In amputation of the limb I do not use drainage, further than the use of a little gauze for two or three days to assist by capillary attraction the discharge of the liquids as they accumulate, and after that take it away, and in the treatment of joint injuries—and I have had a good many—I have discarded drainage unless I have something to drain. If I adhere to the principles of a sepsis or antiseptics I do not have supuration, hence there is no use for drainage, and I believe you get along as well with a sepsis or antiseptics and mobilization. Because when you have drainage you have an opportunity for the introduction of germs into the wound which you do not have if you do not have drainage. And so I must take exception to it, and I base my exception on personal experience as well as the experience of others who were at one time advocates of drainage and have discarded it.

Dr. E. WYLLIS ANDREWS—Admitting the tendency of modern surgery to abolish drainage, yet possibly it is not true that this applies to traumatism equally with the wounds which the surgeon makes in operating. The experiments of Robb and Schimmelbusch have clearly shown that we never really sterilize the skin in its deeper parts. In other words, while we may sterilize the surface of the skin so that it is not possible by mere contact to infect, yet that same skin a few hours later will be septic, because out of its glands material has been poured which carried with it microorganisms, therefore I must say as Dr. Reed has done, surgeons are drifting away from drainage as far as possible, because experience has shown that the moist serum about wounds in every case in twenty-four hours is septic. It is necessarily true that the wound becomes septic where the drainage tube comes out. Why should we assume from that that wounds made through dirty clothing or with blunt or sharp objects themselves septic, should not be subject to the same rule? The writer states that he did not open this wound for twenty-four hours after seeing it, probably because it began to show sepsis, and that would indicate immediate drainage, if not flushing. The knee joint is so complicated that it may almost be said to contain separate pockets, the bearing of which is that to drain a knee joint thoroughly a large number, or more than one opening is invariably necessary, as Dr. Scott has shown. In his case he found for complete drainage it was necessary to make two openings. In order to thoroughly drain a knee joint it is necessary to make several openings; exit must be supplied from six points: one each side of the patella above the condyle; one on each side of the lower border of the condyle, because fluid will gravitate there, and a pair of drainage or a single drainage tube will be necessary well above the patella.

Dr. SCOTT—Dr. Reed made the point that he never used drainage unless he had something to drain. I agree with him, and that is a good rule to practice in general surgery, but I want to make this point: in the knee joint we may have something to drain. Whenever we have a compound comminuted fracture involving the knee joint we have something to drain and if you stitch up your wound the opening in your synovial membrane may close up, you have a sufficient source of irritation there by way of traumatism to cause an outpour of the synovial fluid, even if you have no blood, and you may have both. I believe, laying aside the question of direct infection or the danger of infection following, it is better for that joint that that fluid should escape, and you know it is good practice in simple inflammation of the knee joint to let out the fluid under the skin, and if that is the case in simple uncomplicated inflammation of the knee, why is it not good practice in injuries of this character to let that fluid out? I believe it is the best practice by all means to get that fluid out of there or give it free opportunity to escape.

Dr. REED—I know that the Doctor has taken the ground which has been taken by many eminent surgeons, and a position that I have taken myself in the past but which I have discarded because I find I get along just as well and better without it. We admit that in a compound or comminuted fracture of the knee joint that we have or may have the blood serum, etc., exuding into the joint, but is it necessary for us to drain under all circumstances? Now I say I am in favor of

drainage when necessary, but unless it is necessary I do not want to drain; for instance we have an involved joint lopping off of the condyle in the elbow, does any one think of opening the elbow in a fracture of that joint, and everyone must admit that in that fracture there is blood and serum in the joint. Nobody ever thinks of opening it; yet those cases get well without disturbance or interference of the motion because of immobilizing the joint; the patient gets well and we do not have much trouble with it. I take that as a cause for not opening the joint. If we take the Doctor's argument in question and say because there is blood and serum exuding into the synovial membrane this is a reason for drainage, when we have a condyle fractured and there is exudation of blood and serum we should drain, but we do not drain but depend upon absorption. So in any joint I do not drain and I have better results, unless I have septic material or something of that sort, that would cause a destruction of the knee joint. I base this on my experience, not for argument. I say in my experience in this line of surgery and in treatment of the injury to the knee joint I get better results when I do not drain than when I do, unless I have suppuration or something that is destructive to the knee joint which will not absorb.

Dr. WARD—It appears I have only been attacked on one part of my platform, and that is drainage. I use my drainage just as I do anything else; when I think it is called for I use it; if not, I do not. If in a given case I have a large amount of oozing, dressing completely soiled through every twenty-four hours, I keep it open; just as soon as it becomes reduced in amount to where I think it safe I remove my drainage and allow my wound to heal. The point also to which I desired to call attention was the appliance, the comfort and convenience of my dressing. I do not know of a man that has ever used such an appliance that would consent to use a double-incline plane for injuries of the leg or knee joint. I have not tried it in fractures of the femur, but I never put it on a person yet but what rejoiced in the comfort it afforded, after having had some other dressing upon the limb.

BURNS AND SCALDS.

Read by title at the Third Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 23, 24 and 25, 1896.

BY C. K. COLE, M.D.

CHIEF SURGEON MONTANA CENTRAL RAILWAY.
HELENA, MONT.

In our work as railroad surgeons we are often called upon to treat burns and scalds in their various forms and degrees, and nearly as often find an unsatisfactory state of affairs regarding the condition of the patient. The severity of the burn, its first treatment by rough hands, and the time since the infliction of the injury are all important factors. These, together with some hints as to methods of treatment, will be considered.

Often we find a patient begrimed from head to foot with coal dust, oil and cinders, suffering with a severe burn, received hours before, with the injured member drenched in machine or engine oil and wrapped in dirty, oily waste, and an internal drenching of whisky or brandy. This condition must be met promptly, and here begins the tiresome task of cleansing and rendering the parts aseptic. These are the times that try our patience.

With no means at hand to dress wounds in an emergency, especially when "out on a run," our engineers and firemen can not be blamed for doing the best they can; on the other hand, it is a wonder why there are not more serious results following an improper first dressing that has remained for hours favoring, if not producing, sepsis. With modern surgery we are able to meet these emergencies successfully and bring about satisfactory results. How best to do this will claim our attention.

As far as the conditions, treatment and results of burns and scalds are concerned, it is not deemed advisable to lay down any different line of treatment, they are in all things practically identical; therefore the term burns will include both burns and scalds.

While many of the earlier authors classify burns, according to the extent of the injury, in six degrees, the simpler classification—three degrees—is here adopted for the sake of brevity and the further reason that we believe the distinctions in the six degrees are practically unnecessary, and are in a measure confusing. The classification adopted is as follows (International Encyclopedia of Surgery, Ashhurst.):

First degree. Hyperemia, erythema; irritation or inflammation of the skin without vesicles.

Second degree. Vesication; inflammation of the skin; formation of vesicles or bullæ.

Third degree. Eschars; gangrene, superficial or deep, involving the skin or other subcutaneous tissues; carbonization of part or of entire body.

In the first degree there is rarely any constitutional disturbance (it is true that a severe case of sun burn may prove fatal), the diffused redness of the surface, some tingling or smarting pain, and occasionally some swelling are usually the only symptoms manifest; yet in rare instances the internal complications are a serious factor, depending on the patient's constitution, individual peculiarities, the impression on the internal organs being made through the media of the sympathetic and sensory cerebro-spinal nerves. Exfoliation is complete within a few days and the skin is again normal. These symptoms are also found in burns of the second degree, but intensified because of the greater heat producing them, and in addition there is serous effusion and the formation of vesicles, following the intense hyperemia, either appearing at once or within a few hours; in some cases they continue to form for two or three days. It often happens that the vesicles burst because of the rapid effusion; when this occurs the epidermis lies in shriveled whitish folds on the super-sensitive, inflamed skin, causing pain and uneasiness, and when touched this inflamed, raw surface gives rise to intense pain. Sometimes the usually transparent serum is streaked with blood. When there is no ulceration we may find the epidermis replaced in from five to ten days.

The severity of the burn, the condition of the nervous system and susceptibility of the patient influence the constitutional disturbances. Some authors affirm that in this degree, "in severe cases shock with prostration, even immense prostration, is always present." In our experience, typical second degree cases have been treated with shock and prostration practically absent. Death may be instantaneous from collapse, or perhaps more properly neuro-paralysis, from syncope and suffocation (rarely met with in railroad injuries). If death is not sudden (in the common acceptance of the term) it may be prolonged for hours or days and result from collapse, coma, bronchitis, pneumonia, etc., thoracic lesions, lesions of the abdominal viscera, enteritis, hemorrhage, peritonitis, exhaustion, gangrene, septicemia, etc. With intestinal complications, death may result from ulceration.

The definition given of burns of the third degree indicates plainly the prominent symptoms; the eschars vary in depth and extent; the destruction of tissue, depending on the degree of heat and duration, may be of the skin only, or all the soft and bony tissues of a part may be destroyed. This total carbonization, while not common, could easily happen to one pinioned under a wreck.

If the person survives the shock, we have a group of grave conditions to battle with; severe as are the lesions appearing in the second degree, they are not

to be compared to those now under consideration. Shock is so pronounced that the question often arises, Can anything be done? I have had in my experience cases in which the burned surface was so extensive, the burns so deep, the shock so intense, that it seemed almost useless to try to do anything except relieve the suffering. Recovery did take place, convincing us that while there is life in the body, no matter how severe the injury, our efforts may be rewarded with a life saved. In this class of burns, the constitutional symptoms are usually manifested very early. We may find our patient comatose, from cerebral congestion, with a speedy death. Often there is general congestion of the internal organs, especially the lungs and kidneys. *Albuminuria is always present.* During the intense inflammation, suppuration is active, and the sloughs are rapidly cast off, leaving an exquisitely sensitive ulcerated surface rapidly covered by granulation.

During the process of suppuration, the patient is apt to suffer from exhaustion, intensified by venous or arterial hemorrhage. The nerve centers, intestinal canal and kidneys are now liable to inflammatory changes. At this time, too, albuminuria is produced. This symptom, albuminuria, is not always noted by writers on burns. In this connection, Dr. Thomas George Morton of Philadelphia, says: "The early presence of albumin in the urine has long been recognized, but not so generally as might have been expected, for even quite recently systematic articles have appeared on the subject, supposed to cover the entire question, without a word having been said upon this important pathologic change."

Among the complication of burns, we have intestinal inflammation and ulceration, varying from simple irritation, with perhaps diarrhea, to the stage of ulceration and extensive destruction of tissue. The respiratory organs are often involved. Laryngitis following the inhalation of steam, with marked symptoms of edema of the glottis, dyspnea and intense pain. In burns of the neck and chest pneumonia and bronchitis are frequent complications. In addition to these there are the purely local complications, which include erysipelas, gangrene, deep sloughing and dangerous hemorrhage.

Among the most dangerous complications which can possibly arise, is that of a severe burn occurring at the same time that other injuries are inflicted. This is a condition of affairs which pertains almost exclusively to railway surgery. It is a subject on which the text-books generally do not even touch. No graver complications in emergency practice can confront the surgeon than that of a severe crushing or other injury such as daily occurs, complicated with an extensive burning of the surface of the body. The complication is made graver if, as not infrequently happens, there is considerable hemorrhage. In such a case the shock impression is greatly intensified and the probabilities are that the patient will speedily succumb. In any event it is the duty of the surgeon, however hopeless the outlook may seem, to take immediate and vigorous action with a view of saving or prolonging life. The question here would inevitably arise as to which form of injury most seriously threatens and consequently requires first attention. Steps to prevent further hemorrhage, attention to the condition of the heart and nerve centers, bringing about reaction from shock and removal to a suitable place for further attention, would seem to be the chief

immediate indications and perhaps in the order named. It is impossible to lay down definite rules for the guidance of the surgeon beyond these general considerations. Here, as elsewhere, his own good judgment, common sense and ability to apply quickly and correctly his knowledge must govern. The ideas advanced and rules of practice laid down in the management in this class of injuries by the older writers, are at the present day modified only to such an extent as our modern surgical practice has been changed by a better understanding of antiseptic, coupled with a better understanding of certain reflex nervous phenomena incident to traumatism of the surface of the body. As danger to life in burns of the first degree is in direct ratio to the amount of surface involved, so also are the congestions of the internal organs in large measure directly proportionate to the same cause.

This statement is not invariable or absolute, inasmuch as the danger to life due to these congestions, which not infrequently go on to an actual inflammation, are often very materially modified by the nervous temperament of the patient. A patient of marked nervous impressionability, susceptible to the immediate effects of pain, with a surface burn amounting to little more than an erythema involving perhaps half the surface of the body, if he does not die early from shock may subsequently die of pulmonary edema, pneumonia, bronchitis or some gastro-intestinal complication, death being directly traceable to inflammation of the mucous membranes of these organs, this in turn being directly due to paresis of the vasomotor nerves.

With reference to the treatment in these cases, too much stress can not be laid upon the importance of careful antiseptic. The wounds are always of necessity, when first observed, in a septic condition, and this applies with a special force when the subjects are train men engaged in the discharge of their duties. It is not sufficient to know that chemical antiseptics and germicidal lotions should be used. We must carefully discriminate as to the class of these agents to be employed in a given case. To illustrate, in a case which recently came under my observation, in which the patient's hands were both burned over the entire dorsal and palmar surfaces, the burns on each hand being of equal severity and involving the entire thickness of the integumentary covering, I tried the experiment of treating one hand with dressings of carbolic solution and carron oil, and the other with iodoform dusted over the entire surface after a careful washing with carbolized water. The recovery of the hand thus treated with dry iodoform considerably antedated that of the other. It would be obviously unsafe, however, to attempt this dressing in a burn involving a large portion of the surface of the body. A medical friend of mine, who is an ardent advocate of aseptic and antiseptic methods, recently killed a patient with an extensive burn involving the arms, neck and part of the trunk, by washing and afterward freely applying a bichlorid solution of the strength of 1 in 2,000.

The management of these cases involves many considerations. There is no department of practice which is more justly entitled to be denominated emergency practice than the management of the class of cases under consideration. We have to consider the prognosis not only with reference to life, but with reference to the probability of severe and lasting injury

to the nervous system in its relation to certain vital functions and also the probability of serious deformities, which may by prompt and rational treatment be wholly or in part averted, but which at a later period are extremely difficult to overcome. Of prime importance in the treatment is the necessity of making the involved portion as nearly as possible aseptic.

To accomplish this, the clothes having been removed in a warm room, all blebs should be punctured, shreds of clothing and other debris carefully removed; the surface carefully washed and mopped with some mild germicidal solution, preferably borosalicylic solution, or the standard Thiersch's solution, the whole carefully enveloped in multiple layers, first of borated lint and absorbent cotton, covered with rubber tissue, with either bichlorid or iodoform gauze, constituting the outer layers, held in place lightly by a few turns of a roller bandage. Among the newer remedies applicable in these cases there is one much vaunted and very justly so. I refer to euorphen, which may be used in the form of powder, gauze or a 3 to 5 per cent. ointment; with reference to the latter preparation (the ointment) while it is almost uniformly recommended, I seriously question whether its use is consistent with strict antiseptics. Euorphen has the advantage over iodoform of being non-odorous, practically devoid of danger from toxic effects and, according to some authorities, is better than iodoform in promoting rapid healing, especially in suppurating cases. The exclusion of atmospheric air is a *sine qua non*. This was accomplished by the older practitioners in the use of applications of oil followed by layers of cotton batting. Since the antiseptic era; we know that these dressings constitute a nidus for the harboring and propagating of the various forms of bacteria. For the relief of pain and for its action in sustaining the enfeebled heart the use of morphia and atropia administered hypodermically is perhaps the best remedy to be employed. The use of ammonia, brandy, strychnia and camphorated oil is recommended to stimulate the heart before reaction has set in, but in my opinion in a large number of cases the judicious use of morphia and atropia is most satisfactory. For the relief of pain in superficial burns the use of bicarbonate of soda in solution as a topical application is strongly advised and in many cases where more elaborate treatment is impossible this is *par excellence* the treatment to be employed. The dressings should not be changed too frequently unless the character of the case necessitates the employment of special measures, such as the application of silver to redundant granulations, stimulating applications to promote the granulating process, skin grafting, special posturing, the use of splints or other retentive apparatus to overcome a tendency to cicatricial contraction.

Thiersch's method of skin grafting is probably beyond comparison the best, when such means are indicated. One of the commonest mistakes made in cases of severe burns is the neglect to use the positive means within our power to prevent cicatricial contraction. The tendency to this contraction, especially in the flexures of the joints, should be constantly borne in mind. The great difficulty in overcoming a deformity of this character by operative procedure at a subsequent period, and the comparative ease with which the deformity can be avoided, justifies us in severely condemning the surgeon who from carelessness or want of proper knowledge allows it to occur.

It is true these contractions to some extent occur in deep burns, in certain localities, in spite of the most skillful attention which can possibly be rendered. Pains-taking care in the management of granulating surfaces, stimulating them when necessary, and hindering their too rapid growth, the transplantation of skin, fixing the position of the parts with a view to antagonizing the constant tendency to contraction, are all means which, when intelligently made use of, are calculated to get the best result. After the formation of a new skin, massage frequently and systematically applied together with a reasonable stretching are useful adjuncts.

In these cases constitutional measures should be adopted according to indications; this includes looking after the alimentary tract, the nervous system, the use of general tonics, good food, bathing and outdoor exercise as soon as permissible.

The prognosis in cases of burns and scalds varies with reference, 1, to the degree and extent of the injury; 2, with reference to the age, sex and individual peculiarities of the patient, together with the manner in which the accident occurred; and 3, the surroundings of the patient during the progress of treatment, the time when the first assistance was rendered and the intelligent application in detail of approved methods.

A CLINICAL STUDY OF THE SABULA FOOD POISONING EPIDEMIC.

Read before the Iowa State Medical Society, Marshalltown, May 21, 1897.

BY A. CRAWFORD, M.D.

MILES, IOWA.

The most extensive and serious outbreak of food poisoning ever recorded in the history of Iowa, occurred in the eastern part of Jackson County, in the fall of 1895. On September 11, at a farmhouse three miles from Sabula, there assembled about three hundred guests to witness a marriage ceremony and partake of the good things provided for the occasion. Within a few weeks thereafter, over one-third of the entire company were sick and seven deaths had occurred.

That the disease had its origin at the wedding, could not be doubted, as there was absolutely no serious sickness among the scores of families who were not present on that occasion, nor had the health of the community been better for years, than during the month preceding the epidemic. The house at which the wedding occurred is well located, and there is no history of disease having existed there for many years. The water supply was drawn from a deep well drilled in the rock and so located that drainage or surface water could not contaminate it. The well was in constant use by the family and servants, while all remained in their usual health until after the wedding. An effort was made to show that the disease had been carried to the wedding by some guests from a distance, and that the crowded rooms and heated atmosphere favored the rapid spread of the virus. That it was not thus carried is shown by the following facts: 1. No such disease existed at the home of any of the guests. 2. No case occurred among the scores who were engaged in caring for the sick, during the five weeks following the outbreak, excepting such nurses as had also been wedding guests.

At the beginning of the sickness, the writer was strongly impressed with the idea that the food was the source of infection, and as his investigations advanced,

he became fully convinced that such was the case. When the first few cases were seen, it was thought we might be dealing with a late manifestation of ptomain poisoning, but as the cases continued to come down, this theory was seen to be untenable. It soon became evident that the disease was the result of the ingestion of food infected by some pathogenic micro-organism, the exact nature of which was yet to be determined. No examination of the food could be made, as the first cases did not come under observation until one week after the wedding, but the testimony of the guests was such as to convince the most skeptical that the meats were not in prime condition. The ham was served in sandwiches and, I have reason to believe, was thoroughly cooked. The turkeys were killed the day preceding the feast, some of them were cooked the same day they were killed, while others were kept in the cellar until the next day and then baked in the oven. The chickens were killed the day preceding the wedding, cooked in the usual manner, and as soon as cool enough to be handled, the meat was removed from the bones, chopped, and placed in common earthenware jars. These jars were set on the cellar floor, and allowed to remain there until brought up to be served, more than twenty-four hours afterward. The servants state that no ice was used about the meats, and that the cellar was badly infested with flies. The weather was extremely hot, the mercury ranging between 90 and 100 degrees F. The pressed chicken was too soft to be sliced, so when served had to be dipped out of the crocks with a spoon. That the chicken was undergoing decomposition, the following letter from one of the guests, a man of unquestioned veracity, would seem to establish beyond doubt: "Dear Sir:—The general, and I think I may say the universal, comment here is decidedly against the food, and I believe that most of them would so testify on the stand. My own experience is this: I put a piece of the chicken, or at least what I supposed was chicken, into my mouth and it was so absolutely filthy, slimy and putrid to the taste that I spit it out and ate nothing else." I might add many more such statements, coming from the most reliable people in the community, including the officiating minister and his wife, but this is unnecessary. That some of the guests detected nothing wrong with the meat, I am free to admit, and the only explanation that can be offered is, that it was not all equally bad. A few of the sick denied having eaten any of the meats, but these exceptional cases may be explained by the contamination of other articles of food or drink.

An effort was made to direct attention to the ice-cream as the probable source of infection, but a careful investigation failed to sustain this claim. The cream was furnished by a vendor in Sabula, and as only a part of the quantity prepared was sent to the wedding, the remainder was disposed of to parties in the town, all of whom remained well.

A peculiarity of this epidemic was the great variation in time between the ingestion of the food and the first symptoms of disease. A careful study of forty-five cases, most of which were under the writer's care throughout the entire period of their illness, gives the following data: Of the cases, 50 per cent. came under observation between the fourth and tenth day after the wedding. Almost all of these began to feel ill on the fifth or sixth day, but many of them were able to continue their vocation for a week longer. Three taught school for a week after the first symp-

toms appeared. Between the tenth and twentieth day, 30 per cent. more came down, while the remaining 20 per cent. continued in their usual health until between the twentieth and twenty-eighth day. Those that became ill during the third and fourth week, were apparently as severe cases as those that were taken sick earlier. In 75 per cent. of the writer's cases, the highest temperature was reached on the first or second day after coming under observation. The average temperature, when first seen, was 102.8 degrees F. The highest temperature reached was 105.4 degrees F. The average duration of the fever was eighteen days from the date of the first visit. The mildest cases were feverish for a day or two only, while in the most severe cases the temperature did not reach normal for forty days. Over 20 per cent. of the sick were not confined to their beds, but assisted in caring for those who were more seriously ill. A few of the mild cases were apparently as well as usual in ten days, but the larger number remained weak and miserable for a much longer time.

The appearance of the tongue varied in different cases, and in the same case at different stages of the disease. In most there was a heavy white coating; in others it was brown, while in some it was denuded of epithelium, and was dry and cracked. Of a few patients, the tongue was so swollen as to make speech difficult. A fecal taste was complained of in some, and I found patients scraping the tongue with a knife to get rid of this very offensive symptom. Vomiting was present in 50 per cent. of the cases, while it was very persistent and troublesome in about 10 per cent. Diarrhea was present in about 30 per cent. of my cases, the passages being mostly of a greenish color and a very offensive odor; but constipation was the rule, and laxatives or enemas were often called for. Tympanites was not a prominent symptom and in but a few cases required treatment. Hemorrhage from the bowels was not met with in any of my cases. Epistaxis was noted in 18 per cent. A rash was present in six cases out of the forty-five. In three of these, only two or three spots were discovered, while in the others the rash was more abundant and characteristic. Profuse sweats were a striking feature of the disease, and the odor was so extremely offensive that frequent changes of clothing were necessary for the comfort of the patients. In 15 per cent. of the writer's cases, delirium was present, but in most of the cases it was of a mild character and of short duration. In the fatal cases, this symptom was constant toward the last. No serious pulmonary complications occurred, and only in a few cases was cough a troublesome symptom. Pain was the most prominent symptom in 75 per cent. of the cases. Some patients located their pain in the region of the umbilicus; others suffered but little from abdominal pains, but intensely from pain in the muscles of the extremities. The writer saw cases where the arms were almost as useless as if paralyzed and were exceedingly tender to pressure. In one instance, he found the patient with mustard drafts upon the forearms, so intense was her suffering. Swelling of the muscles was noticed by some. Dr. Pettit of Cedar Falls, who had two of the victims under his care, reported such a case to the writer. Hypodermics of morphin were necessary to control the pain in a number of cases.

The mortality was 6 per cent. All the fatal cases were under 30 years of age and four were between 14 and 20. Two deaths occurred in the third week, three

in the fourth, one in the sixth and one in the seventh. The last death was from perforation of the bowels. There was evidence of profound toxemia in all the cases that proved fatal.

In two cases postmortem examinations were made under the supervision of the President of the State Board of Health. The first body examined was that of a girl of 14 years, who died about the end of the third week. The following is a brief history:

L. W., aged 14 years. Always enjoyed good health. She was taken sick the fourth day after the wedding but continued in school a week longer. She consulted me six days after she began to feel bad, when I found her temperature 103 degrees, pulse 134. She complained of very severe pain in stomach and bowels; pain in eyes; general aching; nausea, etc. Between this and the date of her death sixteen days later, the temperature ranged between 100.2 and 104.2 degrees, often fluctuating 2 or 3 degrees in twenty-four hours, but with no regular curve. Constipation continued until the last week, when a very troublesome diarrhea set in. The passages were of a slimy character, green color and very offensive odor. Hypodermic injections of morphin were necessary to give relief from the severe abdominal pain. The immediate cause of death was progressive heart failure, the result of the profound toxemia.

At the postmortem examination the heart and lungs were found to be in a normal condition. The liver was decidedly enlarged, soft and lighter in color than usual. There was some enlargement and softening of the mesenteric glands and ulceration and softening of the cecum. The mucous membrane of the colon, for three inches below the cecum, was found to be injected and softened but showed no ulceration. The kidneys were healthy; the spleen enlarged, softened and very friable. The stomach presented evidences of inflammation throughout, but no ulceration. The duodenum was normal in appearance and pancreas healthy.

Portions of the various organs and of the muscular tissue were sent to the State bacteriologist and to Chicago for microscopic examination.

The second case was that of a young man of 18 years of age, who had been sick for six weeks. During the third week his temperature declined to a point but little above normal, and it was thought that he would soon be out of danger. A severe nervous shock occurred at this period, and his temperature soon rose to 104.2 degrees and continued high until death. Early in his sickness he suffered considerably, but after the relapse he did not complain of anything. Delirium of a mild character continued during the closing weeks.

The postmortem examination showed the heart and lungs to be in nearly normal condition. The liver was enlarged as was also the spleen. The cecum and colon were ulcerated throughout their entire length, but there were no perforations. In the small intestine there were patches of inflammation but no ulceration.

Sections of the muscular tissue and of the various organs were sent to the State board, to Dr. Le Count of Chicago and to Dr. Hildreth of Cambridge, Mass., for microscopic examination.

The report of Dr. William Royal Stokes of the Boston City Hospital, who examined the specimens sent to Cambridge is very full and complete. His anatomical diagnosis is as follows: Typhoid fever; broncho-pneumonia; general infection with the pneumococcus. This report is in harmony with that made to the State board by Professor Bay. Dr. Le Count reported embryonal trichinæ, when the specimens from the first case were sent him, but undoubtedly failed to find confirmatory evidence from his examination of the second, as he made no report.

Late in the fall the writer treated ten cases of typhoid fever, all of which occurred in families where one or more of the wedding victims resided. Nine of the patients were taken sick between the sixth and ninth week after the outbreak, at a time when nearly all of the other sick were convalescing. All these were typical cases of typhoid—no symptoms being wanting—and were in striking contrast to a similar

group of the wedding victims. But two cases were seen outside of these homes, during the succeeding six months, so that no doubt could exist regarding the source of infection. If we accept the conclusion, that the malady was typhoid, we must admit that it was a very peculiar manifestation of the disease. One of the leading physicians of Clinton treated three cases as remittent fever. Two other physicians, after seeing a number of cases, independently reached a diagnosis of trichinosis. Dr. Le Count of Chicago assured the writer there could be no doubt about the epidemic being one of trichina poisoning. Dr. Pettit of Cedar Falls had two cases under his care and reached the same conclusion. Two of the local physicians made a diagnosis of relapsing fever, while others preferred to wait until the evidence was all in before making a positive diagnosis. Some of these physicians have treated scores of cases of typhoid during the past twenty years, and it seems strange that they failed to recognize the nature of the malady. If the specific bacillus of Eberth is insisted on as being essential to the production of the disease, it remains and must ever remain a mystery, how the meats became infected therewith, as there had not been a case of enteric fever in the community for nearly a year prior to this outbreak.

The treatment, it is needless to say, was determined largely by the diagnosis.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
BY CARL H. VON KLEIN, A.M., M.D.

VII.—THE RISE OF GERMAN SURGERY UNDER AUGUST
GOTTLIEB RICHTER.

(Continued from page 1078.)

No other German physician's style compares with Richter's; not one of them writes so beautifully, represents so clearly and instructs in such an amiable manner and with such a brilliant manner as Richter. He holds the reader so spell-bound that he can not stop. In his classic representation, clearness of expression and freedom of judgment he far surpasses his contemporaries. Later writers, like Dieffenbach and Stromeyer, can scarcely approach him. What he desired is contained in the preface of his work on "Ruptures," in which he says: "I wish to write a book which comprises the entire sphere of the art of surgery in a compact, but complete, explicit and concise form, a book void of all learned adornment, simply useful and for the express purpose of a surgeon, a book as simple as nature. It is much easier to talk scientifically than to converse on experiences. My intention is not to appear learned, for I am not writing for the learned, but exclusively for practical surgeons, wishing to be useful, instructive and plain to them. Greatly do I desire that there be not a single page in my book from which the practical surgeon can not learn something of use at the bedside of the sick." When, seventy years later, Dieffenbach published his "Operative Surgery," he extolled Richter's style by exclaiming: "Would that mine were such a book as his!" We press Dieffenbach's hand for the glowing tribute he accords his old friend, Richter. He, the genial operator, who recognized the best sur-

geons only by the clearness of their ideas and the simplicity of their presentations—for the best surgeons have ever been the best writers and are known by their style—thought Richter's writings worthy of being used as model lessons in the schools. In ingenuity and explicitness he found no German surgeon who could equal Richter, and thought his doctrines and principles still formed the foundation of German surgery; and everything that he wrote, as well as the style of his writings, he considered unexcelled, least of all, the art of presentation. Even when advanced in years, Richter wrote with genial ease and certainty, nowhere to be found in other works, so that Kurt Sprengel, in the year 1805, remarked: "Who of us medical writers living has ever attained Richter's style of writing, to say nothing of excelling it?" There was no trace of learning by citations. The histories of the bedside were brief and contained only the most essential parts, for nothing was more tiresome and boring to him than a dry, lengthy statement of a case, with all the minor uninteresting points; on the other hand, he always expressed his reasons therefor. His penmanship was elegant.

In duty bound to German surgery, we will review *Richter's Complete Works*, but will not, however, give an account of the contents of all of them, as they will again appear later. Nearly all of the short articles were published in Latin in the Commentary of the Göttingen Society of Sciences, but could be obtained in German by the public in general in the surgical library.

1. *De prisca Roma in medicos suos haud iniqua*. Doctor dissertation. Sept. 12, 1764. Six sheets. In it the assertion of Plinius is refuted that Rome was without physicians for 600 years, as well as the later assumption that this circumstance must be considered as a proscriptio instigated by Cato, who hated the Greeks and their physicians. Since Cato's time physicians were plentiful, although they possessed but little knowledge of science.

2. *Casus medicus intumescens et callosi pylori cum triplice hydropo*. Four sheets, one copperplate. October 1, 1764. The pamphlet contains the description of a cancer of the stomach of a deceased patient, and of the section showing the condition of the part affected: nothing else of importance.

3. *Varias cataractam extrahendi methodos succincte exponit* are the introducing words of his address as professor. Three sheets, one copperplate. 1766. Richter upholds Daviel's idea (1745, described 1753) of removing cataract by extracting the lens, and gives the advantages of this method over that of pressing down the same, which is more successful only when the eye lies very deep in the socket and is very movable.

4. *De dignitate chirurgiæ cum medicina conjugendæ*. Lecture held Oct. 11, 1766.

5. *Operationes aliquot, quibus cataractam extraxit, describit*. Eighteen pages. This work, written for his uncle's 75th birthday (Feb. 4, 1768), records the cures by extraction, of two patients afflicted with a cataract.

6. *Observ. chir. Fasciculus I continens de cataractæ extractione*. Göttingen, by Dieterich. 1770. 158 pages. (Chir. Bibl. I, 157). In the same are thirteen chapters on the method of the operation, means of making the eye firm, a knife for making an incision in the cornea, how to cut through the capsule, the extraction of the lens, the adhering cataract, prolapse of the vitreous humor, affections of the pupil, callous cataract, ripe and unripe cataract, conditions after the operation; besides this, ten observations.

7. *Obs. de bronchotomia et de herniis*. In *N. Comment. R. Soc. Gott. T. II.*, p. 54, read Aug. 3, 1771 (Chir. Bibl. III, 328).

8. *Chirurgische Bibliothek*. Fifteen volumes. Göttingen, by Dieterich 1771-1797. With two volumes by Dr. Witting, giving index of names and table of contents. Translated into the Dutch language by Professor Jacobs. It is not easily comprehended now-a-days, what great influence this journal exerted toward the perfecting of German surgery. Everything new and the best possible that appeared in England, France and Germany, was offered in part to our countrymen, very minutely described and bound in a handsome cover. England is represented by some of her best talent, among them: B. Bell,

Bromfield, Cheselden, Else, Gooch, Hill, Home, W. and J. Hunter, Kirkland, A. and D. Monro, Park, Pott and White. Among the French we find Chopart, Desault, Demours, Deschamps, Levret, Louis, Morand, Petit, Percy, Sabatier and Saviard: from other foreign countries, there were Acrel, Camper, Scarpa and others. Besides these the journal contains clippings from the best foreign journals; the transactions of the Parisian Académie des sciences, the Académie de Chirurgie, of the Academies of Vienna, Dijon, Sweden and of the Society of Physicians in London; then there are accurate extracts from the Philosophical Transactions, Medical Transactions, from the Journal de Médecine and many other things. We call special attention to the fifth chapter.

9. *Obs. de morbis sinuum frontalem*. In *N. Comm. T. III.* p. 85, read April 4, 1772, (Chir. Bibl. III, 337).

10. *Treatise on the Extraction of Cataracta, with copperplates*. Göttingen, by Vandenhoek, 1773, 216 pages. The former Latin writings are made the basis, but considerably augmented and improved. This work is of great value in-as-much as the German surgeons have been won over to perform this operation, which had almost entirely been banished from the science of surgery and left to the wandering oculists. It was hard for them, though, to begin at a time when the laity, as advertised by the charlatans, who always promised the best results with the greatest assurance, was accustomed to demand the successful issue of an operation at the hands of the surgeon, a matter which seemed to depend on him alone, and every unsuccessful operation was thought due to his unskilfulness.

11. *Obs. de amaurosi*. In *N. Comm. T. IV.*, p. 77, read Feb. 6, 1773 (Chir. Bibl. III, 344.)

12. *De opportuno herniotomiam peragendi tempore*. In *N. Comm. T. V.* p. 56, read May 14, 1774 (Chir. Bibl. III, 354.)

13. *Obs. de staphylomate*. In *N. Comm. T. VI.*, p. 57, read March 18, 1775. (Chir. Bibl. III, 634.)

14. *De herniis incarceratis*. In *N. Comm. T. VI.*, p. 67, read December 9, 1775. (Chir. Bibl. III, 634.)

15. *Obs. Chir. Fasciculus, II.* Göttingen 1776, 134 pages, contains works published heretofore on the following subjects: Hernias, cirsocele, tracheotomy, diseases of the nasal cavities, amaurosis, staphyloma. The chapters on the extraction of cataracts and polyps are new. (Chir. Bibl. IV, 312.)

16. *Obs. de pterygio*. In *N. Comm. T. VIII.*, p. 50, read March 8, 1777 (Chir. Bibl. IV, 486).

17. *Treatise on Fractures, Part I, 1777. Part II, 1779.* Göttingen by Dieterich, with copperplates. Dedicated to King (George III. (2d edition 1785; 792 pages.) Being a young man Richter did not dare to come forward with a text-book on surgery, but wished first to make a test of his power with this work. It was ranked with the best and caused scientific surgeons to attend to ruptures instead of the ignorant barber surgeons. Dieffenbach very truthfully remarked on this work: "His book, now yellow with age, contains a wealth of experiences, and, indeed, his style of presentation has no equal.

. . . it is a wonderful book and his most valuable production; what he describes, it seems as if you could see it in reality before you." In spite of these great merits, we must confess that principally the practical side of this branch was developed, of course, so completely, that later on but little was added, but neither anatomy was sufficiently considered, nor self-research noted in it, which fact Richter modestly confirms. He relied mostly on the works of Arnaud, Petit, Louis, Morand and Günz. This book established his fame abroad. In France it became known by Professor Rougemont's translation, was highly prized by Desault and B. Bell, as well as warmly recommended in their lectures.

18. *Herniam incarceratam una cum sacco suo reponi per annulum abdominalem posse, contra chirurgum Gallum cl. Louis monet 1777.* (Chir. Bibl. IV, 559.)

19. *Report on Professor Siebold's cutting through the symphysis pubis according to Sigault in case of serious childbirth.* Read February 21, 1778. (Chir. Bibl. IV, 578.)

20. *Obs. de fistula lacrymali in Comm. T. I.*, p. 100, read May 9, 1778. (Chir. Bibl. V, 261.)

21. *De agarico officinali*, Progr. 1778. (Chir. Bibl. V, 698.)

22. *Obs. Chir. de cancro mammarum et cataracta*. In *comm. T. II.*, p. 25, read Feb. 20, 1779. (Chir. Bibl. V, 517.)

23. *De fracturæ cranii*. Progr. 1780. (Chir. Bibl. V, 701.)

24. *De remediis antiphlogisticis externis*. Progr. 1780. (Chir. Bibl. V, 709.)

25. *Obs. Chir. Fasciculus III.* Göttingen 1780, 111 pages. Contains a chapter on pterygium, fistula lacrima, cancer of the breast, on rare diseases of the breast, cataract, agaricus, and on skull fractures, use of exterior antiphlogistic methods. Most of the above chapters had been issued in separate copies. (Chir. Bibl. V, 697.)

26. *Obs. chirurg.* In *comm. T. III.*, p. 25, 1780, contains

chapters on amaurosis, fractures, atresia of the vagina, hare-lip, ptosis and pressure on the skull.

27. *Elements of Surgery*. Seven volumes with 45 copper plates, Göttingen by Dieterich, 1782-1804. This work, begun at a time when Richter had already taught and practiced surgery for fifteen years, was of the greatest importance to German surgery and in the arrangement and representation of the material no other could come up to it. This book was to form a mean between the useless brevity of a compendium and the prolixity of a treatise which went into the minutest details. Fractures and luxations have been omitted and of the instruments; only the most useful ones and least known are illustrated. The book was used by all the physicians and surgeons, from new editions published and translated into various languages, viz.: into the French by Morel, the Italian by Brera and Volpi, and into the Russian by Peken according to an order given by the Imperial Medical College.

28. *Medical and Surgical Notes* Especially made at the Public Free Academical Hospital. First volume (with one copper plate and seventy-one histories of patients. Göttingen by Dieterich, 1793, 315 pages. Reprinted in Linz in 1794. Translated into English by Thomas Spens.

29. *Surgical Meditations*. In Loder's *Journal of Surgery*, Vol. i, 1797. Cases of sphacelus, hernia and tumor of the stomach.

30. *Historia aegrotorum quorundam*. In *Comm. T.* xv, p. 29, read Feb. 21, 1801.

31. *Obs. de phthisi pulmonali operatione chirurgica sananda*. In *Comm. T.* xvi, p. 3, read March 9, 1805.

32. *De usu purgantium in febribus nervosis*, read April 28, 1810.

33. *Medical and Surgical Notes*. Vol. ii, 1813, 178 pages, Berlin. A posthumous work published by his son George August Richter.

34. *Special Therapy*. Twelve volumes, 1813-1836, Berlin. A posthumous work, published by his son, G. A. Richter. (Translated into Latin by Wallroth.) This work is not entirely the father's inasmuch as the son made various changes, but did not set apart his additions and so there are parts that clash with the elder Richter's views.

Richter was the best teacher of surgery in Germany. Although he founded no institution, probably on account of the lack of surgical material in Göttingen, still whole generations of physicians owe the basis of their education and intellectual bearing to him. There was not a single important city in Germany that did not contain one of Richter's pupils within its environments. His teaching talent was unapproachable. To believe this assertion we must abide by the judgment of his most prominent contemporaries (Blumenbach, Mitscherlich, Himly and Stieglitz). From the beginning of his career, Richter exhibited a great talent of expressing and explaining the deepest things in the simplest and clearest way. With a dramatic skill peculiarly his own, he pictured the whole course of a disease and knew how to revert the young minds ever tending toward hypothesis to simplicity, nature and experience. To every one, the disease on which he discoursed became plain; most masterly the symptoms and course were delineated, particular stress being laid upon the embarrassments of the physician and on the difficulties of treatment. Richter's principal aim was to dwell only on the practically useful doctrines. The effect of his very animated deliverance, yet free from all gestures and any affectations whatsoever, is said to have been extraordinary. The students were lost in admiration; even when less interesting subjects were presented they showed no fatigue and left the lecture and clinic highly satisfied and confident of being able to help themselves when placed in tight places at the bedside. Even those who had been educated at other universities and practiced in large hospitals, considered themselves here transported to the pure source of practical knowledge. On account of this real practical aim, no one did more than he to cause students to throng to Stoll's clinic in Vienna and young physicians to travel to London

and Edinburgh. Even if he was charged with neglect of demonstrating operations on cadavers, for which, however, the facilities were scanty, he had a greater chance to display his wonderful teaching power; the most difficult operations he made clear and apprehensible by means of a strip of paper or a chalk line. With a few bones on the desk before him, he would present a subject so graphically that all could grasp it like a vivid picture and he always had a large audience, while his colleague, in spite of expensive preparations, had but a few listeners. Richter took care not to establish a general set of maxims, because he knew that a single case might overthrow the theoretical structure, which had been founded on so many preceding cases. Self-sufficiency, bold, common assertions and authoritative decisions which he considered a reliable proof of ignorance, were repugnant to him; the experienced physician is often uncertain and undecided and only in the study-room and in the shop of the quack is he sure of his art. He frankly acknowledged it when he discovered a former idea to be incorrect; he knew that we often err, when we believe ourselves to be most certain. "I am liable to make a mistake, no matter how carefully I have searched for the truth; but I promise my readers, that if I detect any errors as I proceed, I will be the first one to rectify them." Richter was contented to work in a small sphere; although his hospital contained only fifteen beds he wanted no more. His principle was, "that not the number of patients make a practical experienced physician and that it does not depend upon seeing the sick, but to observe them. Strength does not come from eating, but from assimilating. One case thoroughly studied is worth more than 150 hastily glanced at; nature is not complacent enough to show herself naked to any one who casts a superficial glance at her." Richter proves, that highly talented natures do not require a great quantity of material to achieve much. Dieffenbach thought of him: "No one ever saw with better eyes in so limited a space and no one ever expressed in a more fitting way what he saw." How keen Richter's observation was, even when a young man, is shown by the following instance of ophthalmology: In a case of amaurosis he saw the retina several times in the white background of the eye and plainly discerned here and there red blood vessels and spots. This phenomenon he soon perceived on the entire retina and then again on only half of it.

Some of his contemporaries criticised Richter because he disregarded certain branches considered indispensable now. The proof for this criticism, Blumenbach and others succeeding him found in the following passage taken from the *Surgical Journal* (vii, 131): "A knowledge of polite literature is in nowise essential to the surgeon, and may be very detrimental to him if he takes the time of his solid occupations and devotes it to the study of polite literature, and moreover, it forms a convenient screen for the blockhead. When it became the fad among the medical writers to adorn their works with quotations of ancient Latin and Grecian poets, science was almost at a standstill. The best Latin scholars among the physicians were from the beginning not the best practitioners. Not he who reads much, but he who thinks much, will be a good practical physician. A great mass of undigested facts obtained from books is a positive detriment to a practitioner." To credit Richter with this passage is wrong, because it then represents a repro-

duction of the Englishman, Kirkland's, views. But taking for granted that Richter did fully coincide with them, it is essential to have read both his own and his colleagues' writings in order to understand that when he flourished his whip he had a right to do so, although his derision was at times exaggerated and consequently misinterpreted. With a certain amount of eagerness the great untalented mass magnifies the slightest errors on the part of these great men until they assume the proportions of huge sins, while their accomplishments are thereby forgotten and dwindle away. Richter may not have been learned according to the opinion of his times. We certainly consider him a most highly cultivated surgeon, for he was master of the entire literature existing then, as verified by his *Surgical Journal* and his work on the "Principles of Surgery." He was as proud of resurrecting an old forgotten truth as to discover a new one; even if he himself reaped no fame, science was nevertheless benefited. Just vice versa was the case with the great discoveries that were born daily and died daily; a new instrument or a new operating method did advertise the name of the inventor, but often did not promote the science of surgery. For one to be able to write a truly valuable text-book Richter thought he ought not only to be an experienced and intelligent surgeon and a well-versed author, but also a "very learned" surgeon who is thoroughly familiar with the whole science of surgery. He never neglected to preface his lectures with a list of the best works on the subject in question. But he hated all vain learned ostentation and considered the so-called literature of the ancients mere finery, that everybody could acquire who would sit down a few hours and select that which best suited his fancy. Thus originated his ironical remarks in some of his critiques; for instance, of Percy's work on the "Scissors": "It is impossible to penetrate the dense obscurity which shrouds the origin of the scissors (What a pity!) An impenetrable cloud covers that period when these instruments were first used in surgery (Sad! however, a piece of work for our medical antiquarians). Hippocrates, who mentions sounds, lancets, needles, forceps, hooks, etc., does not say a word of any scissors (It is deplorable!)." It was indeed wrong for him to occasionally sneer at botany, minute anatomy and physiology; for instance, he thought "that the anatomist was seldom able to follow the courses of the acids and foods through the system, and if in pathology nothing were permissible but what was approved by the anatomist, then very little would be done." Also it was wrong that he manifested no interest in some theoretic investigations, as the microscopic investigations of pus and blood, which, being too theoretic, he considered of no value or practical use; neither the knowledge of the spontaneous cure of aneurysms, because on account of its rare occurrence it could not be depended upon and no means existing to produce it. Whether he used a microscope at times has not been divulged. As an excuse for him we might say that physiology then was not closely allied to practical medicine and had not been blended with it. For years, Richter perceived that his uncle's vast amount of knowledge was of no benefit to science; and Baldinger, his well educated colleague, was so crammed with knowledge that he did not know how to use it, except in publishing a medical journal and recommending it to his pupils. (Once he published in the same the music of the four "Ranz des Vaches" as an important therapeutic measure to use in cases of

homesick Swiss patients!) Baldinger, inclined to be rather talkative, often imprudently railed at Richter's studies and thought that, beside theoretic subjects, especially the lectures of old physicians, of which three excelled all others and which he presented as the most important types of that century—namely, Uncle Richter, his colleague Brendel and Professor Triller of Wittenberg—should be brought to the notice of young medical students. No wonder that Richter, a man possessing real practical talent, who had harvested the fine crops of practical surgery in England and in France, not only ridiculed the immense learning of Baldinger, for whom he had no sympathetic feelings, but, smiling in a self-conscious way at the honorable position he had attained in the two great sciences, surgery and medicine, he disdainfully remarked on his colleague's works. His judgment on the auxiliary branches of science was often more affected than a true issue of his convictions, mostly caused by Baldinger's low scoffing. Even if he tended more toward practical medicine instead of theoretic topics, he was well versed in most of the auxiliary sciences, which were indispensable to him when court physician, and often asked advice of his colleagues concerning points unintelligible to him and new discoveries in the same. His son as well as other students he advised not to neglect these studies, and was greatly pleased when they passed a good examination in them. How greatly some failed to appreciate the extent of Richter's learning is shown by the following example: Some one asked a student where the artery could be pressed together in case of the exarticulation of the upper arm, and was surprised to receive the correct answer, believing that Richter was not capable of teaching such knowledge. With him there was nothing like one's own experience: "Thirty pounds of argument do not prove as much as one grain of absolute experience. . . . It is unpardonably bold to oppose experiences on theoretic grounds. The most improbable, incredible occurrence is occasionally true, the most convincing argument false. Experiences must be disproved by experiences." Once when a by-stander defended from experience a dental instrument displeasing to him, Richter complacently listened to him and frankly acknowledged that he had no experience in dental operations. It is not without interest to note that the same criticisms which Richter's contemporaries often passed unjustly upon him, regarding the auxiliary sciences, also befell Desault. Also his taunts on unfruitful learning have been misunderstood by many of his pupils.

Richter was an excellent physician as well as surgeon. Thus he confirmed his oft-repeated assertion that no one can be a fine surgeon who is not also a physician. Whoever saw and heard him at the bedside hesitated which most to admire in him, the penetrating physician or the operating surgeon. Yet Richter was incapable of giving a new rise to the medical sciences, although at that time, when he was more engaged in the practice of medicine than surgery, that science was in a deplorable condition and he had to ask J. Hunter, who had not yet received his degree of surgeon, to demonstrate the theory of inflammation and phlebitis. Richter even occupies a lower round of the scientific ladder as a physician than a few of his contemporaries, the Hanoverian Wichmann, for instance, who asserted that a careful and accurate diagnosis was the main thing, while Richter claimed that general therapeutics should be the physician's guide.

The special conditions were a matter of little consequence to him, because a physician can often successfully treat a case according to its general nature, and in the practice of medicine the important feature is the skill to generalize.

On the whole the diagnosis of all diseases is the *non plus ultra* of science and a perfect diagnosis therefore an unattainable ideal; but the practitioner may console himself that he can now and then successfully and absolutely cure diseases without having made a special diagnosis. Both volumes of his "Medical and Surgical Notes" prove Richter a physician. His models in medicine were the English and Schroeder of Göttingen, but particularly Stoll of Vienna, whom he respected most highly. In revising his "Therapy" some of his achievements for medicine were: The introduction of opium in various diseases and the administration of tartar emetic in small and frequent doses; he also restored purgatives to their rights, recommending them in nervous fevers, restricting them in gastric fevers, etc. He in nowise disdained household remedies and preferred to accept a medicine from a peasant than from an empirical physician. He hated unnecessary hypotheses and systems, which changed so frequently in medicine, for which reason he did not prize that science as highly as the more positive one of surgery. When young, he thought more "of the surgeon, with knife in hand, resolute and confident of his art, than the doctor, with pencil in hand, doubtful and irresolute." He then believed that: "All in all, medicine had done as much harm as good," being based mostly on conjectures. Free from all prejudice, he made his observations regardless of any system and thus we are enabled to see things just as we wish to see them. The period during which the systems held full sway were considered by him the most unfruitful for practical medicine. His opinions on the same appear in connection with the following article on "The Human Intellect," a sample of Richter's graceful literary style:

On the Human Intellect.—It is surprising how different the susceptibility of the intellect is in comparison with reason and proofs. Upon one person a proof makes a deep impression, on another none whatever. It is with the internal senses as with the external. One considers something beautiful, the other does not. Do we ever find three people agreeing on the resemblance of a portrait?

Indeed, the same person at one time may be convinced of a matter, while at another time he will laugh at the same; thinks something beautiful today which at some other time he thought ugly.

What nonsense people have believed since the beginning of the world; and not weak ones either, but very sensible people. I might declare that there is not a single sensible person who does not believe something which another sensible party ridicules.

We now consider ourselves very wise, but our descendants will surely wonder how we could have believed so much non-sensical stuff.

It all depends upon the first impressions, the habits, preconceived opinions, passions, physical and moral dispositions, etc. Poor human intellect! How can we depend upon you?

There are established facts which no one can doubt. Three times three are nine. Everybody in Europe, Asia, Africa and America believes that. But few of such truths are found in medicine. In it we have mostly possibilities. And so the wrangling in medicine will likely never cease. But about what are physicians wrangling? Let the philosophers do as much quarreling as they please, not even a crow would be disturbed thereby. But the contests among physicians are on life and death (Med. chir., Notes ii, p. 1).

On systems in medicine.—For some time the system trade has been flourishing among German physicians. Regarding this business we Germans are still hucksters. The English rid themselves of their damaged goods by sending them to us; we brush them up a little, sell them as the latest styles and the

English laugh at us. This at least was the case with Brown's system.

It is, however, a very easy thing to manufacture systems. To make investigations, to discover new truths, to promote science requires brains, talent and effort. Systems, however, as they are now in circulation, can be arranged in the smoking room over a pipe of tobacco and then cleaned out.

Surely he does not know nature who spends his time making systems. Therefore I always consider him a very narrow-minded person who makes systems. That is the reason why all young beginners like systems.

There is also a little advantage in the manufacture of systems. We believe him who builds a house a more skilful artisan than he who hews only a stone or a timber for the same.

But what constitutes a system? I think that any one who wishes to arrange a system must necessarily, 1, be able to explain all the functions performed by the human body; 2, the effects of the medicines on the body, and 3, be thoroughly familiar with the nature of the disease. Unfortunately, we know very little of all these things. Hence, is it not madness to construct a system? Is it not like one who attempts to build a palace by putting together a few stones and some pieces of wood? Truly, to write coherently on matters of nature is next to a physical impossibility.

Thus is explained the feeling of the system-manufacturers that there is always something lacking here and there. Every one helps himself as much as possible by erecting and patching, the one in one way and the other in another; and finally each one has manufactured a system of his own, clashing with that of his neighbor.

But all patching and propping is of no avail. The first gale will blow the little structure over. So many of these little huts have been wrecked, that I should imagine they would get tired of building them. No system has been more extensively published than Brown's; and stood but a few years when it began to show cracks above and below.

The harm done practical medicine by this mania for systems is unlimited. But as long as the system remains confined to the study rooms, it is comparatively harmless. If applied at the bedside, though, its effects may be terrible.

This system mania has become very general, consequently, on the whole, a very bad thing.

Everyone tinkers at and patches his own system; not one concerns himself to increase the amount of useful truths, the chapter of remarks on human nature. It may be boldly said that for several years no good medical book has appeared in Germany. Bacon of Verulam says, that as soon as a science is begun to be treated according to systems, only little is generally achieved.

Also on the physician, the system mania has its evil effects; it produces *self-sufficiency*. He sits in his own room and explains everything according to his own satisfaction and conviction; and believes everything correct for which he finds his own explanations. Note the language used by these physicians in their writings; how boldly they contradict, how positively they assert, how fearlessly they articulate, how imperiously nature is treated. This can never be the language of the experienced physician, who daily discovers errors in his ideas. The physician who is conscious of making mistakes, is liable to be more careful and so errs less frequently. He who thinks he can not err, is audacious and careless, easily makes mistakes and does much harm; and I think that the experience of modern times has proven this.

I have some fault to find with our modern systemizers. No one can understand the language they employ; so that it seems to me as if their entire productions abound only in new technical words, terms and modes of expressions. When I read such works I sometimes feel as if I were reading the "Annulus Platonis." If any one has anything new and important to say, he would surely like to have it understood. One can express much that is common and familiar in obscure language and thereby give himself the appearance of having written much that is important and new. Try to translate these writings into plain, intelligible German and you will find my remark verified.

In short, the time has not come to construct a system of medicine. All that we can do now is to gather material for the construction. But then, after centuries, he, who might try to erect such a structure, must be a man of extensive talent and consummate experience. (*Ibid.*, p. 3.)

With the beginning of Brown's system, Richter's relations toward his pupils changed. These considered themselves above their teacher and insolently looked down on him as well as all others who did not uphold

the prevailing system and use the new technical terms. It was indeed honorable in him that he remained true to his convictions and did not allow himself to be misled by the decreasing number of his listeners, but he deserves censure that he did not acquaint himself with it, so as to refute it scientifically. But Richter did not protest, except with irony or silence. The students soon noticed that the subjects on which he spoke had not been thoroughly investigated by him. Whether he would have been capable of scaring the crows and jays away and hindered the students in their epidemic of going over to Brown's system will be left undecided; he as one of Germany's most prominent teachers ought however to have made the attempt in the interests of science. The times during which this system flourished filled him with mistrust toward the entire English medicine. He found in the writings of the English mostly shallow knowledge and coarse empiricism, and perceived with regret that this English nonsense had turned the heads of many Germans. When the intoxication of this error had passed away, Richter's good judgment was appreciated and the students attended his lectures as heretofore.

As Richter's special surgical teachings will be discussed in subsequent chapters, we will now bid farewell to the man who was once prized as the father of German surgery and ophthalmology. We have sadly neglected him! Even if our reason places the name of August Gottlieb Richter far below that of John Hunter, our hearts will beat for our countryman, the German surgeon, and forever honor his name!

(To be continued.)

ASSOCIATION NEWS.

AMERICAN MEDICAL ASSOCIATION.

Official Report of the General Sessions of the Forty-eighth Annual Meeting, held in Philadelphia, Pa., June 1, 2, 3 and 4, 1897.

(Concluded from page 1148.)

JUNE 4.—FOURTH GENERAL SESSION.

The Association met at 10 a. m., and was called to order by President SENN.

The minutes of the preceding session were read and approved, after which Dr. JOHN B. HAMILTON of Chicago, delivered the Address on State Medicine. He selected for his subject "Prevention of Tuberculosis." (See page 1110.)

Dr. HENRY D. HOLTON moved that a vote of thanks be extended to Dr. Hamilton for his very interesting and able address.

Seconded and carried.

The next thing in order was the report of the Committee on Nominations, which was read by Dr. E. E. Montgomery, at the request of the Chairman of the Committee, Dr. Walker, who had left the city.

REPORT OF THE COMMITTEE ON NOMINATIONS.

Mr. President and Members of the American Medical Association: Your Committee on Nominations beg leave to report that they have made the following nominations of officers for the ensuing year:

President—Dr. George M. Sternberg, Washington, D. C.

First Vice-president—Dr. Joseph M. Mathews, Louisville, Ky.

Second Vice-president—Dr. J. L. Thompson, Indianapolis, Ind.

Third Vice-president—Dr. F. H. Wiggin, New York, N. Y.

Fourth Vice-president—Dr. T. J. Happel, Trenton, Tenn.

Treasurer—Dr. Henry P. Newman, Chicago, Ill.

Assistant Secretary—Dr. W. A. Jayne, Denver, Colo.

Librarian—Dr. George W. Webster, Chicago, Ill.

Chairman Committee of Arrangements—Dr. J. W. Graham, Denver, Colo.

Board of Trustees—Dr. J. T. Priestley, Des Moines, Iowa; Dr. Joseph Eastman, Indianapolis, Ind.; Dr. Truman W. Miller, Chicago, Ill.

Judicial Council—Dr. D. W. Crouse, Waterloo, Iowa; Dr. T. D. Crothers, Hartford, Conn.; Dr. Wm. T. Bishop, Harrisburg, Pa.; Dr. R. C. Moore, Omaha, Neb.; Dr. G. B. Gillespie, Covington, Tenn.; Dr. C. H. Hughes, St. Louis, Mo.; Dr. Ida J. Hieberger, District of Columbia.

ANNUAL ORATIONS.

On General Medicine—Dr. J. H. Musser, Philadelphia, Pa.

On General Surgery—Dr. J. B. Murphy, Chicago, Ill.

On State Medicine—Dr. S. C. Busey, Washington, D. C.

Delegates to the International Medical Congress at Moscow: G. S. Mitchell, J. E. Hyndman, Charlee Dennison, A. M. Miller, H. L. E. Johnson, George M. Sternberg, D. L. Huntington, A. Marcy, Sr., H. D. Holton, Thomas MacDavitt, I. N. Quimby, George R. Fowler, J. B. Murphy, T. Mortimer Lloyd and Gilbert I. Cullen.

On motion, the report was unanimously adopted.

Dr. C. A. L. REED—Relative to the list of delegates to the International Medical Congress at Moscow, I rise to make an inquiry at this time as to the expediency of designating delegates to the British Medical Association at its next meeting in Montreal. I understand, Mr. President, that an official communication has been promulgated from that organization that the medical profession of the United States is not expected or wanted at Montreal. Under those circumstances I do not believe it comports with our dignity as a body to designate or appoint delegates who desire to attend this meeting.

PRESIDENT SENN—For the information of Dr. Reed, the Chair desires to state that an official communication has reached him asking for the appointment of a delegate from this Association to the British Medical Association, and with your permission, I will appoint Dr. Henry D. Holton to represent the American Medical Association at Montreal.

Dr. BULKLEY read the following report from the Executive Committee:

REPORT OF THE EXECUTIVE COMMITTEE.

The proposal to restore the former policy of the Association in favor of offering annually to members a gold medal for meritorious scientific work, having already been approved by the Association and recommitted for elaboration of details, the Executive Committee respectfully recommends:

1. That the design of the medal shall contain the seal of the United States, or a seal of the Association to be hereafter designed, on one side and an Esculapian staff on the other, together with the name of the recipient of the medal and suitable inscriptions.

2. That the commercial value of the medal shall not exceed \$50.

3. That a standing committee on Prize Medals consisting of three members of the Association, shall be elected by the Executive Committee as follows: One for one year, one for two years, and one for three years, and thereafter one be elected yearly to hold office until, in either case, the successor has been duly elected. In no case shall a member of the Executive Committee hold a place on the Committee on Prize Medals.

4. That competing essays shall be typewritten or printed and shall bear no mark revealing their authorship; but instead of the name of the author there shall appear on each essay a motto, and accompanying each essay shall be a sealed envelope containing the name, address and motto of the author and bearing on its outer surface the motto of identification. No envelope is to be opened by the committee until a decision has been reached as to the most deserving essay, and the other essays have been returned to their respective owners. The committee shall have authority to reject and return all essays in case none have been found worthy of the Association medal. Competing essays must be in the hands of the committee not later than March 1 of each year.

5. The committee shall report to the Association at the last general session of each meeting and the medal shall be publicly awarded by the President with suitable ceremony.

It was moved and seconded that the report be adopted.

Dr. WILLIAM T. BISHOP—While I think it is all right to accept the report of the committee, still it ought to be amended. I do not think it comports with the dignity of this Association, inasmuch as we do not know what the medal would indicate, and I think \$50 is ridiculous. I would therefore move, as an amendment, that \$100 be substituted instead of \$50.

Seconded by Dr. QUIMBY and carried.

Dr. BULKLEY then read the resolutions regarding railroad transportation previously introduced by Drs. Happel and Powell, which were referred to the Executive Committee, saying that the Executive Committee had approved them.

Dr. WILLIAM H. DALY moved the adoption of the resolutions. Seconded.

Dr. W. T. BISHOP—I must object to the passage of these resolutions. I hardly think we are prepared to turn the Association over to the control of the railroads. It is not the proper thing. I think the committee of three to be appointed will cover everything that is necessary as regards the coming meeting, and that we need not wait until 1899. It is too far off. The best thing to do is to simply drop the matter. The question is entirely one of business methods, and I hardly think we can hardly accomplish any good. I think it puts us in a very unpleasant position.

Dr. I. N. QUIMBY—We should not be in too much hurry in deciding this question. I do not think Dr. Bishop caught the animus of these resolutions. I think they are excellent. They do not in any way, as far as I can see, conflict with the dignity of the Association, nor do they delegate any power to the railroads. The gentleman who introduced the resolutions merely wants to put the railroads on their mettle in relation to the place of meeting. For instance, if we are going to have a meeting in New York city, the railroads running into this city would be asked by the committee in charge as to the rates they would offer to our members, whether they will or will not give us half rates. This leaves the matter with the place of meeting. I hope every member will vote for the adoption of these resolutions. They are in the right direction.

Dr. COULBOURN of Alabama—Mr. President: I believe I have a right to speak on this subject. It was myself who made the great commotion regarding railroad rates for this Association at a previous session. The best thing in the world to build up the Association is to secure railroad rates. We have been fighting and petitioning and passing resolutions, and what does it amount to? We have not been favored with the reduced rates that have been accorded to other assemblies. I came from Alabama and have been unable to avail myself of any advantages in this matter whatever. In discussing this question of railroad rates among my friends, I have met very, very few who are opposed to obtaining them. These resolutions outline the best plan whereby we can obtain reduced rates for 1899.

Dr. W. H. DALY—The opposition to these resolutions is made by men who came here on passes.

At this point there were cries of question! question!

The President then put the motion to adopt and the resolutions as approved by the Executive Committee were unanimously passed.

The Secretary read a preamble and resolution from the Section on Ophthalmology regarding ophthalmia neonatorum, and on motion of Dr. QUIMBY, the resolution was adopted.

Dr. BULKLEY read the following report of the Executive Committee:

Notice of amendment: The Executive Committee, in response to a request from the Section on Dental and Oral Surgery, recommend that the name of the Section be changed to that of "Section of Stomatology."

The Executive Committee reports as follows its election of officers: Chairman, Dr. William E. Quine of Chicago; Vice-chairman, Dr. Edward Jackson of Philadelphia; Secretary, Dr. L. Duncan Bulkley of New York.

Additional members of Executive Council: Dr. C. A. Wheaton, St. Paul, Minn., and Dr. H. Bert Ellis, Los Angeles, Cal.

Dr. JOHN B. ROBERTS of Philadelphia—I desire to offer the following resolution:

Resolved, That 3,000 copies of the act of incorporation, as mentioned by the Trustees in their report, and the by-laws as at present in force, be printed for the use of the members.

Seconded by Dr. QUIMBY, who said: "I think the constitution and by-laws ought to be printed together, as it will take very little more money to do this. I therefore move, as an amendment, that the by-laws and constitution be printed with the Act of Incorporation. Seconded.

Dr. ROBERTS—I accept the amendment.

Dr. WILLIAM T. BISHOP—As a further amendment, I would suggest that we include the Code of Ethics.

Dr. ROBERTS—I have no objection to that.

Dr. L. D. BULKLEY—Mr. President: I rise to a question of privilege. Is this not new business, and ought it not to pass through the hands of the Executive Committee before being considered here? "All new business shall be referred to the Executive Committee without discussion." This is one of the by-laws under which we are working, and I would like to hear from Dr. Davis on this point.

Dr. N. S. DAVIS—We have adopted a by-law which requires that all propositions for appropriation of money shall first go to the Trustees of the JOURNAL and receive their approval. While this is not directly an appropriation of money, it practically amounts to it, and if we are working under our by-laws

it should first go to the Board of Trustees of the JOURNAL for their sanction. The reason for the adoption of such a by-law was that there must be some guard against the appropriation of money.

Regarding the other question as to whether all new business should first go before the Executive Committee or Business Committee, I think it is correct. I think it hits both ways.

Dr. TANNEYHILL moved that the matter be referred to the Board of Trustees with authority to act. Seconded.

Dr. DALY then offered a substitute, that the Board of Trustees be requested to carry this matter out. Seconded.

Dr. TANNEYHILL accepted the substitute.

Dr. H. A. HARE—I would ask, before we proceed to direct the Board of Trustees to make a large expenditure of money, whether it would not be wise to consider if we have money to spend in this way. To print and issue 3,000 circulars or pamphlets will cost a good deal, and as Dr. Davis has said, the object of having a by-law on this point is to refer such matters to the Board of Trustees in order to protect the Association from voting funds which it does not possess.

Dr. W. H. DALY—I do not suppose the whole thing will cost more than \$200, both for printing and sending them out. Personally, I am willing to leave this matter to the discretion of the Board of Trustees.

Dr. I. N. QUIMBY—Everybody knows that the Board of Trustees are men of good sense, and if we have not got the money to spend they will not order this work done.

Dr. JAMES F. HIBBERD—Why not place the matter in the hands of the Board of Trustees and let them act as they think best.

Dr. N. S. DAVIS—If you want to accomplish this object why not pass a resolution requesting the Board of Trustees and the JOURNAL to publish the Constitution, the charter and the by-laws in the JOURNAL, and then it will go to every member of the Association. (Applause.)

The President then put the substitute, as offered by Dr. DALY, which was carried.

Dr. H. BERT ELLIS gave notice that at the next meeting of the Association in Denver he would offer the following amendment to the constitution and by-laws:

ARTICLE IX. Conditions for further representation. "Any State or local medical society, or other organized institution whose rules, regulations and code of ethics agree in principle with those of this Association may be entitled to representation on the advice or agreement of the Judicial Council."

Dr. WM. BAILEY of Louisville—I wish to offer a short resolution.

Resolved, That a marked copy of the JOURNAL containing the address of Dr. W. W. Keen be sent to each member of the House and Senate of the United States. Seconded.

In this connection I wish to say that the senator from my State recently elected as the successor of Joe Blackburn is the only regular physician in the Senate of the United States, as I understand it, and one who is opposed to the passage of the Anti-vivisection Bill, and he being a representative of our profession in the Senate, I shall bear him testimony that this Association desires him in the interest of humanity to fairly represent his profession.

THE PRESIDENT—Would it not be well to refer it to the Board of Trustees?

Dr. H. L. E. JOHNSON of Washington—I am afraid that if a marked copy of the JOURNAL is sent to the individual members of the House and Senate it will not be read, and like most other things that are sent to Senators and Representatives, it will be thrown into the waste basket.

Dr. — of Pennsylvania—I do not think there is any necessity of sending a whole copy of the JOURNAL containing Professor Keen's address, but think it better to send the senators and representatives a reprint from the JOURNAL copy of the address. I agree with the last speaker that if this course is not pursued, and a copy of the JOURNAL is sent them, it will find its way into the waste basket. I would therefore offer that as an amendment. Seconded.

Dr. BAILEY accepted the amendment.

Dr. WILLS of California—I think it a great deal better to extract from Professor Keen's address his reference and remarks on the Anti-vivisection Bill and have it sent to the senators and representatives in as brief a form as possible. I think that it will be read if this is done.

Dr. TANNEYHILL—I think the resolution offered by me yesterday covers the whole ground in regard to anti-vivisection, and I move that this question be laid upon the table.

Seconded and carried.

Dr. JAMES T. COULBOURN—I move that the Secretary be requested to ask the railroads for the Denver meeting to extend our railroad certificates for at least ten days. My rea-

son for making this motion is this: I asked our passenger agent why we were not granted more time, and he informed me that we could have it if we had asked for it. The Secretary says he positively asked for an extension of time, but that they would not give it to him.

Seconded by Dr. Daly.

Dr. LISTON H. MONTGOMERY of Chicago—I move to amend by making it thirty days.

The motion as amended was seconded and carried.

Dr. L. D. BULKLEY gave notice that he would move an amendment as follows:

"That all new business shall be introduced not later than the third day of the General Session."

Seconded by Dr. Daly.

The Secretary read the following:

Resolved, That a committee of three be appointed to cooperate with the Committee of Arrangements to secure the best possible railroad rates for the Denver meeting.

On motion the resolution was adopted.

This Committee consists of Dr. H. L. E. Johnson, District of Columbia; Dr. Chas. A. L. Reed, Ohio, and Dr. Henry D. Holton, of Vermont.

The following are additional delegates to the International Medical Congress: Dr. J. Henry Woods of Brookline, Mass.; Dr. John L. Hildreth and Dr. E. Stevens of Cambridge, Mass.; Dr. F. C. Valentine, New York, N. Y.; Dr. E. S. Talbot, Chicago, Ill.; Dr. W. P. A. Bonwill, Philadelphia, Pa.; Dr. Nicholas Senn, Chicago, Ill., and Dr. J. D. Thomas of Pennsylvania.

The following are the officers of Sections, as handed to the Secretary:

Section on Ophthalmology: Chairman, Dr. Harold Gifford, Omaha, Neb; Secretary, Dr. Robert Randolph, Baltimore, Md.

Section on Physiology and Dietetics: Chairman, Dr. Randall Hunt, Louisiana; Secretary, Dr. A. H. Tuttle, Massachusetts. Executive Committee: New member, Dr. A. P. Clarke, Cambridge, Mass.

Section on Dental and Oral Surgery: Chairman, Dr. G. V. I. Brown, Duluth, Minn.; Secretary, Dr. Eugene S. Talbot, Chicago. On the Executive Committee, Dr. J. L. Williams, Boston.

Section on State Medicine: Chairman, Dr. I. N. Quimby, Jersey City, N. J.; Secretary, Dr. Arthur R. Reynolds, Chicago, Ill. Executive Committee: Drs. Liston H. Montgomery, Chicago; C. H. Shepard, Brooklyn, N. Y.; and Elmer Lee, New York.

Section on Obstetrics and Diseases of Women: Chairman, Dr. Joseph Price, Philadelphia; Secretary, Dr. C. Lester Hall, Kansas City, Mo.

Dr. JAMES T. COULBOURN—I would ask whether a vote of thanks has been offered to the local profession and the citizens of Philadelphia for entertaining us, also to the press.

THE PRESIDENT—There has not.

Dr. COULBOURN—I move that a vote of thanks be extended to the local medical societies of this city, to the citizens of Philadelphia, to the press, and to all others who have been instrumental in entertaining us and making our visit a very enjoyable one. Seconded.

Dr. I. N. QUIMBY—I would suggest that Lea Bros. & Co. be also included in the vote of thanks, as we were admirably entertained by them.

Dr. I. N. LOVE—Mr. President: I would suggest that the Secretary be instructed to carefully look over the list of entertainments we have received and the various courtesies extended to us and include them specifically in one resolution.

Dr. COULBOURN—I will accept that as an amendment.

Dr. LOVE—Speaking to the resolution, I know that I voice the sentiments of every man present in favor of its adoption, because never in the history of the Association have we had a better meeting from every standpoint. The Sectional meetings have been well attended and the entertainments have been admirable. In short, we have had a combination of science and sociability, and I do not believe there is a place anywhere on earth where there is more an atmosphere of sentiment and of science than in this City of Brotherly Love. We have all had manifestations of it this week. (Applause.)

Dr. DALY—we know that the Secretary is a very busy man, and I hope that Dr. Love will write these resolutions as he writes a facile pen. I will heartily second them.

The Secretary subsequently submitted the following resolution:

Resolved, That we most heartily thank the Committee of Arrangements, with Dr. H. A. Hare, their Chairman, for the magnificent manner in which they provided for the comfort and pleasure of the members; the University of Pennsylvania, the Jefferson Medical College, the Medico-Chirurgical College, the

Women's Medical College and the Polyclinic for the excellent entertainments and the provision for clinical instruction which each offered in the greatest abundance; the Philadelphia County Medical Society, the Philadelphia Medical Club, the Howard Hospital, the firms of J. B. Lippincott Co. and Lea Brothers Co., Dr. John V. Shoemaker and wife, Provost C. C. Harrison and wife, and especially the Ladies' Entertainment Committee for the charming and highly enjoyable receptions and the ample opportunities for pleasure and profit not only to the members, but also the ladies who accompanied them. Especially do we desire to return our thanks to the business men, the hotel proprietors and the Atlantic City Medical Society, with particular mention of Dr. P. Marvel, the Chairman of the Committee, for a most wonderful opportunity to visit under the best auspices that City by the Sea, and to learn for ourselves its excellent position to give health and recreation to the invalid and the weary business man.

Dr. N. S. DAVIS—I am not quite willing to let this occasion pass without a word. The first convention I went to, to help form the Association was by the old stage coach, and it took longer to go over the hills of Pennsylvania, in and around the corners of it, to get from the village of Binghamton and the Susquehanna and the Chenango Rivers to New York City than it does to go from Chicago to San Francisco. I mention this to show you that the world has progressed. I have followed the meetings of the Association with the utmost interest and with the greatest possible pleasure from the foot of Bunker Hill Monument to the Golden Gate, and from Minnesota to the Gulf of Mexico, round and round. These meetings and the meetings of our State Society have been my pleasure excursions; they have been the only vacations I have ever taken. (Applause.) They are vacations that bring me in touch with my brethren from every quarter, and enable us to stir each other up by thoughts, by contact mind with mind, man with man, and woman with man, if you please. (Applause.) It gives us an elevation, infuses a buoyancy that lifts us out of our ruts at home. When we return to our homes and resume our practice we do so with fresh vigor, with greater confidence. (Loud applause.)

At the conclusion of Dr. Davis' remarks, three hearty cheers were proposed and given to Dr. Davis and the American Medical Association.

The resolutions of thanks were then adopted unanimously by a rising vote.

Dr. Fowler of Brooklyn, moved that the action taken by the Section on Surgery and Anatomy, in the matter of the Senn Medal, be approved by the Association.

Seconded by Dr. Quimby.

Dr. BULKLEY—I am afraid that there will be some confusion with reference to awarding these gold medals, and before any action is taken I think the matter should be carefully considered. I therefore move that it be referred to the Executive Council and not be acted upon hastily here.

Seconded and carried.

Dr. F. W. McRAE of Atlanta—In order to facilitate the work of the Association, it is the sense of this body that our general meetings hereafter should be held at 11 instead of 10 o'clock. And furthermore, that in the future entertainments shall be so arranged as not to interfere in any way with the general sessions or with the work of the Sections. No man appreciates more than I do the magnificent entertainments we have had here, and the success of this meeting in every particular. The Nominating Committee was informed by the Chairman of the Committee of Arrangements from Denver that Colorado and the City of Denver would lavish at least \$10,000 on us next year for the purpose of entertainment. I would request that in the future the Association be entertained in the evenings, or after the meeting has adjourned, and not during the meetings of the Sections and general sessions. I make this as a motion. If some such resolution is not passed, we will sooner or later become a social rather than scientific body. Seconded.

Dr. I. N. QUIMBY—This matter is already fixed by the by-laws in reference to time, and therefore the resolution is out of order.

Dr. McRAE—It is not an amendment to the constitution, nor does it conflict with the by-laws or the constitution. It is simply the sense of this meeting.

Dr. I. N. LOVE—This matter can be arranged by the officers of the Association communicating with the local Committee of Arrangements, and if the officers and secretaries do their duty, there need not be any expression from this body. Our Section work will not be interfered with. At this meeting the Sections have been crowded and have been magnificent successes. I appreciate the sentiment of my friend, Dr. McRae, and believe it is in the right line, but I do not think an expression in the form of a resolution is necessary.

Dr. W. H. DALY—I differ with Dr. Love relative to the work of some of the Sections. The sectional meetings have been interfered with, and it is a wonder to me how my friend, Dr. Bulkley has been able to do so much work on the Executive Committee. I must confess that I have neglected some of the work of the Sections in order to attend social matters.

Dr. I. N. QUIMBY—I move that the motion be laid on the table. Seconded and carried.

Dr. WILLS of California offered an amendment to Article IV of the By-laws to take effect at the Denver meeting. (Not handed in.)

Dr. BENJAMIN LEE of Philadelphia extended a cordial invitation to the members of the Association to be present at the twenty-fifth anniversary meeting of the American Public Health Association, to be held in Philadelphia October 26 to 29, 1897.

President SENN—One of the pleasant duties of your retiring President on this occasion is to introduce your President elect. The honor has been conferred upon a man worthy to occupy the highest position in the gift of the American profession—Surgeon-General STERNBERG, better known as Dr. Sternberg. He has not only been a very able and faithful public officer, but for a long time has devoted his time and attention to scientific investigation. His name is familiar wherever medicine is taught and practiced. I have great pleasure in introducing to you my successor, Dr. GEORGE M. STERNBERG. (Applause.)

Dr. STERNBERG was very cordially received. He spoke as follows:

Mr. President and Fellow Members of the American Medical Association:—I assure you I feel very deeply the honor you have conferred upon me. I have a high appreciation of this honor. I had not anticipated that I should arrive at any such distinction at this time, and it is especially pleasant to me to have been elected your President at this Jubilee meeting, where the profession is so well represented, and I feel and believe that there are some here today who will be present at the centennial celebration of the American Medical Association. Those gentlemen who are young enough to live to that time will, I trust, appear upon the platform and tell the American physicians of that day what they saw in Philadelphia fifty years before; that they had seen Dr. Davis, the founder of the Association, on this platform and had heard his voice ringing through this hall in a most eloquent address.

In speaking now of our reception by the city of Philadelphia, I feel that I am rather at a disadvantage at this moment. I can not add to what has been said by Dr. Love and Dr. Davis as to our magnificent reception here. We all feel that it has been the most successful meeting in the history of the Association, and it may be fifty years before there is any thing that will surpass it. Certainly nothing has been left undone that could possibly have been done to conduce to the interest and success of this Jubilee meeting.

In acknowledging the honor that you have done me there is one thought that comes to me which makes me feel a little bit uncomfortable, and that is that next year I shall have to prepare a Presidential Address, and when I consider the ground that has been so ably covered by Dr. Senn regarding the history of the Association, when I remember what Dr. Davis has told you about its early organization, and what Drs. Hamilton and Keen have told us regarding preventive medicine and surgery, I feel that there is very little left for me except to mount my hobby, and most of you know just as much about that as I do now. However, I shall leave that question for future consideration. Thanking you for your kindness, I hope to meet you all in Denver. (Applause.)

Dr. LISTON H. MONTGOMERY—I think there has been one matter overlooked, and that is the report of the special committee regarding the Department of Public Health. I understand that our efficient Chairman, Dr. Wingate, is ready to make this report.

Dr. U. O. B. WINGATE of Milwaukee, then read the report of the Special Committee on the Department of Public Health, as follows:

REPORT OF THE SPECIAL COMMITTEE ON THE DEPARTMENT OF PUBLIC HEALTH.

Mr. President and Members of the Association:

At the last meeting of the Association, held at Atlanta, Ga., your Committee on the Department of Public Health, which was appointed in 1891, with the object in view of securing the passage of an Act of Congress creating a National Department of Public Health with a Secretary of Public Health in the Cabinet of the President of the United States, made a report of progress through its Chairman, the late and lamented Dr. Jerome Cochran of Alabama. That report suggested that it

was impossible to attempt to secure the passage of an act creating a cabinet officer, and recommended the drafting of a Bill in which the powers of the Marine Hospital Service, which was already a Department of Public Health with important public health functions under the existing laws be enlarged, and that such a department should be so created as to require coöperation with the various State and Territorial Boards of Health; that report was accepted and its recommendations adopted, and in addition the Chairman was authorized to add to the committee by appointing an additional member from each State and Territory.

Your Chairman was appointed by the President of the Association to succeed the late Dr. Jerome Cochran in October last, and in looking over the field found that it was impossible to get either the 54th Congress, or the special session thereof, to take any action on such a measure, so he has appointed the additional members of the committee, a list of which may be found published in the JOURNAL for Jan. 16, 1897, and which is appended herewith, and has drafted a Bill which is presented herewith. Your committee recommends the continuance of the committee with power to have the aforesaid named bill amended to meet requirements, but not to change the general purpose thereof, and to introduce the same into Congress at its discretion, and that the members of the Association be requested to do in their power for its passage.

Your committee desires to report that out of the \$400 appropriated for the use of the committee, \$305 remains unexpended, and that it is possible that more than that sum be required to aid in the attempt to get the measure passed.

Respectfully submitted,

[For full text of Public Health Bill see next page.]

It was moved that the report be received and the Committee continued. Seconded.

Dr. HOLTON—I notice from the report of the Committee that a portion of the fund appropriated for their expenditures has been expended, and I believe the report states that possibly a little more money may be required. In view of this, I move that the Board of Trustees be authorized to allow such an additional sum as in their discretion they may deem wise.

Seconded and carried.

Dr. I. N. LOVE—I desire to make the motion, that in future all committees having reports of public interest, and particularly matters pertaining to legislation, be instructed to make their reports on the second day at the General Session. It is unnecessary for me to say that important legislative matters should not be presented here when there is a paltry few to consider them.

Seconded and carried.

There being no further business to come before the Association, President SENN said: I thank you for the distinguished honor conferred upon me in electing me your President last year. I also wish to thank you for the uniform courtesy extended to me. I congratulate you on the success of this meeting, which has been characterized by harmony of action and by the good work accomplished. I am now ready to entertain a motion to adjourn.

On motion, the ASSOCIATION then adjourned.

A BILL to Establish a Department of Public Health and to Define its Duties.

Be it Enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

SECTION 1. That there shall be established a Department of Public Health, the duties of which shall be to collect and diffuse information upon matters affecting the public health, including statistics of sickness and mortality in the several States and Territories; the investigation by experimental and other methods of the causes and means of prevention of disease; the collection of information with regard to the prevalence of infectious, contagious and epidemic diseases both in this and other countries; also the causative and curative influence of climate upon the same; the publication of the information thus obtained in a weekly bulletin; the preparation of rules and regulations for securing the best sanitary condition of vessels from foreign ports, and for prevention of the introduction of infectious diseases into the United States, and their spread from one State into another, which rules, when approved by the President of the United States, shall, in so far as they are consistent with the existing laws, be adopted and enforced as quarantine regulations at the various ports of entry in the United States, and so far as applicable to interstate commerce to prevent the spread of disease from one State or Territory into another or the District of Columbia, be, and become additional regulations thereof; the advising and informing the several departments of the government on such questions as may be submitted by them to it, or whenever in the opinion of the Department such advice and information may tend to the preservation and improvement of the public health.

A special report of the said Department of Public Health, relative to such action as will most effectually protect and promote the health of the people of the United States may at any time be required by the President of the United States.

SEC. 2. That the Department of Public Health shall be under the control and management of a Commissioner of Public Health; said Commissioner of Public Health shall be appointed by the President of the United States, by and with the advice and consent of the Senate, and his term of office shall be six years; he shall be a regularly educated physician holding a diploma conferred upon him by a legally incorporated medical college in the United States; he shall have had at least ten years' experience in the practice of medicine, and shall be learned in sanitary science, and shall hold a membership in one or more reputable sanitary or medical associations in the United States.

He shall be entitled to a salary of \$6,000 per annum, and his necessary traveling expenses.

That the Commissioner of Public Health shall semi-annually on the first Tuesdays of April and October of each and every year, and at such other times as he may designate, call to meet in the city of Washington, D. C., an advisory council to be composed of the secretary or executive officer of each State and Territorial board of health, and one officer learned in the law, detailed by the Attorney-General of the United States from the Department of Justice; and that the necessary traveling expenses of the said advisory council incident to their attendance on the meeting of the said council shall be paid on vouchers to be furnished by the Secretary of the Treasury, said meetings not to include more than six days at each session, unless a longer continuance shall be authorized by the President of the United States.

That the Commissioner of Public Health may appoint an Assistant Commissioner of Public Health, who shall be a physician in good and regular standing in the medical profession, and skilled in sanitary science, and fix his salary at not to exceed \$3,500 per annum and all actual and necessary traveling expenses incurred in the performance of his duties as Assistant Commissioner in said Department. All officers and persons in the service of the United States, detailed to perform any duty under the provisions of this act, or any existing act, of the Congress of the United States providing for quarantine against diseases, or to prevent diseases from spreading within the United States, shall not receive any additional compensation except for actual and necessary expenses incurred in the performance of such duties, such expenses to be approved by the Commissioner of Public Health or his assistant, and to be paid on vouchers provided by the Department of the Treasury.

It shall be the duty of the Commissioner of Public Health to preside at all meetings of the said advisory council, and in case of his absence on account of illness or any other unavoidable cause, it shall be the duty of the Assistant Commissioner of the Department so to preside.

SEC. 3. That the Department of Public Health hereby created

shall succeed to all the powers and duties now and heretofore conferred upon the Marine-Hospital Service, or any officer thereof, by any law of Congress, except as hereinafter provided, and shall occupy the building now occupied by the Marine-Hospital Service for its offices, and shall have under its exclusive control and management all offices, officers, laboratories, appurtenances and property of whatever name and nature, which are lawfully in possession of the said Marine-Hospital Service at the time of the passage of this act, but it is hereby provided that there shall be in said department a bureau to be known as "The Bureau of the Marine-Hospital Service," which shall be under the exclusive control of the Commissioner of Public Health, and all laws governing the appointment to official positions in said Marine-Hospital Service, and to promotions in said service, shall continue in full effect, and all funds now or hereafter appropriated for the Marine-Hospital Service by Congress shall continue to be disbursed under the supervision of the Commissioner of Public Health by the direction of the Secretary of the Treasury until otherwise provided by law, it being the intent and purpose of this act to continue the Marine-Hospital Service and to confer all duties relating to quarantine and the public health upon the department hereby created.

SEC. 4. That whenever any department of government, or the executive of any state or territory, or the Commissioners of the District of Columbia, or the health authorities of any State, shall request information from the Department of Public Health in regard to any matter pertaining to the protection or promotion of the public health, said department shall promptly furnish such information as it may have on record, together with any necessary or pertinent advice; and whenever any information shall be received by the department which the interests of the public health require should be promptly communicated to any department of the government, or to any state officer, such information shall be forthwith furnished to the respective department or officer.

SEC. 5. That the department shall take such action, by adopting and enforcing such rules, and by correspondence or conference, as will tend most effectually to secure the coöperation of State, municipal, and local boards of health in establishing and maintaining an efficient and accurate system of notification of the existence and progress of contagious and infectious diseases, and of vital statistics in the United States, and said department shall also, by coöperation with the proper health authorities of foreign nationalities and municipalities, endeavor to extend to the United States a reliable system of international notification of the existence and progress of such diseases as cholera, yellow fever, typhus fever, smallpox, bubonic plague, or any other dangerous or contagious disease which may, in the judgment of the department, seem advisable to consider.

SEC. 6. That in sending notifications to, and receiving reports from, the different States or Territories in the United States, the department shall conduct all correspondence through the State and Territorial health authorities, and all information intended for local use received by the State or Territorial health authorities, shall by them be forwarded to the local boards of health, or health authorities, within their jurisdiction, and all reports and information received from local health authorities, and local boards of health, shall pass through the office of the State or Territorial health authorities to the said Department of Public Health.

SEC. 7. That the department shall, when in its judgment it may deem it necessary and proper, make such additional rules and regulations as are necessary to prevent the introduction of infectious and contagious diseases into the United States from foreign countries, or into one State or Territory, or the District of Columbia, from another State or Territory or the District of Columbia, and when said rules and regulations have been made they shall be promulgated by the said department subject to the approval of the advisory council, and the President of the United States, and enforced by the sanitary authorities of the States, Territories, municipalities, and local boards of health, where the State, Territorial, municipal, or local health authorities will undertake to execute and enforce them, but if the State, Territory, municipal, or local health authorities shall fail or refuse to enforce such rules and regulations, the President of the United States shall execute and enforce the same, and shall adopt such measures as in his judgment shall be necessary to prevent the introduction or spread of such diseases, and may detail or appoint officers for that purpose.

SEC. 8. That it shall be the duty of said department to perform all the duties in respect to quarantine and quarantine regulations, which are provided for by this act, or by any existing act of the Congress of the United States, and all duties in regard to the prevention and spreading of diseases throughout the United States as provided for in this act, and to obtain

information of the sanitary condition of foreign ports and places from which contagious and infectious diseases are, or may be, imported into the United States, and to this end the consular officers of the United States at such ports and places as shall be designated by the Commissioner of Public Health, shall make weekly reports to the department of the sanitary condition of the ports and places at which they are respectively stationed, according to such forms as the Department of Public Health shall prescribe; and the Commissioner of Public Health shall also obtain, through all sources accessible, including State and Territorial sanitary authorities throughout the United States, weekly reports of the sanitary condition of ports and places within the United States, and shall prepare, publish, and transmit to collectors of customs, and to State and Territorial boards of health, and through them to municipal health officers, and other sanitarians, weekly abstracts of the consular sanitary reports, and other pertinent information received by him, and shall also, as far as he may be able, by means of voluntary coöperation of State and Territorial authorities, and through them municipal authorities, public associations, and private persons, procure information relating to the climatic and other conditions affecting the public health.

SEC. 9. That it shall be unlawful for any merchant ship or other vessel, from any foreign port or place, to enter any port of the United States, except in accordance with the provisions of this act, and with such rules and regulations of State, Territorial and municipal health authorities as may be made in pursuance of, or consistent with, this act; and any such vessel which shall enter, or attempt to enter, a port of the United States in violation thereof, shall, upon conviction of the Master thereof, forfeit to the United States a sum to be awarded in the discretion of the court, not exceeding \$5,000, which shall be a lien upon said vessel to be recovered by proceedings in the proper district court in the United States. In all such proceedings the United States District Attorney for such district shall appear on behalf of the United States, and such proceedings shall be conducted in accordance with the rules and laws governing cases of seizure of vessels for violation of the revenue laws of the United States.

That any vessel, at any foreign port, clearing for any port or place in the United States, shall be required to obtain from the consul, vice-consul, or other consular officer of the United States at the port of departure, or from the medical officer, where such officer has been detailed by the President of the United States for that purpose, a bill of health in duplicate, in the form prescribed by the Department of Public Health, setting forth the sanitary history and condition of said vessel, and that it has in all respects complied with the rules and regulations in such cases prescribed for securing the best sanitary condition of the said vessel, its cargo, passengers and crew; and said consular, or medical, officer is required before granting such duplicate bill of health, to be satisfied that the matters and things therein stated are true; and for his services in that behalf he shall be entitled to demand and receive such fees as shall by lawful regulations be allowed, to be accounted for as is required in other cases.

The President of the United States in his discretion is hereby authorized to detail any medical officer of the government to serve in the office of the consul at any foreign port for the purpose of furnishing information, and making the inspection, and giving the bills of health hereinbefore mentioned. Any vessel clearing and sailing from any such port, without such bill of health, and entering any port of the United States shall, upon conviction of the Master thereof, forfeit to the United States not more than \$5,000, the amount to be determined by the court, which shall be a lien on the same to be recovered by proceedings in the proper district court of the United States. In all such proceedings the United States District attorney for such district shall appear on behalf of the United States; and such proceedings shall be conducted in accordance with the rules and laws governing cases of seizure of vessels for violation of the revenue laws of the United States.

SEC. 10.—That the Commissioner of Public Health shall from time to time, issue to the consular officers of the United States and to the medical officers serving at any foreign port, and otherwise make publicly known, the rules and regulations made by him, to be used and complied with by vessels in foreign ports, for securing the best sanitary condition of such vessels, their cargoes, passengers and crew, before their departure for any port in the United States, and in the course of the voyage; and all such other rules and regulations as shall be observed in the inspection of the same on the arrival thereof at any quarantine station at the port of destination, and for the disinfection and isolation of the same, and the treatment of the cargo and persons on board, so as to prevent the introduction of cholera, yellow fever, leprosy,

bubonic plague, smallpox, or other contagious or infectious diseases; and it shall be unlawful for any vessel to enter said port to discharge its cargo or land its passengers except upon a certificate of the health officer at such quarantine station, certifying that said rules and regulations have in all respects been observed and complied with, as well on his part as on the part of the said vessel and its master, in respect to the same and to its cargo, passengers and crew: and the master of every such vessel shall produce and deliver to the collector of customs at said port of entry, together with the other papers of the vessel, the said bills of health required to be obtained at the port of departure, and the certificate herein required to be obtained from the health officer at the port of entry; and that the bills of health herein prescribed shall be considered as part of the ship's papers, and when duly certified to by the proper consular officer, or other officer of the United States, over his official signature and seal, shall be accepted as evidence of the statements therein contained in any court of the United States.

SEC. 11.—That the Commissioner of Public Health shall, and at such times as he may deem necessary, examine the quarantine regulations of all State and municipal boards of health, or detail an officer of the said department to make such examinations, and shall coöperate with and aid all State, municipal and local boards of health in the execution and enforcement of the rules and regulations made by the Department of Public Health under the provisions of this act, or any other act of the Congress of the United States providing for a quarantine against disease, and to prevent the introduction of contagious and infectious diseases into the United States from foreign countries, and into one State or Territory, or the District of Columbia, from another State or Territory, or the District of Columbia; and all rules and regulations made shall operate uniformly and in no manner discriminate against any port or place: and at such ports and places within the United States as have no quarantine regulations under State, Territorial or municipal authority, where such regulations are, in the opinion of the Commissioner of Public Health, necessary to prevent the introduction of contagious and infectious diseases into the United States from foreign countries, or into one State or Territory, or the District of Columbia, from another State or Territory, or the District of Columbia, and at such ports and places within the United States where quarantine regulations exist under the authority of the State, Territory, or municipality which, in the opinion of the Commissioner of Public Health, are not sufficient to prevent the introduction of such diseases into the United States, or into one State or Territory or the District of Columbia, from another State or Territory or the District of Columbia, the Commissioner of Public Health, if in his judgment it is necessary and proper, shall, with the advice and approval of the advisory council, make such additional rules and regulations as may be necessary to prevent the introduction of such diseases into the United States from foreign countries, or into one State or Territory, or the District of Columbia, from another State or Territory, or the District of Columbia, and when said rules and regulations have been made and approved by the President of the United States, they shall be promulgated by the Commissioner of Public Health and enforced by the sanitary authorities of the State, Territories and municipalities, where the State, Territorial or municipal health authorities will undertake to execute and enforce them; but if the State, Territorial or municipal authorities shall fail or refuse to enforce said rules and regulations, the President of the United States shall empower the Commissioner of Public Health to execute and enforce the same and adopt such measures as in his judgment shall be necessary to prevent the introduction or spread of such diseases, and may detail or appoint officers for that purpose. The Commissioner of Public Health shall make such rules and regulations, with the advice and consent of the advisory council, and approved by the President of the United States, as are necessary to be observed by vessels at the port of departure and on the voyage, where such vessels sail from any foreign port or place in the United States, to secure the best sanitary condition of such vessel, her cargo, passengers and crew, which shall be published and communicated to, and enforced by, the consular officers of the United States. None of the penalties herein imposed shall attach to any vessel, or owner, or officer thereof, until a copy of this act, with the rules and regulations made in pursuance thereof, has been posted up in the office of the consul, or other consular officer of the United States, for ten days, in the port from which said vessel sailed: and the certificate of such consul, or consular officer, over his official signature, shall be competent evidence of such posting in any court of the United States.

SEC. 12.—That on the arrival of an infected vessel at any port not provided with proper facilities for treatment of the

same, the Commissioner of Public Health may remand said vessel, at its own expense, to the nearest National or other quarantine station, where accommodations and appliances are provided for the necessary disinfection and treatment of the vessel, passengers and cargo; and after treatment of any infected vessel at a National quarantine station, and after certificate shall have been given by the United States quarantine officer at such said station that the vessel, cargo and passengers are each and all free from infectious disease, or danger of conveying the same, said vessel shall be admitted to entry to any port of the United States named within the certificate. But at any ports where sufficient quarantine provision has been made by State, Territorial or local authorities, the Commissioner of Public Health may direct vessels bound for said ports, to undergo quarantine at such said State, Territorial or local station.

SEC. 13.—That whenever it shall be shown to the satisfaction of the President of the United States that by reason of the existence of cholera, yellow fever, or other infectious or contagious diseases in a foreign country, there is danger of the introduction of the same in the United States, and that notwithstanding the quarantine defense, this danger is so increased by the introduction of persons or property from such country that a suspension of the right to introduce the same is demanded in the interest of the public health, the President shall have power to prohibit, in whole or in part, the introduction of persons and property from such countries or places as he shall designate, and for such period of time as he may deem necessary.

SEC. 14.—That whenever the proper authorities of a State or Territory shall surrender to the United States the use of the buildings and disinfecting apparatus at a State quarantine station, the Commissioner of Public Health shall be authorized to receive them and to pay a reasonable compensation to the State or Territory for their use, if in his opinion they are necessary to the United States.

SEC. 15.—That whenever necessary there shall be purchased or erected, under the orders of the Commissioner of Public Health, with the approval of the Secretary of the Treasury, suitable warehouses with walls and enclosures, where merchandise may be unladen and deposited from any vessel which shall be subject to a quarantine or other restraint, pursuant to the health laws of any State, at such convenient places therein as the safety of the public revenue and the observance of such health laws may require.

SEC. 16.—That whenever the cargo of a vessel is unladen at some other place than the port of entry or delivery under the foregoing provisions, all the articles of such cargo shall be deposited, at the risk of the parties concerned therein, in such public or other warehouses or enclosures, as the collector of customs shall designate, there to remain under the joint custody of such collector and of the owner or master, or other person having charge of such vessel, until the same are entirely unladen or discharged, and until the articles so deposited may be safely removed without contravening such health laws. And when such removal is allowed, the collector having charge of such articles may grant permits to the respective owners or consignees, their factors or agents, to receive all merchandise which has been entered, and the duties accruing upon which have been paid, upon the payment by them of a reasonable rate of storage, which shall be fixed by the Secretary of the Treasury for all public warehouses and enclosures.

SEC. 17.—That the master of any vessel employed in transporting passengers between the United States and Europe, is authorized to maintain good discipline, and such habits of cleanliness among the passengers as will tend to the preservation and promotion of health; and to that end he shall cause such regulations as he may adopt for this purpose to be posted up, before sailing, on board such vessel in a place accessible to such passengers, and shall keep the same so posted up during the voyage. Such master shall cause the apartments occupied by such passengers to be kept at all times in a clean, healthy state; and the owners of every such vessel so employed are required to construct the decks, and all parts of the apartments, so that they can be thoroughly cleansed; also to provide a safe, convenient privy or water-closet for the exclusive use of every one hundred passengers. The master shall also, when the weather is such that the passengers can not be mustered on deck with their bedding, and at such other times as he may deem necessary, cause the deck occupied by such passengers to be cleansed with chlorid of lime, or some other equally efficient disinfecting agent. And for each neglect or violation of any of the provisions of this section, the master and owner of any such vessel shall, upon conviction thereof, be severally liable to the United States in a penalty of one hundred dollars, to be recovered in any circuit or district court

within the jurisdiction of which such vessel may arrive, or from which she is about to depart, or at any place where the owner or master may be found, or to imprisonment for a period of not less than thirty days, or by both fine and imprisonment, in the discretion of the court.

SEC. 18.—That whenever the evidence shall appear conclusive to the President of the United States that cholera, yellow fever, typhus fever, typhoid fever, smallpox, diphtheria or other plague, exists in any State or Territory, or in the District of Columbia, to such an extent that there is great danger of the spread of such disease into other States, Territories, or the District of Columbia, by means of vessels and vehicles engaged in the transportation of goods, passengers, and the United States mail, by land and water, or by persons traveling, on foot or otherwise, he is hereby authorized to call together the Commissioner of Public Health and advisory council to take such action as may be necessary to prevent the spread of such disease from one State or Territory into another, or from any State or Territory into the District of Columbia, or from the District of Columbia into any State or Territory, and the Commissioner of Public Health shall make such rules and regulations, by and with the advice and consent of the advisory council, and the approval of the President of the United States, as may be necessary to meet the emergency, and all such rules and regulations shall have the force of law, and supersede all other rules, laws or regulations for the time being at the place designated, and any one violating any such rules and regulations shall, upon conviction thereof, be subject to arrest and imprisonment for a period of not less than thirty days. The Commissioner of Public Health may temporarily employ such inspectors and other persons as may be necessary to execute all rules and regulations adopted as aforesaid to stamp out and prevent the spread of such disease.

SEC. 19.—That the Commissioner of Public Health or any one appointed by him may, with the approval of the Secretary of the Treasury, select suitable localities for establishing stations on rivers and other lines of interstate commerce and travel by railroads, and may cause to be erected necessary temporary buildings for the disinfection of passengers, baggage, cargoes, vessels and vehicles, and may enforce such rules and regulations relating thereto as may have been, or may be, prescribed therefor.

SEC. 20.—That the Secretary of the Treasury is authorized whenever a conformity to such quarantines and health laws requires it, and in respect to vessels subject thereto, to prolong the terms limited for the entry of the same, and the report of entry of their cargoes, and to vary or dispense with any other regulations applicable to such reports or entries. No part of the cargo of any vessel shall, however, in any case be taken out or unladen therefrom otherwise than is allowed by law, or according to regulations and rules adopted and promulgated by the Commissioner of Public Health under the provisions of this act, or any existing act.

SEC. 21.—That the Commissioner of Public Health and the advisory council, created under this act, shall devise such means and methods as they may deem most effective to control and exterminate all domestic diseases transmitted by contact, such as phthisis pulmonalis or tuberculosis, diphtheria, scarlet fever, smallpox, leprosy and all diseases dangerous to the public health. That the said Department of Public Health may, under the direction of the Commissioner of Public Health, make investigations, both in the United States and, if necessary, in foreign countries, into the nature, origin and prevention of contagious, epidemic and other diseases, and the causes and conditions of particular outbreaks of disease in the United States, and in order that said experiments may be made, the Commissioner of Public Health shall, if necessary, enlarge the laboratories of the Marine Hospital Service, erect and maintain such other laboratories as may be necessary, and to equip said laboratories with the best appliances obtainable for investigation into the causes of disease and how to prevent and obliterate the same.

SEC. 22.—That the Commissioner of Public Health may engage the services of experts, not to exceed six in number, in such laboratories in the United States as are best adapted by location, equipment or special fitness, to aid the Department of Public Health in making investigations. The pay to be allowed such experts to be fixed by the Commissioner of Public Health. It shall also be the duty of the said department to investigate the best method for the disposal of sewage, the protection of public water supplies, to ascertain the best sanitary methods, to investigate all matters which relate to the public health, and to gather statistics relating to marriages, births, and deaths, and cause of death, and when the same can be done without prejudice to the public service, the President of the United States may detail officers from the several departments of the

government for temporary duty to act under the direction of said department, to carry out the provisions of this act, and all other acts of the Congress of the United States providing for a quarantine against disease and to prevent the spread of any disease within the United States.

SEC. 23.—That the Secretary of the Department of Agriculture, and the Commissioner of the Department of Labor shall respectively furnish for the use of the Department of Public Health such information as they shall from time to time gather upon the following and kindred subjects, viz.: 1. The investigation of foods; also drugs and wines, their standard purity and their adulteration. 2. The transmission of disease from animals to man and from man to animals, such as tuberculosis, glanders, etc. 3. The statistics of climate with relation to infectious and other diseases. 4. The statistics and conditions relating to consanguineous and other marriages liable to produce physically and mentally defective offspring; and any information leading to race improvement through better marriage selection than obtains at present. 5. The statistics relating to child labor and to confined and unhealthy occupations, etc.

SEC. 24.—That it shall be lawful for the Commissioner of Public Health, when in his judgment it may seem necessary to confer upon any municipal or local health officer, or health authority, through the State or Territorial authorities in which he may have jurisdiction, power also to enforce the provisions of this act and any rules and regulations made in pursuance thereof, and any person who shall knowingly disobey or violate any order, rule or regulation made pursuant to the authority herein conferred, shall, upon conviction thereof, be deemed guilty of a misdemeanor punishable by a fine of not less than \$500 or by imprisonment for a period of not less than one year.

SEC. 25.—That the Commissioner of Public Health shall make an annual report of the operations of the Department to Congress with such recommendations as he may deem important to the public interest; and said report, if ordered to be printed by Congress, shall be done under the direction of the Commissioner of Public Health, and that all mail matter of whatever class relative to the Department of Public Health and its duties, and addressed to the Commissioner of Public Health and indorsed "Official Business, Department of Public Health," or mailed by said department, shall be transported free of postage; and if any person shall make use of such indorsement to avoid the payment of postage in his private letter, package or other matter in the mail, the person so offending shall, upon conviction thereof, be deemed guilty of a misdemeanor and be subject to the penalty prescribed by the existing law.

SEC. 26.—That the Commissioner of Public Health is authorized to appoint for duty not to exceed six sanitary inspectors, at a salary not to exceed one thousand eight hundred dollars per annum each, and their necessary actual traveling expenses; at least two of these inspectors shall be experts in quarantine matters, two shall be skilled bacteriologists, and one shall be an expert statistician. The Commissioner of Public Health is authorized to employ one chief clerk at a salary of one thousand eight hundred dollars; one clerk of class three at one thousand four hundred dollars; and one clerk of class two, at one thousand four hundred dollars; and four clerks at one thousand dollars each, one messenger at eight hundred dollars, one stenographer at eight hundred dollars, one watchman at six hundred dollars per annum.

SEC. 27.—That any officer, or person acting as an officer, or agent at any quarantine station, or other person employed to aid in preventing the spread of disease, who shall wilfully violate any quarantine laws of the United States, any of the provisions of this act, or any of the rules and regulations made and promulgated as provided for in this act, or any other act of the Congress of the United States providing for and regulating quarantine against disease, or to aid and prevent the spread of any disease within the United States, or any lawful order of his superior officer, or officers, shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine of not more than five hundred dollars, or imprisonment for not more than one year or both, in the discretion of the court.

SEC. 28.—That when any common carrier or officer, agent, or employe of any common carrier, shall wilfully violate any of the quarantine laws of the United States, or the rules and regulations made and promulgated as provided for in this act, or any other act of the Congress of the United States regulating and maintaining a quarantine against disease, and to prevent the spread of disease within the United States, such common carrier, officer, agent, or employe shall be deemed guilty of a misdemeanor, and shall upon conviction thereof be punished by a fine of not more than five hundred dollars or imprisonment for not more than two years, or both, in the discretion of the court.

SEC. 29.—That any person who shall wilfully violate any rule or regulation made and promulgated by authority of this act, or any other act of the Congress of the United States, providing for a quarantine against disease, and to prevent the spread of any disease within the United States, shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine of not more than five hundred dollars or imprisonment for not more than two years, or both, in the discretion of the court.

SEC. 30.—All convictions for the violation of any of the provisions of this act, or any other act of the Congress of the United States, providing for a quarantine against disease, and to prevent the spread of any disease within the United States, shall be tried in the district wherein the offense was committed, and it shall be the duty of the United States district attorney for such district to appear on behalf of the United States, and all trials and proceedings shall be conducted in accordance with the rules and laws governing criminal cases triable in the United States courts.

SEC. 31.—That all rules made and promulgated, adopted and published pursuant to the provision of an act entitled "An act granting additional quarantine powers and imposing additional duties upon the Marine Hospital Service," approved Feb. 15, 1893, shall remain in force until the same are annulled, changed, or modified, as provided for by this act, and other acts of Congress providing for quarantine against diseases, and the spread of any disease within the United States.

SEC. 32.—That all rules and regulations made and promulgated to enforce the provisions of this act, or any other act of the Congress of the United States, providing for a quarantine against disease, and to prevent the spread of any disease within the United States, shall be approved by the President of the United States, and when approved by him shall have all the force and effect of law.

SEC. 33.—That the Commissioner of Public Health shall annually submit to the Secretary of the Treasury, for transmission to Congress, estimates of the expense necessary to maintain properly the Department of Public Health for the ensuing year. That there shall be, and hereby is, appropriated out of the moneys in the Treasury and not otherwise appropriated, the sum of \$75,000 for the purpose of this act. The sum of \$1,000,000 already appropriated and known as an emergency fund to be expended by the President of the United States or the balance thereof not already expended, shall be a fund and held and expended at the discretion of the President of the United States in the execution of the provisions of this act.

SEC. 34.—Sec. 1, Chapter 19, Supplement to the Revised Statutes, Vol. 1, second edition, revised and continued (page 637) is hereby amended so as to read as follows:

Sec. 1. *Be it enacted, etc.*, That medical officers of the Marine Hospital Service of the United States shall hereafter be appointed by the President, by and with the advice and consent of the Senate, and no person shall be so appointed until after passing a satisfactory examination in the several branches of medicine, surgery and hygiene before a board of medical officers of said service. Said examination shall be conducted according to rules prepared by the Commissioner of Public Health and approved by the advisory council and the President.

SEC. 35.—Sec. 4,796 and 4,802, Revised Statutes of 1878, Chapter 66, laws of 1878, Supplement to Revised Statutes, Vol. 1, second edition, revised and continued: "An act to prevent the introduction of contagious or infectious diseases into the United States."

Paragraph 9, chapter 130, laws of 1875, same supplement: "An act making appropriations for sundry civil expenses of the Government for the fiscal year and for other purposes."

Sec. 7, chapter 156, laws of 1875, same supplement: "An act to promote economy and efficiency in the Marine Hospital Service."

Chapter 51, laws of 1890, same supplement: "An act to prevent the introduction of contagious diseases from one State to another, and for the punishment of certain offenses."

Chapter 300: An act amendatory to the aforesaid, passed August 18, 1894.

Chapter 114, Supplement of the Revised Statutes, Vol. 2, laws of 1893: "An act granting additional quarantine powers and imposing additional duties upon the Marine Hospital Service," and all other acts, or parts of acts, inconsistent herewith, or repugnant to the provisions of this act, are hereby repealed.

SEC. 36.—This act shall take effect sixty days after its passage, within which time the Commissioner and Assistant Commissioner may be appointed.

Let us have a Department of Public Health!

SOCIETY PROCEEDINGS.

Illinois State Medical Society.

Abstract of the Proceedings of the Forty-seventh annual meeting, held at East St. Louis, May 18, 19 and 20, 1897.

(Continued from page 1152.)

SECOND DAY—AFTERNOON SESSION.

NON-MALIGNANT STRICTURES OF THE RECTUM.

A paper on this subject was read by Dr. A. E. HALSTEAD of Chicago.

A non-malignant stricture of the rectum was defined as a pathologic condition in which there is a permanent and progressive narrowing of the rectal canal as the result of an alteration in the rectal wall, primarily depending upon a loss of tissue, from ulceration or from trauma, the immediate cause being a contraction of the inflammatory tissue that has been substituted for the normal mucous membrane and musculature of the rectum.

Syphilis was undoubtedly the most frequent cause of rectal stricture. Authorities, however, do not agree as to the percentage of cases that should be considered of syphilitic origin. Out of 99 cases of stricture, Allingham found 52 that he regarded as syphilitic. Eugene Frankel found in 7 out of 9 cases of rectal strictures evidences of syphilis. Kelsey in 76 non-malignant strictures found 17 that he regarded of venereal origin, these including strictures which followed gonorrheal or chancroidal ulcerations. In 70 cases of stricture tabulated by Cripps from the records of St. Bartholomew's Hospital, only 13 had a distinct syphilitic history or presented other signs of syphilis. Poelchen collected 222 cases, 96 or 43 per cent. of which were regarded as syphilitic.

Stricture of the rectum is far more common in the female than in the male sex. In 367 cases collected by Ball, 276 were women and 91 men, *i. e.*, a ratio of 3 to 1.

Treatment.—The various measures that have been advocated from time to time for the relief of cicatricial rectal stricture were classified as follows: 1, dilatation, *a*, gradual, *b*, rapid; 2, electrolysis; 3, internal proctotomy; 4, external proctotomy; 5, inguinal or lumbar anus; 6, plastic operations and anastomosis; 7, excision, *a*, perineal, *b*, sacral.

These various measures were then taken up and discussed at length.

The author closed his paper with a report of two cases of rectal stricture in which permanent cures were obtained by amputation of the strictured portion of the gut.

SYMPHYSIOTOMY

was the title of a paper read by Dr. FRANK B. EARLE of Chicago, in which he emphasized some of the most important points and gave a brief report of a case, the favorable outcome of which had led him more ardently than ever to support a procedure which he believes has a legitimate field in obstetrics.

Indications.—Division of the symphysis, for the purpose of increasing the pelvic diameter, has been proposed for, *a*, irreducible brow presentation, *b*, impacted occipito-posterior, and *c*, in face presentations with the chin posterior, when it was impossible either to flex the head or rotate the chin anteriorly, and where version was contra-indicated. It was most valuable where the disproportion between the head and pelvis was moderate, *i. e.*, in the flattened and generally contracted pelvis. It might also be resorted to with advantage in extreme contraction, 7 cm., with death of the fetus, in order that embryotomy might be performed.

Situation.—It should not be performed with a conjugate vera of less than 2.6 inches, 6.5 cm., or above 3.5 inches, 9 cm. Neither should it be performed if the fetal heart tones indicate extreme exhaustion. It should be done as an operation of election and not after repeated ineffectual attempts to deliver by forceps or version. One of the chief reasons why the maternal and fetal mortality was high was because few of the disproportion cases were recognized prior to the onset of labor.

Technique.—The patient is prepared as for celiotomy, placed in the dorsal position with an assistant on each side. The first step should be the introduction into the bladder of a straight metallic catheter or sound, in order to push the urethra and bladder away from the part to be incised. The second step is to locate the symphysis by the depression above, and this could be materially aided by flexing and extending the limbs. It should not be forgotten that the symphysis is occasionally situated laterally.

After the symphysis is located an incision should be made, to extend from above the joint almost down to the clitoris, and the retro-pubic tissues pushed carefully away. Instead of then passing the probe-pointed bistoury, or the Galbiati-Harris

knife posteriorly and dividing the entire pubic joint, as was originally proposed, only the minor pubic ligaments should be severed, from above backward and the sub-pubic ligament dissected and pushed downward, as fully described in the *American Journal of Obstetrics* in 1894. By this method the sub-pubic ligament could be separated from the arch sufficiently to permit the desired degree of separation and undue stretching of the fascia, through which pass important structures, is avoided. This is important, as the danger of laceration, hemorrhage and sepsis is greatly diminished. After the joint is severed and the ends protected by gauze, the question to be determined is whether the patient should be permitted to deliver herself or whether labor should be terminated. Both practices are in vogue, but preference is given to the latter. Except in hospital practice, symphysiotomy is not usually decided upon until after futile attempts at forceps or version have been made and the mother and child reduced to a state of threatened exhaustion. Under these conditions it would be dangerous to wait for spontaneous delivery and even when the operation is an elective one it would seem more rational to terminate labor by forceps or version, than to subject the patient to the prolonged dangers of shock and sepsis. During delivery by *any* method the hips must be firmly supported in order not to endanger the sacro-iliac ligaments. After the completion of the third stage there remain the closure of the incision and any lacerations that have occurred in the genital tract.

The chief dangers to be combated are sepsis and hemorrhage. Regarding the former, it need only be mentioned that in the elective operation it is a preventable accident and should not, at this day, be classified as dangerous. In reference to hemorrhage, it should be stated that it is frequent, many times alarming, and occasionally a fatal accident. Enormous hemorrhage is reported by many distinguished operators, and nearly all agree as to the difficulty encountered in controlling it. By the Harris method the conditions responsible for it are largely, if not completely, obviated.

Cesarean section is preferred by some to symphysiotomy because of an easier and more rapid convalescence, as well as from the fact that the mortality to the mother is about the same and the infant mortality less. Under the improved Sanger method the maternal mortality in section is 5 to 10 per cent. and the infantile 5 to 6 per cent.

Embryotomy, when attempted through a narrow pelvis while the head is yet unengaged, is one of the most difficult of obstetric operations. The mortality is a little less than in section.

Having considered the dangers and advantages as compared to other operations designed to terminate obstructive labor, the author suggested the following points of interest:

1. Many children are today being saved that a decade ago would have been mutilated.
2. Many children are today delivered at term, alive and capable of growth and development, who a few years since would have been prematurely delivered only to succumb during delivery or a few weeks following it.
3. The simplicity of the operation, the easy preparation, the ready consent of the patient and friends, render it possible of accomplishment, while the more formidable section would be either absolutely refused or fraught with greater danger.
4. Both maternal and fetal mortality compare favorably with that of induced labor, embryotomy and Cesarean section.

Dr. JOSEPH B. DE LEE of Chicago read a paper on

ASPHYXIA NEONATORUM, CAUSATION AND TREATMENT.

The author stated that the highest mortality that befalls the human race in one day occurs on the day of birth. Schultz estimates that 5 per cent. of children are stillborn, dying during labor, and 1.5 per cent. die shortly after birth as the result of the labor. Brothers states that in New York city from 1889 to 1892, over 16,000 children died from the labor or immediately after it. Dr. De Lee believes that this figure is not too large. Since in cases of suffocation of the pregnant woman the fetus dies first, because the mother abstracts oxygen from the fetal circulation, this and other conditions in the mother, as anemia, acute and chronic, heart disease, asphyxiation by gas, etc., are dangerous for the child. It is this that makes the prognosis bad for children delivered by Cesarean section from women who died slowly. After the sudden death of the mother the fetus may live, and if promptly extracted may recover. Only 6 per cent. of the hitherto reported cases have lived. Premature separation of the placenta normally implanted; this may happen during pregnancy, and then is almost always fatal to the child, or it may occur near the end of the second stage of labor, when the child may be born alive. The death of the second twin in utero is often caused by two early separation of the common placenta. Besides the signs of asphyxiation shown

by the fetus, external hemorrhage in the intervals between the births gives warning of the danger. Separation of the placenta when it is previa, or compression of the placenta by the breech or colpeurynter used to stop hemorrhage, causes asphyxia. When the placenta is torn by manipulation, anemia is added to the asphyxia, and these are further aggravated by the anemia of the mother, all of which explain the high fetal mortality in placenta previa. Several other causes of asphyxia neonatorum were referred to by the author.

Coming to the treatment, paramount in importance is the recognition of asphyxia beginning while the child is still in utero, and fortunately this is almost always possible. One of the first signs of fetal danger is the decrease in the number of the heart beats. A steady slowing to 100 per minute, and certainly if below this, points to impending fetal danger. In some cases there is an increase in the number to 160 or more. This usually comes after the diminution has been pronounced, and betokens impending death from paralysis of the vagus. It may be primary, however, and should then be accorded the same significance as slowed heart's action. Irregularity of the heart tones, occurring in the intervals between pains, is also significant, and impurity of the first sound of the fetal heart carries important information to the experienced ear.

The second diagnostic sign is the passage of meconium. In breech cases this is of little value unless the breech is high up, and in the other presentations the sign should be accorded significance only when the meconium is fresh.

Another sign, but one that shows that the asphyxia has already become serious, is feeling, seeing or hearing respiratory movements made by the child. When the breech is half delivered one often sees the gasps made by the child. After podalic version the foot can sometimes be seen to move with the respiratory action. In one case the effect of fetal hiccup was thus observed. The obstetrician should recognize the causes of asphyxia and avoid them.

According to the author, there are three grand principles governing the treatment of asphyxia neonatorum: *First*, maintain the body heat; *second*, free the air passages from obstruction; *third*, stimulate respiration or supply air to the lungs for oxygenation.

Of all the methods of artificial respiration, only three have proven of service in the author's hands—compression (rhythmical) of the chest, the Schultze swinging and mouth to mouth insufflation with the tracheal catheter. Asphyxiated children and children delivered by severe operative procedures should always be watched for the first hours and days after labor. Their lungs not seldom fill up and cause secondary asphyxia. Such children are often found dead in their cribs; or they may never have cried vigorously, whining pitifully till death, when a more or less extensive atelectasis pulmonum is found. These children are much more subject to icterus and to sepsis, especially the intestinal and bronchial forms.

□ Dr. CARL E. BLACK of Jacksonville read a paper on

INFILTRATION ANESTHESIA.

He said it has now been five years since the method of anesthesia by infiltration was first introduced to the profession by its originator, Dr. C. L. Schleich of Berlin. He began the use of Schleich's solution with a distinct prejudice against it, but now its merit had forced him to continue using it. After doing a considerable number of minor operations by the method of infiltration, he was called upon some months ago to operate upon a much debilitated patient for tubercular peritonitis, which he did with satisfaction. To give the patient an anesthetic would have been hazardous, and it was decided to try the method of anesthesia by infiltration. He had made a considerable number of operations under anesthesia by infiltration, among them three abdominal sections, and found it very satisfactory. The patients suffer almost no pain and escape all the distress incident to general anesthesia. The giving of a general anesthetic is always accompanied by some depression, and in some cases when ether or chloroform are given, even for minor operations, there is marked depression and shock which is due to the anesthetic. The giving of a general anesthetic produces different effects on different patients, varying from almost imperceptible depression to marked shock or sudden death. The element of shock even in case of a major operation is much modified, to the advantage of the patient, by avoiding general anesthesia. Local anesthesia by infiltration or any other method can never entirely supplant ether and chloroform, but there is a large number of operations which can be performed more expeditiously and with greater safety by local anesthesia, and we should not fail to give our patient the benefit of these advantages. Recently he made an operation for appendicitis by this method with entire satisfaction, the patient making a rapid recovery. It seems to him that primary

cases of appendicitis can easily be operated on early, before any pus formation, by this method, with great advantage to the patient.

Dr. LYMAN WARE of Chicago read a paper on

SYPHILITIC NEURO-RETINITIS.

During an experience extending over many years the author does not recall a single case of syphilitic neuro-retinitis following thorough and prolonged antisiphilitic treatment, by which he meant treatment given more or less continually for two or three years, then irregularly or intermittently for ten or twelve years more. Mercury he believes to be curative, while the iodid of potash in the early stages is only palliative. Syphilitic neuro-retinitis was never a disease that terminated spontaneously in perfect recovery. Without treatment it was sure to end fatally. The most skilful treatment, when begun at an early stage of the disease, might prevent a fatal termination in many cases; yet life was frequently rendered miserable and sad by partial or total blindness. While there were many who consider large doses of potash as the only remedy in nerve syphilis, and while the author believes it of great value in rapidly arresting the disease in some severe or dangerous cases, yet he does not think it compares with mercury in eradicating the syphilitic poison.

The paper closed with a report of five cases.

Dr. WILLIAM E. CASSELBERRY of Chicago read a paper entitled

MEMBRANOUS RHINITIS, DIPHThERIC AND NON-DIPHThERIC.

He said membranous rhinitis, also termed croupous rhinitis and rhinitis fibrinosa, is an acute inflammation of the nasal passages accompanied by a white membranous exudate which covers the whole or part of the inflamed mucosa. A membranous exudate frequently forms in consequence of chemic or electro-cauterization of the turbinated bodies, but this condition differs essentially from genuine membranous rhinitis. The exudate is thick, gray-white in color, confined to the immediate vicinity of the cauterized site, which it overlaps somewhat, shading off to a thin white edge a little distance from the center of the most intense inflammatory action. If this pseudo-membrane be forcibly detached on the second day it redevelops; if allowed to remain it becomes incorporated with the eschar produced by the cautery, and the whole will separate spontaneously like an eschar about the fifth day. From an etiologic point of view we may divide so-called membranous rhinitis into two types, diphtheritic and non-diphtheritic. Corroborative evidence of the identity of the diphtheritic type of membranous rhinitis with true diphtheria is occasionally obtainable in a definite history of exposure to infection while in attendance upon diphtheria patients.

It is seen that a liability to the dissemination of diphtheria lurks in the diphtheritic type of membranous rhinitis; it doubtless escapes medical observation and treatment, many times being regarded by the parents of the affected children merely as a "cold," while in reality, from etiologic and pathologic standpoints, it is a veritable diphtheria, differing only in degree rather than in kind.

Nevertheless, one is not justified in assuming all cases of membranous rhinitis to be diphtheritic, for in many the most careful search has disclosed only cocci. The crucial test lies in the microscopic examination of a culture, which should be deemed imperative in every case.

Pathology.—The structure of the pseudo-membrane is similar to that which occurs elsewhere in diphtheria. Microscopically it is composed of proliferated epithelial cells in a fibrous network.

Symptoms.—The symptoms are much the same for both types of the disease, and are ushered in by dryness and fulness of the nostrils with persistent tickling; later a free discharge, watery at first, but becoming thick and tenacious. By the third day an exudate will have formed which, if torn away by forceps, leaves bleeding points and soon reforms. The fibrinous deposit may occur in one or both nostrils and may embrace any or all parts of the passages, extending a variable distance backward. It rarely embraces the throat, although it may do so, or rather in these instances it seems to originate in conjunction with acute infectious pseudo-membranous inflammation of the faucial and post-nasal tonsils. Much discomfort ensues from the total occlusion of one or both nostrils and from the excoriation and tumefaction of the anterior nares, the external nasal appendage and upper lip being at times so red and swollen as to suggest erysipelas. In fact, it is likely that the micro-organism of erysipelas may be one of those capable of producing membranous rhinitis.

(To be continued.)

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the Association living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JUNE 19, 1897.

AFTER THE JUBILEE.

The effect upon the profession of such a gathering as that at Philadelphia, can scarcely be properly estimated at the time; indeed just such a medical meeting has never been held in this country.

When, for instance, in the history of the ASSOCIATION have so many leaders of the profession of one country been congregated? Were there ever better arrangements for the comfort of the entire company? Were there ever such a variety of professional papers? Was there ever a meeting in which the Sections were better attended? Were ever such clinics planned by the profession of any city, as were given by the teachers of Philadelphia during and following the great convention? The true answer to these questions, when fully considered, must result in assigning to the Jubilee meeting of the AMERICAN MEDICAL ASSOCIATION in Philadelphia an epoch-marking place in American medical history. Nor is the physician himself, as an individual, influenced.

As a painter returning home from an outing must bring home moss and specimens, and a poet, sentiment and images, so the physician returning from this reunion brings home tender recollections of the meetings with his old friends in the profession and a keener professional insight resulting from the sharper contests in the Sections, the new ideas advanced by the experimenters, the improved methods shown him by busy clinicians and the

adaptation of modern pathologic views to hospital and college construction. And the auxiliary meetings! The Academy of Medicine! The Medical College Association! The Conference of State Boards of Examiners! The American Medical Temperance Association and the veterans composing the Rocky Mountain Medical Association, the latter, alas, a constantly diminishing body! All these had pleasant and profitable reunions, and all were animated by the spirit of the founder of the AMERICAN MEDICAL ASSOCIATION, which sought by professional union to foster higher professional aims, to stimulate individual excellence and personal purity of character.

Valete! Fratres Philadelphenses vos palam fertis. Salvete! Fratres Denveri vestri labores difficiles sunt.

THE VETO OF THE OSTEOPATHY BILL.

The Governor of Illinois, the Hon. JOHN R. TANNER, has interposed his veto between the osteopathy bill and the public. The bill had slipped through the Senate unnoticed and unopposed. Some stir was made in opposition in the House, but there was not sufficient time to organize the profession, and the bill passed the House by a vote of 82 to 43.

The following members of the House of Representatives voted for the bill; let the profession take notice:

Anderson, Allen of Vermilion, Alschuter, Atchison, Avery, Bailey, Barnett, Barricklow, Bartling, Booth, Bovey, Branan, Brignadello, Bristol, Buckner, Busell, Busse Robert C., Butler, Cochran, Compton, Conlee, Daugherty, Dewoody, Dickson, Dinnen, Edelstein, Ely, Farrell, Flannigan, Fuller, Funk, Galligan, Garver, Hammers, Hart, Houghton, Kilcourse, Kinche, Ioe, King, Kolstedt, La Monte, Large, Lathrop, Laub, Lovett, Lyon, McEniry, Merriam, Merrill, Metcalf, Montgomery, Morris, Murdock, Murray of Clinton, Needles, Novak, O'Donnell, Organ, O'Shea, Parrish, Perrottet, Perry, Powell of Cook, Quastrum, Rowe, Salmans, Schwab, Sharrock, Shepard, Sherman, Sterchie, Suttle, Tisdell, Torrence, Trousdale, Trowbridge, Wathier, Weidmaier, White, Wilson, Wood, Wylie.

Dr. J. A. EGAN, the Secretary of the State Board of Health, worked hard against the bill, as also did Dr. J. W. PETTIT, the Chairman of the Legislation Committee of the State Medical Society, and Drs. KREIDER and BARTLETT of Springfield, but to little avail.

The slimy thing then crawled to the Governor's office, where in a few days its sponsors sought audience with the Governor, to urge him to put life into it by affixing his signature.

The Governor set a day for the hearing. In the meantime Dr. PETTIT was not idle; medical societies and individual members of the profession throughout the State sent letters and telegrams urging a veto. The day came and the osteopaths, men and women, came into the Governor's office headed by an able lawyer, Senator BERRY, as attorney, and the dubious "homeop." E. H. PRATT of Chicago, both of whom spoke. The Governor asked Dr. EGAN to answer their arguments, which he did, Yankee

fashion, by propounding some questions; among others: "What is osteopathy?" an interrogatory which proved a "poser" to the able Senator. The Governor then very promptly decided in favor of the profession and against the osteopaths. All honor to the Governor!

THE IDEALS OF THE ASSOCIATION.

There is in Dr. SENN's Presidential address, published in a late issue of the JOURNAL, a suggestion that may not favorably impress some of the ambitious juniors in the profession. The idea that six to ten years of active practice should precede participation in the proceedings of the ASSOCIATION may not be a popular one in these days, when the most recent graduate is ready to accept the highest professional positions, and as a rule perhaps considers himself more up to date than his older associates sobered by experience. It is not necessary to assume that this is especially an age when young men are most to the front, but it is an undeniable fact that the tendency to regard age and experience as entitled to special consideration is not so prominent as formerly, and that the "atrocious crime of being a young man" does not exist in any professional or social code of the present day. Youth, and possibly inexperience, has all of its natural advantages in its favor and is reaching out for more. The result is, to some extent, a loss of dignity and of some other desirable qualities, and it is a question whether we are not losers rather than gainers by the change.

Taking this view of the case there is certain reasonableness in Dr. SENN's recommendation. Six to ten years is not an excessive lapse of time in which to gain the experience that ought to finish off the second period of a medical education, after which any man of ordinary ability should be better fitted to edify his fellows with his professional contributions; and when it is a question of speaking with authority on practical subjects where only experience can give one a right to offer original facts, the wider that experience the better, provided that it is combined with an adequate knowledge of the results of the experience of others as found in the literature of the special subjects discussed. The suggestion of Dr. SENN that the young physician select the subject of his early literary work from the primary branches of the science of medicine: anatomy, physiology, histology, chemistry, pathology and bacteriology (understanding by this, really scientific work in these lines), and "reserve his efforts in writing on practical subjects until he has acquired sufficient experience to speak authoritatively," is on the whole, sensible advice, and he points out plainly the evident profitableness of such a course. It is not to be supposed that he would absolutely forbid the giving to the profession of valuable early experiences, unique medical or surgical cases, etc., when such occur,

but even these if worth anything will keep and be better for mature consideration. A caution in this regard might well be given to the older as well as the younger members of our profession. Premature publication of cases has, it is to be feared, been the cause of much useless or worse than useless therapeutic and surgical interference. The temporary good effects of serious operations, prematurely reported without taking into consideration the essential element of time in estimating their effects, has had, it is possible, in our imitative and enthusiastic days disastrous consequences upon many victims who might otherwise endured evils under which they had at least found life still tolerable and desirable. Perhaps if Dr. SENN's further advice as to preparation for the discussion of papers that are read were less needed, if it were a generally appreciated fact that, as he says, it is usually more difficult to discuss a paper intelligently than to write one, and if the discussion itself always exercised a judicious censorship, this might not be so much the case. It is easier and generally pleasanter to commend than it is to criticise, though the latter practice would often be more profitable both to the criticised and to the profession and the public. It is not specially meritorious to cultivate an amiable weakness and the consequences may sometimes be disastrous.

What Dr. SENN says about honesty in reporting the unfavorable as well as the favorable results, ought to need no special endorsement, but should be accepted as only a statement of a self-evident moral truth. The need of its occasional reiteration, however, is none the less, and it was not out of place in his address. The same is equally true of his remarks on much of the medico-political discussions that have occurred in times past, and which have too often been utterly unprofitable and even actually damaging to the standing and scientific reputation of the organization. The ASSOCIATION should first of all be a scientific body; it holds a peculiar position as the most prominent medical society in the country and the higher its scientific reputation before the public and generally, the better for our profession.

The ideals of the AMERICAN MEDICAL ASSOCIATION can not be too elevated and it is well that its President should impress upon it this fact. It is a satisfaction that the session just closed was one that has, it is believed, been an advance in a scientific point of view over prior meetings and in all respects a creditable and successful one.

THE FOREIGN CULT IN AMERICAN MEDICINE.

The latest published utterance of a recently deceased American naturalist, who was second to none in the specialties he had adopted, and was furthermore one of the most philosophic and broadest in his culture, was a protest against a tendency that appears to exist

among scientific students to overestimate the value of the study of the infinitesimal and the culture of Europe as compared with our own. If this is true amongst scientific men it is much more so in medical circles, and his essay may well serve to point a moral for the consideration of our profession. At the present time it is still the fashion to consider no medical education complete without a visit to European medical centers, and there is a certain prestige to a practitioner who has "hospitirt" in the lecture rooms of Berlin or Vienna, or other transatlantic university city. It is assumed that wisdom has been absorbed, whether the sojourn was brief or lengthened, and the question of acquaintance with the language, or of actual study, is seldom or never raised. There are many who claim this prestige who would fail to understand twenty-five consecutive words of a lecture delivered in any other tongue than their own, and whose attendance might have been as well in Moscow or Bucharest as in Berlin or Paris, for any good it has done them. There are others, somewhat better fitted, who enter laboratories and pick up a certain amount of knowledge, which they might have better learned in their own country, and ever after claim the distinction of an acquaintance and familiarity with the great lights of medicine abroad that they turn to their financial profit by advertising it amongst a wondering clientele. Having too often had no experience, and leaving their own land in the callow state of recent graduation, they are liable to only imbibe one-sided and false notions, to the disparagement of their country and its scientific standing, the more so, since by exploiting these on their return they think they contribute to their own glory by shining in the reflected light of their illustrious European acquaintances. There is, of course, another class who honestly admit that a European trip is more for pleasure than business, and a certain number who actually utilize it adequately and estimate it at its proper worth. These, however, are largely special students, and often those who have already done scientific work that has given them a standing, it may be, even abroad. It is abundantly true that an American who is properly fitted can learn something abroad, as the converse is also true that the European could learn something here, if he only could get that fact into his consciousness. Too many, however, of the freshly made doctors, who finish off with a European trip, derive from it no intellectual benefit whatever; their principal acquisitions are liable to be a certain deterioration of morals and a large amount of additional conceit. In time, under wholesome home influences, this will probably wear off, but it is no advantage to have had it exist and it must leave to a proper minded individual an unpleasant reminiscence.

With those who really profit by European study no one would need to quarrel, but for the fact that even

among these there are some who, through want of mental balance or some other defect, come back with an undue estimate of themselves and a disparaging opinion of their own country and countrymen. A "certain condescension in foreigners," humorously noted by Lowell, can be endured, recognizing the fact that it is generally a characteristic of second rate individuals, but to have it encouraged by the peculiarities of our own compatriots is not at all gratifying and is much less endurable. It almost makes a little medical jingoism seem desirable to counteract the silly egotism that tries to magnify itself at its country's expense.

Professor COPE's protest against the undue magnification of microscopic research is also valid in medicine; we have the same tendency to correct. Section cutting and staining learned abroad no more makes a pathologist than it does a biologist, and it is in medicine, as in science, not less really scientific to observe properly with the naked eye than "through a brass tube furnished with lenses." The overestimation of the latter method is responsible for the waste of much patient work and expense, and this is especially true in medical science. What we need is not less careful pathologic work, but more and better clinical observation to guide and interpret it, and it is easier to make a trained microscopist than a really skilled clinician. As it is, however, it often happens that a manual skill and dexterity in microscopic work is valued above far more important and difficult accomplishments, simply because it is more showy and requires the use of elaborate paraphernalia that are beyond the reach of the many. There has been a large amount of imposition upon the medical public in this way, as is shown by the records of much so-called pathologic work in the past. It is to be hoped that there will be less of this in the future, but this result will be brought about more by a correct appreciation of the greater value of good and thorough clinical observations than by anything else. It is worth while to occasionally emphasize this truth.

There is a possibility of becoming eminent in medicine without a European polish to our professional education, but there is a slowness in certain quarters and certain individuals to recognize this fact. Indeed it is even now a matter of surprise and comment amongst some high European authorities that there should be such a lack of recognition, but it is not their interest to complain. The time, however, will come when American centers of medical education will draw European students, and at the present rate of progress it may not be so very far distant. The sooner it appears the better, and we can best aid its coming by discouraging the dishonorable depreciation of what is really good in our own country, and the too prevalent cult of a foreign fantasy in matters of medical science and education.

CORRESPONDENCE.

Food In Diabetes. A Reply to Dr. Cutter.

FORT ASSINNIBOINE, MONT., June 10, 1897.

To the Editor:—The communication of Dr. J. A. Cutter, published in the issue of the JOURNAL for May 29, should not pass without a reply.

In this letter he states "my plan of treatment has been to stop the fermentation of any kind of food in the alimentary tract because such fermentation produces carbonic acid and other paralyzing gases and these gases act directly on the liver and help to increase the production of sugar." (The italics are mine.) This is certainly important if true and, being unable to find any reference to this point in the various works on physiology accessible, I would beg Dr. Cutter to name his authorities for such a surprising statement.

"Again," he says, "American morphologists have shown for over thirty years that starches and sugars promote alcoholic and acetic acid fermentation in the stomach and bowel."

Unfortunately for this statement, Foster's Physiology does not recognize the occurrence of any such condition as alcoholic and acetic acid fermentation in the bowels and, furthermore, it is difficult to understand what "morphologists" would have to do with such a purely physiologic problem; since "morphology" is defined by the Century Dictionary as "The science of the external form and internal structure of animals and plants."

Again he says, "Victor Hugo, in 1862, in his great work 'Les Misérables,' called attention to the kinship of consumption and diabetes and to the rôle that sugar and sweets play in acid fermentation and as a cause of these two diseases." (The italics again are mine.)

It is certainly somewhat extraordinary for a physician to appeal to a layman as an authority on a professional subject and, after we had supposed that Koch had definitely settled the etiology of consumption, to have sugar brought forward as the *fons et origo mali* in the production of two such dissimilar affections as diabetes and tuberculosis. One shudders to think of the awful possibilities lurking in a morsel of sponge cake or box of bonbons.

Dr. Cutter also says, "as to prognosis, a young woman in 1888 with not a large percentage of sugar is living today. I do not know what her condition is, but she is living and I judge in fair health." Permit me to call Dr. Cutter's attention to an admirable article by Dr. Wadsworth, published in the New York Medical Record for May 29, 1897, on the diagnostic value of sugar in the urine in diabetes mellitus. In this article he reports his observations on eleven members of one family, all of whom showed sugar in the urine—in one instance as much as 10 per cent. All of these individuals were previously ignorant of the existence of any abnormal condition and enjoyed good health, the most marked case remaining apparently healthy during an observation lasting over six years. Dr. Wadsworth concludes his article by saying, "Basing my conclusions on the cases I have reported and four other cases which came under observation, three of which were only temporary, I think it should be clearly understood that the presence of sugar in the urine, regardless of the amount is not in itself sufficient to warrant a diagnosis of diabetes mellitus." This point I have endeavored to emphasize in the articles which have recently appeared in the JOURNAL. I am tempted to question the diagnosis of the case quoted by Dr. Cutter and am firmly convinced that far too many patients with sugar in the urine are unnecessarily subjected to the mental suffering, medication and restrictions usually consequent to a diagnosis of diabetes mellitus. I believe that test-tube diagnoses are much too common and that unwarranted conclusions are too hastily reached. Sugar occurs in the urine as a result of many conditions, and, of these, true diabetes is one of the least fre-

quent. A diagnosis based simply on urine analyses without reference to the katabolic condition presented by the patient I should consider as wholly untrustworthy.

Dr. Cutter believes in an exclusive beef diet as a panacea. In this he is opposed by all physiologists to whose works I have access.

Medical men may be surprised to learn from Dr. Cutter that "it has been considered by the profession that beef causes uric acid conditions which lead to coma and death." The production of uric acid is greatly increased under a meat diet but that it is generally believed that this body is capable of producing coma and death, I am not willing to admit. Dr. Cutter denies that he has ever "seen uric acid coma and convulsions caused by beef" and so far as I am able to learn no one else has either. The large amount of nitrates of urea observed so frequently by Dr. Cutter has no bearing whatever on the case, any specimen of urine from cases of fever or wasting disease giving it. Since Dr. Cutter claims credence by virtue of his experience with this disease it may not be out of place for the writer to state that he has been working on this subject over six years and that the case recently reported *in extenso* is the one most carefully studied among several observed during that period.

Dr. Cutter calls for the experience of others as well as myself. In such a necessarily brief communication as this I can do no better than quote the words of Dr. Prescott, published in the Boston Medical and Surgical Journal, Sept. 3, 1896, in which he says, "In looking over the literature of the subject (diabetes) I found there was one man who had a large experience and who was assistant to a man who had even greater experience, Dr. Grueber of Nauna, which is a sanitarium in Coblenz, Prussia. Dr. Grueber has seen 187 cases and the man under whom he worked had seen 3,000 cases. He reports one case which I will read as it is rather instructive as showing what can be done even if it goes against our preconceived ideas.

"Man, 39. Father and sister died of diabetes and brother under treatment for it. For two years lived almost entirely on meat, fish and eggs, but was unable to tolerate so rich a diet and occasionally took bread and potatoes. When first seen was unable to walk, had a peculiar livid flush of the face, edema of the feet. Breath had the odor due to acetone, tongue and lips dry and cracked, constipated, urine 5 per cent. sugar, large in amount and acetone and diacetic acid present. As he thought diabetic coma on the point of developing he advised very little meat and fish, no eggs but as many potatoes as he liked and an ounce of bread per day. Much water was given and 20 drops of nitrous ether three times a day. In two days the urine contained 6.3 per cent. of sugar, very little acetone and no diacetic acid, thirst less and odor from breath scarcely perceptible. On fifth day a stricter diet, but allowed potatoes freely. In three weeks sugar 1.1 per cent., able to walk half an hour at a time, no abnormal thirst. This improvement had continued up to the time the case was reported, about three months. This case was given by Dr. Grueber as a typical one showing the results of the treatment advocated."

This case of Dr. Grueber is almost parallel with my own reported in the JOURNAL for May 8, 1897, but which was observed several years ago. Very respectfully,

EDWARD L. MUNSON, M.D.
Assistant Surgeon, U. S. Army.

Observations on the Semi-centennial Meeting.

DETROIT, MICH., June 7, 1897.

To the Editor:—The most careless listener to the exercises held in Philadelphia, June 2, 1897, must have noted the evolution of the ASSOCIATION from its primary objects.

As to membership: at first this included delegates from med-

ical societies, State and local, from hospitals, and from medical colleges. Now only delegates from medical societies are admitted. The interest of the medical colleges are looked after by the American Medical College Association; the parent organization is interested only as the colleges furnish adequately trained medical men for its membership. To this end it frequently admonishes, and encourages, but no longer takes colleges as such into its fold.

So with hospitals; Boards of Health, city, State and National; these have their representative societies local or National. Formerly the ASSOCIATION by its societies had a voice in regulating the practice of medicine; now State Boards with State authority attend to this duty.

Without going farther into detail it is clear that the only thing left, other than advisory, is the development of the science and art of medicine, and cultivating the spirit of National brotherhood. Thus it has cut loose from all financial interests, from all vested professional rights of any sort, and restricted its efforts to the gathering in the largest amount of professional research and after classifying, scattering it abroad through its JOURNAL. The JOURNAL is the center of its active life. This active life will be strong just as the Section work of the ASSOCIATION meetings is broad and thorough.

Such Section work can only be accomplished by the disinterested planning of Section Officers and members. The interests of the Section must be held of the first importance by each member of the same, in order that each may do his best. Each must see that such action will return the largest return for the expense and loss incident on attendance at ASSOCIATION meetings. Such return will be largest when there is no obstacle to work in the Sections during the entire day, reserving the evening for social commingling. Such Section work calls for the placing of the duties of the nominating committee in the hands of the present business committee; the restricting the President's address to fifteen minutes, and all public ASSOCIATION speeches to ten minutes, and discussions to five minutes. Really the only good purpose of the general meetings is to accept or reject committee reports, indulge in a few formal platitudes for the sake of seeing and hearing a few voices. No important business, or question of medical science or art can be discussed in a large public gathering like the ASSOCIATION. Recognizing this it has already made permanent committees so as to have its affairs thoughtfully studied and regulated. One hour a day should be ample to transact all general ASSOCIATION business, and the rest ought to be scrupulously assigned to the Sections. The placing of the nominations in the hands of the business committee would save the members much time and not a little temptation to wire-pulling. However it will be noticed by all that the power of the President of the ASSOCIATION has gradually diminished, until even now it is of far less importance than a chairmanship of one of the live Sections. It is also noticeable that in the best Sections there is no wire-pulling over the selection of officers. The prosperity of the Section depends so entirely upon the selection of persons who are able and willing to sacrifice themselves to promote the interests of the whole, that more deliberate thinking enters into their selection.

Clearly in its process of evolution the Sections of the AMERICAN MEDICAL ASSOCIATION are moving toward a time when to be an active member of a Section will be regarded as more desirable than an official position.

It is easy to see that such a state of things would leave a large increase of energy free for the real Section work; it is just as clear that in that day the power of the ASSOCIATION would be incalculable for good and as full of delight as of profit to its members.

The scientific medical men of the United States have the Sections of the ASSOCIATION absolutely within their control. If these Sections do not accomplish what they might desire, they have only themselves to reproach. Yearly it is noted they

are flocking in larger numbers to the Sections and fashioning them in accord with their purpose. They see in such a course a means of profit and pleasure to themselves nowhere else afforded.

Two reforms are imperative ere the highest development of the ASSOCIATION is reached. By the first the nominating committee is merged into the present executive committee. This adequately represents by a permanent body the Sections, and so the entire profession. The second changes membership to a single class, viz., those who are members of recognized medical societies, State or local, and who agree to support the ASSOCIATION'S Constitution and By-Laws and Code of Ethics, and pay their annual dues. This latter would admit of an actual membership as great as that of all organized medical societies, while the existing machinery of the ASSOCIATION would accord to each equal rights and privileges. With such a backing the JOURNAL must needs become the most powerful in the world and lead the profession in its process of higher development.

In one respect the Sections of the ASSOCIATION have an immense advantage over the special societies, viz., in the inexhaustible source of membership. The recognized medical societies ramify into every part of every State; each member of these is eligible to membership in one of the Sections. Once actually in that Section he takes the place his talents and industry accord. If a real addition to its working force he stays, if not, he naturally finds the atmosphere uncongenial. In this manner, by operation of natural law, that which is good will be retained and the undesirable will vanish. The whole Section is really the examining board which each member of the Section must pass before he attains a comfortable membership therein. No matter how many are rejected the supply is never exhausted.

We all know the heart burnings, the disagreeable features of the methods adopted by existing special societies. We suggest that the methods of the Sections of the AMERICAN MEDICAL ASSOCIATION are more in accord with the laws of medical sociology and in the end more satisfactory.

It is granted that this method calls for the eternal vigilance of the real leaders, but this is essential in all coöperative work. Such leaders have appeared in several of the Sections, and others are rising in the rest, so that in the near future all will have as desirable a record as the ophthalmic.

Enough has been noted to support the claim that the AMERICAN MEDICAL ASSOCIATION enters upon the beginning of its second half century organized for better work than ever, and with good hope of improving such organization, so as to vastly extend the bounds of its working membership, with a membership larger than ever and more devoted to the advancement of its interests. LEARTUS CONNOR, M.D.

PUBLIC HEALTH.

New York City's Lowered Death Rate.—The Bureau of Vital Statistics gives out the fact that the death rate of the first week in June is lower than for any corresponding week in the last twenty years. There were only 351 deaths during the lapse of four days, as against 606 in 1894 and 841 in 1895.

Money More Needed Than Food.—Julian Hawthorne on the famine in India, says that "food is hoarded in the country and the starving ones only need money to save their lives." His estimate of the mortality is 8,500,000 of a given population of 287,000,000, and this latter number is made to represent the wealth of lives in British India.

Precautions Against Smallpox.—The Board of Health of Boston have sent out a circular to the physicians of that city requesting especial care in the examination of all cases of chickenpox, and

that they be reported to the board. This precaution is taken owing to the possible danger of a mild case of smallpox (and this is the type of the cases recently discovered in Boston) being mistaken for chickenpox.

The Danger from Bovine Tuberculosis.—Dr. W. L. West of Ellsworth, Me., has reported to Dr. G. H. Bailey that two children of a man named Luther Bridges have recently died of tuberculosis, due to drinking milk from a cow which was found, when killed, to be the subject of extensive tubercular disease, largely localized in the udder. Five of Bridges' nine children are suffering from pulmonary tuberculosis and several are now, according to the report, fatally ill.

The Mortality Rate of European Cities.—According to the published Belgian statistics, Frankfort-on-Main leads the sanitary record, the mortality being only 15.6 a thousand. The Hague follows next with 16.6; then comes Edinburgh, with 16.8; Stockholm and Genoa, with 17; Copenhagen, 17.1; Turin, 17.2; Amsterdam and Hamburg, 17.8; Berlin, 18; Rotterdam and Nice, 18.5; London, 18.8 and Brussels, 18.9. Thus it appears that Nice has a larger pro rata mortality than Berlin, Edinburgh or Hamburg. Still this may be due to the invalid contingent disappointed in their search after health.

Not Altogether Irrational.—Mr. Arnold White, the philanthropist, as quoted by the *Medical Mirror*, says in regard to what he styles "the supply of the suffering," that "Foreign generals note the contrast between the physical renaissance of the continental generals and the fool's paradise in which England basks. Our separate caste of fighting men, our cult of sickness and worship of weakness, our heedless conversion of the rural population into pastry-faced townsmen, and our cheerful dependence for food products on healthy races and possible enemies, are matters that are watched abroad with delighted surprise."

Famine in China.—The secular press speaks of the "cruelly severe" famine in the north and east of Szechuen province, China. The relief commissioners saw a large number of decomposed bodies on the way to the thickly populated districts involved in the visitation, and a returned traveler reports that about half of the inhabitants of a stricken town had perished from either starvation or the resulting complications. The government has forwarded 120,000 piculs of rice, but is much hampered through want of transportation facilities. There are also more serious obstacles to benevolence, for many rich Chinese are so accustomed to accounts of famine and plague that they refuse to contribute. In Shanghai only 103 taels in money could be collected. It was given to the Protestant missions for distribution.

A Death from Yellow Fever.—The Columbian Line steamer *Advance*, from Colon to New York, arrived at quarantine June 11 with ship's crew and first cabin passengers all well, but a second cabin passenger attacked with yellow fever two days after sailing died a few hours before coming within jurisdiction. The statement was that none of the crew were allowed ashore at Colon, and that every night the vessel was moored away from its pier. Health officer Doty had no fears of a spread of the disease in New York or vicinity, as cremation of the corpse at Swinburne Island had been ordered, the ship was to be thoroughly disinfected, the forty-seven first cabin passengers were to be brought by steamboat to the city, there to be under observation, while the second cabin passengers were to remain five days at Hoffman Island. The *Advance* was subsequently allowed to proceed to her pier.

NECROLOGY.

JOB LEWIS SMITH, M.D., an honored member of the AMERICAN MEDICAL ASSOCIATION, who died in New York City June 9,

was born in the village of Spafford, N. Y., October 15, 1827. He prepared for college at the Homer Academy in Cortland County, N. Y., and entered Yale in 1847 as a member of the same class with President Timothy Dwight. A graduate in 1489 he began the study of medicine with Drs. Goodyear and Hyde and later with Dr. Caleb Green. Then he attended lectures at the Buffalo Medical School in 1851 and 1852, after which he went to New York and entered the College of Physicians and Surgeons, graduating in 1853. Dr. Smith then began the practice of medicine, giving special attention to the diseases of children. He was a worker for over twenty-five years in the Infant Asylum and the New York Foundling Asylum, constantly contributing to medical societies and periodicals. He prepared a general treatise on the diseases of children, which is regarded as a standard in this country, and which has enjoyed the honor of many translations. His reputation as an expert led to his appointment as Clinical Professor of Diseases of Children in Bellevue Hospital Medical College, and to his election as an active and honorary member of many medical societies. He was consulting physician to the children's class in the Bureau for the Relief of Outdoor Poor and physician to the Charity Hospital. Four daughters and two grandchildren survive him. His was a life of good works.

CHARLES O'LEARY, M.D., died at his home in Providence, R. I., June 1, of Bright's disease. Dr. O'Leary was formerly president for two terms, 1881 and 1882, of the Rhode Island Medical Society, and was at one time connected with the faculty of St. Mary's College, Emmetsburg, Md. While there he wrote a Greek grammar that for many years was the standard work in Roman Catholic colleges. He served as surgeon and medical director during the civil war. He was a graduate of the Long Island Medical College, in the class of 1860. During the time of his residence in Cincinnati he served as a professor of chemistry in the Medical College of Ohio and resident at the St. John's Hospital. For nearly twenty years he was surgeon of the Rhode Island Hospital. Two sons are physicians of Providence.

ASA F. POTTER, M.D., Boston, June 1, aged 62 years, a descendant from a long line of physicians back to William Potter, who was physician to Oliver Cromwell and Charles II. In 1857 he received the degree of M.D., from Dartmouth College; in 1864 entered the army as assistant surgeon; and in 1883 was elected professor of materia medica and therapeutics and lecturer on nervous diseases at the College of Physicians and Surgeons. He was a member of the Massachusetts Medical Society, the AMERICAN MEDICAL ASSOCIATION, for several years president of the Boston Therapeutical Society, and an honorary member of the Botanical Society of Italy.

HENRY E. TURNER, M.D., University Pennsylvania, 1836, who recently observed the sixtieth anniversary of his diploma, died in Newport, R. I., June 2. He was born in Greenwich, R. I., 81 years ago and early went to Newport, where for a long time he was city physician.

FRANCIS L. DICKINSON, M.D., of Rockville, Conn., died in New Haven, Conn., June 2. He was born in Chatham, Conn., in 1817, and was graduated from the Yale Medical School in 1840. He served several terms in the State Legislature and was a State senator in 1877 and 1878. He leaves two sons.

EDGAR A. KEELER, M.D., died at Little Falls, Passaic Co., N. J., June 7. He was a graduate of the College of Physicians and Surgeons, Baltimore, Md., class of 1880.

EDWARD SEAMAN BUNKER, M.D., died at Bath Beach, Brooklyn, N. Y., June 8, in his 57th year. In 1857 he was graduated from the Polytechnic Institute and for ten years remained there as a teacher of classics. In 1871 he received his degree from the Long Island College Hospital.

WILLIAM D. ALDRICH, M.D., Dartmouth, 1872, an active assemblyman of New York State, died June 4 at his home in Warrensburg. During the forenoon he complained of not feel-

ing well and retired. About 2 o'clock his wife visited his room and found his lifeless body.

W. H. STRANGE, M.D., died in Toronto, Canada, June 4. He rose early to go to Niagara, but died after only a three hours' illness. He was Deputy Surgeon General of the militia forces of the Dominion.

ROBERT SCOTT, M.D., of 325 East 69th Street, New York, died in the Presbyterian Hospital June 9, of cancer of the stomach. He was a Scotchman, unmarried, and a graduate of the Edinburgh University.

CHAS. E. ENGELS, M.D., Chicago, aged 35 years.—Karl Esch, M.D., Peoria, Ill., June 10, aged 37 years.—Robert Moffitt, M.D., Mt. Pleasant, Iowa, June 10, aged 30 years.—Thomas Aquinas Purcell, M.D., Holyoke, Mass., May 31, aged 36 years.—Joseph Waggoner, M.D., Ravenna, Ohio, June 7, aged 75 years.—E. J. Longshore, M.D., Scranton, Pa., June 7, aged 53 years.—H. C. McCarthy, Altoona, Pa., June 6, aged 56 years.—George T. MacCord, Pittsburg, Pa., June 7, aged 51 years.—Wm. H. H. Hutton, M.D., Surgeon U. S. Marine-Hospital Service at Detroit, Mich., June 14.

SOCIETY NEWS.

Congress of the French Society of Otology and Laryngology, Paris, May.—Moire terminated his address on ozena by protesting against the too frequent assumption that ozena is incurable. His treatment is merely nasal and retro-nasal antiseptic irrigations with sprays of the same and of oil after removal of the crusts when the patient wishes only to be relieved of the fetid odor. When more complete treatment is desired he adds vibratory massage every second day for a fortnight, then twice a week for a month, then once, and more rarely after this. The massage is followed by irrigation and removal of all the crusts and then with a spray of 5 to 25 per cent. nitrate of silver. He reports numbers of cures with this method sufficiently prolonged. It also enables the existence of complications to be determined and cured. General tonic treatment is necessary with it as indicated. Luc presented a couple of patients cured of empyema of the maxillary sinus by his new method, which he claims combines the advantages of other methods without danger of infection through the mouth and proves a rapid and complete cure for this obstinate trouble. He opens into the sinus through a large incision in the gum, resects the anterior wall, cures with extreme care with electric light and cauterizes with a strong solution of chlorid of zinc. He then makes an opening between the sinus and the nasal fossæ and introduces a drain into this opening, passing through the nose and ending outside. After dusting the sinus with iodoform through the incision in the gum, the latter is then sutured with fine catgut and soon heals. The sinus is irrigated through the drain with iodoformed ether; later with solutions of formol and boric acid. By the end of the fifteenth or twentieth day the drain is removed and the patient is definitely cured. The subjects to be discussed at the Congress next year are "Acoustic Unity and Pathology of the Tonsils."

Congress of the French Obstetric Society, Paris, April.—Habitual abortions without appreciable cause, was discussed among the other subjects. Charpentier has succeeded in curing this tendency in plethoric women by applying leeches to the cervix, but he usually restricts his treatment to wet cupping over the kidneys. Metritis is a frequent cause, and he advises the cautery for such lesions of the cervix and curetting for metritis of the fundus. Lefour has succeeded by rendering the uterus tolerant by the insertion of an interuterine pencil for eight months to a year, with repose in bed during the menstrual molimen and the administration of opiates and bromid. The congress resolved to urge the creation of special services at Paris for infected obstetric cases and pregnant suppurating cases, and

also the examination of the midwives of the Benevolent Bureau. The subjects announced for next year are placenta previa and applications of the forceps to the superior strait in flat pelvis, with classic presentation. A blank for infant's bulletins was presented, with the normal curve of weight during the first year for comparison. It was asserted that an effectual way to increase the mammary secretion when a woman is unable to supply sufficient milk for one child, is to give her two or three more children to nurse. The greater the demand the larger the supply.

New Hampshire Medical Society.—The one hundred and sixth annual meeting of this Society was held in Concord, May 24 and 25, 1897. There were about one hundred and fifty present and fifty new applications for membership. The first day was occupied in the reading of papers, while at the evening session the members listened to an address on "Medical Expert Testimony," by Hon. William L. Foster of Concord, ex-Judge of the superior court, also to a scientific description of the X-ray with a practical exhibition of its application to surgery, by Prof. J. Milner Coit, Ph.D., of St. Paul's School, and Dr. Adrian H. Hoyt, General Manager of the Electrical Instrument Co., Penacook. On the second day a paper on "Causes and Recent Treatment of Neurasthenia," by John D. Quackenbos, M.D., of New London, and a paper entitled "When to Call a Surgeon in Acute Abdominal Affection," by George W. Gay, M.D., Boston, were presented. President Richardson read his annual address. The following officers were elected: President, Dr. Moses C. Lathrop of Dover; vice-president, Dr. George H. Saltmarsh of Laconia; treasurer, Dr. M. H. Felt, Hillsboro Bridge; secretary, Dr. Granville P. Conn Concord.

Congress of Syphilography.—The Congress to Arrest the Spread of syphilis in Russia, recently summoned by the government, was attended by over 500 persons, including physicians, teachers, professors, heads of penal and other institutions, inspectors of factories, military and marine officers, etc. We note among the measures proposed, stricter supervision of the morals of the young, and cultivation of outdoor sports; education of the public to the dangers of syphilis by popular illustrated lectures, ably written pamphlets, etc.; soldiers encouraged to practice some trade; the adoption of a uniform blank for recording all cases, and for annual reports to a central bureau, suppressing names; rigorous physical examination by female physicians of prostitutes, and Tarnovsky urges the examination of the men who visit them. Foundlings should be fed artificially until six weeks have passed without evidences of syphilis, and syphilitic infants should only be given to syphilitic nurses. Rigorous and compulsory general medical examination of the employes in factories, public baths, etc., was also urged, with the organization of flying medical squadrons like those sent out a while ago to fight eye diseases. Fairs and large gatherings should have a special medical force provided. Home physicians of discharged syphilitic soldiers should be confidentially notified. With all this, strict professional secrecy is imperative, personal liberty respected, and to avoid inflicting a stigma upon the patients, there must be no specialism, but the hospitals, medical squadrons, etc., must examine all alike and treat all diseases. The proceedings are given in full in the *Ann. de Derm. et de Syph.* for April. The promoters are confident that the numerous practical and appropriate measures proposed bear the stamp of realization. They assume the coöperation of local benevolent societies in various ways and greatly increased gratuitous medical and hospital facilities.

An International Congress of Neurology, Psychology, Medical Electricity and Hypnology will be held in Brussels, Sept. 14 to 19. The addresses announced in neurology are: "Surgical Treatment of Epilepsy," Professor Winkler, Amsterdam; "Exophthal-

mic Goiter," Professor Eulenburg, Berlin; "Pathogenesis and Semeiology of the Reflexes," Professor Mendelssohn, St. Petersburg; "Influence of Delivery on Later Nerve and Brain Troubles in Children," Professor Anton, Graz; "Muscular Rigidity and Contractions in Organic Affections of the Nervous System," Professor Van Gehuchten, Louvain. Psychiatry: "Diagnostic Value of Prodromal Symptoms Preceding the Manifestations of Progressive Paralysis a long while." Professor Thomsen, Bonn; "Psychoses and Dreams," Dante de Sanctis, Rome; "Modifications in the Picture of Progressive Paralysis in the last Thirty years," Professor Mendel, Berlin; "Relations Between Psychoses, Mental Degeneracy and Neurasthenia," Lentz, Tournay. Medical Electricity: Semeiologic Value of the Electric Reactions of Muscles and Nerves," Professor Doumer, Lille; "Therapeutic Value of Currents of High Frequency," Professor Bergonie, Bordeaux. Hypnology: "Therapeutic Value of Hypnotism and Suggestion," Milne Bramwell, London; "The Question of Criminal Suggestions," Professor Liegeois, Nancy. Applications for membership should be addressed to Dr. Crocq fils, 27 Avenue Palmerston, Brussels. Fees, 20 francs.

Twelfth International Medical Congress, Moscow.—The Czar has taken the Congress under his protection and the delegates are to be presented to him by the ambassadors from the various countries. All members of the Congress are to be carried free from the frontiers to Moscow and return, and no customs levied on instruments or small quantities of drugs. (*St. Petersb. Med. Woch.*, May 8.)

The program announced by the Section for Nervous and Mental Diseases is as follows: 1. Pathology of the Nerve Cell, Van Gehuchten, Belgium; Dana, New York; Van Giesen, New York. 2. Syringomyelia, Schultze, Bonn; Schlesinger, Vienna; Minor, Moscow. 3. Tabes Dorsalis, Obersteiner, Vienna; Pierret, Lyons; Erb, Heidelberg; Grasset, Montpellier; Althaus, London; Darkschewitsch, Russia; Borgherini, Padua; Eulenburg, Berlin; Benedikt, Vienna; Raichline and Hirschberg, Paris. 4. Operative Treatment of Diseases of the Brain, Oppenheim, Berlin; Sachs, New York; Voisin, Paris.

Addresses on other subjects will be given by Lombroso, Turin; Crocq, Brussels. 1. Hallucinations and Fixed Ideas, Pitres and Regis, Bordeaux; Shaw, Liverpool. 2. Paralysis of the Insane, Binswanger, Jena; Althaus, Homen, Helsingfors; Muratow, Moscow. 3. Hypnotism and Suggestion, Bernheim, Nancy; Tokarski, Moscow; Robertson, Glasgow; Gorodichze, Paris. Other speakers: Morel, Ghent; Fürstner, Strassburg, Francotte, Liège; Shuttleworth, England; E. Christian, France; Meschede, Germany; Leyden, Berlin; Henschen, Upsala; Ballet, Paris.

The Section for Hygiene sends out the following program: 1. Scientific Principles applied to the judgment of potable Water, Hueppe, Prague; Vaughan, Michigan; Gintl, Prague; Jolles, Vienna; Bujwid, Cracow. 2. Physical Training of Youth; how best attained by school Gymnastics, Palmberg, Helsingfors; Baginsky, Berlin. 3. Investigation of mental Overwork in Schools, Wirenius, Petersburg; Baginsky. 4. Alcoholism from the standpoint of social Hygiene, Duties of the State and of Society in this respect, Felix, Bucharest; Bergeron, Paris; Korowine, Moscow. 5. Importance of first help Societies, Frey, Vienna. 6. Homes for the Poor in large Cities and homes for Artisans in industrial Localities, Nagyvany, Budapesth; Berthensen, Petersburg. 7. Conditions for the spread of Tuberculosis and measures to prevent it, Vaughan; Nocard, Paris; Ostertag, Berlin; Morot, Troyes; Bujwid. 8. Hygienic measures in infective Diseases and value of protective Vaccination, Hueppe; Bose, Montpellier; Kral, Prague, etc. 9. Organization of sanitary Statistics, Felix, Gutstadt, Berlin. 10. Importance of medical instruction for Women.

In the Section of Obstetrics and Gynecology, Pinard, Paris; Varnier, Paris, and Zweifel, Leipsig, will speak on Symphysectomy. Leopold, Dresden; Hennig, Leipsig, and Varnier, on External Investigation. Bar, Paris, and Varnier on serum therapeutics in puerperal sepsis. Fritsch, Bonn; Leopold and Sänger, Leipsig, on the Connection between Gonorrhoea and Puerperal Troubles. Colpotomy in diseases of the Adnexa, displacement and Neoplasms of the Uterus, Candela, Valencia; Doyen, Rheims; Dührssen, Berlin; Martin, Berlin. Gonorrhoea, and its Therapeutics in the non-pregnant, Sänger, Leipsig; Truzzi, Parma. Surgical treatment of Peritonitis, Martin; L. Tait, Birmingham; Winckel, Munich. Value of the different methods of operating Carcinoma of the Uterus, in respect to relapses, Sänger; Tait; Winter, Berlin. Addresses on other subjects are announced by Chrobak, Vienna; Clarke, Boston; Sneguirew, Moscow, etc.

MISCELLANY.

Undoubtedly Antivivisectionists.—The American Pet Dog Club met at Wildhurst, N. J., June 10, and adopted a badge. One hundred and ten ladies were present, including delegations from St. Louis, Philadelphia and Atlanta.

Personal.—P. M. Woodworth, M.D., Chicago, has been appointed by Governor Tanner to the Lincoln Park Board. Joseph C. Gordon, M.D., of the National College of Deaf Mutes, Washington, D.C., has been appointed Superintendent of the Illinois Deaf and Dumb Institution at Jacksonville.

Alcohol and Suicide.—At the recent international Congress of Psychology Dr. Müller gave an interesting historic sketch of the etiology of self-murder and, by means of an elaborate series of statistics, traced to alcohol the primary cause of its marked increase of late years. The author estimates the number of suicides in Europe at 50,000 a year, thus showing that the evil is increasing at a greater rate than the population. The most favorite month for suicides is June, the least December. Early morning is chosen in preference to the night; the mechanic class furnishes the largest number of subjects, and the peasant the least. Dr. Müller considers brandy the most pernicious form of alcohol, and traces to its influence the blunting of those weapons which in the struggle for life are the most necessary to sustain the conflict.—*Westminster Gazette*.

Disease Contracted "in the Line of Duty."—The United States circuit court of appeals holds, in *Rhodes v. United States*, March 1, 1897, that although an applicant for a pension might have contracted the disease (here it was alleged to be catarrhal ophthalmia of both eyes) before he entered the service, yet, if he was cured of it, so that he was a sound man when he enlisted, and he subsequently contracted it again while he was in the service and in the line of duty, his statement to the latter effect will not be deemed false. The phrase, "in the line of duty," it further construes to denote that the disease must have been contracted as a result of his service, or as a result or by reason of the fact that he was in the service, making the service the cause of the disease, and not merely a coincident in time.

The Paris Horror.—The medical profession at Paris was sadly involved in the catastrophe at the charity bazar. Dr. Henri Feulard and his daughter and Dr. Rochet were among the victims; while the families of several other physicians, Nélaton, Nitot, Picque, Vimont, Le Sourd and Simon, lost one or more members. Dr. Feulard was a distinguished and popular dermatologist. The *Annales de la Société de Dermatologie*, of which he was secretary, and the reports of the dermatologic congresses contain many valuable contributions from him—always a leading spirit. His early, tragic death at 40 is a great loss to science and shock to his friends. It seems incredible that in the boasted "center of civilization," Paris, such a long time elapsed at the charity bazar horror before an ambulance arrived, the dead lying piled up on the sidewalk and the injured being carried into neighboring houses. It was an hour and a half, according to the *Figaro*, before the special emergency ambulances reached the spot. Among the 1,500 persons in the building there were about four hundred men, organizers of the fête, priests, etc., but all of the men managed to escape except three. Two of these were physicians; one, Feulard, had escaped but returned to save others, and ten of the 120 female victims were the wife, daughter or sister of a physician. The medical fraternity thus furnished a tenth of the victims.

Schlatter the "Healer" Dead.—Denver, June 6.—A dispatch to *The News* from El Paso, Texas, says that Francis Schlatter, who said he performed miraculous cures by divine power, was recently found dead in the foothills of Sierra Madre, thirty-five miles southeast of Casa Grande, in the State of Chihuahua.

hua, Mexico. He had been fasting, and apparently starved to death.

While in Denver, from August 22 to Nov. 13, 1895, about three hundred thousand people visited Schlatter. Francis Schlatter was an Alsatian peasant, ordinarily educated and intelligent, who came to this country several years ago and settled in Jamesport, Long Island, as a shoemaker. His record in Jamesport was good. He was addicted to no bad habits, made excellent shoes, paid his way and saved money. He was in love with a young woman, who, however, refused to marry him. In the society of the village he was known as a good fellow with queer views, who could "talk like a book." He had "visions," also, and had much to say about the great questions of life and destiny. But at this time he made no pretensions to the possession of any unusual powers. In 1894 he went to New Mexico, and was next heard of as a wonderful "New Messiah," with an extraordinary power of curing diseases. He at once became locally famous. It is said that he was imprisoned in that Territory for falsely claiming divine powers. However that may be he went to Denver in the summer of 1895, and his career there attracted widespread public interest. His presence made Denver the central point to which journeyed thousands of sick and afflicted from all over the country. Schlatter lived in Denver with Alderman Fox, and gave public "treatments" in a hall or theater, at which an admission fee was charged. Then there were "treatments" to all who came to Mr. Fox's house. He became known as the "New Messiah," and "The Healer." He blessed handkerchiefs, and it was said that any one touching these handkerchiefs would be "healed." "Fakirs" did a thriving business in this line. They advertised "blessed handkerchiefs" for the small sum of \$1, and raked in hundreds of dollars, until they were arrested by the authorities. Schlatter was wanted as a witness in this case, and many thought that he disappeared from Denver on November 13 because he did not want to testify. He left a note in his handwriting, saying:

Mr. Fox—My mission is finished. The Father takes me away. Goodby.
FRANCIS SCHLATTER.

After he disappeared from Denver Schlatter was reported at various times in the mountains of Arizona and New Mexico, and many weird stories were told of his flight. Many remarkable stories were told of cures made by Schlatter in Denver. On the last day he was in the city he "treated" no fewer than five thousand people. He did not profit in a worldly way by his months of self-imposed labors, which were of an extremely fatiguing nature. After the six hours daily spent in standing at the head of the line, clasping the hands of his visitors, he retired to the house, rested for a time and then set to work upon his mail, answering letters until long into the night. That mail is estimated to have amounted toward the end to over forty thousand pieces a day.—*N. Y. Tribune.*

Eulogy on Jerome Cochran, M.D.—Remarks in support of the resolutions offered, relative to the death of Jerome Cochran, M.D. (see *JOURNAL*, June 12, p. 1147) by W. H. Sanders, M.D., of Alabama.¹

The resolutions just read recite in very brief words some of the salient points in the character and life-work of a man who impressed himself to an unusual degree upon the times in which he lived.

A career such as his richly repays close study and analysis, for from it may be drawn not only wise lessons, but living inspiration.

A man's claims upon the homage of the world should be measured by two standards; 1. What he was. 2. What he did.

Let us apply these tests to the character and life-work of our deceased colleague, and see what tributes they demand.

Some of you knew him well, and therefore need not be told what he was.

May I be allowed to ask those who did not know him, to imagine a man somewhat below medium stature, and inclined to be stooped and bulky, with a face and head that plainly revealed a solid and well-poised character, with an eye that, though mild, yet unconsciously betrayed the intellectual strength that lay behind it; a man possessed of a mind cast in a heroic mold and one that had enriched itself by extensive conquests from every field of human learning, a man with genius to conceive and power to execute, a man dominated by lofty purposes and inspired by unyielding courage to pursue those purposes against odds however great, a man who stood upon the mountain tops of ethical philosophy and proclaimed in luminous and living words that truth should be

sought and right be done for their own sakes. I say, imagine a man endowed with these gifts and powers, and you have a feeble picture of what Jerome Cochran was.

In disposition he was gentle but courageous, unassuming but potential, tenacious of his opinions, but fair-minded and just, and when his judgment so dictated would agree with an enemy or differ from a friend with equal readiness and positiveness. But it was the man's mind that made the man! It stood forth serene and majestic, above prejudice or passion, undaunted by fear and unswayed by favor, and therefore reached its conclusions by the purest processes of logic, and having once reached them was as true to them as the mother to the child.

While in no sense an orator, he was more; a master of clear, lucid and forceful English; always ready for a polemical battle, he was never known to furl his colors or to suffer defeat in the presence of any antagonist. It is no wonder that such a man should have been the author of great conceptions and the architect of great achievements.

Born in Tennessee, reared in Mississippi, Alabama was the immediate theater of what he did. Being a profound student of sociologic science no doubt led him more than a quarter of a century ago, without a model to guide him, or so much as a blazed way through the wilderness of unorganized medicine that then existed, to conceive and formulate a scheme for organizing the medical profession of Alabama, which for wisdom of conception, for logical arrangement and completeness of detail, challenges the world for a superior. This scheme sprang full-grown from his fertile and masterful brain, and was not the result of a slow process of evolution, as is usually the case in similar schemes. The first great principle it proclaims is that the interests of the people at large is the object to be sought by organization, and not the interests of the profession. Another great principle it asserts is the members of the medical profession should control in sanitary matters, and so it is in Alabama. Throughout the length and breadth of the State no layman occupies a position on a board of health, the boards being composed of physicians alone. Out of the assertion and maintenance of this principle grows directly another, and one of the most stupendous importance, namely, the radical, practical and eternal divorcement of the sanitary interests of the people from political and commercial influence. Politics and commerce, therefore play no part in disturbing the enforcement of sanitary and quarantine laws in Alabama, a happy state of affairs due solely to the wisdom and foresight of Jerome Cochran.

These principles, with others I can not now mention, have already borne the richest and most beneficent fruits, some of which may be briefly summarized:

1. A coherent and efficient State Medical Association has been built up, with subsidiary and supporting societies in every county of the State, all being endowed in their respective spheres, with important legal and public health functions, and all exercising these functions under a perfectly uniform system of organization.

2. An efficient law for the collection of vital and mortuary statistics.

3. The ethical tone and medical knowledge of the great body of physicians of the State have been markedly elevated and enlarged, thus rendering the doctors more efficient and skilful when called to the bedsides of the sick.

4. Quacks have been almost wholly banished from the State.

5. Scientific principles, according to which quarantine should be proclaimed and practiced, have been formulated, resulting in complete abolition of the old shotgun system, based, as it often was, upon panic, and enforced in a thoroughly unscientific way, a change that has saved thousands upon thousands of dollars to the railroads and commerce of the State.

Were I asked what citizen of Alabama, living or dead, had done most to promote her interests, giving to the word its broadest and deepest signification, conviction and candor would compel me to answer, Jerome Cochran. Did time permit I would undertake to defend this proposition by an array of unimpeachable facts, but I must content myself by saying that he set into motion forces for good that will go on and on, continually gathering strength, until sanitary law shall reign supreme and enlightened medical science shall penetrate into every sick room of the State, with all of the attendant blessings that such a fruition will bring. Neither were the beneficent results of his labors confined within the boundaries of his own State, but, extending beyond, made themselves widely felt wherever there was occasion for the application of the principles of enlightened and advanced sanitary science.

As a member of the Yellow Fever Commission of 1878, and subsequently of a Board of Yellow Fever Experts; as a participant in national sanitary and quarantine conventions; as a member, and sometimes chairman, of the most important com-

¹ Received too late for publication in *JOURNAL* June 12.

mittees raised by this body, he always exhibited a grasp of mind and familiarity with details that easily placed him among the masters of the profession.

Lest you deem my words born more of enthusiasm than of justice, I beg to quote from some of the numerous replies received from corresponding boards of health when notified of Dr. Cochran's death. The first one from which I quote is by the eminent Secretary of the State Board of Health of this great Commonwealth; Benjamin Lee, who says: "The information of the death of your predecessor, Dr. Jerome Cochran, is received with sincere regret. I had the pleasure of quite an intimate acquaintance with the Doctor, and considered him one of the ablest sanitarians in the country."

The next one from which I quote is from the State Board of Health of Missouri, through its distinguished Secretary, Willis P. King, M.D., and the quotation reads as follows:

"WHEREAS, Dr. Jerome Cochran was one of the leaders in the application of the principles of sanitary science in this country, and has by his able efforts been of great benefit to the human race; therefore, be it

"Resolved, That this Board extend to his family and to the profession and people of Alabama, our sincere sympathy and condolence, and join with them in mourning the death of their able physician and eminent citizen."

Could a nobler tribute be paid any man than to proclaim that he had "been a benefactor of the human race?"

At a recent meeting of the State Medical Association of my State it was unanimously and enthusiastically resolved to honor the services of Dr. Cochran by the erection of a monument to his memory, and while we have not ventured to expect that our undertaking would, in any sense, become National in its scope, yet the sympathy and approval of the profession and people of the Nation would be to us extremely grateful.

It is contemplated to erect in the near future a monument to Benjamin Rush, one of the fathers of the profession in America, which, when erected, may be taken to represent the early period of American medicine.

Recently the veil has been drawn from a monument to one of America's greatest surgeons, which may be taken to represent the middle period of American medicine.

May we not hope that the monument to Cochran, when builded, although not National in scope, may be taken to represent the modern period of American medicine—that period characterized by great advances in fraternal organization and in preventive medicine?

At the last meeting of this body he was one of us, but now his voice is hushed in death. Let us endeavor to perpetuate the principles it so ably proclaimed, and to cement in closer and tenderer ties that fellowship he had done so much to promote. To his death he went down with the same imperturbable coolness that had characterized him in every emergency, and without having invoked, until the last week of his life, any aid from that science to which he had been so devoted, to delay the approach of the pale messenger.

He sleeps in one of the cemeteries at Mobile, on that Gulf-shore he had done so much to protect from invasion by disease, and may we not hope that when awakened to appear before the final judge, the interceding angel will plead his great services for his fellowmen, and that like Abou Ben Adhem, "his name will lead all the rest."

New York.

ARTICLES OF INCORPORATION for the Hospital Saturday and Sunday Association and the New York Medical League were curiously enough signed on about the same day. May not congratulations be offered to both without suspicion of duplicity?

THE GRADUATING CLASS of the College of Physicians and Surgeons, New York, numbered only forty members. The class of 1847 exceeded this count by seventeen.

Hospitals.

YARMOUTH, Nova Scotia, will celebrate Queen Victoria's Jubilee by establishing a Victoria Hospital.—Colorado Springs, Colo., is to have a \$10,000 hospital for the Union Printers' Home.—The new City Hospital, Kenton, Ohio, was opened June 2.—The Buffalo (N. Y.) German Hospital receives \$5,000 from the estate of the late Gerhard Lang.—The hospital building recently added to St. Christopher's Home at Dobbs-Ferry-on-the-Hudson was dedicated June 5. It is the gift of the Epworth League of the New York District of the Methodist Episcopal church.—St. Mark's Hospital, New York city, treated 3,430 indoor patients from March 1, 1896 to Nov. 1, 1897. Of these 2,533 were cured, 635 improved and 67 died. Outdoor patients were treated to the number of 2,666. Of 1,200 operations performed during the year, 122 were laparotomies.

Societies.

THE NINETEENTH semi-annual session of the Southern California Medical Society was held at Santa Ana, June 9.—The Fox River Valley Medical Association held its sixty-fourth semi-annual meeting at Elgin, Ill., June 10.—The Vigo Medical Society held a meeting at Terre Haute, Ind., June 3.—The Des Moines Valley Medical Association met at Ottumwa, Iowa, June 17.—The annual session of the Maine Medical Association closed June 4. The following officers were elected: President, Dr. Wallace K. Oakes of Auburn; vice-presidents, Drs. E. A. Thompson of Dover, G. M. Woodcock of Bangor; corresponding secretary, Dr. H. B. Palmer of Farmington; recording secretary, Dr. Charles D. Smith of Portland; treasurer, Dr. A. S. Thayer of Portland; censors, Drs. W. B. Moulton of Portland, F. C. Thayer of Waterville, W. J. Maybury of Saco, E. M. Fuller of Bath, A. King of Portland.—The State Medical Association convened at Moreland City, N. C., June 9.—The 116th annual meeting of the Massachusetts Medical Society was held in Boston, June 8 and 9.—The Grand Rapids (Mich.) Medical and Surgical Society held a regular meeting June 7.—The St. Louis Medical Society of Missouri held a meeting June 12.—The Central Missouri District Medical Society met at Jefferson City, June 4.—The twenty-second annual session of the Grand River Medical Society was held at Chillicothe, Mo., June 4 and 5.—The Jasper County Medical Society met at Carthage, Mo., June 2.—The Erie County Medical Society met at Buffalo, N. Y., June 7.—The thirteenth annual meeting of the Third District branch of the New York State Medical Association was held at Norwich, June 8.—The Medico-Chirurgical Society of Central New York convened at Syracuse, June 3.—The Elmira (N. Y.) Academy of Medicine held a regular meeting June 2.

THE PUBLIC SERVICE.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending June 12, 1897.

Surgeon M. H. Simons, ordered to the "Iowa" June 16.
Washington B. Grave, commissioned Asst. Surgeon from June 8.
P. A. Surgeon R. P. Crandall, detached from naval hospital, Norfolk, June 14, and ordered to the "Iowa" June 16.
Medical Inspector W. G. Farwell, detached from Special duty marine rendezvous, Philadelphia, and continue other special duty.
Surgeon D. O. Lewis, after completion of examining board, naval academy, ordered to the marine rendezvous, Philadelphia.

CHANGE OF ADDRESS.

Broughton, Geo. A., from Pomona to Chino, Cal.
Bahecock, Robert H., from 34 Washington St. to 103 State St., Chicago.
Curry, William, from Nebraska City to Palmyra, Neb.
Cottrell, D., from 200 N. Clark St. to 279 E. Indiana St., Chicago.
Clements, Joseph, from 1719 Holly to 1113 W. 15th St., Kansas City, Mo.
Derwent, A. E., from Chicago to Elma, Ill.
Dalton, M., from Summerfield, Ill., to Fenton, Mo.

PROGNOSIS AND THERAPEUTIC INDICATIONS IN CHRONIC DISEASES OF THE HEART.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, June 1-4, 1897.

BY DELANCEY ROCHESTER, M.D.

ADJUNCT PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE, MEDICAL DEPARTMENT, UNIVERSITY OF BUFFALO.
BUFFALO, N. Y.

For the purposes of discussion, the prognostic factors in diseases of the heart may be conveniently divided into three groups:

1. The condition of the cardiac valves.
2. The condition of the capillary and venous circulation.
3. The condition of the muscle of the heart and of the muscular coat of the arteries—especially of the arterioles.

Of the abnormalities of the mitral valve the obstructive lesion is more serious than that of insufficiency, provided the myocardium is in fair condition; a double mitral lesion is more serious than either single one. Obstruction at this orifice is serious in two ways; if it is due to vegetations on the free edges of the valves or on the margin of the orifice at place of attachment of the valves, these vegetations may be swept off by the blood current and form infarct of the brain with all its serious consequences; if the obstruction is due to stenosis of the orifice from fibroid contraction it throws great strain upon the left auricle, dilating it and causing serious obstruction to the pulmonary circulation and backward pressure through the right heart, causing general venous engorgement of the viscera.

In all mitral diseases careful study of the pulmonary circulation and the condition of the right heart is of utmost importance. Before evidences of pulmonary engorgement show themselves an accentuation of the second heart sound over the pulmonary valve, as compared to that over the aortic, gives the first signal that the left auricular wall is yielding to the strain put upon it and the auricle is not emptying itself as it should. Next in train come evidences of pulmonary congestion and pulmonary edema; then the right heart shows the strain that has been put upon it, first by incomplete emptying of the ventricle into the lungs, thus producing an inability of the right auricle to empty itself, and bringing about a venous engorgement of the various organs of the body. Careful study of the right side of the heart during this process generally reveals an increase of its size. In such conditions there is heard in the tricuspid region a soft systolic murmur; this sometimes occurs early, more often later in the disease, and is always of very serious prognostic import.

Of the lesions of the aortic valve, obstruction is generally less serious than insufficiency. Vegetative growths, causing the obstruction, are less often observed here than at the mitral orifice, but when present are just as dangerous in their possibilities; on the other hand the left ventricle normally has good hard work to do to throw its contents into the arterial system, where there is normally more or less resistance, and on that account its walls are thick and strong; a slight obstruction of the aortic orifice means a little greater effort, a little more muscular development, a compensatory hypertrophy and unless the obstruction increases that is all. Nevertheless, no patient with aortic disease, even though only slight obstruction, should be allowed to do anything to weaken or strain his left ventricular wall, especially as aortic valve disease is so frequently associated with arterial disease.

In aortic insufficiency we have the most serious form of valvular disease; it is not as we might almost say of aortic obstruction, an exaggeration of a normal state of affairs; on the contrary it is absolutely abnormal. As soon as the left ventricle has emptied itself and diastole begins, blood rushes back into the ventricle through the leak in the valve, and also rushes into it in its normal course through the mitral orifice; thus the ventricle becomes distended and dilatation occurs earlier than in any other form of valvular disease. Uncompensated dilatation is the most serious cardiac condition with which we have to cope.

Thus we see that valvular lesions are serious in proportion to the extent to which their existence brings about degenerative changes in the cardiac muscle. Let us turn our attention to the second group that I mentioned as worthy of study from a prognostic standpoint, the condition of the capillary and venous circulation. In health the blood circulates, within certain limits, at about the same rate and with about the same force, producing about the same degree of tension in the blood vessels. Now if the central source of the power that is the chief factor in keeping up the circulation is structurally weakened it shows that weakness in the peripheral circulation. All valvular diseases of the left side of the heart lead eventually to the same state of affairs, namely, a diminution in the amount of blood in the pulmonary circuit, congestion of the lungs, edema of the lungs, over-distension of right heart, venous engorgement, capillary distension, edema of various organs and effusion into the serous cavities. Sometimes the right heart yields, lets the tricuspid valve slip and relieves the impending edema of the lungs by causing over-distension of the systemic veins. The general edema becomes marked and the edema of the lungs comes as the terminator of life. We can perceive indications of failing circulation by study of the capillary circulation as revealed by the edema of the skin and subcutaneous connective tissue; by the diminution in

quantity of the urine and the occurrence in it of albumin, blood, casts, etc., indicative of congestion of the kidneys and, in cases of long standing, of cyanotic kidney; by the condition of the liver as revealed by physical examination of that organ; a large liver due to congestion shows that the left heart is weak and sometimes that the right heart is beginning to fail. If ever a pulsating liver is found it is generally indicative of tricuspid regurgitation and is of serious import. The occurrence of ascites in heart disease is associated with occurrence of general edema and is only another indication of the failing circulation, but is usually a comparatively late one unless there is associated disease of the liver or peritoneum; ascites occurring in the course of a case of heart disease under these circumstances (*i. e.*, absence of disease of the liver or peritoneum) is a sign of bad prognostic import.

Cyanosis, dyspnea, orthopnea and the physical signs of edema of the lungs, reveal the failure of capillary circulation in the lungs and are of very serious prognostic import; if in addition to these we also have signs that the pleural cavities are also filling up, the prognosis becomes so much the worse. When we also get the symptoms of edema of the brain or of effusion into the ventricles or between the meninges the prognosis is still worse.

All these various conditions, which I have briefly mentioned, are indicative of a failing circulation, and that means lack of muscular power in the walls of the heart and of the arteries. Even in the most serious form of valvular disease of the heart I do not give an absolutely hopeless prognosis until I have tried certain measures calculated to improve the musculature of the heart and of the arteries.

How are we to estimate the strength of the heart muscle? By the force and frequency of the heart's action, by the relative length and strength of the first and second sounds, by their relation as to intensity and duration of the pulmonary to the aortic second sound, by the size of heart as shown by percussion, by the position and character of the apex beat, by the condition of the peripheral capillary circulation and by the condition of the pulmonary circulation.

It seems plain to me that in a given case of disease of the heart the prognosis depends upon the condition of the muscles of the heart and of the arteries, and whether or not they are capable of being so improved as to compensate for whatever may have led to the present condition of failing circulation. If this be true, it is evident that the therapeutic indication is to institute such measures as will tend to improve the muscle strength of the heart and arteries and restore the normal circulation and prevent accumulation in the veins.

I think I can not do better than cite a case illustrative of almost every point that I have made.

March 5, 1897, I was called to see G. M., male, aged 48, American. Family history, good; personal history, rheumatism and alcohol; has had heart trouble for several years. Present condition: Temperature 97 degrees, pulse 110, respiration 30, cyanotic, anasarca, some ascites, marked dyspnea upon exertion, cough very irritating, no sputum.

Examination of urine: Amount 625 c.c., highly colored, strongly acid, sp. gr. 1029, urea 15.6 gm., trace of albumin, no sugar, 1 hyalin cast and 1 cylinder in three slides.

Physical examination of chest showed some edema at bases of both lungs, especially of the left; a hypertrophied and dilated heart, the apex beat of which was diffused to a marked degree, being felt as a feeble wave over an area bounded by the left mid-axillary line, the upper border of the eighth rib, a line a quarter of an inch to the right of the anterior axillary line and the lower border of the seventh rib; the area of cardiac dulness was marked on the right by a line extending from a point at the upper border of the third rib a half inch to the right of the right edge of the sternum down to a point on the fifth rib, three-fourths of an inch to the right of the right edge of the sternum; here the cardiac dulness was merged into liver dulness. On account of the increase in size of the left lobe of the liver, it was impossible to mark out accurately the lower border of the right heart, but that of the left was on a level with the top of the eighth rib; the left edge of the heart was marked in the mid-axillary line at the bottom of the seventh rib in the anterior axillary line at the top of the sixth rib, gradually approaching the median line, until at the top of the third rib it was midway between the para-sternal and nipple lines. Palpation revealed an irregularly pulsating heart, feeble and wavy in its impulse, with a distinct diastolic thrill to be felt in the fourth and fifth left intercostal spaces between the sternal and nipple lines. Auscultation revealed that the sounds of the heart were not to be heard at all, but were entirely replaced by murmurs; the murmurs at the apex were of very slight intensity and grew distinctly louder as the stethoscope passed to the right and upward; in the mid-sternal region, at the level of the third rib, the two murmurs were very loud, the diastolic especially so. Very careful study of this heart enables me to say without going into further details of the physical examination, that there was insufficiency of the mitral valve, obstruction and insufficiency of the aortic valve and insufficiency of the tricuspid valve. The liver was tremendously enlarged, the area of dulness extending from the top of the fifth rib to a point two and one-half inches below the free border of the ribs; the left lobe extending over as far as the nipple line on the left side, was merged in cardiac dulness above, and extended downward in the epigastric region midway between the end of the ensiform cartilage and the umbilicus.

The physical condition of the heart was one of unquestionably organic lesion of the aortic valve, causing some obstruction and permitting tremendous regurgitation; of insufficiency of the mitral valve possibly due to disease of the valve, possibly due to the great dilatation of the left side of the heart; of insufficiency of the tricuspid probably due to the over-distension and dilatation of the cavities of both sides of the heart, especially the left, and to great thinning of the myocardium of the left ventricle.

I will briefly relate the treatment of the case and then give my reasons for the treatment.

Rest in bed, catharsis, restricted diet, diuresis, diaphoresis, massage, passive exercise and finally some active movements with resistance. In this case the Schott baths were tried without benefit.

Under the treatment outlined above the case has improved markedly; the anasarca and ascites and edema of the lungs have disappeared, with the slight exception of a very small amount of fluid in the abdomen and very slight remaining edema of the very base of the left lung posteriorly. The heart has diminished

materially in size, the apex being now in the sixth intercostal space a little to the right of the anterior axillary line, the borders of the heart having contracted proportionately. There is now some muscular quality to the first sound of the heart, the tricuspid murmur has disappeared and the heart beats regularly about eighty to eighty-six per minute. The liver still remains large but is smaller than it was.

The methods of the treatment were as follows: The rest in bed was absolute for the first six weeks, except when he was lifted in and out of bed for the purpose of the bath, while we were trying the Schott baths; the catharsis was produced by calomel followed by epsom salt, and bowels since kept free by saline cathartics, with an occasional dose of calomel; the diet was limited to milk, koumyss and malted milk for a month, and has since been gradually increased; the diuresis has been produced by the use of diuretin; some difficulty was encountered at first in producing diaphoresis; hot air failed, steam failed, hot pack failed but when we gave a steam bath preceded by a hypodermic injection of pilocarpin hydrochlorate 0.0035 gm. the diaphoresis was profuse.

The object sought and obtained by these procedures was to give the heart as much rest as an organ that works all the time can have. However, rest alone will not restore a weakened muscle to a normal condition; proper food and proper exercise are necessary to complete the cure. Where the muscle of the heart alone is implicated we may hope by long and careful treatment to restore it to a normal condition by exercises carefully graduated according to results. Some cases progress much faster than others. However, in a case where there is permanent valvular leakage, we must recognize the fact that that leak will always remain, and we must bend our energies to devising means for improving the circulation not merely by improving the strength of the heart muscle at one point and removing the fluid from the surrounding tissue and from the veins at another point, but by improving the musculature of the arterial system in general and of the arterioles in particular. Herein comes the benefit of carefully and scientifically administered massage. The muscles of the arteries and arterioles are so improved in tone and strength that they take up with renewed vigor their rhythmic contraction and relaxation and give to the blood current a new impetus all along the line.

It seems to me that herein lies the value of salt baths, carbonic acid gas baths and, when it is of value, of the undirected simple rubbing of the skin, in that the rhythmic contraction and relaxation of the arterioles is stimulated. Results are much more pronounced when the massage is administered with this definite object in view. By the massage we may also directly affect the movement of the blood in the veins.

To briefly sum up, we may state that in a given case of disease of the heart the prognosis depends chiefly on the condition of the heart muscle and of the walls of the arteries, chiefly of the arterioles; that the chief therapeutic indications are rest, removal of peripheral obstruction to the circulation and then the restoration and development by baths, massage and exercise of the muscular tissue in the walls of the heart and the arteries and arterioles, and the stimulation by these same means of the rhythmical contraction and relaxation of these muscle fibers.

THE USE OF DIGITALIN, WITH REFERENCE TO DOSE.

Read in the Section on Practice of Medicine, at the Forty-eighth Annual Meeting of the American Medical Association, at Philadelphia, Pa., June 1-4, 1897.

BY HENRY BEATES, M.D.

PHILADELPHIA, PA.

Early in my practice, circumstances found me active in that class of diseases which center about the circulatory system, and as a consequence, the much debated therapeutics of that remedial agent, *digitalis*, about which has incessantly waged a warfare of theory and discussion, engaged especial attention. Results were achieved which seemed to substantiate the claims of both advocates and antagonists, and presented a problem manifestly complex, and far from having been elucidated. On the one hand, cases representing a definite clinical type were markedly benefited, while on the other, apparently identical conditions were incapable of being favorably influenced, because of the occurrence of unpleasant symptoms which prevented the administration of the remedy in proper doses or in smaller quantities, sufficiently frequently to reestablish the lost circulatory equilibrium which was so urgently demanded, and what seemed to be facts confirmatory of each of the contending therapeutists, were thus confronted. Recognizing, in *digitalis*, a remedy possessing active principles of diverse nature, and realizing that in this respect it was not an exception to the vegetal kingdom in general, in which commonly one element of an organism possesses component parts varying greatly in the percentage of these, the opinion prevailed, that in this fact reposed the underlying determining causes of such manifestly contradictory therapeutics.

Observation clinically proved great variability in the effects of the crude drug itself, as well as the official preparations; some would control circulatory function without disturbing the digestive tract, while others developed the latter distress to such a degree as to compel the exhibition of smaller and consequently inadequate doses, the abandonment of the drug entirely, or the contemporaneous use of one or more of the group of cardiac stimulants as auxiliary, either of these being followed by indifferent results and failing to solve the mooted question. This led to the abandonment of the crude drug and its official preparations, and the employment of its alkaloidal derivatives or active principles. Concerning these as ordinarily procured from the shops, I found the same objection obtaining, viz., complexity of composition, *as manifested by variability of effect.*

Digitalin was recognized as a name applied to a glucosid, an amorphous powder and crystalline principles. Finally, the derivatives, digitin, digitalin, French and digitalin, German, pure, of Merck were studied, and their therapeutic powers which have stood the close scrutiny and clinical tests of years of use, will be submitted to your attention without further consuming time with the details leading to their recognition. The conclusions submitted are marked by so wide a departure from the generally accepted teachings regarding the value and use of this medicament, that it is felt that your consideration will not have been engaged fruitlessly. The special derivative employed, which forms the basis of this contribution, is digitalin (German, *pure*, of Merck). This, experience proves to be a simple, *i. e.*, individual alkaloid which is not contaminated by other active principles; therefore its

physiologic effects, other things being equal, are characterized by uniformity and definiteness.

It occurs as an amorphous powder, freely soluble in water and quite readily in alcohol, while in ether it is almost insoluble. These properties serve to distinguish it from another derivative known as digitalin French, Merck, also an amorphous powder which, in addition to its power to greatly stimulate the pneumogastric inhibitory function and augment the force of the cardiac contraction, possesses other features beyond the scope of this paper. However, it may be well to state that this latter principle is very sparingly soluble in water, a feature markedly in contrast with the remedy under consideration, freely in chloroform and alcohol and, like the German, slightly so in ether. The dose of the French is much less, *i. e.*, about one twenty-fifth.

With these brief preliminary remarks, your attention is invited to the consideration of dosage. Originally departing from the *utterly inadequate* but generally prevalent conventional one-hundredth and one-sixtieth grain doses, because practically no effects were secured, larger quantities were gradually and carefully exhibited and the effects closely observed. It was found ultimately, that one-tenth of a grain for the minimum adult dose and one-half grain as a maximum, were always, other things proportional, followed by definite and positive results. The administration of the drug, more or less constantly, for months and even years, in doses adapted, within these limitations, to the needs of the particular patient under treatment, is the basis upon which the statement is made.

One feature rendering this derivative especially valuable is the absence of a proneness to produce irritation of the digestive tract. The importance of this, in instances of advanced cardiac diseases requiring the larger doses, is self-evident. As to cumulative action, in no instance has so much as an indication presented itself, and after the long and liberal use under these conditions, it is proper and safe to assert, that that much debated property of digitalis is *not* possessed by this alkaloid.

Occasionally, where the larger doses, one-third and one-half grain, are essential, some gastric disturbances will occur, but the exhibition of pepto-hydrochloric acid, combined with a simple bitter and bismuth, overcomes the objection and permits the continuation of the remedy.

The scope and usefulness of this medicament is greater by far than appears at first glance. In all lesions of the heart, with the single exception of mitral regurgitation complicated with dilatation of the auricle, this drug is a *sine qua non*. The non-interference with the stomach, and its certain action upon the cardiac system and vaso-motor area, in the doses recommended, bring it into prominence when its achievements are contrasted with those of the usually employed official preparations. Its superiority can be better demonstrated by citing two cases which, beyond question, served as severe tests.

An adult male, 57 years old, was apparently in the last stages of eccentric cardiac hypertrophy, the ultimate result of a mitral regurgitant lesion of rheumatic origin. When first seen, the anasarca was so intense that the cutaneous structure of the lower limbs had ruptured in several places, and the oozing of serum was constant and troublesome. The scrotum and peritoneal cavity were much distended by the effusion, and the latter intensified the distressing dyspnea by me-

chanically preventing complete diaphragmatic action. Cough and profuse sero-mucoid expectoration were severe, while the inability to assume a recumbent position, and the loss of sleep and rest, were factors contributing to rapidly approaching death. He was under the care of excellent and skilled attendants, and *secundum artem* was treated with the conventional doses of the tincture of digitalis, the leaves, infusion and extract, in the vain endeavor to secure relief, but with the results just described. Four consecutive one-half grain doses of digitalin (German, Merck) were administered, each after an interval of two hours, with recognizable relief. Smaller doses, one-fourth grain, were employed at the same intervals for the next day, with results as surprising as unexpected. After some weeks, the sufferer was enabled to be about, and ultimately served as a night watchman for almost five years. During this period the remedy was taken almost continuously in from one-sixth to one-fourth grain quantities, three or four times daily. The periods during which the drug was stopped were never longer than two months, as by the end of that time, its necessity was indicated.

The other remarkable case is that of a lad afflicted with a mitral and aortic stenotic lesion. He is in his fifteenth year. Two years ago, when first seen, his distress was such that he practically lived in a chair. Edema to the middle of the thighs, cough, cyanosis, most distressing paroxysmal dyspnea in addition to the habitual, with emaciation and fast increasing asthenia, were the chief symptoms. Enormous eccentric hypertrophy had developed. The cardiac action was tumultuous, arrhythmic and feeble; the sounds indistinguishable. The usual official preparations of digitalis had been tried, one after another, and in the conventional doses. He was rapidly brought under the physiologic effects of digitalin (German) and promptly relieved from the agonizing distress. After some weeks of daily use of one-fourth grain doses he could slowly, but with comfort, be about. The dosage was carefully suited to his improvement and uninterruptedly employed until the present. He is taking little less than one-fourth grain with each meal serially, *i. e.*, for two consecutive days, then omitting one day, then resuming for two, and so on. What has been the result? On Saturday he rode his bicycle from the suburban town of Roxborough to the Washington Monument recently unveiled at the Green Street entrance to Fairmount Park, and back again.

Another class of cases in which really wonderful results are to be achieved, is that of senility. Here, where the whole venous system is so commonly the seat of passive hyperemia as indicated by prominently distended and tortuous veins such as the temporal, a group of symptoms impairing comfort and usefulness, usually presents in the form of shortness of breath upon comparatively trivial exertion, an annoying and somewhat paroxysmal cough, which subsides for a few hours after the expectoration of a small pellet of viscid mucous; inability to remember the usual details of daily duties (forgetfulness), a tendency to insomnia or at least interrupted sleep and vitality, constitutes a type especially amenable to this remedy. The cardiac phenomena accompanying this condition need not be related as they are so well known. If one-third to one-sixth grain doses are given in these cases, it is the rule to see the difficulties mentioned disappear, and a degree of normality reinstated amounting practically to health.

In more advanced senility, characterized by retrograde changes in the venules and associated degenerations, and in which the *arcus senilis* is established, where the premonitory phenomena of apoplexy occur and are indicated by such marked symptoms as confusion of the intellect, incomplete aphasia with facial and other partial but transient palsies, the drug is, *contrary to usual belief*, indicated. This position is assumed after years of careful observation, with results that can not be disputed. The symptoms mentioned are due almost entirely to degenerative changes of the walls of the blood vessels. The vasomotor constrictors have failed in their function and that condition so essential to normality—*circulatory equilibrium*—is lost. The peculiarity of the venous system in having the capacity for containing the entire volume of blood in the body is here well shown, and the tension and pressure, always present in this condition, ruptures the altered radicals, as well as interferes with the phenomena of nutrition. The indications for treatment are plain, both from the mechanical and vital standpoint; restoration of the weakened heart, as far as possible, and especially of the vasomotor tone. This, this remedy accomplishes, and in so doing, the circulatory equilibrium is established and the distending forces upon the friable venules proportionately removed. Again, nutrition is rendered possible and life prolonged under the influences of the drug. Today there are living individuals who have enjoyed immunity for from one to three years from symptoms which had long ago threatened destruction.

Another type of senility is constituted by albuminurics, who furnish examples of cyanotic kidney and who, with the usual concomitants of age, are additionally exhausted by the loss of albumin. This form of albuminuria greatly improves under the proper use of the remedy, and gain of flesh, strength and comfort is assured and pronounced. A typical instance is that of a gentleman, 67 years old, who, during the early summer of 1895, suffered from an advanced state of this condition. The surcharged venous system was marked and the loss of albumin such as to engender great weakness. Disability from this latter was almost total and he was invalided. He has been, and is taking, thrice daily one-quarter grain doses, and notwithstanding the occurrence eleven months ago of sarcoma of the tonsil, which is treated by fragmental removal as occasion demands, he is so far bettered as to be able to comfortably engage in the lighter duties of every-day life. Fatty or primary degeneration of the cerebral cortex, if treated in the incipient stages, seems to be checked for considerable lengths of time.

The muscular weaknesses and vasomotor phenomena of those who recover almost entirely from hemiplegia except in these particulars and whose cardiac tone remains impaired, are much benefited.

Its use in overcoming the vasomotor element of shock and in proper cases of disease requiring capital surgical procedures, in which by reason of a poor circulatory system an anesthetic is dangerous, has been successfully tried in a limited number of cases, but sufficiently to prove its value. The circulatory crisis of acute disease, such for example as is encountered in acute lobar pneumonia, can be overcome, and the author has twice within the last few months so done by administering 2 grains of this alkaloid within two hours. Sufficient has been adduced to permit of the following conclusions:

- 1, Digitalin (German, pure, Merck) is a derivative of digitalis, not contaminated by other active principles;
- 2, it possesses a uniform and unvarying strength;
- 3, it is relatively free from that property which produces gastric irritation;
- 4, is a powerful stimulant to the whole cardiac apparatus;
- 5, is a reliable and pronounced stimulant of the vasomotor system;
- 6, it does not develop cumulative action;
- 7, its adult dose ranges from the one-tenth grain as a minimum to one-half grain for a maximum.

TRUE (IDIOPATHIC) ANGINA PECTORIS. ITS ETIOLOGY, PATHOLOGY AND THERAPEUTICS.

Read by title in the Section on Practice of Medicine at the Forty-eighth Annual Meeting of the American Medical Association, held at Philadelphia, Pa., June 1-4, 1897.

BY THOS. L. MADDIN, A.M., M.D.

PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM AND GENERAL PATHOLOGY, MEDICAL DEPARTMENT, UNIVERSITY OF NASHVILLE, TENN.

Case 1.—Mr. E., a merchant from early manhood, habits excellent, possessed of a fine constitution, never seriously sick, 60 years of age, consulted me in reference to a severe paroxysmal itching in his arms, vertigo, and torpid liver; these discomforts yielded to a simple line of treatment addressed to his liver, viz., frugality both in reference to the quantity and quality of his food, and much time in the open air. A few months afterward I was called to see him, in the early hours of the morning, on account of a severe and sudden paroxysm of bronchial and cardiac asthma. I found him almost cyanotic, with the most characteristic symptoms of asthma, and a scarcely perceptible and irregular pulse. The symptoms yielded readily after a hypodermic of morphia one-third gr. and atropia one hundred and twentieth gr. This was his first asthmatic paroxysm and there was no history of it in his family; he had only slight returns of it, but often from slight causes would have temporary palpitation of the heart, with profound disturbance of rhythm, but no evidence of organic disease. He also had great distress in the precordial region, agonizing pains over the left chest and down the arm. These paroxysms were traced to indigestion, worry, walking rapidly up hill, close confinement to office work, etc. I advised him to take a trip to California, be much in the open air, be prudent and frugal in his food, and give special attention to his bowels and the state of his liver. I furnished him with a written description of his condition, my diagnosis of the pathology involved and therapeutic indications for its treatment, so that in the event of having to call in medical aid, the physician could come to a quick knowledge of his needs. He first went to New York City and I advised him to call upon Dr. Austin Flint while there, show him my paper and request him to make a critical examination of his condition, especially of his heart, to see if there was any organic disease that I had failed to discover. A very thorough examination was afforded and Dr. Flint also had an opportunity to see my patient in one of his bad paroxysms; he endorsed the opinion expressed in my paper. Mr. E. was soon sufficiently relieved to start on his trip, was absent three months without any return of the paroxysm, and when he returned to Nashville had apparently recovered. He soon resumed his mercantile habits—close attention to the details of office business in an over-heated room, but little outdoor exercise, liberal indulgence in rich viands of the table, with recurrence of indigestion, paroxysms of palpitation and pectoral distress. I visited him one morning and found him cheerful and comfortable; he said that when seized with one of his spells the distress was so great he felt that one moment more would cause his death. This caused me such anxiety that I made an unexpected visit at 9 P. M.; he answered the door in person, expressed surprise at seeing me and said he "had not felt so well for several months." On my leaving he at once retired; his son occupied a bed in the same room and during the night was aroused by his father who remarked that he had gone into the library to see what time it was and found he had been sleeping two hours and was feeling so well he would not need any of the doctor's composing remedies. In about fifteen minutes his son thought he heard him move and raised up in bed to see, but as his father seemed to be asleep he gave himself no further concern. Early next morning the family servant came in, thought the old gentleman was very quiet, and found he was not only dead but rigor mortis was fully established. It was my opinion that

he died when his son heard him move fifteen minutes after twelve o'clock, and that his death was instantaneous, for the covers of the bed were not disturbed.

Case 2.—Chancellor S., a man of fine constitution, but delicate from studious habits, little exercise in the open air and torpid liver, was about 65 years of age; the pathology and symptoms of his sickness gave a clinical history parallel to that of Mr. E.; he died almost as suddenly. He had passed a quiet night, waked up at 4 A. M., and was dead in less than fifteen minutes, of a paroxysm of angina pectoris. He was not the subject of any organic disease of the heart or blood vessels, but in my opinion was poisoned with the product of mal-disintegration of the worn-out albumins of his own body—auto-intoxication.

Case 3.—Judge H., 55 years of age, had never been seriously sick, inherited a good constitution, was called upon to perform heavy and responsible duty under very discouraging circumstances; the needs in reference to his own health were neglected, his liver was torpid, bowels constipated, complexion sallow and mind depressed; after exposing himself one evening to inclement weather he was seized with a severe paroxysm of asthma—of bronchial tubes, diaphragm and heart—with intense pain in the left chest, shoulder and arm. His condition was so critical that I administered, hypodermically, morphia one-third gr. and atropia one one-hundred and twentieth gr.; this gave quick relief and he was soon asleep. There was no asthma afterward, but after three weeks he had seizures of the heart, with all the symptoms of angina pectoris, and died very suddenly in one of them. There was no organic disease of the heart or arteries.

Case 4.—Mr. F., 50 years of age, is the subject of many paroxysms of angina pectoris; he has a delicate constitution, a sensitive nervous temperament, is intense in application to business and sleeps badly. His seizures come suddenly with intense precordial and substernal pains reaching to the left shoulder and to the elbow, and with a cord-like binding sensation around the chest, labored breathing, dry tongue and fauces, cold extremities, pale face, distressed expression, pulse scarcely to be detected, a sense of impending death, totally helpless, accumulation of gas in the stomach and intestines. He can not endure to be moved, and any imprudence in food, emotional worry, or other strain upon the nervous system will provoke a paroxysm. There is no organic disease in the heart or blood vessels.

Case 5.—Mr. G. has for many years been the subject of angina pectoris. The seizures are sudden and he falls wherever he may be; can not be moved, is cold, pale, visage haggard, pulse irregular, rapid and scarcely perceptible, great precordial distress extending to the left shoulder and elbow. The relief comes as suddenly as the seizure; sometimes the attack is short, at other times lasts three or four hours, or longer; large quantities of gas in the stomach and intestines are always developed. He is torpid in his liver, while constipation and indigestion accompany a paroxysm. The exciting cause is imprudent indulgence in food.

The above cases furnish material for making the distinction between true and false angina pectoris; all systematic writers make this classification. Trousseau in his "Clinical Medicine," calls the true angina pectoris "idiopathic," the false "organic." We eliminate all organic disease of the heart and arteries from the discussion—fatty infiltration, fatty degeneration, stenosis of the gateways of the heart, valvular disease, hypertrophy and atrophy of the walls of the heart, dilatation or contraction of its cavities, atheromatous conditions of the heart or aorta, etc. These diseases may complicate true (idiopathic) angina pectoris and any further mention I make of them will be only as complications.

I claim that true (idiopathic) angina pectoris is a neurosis and may express itself in many forms—epilepsy of the heart, tetanus of the heart, asthma of the heart, chorea of the heart, syncope of the heart. The etiologic factor makes its impress upon the nerve centers that control the heart, arteries, capillaries and veins. The behavior of the muscles concerned in the circulation is determined by the exciting and immediate cause operating on the nerves and the nerve centers.

The etiology may be reflex from the alimentary canal, profound emotion either of pleasure or distress even from a dream; the most prolific cause is from auto-intoxication. We have in the manifold pathology included under the term uremia, a generic term given to the product of mal-disintegration of albuminoids—gout and rheumatism claim this form of paternity. When the kidney is afflicted with Bright's disease, and fails to excrete or there is a failure of any other emunctory in its excretory duty, the blood is loaded with these impurities; they act as irritants to the nerve centers and develop many forms and degrees of ataxia—the *coma vigil* of fevers, *subsultus tendinum* and the different convulsions; many varieties of ataxia are expressed in the heart, arteries, capillaries and veins when the vaso-motor nervous system is irritated with these impurities. Ramborg says the abuse of tea, coffee, tobacco, etc., or reflex action from the stomach or intestine, uterine and ovarian disease, or great and continued strain of the mind or emotions, are at times the cause of angina pectoris. The great John Hunter was the subject and finally the victim of this disease. He was in the habit of saying that his life was suspended upon any emotional whim that might happen to him. Sedentary life in close confinement and overheated air, and too liberal indulgence in rich food are the things that predispose to, and are often the exciting cause of angina pectoris; sometimes heredity is a factor.

We proceed now to analyze this neurotic disease: There are three essential factors pertaining to the nervous system concerned in the rhythmic muscular contraction of the heart—sympathetic, inhibitory and sensory (muscular-sensation); each of these is represented in maintaining physiologic equilibrium, not only of the heart but also of the arteries, capillaries and veins; it is through this nervous mechanism (nerve centers, nerves, ganglion and subsidiary nerve cells), that the katabolic force is dispensed and applied to the muscular tissue. According to the stimulus applied to the sensory factor, we will have a regular and normal rhythm, or some form of ataxia (a rapid or slow, a regular or irregular, high tension or low tension pulse), indeed all the modifications of the circulation are dependent upon and due to these nerve centers. In any case, when the sympathetic nerve centers prevail and cause the death of the patient, the heart is contracted, is empty; its muscular tissue is in a state of tonic spasm (systole), the inhibitory centers are practically paralyzed (diastole), and from its similitude we may call it a cramp colic of the heart, the arteries or the capillaries, for it is irregular peristalsis and may lead to a tonic or clonic spasm and closure of their lumen; on the other hand, if the sympathetic nerve centers from whatever cause are inadequate to balance the katabolism of the inhibitory nerve centers, the patient dies in diastole, with the heart cavities full of blood.

This want of physiologic harmony is often caused by auto-intoxication, a torpid liver and a failure of its disintegrating function in reducing the refuse albumin to urea; this establishes a diathetic condition which may show its presence under any trivial exciting cause, in a paroxysm of prurigo, asthma of the bronchial tubes, diaphragm, heart, etc.; all of these conditions are the offspring of the same parentage. When death is caused by angina pectoris the heart may be in systole, diastole, or *in statu quo*, according to whether the sympathetic or inhibitory nerve cen-

ters are affected, or both are alike impressed with the toxic cause, at the same time and to the same degree.

We give another path by which angina pectoris may be and often is caused; it is known that the heart does not receive its nutrition directly from the blood passing through its cavities (auricles and ventricles), but that there is a special provision made for its nourishment—the coronary arteries, capillaries and veins; and the same system of centers, nerves and ganglia (sympathetic, inhibitory and sensory) determine their action. Any cause that breaks the harmony of these katabolic forces, will interfere with the blood supply for the nourishment of the heart tissue; every grade of ischemia or passive congestion may be present, nutrition be impoverished, potential or stored force fail and molecular and dynamic work be suspended; gradual fibroid stenosis of the walls of the coronary arteries (senility), regurgitation of the blood to the left ventricle (from valvular disease of the aortic opening), preventing the adequate supply of blood to the coronary arteries; spasm of the muscular walls of the coronary arteries may make a complete closure of their lumen, giving syncope of the heart. If the closure is only partial, nutrition fails to the same degree, entailing a corresponding asthenia.

I wish here to demonstrate the nature of the homogeneous substance of which the capillaries are made and claim that they have the function of contractility, which is a vital property, while elasticity is a mechanical and physical property. All muscular tissue is composed of sarcous cells and these are built of sarcous molecules, and each molecule is a muscle endowed with the property of contractility. Nutrition is the highest assimilating function and consists not only in storing matter, but also of force (potential). Each molecule of a muscle is thus made vital with tonicity that is made manifest in contractility through metabolic disintegration. In order to realize this vital function it must be brought into relation with the nervous system, which is built up with nerve-cells made of nerve plasma, and this of molecules as its ultimate histologic analysis. We see and study muscular and nerve organs *en masse*, but when we analyze these two tissues in order to realize contractility, such as we have in the walls of the capillaries, the membrane of which it is made must consist of these two tissue molecules, viz., nerve and sarcous molecules. The nerve bioplasm, which forms a part of homogeneous membrane, is endowed with sensory, motor and inhibitory properties, precisely as we have claimed is due the nerve centers, nerves and ganglia which determine the rhythm of the heart and arteries.

If I am correct in this claim, we may have a systemic capillary spasm closing their lumen, which may be partial or general, constituting a *vis a fronte* obstruction and damming the blood back into the arteries and heart. In this way we may have a peripheral or visceral condition that will realize one variety of angina pectoris. This peripheral high tension of arterioles and capillaries will bring the heart and large arteries to a standstill, overfilled with blood, in which case death may be immediate. It produces a pathology in the walls of the capillaries and arterioles that simulates an epileptic seizure of them, or the inhibitory nerve influence may prevail over the sympathetic and then the reverse condition will be present, or the sympathetic (systole) and inhibitory (diastole) may be impressed by the exciting cause at the same time and to the same degree; then we will have their walls

in the condition of *in statu quo*—this simulates the cataleptic state.

What I claim is: That true (idiopathic) angina pectoris should be understood to be a generic term, covering many causes and many pathologies, but in every case it is a neurosis, in which the nervous system which determines and regulates harmony in the mechanism for the circulation of the blood, has been violated by some pathogenic cause. When we apply the above facts to the coronary arteries, arterioles and veins, we have another angina pectoris in which syncope is the pathologic factor. Syncope of an organ causes the suspension of the function of the organ; this is well illustrated in that form of aphasia (word blindness) in which the arteries, arterioles and capillaries supplied to the supra-orbital convolution of the brain are seized with a tonic spasm, and when it is relaxed and blood is again supplied to them, their syncope is relieved and their function is reestablished. The same behavior of nerve forces (sympathetic, inhibitory and *in statu quo*) which I have mentioned in other forms of angina pectoris, pertain to the coronary arteries, capillaries and veins. When the spasm of the coronary blood vessels is relieved, by whatever cause, and the blood again flows through them, the heart resumes its function just as we have seen in paroxysmal aphasia. The fibroid change in the walls of the coronary blood vessels in the senile heart, which is one of the inheritances of age, leads to a progressive diminution of their lumen and to a gradual ischemia, that leads to a formidable complication of idiopathic angina pectoris, but this fibrosis of senility is not strictly an organic disease; as its genesis is physiologic, we will reckon it as making the heart more vulnerable to the causes of idiopathic angina pectoris.

Porter has recorded experimental investigation in closure of coronary arteries of dogs. He found that complete closure was followed by arrest of the heart pulsations; but if one artery or a branch of it was closed, then there was irregular action or cessation of function, corresponding to the region of ischemia—the branches of the coronary arteries are physiologic, if not anatomic, terminal branches; on removing the obstruction the normal action of the heart was restored.

Résumé.—Angina pectoris, false and true:

1. The false—all forms of organic diseases of heart, arteries, capillaries and veins.
2. The true—idiopathic (functional).
3. The blended type—when the organic is a complication of the idiopathic.
4. The true angina pectoris is a neurosis and may express itself in many forms.
5. The nervous mechanism involved contains three physiologic factors: *a.* Sympathetic centers and nerves—systolic (efferent). *b.* Inhibitory centers and nerves (sp. accessor)—diastolic (efferent). *c.* Sensory centers and nerves (vagus)—muscular-sensation (afferent).
6. Each of these physiologic factors is represented in the vaso-motor system of the centers, ganglia and nerves of the heart, arteries, capillaries and veins, and their physiologic equation determines the rhythmic harmony of the circulation in health.
7. From a chronic cause, a diathetic condition which establishes a vulnerability in the nervous system is produced—as in the mal-disintegration of nitrogen compounds and their failure of excretion, or some error in the product of the ductless glands, etc.—which on the action of some exciting cause will determine an explosive paroxysm of systole, or of diastole, or of

both at the same time, locking the sarcous substance *in statu quo*; this may be of the heart, arteries or capillaries, or of all at the same time; and in many cases the diaphragm and bronchial tubes are similarly impressed.

8. Symptoms of sensation: breast pang, dyspnea of the heart, sudden onset of precordial agony, pain extending from the heart to the left chest, shoulder and arm, sometimes to the right chest and shoulder; constriction of chest, an overpowering sense of impending death (all movements are dreaded lest they may precipitate that result), cold skin, deadly pallor, tension of arterial walls so that the pulse is arrhythmic, diminished in strength and volume; the paroxysm often lasts a few seconds, minutes or sometimes is protracted; in many cases eructation of gas is present and often a quantity of pale urine is passed.

Treatment.—This is properly divided into three indications: 1. Curative—to treat the predisposing cause (the diathesis). 2. Preventive—to avoid all exciting causes. 3. Emergent—to relieve the immediate paroxysm.

1. Study the conditions that have produced the diathesis—heredity, bad habits and environments, but especially the quality and quantity of the food, and fortify the patient against them.

The most fertile cause of this diathesis is the quantity of fulminating food—that which is rich in nitrogen; therefore, it is best to refrain from the use of a meat diet; fruits are especially indicated, and much outdoor air, change of climate, pleasant companionship, etc.; in cases having any suspicion of a syphilitic element, bichlorid of mercury and iodid of potassium are indicated; these remedies, also Fowler's solution of arsenic are of curative value in many cases of auto-intoxication from errors of metabolism and the products of the ductless glands.

2. The second indication of treatment is to avoid the exciting cause of the paroxysm (indigestion, torpor of the liver, constipation, auto-infection from the intestines), and look especially after the disintegrating function of the liver, in order that its metabolism of nitrogenous compounds may be reduced to urea—the physiologic diuretic; avoid physical strain, mental strain, emotional strain, and be discrete in personal habits and hygiene; be much in the open air, with invigorating environments and pleasant social contact; repetition of physical, mental or emotional activity begets automatism; therefore, vigilance with reference to these physiologic habits should be practiced, before they have out grooves of activity into the nervous system.

3. The third indication of treatment is to relieve the patient from a paroxysm. The remedies do not aim to modify structure but to influence the function of the vaso-motor nervous mechanism. The following catalogue is a partial list of the medicines from which the physician selects: morphia, atropia, digitalis, strychnin, strophanthus, methylene-blue, veratrum viride, nitro-glycerin, nitrite of amyl, nitrite of sodium, hyoscin hydrobromate, etc., to be administered hypodermically when the emergency is great or by inhalation when practical.

We have in this list drugs that are prominent in their therapeutic virtues, from three points of view—systolic, diastolic and analgesic. Digitalis is eminently fitted to improve tonicity, regulate the rhythm of the heart, arteries and capillaries; it acts alike on the nerve mechanism, both of systole and diastole, it pro-

tracts the time of rest in the events of a rhythm and thus promotes the nutrition of their walls. But it is not safe to give it until the tonic spasm is relaxed, whether it is in the heart, arteries or capillaries; it would be equivalent to give ergot in parturition when the uterus or its cervix or the perineum is in a state of spasm, or to give medicine to promote peristaltic action of the intestine when a section of it was locked in a spasm of cramp colic, or to give strychnin in tetanus. When the condition justifies its use, it is without a rival in improving the rhythm of the heart and blood vessels and in securing relief to the cardio-respiratory distress.

Strophanthus improves the systole and diastole of the heart similar to digitalis, but in less degree; it differs from it in not impressing the arteries, capillaries and veins; therefore, it is indicated when the heart needs a spur to improve the vigor of its action and the lumen of the blood vessels is not offering any resistance.

Strychnin is another heart tonic, but it is so only as it improves the tonicity of the entire nervous system, and causes quick response in converting potential into kinetic dynamics; this is soon exhausted unless assimilative metabolism is sufficient to compensate the over-draught occasioned by the strychnin. These three remedies, strychnin, digitalis and strophanthus are invaluable cardio-vascular tonics with some latitude of difference in their therapeutic value; but when administered with proper discrimination of the pathology involved, they make more stable the results obtained by the next class of remedies; ethyl nitrite (nitrous ether), morphin and atropia, nitrite of amyl, nitrite of sodium, nitroglycerin, methylene-blue, hyoscin hydrobromate, etc. These fulminant remedies are complex in their molecular construction, unstable chemically, and, notably, nitrogen is one of the elements present and the one that determines their wonderful physical and dynamic properties. These substances are remedies of great value, for quick results, in relaxing the high cardiac, arterial and capillary tension, whether it be that of systole, diastole or *in statu quo*. They reach their therapeutic virtue through the sensory pathway of the vagus, its ganglia and its center in the medulla. This constitutes one of the special distinctions of this class of remedies. Whenever there is a tonic or clonic spasm, whether it is in the heart and blood vessels, or the intestine, or any other viscus with muscular walls, relief comes from remedies that are analgesic (sensory-pathway). They are classed as stimulants to vaso-motor mechanism, but they are only so by unlocking the tonic muscular contractility, either systolic or inhibitory, through the sensory mechanism; then the rhythmic function is re-established. Nitroglycerin is possibly the best of the class, while not so prompt as nitrite of amyl, its effect is more enduring. A proper blending of the medicines above discussed, according to their therapeutic virtue, a general nerve tonic (strychnin), a vaso-motor tonic (digitalis) and the analgesic remedies (nitrite of amyl or nitroglycerin, etc.), give us theoretically, all that the most critical analysis of the indications involved and demanded in the treatment of the paroxysmal factor of idiopathic angina pectoris. I have at this time a patient, a woman aged 50 years, who at various times for the past ten years has been the subject of this disease. Her paroxysms realize all the characteristic symptoms, often with severe asthma and ataxia of the diaphragm, which has been relieved with morphia and atropia hypodermically; within the past

month she was seized with one of her paroxysms but one more urgent and critical; I administered hyperdermically, a combination dose of strychnin 1-40 gr., nitroglycerin 1-100 gr., and digitalin 1-100 gr., obtaining relief and very much more satisfactory results than the morphia and atropia had previously given.

ATROPHIC RHINITIS.

CANDIDATE'S THESIS FOR THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

BY JOHN EDWIN RHODES, A.M., M.D.

Professor of Physical Diagnosis and Clinical Medicine Northwestern University Woman's Medical School; Lecturer on Laryngology and Diseases of the Chest, Rush Medical College; Fellow of the American Laryngological Association, etc.

Atrophic rhinitis is a chronic inflammation of the lining membrane of the nasal cavities resulting in atrophy of tissues, with occasional corresponding changes in the bony structure, and the formation of crusts. It is frequently accompanied by ozena.

While all authorities are practically agreed as to the final sclerosis of the tissues in atrophic rhinitis, there are differences of opinion among observers as to the exact pathologic process by which such a result has been brought about. Is the atrophic condition essentially such from the beginning or is it preceded by hypertrophy? Manifestly, opinion founded upon clinical observation must be surrounded with difficulties. Patients are usually seen during some stage of the process and are seldom under observation from the inception of the disease; often the disease has extended over many years and a satisfactory history of it during the early stages can not be obtained. Occasionally observers have been able to follow the process from its beginning. Thus Schäffer found cases in which there had been hypertrophy for eight or ten years which was followed by atrophy. It is not uncommon to find in one side of the nares, hypertrophy of the turbinates and in the other atrophy; there frequently is also within one nasal cavity hypertrophy of the middle turbinated with atrophy of the lower, or vice versa—a condition observed also by Capart¹ and others. Again, it has been common, on inquiry, to find that the obstruction of the nasal cavities was the predominant early symptom. In our histories of 142 cases of private patients, I find one in which we observed the process from its inception. The patient was a girl, aged 15. She was only treated at very long intervals, so this could have had no bearing on the result. In this case the hypertrophy was well marked when the case first came under observation. Within two years atrophy had taken place, which subsequently became extreme. More² marked the coincidence of atrophic and hypertrophic rhinitis in eighteen out of eighty cases. I have but recently seen a well-marked case in which there was hypertrophy of the inferior turbinated upon one side and atrophy well advanced upon the other. In our list of cases I find several in which similar conditions existed.

J. N. Mackenzie³ believes that in this form of rhinitis we have the concluding stage of nasal inflammation, and that it is usually the sequel of a hypertrophic condition. In support of his position he traces the pathologic processes from an intumescent condition, resulting in the temporary obstruction of one or both nares. At first there is an engorgement of tissues mainly confined to the erectile spaces, with perhaps a slight cellular infiltration of the submucous tissues and an unchanged epithelium. When permanent swelling of the membrane has taken place the intercellular walls are changed into a dense

fibrous structure, encroaching more and more upon the erectile spaces, and a fibrous deposit in the submucous tissues compresses the glandular elements and gradually obliterates them. These conditions also invade the superficial layers, and the blood supply is interfered with, causing destruction of, or changes in the epithelial layer. In the obliteration of the erectile spaces he also observed in two specimens the presence in the spaces of masses of round cells; also in certain cases the formation of parietal thrombi and occasionally bulbous processes projecting from the walls of the cavernous sinuses. Finally the histologic condition seems to be a gradual atrophy of the different layers of the membrane, and as has been shown in the studies of Eugene Fränkel and others, we have presented to us a cirrhotic process in which the mucous membrane shrinks away by being changed into a fibrous connective tissue.

Browne,⁴ while willing to accede to a quite generally antecedent hypertrophy, in which there is an increase of the connective tissue elements, which culminates in fibroid shrinking, is of opinion that there are cases in which the process is atrophic from the beginning. Seiler's views coincide with this statement. Sajous⁵ is satisfied that atrophy is an occasional result of hypertrophic rhinitis, and that the pressure of dried secretions on the membrane is an important factor in the production of atrophy. The pressure of dried secretions can not be a constant factor, because in some cases of atrophy the secretions are either fluid or are easily removed. Atrophy has already begun in many cases and proceeded to quite an advanced stage, in which dried secretions have not been a feature. Over much of the membrane, especially at the anterior portion of the external wall of the nares, the crusts in many cases have never formed. It does not seem possible that, frequently at any rate, there could be sufficient pressure to interfere in any marked degree with the vascularity of the tissues. The increase of the crust takes place upon the surface of the membrane, and as it increases it is forced further from the membrane and the extreme, dry, contracting portion is upon the external free surface of the crust, the under part being usually moist and semi-liquid.

Delsaux⁶ believes that a simple chronic rhinitis is the precursor of atrophy, and does not admit that hypertrophy always precedes it. Ingals⁷ favors the theory that in most cases atrophy is the result of a previous hypertrophy. B. Fränkel⁸ also states that in most cases atrophy is the result of a preceding hyperplastic condition. Cohen⁹ affirms that in these cases we early find hypertrophy. A similar belief is expressed by M. Mackenzie.¹⁰ Abel¹¹ believes the *bacillus mucosus capseolatus*, causing a simple catarrhal inflammation, leads to primary hypertrophy and then to atrophy. On the other hand, Bosworth¹² does not admit that hypertrophic rhinitis is in any case the cause of the atrophic, but that the morbid changes are atrophic from the outset. Capart¹³ also believes that the disease is atrophic from the beginning and not the result of a preceding hypertrophy.

It was formerly quite generally believed that the syphilitic or strumous diatheses played an important rôle in the etiology of the disease. It is probable that these conditions may increase the susceptibility, and exercise some influence in its production, but the affection, in the majority of cases, develops in an otherwise perfectly healthy individual.

B. Fränkel¹⁴ says that a majority of cases depend on a dyscrasia, but recognizes the fact that there are other cases in which no such condition exercises any influence in developing the disease. Schäffer¹⁵ goes farther than this in stating that ozena is always due to struma or syphilis, hereditary or acquired. Clark¹⁶ has recently made an examination of 100 phthisical patients and 73 of them showed signs of atrophy. Strübing does not consider that predisposition is a factor of much importance, however, as perfectly healthy people get the disease. Beverly Robinson¹⁷ affirms that the presence of syphilis, struma or herpetism, are diathetic conditions which are efficient causes in many of the symptoms observed in this form of catarrh. Cohen believes that it is sometimes engrafted upon the strumous diathesis. M. Mackenzie, I believe, expresses the general sentiment of investigators, at present, in saying that the disease is not constitutional in the true sense of the word.

The statement of Abel that the disease is infectious is not corroborated by clinical experience, and animal experiment has proved that the crusts possess no infectious property. Neither is the disease hereditary nor congenital as shown by Zuckerkandl, who examined 252 skulls of children without finding a case of congenital atrophy. It can not be denied that we occasionally find two or more members of the same family who have atrophic rhinitis.

Bacteriology has been invoked to settle the question in regard to the odor of ozena as well as the etiology of the disease. Löwenberg's¹⁸ investigations showed the constant presence in the crusts in ozena of a highly pathogenic "cocco bacillus," large bacilli in short chains, or in masses, appearing as diplococci. Hajek,¹⁹ in his experiments, found immense numbers of bacteria of four or five varieties, in the secretions of ozena. In seven out of ten cases he found the pneumonia bacillus of Friedlander. In seven out of ten cases he cultivated a bacillus which he names the "bacillus foetidus ozenæ," which he believes causes the odor of the disease. The difficulty of mechanical removal of crusts is an important factor in the production of the odor, as it affords the bacillus ample time to develop, an assertion favored by the statement of Strübing, that fresh ozena secretions do not smell, and the odor is developed only when the secretion dries. The bacteria do not cause the disease, but simply the odor, and no bacteria are found in the membrane itself. Abel²⁰ examined sixteen cases of pure ozena in Strübing's clinic and decided that the cause of ozena was a well characterized bacillus. Since that time he has examined 100 cases and always found this bacillus. This is the same bacterium that was found by Löwenberg and Hajek. Fränkel believes that the odor is due simply to decomposition of the stagnant secretions. M. Mackenzie accepted Fränkel's earlier theory that it is due to fermentation. Krause attaches great importance to the degeneration of newly formed mucous cells and the production of fatty acids. Schuchard and Valentin affirm that atrophied membrane throws off a secretion which dries rapidly, becomes offensive, and emits the peculiar odor. This seems to be a purely speculative theory, as fetor may exist without atrophy; indeed, it sometimes occurs with hypertrophy. Baurowicz²¹ made an examination of fifty cases for bacteria. Fifteen of these were cases of atrophy, of which seven had fetor. In the fifteen cases only, he found the capsule bacillus of Löwen-

berg and Abel. As these were not found in other cases where suppuration or necrosis had taken place, they can not be considered the result of putrefaction. Belfanti and Della Vedova,²² from their experiments at the Institute of Serum Therapy, Milan, believe ozena is caused by an attenuated bacillus identical with that of Löffler but with virulence much lessened; this was found not only on the surface of the mucous membrane and in the exudate, but beneath it, and they believe it causes a chemical change in the secretion and a resulting atrophy. Vansant,²³ in a series of 100 cases, examined with special reference to the Klebs-Löffler bacillus, found twenty having chronic atrophic rhinitis. These bacilli and others were found in twenty-six different cases, of which eleven were atrophic. The presence of the bacilli was attributed to infection, a pathologic condition in the nasal chambers providing a suitable soil.

In other cases it is undoubtedly true that neglected or improperly treated catarrhal inflammation is the primary cause for a final atrophy. Certain anatomic and other conditions of the nasal chambers may possibly favor catarrhal inflammation, as, for example, abnormal patency of the anterior naris, and the "upturned nose," mentioned by Browne; deformities of the nasal cavities, congenital or acquired, which interfere with a blast of air sufficient for the removal of secretions; the neglect of children to blow the nose; the quality of the inspired air, or anything which lessens the sensitiveness of the membrane to the presence of foreign substances.

In our records of 142 cases in private practice, 80 were males, 62 females; the youngest was 6 years of age, the oldest 81; 58 were between 25 and 40 years of age, 37 were between 15 and 25, only three were under 10, 15 were between 40 and 50, and 8 were between 60 and 65. Of these cases, 55 complained of fetor, more or less marked. In 47 the sense of smell was impaired, in 20 there was anosmia. In 28 of the cases the hearing was affected.

The preceding history of the catarrhal condition before presenting themselves for treatment showed that they had suffered from seven to twenty-five years in seventy-two of the cases, and less than two years, in twenty-five. Only eight of the cases showed signs of tuberculosis, one of them being laryngopulmonary tuberculosis; in two there was a distinct scrofulous history; in five there was a history of syphilitic infection.

Symptoms:—Patients otherwise in excellent health may have atrophic rhinitis, with, perhaps, a history of catarrh extending over a period of months or years. In other cases this prolonged catarrhal condition has affected the general health. The main symptom is, in most cases, the formation of crusts in the nasal cavity, which are removed with difficulty. There is sometimes a history of stopping up of the nose, which is relieved when the crusts have reached a sufficient size to be expelled by vigorous blowing of the nose. Sometimes there is a sensation of dryness or irritation in the nose which the patient may try to relieve by picking or scratching the anterior portion of the septum and perforation may have resulted from the habit. A quite frequent symptom, as shown by our case records, is frontal headache. There is occasionally simply pain across the upper part of the nose. Hoarseness and a hacking cough are common. In many cases the hearing is affected, in some there is marked deafness. The sense of smell is frequently

obtunded or lost, and the sense of taste may be much impaired. Bleeding from the nose and occasional severe epistaxis are not infrequent symptoms. Sometimes there is complaint of dryness of the throat and naso-pharynx, although this condition may often be present and cause the patient little annoyance. Sneezing is not a common symptom. In a large majority of cases, however, the predominant symptom is the excessive discharge, either semi-liquid in character, or, usually, formed into crusts. Involvement of the accessory sinuses occurred only once in our 142 cases.

If ozena be present the odor may be imperceptible to the patient even in the most extreme cases. He usually, however, has either recognized the condition himself or has been informed of it by his friends. The odor is characteristic and once it has been detected can thereafter be readily recognized. In most cases the odor is perceptible only in close proximity to the patient, but I have seen cases in which the stench permeated the atmosphere of the entire room and remained long after the patient had quitted the apartment. The crusts vary in color, being a dirty, yellowish white, or brown, or they may be greenish, or almost black in color. They conform in shape to the portion of the cavity from which they have been detached. The outer surface of the crusts may be of a soft consistency or may present a tough, thick, hardened surface. The under surface of the crust is frequently of a soft muco-purulent character. The crusts on being torn away from the mucous membrane sometimes leave a bleeding surface beneath.

The general appearance of the patient may be changed somewhat by unusual broadening of the nasal bone and the alæ may be dilated. If the patient blow the nose vigorously the lessened resistance to the expulsive blasts of air may be readily detected by the sound and is quite characteristic of a roomy nasal cavity. On examination of the nasal cavities, their roominess is at once apparent. In many cases the lower turbinated bodies are so shrunken that the posterior wall of the naso-pharynx is easily seen. The middle turbinated body is quite normal, in many cases; usually it is atrophied, but it may be hypertrophied. Bresgen,²⁴ however, thinks that very often atrophy begins in the middle turbinated body and middle meatus, while the lower turbinated may remain normal. Crusts will be seen adhering to the turbinated bodies and the septum, more particularly at the middle and upper part of the cavity. The membrane is usually paler than normal, but on cleansing thoroughly the parts may become hyperemic for a time, probably from irritation of the cleansing process. The mucous membrane of the pharynx is apt to be dry, and covered with thick, tenacious secretion, and in the naso-pharynx there may be found a blackish crust closely adherent to the vault.

Diagnosis.—In the early stage an inspection of the nasal chambers may not reveal any striking change of the mucous membrane of the turbinated bodies, and the naso-pharynx may be quite normal. Sometimes fetor is present in this early stage. When shrinking of the membrane has taken place to any marked degree, the roominess of the nares becomes apparent, and the characteristic crusts are found. Fetor is present in a majority of cases in this stage. When the stench is a leading symptom, especially if it be found to proceed from one naris, a careful search

should be made for rhinoliths or foreign bodies, after a thorough cleansing of the passage.

In syphilis of the nose there is often a disgusting odor which might be mistaken for ozena accompanying atrophy. There would usually be a specific history, and a careful examination would probably disclose the presence of dead bone or ulceration in the nasal cavities. In these cases, too, the patient is usually conscious of the odor. The odor is removed by cleansing only temporarily, and it quickly returns. Michel's view that ozena is due to chronic suppuration of the accessory sinuses can not be sustained. The discharge in such cases may be accompanied by fetor, which proceeds from one nasal cavity, and the odor is present at the moment of the discharge from the sinus. This discharge rarely remains in the cavity sufficiently long to form crusts. The patient is deeply conscious of the fetor, inasmuch as the sense of smell is not impaired.

Prognosis.—If by a cure we are to understand a restoration of a fibrous structure to the function of the original turbinated body, we shall be obliged to accept the hopelessness of the conditions. I fully believe, however, that, in many early cases, by a vicarious activity of the unimpaired glands and vascular structures remaining in the membrane, the patient can be so nearly restored to his normal condition that symptoms will have been relieved, a restoration of function brought about to a degree, and treatment can be practically abandoned. In all cases relief can be obtained to a greater or less extent, but, in many, persistent treatment must be adopted, vigorous at first but less energetic later on, and persisted in for many months. When the odor has disappeared and crusts have ceased to form it may still be necessary to use some simple toilet daily, or less frequently, for years. As middle life is passed the odor usually disappears without treatment and all symptoms are alleviated. The sense of smell once lost, in these cases, can not be restored. If the hearing has become affected little can be done to relieve it.

Treatment.—The problem in the treatment of atrophic rhinitis is not only to remove the secretions, thus dissipating the odor temporarily, but also to prevent their reformation and to stimulate to a renewed activity those portions of the mucous membrane whose functions have not been altogether destroyed by the atrophic process. In times past the Thudichum douche has had many advocates, but since Roosa²⁵ published sixteen cases in which middle ear disease followed its use very many have abandoned it altogether. Hovell²⁶ condemns it because of the possible middle-ear involvement and the severe, persistent headaches that may be caused by the entrance of the fluid into the frontal sinus. If proper precautions are taken, however, it may sometimes be used with perfect safety. I believe that with the extreme roominess of the nasal cavity in marked atrophy, if a low pressure is used, the head held well forward, the mouth kept open, and an attempt to swallow be refrained from during the douching, the stream will flow into one nostril and out the other freely, and rarely, if ever, finds its way into the eustachian tubes. Simply sniffing water from the open hand through the nasal passages, preferably one at a time, the other being closed by pressure upon the ala of the nose, is better than the douche, because very little pressure is exerted in drawing the liquid to the naso-pharynx. I have usually employed this

method and very rarely have there been complaints of fulness of the ears following the washing. The Bermingham douche, which consists of a cup, with a nasal piece expanded near its opening can be used with comparative safety. The liquid is poured into the nasal passage with the head thrown well back and with the mouth open to prevent the entrance of the fluid into the throat. The head is thrown forward quickly and the liquid finds an easy exit. The whole surface of the nasal passages and the naso-pharynx can be reached in this way. The post-nasal syringe may be used where the crust can not be dislodged from the pharynx and naso-pharynx by the other methods. The coarse spray-producer is strongly recommended by Robinson, who condemns the douche. It may be used with perfect safety. In many cases, however, the patient can not remove the crusts satisfactorily by this method and is obliged to resort to one of the others mentioned. The crusts may be located by inspection and, after softening with spray or otherwise, they can usually be detached readily by means of an applicator wrapped with cotton. Little force should be used in detaching them. It is often advisable to have the patient wash out the nose for several days before attempting to make other applications. The wash should be warm and used by the patient two or three times a day. It is necessary certainly that the nose should be made clean and kept clean; this can best be accomplished by the employment of a wash that will both soften the crusts and disinfect the nasal cavities. The simple alkaline wash, a teaspoonful of salt in a pint of warm water, is a popular household cleansing solution, and quite as effective as some others. A combination may be used as follows:

Sodii chloridi			
Sodii bicarbonatis.	āā	3x	4000
Sodii salicylatis.			
Sodii bivoratis,	āā	5v	2000
Misce.			

A teaspoonful in a pint of tepid water makes an unirritating alkaline solution.

McBride²⁷ favors douches and recommends as the best aceto-tartrate of aluminium, a 50 per cent. solution, using a small teaspoonful in a pint of water. Dobell's solution makes an excellent spray for cleansing purposes. A large number of medicaments have been suggested by different authorities, combinations containing sodium salts, carbolic acid, potassium permanganate, boric acid, chlorin water, hydrogen peroxid and others. The following formula has given me more satisfaction than any other. I have had it put up in tablets, one of which, dissolved in from one-half to two-thirds of a glass of warm water, makes a solution of proper strength. This not only cleanses the passages but the thymol destroys the odor:

Potassii chloratis.	grs.	iiss	15
Sodii bicarbonatis	grs.	x	60
Sodii chloridi, C. P.	grs.	x	60
Sodii salicylatis	grs.	v	30
Sodii bivoratis.	grs.	v	30
Thymol.	grs.	$\frac{1}{8}$	008
Eucalyptol.	min.	$\frac{1}{4}$	016
Misce. Make one tablet.			

After the nares have been thoroughly cleansed, stimulating or alterative treatment should be instituted, according to the stage of the disease reached, and the susceptibility of the patient. It is here that many different remedies have been used and many methods tried, some with indifferent success, others

with very beneficial results. When the nares are clean I am in the habit of having the patient use a powder like the following:

Sodii bivoratis	grs.	ij	12
Hydrarg. oxidi flav	grs.	ij-v	12.30
Iodol.	grs.	j	065
Cocain hydrochlor.	grs.	iiss	15
Magnes carb. levis	grs.	ij	12
Sacch. lactis, q. s. ad	grs.	100	650

The powder is quite impalpable and as it spreads over the membrane it dissolves readily without forming a pasty mass. About one and one-half grains should be used in each naris, two or three times a day. The yellow oxid of mercury is one of the best of the stimulating and disinfecting remedies. The iodol is a good disinfectant and the cocain, suggested for persistent use in this disease by Ingals, is highly recommended. The first effect of the cocain, when locally applied to the membrane, is to cause contraction of the blood vessels and an excitation of the mucous glands. If its use is continued for any length of time there is apparently paralysis of the vasomotor nerves, with dilatation of the blood vessels and increased nutrition of the parts. We have frequently observed slight hypertrophy of the nasal mucous membrane which, under the continued or excessive use of cocain, was greatly increased; and in other cases a simple congestion, without hypertrophy, subjected to the persistent action of cocain, which has resulted in a few months in marked hypertrophy. In the atrophic condition, then, where stimulation of the remaining healthy tissue is sought, we have a valuable remedy in cocain. It should be supplied by the physician and used in small quantities only. A prescription which would enable the patient to obtain it *ad libitum* should never be given. In none of our cases when used in such a formula as given above has it had any decided constitutional effects. We have treated many cases in this way with benefit, and, in two or three, extended treatment has resulted in restoration of the tissues, in appearance at least, to a nearly normal condition.

Among the other remedies that have been suggested in atrophic rhinitis, in various combination are: Berberin muriate, pulverized benzoin, pulverized galanga, pulverized tannic acid, menthol, iodoform, ichthyol, euophen, aristol and thymol. I have recently used in a few cases trikresoliodin, a preparation containing iodine in a free form. It is not escharotic and seems to be a very good antiseptic, stimulant spray. Sprays with a basis of liquid albolene, benzoinol or some other of the oils of a like character are often useful, especially if there be difficulty in removing the crusts, or in cases where their removal leaves a raw or bleeding membrane. There may be combined with it for disinfecting or stimulating purposes, carbolic acid, min. iij to v, to the ounce; menthol, grs. ij to x; oil of cloves, min. iij to x; oil of cinnamon, min. v to x; thymol, grs. $\frac{1}{8}$ to iij; ichthyol, grs. v to x, or other medicaments. The weaker solutions should always be used first and the strength should never be enough to cause much discomfort. It is well that these patients be treated by the physician two or three times a week for a time, in order that there may be certainty as to cleanliness, and as to the effect of the remedies prescribed. Thereafter less frequent consultations are advisable, and when once a proper line of treatment has been established the patient need be seen at rare intervals only.

Gottstein's tampons may be placed in contact with the mucous membrane and allowed to remain for a time daily. These are said to act as an irritant and stimulant to the membrane, and to destroy the odor. Franz Bruck²³ considers it the easiest method of treating ozena, but says that with tampons impermeable to moisture the effect is not so good. Hydrophil cotton is preferable, because it excites secretion and absorbs it. Inasmuch as only the dry secretions smell, the tampon must be renewed before the secretions again become dry, every two or three hours being sufficient in light cases. In the severer, he suggests that hydrophil gauze be introduced by a bougie, over the end of which the strip is folded, but it should not be large enough to prevent nasal respiration with the mouth closed. When this becomes filled with secretion it can be blown out and replaced by the patient. The effect is that an increased blood supply warms the air, the gauze catches the irritating particles and the inspired air is more freely moistened. I have recently made use of strips of surgeon's lint, introduced with flat probe, in a similar manner, and believe patients have derived much comfort from the treatment. Strübing²² considers the treatment of great value, but he medicates the tampons with creolin, aristol, sozoiodol, etc., and recommends steam for cleansing purposes. Säger³⁰ advises a curious method of treatment by means of a U shaped clock spring, with zinc plates attached, trimmed to fit the nares, leaving a space for air. His theory is that this causes rarefaction of air in the nasal passages in inspiration, dilatation of blood vessels, increased secretion and softening of crusts. Fränkel was the first to advocate the use of the galvano-cautery, at white heat, over the site of the crust formation. Sajous³¹ favors the practice, as does Lennox Browne. Belfanti and DellaVedova,³² following out the therapy suggested by their investigations of the diphtheria bacillus in their cases, employed antidiphtheric serum in thirty-two cases, sixteen of which were said to be cured, seven almost cured, five improved, and four showing slow improvement.

Hartman,³³ following Shurly and Delavan, reports excellent results from the use of the galvanic current, the positive pole being placed at the nape of the neck, by sponge electrode, the negative to the nasal mucous membrane by means of pledgets of cotton wrapped around insulated wire, and well moistened. The seances were from five to fifteen minutes, three or four times a week. Capart,³⁴ and his assistant Cheval,³⁵ make extended reports of treatment of this disease by electrolysis. They introduced a copper or silver needle, on the positive pole, into the middle turbinated, and a steel needle through bone and membrane of the lower turbinated, of the same side. They claim that there should be 90 per cent. of cures by this method, and that often one sitting is sufficient. The current used is about twenty milliamperes, from seven to fifteen minutes. In 300 treatments they had no accident. Bayer, however, reports a case in which developed a hemorrhagic otitis media, followed by meningitis and death. They report disappearance of crusts and odor, and return of the membrane to its normal appearance. To those who have treated many cases of atrophic rhinitis their claims seem very extravagant.

G. Hunter Mackenzie³⁶ reports that he has succeeded well by curettement in a number of cases. He follows the operations with oily applications, as a

mixture of ichthyol and olive oil. Berens²⁷ reports good results from the use of undiluted ichthyol applied by a tampon in each nostril, and allowed to remain about fifteen minutes. This was followed by massage by means of a pledget of cotton wrapped on a probe and saturated with ichthyol.

Seiss³⁸ recommends a drachm of a 30 per cent. solution of peroxid of hydrogen, as a spray for each naris as a cleanser. When the crusts have been removed he uses massage by a probe wrapped with a cotton swab, well oiled, covering the whole area of the membrane rapidly for three to six minutes, care being taken not to denude the tissues. He follows this with stimulant applications, such as euophen, thymol, or cinnamon oil in albolene.

Skin grafts have been tried in these cases, but we can not hope for success in this treatment, inasmuch as it is an impossibility to replace the ciliated columnar epithelium by such grafts. The general health and hygienic surroundings of the patient should be carefully attended to.

It is no reproach to our profession if we shall not restore an atrophied membrane to its normal condition. There need be little discomfort to the patient or to others, if the disease is persistently and properly treated. Prophylaxis lies in the cure of the antecedent catarrhal condition.

TRACHEAL INJECTIONS IN THE TREATMENT OF LARYNGEAL AND PULMONARY INFLAMMATIONS.

Read before the American Laryngological, Rhinological and Otolaryngological Society, Washington, D. C., May 1, 1897.

BY J. A. THOMPSON, M.D.

CINCINNATI, OHIO.

The first physician who left us a record of a systematic study of intra-tracheal medication was Dr. Horace Green of New York. Long before the invention of the laryngoscope he had attained remarkable dexterity in passing a sponge probang, saturated with a solution of nitrate of silver, into either bronchus. His reports of his methods and results were so extra-

ordinary that the New York Academy of Medicine appointed an investigating committee to determine the truth or falsity of his statements. The committee agreed that he could and did employ the method described, but a majority condemned its use. With the invention of the laryngoscope there was no immediate revival of the method of direct medication in the treatment of laryngeal and pulmonary inflammations. It is only within the last few years, that occasional reference to this subject can be found in medical literature.

There are several reasons for the slow growth of this manner of treatment, in professional favor. The principal one is, that, few physicians are sufficiently expert in the examination and treatment of the upper air passages to employ it. As a rule they consider all lesions of the nose and throat as local, with but little influence on the health of the patient. This lack of appreciation of the importance of these conditions is largely responsible for the neglect of direct medication. Another reason for the limited use of intra-tracheal injections, is the mistaken opinion, that they are necessarily painful and irritating. Our ideas of the sensibility of the tracheal and bronchial mucous membrane, have been erroneously deduced from that of the larynx. Below the glottis, the nerves of sensation are few, and the membrane is not irritated by solutions much stronger than those we use in the larynx. While these reasons have been potent in preventing the more general knowledge and use of this method, there are other and much better reasons for the general use of direct medication in inflammatory diseases of the larynx, trachea, bronchi and lungs.

By the method of intra-tracheal injection we get the direct local action of the medicines on the diseased areas. In bronchi ectasis, no medicine given by the mouth, will prevent the decomposition of the secretions in the dilated bronchi. The odor and the absorption of septic material from them can not be controlled. A few tracheal injections will usually disinfect the cavities so that the odor disappears and the temperature becomes normal.

It is possible by intra-tracheal medication to produce a rapid and prolonged general effect. Anesthesia gives daily and hourly evidence of the rapidity with which volatile medicines are absorbed through the lungs, and their effect on the whole organism. From three to five minutes is a sufficient time for an expert to obtain chloroform anesthesia. You can produce as rapid an effect, and one much more durable, by injecting into the trachea, medicines which volatilize slowly at the temperature of the body. Where a dose of menthol had been given in this way, you will find the surface flushed in five minutes; the cold extremities have become warm and sometimes the patient breaks out in a profuse perspiration. This stimulating action lasts for hours.

Medicines used by tracheal injections are not changed by passing through the digestive organs into unknown compounds. For this reason we can be more certain of their action. No one would think of treating a tubercular laryngitis by internal medication alone. There is just as much reason for applying medicines of known beneficial, local action, directly to the lungs, as there is for using them in the larynx.

Where medicines are injected directly into the trachea they have no deleterious effect on the organs of digestion. Our valuable expectorants such as are used in acute and subacute catarrhal diseases, act in-

juriously on the stomach and intestines. The name of one class, nauseating expectorants, testifies to the universal recognition of this fact. The cure of a bronchitis by direct medication without interfering with nutrition is an advance in therapeutics.

Direct antisepsis can be secured by local medication. It is not possible to obtain this result by remedies given internally. We are prone to forget, that in tuberculosis, we are dealing with a mixed infection. In the stage of ulceration and breaking down of tissue infiltrated by tubercular matter, there is always a secondary infection by the germs of suppuration. It is to these, in all probability, that most of the fever, the night sweats, and the other evidences of sepsis are due. We do not attempt to disinfect a leg ulcer by medicating the stomach. It would be just as rational to do so as it is to attempt to disinfect suppurating cavities in the lung by medicine administered per os. In cases where tracheal injections can be tolerated, the antiseptic action of the remedies chosen will be very speedily shown, by the subsidence of the cough, by change in the character of the expectoration, and by the decline in the fever.

The administration of medicines by intra-tracheal injection, does not interfere with any other line of treatment. Diseases in other organs may be treated or tonics given, while local treatment of the lungs is being used, without any incompatibility.

Where medicines are given by the tracheal rather than by the esophageal route, we can relieve symptoms in hopeless cases without narcotics. We thus avoid their bad effects on nutrition. We also escape their secondary depressing action on the nervous system. A little menthol injected into the trachea will quiet a cough longer and more effectually than will a quarter of a grain of morphia given hypodermically.

Conditions not affected by constitutional medication can be cured by tracheal injections. Gummata in the lung, which resisted all other treatment, have been cured quickly and easily by direct medication of the suppurating cavities.

There are several conditions necessary for success in this method of treatment. The first essential is that the doctor himself be skilful enough in laryngology to do the work rapidly and delicately. The patient must possess a reasonable amount of self-control and be willing to follow directions implicitly.

It is probable that the medicines used for this treatment should be such as volatilize slowly at the temperature of the body. They should be soluble in the vehicle employed. The solutions used should not be too irritating. The most serviceable solutions are menthol, 2 per cent.; guaiacol, 1 per cent.; creosote, 1 per cent.; camphor, 2 to 3 per cent. Any of these may be combined. In acute diseases the menthol and camphor solutions are most efficient. In tuberculosis menthol and guaiacol give the greatest relief. Guaiacol gives good results in any septic condition in the lungs or bronchi. The vehicle used should be one of the light petroleum oils or olive oil. Alcohol and water are too irritating and produce violent coughing. There is ordinarily no spasm and but little cough or distress after an injection of the above solutions. The dose is from one to four drams. The diseases in which intra-tracheal medication will be of service must be determined by clinical observation.

I wish to present only a few deductions from my experience with this method of treatment during the last five years. The necessary condensation may

make my statements seem too dogmatic. All are based on cases actually treated and are deductions drawn from results thus obtained.

My first notable success was in pulmonary tuberculosis. In August, 1892, I began treating a woman with every symptom of this disease. Her attacks of coughing were so prolonged and violent that she frequently vomited and was unable to sleep at night. An injection of a solution containing menthol, 2 per cent., guaiacol, 1 per cent., at 4 o'clock in the afternoon would control the cough so that her dinner would be retained and she would get a good night's rest. The cough did not return, as a rule, until the following morning. The patient's symptoms entirely disappeared and treatment was discontinued. A little more than a year after she ceased treatment she became pregnant, and with the digestive disturbances incident to this condition, there was a return of the cough, vomiting and inability to sleep. The treatment by tracheal injection was resumed, again resulting in apparent cure. The pregnancy was uninterrupted and the patient has had no further occasion for treatment during the last four years.

In other cases of pulmonary tuberculosis, symptoms have been greatly relieved, but I have no other cures, where a sufficient interval has elapsed since treatment to make the statistics worth recording.

A few cases that I have seen, where the tubercular disease was making very slow progress, have not been benefited by tracheal injections. Where the diseased process is a chronic, not an acute one, the symptoms have been aggravated by the remedies used.

My next notable success in this treatment was in pulmonary syphilis. Fortunately, this is a rare condition, but there are some cases where gummata form in the lung in the tertiary stage, and where the disease is not controlled by constitutional medication. I reported a case of this kind in the *Medical Record*, Oct. 21, 1893. I have recently seen this same patient and there has been no recurrence of the trouble at the site of the original lesion.

In the first stage of acute bronchitis, where there is no secretion, tracheal injections have proven irritating. I have abandoned them at this stage and give something to induce free sweating instead. In the second stage, after free secretion has been established, intra-tracheal injections of menthol and camphor will relieve the cough more than any other treatment, and daily injections will shorten the attack at least one-half, as compared with cases treated by a stomach medication.

In chronic bronchitis there is no comparison between the two methods of treatment. The results are so much more rapid and satisfactory by intra-tracheal medication, that no patient, who has once been given this treatment, is ever willing to continue internal medication.

There is a condition rarely mentioned, often associated with chronic diseases in the upper air passages, which gives rise to many of the symptoms that we attribute ordinarily to chronic laryngitis. This is chronic catarrhal inflammation of the mucous membrane of the trachea. You will also frequently find in cases of acute bronchitis that the trachea remains inflamed, as can be seen by laryngoscopic examination, after all the physical signs of bronchitis have disappeared. This is especially true of cases where there is chronic rhinitis and laryngitis, as the underlying cause of the acute attack. This chronic inflam-

mation of the tracheal mucosa gives rise to more or less cough and a feeling of soreness, and sometimes to distinct pain in the chest. Physical examination in this condition shows no signs. It can only be detected by direct examination of the trachea, either by the laryngoscope or by the autoscopic method. Where this tracheal inflammation is coexistent with a chronic laryngitis, the ordinary treatment for laryngitis will fail unless combined with tracheal injections for the cure of the disease of that organ. Stimulant expectorants, given internally, have little influence on the course of a tracheal inflammation. Direct local medication ordinarily results in a very speedy cure.

Some cases of asthma are notably relieved by tracheal injections. The paroxysm is relieved for hours after the treatment. The bronchitis which usually accompanies this condition, is cured more speedily by direct medication than by internal treatment. Some cases of pulmonary emphysema have been given great relief by tracheal injections. The effect was probably obtained through the cure of the chronic bronchitis which usually accompanies this condition.

Where the remedies to be used are not irritating, it is not necessary to spray the larynx with cocain. The injection can be given while the patient takes a slow full inspiration. The process can be repeated until a sufficient dose has been administered. Where strong solutions or those irritating to the larynx are to be employed, that organ must be anesthetized. The tip of a properly curved tube of a syringe is then introduced between and below the vocal cords, during inspiration, and the whole dose given at once.

To an expert laryngologist there are a few technical difficulties in the treatment. There are none which need discourage the family practitioner and prevent him from attempting it. The method is useful in so many pathologic conditions frequently seen by every practitioner, that all should know of it and use it. When they do, they will learn as a few have already learned, that in the method of intra-tracheal injections we have a means of promptly relieving symptoms, and curing some diseased conditions that are not benefited by any other treatment.

THE STREPTOCOCCUS PYOGENES · THE CAUSE OF DIPHTHERITIC CONJUNCTIVITIS IN A CASE OF MEASLES.

Read at the meeting of the Chicago Pathological Society, April 12, 1897.

BY H. A. BRENNECKE, M.D.

INTERNE IN THE COOK COUNTY HOSPITAL, CHICAGO.

The following case is thought to merit a somewhat complete report because it was diagnosed clinically as true diphtheria of the conjunctiva, by Dr. Cassius Wescott on the strength of the macroscopic appearance of the eye, whereas the microscopic examination demonstrated the absence of the diphtheria bacilli and the presence of the streptococcus pyogenes in short chains, not only in the eye but in the blood and various organs.

The case occurred in a boy three years old. The patient had been living at "The Home of the Friendless" from which a number of patients with measles had been brought to the Cook County Hospital into the service of Dr. W. L. Baum. The patient had been sick three days before admission, complaining of sore

throat, headache, slight coryza and had vomited once.

On examination the body was found well nourished, eyes with slight conjunctival injection, the expression was dull and there was photophobia, lachrymation and serous discharge from the nose. The pharynx was injected, tongue coated, tonsils enlarged, as also the cervical glands. The heart's action was accelerated. The lungs revealed numerous dry râles. The abdomen showed nothing of interest. Skin: On the face there were numerous crescentic, round and irregular "blotches" of a red papulo-macular variety, which became diffused over the entire body on the second day.

During the course of the disease the following observations were made: On the day of admission the pulse was 124, temperature 102.4, respiration 36; after this they varied as follows: pulse 130-160, temperature 101-105, respiration 40-48 up to the last day, when the pulse was 172, temperature 102.3, respiration 56-64.

On the fifth day an examination of the urine showed the presence of albumin and hyalin and epithelial casts. The conjunctiva of the right eye was markedly injected, particularly that of the palpebræ. The following day the injection was more intense, the lower lid much swollen and on eversion showed a heavy white exudate. On the eighth day both lids were edematous and their conjunctivæ covered with a heavy white membrane. The bulbar conjunctiva was injected and the cornea smooth and shiny. The discharge from the eye was abundant and milky. The left eye was unchanged.

At about the same time that the changes in the eye were noted, superficial ulceration about the alæ of the nose appeared, which gradually extended and caused an occlusion of one of the nares.

As the condition in the eye had been diagnosed a true diphtheria of the conjunctiva, repeated cultures were made on blood serum from the nose, eye and throat, but only micrococci, staining with Gram's method, were found, which grew in fine white translucent and yellow circular colonies. Direct cover-slip preparations made from the eye showed only micrococci.

On the tenth day the following note was made: Patient restless, often refuses nourishment, pulse rapid but of fair quality, respiration rapid, skin rough and dry and the back and shoulders as well as other parts of the body show diffuse irregular patches of red which do not disappear entirely on pressure. The nose is but little changed. The mucous membrane of the mouth shows irregular white patches. The eye is the same with the exception of a hazy cornea. Examination of the lungs reveals numerous subcrepitant and mucous râles diffusely spread, most marked over the lower lobes. A large area of dulness with increased voice sounds is found over the right lower lobe.

Death took place eleven days after admission. The postmortem examination was made twelve hours after death. Only the essentials are given here. The body was well nourished. The heart showed no changes except paleness. The trachea was ecchymotic. Both lungs contained numerous areas of consolidation of grayish red color and which reached a considerable size in the right lower lobe. The lung tissue around the smaller bronchi was infiltrated with blood. By pressure a muco-purulent fluid was forced from the bronchi. The spleen was firm, enlarged and mottled

on section. The kidneys showed fetal lobulation, the capsules peeled readily leaving a smooth surface, on section they were pale and the cortical markings were distinct. The mesenteric, cervical and peri-bronchial lymph glands were enlarged. The tissues about those of the neck were edematous. The right eye showed the lids swollen, their conjunctivæ covered with a dirty gray membrane and the cornea hazy. Cover-slip preparations made from the blood and stained by Gram's method showed streptococci.

The bacteriologic examinations were made with the aid of Dr. Geo. H. Weaver. Inoculations were made on blood serum from the following organs: the blood of the heart, the lungs, the cellular tissue and glands of the neck, the spleen, the kidneys, the right eyeball and the liver. The blood, spleen, kidneys and liver showed a pure culture of fine, white, circular, translucent flat-topped colonies. Cover-slip preparations made from each stained with Gram's and showed streptococci. The organism appeared in similar growths on 5 per cent. glycerin agar. Stab cultures in gelatin produced a fine globular growth along the puncture which became confluent and did not liquify the gelatin. Litmus milk was changed to a slight reddish color and was not coagulated. Bouillon showed a fine gray sediment leaving the medium above clear. Potato showed no visible growth in four days. The cultures grew more rapidly at the temperature of the thermostat; 5 c.c. of a bouillon culture two days old injected into a vein of the ear of a full-grown rabbit did not cause death. From the above peculiarities it was concluded to be the streptococcus pyogenes.

From the eye, lungs, glands and cellular tissues of the neck a second micrococcus with following characteristics was obtained. On blood serum, 5 per cent. glycerin agar and potato the colonies were heavy, circular and light yellow in color. Gelatin was liquified, made turbid and of foul odor. Bouillon was likewise rendered turbid and foul. It grew best at room temperature; 2 c.c. of a bouillon culture injected into the peritoneum of a rabbit produced no marked symptoms. It was concluded to be a saprophytic micrococcus.

Histologic examination of the various organs showed the following: In the right eye the cornea shows the epithelium destroyed, round cell infiltration into its tissues and there is also infiltration into the anterior chamber, sclera, ciliary body and optic nerve. On the outer surface of the sclera and cornea there is a layer of granular homogeneous material which in part takes the hematoxylin stain and shows extensive nuclear fragmentation and fibrin, evidently a superficial necrosis. The lung shows the changes of broncho-pneumonia. The spleen and the glands of the neck show an increase of cellular tissue. The heart, liver and pancreas show no changes.

Sections of the various tissues stained by Gram's method show streptococci in the vessels.

Summary.—The bacteriologic examination showed the presence of the streptococcus pyogenes in the right eye as well as the body generally. On account of the simultaneous ulcerative condition in and about the nose it can not be positively stated that the eye formed the atrium for general infection. On the other hand it is quite probable that the eye became involved by the streptococcus being brought there by the circulating blood. The primary atrium for infection may have been in the throat.

PURULENT PERICARDITIS WITH REPORT OF A CASE DUE TO TRAUMATISM.

Read before the Michigan State Medical Society, Grand Rapids, Mich.,
May 14, 1897.

BY FRANK W. GARBNER, B.S., M.D.
MUSKEGON, MICH.

Purulent pericarditis presents essentially the same chain of symptoms as those shown by a non-septic pericardial inflammation. The history of the case may point strongly in the direction of a purulent effusion, but the aspirator alone can determine positively the nature of the fluid. The disease may even run its course without such aids to diagnosis, as fever and edema of overlying tissue. A preëxistent or a co-existing ulcerative endocarditis, a pyemia, tuberculosis or an empyema, an abscess of the mediastinum, caries of the ribs, gangrenè of the lungs, or a trauma may make evident the presence of pus, and are among the leading causes of purulent effusion into the pericardium. Pericarditis whether purulent or non-purulent is a secondary trouble, and is probably frequently overlooked by the physician.

The healthy pericardial sac of an adult holds from 420 to 630 grams. It is somewhat pyriform in shape and lies back of and to the left of the sternum, extending from the third to the seventh ribs with its broadest portion at its diaphragmatic attachment. Upon the greater or less distension of this sac, together with the intensity of the inflammation and the character of the exudate, depend the phenomena of pericarditis. As effusion takes place, the sac gradually distends from below upward, the area of precordial dulness broadening and rising as the quantity of fluid increases. The lungs are crowded back and to either side. The diaphragm is depressed. The dulness may extend from the xiphoid process to the top of the sternum, and from nipple to nipple. As the amount of effusion increases, the site of the heart's impulse is raised and carried outward, sometimes reaching as high as the third interspace. With encroachment upon the lung space come dyspnea, and an interference with the normal respiratory movements. The play of the upper ribs is increased and there is limited motion on the left. The lateral movements of the abdomen are lessened, the play of the left side being less than that of the right. Pressure upon the vena cava and the pulmonary veins tends to venous engorgement, and the dusky countenance so frequently seen. In the young, and where there are large accumulations of fluid there may be precordial prominence. There may be friction sound, and an intermission of the radial pulse during inspiration, at a time when there is no intermittent heart action. Accentuation of the pulmonary second sound is remarked as one of the most constant signs of pericarditis. If to the symptoms enumerated there are added hectic, sweating, and such other familiar signs of confined pus as are characterized by empyema, the diagnosis of purulent pericarditis becomes reasonably certain.

As far back as the seventeenth century, we find clinicians discussing the advisability of opening the pericardial sac for the relief of pericardial effusion. It was not until 1819, that the operation was first successfully performed. Romero of Barcelona operated by incision, in three cases, two of which recovered. In 1840 paracentesis was performed by Schuh for pericarditis due to cancer, the patient living six months after the operation. The first instance of tapping of the pericardium, in this country, occurred in the

practice of Dr. Warren of Boston, in 1852. These operations were all for the removal of non-purulent effusions, though tapping has been recommended and practiced until recent years for the relief of either class of cases.

The first authentic case I have been able to find of the treatment of purulent pericarditis by the scientific and reasonable method of incision and drainage, is found in the fifth number of the *Berliner klin. Wochenschrift* of 1881.

A boy ten years of age had suffered from empyema which failed of relief by tapping. Indications pointed to a pericarditis, which by aspiration was found to be purulent. Though several ounces of pus were removed by this method, no improvement followed, but rather, increasing dyspnea, lividity and edema of feet and legs. Sleep became broken and the general condition poor. An incision into the pericardial sac, between the fourth and fifth ribs near the border of the sternum, was then made under the antiseptic precautions then in vogue. Two drainage tubes were placed in the opening and the wound inclosed in a Lister dressing. Prompt relief followed though recovery was retarded by co-existing empyema, which was finally relieved by incision and drainage.

Operation by incision and drainage was performed for the first time in England by Dr. Samuel West in 1883. Great success followed the operation. There was no deformity of the chest and only a very small scar remained.

In 1885, Michaeloff, after a preliminary tapping which was followed by slight improvement, incised the pericardium of an adult female in whom the purulent pericarditis seems to have been a sequela of Bright's disease. Temporary improvement followed, but the patient died a short time after the operation. Postmortem revealed a fatty degeneration of the heart with great dilatation.

In the same year, Gussenbauer resected five ribs and washed out the pericardial sac with a thymol solution. His patient recovered.

Davidson reported in the *British Medical Journal*, March 1891, two cases treated by incision and drainage. The first case was that of a boy of six in whom pyopericardium was secondary to necrosis of one of the metatarsal bones, and further complicated by pneumonia and a subperiosteal abscess of the eighth rib. A free incision was made in the fifth interspace, and eight ounces of pus were evacuated. There was some temporary relief but the patient died within a week. The second case occurred in a boy of seven, and followed a purulent pleuritic effusion which had been appropriately treated without giving any apparent relief. Examination revealed the presence of a pericarditis which proved to be suppurative. The sac was opened, free drainage established and the patient made an uninterrupted recovery.

Beekman and Stall report a case in which the pericardium was opened after trephining the sternum. Recovery followed.

Bronner relates a case of pericardiotomy in a girl of 11, which terminated fatally after twenty-five days.

Scott reported a case of pyopericardium (*New Zealand Medical Journal*, July 1891), in which he opened the sac, removed a large quantity of pus and irrigated the cavity with a solution of carbolic acid (15 to 1000). The operation was followed by complete recovery.

In the *International Medical Magazine*, June 1893,

Edwards gives the details of a case treated by incision and drainage. The patient was a poorly nourished and illy developed child of 6 who for a month had complained of pains in the left costo-sternal region. There were continuous fever, dulness over the precordial region, dyspnea, edema of face and ankles, and albuminuria. The operation was followed two weeks later by a purulent pleuritic effusion, the relief of which gave no signs of improvement, and the child died of exhaustion at the end of the third week.

Eiselberg of Vienna, reports a case which is of especial interest in connection with this paper, because like my own case, it was traumatic. A boy of seventeen received a stab wound which penetrated the pericardium. Pericarditis followed. Relief from the distressing symptoms was sought by tapping, but without permanent improvement. The cartilage of the fourth rib was accordingly resected, the pericardium exposed, and about two liters of sero-purulent fluid evacuated. The sac was irrigated, the borders of the sac stitched to the edges of the wound, and two drainage tubes inserted. The boy had completely recovered at the expiration of a month. Eiselberg insists on the necessity of stitching the pericardium to the lips of the wound to prevent infection of the pleura, a procedure which seems to have some theoretical warrant, but which in fact seems hardly necessary, as the danger of entering the pleural cavity through the fifth interspace at the point of election is very remote. If we draw a line from the left nipple to the end of the xiphoid process, bisect the line, and with this point of bisection as a center inscribe a circle with a radius of one inch, we shall inclose within this area a portion of the pericardium which in health is not covered by the pleural sac. This area is greatly increased in pericardial effusion.

The following are the details of my own case, the happy termination of which makes the indications for treatment in this class of cases none the more positive though encouraging, perhaps, to larger fidelity to fixed surgical principles, no matter what part is involved.

M. H., a healthy well-developed girl, aged 21 years, in a scuffle with some companions, ran a steel crochet needle into her chest about an inch to the left of the sternum and in the fifth interspace. The needle passed into the tissue, one and a fourth inches, and broke off. The accident occurred in the evening of Jan. 12, 1897, and the patient came to me within a few hours following. She was somewhat nervous, but apparently suffered no pain, while there was only moderate acceleration of the pulse. A small point showing the place of entrance of the needle was all that could be seen. Palpation did not reveal anything and an aseptic incision was made to a considerable distance into the tissue without disclosing anything. I therefore concluded that the broken end of the needle had not remained in the tissue, but had been lost in the excitement following the accident. Acting on this belief, the patient was sent home, with instructions to return again. The search of the following day convinced me that the needle was still there and the patient was advised to have an anesthetic and such operation as was necessary to relieve her. Her consent to such procedure could not be obtained however, until three days from the time of the accident had elapsed. There was at that time considerable rise of temperature and an increased pulse rate. A crucial incision was made, having the point of entrance of the needle, the point of intersection of the

lines of incision. The flaps were dissected back, and, after considerable search the end of the needle was found in the intercostal muscle flush with the costal cartilage. It required considerable effort to remove it, and it was found that the hook of the needle had carried a thread of cloth into the pericardium, into which it had entered and in which the needle had remained ninety-six hours. Septic pericarditis was feared, as there was already a temperature of 101 degrees and a pulse of 125. It was not thought justifiable at this time, to incise the pericardium. For the twenty-four hours following the removal of the needle, the patient's condition remained much the same, temperature and pulse not declining. On January 17, two days following the removal of the needle, the temperature began to rise and the pulse became more rapid, though there had been no chill. January 18, at 10 A.M. the temperature was 102 degrees; at 8 P.M. 103.5 degrees with a pulse of 140. The face became somewhat dusky, the lips bluish, and the tongue took on a heavy brown coating. There were constipation and much restlessness. She was unable to sleep on the nights of January 18 and 19. Up to January 21, much the same general condition obtained. There remained the same cast of countenance. The pulse remained regular but rapid. Both heart sounds were audible. There was no dyspnea, but great restlessness. There was unusual mental alertness. The eyes were bright. There was sighing at times. She had no appetite and was almost free from pain. There was an increase of the precordial dulness. A diagnosis of septic pericarditis was made and an incision with flushing and drainage advised and declined. On January 21, the temperature subsided and the pulse went down to 109. This period of apparent improvement lasted until January 25, when the temperature again began to rise and the area of precordial dulness to increase, indicating an increasing effusion. An operation was again urged, and, in view of the gravity of the case, accepted. Accordingly on January 26, with the able assistance of Dr. J. Vanderlaan and Dr. G. S. Williams, the wound for the extraction of the needle was enlarged, and an incision carried down through the intercostal muscle one and a half inches to the left of the sternum in the fifth interspace, keeping as nearly as could be to the point of entrance of the needle. A careful dissection soon carried us through the pericardium, which seemed to be attached to the anterior wall. About an ounce of thick pus and a considerable amount of puro-sanguinoform half clotted matter were evacuated. No effort was made to make extensive exploration, but the finger detected within the pericardium much soft fibrinous material which was easily broken down. The cavity was flushed with a saline solution and an iodoform wick inserted. No great shock was suffered. The temperature was normal on the evening of the day of the operation, with a pulse of 108, and never again went above 100 degrees. The patient made an uneventful recovery, being discharged cured just twenty-four days after the operation.

The extreme gravity of a case of purulent pericarditis warrants almost any measure that holds out hope of relief. When that measure is so well grounded a principle of surgery as that of the free evacuation of septic material whenever found, it is gratifying to find its application in practice followed by so encouraging results as a review of the preceding cases shows. Out of twelve cases here reported, some of which were

complicated with diseases in themselves necessarily fatal, there were eight recoveries. It is my belief that under proper precautions, pericardiotomy is attended by no greater danger than pleurotomy, and in cases uncomplicated by maladies tending toward a fatal termination, the results will be equally as good. It is the only procedure which justifies itself to the modern surgeon. The dangers attending incision and drainage are not to be compared with the danger of expectant inactivity, and I am certain that many of them are overestimated. Pericardiotomy offers the only chance for safety in these cases, and must take its place among the operations sanctioned by good usage and good sense.

159 Jefferson Street.

A NEW INCISION FOR THE SURGERY OF THE BILE TRACTS.

BY A. D. BEVAN, M.D.

PROFESSOR OF ANATOMY, RUSH MEDICAL COLLEGE; SURGEON TO PRESBYTERIAN AND ST. LUKE'S HOSPITALS. CHICAGO.

The subject of the surgery of bile tracts is of recent development. In 1867 Bobbs of Indiana performed cholecystotomy. In 1882 Langenbuch removed the gall bladder, cholecystectomy. In the same year Gaston suggested cholecystenterostomy, which was later perfected by the introduction of the anastomosis button by Murphy. In 1890 Courvoisier performed and advocated choledochotomy, and later the removal of stones from the cystic duct and hepatic duct were reported.

In the last five years the value and possibilities of the surgery of the bile tracts has been so thoroughly demonstrated, that it is today a recognized field to all men doing abdominal work.

A few years ago, when I began to do surgical work on the bile tracts, I carefully reviewed the topographic anatomy of this region. I was surprised to find how completely the subject had been neglected by both anatomists and surgeons. And here let me say a word in behalf of surgical anatomy. It is the boast of some surgeons of the present brilliant aseptic period that they ignore anatomic boundaries and anatomic reasoning in their operative work. It is so easy to cut and ligate and suture deep and superficial structures and obtain primary union, that a careful study of operative procedures is regarded often as unnecessary, and is as a rule neglected.

In surgical training, for the time being, anatomy is overshadowed by pathology, and as a result, the surgeons of today are better pathologists to be sure, but much poorer anatomists than the surgeons of the past generation. This is a fault which is often evident even in the work of eminent surgeons, and which must be corrected. A perfect mastery of the surgical anatomy is absolutely necessary for the performance of the best operative surgery in any field of surgical labor. This applies with special force to the surgery of the bile tracts, and yet many operations on this region are performed by men who have no clear idea of the anatomic relations of the parts or of the possible dangers, and who do not see the necessity of preparing themselves by cadaver study before undertaking such work. Such brilliant work as Kocher's teachings of making incisions in the lines of normal cleavage, as Bassini's hernia operation, as McBurney's and McArthur's splitting operation for appendicitis, as Hartley's removal of the Gasserian ganglion, as Mc-

Ewan's studies of mastoid disease and brain abscess, as Kraske's incision for removal of the rectum, are all results of anatomic studies applied to surgery; they are what might be called anatomic surgery and they demonstrate its value.

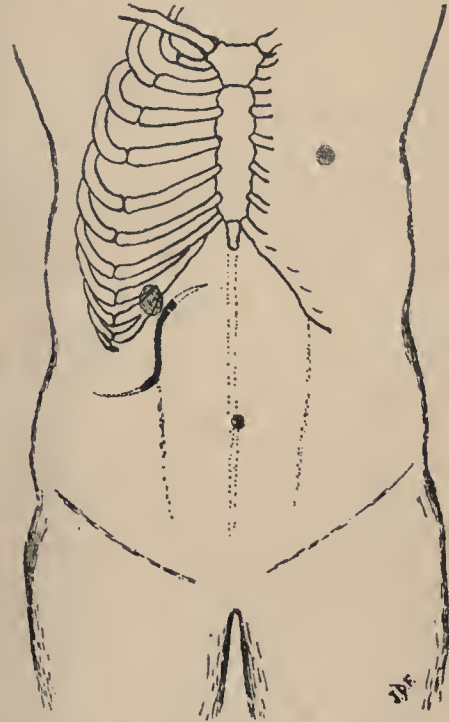

FIG. 1.—Heavy line the primary and light lines the extended portions of incision.

FIG. 2.—Abdomen opened and anterior layer of lesser omentum removed. Gall bladder, cystic, hepatic and common duct, portal vein, hepatic artery and branches in view. Arrow in foramen of Winslow.

With the objects of determining the best method of exposing the bile tracts for exploration and operative procedures, and for determining the position and relation of the bile tracts to other structures so that operations could be conducted with a minimum of danger to important structures, I undertook a series

of twenty dissections. In this brief report I desire to present not the entire results, but one of the results of my investigations, namely, the abdominal incision which is best adapted for bile tract surgery.

In my early clinical work I made use of the incisions which have heretofore been generally employed. First, the vertical incision along the outer border or through the substance of the rectus; second, the transverse or liver border incision of the Germans; third, the \neg shaped incision made up of an incision along the outer border of the rectus and one joining it at right angles; and fourth, the incision in the upper half of the linea alba for common duct work.

The objections to these incisions are many. They could be summed up in a few words. These incisions

The vertical incision along the outer border of the rectus answers very well for cholecystotomy, but does not give sufficient room for bile duct work unless made very long, and even then the edges of the incision are tense and much traction is required to expose the field of operation. The result of such extensive incision is to cut off the nerve supply of the right rectus muscle and thus weaken the abdominal wall. The \neg shaped incision can be made extensive enough to expose the bile ducts freely for operative work, but it is the most objectionable incision that can be employed. It is difficult to suture properly. It is difficult to obtain good union at the point where the incisions meet. I have seen necrosis of the sharp corners of the flaps at this point. It is prone to leave

FIG. 3.—View of structures seen in incision after removal of anterior layer of omentum. Natural size.

do not give room for extensive work unless they are made very long. When they are made very long, they carry with them the danger of hernia. Every one who has done much common duct work must realize the difficulty of obtaining free access to the operative field through the incisions usually employed, and in spite of statements to the contrary, hernias after extensive incisions for bile tract procedures are not uncommon. No surgeon can tell before opening an abdomen for an operation on the bile tracts how extensive an operation may be required, and it is therefore desirable to adopt an incision which will be suitable for exploration and simple procedures and which, at the same time, can be readily extended to meet the demands of the most extensive operation.

a weakened abdominal wall. In my own limited experience I have had three hernias following this form of incision; two after nephrectomies and one after cholechochotomy.

The transverse or liver border incision is not as objectionable as the two above mentioned, but it does not meet the requirements as completely as the incision which I shall describe. The incision in the upper part of the linea alba for work on the common duct is objectionable because it does not give free access to the gall bladder, and in many cases of common duct work the gall bladder also requires operative treatment. The problem which was before me in my dissections was to develop an incision which would answer for exploration and which, in case of need, could be

extended sufficiently to obtain free and easy access for the performance of any operation required, and at the same time this incision must impair the integrity of the abdominal wall as little as possible and carry with it a minimum of danger of subsequent hernia.

The incision which I have developed, I believe, meets these requirements, and as it can now be urged both from anatomic grounds and clinical results, I feel warranted in presenting it to the profession as a small but not unimportant contribution to the surgery of the bile tracts.

My incision should be divided into a primary portion and the extended parts of the incision. The primary part, which can be employed for exploration or simple cholecystotomy, is an italic letter *f*-shaped incision along or through the outer border of the rectus muscle, as shown by the heavy line in Fig. 1. This may be made from three to four inches in length. The extended parts of the incision are added to this when required. These extended portions are seen as the faint lines in Fig. 1. These extended portions can be made from an inch to three inches in length as the thickness of the abdominal wall and the character of the operation demand. When complete, the incision furnishes much freer access to the gall bladder and bile ducts than can be obtained by any other form of incision. The edges of the incision are readily held apart without tension, and the entire bile tract is freely exposed for examination and operative procedures.

Anatomically the incision injures a minimum amount of the nerve supply of the abdominal wall, because, even though the incision is made of great length, the extended parts of the incision run almost parallel with the nerve supply of the abdominal muscles. By a division of the rectus in part and of the internal and external oblique and transversalis muscles, the incision can be widely separated without tension. The fact that the incision is in close contact with the costal arch makes resulting hernia improbable, as a cicatrix in the upper part of the abdominal wall does not as readily yield and produce hernia as a cicatrix in the lower portion of the abdominal wall.

The following structures are divided in the incision: Skin, superficial fascia, external oblique muscle and aponeurosis, internal oblique muscle and aponeurosis, transversalis muscle and aponeurosis, rectus muscle, the transversalis fascia, which is here very thin, and the peritoneum. A few of the terminal branches of the intercostal nerves to the rectus are divided, and the anastomosis between the internal mammary and deep epigastric arteries in the substance of the rectus is divided and usually needs ligating. The incision should not be nearer than three-quarters of an inch to the costal arch.

When the complete incision is made the following structures can be seen as represented in Fig. 2: the liver and gall bladder above, the round ligament of the liver and the stomach to the left. The duodenum, the transverse colon and great omentum below. The transverse colon and omentum should be pushed downward, the stomach to the left, and the liver should be held up by the fingers of an assistant. We will then have exposed to full view the gastro-hepatic or lesser omentum, which contains the following structures between its two layers: the portal vein, the hepatic artery, the common, cystic and hepatic ducts, the gastro-duodenalis artery and sometimes vein, the nerve supply of the liver and the lymphatic vessels

and several lymphatic glands. The foramen of Winslow is at the right free edge of the lesser omentum. These structures and their relations are well seen after the anterior layer of the lesser omentum has been removed, in Fig. 3. The left index finger can be passed into the foramen of Winslow and the extra-hepatic ducts palpated throughout their extent except the portion of the common duct covered by the pancreas.

It must be understood that as a rule in operations on the living subject that the normal conditions are altered by adhesions and changes in shape and size of the gall bladder and bile ducts, but after the separation of the adhesions the relations will be found practically as here represented.

In closing the incision, silkworm gut sutures should be passed through the entire wall, the margins of the wound approximated, and then before the silkworm gut sutures are tied, the abdominal muscles and aponeuroses are sutured accurately with buried catgut.

I believe that the incision which I here present is based upon good anatomic and surgical grounds and that its adoption will be a step in advance in the surgery of the bile tracts. It makes better work possible by giving freer access to the field of operation; it will enable the surgeon to work more rapidly and in some of the prolonged operations on the bile ducts this is a vital point. It will reduce to a minimum the dangers of hernia after these operations. It can be employed in all cases, in exploration, limited or extensive operations.

The accompanying plates were drawn from my dissections by Dr. J. D. Freeman of the house staff of the Presbyterian Hospital.

BLUE PYOKTANIN IN THE TREATMENT OF INOPERABLE MALIGNANT GROWTHS.

Read before the Georgia Medical Association, April 21, 1897.

BY HENRY R. SLACK, PH.M., M.D.

PROFESSOR OF CHEMISTRY AND PHYSICS AND LECTURER ON PHYSIOLOGY
IN THE SOUTHERN FEMALE COLLEGE.
LA GRANGE, GA.

There is no disease to which flesh is heir that so appeals to the sympathy of the physician as an inoperable case of cancer. Not even consumption's ghastly form is so dreadful to the patient and to the physician hopeless of results. The sufferer from tuberculosis is almost invariably buoyed up by an ever present but delusive hope that "as soon as I get rid of this heavy cold I will be all right," but the cancer patient is bereft of hope. He sees the vultures, Prometheus like, feeding upon his vitals, but has little hope of Hercules coming to the rescue.

Now, what are we to do in such cases? To dismiss them because we can not promise cures would be inhuman and cowardly. These patients should be treated on the same principles as those unfortunate beings afflicted with chronic nephritis, consumption or any other disease recognized as incurable. When the surgeon admits that his knife can promise no hope, he should bring to bear upon the case every other means to make it *yield* to scientific treatment. Even though he may not effect a permanent cure, if he can alleviate the excruciating pains, foster hope, and prolonging life make it more tolerable, he performs a duty worthy of his high calling and receives alike the gratitude of the patient and his friends, to say nothing of that highest of rewards, the approval of conscience that comes from a knowledge of duty faithfully discharged.

Since the work of Professor Von Mosevig of Vienna, and Dr. Willy Meyer of New York, with pyoktanin, Dr. Coley, by the inoculation of erysipelas, and Adamkiewicz, by hypodermic application of neurin, we labor "not as those who have no hope."

In January, 1891, Professor Von Mosevig presented a very instructive paper entitled, "A Contribution to the Treatment of Inoperative Malignant Growths," to the Vienna Society of Physicians, reporting on his experience with blue pyoktanin in such cases. Shortly after (April 25, 1891) appeared an article from Dr. Willy Meyer, in the *Medical Record*, "Notes on the Effect of the Anilin Dyes, especially Blue Pyoktanin, in the Treatment of Inoperable Malignant Growths." Dr. Meyer also has another article on the same subject in the *Annals of Surgery* for November, 1893. Here I wish to acknowledge my obligations to Dr. Meyer for kindly furnishing me his valuable reprints and a list of the literature of this subject.

Billroth, true to his instinct as a great surgeon, had little faith in the use of pyoktanin and did not believe it had any specific influence whatever. He asserted that it was merely the water forcibly pressed into the tissues that made them swell and unable to live. He reported that three of his patients got worse under its use and one died of sepsis.

Fortunately, Von Mosevig and Dr. Willy Meyer had better success, and my experience agrees with theirs, as a report of the following cases will show:

Case 1.—October 21, 1896, J. E. C., age 43, white, male, farmer. Father died of cancer. Complains of sore throat and difficulty in swallowing for the last two months. Examination showed a neoplasm the size of a hickorynut on the dorsum of the tongue a little left of the median line. Has warty appearance and the papillæ all around are enlarged and indurated. Tumor can be felt from outside and submaxillary glands indurated.

October 24. Tumor growing. Pain extends further down throat and deglutition more difficult. Treated with Lugol's solution and gave gargle of same containing 2 m. carbolic acid to the ounce.

November 14. Tumor getting larger, covered with a mucous and becoming more painful, especially at night. Necessary to use morphin in order to sleep.

November 19. Complains that he could not sleep last night, as it seemed he would choke to death. Iodin doing no good, ordered blue pyoktanin pencil and powder. Dr. F. M. Ridley saw the case in consultation. Decided inoperable and approved of the trial of pyoktanin.

December 8. Patient has been to Atlanta and consulted six surgeons of that city, including two ex-presidents of this Association, one of whom he heard remark, "It is cancer. Prognosis bad; not one chance in a hundred from operation and he will not live until New Year." Necrosis has begun, odor very offensive. The tumor now is as large as a hen's egg and very painful. Can hardly use tongue enough to articulate his words. Treatment: Parenchymatous injection of 1.5 c.c. of a 2 per cent. solution of blue pyoktanin and gave patient pencil to apply daily.

December 12. Patient says he has not suffered so much as before using paint and can talk a little plainer. Treatment: Injection of 1.5 c.c.

December 19. Has suffered very little pain. Can talk without difficulty. Necrobiosis has set in and the tumor has diminished considerably. Injected 1.5 c.c.

December 22. Patient improving. Small nodules beginning to drop off and under them granulating surfaces appear. Reduced about one-fourth. Injected 1.5 c.c.

December 27. Feels much better. Does not have to use morphin at all. Injected 1.5 c.c.

Jan. 2, 1897. Improvement continues. Tumor not one-half as large as when I began parenchymatous injections. Injected 1.5 c.c.

January 9. Patient feels much relieved. Cachexia nearly all gone. Fetid odor no longer present. Appetite returning and anxious to try solid food, which was allowed. Injected.

January 12. Tumor has reduced to less than one-fourth of the original size. Patient eats solids and swallows without difficulty. Color good and strength rapidly returning. Injected.

January 16. Improvement continues. Injected.

January 23. Feels no inconvenience from neoplasm, which is not now over one-sixth of the original size. Says, "I am about well now." From then until February 28 he received only one injection weekly. I was called to New Orleans and was absent two weeks, during which time the patient took cold and I found on my return that the neoplasm had grown some. Gave two injections weekly and necrobiosis at once began.

April 17. Tumor diminishing in size, though somewhat painful. Pain was relieved by injection of the pyoktanin solution. June 15. Still under treatment and doing well.

Case 2.—Jan. 23, 1897. R. H., age 37, colored, female. Has had seven children, no miscarriages. Family history negative. Now has a four months' baby and since birth of this child lochia has continued. During last four months of last pregnancy had occasional hemorrhages. Patient fairly well nourished, though much weaker than after birth of other children. Prescribed injection of bichlorid of mercury, 1 to 4000, aromatic sulphuric acid and elixir calisaya, as an astrigent tonic, and told her to return in a week prepared for an examination.

February 3. Patient says, "Do not bleed so much, but still have bad smelling discharge." Examination showed a large ulcerated cauliflower neoplasm enveloping the entire cervix and extending well up the posterior portion of the body of the uterus. It was as large as a small orange and bled freely when touched. Dr. Cason saw case with me and agreed that it was an inoperable carcinoma.

Treatment: Washed out vagina and washed off the neoplasm with solution of bichlorid of mercury, 1 to 2000, and gave parenchymatous injection of 2 c.c. of a 2 per cent. solution of pyoktanin. I also gave the patient wash of bichlorid of mercury to be used daily, after which she uses 6 c.c. of 1 per cent. solution pyoktanin.

February 9. All hemorrhage has ceased and patient feels better. Injected 2 c.c.

February 12. Discharge not so offensive as before; pain has diminished. Injected 2 c.c.

February 16. Improving; necrobiosis established and nodules are supported by smaller peduncles. Injected.

February 19. Improvement continues. Injected.

February 23. Patient says when she injects the bichlorid of mercury wash, small pieces of flesh from the size of rice to a pea are washed out. While treating, a nodule size of a large pea dropped off. Surface presents healthier appearance.

I have continued parenchymatous injections of 2 c.c. of the pyoktanin twice a week ever since. During my absence Dr. Cason kindly continued treatment and has since seen it several times. The size of the tumor is steadily diminishing and the patient now (April 17) suffers absolutely no inconvenience.

Case 5.—April 6, 1897. Mrs. S. A. J., age 47, white. Had eight children, youngest 3 years. Family history negative. First trouble occurred when nursing last child. Three years ago noticed lump in right breast, size of a marble, that grew steadily; breast was removed in May, 1895, and all healed up but a little place the size of a pea, but this remained hard and in October began to ulcerate. Poorly nourished woman with recurrent cancer of right breast; open, ulcerating wound, 10 cm. long by 3.5 cm. wide, eroded edges; erosions being in some place 2 cm. deep. The whole wound is covered with necrotic tissue and the cavities filled with a fetid, cancerous secretion. The glands of the axillary region are indurated; painful and cancerous nodules depend from the wound near the axilla; the induration extends up to the clavicle and patient complains of pain in neck and on moving arm.

Treatment: Cleansed wound out thoroughly with hydrogen peroxid and then bichlorid of mercury; gave parenchymatous injection of 2 c.c. of the 2 per cent. solution pyoktanin and then dusted the wound over thoroughly with a 2 per cent. powder.

April 10. Has not suffered so much since using paint and sleeps better. Treated.

April 13. Rests easier now and has better use of arm. Treated.

April 17. Complains of some pain, but after the injection this disappeared. There is softening in the injected area and general appearance of wound and patient has improved. June 15. Still under treatment and improving steadily.

I have two other patients under treatment; one carcinoma of the uterus and the other of the breast; both are improving. There seems to be a reasonable probability of the ulcerating uterus healing, at least the improvement since I began treatment with pyoktanin (March 15) is marked.

A word as to the technique of the treatment, which

varies with the location. The injection should be made under strict aseptic and antiseptic precautions. The skin where the needle is to enter should be thoroughly cleansed with bichlorid solution. The needles may be long, short or curved, but must not be of too small caliber and should be boiled after using.

I used the large hypodermic syringe and injected from 1 to 2 c.c. of a 2 per cent. solution. This is more than twice as strong as recommended by Drs. Meyer and von Mosetig. The patient is given the pyoktanin pencil, 1 per cent. solution or a 2 per cent. powder, as the case may require, to apply daily.

Thus far I have seen no untoward effects from its use. I always employ Merck's because I can rely on its purity. The only objection to it is that it stains everything with which it comes in contact, but what is the soiling of linen when compared with the following advantages? 1, its analgesic effects are marked, as patients soon rest easily without the aid of morphin; 2, "the improvement of the function of the part involved." The man who could hardly speak so as to be understood talked without difficulty after the third injection; 3, the improvement in general health which has taken place in all five of my cases; 4, the element of hope that is added to the life of suffering man, brightening the remainder of his sojourn.

While I do not claim to have cured my patients, still I have relieved their pain and rendered them less burdensome to themselves and their friends. I agree with Dr. Meyer in von Mosetig's conclusions, "that it has been proved by practice, that parenchymatous injections of inoperable malignant growths with pyoktanin can produce disappearance of malignant tissue, though in exceptional cases, and can heal neoplastic ulcerations."

Pyoktanin, when properly used, is certainly a palliative treatment for cancer that deserves an honest, hopeful trial, for by its use many have been relieved and some cured.

LITHOLAPAXY.

SUCCESSFUL REMOVAL FROM THE BLADDER OF A GIRL OF SIXTEEN OF A CROCHET NEEDLE THREE INCHES LONG, IMBEDDED IN A MASS OF URIC ACID AND LIME PHOSPHATE.

Read by title at the meeting of the American Surgical Association, held at Washington, D. C., May 4, 1897.

BY W. S. FORBES, M.D.

PROFESSOR OF ANATOMY, JEFFERSON MEDICAL COLLEGE; CLINICAL SURGEON TO JEFFERSON MEDICAL COLLEGE HOSPITAL. PHILADELPHIA, PA.

I am indebted to my friend, Dr. C. C. Moyer of Hartleton, Pa., for this patient, a girl 16 years old, short in stature, light in weight and delicate-looking. She had been suffering from severe vesical trouble for fourteen months. Dr. Moyer said he had sounded her bladder and discovered a large vesical calculus. On the 30th of March last, I placed her in the Jefferson College Hospital. On examination there was no difficulty in confirming Dr. Moyer's statement.

Recalling that the relative frequency of stone in the bladder of men to women is as four to one, a fact due, no doubt, to the ease with which an ordinary nucleus can escape from the short and easily dilated urethra of the female, I expressed my surprise at finding so large a calculus in so young a girl. Dr. Moyer had asked her if at some time something could not have slipped into her bladder, but the answer was "no, never."

Remembering my patient with a willow twig seven inches long which I successfully removed from the bladder (see *JOURNAL AMERICAN MEDICAL ASSOCIATION*, Nov. 28, 1896), I stated my belief that, notwithstanding the denial of the girl, the nucleus of this large stone was most probably a foreign body that had "slipped" into the bladder through the urethra.

On Friday the 9th of April the patient, having been etherized, was brought into the operating room of the hospital, and before a large class of students and physicians the urethra was dilated; introducing my finger into the bladder, the stone was found to be a flattened oval, lodged transversely in the bas-fond. I then introduced a No. 23 Forbes lithotrite, and grasping the stone I attempted to lift it from its position in order to crush it, when it was found to have its poles firmly imbedded in the side walls of the bladder. Several times I seized the stone and endeavored to disengage it from its position, but could not do so without endangering the walls of the bladder.

Skilagraph showing the protrusion of a crochet needle from the calculus in situ.

It was now manifest that if I opened the bladder above the pubes I would still have to divide that stone before I could safely remove its poles from their mortised position in the bladder walls. I therefore decided to operate through the urethra and attempt to crush the mass near its middle and then withdraw each extremity from its mortised position in the bladder wall. This I found was no easy matter.

The blades of my lithotrite were finally adjusted from above on the stone near its middle. In screwing down the male blade the resistance was great and my sense of touch informed me that there was something more resisting than the stone. The impression conveyed was that the mass was becoming more and more condensed as I screwed down the blade. At last, after great resistance, the division was accomplished and the lithotrite withdrawn. On introducing my finger several small fragments of stone were felt loose in the bladder, but the two poles were still in their original position.

The bladder was now washed out and the loose fragments removed by means of a large canula and the evacuator. In placing my finger again in the bladder I found it had contracted and that the fissured surfaces of the mass were in juxtaposition; finding, however, that I could depress the right fragment below the plane of its neighbor, I introduced a female catheter beneath my finger which was still in the bladder, and depressing the fragment on the right side of the bladder, with my finger nail I dislodged the left fragment from its mortise and brought its pole around to and through the external meatus of the urethra. It proved to be the white pointed extremity of a foreign body. I then seized it with a strong pair of dressing forceps, but could not withdraw it on account of a large piece

The bladder was then well washed out with a warm borated solution and the patient was carried to her bed.

Much of the débris from the crushed calculus was lost during the operation. I should say at least one-half of it, that collected, weighed 315 grains. The crochet needle was broken into seven fragments.

The patient was under ether one hour and twenty-five minutes. She was walking about the ward of the hospital on the fifth day, and went home perfectly well on the seventh day after the operation.

I have now operated by this method twenty-seven times, in patients from 4 to 82 years of age. In three of these cases, aged from 60 to 70, death followed the operation from suppression of urine.

Diagram showing the relation of the X-ray tube and focus-point so arranged as to secure the shadow of the bladder contents upon the photographic plate in an area not having any bone shadow. A, platinum plate from which the rays are being given off; B, os pubis; C, umbilicus; D, bladder showing contained stone; E E, X-ray plate (photographic plate) upon which between the points, F F, the shadow of the stone is projected through the floor of the pelvis in a field free from any bony obstruction; G, tip of coccyx.

of calcareous matter, which projected from its side like the fluke of an anchor. This I broke off with the forceps, and then withdrew easily a part of foreign body, which was found to be the extremity of a crochet needle. One large piece still remained in the original position on the right side of the bladder; I dislodged it with my finger and broke it up with a pair of forceps.

In bringing out one large piece of the crochet needle on which there was a projecting piece of encrustation, the external meatus of the urethra was divided to a very slight extent with a bistoury.

The accompanying skiagraph was taken the day before the operation by Professor Coplin. It is interesting to note the manner in which the exposure to the X-rays was made. By placing the patient in a supine position and arranging the Crooke's tube in the manner shown in the diagrammatic sketch, the rays are given such obliquity that they pass through the pelvis without meeting any bony obstruction, escaping above the os pubis (B) and below the tip of the coccyx (G).

901 Pine Street.

SURGERY ONE HUNDRED YEARS AGO.

AN HISTORICAL STUDY

BY DR. GEORGE FISCHER.

DEDICATED TO THE GERMAN SURGICAL ASSOCIATION.

TRANSLATED FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
BY CARL H. VON KLEIN, A.M., M.D.

(Continued from page 1187.)

VIII.—PROFESSORS OF SURGERY AND PRACTICAL SURGEONS
(WUNDAERZTE).

Van Swieten's reforms; Joseph II and Maria Theresa; The Medico-Surgical Josephsakademie at Vienna; Masters and Doctors of Surgery; Institute for surgical operations; Austrian surgeons: Brambilla, Leber, Plenk, Steidele, Hunczovsky, Mohrenheim, Wrabetz and others; C. C. von Siebold; J. B. von Siebold, Brünninghausen, Hesselbach; Henckel, A. F. Pallas, Zenker; Loder, Köhler; Arnemann, Wardenburg, Michaelis; Rougemont, Isenflamm, Weidmann, Metzger, Sommer, Löber, Sprengel, E. Platner; The practitioners Thilenius, Brückner, Ehrlich, Eckoldt, A. F. Vogel, Schneider, Jäger, Fielitz, Böttcher, Bernstein and others; The oculists Barth, Schmidt, Beer, Lobstein, Hellman and others.

"Ten ducats to the Vienna Medical Faculty, that they may dine in pleasant memory of their deceased colleague," was the last direction of Dr. Franz Emerich of Troppau, the first professor of surgery appointed in Austria (1537). In 1555 the imperial government commissioned the medical faculty to institute surgical lectures, to which they replied in the German language as follows: "That such a course was conducted with great diligence in all universities in foreign countries and were stipendiary, and although in the German universities it was not actually customary, yet such a course is given in this university by a doctor of our faculty (Emerich), for which he is paid 52 florins. For the reason that surgery must unavoidably involve the health of people, it is necessary that our surgeons be instructed in anatomy, which properly belongs to the professor of surgery. Much attention is given to the dislocation of limbs, to cauteries, to tortures, and to all kinds of good and useful plasters, which operations and explanations belong to a surgeon. Therefore we regard such a course as fitting, useful and necessary." (Hyrtil, *Vergangenheit und Gegenwart des Museums für menschliche Anatomie a. d. Wiener Universität*, 1869, p. 14.)

We can safely pass over two hundred years, during which period science in Austria was enveloped in darkness. Even in the first half of the eighteenth century, when at small, north-German universities certain great teachers had awakened medicine to active life, Vienna still lay in deep slumber. With *Gerhard van Swieten* there came, not only in the medical faculty, but also in the spirit of all instruction, a time of thorough-going reforms. The university was obliged to submit to a complete revolutionizing of its constitution; it lost its hitherto so carefully guarded anatomy and was from that time on no longer ruled by an self-elective consistory, but only by the will of the empress. The state seized its property, assumed the conduct of its finances and thereby extinguished the last spark of its corporate life. Only the external form remained; the university had become a state institution. For that which had been taken from it the empress gave it a new building, with adequate rooms for the faculties of medicine and jurisprudence (1756). Men quite independent of the faculties were placed at their head and they specified the substance and import of the public lectures. They were under the chancellor of the empress, and with him as chair-

man composed the academic court commission, afterward so lamentably degenerated, which reported directly to the monarch. The strong and unbending will of the court physician, van Swieten, who, loaded with favors, possessed the unbounded confidence of Maria Theresa, was the soul of these reforms. In his high place, and as a foreigner, he did not concern himself with Austrian traditions, and he was easily prepared for all the obstacles which he encountered. Austria honors him as the bold creator of a new era in medicine, which raised the Vienna school to a height never before anticipated.

While medicine was greatly enriched by him, and by de Haën, Störk and Stoll, surgery "went begging." The Vienna surgeons were without any scientific training or thorough education, and could not be compared with physicians by whom they were deposed. By reason of their close connection with the bath-keepers, a change for the better was hardly possible with them. The barber shop still remained their highest ambition. Van Swieten's regulations were scarcely able to help surgery much. In 1779 he elevated *Joseph Jaus*, who had at first been appointed demonstrator in the anatomic amphitheater, to the professorship of anatomy and surgery. In the summer Jaus gave lectures on theoretical and practical surgery, instruments and bandaging, and entrusted the teaching of anatomy to a young docent, Gasser, whose name has been immortalized by the Gasserian ganglion. Men of real culture, who devoted themselves to surgery, were quite isolated. The war between Austria and Prussia made the lack of good surgeons sorely felt. French surgeons were appointed in both armies, until finally the necessity in Austria became so great that Emperor Joseph resolved upon the founding of a medico-surgical academy for the better training of surgeons.

Joseph II. was a prince who, in spite of his many-sided knowledge and his keen understanding, was yet a theorist. Sanguine in undertaking, tirelessly active and ardent, he was often inconstant in execution, and in his youthful enthusiasm he would carry everything by storm. The emperor experimented much in all humane projects and all effort in behalf of townsman and peasant, undertook the most difficult things without consideration, and gave them up just as readily. He possessed, in common with Frederick the Great, a simple, homely mien, and, like him, enjoyed the worshipful veneration of the people, in spite of which they both suffered discontent in their old age. In his last years, Joseph complained that with all his care and patience he could accomplish nothing because most of his officers did not comprehend his plans and intentions, and when he died, in 1790, his last words contained the melancholy burden that he had seen all his undertakings wrecked.

If the two German princes, Joseph and Frederick, be compared with each other as statesmen, the result is to the advantage of the latter; to physicians the figure of the Emperor is more attractive. He extended to our science and to our profession far more sympathy than did the Prussian king. If, in Joseph's liberality and humanity there was concealed a good share of despotism and absolutism, yet in that he was only consistent with his century. The subject of public health lay close to his heart, and also to that of his mother, *Maria Theresa*, with whom he became joint ruler in 1765. The empress had given the kingdom of Bohemia (1753) a medical ordinance in which

all country, district and city physicians, doctors, *medicinæ practici*, surgeons, apothecaries, bathers, oculists, rupture surgeons, lithotomists and obstetricians must conform. Then followed (1770) detailed sanitary regulations for all hereditary estates, according to which sanitary commissions were everywhere instituted, to which all persons practicing medicine were subordinated. Let us notice certain "court resolutions" of both monarchs. The empress forbade young people to apply themselves too early to hard work, that growth might not be checked nor bodily injury be sustained; and in severe winter weather children in the country, from 8 to 10 years old, were obliged to attend school. She forbade entirely severe corporal punishment of school children, as "using a rawhide, dangerous slavish rude blows, boxing their ears, striking or beating them with the fist, pulling their hair or ears;" only the rod was permitted, and a very moderate use of that, so they should not be disgraced. Joseph hated the corset and ordered that no girl with a bodice be received in school, because this garment was detrimental to growth; he banished it from all monasteries and schools for girls. Dancing was put under police supervision; Maria Theresa had already forbidden waltzing in Bohemia, as injurious to the health and dangerous to morality. The magistrate in Basel later shared this view. Various sanitary police regulations for public intercourse were devised. Maria Theresa restrained pregnant women from going on the streets, because of the crowding there, and for the same reason would not allow roving beggars, who were frightfully crippled or deformed, in the alleys. The emperor ordered that in summer, on account of the dust, the streets of Vienna be sprinkled, and had communities build morgues in which the dead were kept till burial, which, just as in case of dissection, was not allowed till forty-eight hours after death. He also abolished the custom of entombing bodies in the Vienna churches and had them taken at night to the churchyards in the suburbs. His suggestion to bury them in a cloth sewed into a sack, and nothing further, met with no approval. General Potrosch, out of respect for his emperor, had himself buried in that way. The friars were admonished not to destroy their health through the loud singing of choruses. He ordered the strictest secrecy in the lying-in hospitals and removed the stain of illegitimate birth in all classes. His mother abolished torture, he, the death penalty, though he was obliged to restore the latter because of the increase of crime. We have mentioned that in Joseph's reign, any Protestant or Jew could for the first time become a doctor and that he made German the official language for lectures. The name of the emperor is indelibly associated with his benevolent institutions: The General Hospital, the Military Hospital in Vienna, the Foundling Hospital, the Deaf and Dumb Institute, the Medico-Surgical Academy and also various valuable collections and libraries which he bought.

The emperor showed a great partiality for surgery, although he had frequently been subjected to the surgical knife. Near the beginning of his reign he was operated on for a tumor on the head, while he often had hemorrhoids cut away, and six months before his death had an operation for a rectal abscess and fistula. Besides the ills mentioned, he suffered for a long time from his eyes. He from the first visited the hospitals frequently, rectified the mistakes which he discovered, and in spite of all dissuasion,

could not be deterred from endangering his life in the infected places. When the General Hospital was established, scarcely a week went by in which the emperor did not go through the wards and inquire closely into everything. He sometimes even discussed medical matters with the physicians in Latin. In Paris, whither he journeyed to visit his sister, Marie Antoinette, he inspected the hospitals as well as the academies and collections. On the journey there he went out of his way to see A. von Haller in Berne, in doing which he took no notice of Voltaire. He found the great scholar very weak, and when soon after his return to Vienna he sent him a quantity of wine and Peruvian bark, von Haller had died a few days before.

Joseph II. was the first German prince who took any interest in surgery, and rightly comprehended that its advance could only come to pass by uniting it with medicine. The honor of freeing from the bonds of slavery the science so long despised in Austria is unquestionably his. Like medicine, it should be a free art, and no longer a trade. On that account the emperor released the surgeons from the restraints of the guilds and the barber shops, so that one who had learned surgery thoroughly could practice it without belonging to a guild. To combine the study of the two sciences, he himself (1786) outlined a common course for physicians and surgeons. In the first semester he placed anatomy and chemistry, in the second general and special surgery and botany, and throughout the entire year special natural history; in the second year, physiology, higher anatomy, operations, instruments, bandaging and obstetrics; in the third year, pathology and materia medica; in the fourth year, medical and surgical instruction by the sick beds, with practical work in the lying-in hospital and in the General Hospital. Besides, a course was given for country surgeons who, on account of less complete education, could not take part in the above course of study. From that time on, whoever wished to become a doctor of medicine must attend the surgical lectures.

To the emperor, no amount of money was too great to be used in training skilful physicians and surgeons for his empire. A year after the founding of the General Hospital, the *medical and surgical Joseph's academy in Vienna* was established. It was the first institution in Austria in which surgery was thoroughly taught. It grew out of the medical and surgical school which Joseph had founded soon after his mother's death, upon the suggestion of Brambilla, in the military hospital at Gumpendorf (1781). In this institution were gathered thirty over-surgeons for two years' study, and they were divided, according to their attainments, into two classes. From the first the regimental surgeons were chosen; from the second, the district and county surgeons for the provinces. At the close of their studies thirty others were called, and as a general rule, no army surgeons were appointed who had not finished this course.

When the institution proved itself worthy, it was enlarged into the *Academia caes. reg. Josephina Medico-chirurgica Vindob.*, as Joseph said in its charter, "in order to express our especial regard for that part of the nation who expose their lives to every danger for the defense of the common fatherland, for the rights of our throne and the safety of their fellow citizens, and to contribute to lighten their honorable but burdensome duties." On Nov. 11, 1785, the inauguration took place. Field marshals, generals, ministers and professors, the medical faculties, offi-

cers, regimental surgeons, two hundred uniformed students—in short, about six hundred persons, gathered to hear the Latin address of the court surgeon, Alexander von Brambilla. After the ceremonies he presented, in the name of the emperor, to the five newly installed professors, Hunczovsky, Böcking, Streitt, Gabriely and Plenk, and to the staff surgeons, Göpfert and Beinl, a gold medal of the weight of forty ducats. The building of the academy, an open square with two stories, was one of the most beautiful in Vienna, and was adorned with many exquisite statues. Everywhere there was the greatest luxury. Six hundred cases of instruments and 250 of medicines were ready whenever war might break out. Besides mathematical and physical instruments, they had a large collection of anatomic and pathologic specimens, among them sixty-four of the rarest surgical diseases, which Hunczovsky had prepared from nature, in wax. In addition, there was the previously mentioned celebrated collection of wax specimens from Florence, which were kept in 300 gilded caskets of rosewood and Venetian plate glass. In cases of red leather, with gilt shields and clasps, were their instruments and bandages. The library, which was opened daily, contained 10,000 volumes; the hall of the amphitheater accommodated 600 persons. Two hundred students were received in the academy, and lived there with the professors. Each of the professors had six rooms, in two stories, with furniture, and stabling for two horses, and received a salary of 1,250 florins. Close behind the building, the emperor had erected a large military hospital for 1,200 patients, in order to combine theoretic and practical instruction. Alexander von Brambilla was director, and as such stood immediately under the monarch and gave the academy its statutes. Hunczovsky was vice-director and Plenk permanent secretary. The members were at first Gabriely, Streitt, Böcking, Göpfert, Anton von Brambilla, Jennat, Prochaska, Scarpa, Stahly; the foreign members were Anton Louis, von Kelchen, Malacarne and Cruiskschank. The academy divided its members into three classes: Active, thirty; associate, twenty; corresponding, twenty. They taught anatomy and physiology, surgical pathology, operations, instruments, bandaging, legal surgery, obstetrics, practical medicine and materia medica, besides chemistry, botany, geometry and physics. Each course lasted a half-year; at its close, medals worth five and ten florins were distributed. Prizes of gold medals were offered for treatment of specified questions. Among those for the first year were the following: Which, cut or torn wounds, should be healed by joining together, which by suppuration? What is the best and safest method of healing gunshot wounds? What causes can make a slight wound from a sharp or a dull instrument dangerous or fatal? Besides these inducements for the young men, the most important means to place surgery in the same rank as medicine, was the right given to the academy of conferring the degree of *Master and Doctor of Surgery*. With privileges in every way equal to the physicians, the surgeons could practice their profession anywhere in the empire. This right the Academy had in advance of the medical faculties, for according to an earlier ordinance, they could graduate only six doctors of medicine a year. Whoever wished to become a Master must attend the Academy two years, practice four years in the hospitals, and finally pass a theoretic and practical examination. The same training was required of

the doctor of surgery, only he must practice in the hospitals six years. He must pass three examinations, the first in the sciences previously mentioned; then he must perform in public upon a cadaver an operation drawn by lot from a number specified by the professor, and must himself select the instruments for it. To this was added an examination concerning the indications and after-treatment of operations, and an anatomic demonstration. In the doctor's oath, he swore, among other things, to have weak newborn children immediately baptized, or baptize them himself, to produce no abortions, to employ no heroic remedies, such as arsenic preparations, to accept no money or gifts from apothecaries and to sell no antidotes or medicines. The fees for the degree of Doctor of Surgery amounted to 24 florins, for that of Master of Surgery to 12 florins, but they were abated for one without means, but having extraordinary talents. To the Latin diplomas, printed upon parchment, a seal was attached by a yellow and black cord; those for the Masters in wooden cases, for the Doctors in metal. The name *Feldscher* was abolished, under penalty. At the inauguration of the academy, the emperor conferred the degree of Doctor of Surgery upon Brambilla, Hunczovsky, Plenk and Göpfert, and gave the title without charge to all professors of surgery who were not already doctors. From that time on, only those military physicians who were Doctors or Masters were advanced. Older men suffered thereby, and one battalion surgeon shot himself (1788) and ascribed his suicide to Brambilla: "Only because the world scorned me do I do this deed. . . . Since Brambilla, by whom all these persecutions come, treats all men grown gray in the service of the master so finely. I advise all honorable men to be anything but a surgeon in the imperial army." Soon the new academic degree found a willing reception in other lands; but there were abuses connected with it.

Brambilla's inaugural address caused much bad feeling among the physicians. He extolled the superiority of surgery over medicine, decried the merits of the latter in an unjust way, and did not indicate that he wished to unite the two sciences. The doctors felt their dignity deeply wounded, thought they had not deserved such humiliations, and saw in advance how the doctor's title would turn the heads of the Vienna surgeons. It was not long till Brambilla was decried as the oppressor of medicine in Austria. Much greater was the joy in the camp of German surgeons, who greeted Brambilla as the restorer of the surgical profession in the Austrian states. A. G. Richter was quite enraptured over the establishment of a surgical academy in the fatherland. "All Germany," he said, "takes a certain part in the honor of this academy, in the successful advancement of its labors, in the choice of its members, since it is from them that the surgery of Germany will expect guidance, direction and enlightenment; according to the successful or unsuccessful outcome of their labors, will foreigners judge of the value of all German surgery; among them one will always seek the most renowned surgeons of Germany; to their proceedings we will look for the most important productions in German surgery." Richter deceived himself completely. *The Medico-Surgical Joseph's Academy contributed to raise the standard of surgical instruction and the position of surgeons, but it did nothing for the advancement of surgical science in Germany.* How was that possible when

the emperor had built the most magnificent institution, and had done more to elevate surgery than any prince before him, indeed, as an exuberant hymn says, more in six years than the kings of France had done in four hundred years? For the most part it lay in the fact that Joseph II, in the choice of Brambilla, a wholly incapable Italian, had made a far-reaching mistake. From now on progress was slow; the academy published its first volume of memoirs in the year 1787, and the second in 1801. With that it ceased! and what it offered was insignificant! Let one read the preface to the first volume and compare it with that of the memoirs of the Académie de Chirurgie in Paris, which was founded forty years earlier, in order to know the spirit which pervaded the Vienna institution. Brambilla first inquired into the age of surgery as compared to that of medicine, over which useless questions others were then worrying themselves; he began with Adam, the umbilical cord of whose children must have been cut, quoted further from the books of Moses, and discovered in Tubal Cain the first maker of surgical instruments. Even Christ was adduced, because he never employed internal remedies for the sick, but always surgical methods. Examples from Homer and Virgil were produced. Brambilla then showed the superiority of surgery over medicine, and finally burned incense to the Emperor Joseph.

Brambilla's weak policy soon showed itself. When shortly afterward the war with the Turks broke out, he ordered (he was at the same time surgeon-general of the army) that no physician who was not also a surgeon would be allowed to accompany the army; all matters were to be looked after by his medico-surgeons. There was loud and general complaint against this order. Even the aged Haudegen Laudon begged the emperor to appoint physicians to serve in the field-hospitals in the future as had formerly been done. But no change was made. The dissatisfaction grew, until finally Emperor Leopold (1795) deprived Brambilla of his office as surgeon-general, abolished the office, and committed the management of Joseph's Academy to a permanent military health commissioner. A chief military physician (Professor Mederer, of Freiburg) was appointed director of the personnel of the army physicians, with a salary of 3,000 florins.

In the beginning of this century a *Royal Imperial Institute for Surgical Operators*, was established (1807) for the advancement of surgery in Vienna. From those who had taken the two years public course of instruction, and distinguished themselves, six students without means, were chosen, to be trained as operators in this institution, under the private instruction of Professor Kern. The course lasted two years; in the second half the students were obliged to perform every operation publicly upon the patients. They received 300 florins a year and were preferred for public appointments.

Austria can lay no claim to honor for her surgeons of the last century. Almost everywhere obsolete opinions and orthodox views prevailed, and there was nothing to give a new impetus to science. Surgery slept until Rokitansky and Skoda came. Let us give the court physicians precedence.

Alexander von Brambilla (1728-1800), born in Pavia, lord of the barony of Carpiano in Austrian Lombardy, Associate of the Paris Académie de Chirurgie, filled the highest positions in the state, but

was nevertheless destitute of all scientific culture, even priding himself upon that fact. Himself a crude empiric, he would have nothing to do with theoretical knowledge because it was of no avail at the bedside. He comforted himself and others with the fact that great scholars had often declared patients incurable, who were afterward restored to health by physicians who were considered ignorant but who were practically skilful. His writings, disgustingly detailed, unintelligible, without order, containing nothing useful, and above all, full of boasting, are no longer read. These qualities characterize particularly his two-volume work on phlegmons, which had been translated from the Italian into a jargon of German. In the first volume of the proceedings of the academy, he presented some worthless articles on white swellings and lead colic; in another confused essay he contended against the abuse of oxycrates and dry lint. In operations for fistula of the anus he prescribed special instruments, which, however, found no acceptance. Besides, he composed various rules for the Austrian field surgeons.

(To be continued.)

SOCIETY PROCEEDINGS.

Medical Society of the State of Pennsylvania.

Minutes of the Forty-seventh Annual Session.

The meeting was called to order at 9:30 A.M. Tuesday, May 18, at the Alvin Theater, Pittsburg, by Dr. E. E. MONTGOMERY of Philadelphia, the President.

The address of welcome was delivered by T. DAVIS, Chairman of the Committee of Arrangements. The Secretary reported a steady improvement throughout the State among the County Medical Societies, so that the number of physicians in affiliation with the State body was much increased over the previous year. No new societies had been added nor had any fallen into decadence. There were now over 3,000 members of county societies.

In regard to the matter of synthetic preparations, the payment in the United States of such large excess for these articles over what is paid in Canada, in some twice and three times the amount required in Canada, the committee submitted the following:

Resolved, That we recognize in the contract existing between Messrs. Dickinson, Brown & Co., and the German government that the sale of many of the alkaloids is in our consideration a monopoly and neither in accordance with our Code of Ethics, nor humane; because the effect it has in making the price of such drugs so high as to be beyond the reach of the suffering, therefore be it

Resolved, That we refer the matter to the consideration of the AMERICAN MEDICAL ASSOCIATION with the request that that body use its influence to secure the repeal of all legislation recognizing such laws as will give any parties exclusive control over such drugs.

The resolution was unanimously adopted.

The Committee on Rush Monument reported little progress, and slight additions to that fund.

The Committee on Pharmacy reported: The main interest of the year centered in antitoxins; proof exists that these are of great value; Dr. Koch's new tuberculin was mentioned as of very great value; creosote is being further employed externally in fevers; it shortens the paroxysm and lessens the severity, does not depress the heart; there is urgent need of a form of this drug which will be better borne by the stomach; esote has been proposed by a Berlin manufacturer, a creosote valerianate, without toxic or caustic powers, odorless and tasteless, well borne even in large doses, and inexpensive. Bromoform for whooping-cough seems of positive value. Its use is better understood, and prejudice is disappearing; it is best administered in water, with care that the whole dose is swallowed, as its specific gravity causes it to sink to the bottom of the vehicle; generally, prompt in action, and flavor agreeable. Eucaïn, a rival of cocain, a local anesthetic, less toxic, and with no effect on the pupil. A 5 per cent. solution renders the eye sufficiently insensitive to operation. Also used in dentistry and laryngology with satisfaction. It is said to be fully equal

to cocain but causes local hyperemia, but the latter causes anemia; doubtlessly it will supplant the other. Bromid of strontium has grown in favor. Severe epilepsies have shown better results with this remedy, it is acceptable to the stomach and does not interfere with appetite. Formaldehyde, a new antiseptic, is worthy of notice; non-irritating, non-toxic, general antiseptic for wounds, abscesses, and for clothing disinfection of rooms, etc., better than sulphur; applied in vapor or solution; in surgery $\frac{1}{4}$ to $\frac{1}{2}$ per cent. solution; for general antiseptis, $\frac{1}{2}$ to 2 per cent. or in vapor; for sterilizing and hardening catgut so that it may be boiled without injury, 4 per cent. Generators in form of lamps are sold; a solution called formalin, containing 40 per cent. formaldehyde is made. It is used for a number of skin diseases, soft chancres, and in 1 to 5 per cent. solution in acute, chronic gonorrhoeal and tubercular cystitis. Thyroid extract is said to be indicated in operative and spontaneous myxedema, obesity, non-cystic goiters, some mental diseases; it is exceptionally advantageous in special cases of exophthalmic goiter, but caution is necessary; also successful in some chronic affections of the skin, particularly psoriasis; in any event recurrences are frequent.

Thyroid-iodin from the thyroid of the sheep contains 9.3 per cent. iodine and 0.5 of phosphorus, its action is said to be similar to the regular thyroid extract. Tannoform is a condensation product of tannic acid and formic aldehyde. Its advantages are tastelessness, non-irritating when applied to the intestine without undergoing any change. It is a useful intestinal antiseptic and astringent in infantile diarrhea. Externally the antiseptic and drying effects are marked without irritation of the skin. Useful in numerous affections of the skin, as hyperidrosis of the palms and soles, indolent and infectious ulcers, ulcerated lupus, impetigo, sczema, etc. The proper attitude of the profession to the manufacturing pharmacist is still a subject of dispute. While the physician should be the foe of everything that smacks of ignorance, mystery or charlatanism, and the champion of candid, honest and humane therapeutics, there are many worthy men who believe that to the persevering efforts of the conscientious manufacturing pharmacist are due the great improvement made during the last score of years in the reliability and palatability of our remedies. The difficulty is to separate the wheat from the chaff which is offered the profession; and while we would denounce imposters whether manufacturing at wholesale or selling at retail, we would urge a careful discrimination in our denunciation, and while advising a more general use by the profession of the United States Pharmacopoeia and the National Formulary as their guides in the selection of remedies where it is to the equal advantage of their patients, yet we believe it is proper and in accord with the ethics to use any remedy which may cure provided there is satisfactory evidence of candor, reliability and honesty in the manufacturer, and that there are such manufacturers it would be neither fair nor just to deny.

A resolution was adopted by unanimous vote asking the legislature to maintain the present law requiring vaccination as a prerequisite to admission to the public schools.

At the afternoon session the

ADDRESS IN SURGERY

was delivered by Dr. J. CHALMERS DACOSTA of Philadelphia. He reviewed recent changes. He selected certain changes as all would be a herculean task. Every change is not improvement. Mankind is apt to fall a prey to "pestilential novelty." Great discoveries suddenly made are rare in medicine. Such as the discovery of the circulation by Harvey; anesthesia by Morton; vaccination by Jenner; the germ theory by Pasteur. We must add the Roentgen ray made public in December 1895 in a paper notable for profound learning, scientific accuracy and logical force but also for its genius and beautiful modesty. At a time when not a few cry their wares in the thoroughfare, and many fail to distinguish between the golden trump of fame and the tin whistle of notoriety, it is pleasant to listen to this calm deep thinking German scientist, one of the nobility of the craft, one of those who follow science for its own sake and for mankind. Roentgen's discovery was made by a sort of accident, but the genius was present to take note of the accident, and interpret its events. Not in grand University, of costly equipment, but in a laboratory poorly equipped, containing a Rhumkorff coil, a Crooke's tube and Roentgen himself. It is startling and unique. A pathway blazed through a jungle where no one thought of entering. It annihilates notions of centuries of time. Much is yet to be learned of it. The pathway is open, but there are yet dragons to conquer, giants to slay. No man knows what these rays are, but we are getting a clear comprehension as to what they can do. In doubtful cases we need a skiagraph, and one advantage is that special technical

knowledge is not requisite to use it successfully. Skiagraphs to be useful must be taken by an expert, trained in a knowledge of electricity to get the best results from an X-ray apparatus. Foreign bodies can be located with certainty in the tissues. A bullet can be detected in the lung substance or in one of the bronchi; yes, even in the brain. In cases of doubt pictures must be taken in different attitudes. Though a needle may be located, yet it is not always easy of extraction; a piece was visible, incision failed to find it, other skiagraphs were taken; experiments with a skeleton led to the belief that the needle lay in the sheath of the peroneus longus muscle. The sheath was incised without finding the needle. A guide needle was inserted; another operation failed. Foreign bodies in the abdomen may be recognized, but it is hard to determine the exact position. In dealing with bullets the X-rays often enable us to decide if it is lodged in a safe region, whence it is not necessary to remove it—if it is deep and difficult of access, etc. Von Bergman insists against meddling surgery, where bullets, etc., are doing no harm. Foreign bodies have been located in the esophagus, in the trachea and the larynx, in the eye, and Sweet has devised a most ingenious addition to the ordinary apparatus which enables us to locate the exact depth and position of the foreign body. Vesical calculi have been caused by a hairpin in the bladder; Forbes obtained a skiagraph of a stone with a long metallic nucleus, this proved to be a knitting needle. Gallstones transmit the X-rays and cast very faint shadows; they can not be found in the gall bladder. Stones in the kidneys and ureters have been skiagraphed. But a failure does not prove that a stone is not there. Henry Morris sets forth the following difficulties: depth of kidney, thickness of tissues over it, situation under the ribs and close to the vertebral column. In examining bones and joints the new process is of great value. Tuberculosis is plainly visible. The tuberculous area is much lighter than the adjacent sound bone; several have reported the detection of spinal caries. Again we may know the state of the bone in crushed limbs; thickening of the periosteum, of bone, tumors, deformities, etc. In fractures, the rays are a great aid in finding the fracture, its direction, kind of deformity, splintering and impaction, muscle between the fragments. If manipulation has reduced the fracture and our splints are keeping it in place, it is now unnecessary to make an exploratory incision to determine the condition as before.

The speaker had been impressed with the practical value by some of his own cases—a fracture of the ulna united, the radius not—a supposed case of gouty arthritis which proved to be a fracture of the head of a metacarpal bone—a fracture of the styloid of the ulna supposed to be a sprain; a dislocation of the humerus with an epiphyseal separation. There is no question that unscrupulous lawyers will try to put us to trouble by skiagraphs of fractures united at a slight angle or with trifling shortening. Pictures should be kept of all such, as they may prove useful later. Again we recognize obscure dislocations; the outlines of the heart may be defined, etc. A sinus may be pictured. Many absurd statements have been made in non-medical journals, and wild theories put forth as to influence of the rays on vegetable life, etc. Nevertheless, this is one of the most marvelous discoveries of all time.

Ambulatory treatment of fractures.—This is springing into popularity. Properly employed it is useful. It can be used even when the fracture is as high up as the middle of the femur; it is best for fractures of the leg. Apply a solid dressing or apparatus to reach below the sole of the foot and have a space between it and the sole. In thigh fracture the body weight should be transmitted from the lower end of the pelvis to the apparatus, and in leg fracture from the middle of thigh to the apparatus. In one week a thick soled shoe is plated upon the sound foot, and the patient permitted to walk about. Some say three days. It is claimed that walking is a stimulant to callus formation and fibrous union, that movement of the fragments which within certain limits is desirable and do not prevent union as with fracture of the ribs. Further, patients escape danger of lung trouble as in long confinement to bed. The muscles escape the usual atrophy; it is especially useful to children. Caution is needed. Do not use the method if there is great swelling, as this may be due to thrombus and give rise to emboli; even massage is dangerous in thrombus.

Toxins and antitoxins.—It is well to recall that human blood contains in health and in disease certain substances which may protect from bacteria and secure immunity of the organism. The alexins described by Buchner kill bacteria. The antitoxins antagonize bacterial poisons but do not kill bacteria. Healthy blood may contain antitoxins; the blood of a person who has acquired immunity to an infectious disease contains them. Blood serum has a lysogenic power upon bacteria which causes the organism to swell up, become granular and dis-

solve. Modern nature is endeavoring to use drugs of nature's own compounding. The value of serum therapy, etc., has been much debated this year. Some are enthusiastic, others are jeering doubters, the bulk of the profession are somewhat skeptical but aid and encourage the experimenters—look for proof but do not find it now. In streptococcus infection (erysipelas and puerperal fever) Marmorek feels sure that the serum is efficient. He treated 411 cases with a mortality of 3.4 per cent. Maragliano thinks this encouraging, but Germany doubts. We do not yet know with certainty the pith of the matter.

In tuberculosis, Richet and Hericourt have obtained no results from the injection of serum of animals refractory to consumption. Koch has modified his tuberculin and believes it is now a trustworthy agent. The new tuberculin is made thus: Dried cultures of bacilli are mixed with distilled water, the fluid is placed in a centrifugal and agitated. Two layers are separated. The upper is the old tuberculin (tuberculin O). The lower layer is the new tuberculin (tuberculin R).

This is given hypodermatically, first in very small doses, finally in doses as large as 20 mgs. Cases far advanced or with much fever are not treated. Koch does not claim cure but does claim great improvement.

In syphilis the serum of rams and dogs is alleged to have produced benefit. It is claimed that we can treat primary syphilis with the blood serum of an individual with tertiary syphilis and obtain early healing of chancres. In cancer serum has been useless. In tetanus we lack proofs of value. Again the diagnosis is not always sure. Inoperable malignant tumors have been treated. Some are enthusiasts; some, as Senn and Keen, disbelieve entirely.

Operations for insanity and idiocy: Drugs have been used in infinity. Superstitious rites, etc., every herb and plant has been pronounced the proper thing for these forms of disease. Trephining long was popular, one bored twenty-seven holes in the skull of a patient, today he would perform linear craniotomy. The comparative safety of operations has impaired the judgment of surgeons. Now most agree that if there is obvious injury of the head with cerebral symptoms and doubt as to the existence of fracture, the surgeon turns down a flap of the skull to see. But we no longer trephine in simple fracture without depression or cerebral symptoms. In children a moderate depression may bulge to the natural level by nature's processes. But when marked he trephines; this is known as preventive trephining. In discussing the question of traumatic origin of insanity we wish it to be distinctly understood that our belief is that traumatism can be a cause, but extremely rare. Traumatism, is often given as a cause by the relatives, usually it is only one of many causes, as heredity, inebriety, mental worry. It is probable that in the healthy brain an injury can produce insanity. This in several ways—concussion, fear; the lesions described as causative are sclerosis, pressure, inflammation, hyperemia, edema, congestion, etc. Symptoms may be early or late. But when late there are usually prodromics of change of character, irritability, moodiness, alteration of sentiments. Types vary; prognosis as a rule is bad. Some have apparently been cured by operation. Many have followed it. We should operate where there has been no obvious traumatism indicated by scar, depression, etc. We should not operate in paresis; improvement has been known to occur without. Again much want of care is seen in describing a case of insanity. My own conclusion is that while a certain proportion of insanities have been due to traumatism, in few is there a causative lesion. Many cases are not cures. Craniotomy for idiocy is now going out with the tide. Microcephalic idiocy is rare. Pressure is not the cause of idiocy. Much can be done by skilful training. It may safely be said this operation is a failure. "You may as well forbid the sea to roll, etc."

Among a multitude of ideas, facts, disputes and tendencies we may mention as worthy of thought and attention—the determination that operations for cure of epilepsy are rarely permanent in result, the great value of operations for meningeal hemorrhage, cerebral abscess and infectious sinus thrombosis, the slight value of most other operations upon the brain—the diagnostic usefulness of lumbar puncture by Quincke's method and its therapeutic usefulness. The great appendicitis controversy which is still under headway and undisturbed in viciousness and irascibility: When shall we operate? Shall we always remove the appendix in abscess cases? These are the questions which are in course of solution. The decadence of the supreme position of the chemic germicide and increased confidence in asepsis rather than antiseptics. The use of Bier's method of congestive hyperemia in tuberculosis lesions. Infiltration anesthesia as devised by Schleich; local anesthesia by eucain and the sloughing apt to follow it; Rosenberg's method

by cocainizing the nares before chloroform, the dangerous nasal reflex being abolished by the time the chloroform is inhaled; the mass of contradictory evidence as to ether and chloroform on the kidneys; the use of oxygen with ether and chloroform, etc. In general, of late, destructive radicalism has lessened its sway and scientific conservatism enlarged its domain. Conservatism, save without operation, does not mutilate. The spirit which animates the real leaders of modern surgery is the same spirit which was in the temple with Hippocrates and in the school with Herophilus; by the lonely lamp of Celsus and in the solitary study of Vesalius; which was with Harvey in the laboratory and Paré on the battlefield; which was in the lion heart of Abernethy and which filled the lordly soul of Hunter; which stimulated the labors of Gross and guided the scalpel of Agnew; a spirit which ennobles, elevates and dignifies the magnificent science of modern surgery.

The address in mental disorders was by Dr. THEO. DILLER, Pittsburg.

THE SCIENTIFIC EVOLUTION OF STATE HOSPITAL FOR THE INSANE.

Mental diseases must be studied from several standpoints, as that of the humanitarian, the anthropologist, the social scientist, the political economist, the alienist. Each overlaps the other. But small fragments can be treated in the limits of such an address, hence he chose to consider the hospital and asylum. These are greatly overcrowded. In them are over 1,200 more than can be accommodated. Hence they can not receive proper treatment. A scheme for the care of the chronic insane has been in successful operation in Wisconsin for sixteen years. Twenty-six hundred cases are cared for in twenty-three county asylums connected with farms. Each has a capacity of 100 to 123. The State pays them \$1.50 for the care of each case, and exercises strict supervision over them. Cases are admitted not directly, but sent from the State hospital when it is evident they will not be benefited by hospital treatment. They are placed nearest their homes, accessible to visits by relatives. Ample opportunity is secured for work out and in-door. Three thousand of the 5,600 cases in the State are incurable. If Pennsylvania were to adopt this plan the State would save \$300,000 yearly, leaving the hospitals filled only to two thirds their normal capacity. The State board of lunacy should be abolished. A commission of three members, well salaried, should devote their entire time to the work. All the haphazard work should cease. These insane hospitals need a central guiding power. Civil service should be established for all. Superintendents should meet the commissioners monthly for advice. A pathologic laboratory should be provided for all. Pennsylvania needs separate institutions for criminal insane. Inebriates need a separate place. Today the outlook is encouraging. He quoted largely the results of the Massachusetts hospitals. Internes are appointed after competitive examination, serve without pay other than lodging and board. Thus we may double the medical force with little expense. A neuropathologist of the highest grade is selected. Nurses should be trained for the care of the insane. In such places the clinical work is of the highest order. Pathology is done in a number of hospitals, and the number is growing. The friends of scientific evolution of insane hospitals can hope for much when we see what has already been done. Pennsylvania should take a step forward, imitate the example of New York.

Dr. C. W. DULLES gave "Some comforting Facts about Consumption." The disease is not contagious. By care much has been done to prevent the spread of this disease. We see a great decline in its prevalence.

Dr. S. M. SMITH, Philadelphia, read a paper on

CHRONIC SUPPURATIVE OTITIS MEDIA.

Here we have an enormous field for preventive medicine. Arrest the initial tympanic inflammation, give prompt relief should it advance to acute suppuration. There are several varieties of this disease: Inflammation confined to the lower part of middle ear cavity with opening in the membrane, granulations protruding, caries relatively infrequent. Or perforation may involve the entire membrane, the ossicles changed by necrosis, deafness marked, obstinate discharge and proneness to mastoid and brain complications. Prognosis of first mostly favorable, while attic disease is serious. We must relieve or modify the persistent discharge, remove masses of granulation, polypoid growths. Absolute cleanliness, general antiseptics; irrigation or syringing to be used only in selected cases. Cleanse the ear carefully by mopping with sterilized cotton saturated with hydrogen peroxid; then many are cured by applications within the tympanum of nitrate of silver or liq. plumbi subacetatis, loosely packing with iodoform gauze once or twice a week, gradually ceasing as the discharge ceases. Dusting the surfaces with acetanilid powder is also valuable. Granulation may be destroyed with strong solutions of chromic acid, but better with

instillations of absolute alcohol. Pain from this is reduced by a 50 per cent. solution of boroglycerid in the proportion of one dram to the ounce of alcohol. Pack the canal after each with iodoform gauze. Boracic packing is useless and objectionable, preventing free drainage. If no improvement in a few weeks, enlarge the tympanic opening, remove all inflammatory products, taking care not to disturb the ossicles, and again follow the line as above. Care of the naso-pharynx and the general health is needed. Perforations high up with more or less necrosis of the ossicles and walls, indicate a more formidable disease, the dura mater may be infected and diffuse meningeal trouble occur. Here we must establish free drainage, remove the ossicles and all other pathologic products.

Dr. A. C. WENTZ of Hanover spoke on "The Umbilical Cord." Its affections are hemorrhage, vegetations from suppuration, tetanus, sepsis. Treatment of the cord is as various as the mind of the attendant. He quoted the plans adopted by the best minds, as Doktor, Noble, Boyd and others, in various institutions. After long unsatisfactory attempts in various methods he concluded that calomel, or that and boric acid, are the best that can be used for dressing the stump for both rich and poor alike, the city or the country, and for the reason that calomel is an antiseptic, keeps the surface of the skin free from urinary and fecal chafing; they are cheap, easily carried in the obstetric bag, easily applied, a teaspoonful being sufficient for a two weeks' dressing.

Dr. C. A. VEASEY of Philadelphia, read a paper on

THE TREATMENT OF COMPLICATED ULCERS OF THE CORNEA,

in which, after defining that he meant by a complicated corneal ulcer one that was more or less extensive and that showed a disposition to spread rapidly and involve other portions of the cornea than that first affected, he advocated the institution of the following treatment:

1. Examine thoroughly the conjunctiva, the lachrymal ducts, the nares and naso-pharynx, as well as the cornea itself, and if any abnormal condition be found that is either the primary cause of the ulcer or that is keeping up the condition, direct the treatment against it as well as against the ulcer itself.

2. Employ moist heat by means of the local application of pieces of lint or flannel wrung out of hot water at a temperature of 120 F. from fifteen to sixty minutes at a time, repeating at intervals varying from two to four hours, according to the virulence of the disease.

3. Cleanse the ulcer and the conjunctival cul-de-sac with some warm antiseptic solution immediately after the employment of the moist heat, and between the times of its employment if there be much discharge. For this purpose may be used a saturated solution of boric acid, a solution of bichlorid of mercury (1 to 6000) or a solution of formaldehyde (1 to 4000).

4. Instil a drop or two of a solution of atropin (four grains to the fluid ounce) once or twice daily if the ulcer be central; but if it be peripheral, a solution of eserin (one-sixth of a grain to fluid ounce) may be employed from three to six times during the day and the atropin solution instilled once at night.

5. The eye must be protected by dark glasses or an evenly and lightly applied bandage. As a rule the former should be used in those cases in which there is considerable discharge, the latter in the cases in which very little discharge is present.

6. Should the above means fail to check the progress of the ulcer, it should be curetted and, after dusting on its surface some iodoform previously pulverized and sterilized, a bandage applied.

7. Should the ulcer continue to spread, after being curetted it should be touched with some of the chemical agents employed for the purpose. Of these the tincture of iodine, liquid carbolic acid and silver nitrate (the latter in the strength of ten to twenty grains to the fluid ounce) seem to be the best.

8. The actual cautery should be applied after the previously described remedies have been employed without beneficial result, or even before these have been used if it be seen that the ulcer has assumed a malignant type, that is if the cornea is becoming so rapidly involved that the destruction of all or a large portion of its tissue is threatened.

9. During the treatment of any case of corneal ulcer, be it ever so mild, if there be present any pathologic condition of the lachrymal passages, of the nares or naso-pharynx, it should be very carefully treated at the same time that treatment is directed toward the ulcer itself.

10. Any unhygienic condition, dietetic error, or constitutional diathesis should be corrected.

Dr. W. J. K. KLINE of Greenburg, read a paper on

SCIENCE IN MEDICINE.

This paper discusses the uncertain and unsatisfactory methods of the treatment of disease as exhibited in the medical practice of the part, and endeavors to show that further

progress in ascertaining the properties and a chemical basis should be the paramount object in the labors of those who are especially engaged in analyzing the various articles of medicine by ascertaining their exact chemical formulas and so arrange them that their therapeutic properties would be readily ascertained and known.

A complete system on this basis would do away with the numberless varieties of medicinal agents and would not only simplify the practice but would vastly enhance the beneficial results of treatment and place upon a higher plane the whole professional character.

Some examples were given to indicate the direction of thought, and the method of overcoming difficulties was outlined.

Dr. J. C. LANGE of Pittsburg read a paper on "Asphyxiation by Carbonic Acid as the Death Penalty." He spoke of the horrors of hanging, the dread of strangling, perhaps the breaking of the rope, the head being entirely jerked off, or the rope being too long, its failure to cause death, etc. All, however, acted as an element of punishment, while the easy, speedy death by carbonic acid would rob the law of its terrors.

Dr. E. B. BORLAND of Pittsburg spoke on the subject of "Rheumatism." It is second only to tuberculosis. Less importance is attached to heredity. Many regard it as a germ disease. No specific germ has been isolated to prove its existence. The blood contains toxins, rarely germs; it is an intoxication rather than infection. The tonsils are believed by some to be the seat of entrance. Majority of sufferers have intestinal indigestion, fermentation; a sour odor is noticed from the stools and stomach, then in the urine and perspiration. He believed the depraved small intestine contained indigestible food, furnished the medium for culture germs, the toxins of which produce the rheumatic blood state. It is thought the pus-producing germs are the factors. Pathology: The toxins give rise to increased oxidation, fermentative acids are thus caused in the blood, nitrogenous waste is also increased by the presence of toxins. Red corpuscles are diminished, fibrin increased. The disease is associated with malnutrition, imperfect digestion, and its poisons have a special affinity for fibrous tissues. General febrile phenomena have little diagnostic significance, the sour, pungent stools, perspiration and urine, even sometimes acidity of alkaline fluids in the earlier stages of acute attacks; the metastasis to and involvement of parallel joints with inflammation of the larger articulations, heart lining and covering easily make the diagnosis. Under middle age the patient ought to get well; average lasts six weeks. Treatment consists in complete rest, hygienic surroundings, wool clothing and bed covering, easily digested food, abundance of water (five to twelve pints a day). Special treatment: Neutralize the acidity, remove the source of the poisons; move bowels well, administer alkalies till urine is neutral; quinin is valuable; soda salicylate acts partly as an intestinal antiseptic; methyl salicylate is better, not so depressing and a moderate blood and intestinal antiseptic; phenol salicylate (salol) is a decided advance, yet it irritates diseased kidneys, therefore the urine should be examined before using it, 10 grains every two hours. It is pleasant to take, splits into carbolic and salicylic acids in the small intestine, relieves pain, does not depress, lowers temperature. About one hundred grains should be given in divided doses in twenty four hours.

Dr. C. W. DULLES, Philadelphia, made a report on "Hydrophobia," which gave a history, as far as obtainable, of all cases published since his last report. He was, as usual, very emphatic in his belief as to this disease and provoked quite a discussion as to the reality of the disease.

The report of the special committee on the publication of the Transactions was read and it was agreed to publish in journal form, as several offers from journals had been presented. After some discussion the matter was postponed for a full report on each of these.

In the evening at Carnegie Hall the President delivered the annual address. His subject was the

ADVANTAGE OF MEDICAL ORGANIZATIONS TO THE PROFESSION.

He alluded to the originators of the Society with reverence, Alfred Stillé yet remaining. It was started by physicians of Chester and Lancaster Counties. This is the fourth meeting in this city. When it was organized the practice of medicine was largely empiric; blood letting and mercurialization were the accepted methods. Pathology was unknown, surgery was sacrificial, not conservative. The Atlees had but begun the revival of ovariectomy, which has now developed that important department, abdominal surgery. Communication was difficult, traveling slow, journals infrequent, new procedures in any branch were long doubted. Medical societies have stimulated the profession, we have concerted action, medicine has progressed; we have new drugs, new surgery; every part

of the body is reached with the knife, entire revolution has occurred. Old things have passed away, all things have become new. Now, every plan is heralded in all parts of the world, tried by every one; we find the cavities illuminated and explored; the individual can register the beauties of his own skeleton. The germ theory has given us scientific treatment. We will be occupied with the bacillus, but we will employ him to aid us in our work, one to destroy a malignant form. He alluded to the work of surgery in the region of the peritoneum, of the appendix and similar troubles. Medicinal agents are now manufactured by large establishments, made more useful, attractive to the eye and the palate. Many companies would almost persuade the patient by their explicit directions how, when and where to use these manufactures that the physician is no longer needed; they give the compounds under names which give no clue to the ingredients and resent his want of confidence and preference for articles better known. It is a question whether the facility with which elegant preparations are secured is an unmixed evil. The physician should insist upon a knowledge of the chemic and qualitative composition of every compound he dispenses. The importance of careful training was early recognized by this society. Licensing was at the first meeting proposed, a measure requiring forty years to accomplish. Longer periods of study were urged, four years was none too long then in the estimation of our founders. With the present year the first class of four-year men graduates at the university. The record of this society is glorious and the decision to publish a journal affords an opportunity to get to the members early all its doings and in a form most acceptable. We have 3,000 in affiliation, yet we expect of the 7,000 physicians in the State many will become subscribers to the journal as has been seen with the AMERICAN MEDICAL ASSOCIATION. Still it is a field in which labor may not fully succeed as in the AMERICAN ASSOCIATION, as yet only about eight thousand or more out of 70,000 physicians are subscribers. There should be no turning back, the journal must be a success or not be attempted. Subjects should be associated of a similar character, rather than have a paper and discussion on one day, then a similar paper next day. The ground is again to be threshed over, or this paper, perhaps a better one, left undiscussed. We can thus economize time. Encourage the ablest men to read papers or discuss them, thus we can add to the great value of the meetings. He felt it would be better to assign one day to surgery, another to obstetrics, etc., so that those who desired could attend and hear those papers in which they were interested. He suggested that in place of the present Committee on Scientific Business there be appointed a committee of three representing the three divisions of medicine, who shall arrange the program, that these three shall prepare addresses in their branches to be presented as the first article on the program, the order of subjects to change each year. This would make the president interested in and responsible for the success of the meeting over which he presides, insures the specialist one day adapted to his needs, affords the general practitioner opportunity to compare notes with men of authority and large experience and will be advantageous to all. It should be so well prepared that every member could not afford to miss a single meeting. A night session on the second day to consider some special subject would be useful. The subject to be opened by a speaker on either side and after the debate the conclusions closed by the principals. This would be extremely valuable and add much to the circulation of the journal. Within a few months we have lost three ex-presidents, Drs. Hiram Corson and Traill Green were long in the profession, had outlived the usual period allotted to man, were of strong, positive character and devoted to the profession. Dr. J. B. Murdoch of this city, the genial gentleman, skilful surgeon, the earnest teacher, whose years were shortened by his devotion to study. I can not close without reference to another whose gentlemanly, kindly manner has endeared him to all, I allude to William H. Pancoast.

On Wednesday the "Address in Hygiene," by Dr. A. P. BRUBAKER, was devoted to a consideration of the views of the day on hygienic matters.

Dr. T. J. ELTERICH of Allegheny reported

SIXTEEN CASES OF LARYNGEAL DIPHTHERIA TREATED BY ANTI-TOXIN AND INTUBATION.

Membranous croup is now regarded by most authorities as always diphtheritic, and while it is acknowledged that cases may occur which are non-specific, non-contagious in character, they are undoubtedly rare in number. The writer considers all cases of pseudo-membranous laryngitis, not of traumatic origin, as local manifestations of diphtheria, and bases the treatment on that diagnosis. Of course, the presence of the Klebs-Löffler bacillus is a definite criterion of diphtheritic pseudo-membrane.

Dr. P. J. EATON, Pittsburg, read a paper on the "Daily Medical Inspection of the Public Schools." He alluded to the need of understanding infection and contagion, explained the general views on these, the proper methods of preventing disease spreading by isolation, etc.; quoted largely from the work done by various health boards, in New York, Boston, etc. The first requisite is a board of health with power to enforce its decrees; then the appointment of school inspectors to examine all complaining scholars, sending home those sick, defining for each the disease, etc., gave the proper plan for disinfection, a series of cards and certificates to be used for the entire work; finally the plan for real isolation, that would prevent any possibility of contagion. He would divide a city into districts of convenient size, in each have a competent medical man as inspector, to visit each school daily, all complaining children to be mustered in a central office, there examined, a certificate given each, the health board notified where necessary, the family physician also.

Dr. X. O. WERDER, Pittsburg, read a paper, "Report of Two Interesting Cases of intestinal Resection and Anastomosis." In one a very large portion of the small bowel was resected with complete recovery.

Much discussion followed upon this paper as a subject of unusual interest.

Dr. F. BLUME of Pittsburg read a paper,

OVARIAN TUMOR COMPLICATING PREGNANCY; PORRO-CESAREAN SECTION.

Mrs. C. S., 38 years old, mother of four children, was kindly referred to me by Dr. G. L. Bumgarner of Natrona, Pa., with the diagnosis: Pregnancy complicated by a tumor obstructing the birth canal. She entered the gynecologic service of the Allegheny General Hospital June 13, 1895.

On examination the uterus was found to correspond in size and position to an eight months' pregnancy. The pelvic cavity almost completely blocked with a dense ovarian tumor. The cervix uteri, high up and pushed to the right, could only with difficulty be reached by passing the finger between the tumor and the pubes.

An attempt to push the tumor back was not successful. The question arose: Could the tumor be removed without interrupting pregnancy? If so, immediate ovariotomy would probably be the safest method of procedure. Ovariotomy, however, before the uterus was emptied of its contents was deemed impossible on account of the location of the tumor and its inaccessibility. Condition of the patient being good, it seemed to be proper to postpone interference in the interests of the child. Advised the Porro operation with removal of the growth and decided to operate a week before term.

Operation July 12, 1895. Long incision. Uterus delivered from the abdominal cavity, the upper part of the incision closed to prevent escape of the intestines. A rubber ligature loosely applied around the cervix, to be tightened in case of hemorrhage. Uterus incised, membranes ruptured and the child delivered. The cord cut between forceps and the child handed to an assistant. Cervix constricted with the rubber ligature, transfusing pins applied, the placenta removed and the uterus amputated. The tumor, which arose from the left ovary and was bound down by adhesions, was enucleated, lifted out, ligatured and cut away. Peritoneum sewed around the stump below the rubber ligature. Abdominal incision closed and stump dressed with iodoform and iodoform gauze.

The tumor, which was larger than a child's head, proved to be a multilocular cyst.

The patient made a splendid recovery. The child, a fine boy weighing nine pounds, was put to her breast on the third day following the operation, and lactation continued uninterruptedly. She visited me with her boy last summer. Both were in excellent health. Upon examination I found the cervix uteri very small, attached to the abdomen and giving no inconvenience. No ventral hernia.

(To be continued.)

Chicago Pathological Society.

Regular meeting held March 8, 1897,

Dr. JAMES B. HERRICK, President, in the chair.

Prof. EDWIN KLEBS read a paper on "Some Remarks on Malignant Growths" (*vide JOURNAL* p. 575).

ICTERIC NECROSIS AND NATURAL INJECTION OF THE INTRACELLULAR PASSAGES IN THE LIVER.

Dr. GUSTAV FÜTTERER—The case from which these specimens were obtained was one of primary carcinoma of the gall bladder. The illustrations which I pass around show carcinoma of the wall of the gall bladder growing into the liver

substance and along the hepatic duct, and causing obstruction of the hepatic duct. It was a glandular carcinoma, and the first photograph shows this very nicely. The next illustration shows how carcinoma begins and grows into the liver substance. The obstruction of the bile duct caused a dilatation of all the bile ducts inside of the liver. When I came upon the bile ducts and opened them, they were filled with absolutely clear mucus. Their walls were thickened. A microscopic examination revealed necrosis around some of the gall ducts, which was due to pressure by the dilated duct. This pressure necrosis was only found in comparatively small spots. Inside of the acini icteric coloring was observed in every one of them, occupying a central zone around the central vein, increasing more and more the nearer it got to the central vein. All through the liver, the central vein was surrounded by an inner row of preserved liver cells, which leads me to conclude that the lymphatics have carried off the main part of the lymph. A more minute examination of the cells inside of the icteric necrotic portions showed the following: Surrounding the necrotic portions a great number of small, contorted, greenish masses were found inside of the cells, masses which were formed like corkscrews when they were rather small, but which became more and more straightened out as they grew larger. They were mostly found around the nuclei as concentric rings. It was seen that bile had been retained inside of the liver cells, and normal bile channels inside of the liver cells could thus be seen. How did this come about? The current of bile must have been reversed. For some reason or other, the bile has not entered the interlobular gall ducts. Whether the pressure of the mucus that filled the gall ducts prevented the bile from running in that direction, or whether it was caused by obstructions between capillaries and ducts, I am unable to say; the fact remains that the current has been reversed to the center, for there we find the icteric necrosis. The peripheral portions and the cells of the intermediate zone got rid of their bile almost as fast as it was produced, while the central portion was continually overloaded. Thus the cells in the central portion were not able to get rid of their bile, and in our microscopic specimens, which were well preserved in formalin, thickening of the bile had taken place, inside of intracellular channels. I exhibit a photograph showing a high degree of destruction of the liver cells which progresses to complete dissolution. I show a drawing which points out the connection between the extracellular and intracellular bile channels. If you will look closely at the drawing, you will see that one of the intracellular branches dives down under a nucleus and comes out again on the other side. I show you photographs of small channels that are contorted. Some of the photographs show how the cells become actually destroyed and the network dissolved. In one photograph we have a perfect network. Of course, we can not expect a clear, perfect picture, as the loops occupy different planes, and you would have to photograph a number of sections to get a proper view of the whole network of a certain cell. But if you will look at the photographs with a magnifying glass you will be able to see these channels very plainly. You probably know that experiments have been made by numerous investigators, who have succeeded in driving the fluids which are used for injection of the bile ducts into the cells, but it has always been a question whether these were artefacts or not. Here we have a natural injection of the intracellular channels with bile, which tends to prove that those who made artificial injections of the bile duct system have succeeded in driving the liquids used into the intracellular roots of the whole system.

My conclusions would be: A stenosis of the hepatic duct has caused stagnation of bile inside of the gall ducts, this causing a dilatation of the ducts, a thickening of their walls, and patches of necrosis of liver cells. The bile contained in the ducts was gradually replaced by mucus produced by the glands of the ducts. About two-thirds of the volume of the liver substance was apparently unchanged and the liver produced large quantities of bile, which, however, were not excreted by way of the gall ducts, probably because the thickening of the walls of the gall ducts caused obstruction of the entering capillaries. The reason why I would prefer to accept this explanation is because I find no dilatation of bile capillaries in the peripheral zones of the acini. Not only has the bile been prevented from running in the normal direction, but its current has been reversed and it has entered mainly the perivascular lymphatics which surround the central vein, but also to some extent the latter. Further, the constant overloading of the central zone of the acini with bile, prevented the cells of these portions from expelling the bile produced by themselves, thus enabling me to study the intracellular bile channels and even have them photographed with oil immersion. The study of those channels shows that they are very small, contorted, that

they surround the nuclei as rings or approach them in radial directions, that they form networks in the protoplasm of the cells, also around the nuclei, and that they communicate with intercellular ducts. These channels lose their contorted appearance as they become dilated more and more, and as they grow larger, the substance of the cell and the nucleus degenerate, until at last nothing but detritus tells of their former existence.

DISCUSSION.

Prof. EDWIN KLEBS—I have been very much interested in Dr. Fütterer's demonstration. The question is, What is it that fills up these canals? Can it be only bile? I think not. As bile is fluid and stains the liver cells diffusely in icterus, can it not be that hyaline masses, formed in the liver cell, are the cause of obstruction of these intracellular canals? Impregnated with bile, this suggestion seems to explain much more clearly the dilatation of the canals, than by fluid masses. A very similar process may be seen in phosphorus intoxication. There the intercellular canals are filled up with such hyaline masses (O. Wyse and Alter). New researches will show possibly also intracellular canals.

Dr. LUDVIG HEKTOEN—In addition to the artificial and natural injection of intracellular passages, there is another way of demonstrating them, namely, by means of Golgi's stain. I show you here the plates illustrating Erik Mueller's beautiful work on "Intracellular and Intercellular Passages." This plate represents the intracellular passages as revealed by Golgi's method in the liver.

THE FATE OF GIANT CELLS IN HEALING TUBERCULOUS TISSUE.

Dr. LUDVIG HEKTOEN presented a number of microscopic specimens from a case of healing tuberculous leptomeningitis and made the following remarks concerning the changes in the giant cells: The investigations into the nature and the importance of the giant cells of tuberculous tissue have not led to uniform results. Baumgarten, Weigert and others look upon them as necrobiotic from the inception. Metchnikoff and his school regard them as active, living, defensive cells. The mode of formation, the sources, the relation to bacilli, the degenerative changes of giant cells have all been studied, but the further definitive changes that occur when the bacilli are removed or their action neutralized before the giant cells become necrotic have received but very scant attention. Are the giant cells left capable of progressive changes, do they continue to exist as giant cells, or are they removed by way of disintegration? Manifestly a definite answer to some of these questions would throw some light upon the nature of the giant cells. D. J. Hamilton remarks that sometimes giant cells live on and organize, *i. e.*, secrete or form fibrous tissue. The numerous investigations into the healing of tuberculous peritonitis make no reference to the part played by the giant cells. The most extended statement occurs in the work of Professor Klebs on "Die Causale Behandlung der Tuberculose"; he states that giant cells in healing tuberculous tissue in guinea pigs subdivide into uninuclear cells and become part and parcel of the living tissue, more particularly of the endothelial lining of vascular channels and spaces.

In an unusually long case of tuberculous leptomeningitis in a 35-year-old man, the symptoms, consisting of headache, optic neuritis, occasional vomiting, extended over four months, death resulting from a pneumococcus pneumonia—the post-mortem showed a chronic tuberculous basal leptomeningitis, tuberculous of the peribronchial lymph glands, chronic nephritis and lobar pneumonia. At the base of the brain there was much turbid fluid and a thick layer of firm translucent material containing pin-head sized and large nodules. In the exudate, tubercle bacilli were demonstrated by means of culture. Microscopic examination of the leptomeninx showed a chronic fibrous endarteritis, and the production of much loosely fibrillated young connective tissue with larger and smaller fibroblasts, young blood vessels and very many multinucleated giant cells. The giant cells—as seen in the specimens exhibited—present various changes in various degrees. There are giant cells that seem to be dividing, but this division is accompanied with much nuclear disintegration, vacuolation of the protoplasm, and phagocytosis; there are also some karyokinetic figures in single nuclei in the giant cells from the disintegrating cells. There are also giant cells that seem to be dividing into smaller cells without nuclear disintegration, but the fate of the smaller cells could not be made out; they did not appear to form new blood-vessels. The following reasons allow this case to be regarded as a chronic, healing tuberculous meningitis: 1, the process has reached the same stage throughout the whole area involved; 2, there is but very little caseation; 3, there is present a chronic endarteritis; 4, acute inflammatory changes are absent; 5, the presence of a fibrillated, vascular, embryonal tissue; 6, the changes in the giant cells. The fact that tuber-

cle bacilli grew from the fluid inoculated on glycerin agar show that the cells in the pia were, so to speak, immune to their action; while the mechanism of this immunity need not be discussed, it is plain that the cells survived the action of the bacilli and retained vitality enough to form new tissue. There is a large number of giant cells, many of which are splitting up and show progressive changes side by side with retrogressive: the nuclei in the giant cells present my independent foci of activity; they are independent centers. Whatever the mode of origin of the giant cells may have been—whether by fusion, mitosis or amitotic division of the nucleus without division of the protoplasm, the mode can not have been incompatible with viable descendants.

Conclusions.—In healing, non-degenerated tuberculous tissue the multinucleated giant cells may in part disintegrate and become absorbed, in part form small cells; both these changes usually affect the same cells, but in one class—presumably the older and weaker—the retrogressive changes predominate, while in a second—presumably the stronger and younger—the progressive changes are the more marked. The fact that giant cells in tuberculous tissue under some conditions undergo progressive changes and separate into small, living cells proves that they are not, as claimed by Baumgarten and others, necrobiotic elements that are predestined to destruction; it lends more strength to the teleologic view of Metchnikoff that they are living cells, defensive, formed for a distinct purpose.

DISCUSSION.

Prof. EDWIN KLEBS—In a case of tuberculosis of the testicle I was very much surprised to find a great number of giant cells lying very close to each other. In places there were fresh tubercles, round cells, with a few tubercle bacilli, so that we can say that the process in this case showed the same features of healing as in the case just described by Dr. Hektoen. In tuberculosis of the testes the giant cells as a rule contain no tubercle bacilli, but it was very curious that the greatest number of them, in my case, were found in connection with striated muscular fibers. Some of the cells surrounded the muscular fibers. Others could be seen in long rows along the muscular fibers. In some of the cells which were near the muscular tissue I observed small crest-like masses included in the giant cells. That the clear centers of the tuberculous giant cells are not necrotic, seems to be evident in those cells that originate from vascular tissue.

I am not inclined to accept the theory of Metchnikoff, that the giant cells are organs of destruction of microbes or of red blood corpuscles (Langhans) or of bone (the osteoclasts of Kölliker). This suggestion would seem acceptable if the giant cells had the force of contraction. But the many projections of their substance are absolutely immovable, as I have often observed in living giant cells of different origin. The same has been proven by the persistence of the rigid projections in the dead cells, whereas, the ameboid projections of leucocytes are retracted in death. Giant cells are not necrotic for they are continually developing fresh nuclei. I have seen such giant cells in cases of carcinoma in which we observe the production of new nuclei in successive generations. The same feature must characterize the formation of giant cells in healing, tuberculous tissue. They are formed under every circumstance from the endothelial cells of the tissues under the influence of regenerative processes. That they contain in tuberculosis sometimes tubercle bacilli has no other signification than the inclusion of foreign bodies or tissue constituents.

The positive demonstration by Dr. Hektoen that they finally return to the normal tissue cells, or split up in their first constituents, is in conformity with my own observations ("Causal Treatment of Tuberculosis," 1894), and seems to me to be of the highest importance and shows clearly that they are in a living condition. If one might express a theory as to their formation, one could say that the hardened character of the protoplasm of giant cells constitutes a favorable condition for the new cell development in the struggle against destructive microbes or foreign bodies, or dead material of the body itself.

DIFFUSE SCLERODERMA ASSOCIATED WITH CHRONIC FIBROUS CHANGES IN THE THYROID AND GREAT DIMINUTION IN THE AMOUNT OF THYROIDIN; INCREASE IN THE CHROMOPHILE CELLS AND OF THE COLLOID IN THE HYPOPHYSIS.

Dr. LUDVIG HEKTOEN—Through the courtesy of Dr. Noel an opportunity was given to study the organs of a case of diffuse scleroderma in a woman 51 years old. The clinical history, for which I am indebted to Dr. H. E. Brennecke, shows that the disease had lasted about one year and that it had pursued a typical course and rapidly become almost universal in its distribution. The patient died after having been unconscious for three days.

The anatomic diagnosis reads as follows, the postmortem having been made immediately after death: Diffuse scleroderma, atrophy of the thyroid, arterio-sclerosis, fatty and atrophic liver, chronic nephritis, interstitial myocarditis and hypertrophy of the heart, gummas (?) of the liver, chronic caseous tuberculosis of the retroperitoneal glands, edema of the lower extremities, adhesive pleuritis and pelvic peritonitis. The skin over the face, neck, chest, abdomen and parts of the extremities as well as of the back is hard and tight, smooth and without any wrinkles; it seems thin, but cuts with resistance. The thyroid is small and fibrous, weighing 14 grams, the isthmus is absent. The condition of the other organs is sufficiently well set forth in the anatomic diagnosis. The microscopic examination showed the brain and spinal cord to be quite normal. The areas in the liver that were thought to be gummatous are found to be aberrant or obstructed bile ducts. The thyroid is the seat of extensive fibrous changes with atrophy and destruction of the glandular portion, resulting in the formation of larger and smaller cysts, in which is inspissated colloid material. Normal follicles with normal lining and normal colloid contents are very rare. The arteries in the thyroid are the seat of a general and greatly advanced obliterative thickening. The hypophysis weighs .7 gram; it is consequently very large; the number of chromophile cells and the colloid material are increased, as can be seen in the sections under the microscope. The changes in the skin may be summarized as follows: There is a great hyperplasia of the collagenous intercellular substance in the corium with flattening of the papillary body, together with a breaking up and spreading asunder of the elastic fibers, obliterative thickening of the blood vessels, atrophy of the interpapillary epithelium as well as of the epidermis, the hair follicles and the coil glands. These changes are diffuse, practically universal, although not always of the same degree. The appearances were studied in sections prepared according to Benecke's, Unna's and other methods for demonstrating collagen and elastin.

The chemic examination of the thyroid was made by Mr. H. G. Wells and the following is his report:

"The thyroid gland in this case when fresh weighed 14 grams. This is very much below the normal weight, for sixty glands from persons between 25 and 65 averaged in weight 22 grams, over one-half more than did this gland. When dried, allowing for the portion removed for microscopic purposes, it weighed 3.23 grams, the average dry weight of twenty normal glands from the same series being 5.37 grams. This dried gland was analyzed to determine the amount of iodine it contained, using the colorimetric method advocated by Baumann in his original work on the iodine contents of the thyroid gland. The analysis was made in duplicate, both determinations agreeing closely, and it was found that in each gram of the gland was contained 0.91 mgr. of iodine, giving a total amount of 2.94 mgr. as the contents of the entire gland. Analysis of a series of twenty normal glands from residents of Chicago has given as the average amount of iodine in each gram of the dry gland 2.01 mgr. The average total contents of iodine in these cases was 10.79 mgr. Therefore in this gland the proportion of iodine was less than half the normal and the total quantity of iodine between one-fourth and one-third that usually contained in a normal gland. It is also far below that of any normal glands in the series quoted, for the smallest amount found there was 7.46 mgr. and in that case the amount of iodine in each gram was 1.98 mgr. From this it is evident that not only was the gland quantitatively atrophic but probably also functionally, for as a general rule, the smaller a normal gland the larger the proportion of iodine it contains, so bringing the total iodine contents up to a certain standard, which in this vicinity appears to be about 10 mgr. whereas in this case despite the small size of the gland, the proportion of iodine was much below that one would expect to find in a gland of much greater size. The hypophysis would seem to be correspondingly enlarged, for in a series of twenty-one glands the fresh weight was found to be but 0.4 gram, while in this case the weight was 0.7 gram. In the series mentioned but one gland was found of so high a weight and this was probably not a normal gland, for it contained an unusual number of cyanophile cells which greatly outnumbered the chief cells. It is probable that the iodine in the hypophysis is contained in the colloid material, just as Hutchinson has shown it to be in the thyroid. Analysis of fourteen normal hypophyses gave as the average amount of iodine in each gland 0.0036 mgr., which represents for each gram of dried hypophysis 0.04 mgr. This is but about one-fiftieth as large a proportion of iodine as is found in the thyroid gland, and corresponds to the relatively trifling amounts of colloid that the hypophysis contains. Unfortunately, the hypophysis from this case could not be examined chemically, as it was used for microscopic

purposes, but it is probable that because of the increased amount of colloid it contained that a comparatively large amount of iodine would have been found."

We have in this case the cutaneous changes characteristic of scleroderma associated with fibrous changes, atrophy and diminution of iodine in the thyroid and increase in the chromophile cells and colloid in the hypophysis. These changes in the hypophysis were found quite frequently by Schönemann in connection with goiter and their exact nature, whether degenerate or compensatory and hypertrophic, can not be stated because the writers are not in entire accord as to the significance of the chromophile cells, *i. e.*, cells with an eosinophile or cyanophile cytoplasm.

The causes of diffuse and other forms of scleroderma are not known. The neuropathic theory of Schurminer remains to this day without any anatomic substratum. The chief objection to Dinkler's view, that the obliterative arteritis is the primary lesion in the process, is that it is difficult to understand how the arteritis can lead to such a degree of collagenous hyperplasia. Singer found the thyroid the seat of chronic fibrous changes in a case of scleroderma, and urges strongly the view that this disease as well as myxedema and exophthalmic goiter are due to dysthyreosis; but this present case is the first one in which an actual diminution of the active constituent of the gland has been demonstrated. Pisko, Marsh, Steglitz and Grünfeld obtained good results with thyroid treatment in various forms of scleroderma, and Marsh and Grünfeld saw in the sudden improvement something more than a mere coincidence. On the other hand, Franke, Unna and others have had negative results. In connection with this the relation of the thyroid to myxedema becomes significant. The changes in the skin in myxedema vary, but it seems established that the elastic tissue is increased and the collagenous tissue diminished. Now, if athyreosis can produce such changes there can be no inherent reason why dysthyreosis, due to various causes, may not lead to scleroderma. In this case it lies temptingly near to assume that the endarteritis of the thyroidal vessels may have been the essential cause of the changes in the thyroid and, in accordance with the suggestions already made, indirectly of the scleroderma. Arterio-sclerosis might, it would seem, lead to parenchymatous atrophy and fibrous growth in the thyroid as well as in other organs. Viewed from this point the arterio-sclerosis would seem to play an indirect but essential part in the genesis of the diffuse scleroderma of the old rather than the direct rôle advocated by Dinkler and others. The causes that may disturb the functions of the thyroid and the results thereof are various, and it seems warranted to suggest that the relations of arterio-sclerosis, dysthyreosis and scleroderma merit further study.

ACTINOMYCES-LIKE BODIES IN THE TONSILS.

Dr. J. W. ELLIS—While studying a series of tonsils in the pathologic laboratory of Rush College my attention was called to an article which appeared in the *Zeitschrift für klinische Medizin*, Vol. 30, parts 5 and 6, which in substance is as follows: "In the histologic examination of twenty-five tonsils from patients suffering from various diseases, as tuberculosis, syphilis, chlorosis, broncho-pneumonia, acute tonsillitis, etc., he found in four cases from Gerhard's clinic bodies which resembled actinomyces."

The diseases from which these patients suffered bore no relation to the tonsils. The ages of the patients varied from 7 to 22 years.

These bodies to the naked eye were small yellowish specks. The microscope revealed the fact that there were only a few in a section—never more than six—and that they were invariably found in the crypts of the tonsil. They stain with the ordinary hemotoxylon stain, and are round or oval and from .5 to 1 mm. in diameter. The center had the appearance of a tangled mass, while the periphery had a more or less clubbed appearance. By Gram's method the body was seen to be made up for the most part of longer or shorter threads, and distributed throughout the mass were seen cocci-like particles, which also retained the stain. The tangled mass of threads in the center under the highest power was seen to be composed of more or less curved staves, which were seen to be continuous but did not stain at the point between the staves. Toward the periphery the threads radiated, branched and stained more evenly, while the outer threads were stained throughout.

On counter-staining with a body stain the whole mass appeared to be bedded in a homogeneous mass with brighter spots.

The bodies did not stain by Günther's modification of Gram's method. In the vicinity of the bodies there was more or less round cell infiltration, but he did not think it was due to the presence of the bodies as the tonsil from the opposite

side showed the same round-cell infiltration, but he did not find the bodies. He concludes from their frequency—four cases in twenty-five and their not producing any change in the adjacent tissue—that they do not have any pathologic significance. He classified them among the ray fungi, and according to Tarni they are a form of actinomyces and are to be differentiated or distinguished from the actinomyces Horninis by not staining with Günther's modification of Gram's method. I have placed some sections of an apparently healthy tonsil which contains some bodies that answer the above description under the microscope for your inspection.

Notice to Physicians and Librarians of Public Medical Libraries.

[Medical Journals are requested to copy this notice.]

1. Correspondence in relation to the enterprise should be addressed to Dr. Geo. M. Gould, 119 S. 17th St., Philadelphia.
 2. Librarians of public medical libraries are requested to notice these exchange lists and to correspond direct with the advertised donors and recipients; and are also urged to forward to Dr. Gould: 1. Accurate lists of periodicals, books or pamphlets needed to complete their files. 2. Lists of duplicates which they will give other libraries or exchange for numbers desired. *Give both volume numbers and dates of periodicals.*
 3. Every physician is to inspect these lists and to give the books and periodicals for which he has no further use to public libraries, and having no particular choice, to correspond with Dr. Gould in reference to their disposal, in order to secure the greatest usefulness by the profession.
 4. Owing to the additional labor it would involve, queries concerning the supply of desired items to private libraries can not be answered.
 5. The conditions of all gifts are that the recipients shall be reputable organizations, composed of the regular medical profession; that the library shall be a public one—*i. e.*, open for consultation during stated times to physicians generally; and that, if unbound, the periodicals and books received shall be bound and catalogued.
 6. Send nothing before corresponding, in order that the gifts may go direct from the donors to their proper destination.
 7. In order to secure the best success, physicians and librarians of other countries are invited to cooperate.
 8. Notify Dr. Gould of any gifts or exchanges effected.
- Previous list:* January 30, 1897.

DUPLICATES FOR DONATION OR EXCHANGE.

DR. E. R. KING, MUSCATINE, IOWA, WILL DONATE:
Medical News, 1882-1895 inclusive, bound in manilla paper and in good condition.

DR. S. P. DEAHOFF, MINERAL POINT, WIS., WILL DONATE:
American Journal of Obstetrics, vols. 25 and 26.
JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Jan. 2, 1892 to Dec. 31, 1896.

Archives of Pediatrics, vols. 6, 7, 8, 9, 1889-1892.

THE BRISTOL MEDICAL LIBRARY, UNIVERSITY COLLEGE,
BRISTOL, ENGLAND, HAS THE FOLLOWING UNBOUND
PERIODICALS FOR DONATION:

American Journal of the Medical Sciences, 1880, complete; 1882, complete; 1883, April; 1884, Jan.; 1886, complete; 1887, Jan., April, Oct.; 1888, Jan.-March, May-July; 1890, July-Dec.; 1893, Jan. June.

Amer. Jour. Ophthalmology, 1894, July, Oct.; 1895, Aug.
Annals of Surgery, 1889, Aug.

Archives of Surgery, 1890, April.

Asclepiad, 1884, part 1; 1885, part 4; 1886, parts 1, 3; 1890, complete; 1892, part 1.

Australian Medical Gazette, 1889, Nov.; 1896, Feb. July, Sept.-Dec.

Australian Medical Journal, 1890, June.

Brain, 1889, Jan.; 1893, Spring-Summer.

Birmingham Medical Review, 1887, Oct.; 1889, Feb.

British and Foreign Medico-Chirurgical Review, 1853, July; 1855, complete; 1873, July; 1876, Oct.; 1877, Jan.

British Journal of Dermatology, 1889, Jan.

British Medical Journal, 1873, vol. 2; 1874, vol. 2; 1879, vol. 1; 1880, vol. 2 (except Aug. 14); 1881-85; 1886 (except June 26); 1887; 1888-89; 1890, vol. 2; 1891.

Bulletins et Mémoires de la Société de Médecine et de Chirurgie pratiques de Paris, 1894, Fasc. 2, 3.

Canadian Practitioner, 1894-96.

Centralblatt für Chirurgie, 1894, März 17-Mai 26.

Clinical Journal, 1892-3, vol. 1, Nos. 4, 5, 8, 10, 16, 18, 22, 26; 1893, vol. 2, Nos. 3, 9; vol. 3, No. 8; 1895, vol. 5, No. 19.

Cincinnati Lancet-Clinic, 1884, July 5, 12, Oct. 18, 25.
 Dublin Med. Jour., 1887; 1889, Oct.-Dec.; 1890, Jan.-Oct.
 Edinburgh Medical Journal, 1856, July-Dec.; 1857-58; 1859
 (except Feb.); 1860; 1861, Jan.-June; 1862, July-Sept.; 1864,
 July-Dec.; 1867, Oct.; 1871, July-Dec.; 1872; 1888, July-Oct.;
 1889, Feb.-June; 1890, July-Dec.; 1891; 1892, Jan.-Nov.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JUNE 26, 1897.

ANTIVIVISECTIONIST SENTIMENTALITY AND
BRAIN DEFORMITY IN THE DEGENERATE.

A degenerate sexual pervert recently executed for lust murder, at Paxton, Ill., has had his mental soundness doubted because of his sentimental kindness toward animals. Sentimentality of this type is exceedingly common among criminals and other degenerates about whose legal responsibility no true alienist could entertain a doubt. They have both a knowledge of right and wrong with a power of self-control, which alone would be sufficient evidence of responsibility under the true legal test which depends on whether freedom of the will be impaired. Despite the assertions of the antivivisectionists, misanthropy is often associated with great love for the lower animals, and the races characterized by their great tenderness toward animals are the most cruel toward men. This was singularly well illustrated in the Sepoy rebellion, where fanatics indignant at the killing of cows, butchered men, women and children with horrible atrocity. The same thing is illustrated in the suspicious world-betterers who so marred the French Revolution. COUTHON, one of the most merciless of "the committee of public safety," was very much devoted to spaniels. CHAUMET exceeded female sentimentality in his tenderness to his birds. The murderous FOURNIER carried on his shoulders a pretty little squirrel attached by a silver chain. PANIS was intensely devoted to his pheasants. MARAT reared doves. SERGENT, another

agent of the Reign of Terror, was also devoted to spaniels. A lady came to implore his protection for a relative confined under sentence of death. He scarcely deigned to speak to her. As she retired in despair she trod by accident on the paw of his favorite spaniel. SERGENT, enraged and furious, exclaimed, "Madam, have you no humanity?" It may seem, as HAVELOCK ELLIS remarks ("The Criminal"), a curious contradiction of what has been set down concerning the criminal's moral insensibility, his cruelty and his incapacity to experience remorse when it is added that he is frequently open to sentiment. It is however true. Whatever refinement or tenderness of feeling criminals attain, reveals itself as what we should call sentiment or sentimentality. Their cynicism allies itself with sentiment in their literary productions. Their unnatural loves are often sentimental as revealed in the character of the tattoo marks. Two interesting examples of criminal sentiment have recently been recorded by Dr. LINDAN. A German criminal (it is perhaps as well to note that he was a German) having murdered his sweetheart most cruelly, went back to her house to let out a canary which might suffer from want of food. Another, after having killed a woman, stayed behind to feed her child which was crying. LACENAIRE, on the same day that he committed a murder, risked his own life to save that of a cat. BULWER recognized this principle when he depicted EUGENE ARAM as very indulgent to animals. WAINSWRIGHT was always very fond of cats. In his last days his sole companion was a cat, for which he evinced an extraordinary affection. One of the chief characters of WAINSWRIGHT's essays is their sentimentality. Himself when in prison he described as the possessor of "a soul whose nutriment is love and its offspring art, music, divine song and still holier philosophy." All prisoners make a pet of birds or animals or flowers if they get the chance.

In the brain of the degenerate, to whom reference is made, the cerebrum was said to be abnormal because it did not cover the cerebellum. This condition of things was alleged by BENEDICT of Vienna ("Brains of Criminals") to characterize the brain of the criminal. It has been demonstrated, however, conclusively by SPITZKA (*American Journal of Neurology and Psychiatry*, Vol. I) that this non-covering of the cerebellum by the cerebrum in man and the anthropoid apes was due not to any condition of deformity but to careless manipulation. If therefore this condition be found in the degenerate to whom reference has been made, it is due purely to an erroneous necropsy and in no respect is an evidence of either irresponsibility or degeneracy.

SICKNESS AND WOUNDS IN THE SPANISH
ARMY IN CUBA IN 1896.

Inspector General DE LORADA of the sanitary corps of the Army of the Island of Cuba has instituted and

published a graphic comparison of the sanitary condition of the Spanish troops in Cuba in the years 1876-77 and 1896, which shows markedly in favor of the latter year. In the absence of satisfactory statistical data of the earlier campaign the first four months of 1876 and the second and third of 1877 were taken to make the comparison. The publication consists of a large sheet on which are fourteen tables showing by red and blue lines on a graduated scale the data for each month of the respective years. Excepting cases and deaths from yellow fever and wounds in relation to strength, the statistics indicate the existence of better conditions now than formerly. As regards yellow fever it is to be remembered that the greater part of the army in 1876-77 consisted of acclimated men, while the excess of wounds in recent campaigns is due to the greater activity of the troops in field service against the insurgents. It is difficult to read the exact figures from the numbers on the plates, but the following gives a close approximation: 1. Number of sick per 1,000 of strength. The rates in both years were relatively low from January to June and high during the remaining months. In 1896 the low monthly rates ran from 115 to 160 per 1,000 of strength as compared with 165 to 260 in 1876-77, and the high rates from 210 to 318 as compared with 325 to 392. The annual rate was about 2,400 per 1,000 in 1896 as compared with 3,400 during the earlier year. 2. The highest monthly death rate in the past year was 11.7, in August, while in 1877 this rate was greatly exceeded in each of the five months July to November, the highest rate being 28 in September. The annual death rate was about 74 in 1896 as compared with the former excessive rate of 160 per thousand of strength. 3. The fatality of disease or the number of deaths per thousand of sick varied in 1896 from a monthly minimum of 15 to a maximum of 54 as compared with a minimum of 22 and a maximum of 75.2 in 1877. 4. This diagram shows the greater prevalence of yellow fever in 1896, the monthly rate of cases per thousand of strength varying from 4 to 12 during the first half of the year and from 18.8 to 36.8 during the last half as compared with rates somewhat less than half as large in 1876-77. Aggregating these monthly rates the rate for the past year among the unacclimated recruits sent out from Spain was 211 as against 70 among the troops operating in the island twenty years ago. The 5th diagram represents the deaths from this fever, 51.9 per thousand of strength during the year 1896 and only 33.2 in 1876-77. But although the prevalence and mortality of this fever was greater among the unacclimated troops during the present campaign the virulence of the disease was not so active in individual cases, for the rates of deaths to cases are shown by table 6 to have been greater in 1876-77, the average fatality rate having been 40.1 per cent. as against 25.8 per cent. in 1896. Table 7

gives the wounds in monthly rates per thousand of strength and shows a very uniform occurrence in all the months of both years, as if active operations had been carried on in the unhealthy as well as in the healthy seasons. The annual rates amount to 47.7 per thousand of strength for the year 1876-77 and to 121.1 per thousand for 1896. The death rate from wounds in relation to strength also was greater in the present campaign; but the deaths therefrom, in relation to the number of wounded was considerably larger in 1876-77 and the term of hospital treatment for both sick and wounded was much more extended in that year than in 1896. These facts are shown in tables 8, 9 and 10. Tables 11 and 12 give the rates per thousand of strength and per thousand of sick returned to Spain for recuperation. In both instances the summary is distinctly in favor of the year 1896. The last two tables give the rates of discharge for disability per thousand of strength and per thousand of sick. In 1896 the annual rate of discharge was 14.6 per thousand of strength and in 1876-77 16.65; per thousand of sick the rates were respectively 81.7 and 65.9.

THE TWENTY-SECOND ANNUAL MEETING OF THE AMERICAN ACADEMY OF MEDICINE.

This meeting was held in Philadelphia, May 29 and 31. Large accessions were made to its membership, and an unusual number took an active part in the proceedings.

The work of the Academy is distinctively along lines of medical sociology. At first these lines related mainly to the one object of increasing the general mental culture of students desiring to enter upon the study of medicine. Medical societies and medical journals took up the work, until at present the Academy's primary object is largely attained; most medical colleges have some sort of entrance examination; some a high one, and one admits only those possessing a degree of A. B. Others announce that such a degree will be demanded in the near future. More will follow until a satisfactory preliminary training will be exacted of every medical student ere beginning the study of medicine. In this result the Academy as a whole and its individual members have been an important factor.

After some years it broadened its studies and efforts, so that it now includes the whole range of medical sociology. It is believed that definite laws regulate the relations of physicians to each other, to the public, to medical schools, to hospitals and dispensaries, to medical journals and medical publishers, to secular journals and secular publishers; to pharmacists, to retail and wholesale manufacturers; to the defective classes; to schools, from the kindergarten to the university, etc., in short the laws of medical sociology start from the physician as a center and ramify

throughout all professions, callings, enterprises, medical or secular.

When it is remembered that obedience to law brings profit, comfort and prosperity, and disobedience strife, loss, disease, death, untold misery and confusion, it is evident that a knowledge of the laws of medical sociology is of the highest practical moment. To the investigation of these the Academy has devoted itself, with some tangible results that have promoted the work of many individuals and some medical societies and institutions.

Among the subjects discussed at the late meeting were two groups: the first dealing with the "associated duties of the physician," the second "the relation of the college to the medical school." On the first were ten papers treating of "the true principles on which the medical profession should be associated," "physicians' mutual societies," "the rewards of medical work," "a sociologic inquiry of the up to date physician," "the relation of the physician to the public press," "some relations of author, publisher, editor and profession," "medical reviews," "the influence of a liberal education with reference to medical ethics," "the organization and support of medical libraries," etc.

The relation of the college to the medical school was discussed from the medical-school side by Dr. BAYARD HOLMES, from the side of the college by President WARFIELD of Lafayette College; and from the side of the university by Dr. PEPPER, Ex-Provost of the University of Pennsylvania. It is certain that these papers with the discussion following will materially aid such as are honestly seeking for light upon the best training of medical students. It was both broad and deep, beyond what is usually heard in medical societies, and along lines of scientific inquiry. Only when such lines are made to accord with the nature of existing things can the highest prosperity of the profession be expected.

From this brief statement it will be seen that the Academy is the rival of no existing medical society, but that it supplements and complements all, and so merits the support and consideration of such as are seeking for light on the intricate and obscure relations of the physician's vocation.

Its officers for the ensuing year are Dr. L. DUNCAN BULKLEY of New York, President; Dr. JOHN B. ROBERTS of Philadelphia, Dr. BOWDITCH of Boston, Dr. CHARLES DENNISON of Colorado, and Dr. F. T. ROGERS of Providence, Vice-Presidents; Dr. CHARLES MCINTIRE, Boston, Secretary and Treasurer; Dr. WALTER L. PYLE, Philadelphia, Assistant Secretary.

SECTION ON NEUROLOGY AND MEDICAL JURISPRUDENCE.

This is one of the younger Sections of the AMERICAN MEDICAL ASSOCIATION, which has already attained

prominence, and will no doubt in the near future rival all the other Sections in interest and popularity. Questions of neurology and jurisprudence are increasing in every department of practical medicine. The new researches of brain physiology give promise of therapeutic revolutions as startling as in any other field of medicine. At the Philadelphia meeting fifty-one papers were read by the authors and by title. Of these only three related to medical jurisprudence, three to the influence of alcohol on the brain and nervous system, and two to hypnotism. Seven papers were devoted to neurasthenia and its treatment, and three to insanity. The other papers were mostly devoted to diseases of the spinal chord and brain. The authors of the latter were very largely teachers of neurology, and were expected to present the latest and most authoritative facts on these topics. How far these papers together exceeded the papers read at previous meetings of the Section, can not be easily determined. Evidently they were more technical, and confined to the more obscure lesions of the brain and cord. Some of these papers had a pedagogic cast, indicating unfamiliarity with audiences of general practitioners, and inability to isolate and emphasize the central facts of the topic. Many excellent studies are covered up and made useless in all the Sections, by the inability of the reader to reach the level of his audience, and condense his facts so they can be understood without effort. The popularity of the Neurological Section has come from the fact that its wide range of topics have been presented by practical men and specialists, who avoided all effort to exhaust the subjects and sought rather to make prominent some particular facts. This has given a certain suggestiveness to the papers which were stimulating to all hearers. Several papers read at this meeting were prominent in this respect and will be read in the JOURNAL with great interest.

The officers and leading men in this Section have long ago recognized the need of more practical helpful papers to the general practitioner and members of the ASSOCIATION who yearly come to the meetings for facts and hints that can be used in a general every-day practice. It is proposed to have the same Secretary elected every year, so he can become familiar with the leading men of the country who are members of the ASSOCIATION, and able to contribute strong papers on the topics of the Section. This will be a great improvement over the present methods, and enable the Secretary to arrange and bring out certain topics more fully than in any other way. Symposiums of questions still unsettled can be arranged and carried out, and special topics can be presented by leaders not readily accessible to a new unknown Secretary. It was proposed to devote one or more sessions to medico-legal questions exclusively, and have certain topics uppermost in the

public mind discussed. This will give a certain solidity and permanence to the work of the Section, which will be followed by others.

There are probably more difficult unknown questions coming up in every branch of practice concerning neurology and jurisprudence than in any other field. The medical teacher will give general principles, but he is unable to go beyond certain narrow lines. The new problems that are ever coming up require the study of matured practical men, and discussion from all sides. This is often aptly illustrated in sectional meetings where live topics bring out most suggestive spirited discussions.

This Section, in common with other Sections, suffer from the reading of papers which are technical exhaustive studies of some narrow phase of the subject, which are of little interest, even to experts. Such papers always drive away the audience or put them to sleep. There are some quite prominent men whose papers are so minutely exhaustive, as to destroy all practical interest in the subject. Others equally learned have such an involved, obscure style, that it requires much effort to follow them. Often such writers present many original views which are covered up and lost except to some careful student who discovers them and announces them as his own. There follows an acrimonious debate of priority. The Neurological Section has started a movement to reform these errors, and at the next meeting will attempt to lead all other Sections in broad, practical studies and presentations of papers which will be both suggestive and helpful to all its hearers.

THE OCULAR MANIFESTATIONS OF MALARIAL INFECTION.

The general practitioner of medicine, accustomed as he is to the discovery of lesions in the spleen and liver as the result of acute or chronic malarial infection, is also apt to ascribe symptoms which seem difficult of explanation to the same causative factor when, in a certain proportion of cases the condition arises from very different causes. On the other hand it is possible that he is not ready enough to ascribe lesions of special organs to this cause and regards troubles arising in the eye or ear as coincidences rather than direct results.

One of the most interesting manifestations of malarial infection, aside from the pathognomonic types so well recognized, is the effects which may be found in the eye of certain susceptible individuals, and it is also of interest to note that in malarial disease the various tissues composing the eye may each or all of them become involved. This is but natural when we recall the fact that the ocular apparatus is composed of parts which represent almost every tissue found elsewhere in the human being.

While malarial disease affecting some part of the

eyeball is somewhat rare, and still more rarely recognized by the general practitioner, it is a condition of by no means recent observation, for as long ago as 1828 HUETER wrote two papers upon it and the next forty years brought forth ten other papers in the *Annales d'Oculistique*. In many instances the observers of the case, or cases, were ophthalmologists of note, such as LANDOIS, DERBY and PAGENSTECKER. Still more recently cases have been recorded by MILLER and other clinicians, and a classic paper giving a complete summary of the subject has been compiled and published by G. E. DE SCHWEINITZ of Philadelphia.

Ophthalmia is by no means infrequently met with in malarial subjects and is often associated with malarial neuralgia or brow ague, and PAGENSTECKER records cases which were sometimes associated with paralysis of accommodation. Again, it is evident that a malarial keratitis may arise in distinction from the inflammation of the cornea which is so apt to occur to persons whose general health is seriously impaired, although, of course the latter condition is often seen and, as well emphasized by KIPP of Newark, N. J., in 1880 and 1889, the malarial form of keratitis consists in a very large proportion of cases in a peculiar narrow, serpiginous, superficial ulcer with lateral offshoots, accompanied by much lachrymation and often beginning with great supra-orbital pain. The greatest number of these cases occurred in the summer and fall months of the year. KIPP's studies not only deserve careful reading because of their thoroughness, but in addition it is to be recalled that HOTZ of Chicago, MILLER of Providence, and NOYES of New York, and MINOR have largely confirmed his observations. The practical deduction to be drawn is that when keratitis takes place in a patient with a malarial history, even if no other malarial manifestation be present, quinin and arsenic are to be given with the object of combatting the malarial germ, if it be present, or at least improving the general health and overcoming cachexia.

Iritis while possibly produced by malaria is rare, and gout, rheumatism, syphilis, and particularly pyemia, should be excluded from the diagnosis before this form of inflammation is ascribed to infection by the hematozoon. It is, however, in connection with the subject of amblyopia and amaurosis and the changes which take place in the nervous portions of the eye that the influence of malarial infection develops the greatest interest. These symptoms are of great importance, too, because full doses of quinin may readily produce them, and it may be necessary for the physician to determine whether quinin is needed to combat a malarial amaurosis, or is contraindicated, because the doses which may already have been given have acted excessively on the optic nerve and the blood vessels of the eye on account of idiosyncrasy on the part of the patient. Again, it is not to

be forgotten that the amaurosis in such cases, even if a distinct malarial history be present, is perhaps more apt to be due to renal disease than directly to malaria. The examination of the urine will aid very greatly in excluding the renal possibility and the ophthalmoscopic appearances of the retinal arteries and color fields; the quinin amblyopia, from that due to malarial disease. In the latter condition we find edema of the end of the optic nerve, neuritis, optic atrophy, retinchoroiditis and finally hemorrhages into the retina and even into the vitreous. These hemorrhages may, however, be present without neuritis, as reported by JONES and by BRUNS of New Orleans, the hemorrhages being usually near the disc and by the side of the greater vessels. Actually optic atrophy is very rare but has been recorded by BULL of New York and by McNAMARA and CARTER.

The most common lesion in the vitreous and choroid is hemorrhage.

THE MEMBERSHIP LIST.

In our issue of June 12 we printed the list of members of the AMERICAN MEDICAL ASSOCIATION revised up to May 15, 1897. Many additions to this number were made at the Philadelphia meeting, and a supplementary list will be published as soon as these names are received. Those who have discovered any inaccuracy in the manner in which their names or date of joining the ASSOCIATION appeared in the record will confer a favor by sending in their corrections at once to this office, as a list of corrections will soon be published.

CORRESPONDENCE.

Medical Instruction of the Laity in the Lay Press.

ELMDALE, KAN., June 14, 1897.

To the Editor:—I have watched with some interest the comment on Dr. Shastid's letter as it appeared in Vol. 28, No. 17, of the JOURNAL. I can well see why it is a subject of no particular fascination to the profession, and why therefore it is so adversely criticised. It is not only in the columns of the professed advertiser, but also from the pens of men who from their positions successfully dispute the epithet of anything but leadership in the profession, that we have seen more than would be characterized by the term diplomacy. I refer to health officers of distinguished cities and heads of hospitals, public, endowed and private. However well meant some of these contributions (signed) to the lay press may be, they yet carry so much of the stigma of the advertiser that the profession can not fail to be insulted by their odium. And yet it takes no special effort on the part of the practitioner to see the great need of improvement in the conceptions of matters connected with medicine in the minds of the laity.

All know how common it is to see all sorts of filthy lotions and linens applied to the open wound. And who has not known the kindly intention of the would-be good Samaritan thwarted, as with unwashed hands and through septic parts she makes the digital examination of the parturient to at least show her good intentions. Labor over, the parts are again inspected with the same want of cleanliness, a filthy piece of linen applied to absorb the discharges, and to avoid

“taking cold” instructions given to not change the soiled linens of the bed for twenty-four to forty-eight hours, and not touch a drop of cold water with finger or lip. At the end of several days a chill, and with the heavy weight of remorse the patient confesses that being so uncomfortable she thought there would be no harm from it and after twelve to twenty hours she did put on fresh linens. How often are stimulants given in cases noted for their sthenic character or the congestion of middle-ear disease reinforced by agents that stimulate the cerebral circulation? A man with typhoid came under my care, who to cure the malady, had bought a gallon of brandy and consumed the greater part of it in two days during the stage of excitement. The over-stimulation resulted in exhaustion, so that in spite of the most vigorous efforts to support the heart it quickly failed and the patient, a strong man, died in a few days and about the fifth or sixth day of the fever. A child 7 years of age with pain in the right ear from inflammation of the middle ear was given ten grains of quinin and not only the right but both middle ears suppurred.

The use of medicine prescribed by the laity should be stigmatized as dangerous and the reasons for the same given. Quinin improperly used may be as potent for evil as properly used for good. We can not hope to make doctors of the laity and the plan of instruction must be principally toward restraint in self-medication.

The method of Dr. Shastid seems quite ingenious, though it is certainly necessary that the public understand that the literature thus supplied is by worthy authority. This could easily be so by signifying the authority of the AMERICAN MEDICAL ASSOCIATION, which would soon be understood to be the very highest possible authority, and an authority the honor of which every worthy physician may share. As to a point raised in one of the comments, I did not understand Dr. Shastid to mean that the literature thus supplied should be without remuneration to the writer, but that the press should not compensate the writer. And personally, I see no good reason why after remunerating the writer for his services, the articles then becoming the property of the ASSOCIATION, the ASSOCIATION should not through a duly authorized committee, as for instance, the editorial staff of the JOURNAL, receive a fair sum for the literature. But no individual names should ever be in any way connected with the articles. It is quite sufficient to know that they are authorized by the AMERICAN MEDICAL ASSOCIATION. This class of literature is not without value to the newspapers, and with the assistance of the Associated Press there would be no trouble to give it the widest possible distribution.

J. F. SHELLEY, M. D.

Railroad Transportation.

BROOKLYN, N. Y., June 15, 1897.

To the Editor:—I send the following clipping from the Brooklyn Times, June 15, 1897, to the JOURNAL, to call it to the attention of the Committee on Transportation: “SINGLE FARE FOR THE ROUND TRIP TO PHILADELPHIA VIA PENNSYLVANIA RAILROAD ON ACCOUNT OF THE NATIONAL SAENGERFEST.—The Pennsylvania Railroad Company announces that for the Eighteenth National Saengerfest, to be held in Philadelphia June 21 to 24, 1897, it will sell excursion tickets to Philadelphia from all points on its line June 19 to 23 inclusive, good to return until June 26, 1897, inclusive, at a single fare for the round trip. No rate, however, will be reduced to less than 50 cents.” Respectfully,

N. W. L.

Twelfth International Medical Congress.

NEW YORK, June 14, 1897.

To the Editor:—The undersigned, chairman of the American National Committee which was established at the request and under the authority of the General Committee of the Twelfth International Medical Congress, begs to inform the numerous gentlemen who are constantly applying for information concerning certificates, trip, fares, hotels, etc., that he has none to give, not having heard from the General Committee these two months. Very respectfully, A. JACOBI, M. D.

ASSOCIATION NEWS.

Report of the Rush Monument Committee.—Albert L. Gihon, A.M., M.D., Medical Director U. S. Navy (retired), Chairman of the Committee, submitted the following report at the recent meeting of the ASSOCIATION:

After what the President of the ASSOCIATION has said, a brief report from me as Chairman of the Rush Monument Committee is only necessary. In fact, what have we to report?—that \$75,000 have been subscribed for the erection of a monument in the city of Washington—that designs have been solicited from the most distinguished sculptors in the country and that one of these has been selected, which has met with universal praise for its beauty and artistic excellence, and that steps will soon be taken to put this design in marble and bronze? Alas! the name that will be engraved upon the pedestal of that monument will not be Benjamin Rush, but Samuel Hahnemann, and the future visitors to the Capital of the United States will look upon this exquisitely beautiful unrivaled work of art, and then when they go to visit the splendid U. S. Naval Museum of Hygiene, will see standing conspicuously at its approach, on a knoll in the park fronting it, at the site generously donated by the Government last year, an humble figure, a mere bust in bronze, the evidence of the liberality and measure of the appreciation of "the greatest physician this country has ever produced" by the hundred thousand and more members of the medical profession in the United States. Oh! brethren, pitiable contrast! What physician can ever go to Washington and look upon these two statues—the one costing \$4,000, the other \$75,000—the one the contribution of a hundred thousand men, the other of six or seven thousand; the one the result of thirteen years of ceaseless importunity, entreaty and personal appeal, the other originated and the funds spontaneously subscribed in less than four by a few sectarians, without a feeling of shame and humiliation? Today I ask you, shall this be? And it is the last appeal I shall make, for I am admonished of the uncertain tenure of life by my own desperate illness of last winter and this spring, and by the fact that six of the nine projectors of this monument already sleep the sleep that knows no waking. Only last week, a few thousand employes of the Manhattan Elevated Railway Company of New York, a few poorly paid ticket-sellers, guards and gatemen, dedicated a monument at Danville, Pa., to their late vice-president and general manager, Colonel Hain, which cost \$3,500 (only \$500 less than our own fund), which was raised by voluntary subscriptions during the twelve months after his death. If the ASSOCIATION did not intend to carry out this project in good faith, why did it deliberately and unanimously resolve at its meeting at Washington in 1884, "That this ASSOCIATION undertake to erect a statue to Dr. Benjamin Rush in the city of Washington by the members of the profession of medicine in the United States," and why has it, year after year, renewed with no less enthusiasm and unanimity its indorsement of the project? I hold the honor of the ASSOCIATION is at stake and the time has come for final decisive action. During the past winter, an appeal was issued in these terms, and I can not command language more direct and emphatic:

MY DEAR DOCTOR.—The remarkable success of the relatively small body of Homeopaths in the United States, in collecting \$75,000 for their monument to Hahnemann, to be erected in Washington, ought to make every reputable regular physician in the country keenly alive to the necessity for promptly subscribing to the fund for the long-delayed monument to Benjamin Rush.

The model for the monument to Hahnemann, which has been on exhibition in New York City, has attracted general admiration on account of its great beauty and artistic excellence, which will make it unrivaled as a work of this kind.

The regular medical profession, numbering over one hundred thousand more than the entire body of Homeopaths, has thus far subscribed less than \$4,000 toward the projected monument to Dr. Rush, for which the Navy Department has already generously designated a commanding site in the park fronting the U. S. Naval Museum of Hygiene, where it will be one of the most conspicuous features of the National Capitol.

Are the regular physicians of the United States willing that this illustrious Signer of the Declaration of Independence and the distinguished hero of the Revolution, shall be commemorated by an insignificant bust or a mediocre statue, in pitiable contrast with the splendid testimonial at their Capitol city to a foreign theorist by a comparatively small body of his misguided followers?

The crowds of visitors to Washington can not fail to attach disparaging significance to the spectacle of these two monuments; and we appeal to you to aid the Committee in its endeavor to do justice to the memory of this great father of American Medicine, pure and undefiled, by sending by *return mail* to either of the undersigned as large a contribution as you may be able to make.

Albert L. Gihon, M.D., Chairman R. M. C., 8 West 127th Street, New York City. George H. Rohé, M.D., Secretary and Treasurer, R. M. C.,

Sykesville, Md. W. Murray Weldman, M.D., Chairman of R. M. Committee for Pennsylvania, Reading, Pa. Henry D. Holton, M.D., Treasurer American Public Health Association, Brattleboro, Vt. Charles McIntire, M.D., Secretary-Treasurer American Academy of Medicine, Easton, Pa.

Thousands of copies of this appeal were distributed and the Committee earnestly hoped that thousands of dollars would be subscribed, but the fund which amounted to \$3,787.64 has only increased to \$4,006.19, and this partly from interest on the amount invested.

What is the explanation of this indifference? At the fortieth annual meeting of the ASSOCIATION at Newport, Rhode Island, Dr. William Pepper, then Provost of the University of Pennsylvania in his eloquent address on Medicine, made Rush his theme and eulogized his remarkable career. Those of you who were present on that occasion must remember the loudly expressed commendation of his statements and the hearty indorsement of the projected movement. A large part of the existing fund was subscribed at that time by members present. At the meeting in Baltimore in 1895, the report of the Committee was received with the most enthusiastic approval. It was then that Dr. Henry D. Holton of Brattleboro', Vermont, who deserves to be President of this body for that act alone, arose amid the applause that followed the reading of the report and warmly seconding the sentiments expressed in it, offered himself as one of one hundred members of the ASSOCIATION to subscribe \$100 each for the fund. His offer was quickly followed by similar tenders of \$100 each on the part of Dr. William H. Daily of Pittsburg, Dr. U. O. B. Wingate of Wisconsin, Dr. Henry O. Marcy of Boston, Dr. James M. Keller of Arkansas, Dr. S. M. Free of Pennsylvania, Dr. Jerome Cochran of Alabama, Dr. Alonzo Garcelon of Maine, Dr. J. M. Ridge of New Jersey, Dr. I. N. Love of Missouri, Dr. B. D. Evans of New Jersey, Dr. Donald Maclean of Michigan and Dr. O. B. Will of Illinois. Dr. J. M. Reeves of Tennessee and Dr. A. C. Cotton of Chicago, gave \$50 each, and Dr. Patrick Espy of Norwich, Conn., gave \$25. Then Dr. John A. Wyeth of the city of New York arose and offered to be one of five other men to subscribe \$500 each, while your worthy President of today quietly slipped \$100 into my hand, begging me not to announce his name.

Is it the fact that there are not five other men in the profession able to meet Dr. Wyeth's gage? Are there eighty-seven others whose means permit them to follow Dr. Holton's and his twelve companions' lead in guaranteeing \$100 each? If there are, the matter is a *fait accompli*. Had these offers been met, or if they shall now be met, our fund will amount to \$17,000 instead of \$4,000. There ought to be at least fifty cities in the United States, whose physicians simply or in the aggregate are able to contribute from \$200 to \$500 each to this fund, and fifty others \$100 each. There are medical societies enough in the United States which can subscribe, if only a moderate sum each, an aggregate sufficient to send a creditable if not a magnificent statue.

The Committee has exhausted its own resources and it now appeals to the ASSOCIATION to determine at once and definitely what further steps shall be taken. It is not to be believed that the ASSOCIATION has been insincere in its approval of the project, or that it repudiates the indorsement it has annually given to it without a dissenting voice during the past thirteen years. That assumption would be unworthy the dignity and reputation of this, the great national representative body of the profession of medicine in the United States. Neither Marion Sims nor Samuel D. Gross—of whom statues have already been erected, that of the latter began since our own and unveiled and dedicated less than a month ago—had the claims of Rush to national recognition, and if their admirers, students and colleagues could so commendably commemorate them why should not the great body of the profession honor the memory of this illustrious medical hero of the Revolution?

I do not believe there is another profession, trade or occupation, which could claim such a man as its Revolutionary hero, which would not long ere this have honored him not in bronze or granite but in the purest marble ever quarried in Carrara. Benjamin Rush was first intended for the law, and had this choice been adhered to, to what high eminence might he not have attained? To the non medical reader of history, his brilliant attainments and life-long devotion to the public good, would seem to entitle him to the admiration and high regard of his professional brethren for all time, but what do we see in truth? A great ASSOCIATION professing this admiration and regard, resolving to render him the honor he deserves, appointing a Committee to execute their resolves, and then turning indifferent to that Committee's pleadings for the means to do.

Benjamin Rush was no ordinary man. He was not one among ten, nor one among a hundred, but one among a thousand of the patriotic sons of America, who sowed the seeds of

liberty in this country. He was *the one par excellence*—the illustrious, incomparable physician, who having made himself master of his craft by long study, devoted himself to its higher development and became famous as its expounder; who, when his country required his services, with equal alacrity and whole-souled purpose gave them to her and became famous as her defender; who, when the crisis was over and the new Republic became an established government, resumed his professional work and in a hundred ways and a hundred years in advance of his time sought to improve social and sanitary conditions, and became famous as a great reformer, philanthropist and sanitarian; who doing all this faithfully performed the duties of his calling as a practitioner of medicine and sought to minister to his suffering fellow citizens at the hazard of his own life, which he at last offered up a victim of the prevailing epidemic of typhus—and became famous for his heroic martyrdom.

But you all know this. Year after year you have listened to the recital of the incidents of his remarkable career. While it is enough in most men's lives to have one special class of individuals interested in their achievements, this man claims the homage of every lover of his country because of his courage in maintaining its liberties at the hazard of his life—of medical military men especially, because he was the surgeon-general of the Revolutionary army and vigorously insisted upon the proper organization of its medical department—of practitioners of medicine because of his acquirements and skill as a practitioner—of the literary world because of his attainments as a chaste and elegant writer—of scholars and professors because of his ability as lecturer and teacher.

If, however, the members of the profession are unwilling to contribute to this memorial I do not see how they can be coerced into doing so, and since the project has gone too far to be abandoned, better legislate an annual subscription by the ASSOCIATION for a term of years, until a sufficient sum shall have accumulated to erect a monument worthy the subject and creditable to yourselves. Failing this, your Committee can only proceed to use the fund in hand, small as it is, for such a simple bust in bronze of heroic size upon a granite pedestal as can be procured for the money.

Your Committee reports the facts as herein stated and awaits your instructions. All of which is respectfully submitted,

ALBERT L. GIBON, M.D.

Chairman Rush Monument Committee.

[For action on this report see minutes, JOURNAL p. 1140-1.]

Competition for the Senn Medal.—Pursuant to a resolution adopted by the Section of Surgery and Anatomy of the AMERICAN MEDICAL ASSOCIATION, June 4, 1897, I have been appointed by the Chairman, Dr. Reginald H. Sayre, as Chairman of the Committee charged with the awarding of the Senn Medal for 1898. The other members of the Committee are Drs. I. O. Walker of Detroit, Mich., and S. H. Weeks of Portland, Me.

1. A gold medal of suitable design is to be conferred upon the member of the AMERICAN MEDICAL ASSOCIATION who shall present the best essay upon some surgical subject.

2. This medal will be known as the Nicholas Senn Prize Medal.

3. The award shall be made under the following conditions: *a.* The name of the author of each competing essay shall be enclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device. The title of the successful essay and the motto or device to be read at the meeting at which the award is made, and the corresponding envelope to be then and there opened and the name of the successful author announced. *b.* All successful essays become the property of the ASSOCIATION. *c.* The medal shall be conferred and honorable mention made of the two other essays considered worthy of this distinction, at a general meeting of the ASSOCIATION. *d.* The competition is to be confined to those who at the time of entering the competition, as well as at the time of conferring the medal, shall be members of the AMERICAN MEDICAL ASSOCIATION. *e.* The competition for the medal will be closed three months before the next annual meeting of the AMERICAN MEDICAL ASSOCIATION, and no essays will be received after March 1, 1898.

Competitors will address their essays to the undersigned

J. McFADDEN GASTON, M.D., Chairman.

1½ Edgewood Ave., Atlanta, Ga.

The Excursion to Atlantic City.—Among the enjoyable features of the Jubilee meeting was the trip on the last day to Atlantic City, where over a thousand availed themselves of the benefits of the excursion.

The members were met at the depot by a large delegation of

citizens, and about an hour later were assembled at the Brighton Casino, where a meeting in their honor was held, with Dr. Marvel in the chair. Dr. W. Blair Stewart escorted the speakers to the stage and presented Mayor Stoy, who welcomed them in a short but interesting address. Dr. Thomas K. Reed, the oldest resident practitioner of Atlantic City, delivered a formal address of welcome, which was listened to with close attention and much appreciated.

Dr. Stewart then introduced Dr. James North in flattering terms as the poet laureate of the city. Dr. North welcomed his fellows as follows:

Friends by the sea! Where once he loved to stray,
Great Æsculapius, of our art divine
High Priest, doth from his silent bed of clay,
His greetings send by this weak tongue of mine,
And bids you seek, where purple billows roll
With majesty to meet the shore's embrace,
Those secrets hid within its troubled soul
And pregnant with the welfare of our race.

For since the gods from high Olympus fled,
And Epidarus' temples ruined lie,
He dwells in silent chambers of the dead,
Nor looks upon the blue and arching sky.
But that great heart which throbb'd for all mankind,
Doth silent yearn and hope for mortals' good;
And his disciples o'er the earth would blud,
In one great universal brotherhood.

"Physician blameless," as blind Homer sang,
Fruit of Apollo's loins and fair Corou's womb,
Thy fame that through the hollow centuries rang
Were poor excuse to 'wake thee from the tomb
And drag thee forth into the garish light,
That Science turns on filial works of men;
How dense will be the darkness of thy night
When I shall leave thee to thy grave again.

Peace to thine ashes! While I turn to greet
These noble ones on whom thy mantle rests,
Thy brotherhood of good, whose tireless feet
And sturdy arms protect the naked breasts
Of frail humanity against the darts
Of Grim Disease; who in the crowded field
Would baffle all the virtue of their arts
But for thy daughter Hygea's golden shield.

Here 'mid such scenes as poets sang of old
You meet Past Masters by the sounding seas,
To weld fraternal links, stronger than gold,
In that long halo of which Hippocrates
And Galen, 'mid the lesser lights, shine bright,
Like stars along the heaven's milky way,
Changing the darkness of the centuries' night
Into the splendor of the present day.

Not 'neath Argollan skies, as oft of yore,
Where temples white her sacred groves begemmed;
But here beside the wavelet-wooled shore,
Where fair Health dons her brightest diadem,
And prints on careworn cheeks her rosy seal,
Her votaries lie, lulled by the summer breeze,
Tasting of joys that only gods could feel,
And dance like nymphs in far Hesperides,

Or glide like mermaids through the crystal waves,
Rocked for a moment in their giant arms,
While loving water amorously laves
The glowing beauties of unguarded charms;
'Till mad-cap breakers, with a rush and whirl
And flying spray, speed onward hand in hand,
To leave their burden, like a beauteous pearl,
Panting with pleasure on the shining sand.

Here, gazing o'er the ocean's broad expanse,
With heart attuned to Nature, thou shalt hear
The music of the spheres, as in a trance,
Which fell upon Apollo's listening ear.
Or see Aurora from her purple bed—
The fairest child of old Hyperion—
Throw back the rosy veil from off her head
To herald forth the coming of the sun.

And when brave Helios in flaming car
Aid fiery steeds speed up the azure skies,
The glory of the sun-god from afar
Is like the splendor-burst of Paradise;
And all around the spirits of the blest
Sweet converse hold, and then realized seem
The wondrous peace of Eden's perfect rest,
Of Dante's visions and of Milton's dreams.

And when the moon in the empyrean swings,
The shade of one Aurelius Celsus walks
And listens to the wavelet as it sings,
Or with the ghost of Ambroise Paré talks
Of Fame's sweet touch, as soft as kiss on brow,
By wooing winds of vineclad Abydos,
Of golden palms and laurel's greenest bough,
To bind a wreath for our immortal Goss.

Not he alone whose marble statue, reared
By reverent hands, thy loving eyes have seen,
Close by the towering shaft of one revered
By all the world, whose laurels, ever green,
The deepening dust of centuries can not dim,
But other names which Fame elaims as her own,
Dear to our hearts who led or followed him,
With graves unmarked or decked with costly stone.

'Tis well that in the city of his fame,
Of Physick's home, of Paucoast's memory dear,
The sheltering shrine of Agnew's honored name,
And Ledy's works, you celebrate this year,
Whose glad bell peals upon the startled air
Proclaimed throughout the land, sweet liberty,
'Neath the peace-angel's spreading pinions fair,
That you should hold your golden jubilee.

'Tis meet that now, your arduous labora done,
You seek relief in ocean's breath benign;
And while from glasa of life the sand doth run
Drink deep ambrosial draughts of air divine
On this fair shore where fortune gladly came
To dwell in love with Hospitality,
We bid you welcome in her sacred name,
To our Queen City by the whispering sea.

Here at your councils may Athene preside,
While Bacchus crowns with bays your festive board,
May Lares guard your absent fireside
'Till your dear ones shall welcome back their lord.
In that blest meeting of the loved apart,
Forget not those who by the boundless sea
Clasped hands and spake with you as heart to heart,
And wished you well through God's eternity.

SOCIETY NEWS.

Washington State Medical Examining Board.—The Governor has appointed the following new members of the State Examining Board: Dr. J. H. Hoxsey, Spangle; Dr. J. P. Turney, Davenport; Dr. E. Van Zandt, New Whatcom.

Oregon State Medical Society.—The twenty-fourth annual meeting of the Oregon State Medical Society was held in the parlor of the Imperial Hotel, at Portland, June 8 and 9. The attendance was quite large, delegates from both the California and Washington State societies being present. The interest and discussion elicited by the papers was much more pronounced than usual. The following papers were presented, viz.: "Optical Illusions," Dr. R. Nunn, Portland; "Tuberculous Osteomyelitis and Bone Abscess," Dr. F. M. Robinson, Beaverton; "Are Women Doctored Too Much?" Dr. J. A. Fulton, Astoria; "Radical Cure of Hernia, with Report of Sixteen Cases," Dr. W. H. Saylor, Portland; "New Mexico as a Health Resort for Consumptives," Dr. F. Cauthorn, Portland; "Why Female Diseases," Dr. C. H. Hall, Salem; "Perforating Intestinal Ulcer of Typhoid Fever, with Report of a Case. Operation. Recovery," Dr. A. C. Panton, Portland; "Peculiar Forms of Enteric Fever," Dr. J. A. Giesendorfer, Arlington; "Sanitary Plumbing," Dr. Mae H. Cardwell, Portland; "Chemical Analysis of the Urine and its Diagnostic Value," Dr. L. Victoria Hampton, Portland; "Asexualization of Criminals" Dr. T. C. Humphrey, Portland; "Inflammations of the Middle Ear, and their Relation to Nose and Throat Diseases," Dr. J. F. Dickson; Portland; "Bromin-Iodin Injections in Tuberculosis," Dr. W. H. Saylor, Portland; "Deflections of the Nasal Septum," Dr. Edward N. Wilson, Portland; "The Complexion," Dr. W. E. Maxwell, Portland; "Chorea," Dr. Henry W. Coe, Portland; "Differentiation between Epilepsy and Reflex Epileptiform Attacks," Dr. S. E. Joseph, Portland; "Treatment of Gonorrhoea in Women," Dr. William F. Amos, Portland; "The Utility of Roentgen Rays in Detecting and Locating Metallic Particles in the Eye," Dr. A. B. Kibbe, Seattle; "Address of Retiring President," Dr. Andrew C. Smith, Portland.

The officers elected for next year were as follows, viz.: President, Dr. Wm. Jones, Portland; vice-president, Dr. C. H. Hall, Salem; secretary, Dr. W. F. Amos, Portland; treasurer, Dr. Mae H. Cardwell, Portland. The next annual meeting will be held at Portland in June 1898.

Twelfth International Medical Congress.—The Committee of Organization of the Congress has received from the Ministry 7,000 free tickets of first-class transportation, which have been placed at the disposal of the Congress for their trip to Moscow going and returning. These tickets have been issued to the Committee of Organization by the Russian Ministry under the following conditions:

1. The Committee of Organization in sending each ticket to the member of the Congress for whom it is destined, will inscribe his name and the station from where he will leave, and for foreign visitors, the first Russian station on the frontier, also the route by which they will go to Moscow and return.

2. Independently of this the Committee of Organization will furnish the members of the Congress with a certificate indicating that the bearer is a member of the Congress. This

certificate should be presented to the conductor of the train on demand.

3. These tickets will only be available for the return trip from Moscow when bearing the stamp indicating that the bearer has taken part in the International Congress.

4. The names of the members of the Congress will be inscribed according to the opinion of the Committee of Organization, not only in Russian but in foreign languages.

5. The tickets of going to Moscow should be presented at the station of departure, or the first Russian station on the frontier, and there application should be made to have the tickets stamped. On return these tickets will be presented at the depot in Moscow, where they will be stamped with the date of departure.

6. The return tickets are good up to the 1st (13th) of September of the present year.

7. Bearers of these tickets will have the right to free transportation of baggage to the amount of 16 kilogrammes.

8. As soon as the Committee of Organization will have given notice of the time and number of members crossing the frontier stations, the railway companies will make arrangements to permit them to get most conveniently, comfortably and promptly to Moscow, and they will take the same measures on their return from that city.

9. In conformity with these conditions, in order to have a free ticket, each member of the Congress should inform the Secretary General of the route by which he will go and return.

10. The Executive Committee have the honor also to give notice that ladies and other persons, who have no scientific title, accompanying the members of the Congress, under rule 3, can not be inscribed as taking part, nor pay any admission fee, nor can they receive gratuitous tickets on the Russian railroad lines.

BOOK NOTICES.

A New Classification of the Motor Anomalies of the Eye, based upon physiological principles, together with their symptoms, diagnosis and treatment. By ALEXANDER DUANE, M.D., Assistant Surgeon of Ophthalmic and Aural Institute, New York. J. H. Vail & Co. 1897.

This excellent little book consists of two parts; the first part reviews the normal movements of the eye, and the tests employed in their examination. The second part introduces the author's new classification of the muscular disorders and gives a very clear and comprehensive description of each of the six groups into which the motor anomalies are classified. Instead of subdividing these anomalies simply according to the deviations presented (which has been the usual plan adopted by writers heretofore) the author proposes the following classification; Disorders of individual muscles. 2. Disorders of associated parallel movements. 3. Disorders of convergence. 4. Disorders of divergence. 5. Disorders of sursumvergence. 6. Disorders of the rotation (or swivel) movements.

These divisions form groups, distinct in nature and symptoms, and frequently requiring widely different methods of treatment and readily distinguishable in practice by the signs they afford. The new classification therefore furnishes a good working basis for the diagnosis and management of motor anomalies; and we recommend the careful and repeated perusal of this brochure to every one who wishes to study and understand thoroughly this very interesting and important, but also very perplexing subject.

A Handbook of Medical Climatology, Embodying its Principles and Therapeutic Application, with Scientific Data of the Chief Health Resorts of the World. By S. EDWIN SOLLY, M.D., M.R.C.S., late President of the American Climatological Association. In one octavo volume of 470 pages, with engravings and colored plates. Cloth, \$1. Lea Brothers & Co., Publishers, Philadelphia and New York, 1897.

This work is intended to be a systematic treatise on Medical Climatology and essays to report the climates of the world. It is a subject which has engaged the author's attention for nearly thirty years.

Those who have the pleasure of personal acquaintance with the author will not fail to recognize in this work evidence of his fairness and cool judgment and in his description of various

climates and in the rules of climatotherapy there is not the slightest bias or variation from what he conceives to be the truth of the case. The book is divided into three sections. Section 1 having five chapters devoted respectively to the principles of Medical Climatology, Physiology, Ethology, Geographical distribution of diseases, and Classification of Climates.

Section 2 has an introduction and four chapters, viz., Phthisis, Forms of phthisis as influenced by climate, result of the treatment of phthisis by change of climate, forms of disease other than phthisis as influenced by climate.

Section 3 has an introduction and ten chapters, viz., North America, Eastern Climate, Southern Climate, Rocky Mountain Climate, Pacific Slope Region, Mexico, South America, Europe, Africa, Asia, Australasia and Island Climates.

There are various charts and relief maps explanatory of the text and altogether it is safe to say that Solly's Medical Climatology will be accepted as a fair and authoritative presentation of the existing knowledge of the subject for some time to come. The author has not attempted under the head of Climatology to prescribe special climate for particular diseases but has endeavored to lay down the broad principles of the subject leaving to the practitioner the duty of forming his own opinion in individual cases.

With some verbal changes the work will answer very well for class recitations. As a work of reference it will be valuable to every practitioner.

Lippincott's Medical Dictionary. A complete vocabulary of the terms used in Medicine and the allied Sciences, with their Pronunciation, Etymology and Signification, etc. By RYLAND W. GREENE, A.B., assisted by John Ashhurst, Jr., M.D., LL.D., George A. Piersol, M.D., and Joseph P. Remington, Ph.M., F.C.S. Philadelphia: J. B. Lippincott & Company. 1897. 8vo, cl., pp. 1154.

This dictionary in its general plan is based on the dictionary of Dr. Thomas. In spelling both old and new forms are used, but in the pronunciation the English method has been given precedence. At the same time it is admitted in the preface that the Roman pronunciation is increasing in use. A number of new words have been introduced and will be found very useful. While we object *in toto* to the English pronunciation of Latin words, we must concede that with the exception of pronunciation, there is little to criticise and much to commend.

By reason of changes in medical science, in order to keep pace therewith one must have the latest dictionary, and we can not have too many of them. The alleged phonetic system of pronunciation, of which this book is an exponent, presents a queer appearance at times, and in many instances one would need a translation of the phonetics; for example, the word "saline" has for its phonetic se-lain' or se'lain, and Samuel—which most people know how to pronounce in their mother tongue, looks rather unfamiliar in the phonetic, Sam'iu-el. Obtusion must according to this dictionary be pronounced "ob tiu'zhon," and the plain word "puke" is pronounced "pitic."

We do not speak of this for the purpose of criticising unkindly those who believe that correct English pronunciation has been entirely lost by those living in the present century, but it certainly is very far from the tendency of the day to use needless letters anywhere, much less by way of making an explanation which does not explain. In other respects the dictionary is an excellent one.

A Compendium of Practical Medicine for the Use of Students and Practitioners of Medicine. By WILLIS WEBSTER GRUBE, A.M., M.D. Toledo, Ohio: The Hadley Publishing Co. 1897. 8vo, calf, pp. 664.

This is a catalogue of diseases arranged alphabetically, each accompanied by a short description; some of them give causes and all have a treatment. At the end of the work there is a

clinical index which is really a therapeutic index. The book is printed in large clear type, and is handsomely bound and on heavy paper. The old system of dosage has been used. The work is elementary and will no doubt be useful to medical students. But we question whether or not such books as this should be implicitly relied on even by students. For instance, page 33, the author says: "Pus when thick and clear is known as healthy or laudable pus or living pus; when thin and watery, puriform or dead pus; when blood-stained, sanious gummy pus and contagious pus in smallpox, gonorrhoea and venereal ulcers." On reading such a paragraph one is apt to rub his eyes and re-examine the title page of the book to see if it is really printed near the close of the nineteenth century.

It must not be inferred that this book is a systematized treatise on medicine; it is in effect a dictionary of certain terms and concerning which the author has given more or less description according to his opinion of their relative importance. Viewed from this standpoint, much of the criticism that it would otherwise obtain falls to the ground.

Exactly why a fee bill has been placed at the end of the work, or whose fee bill it is, it would be difficult to state, as there is nothing in the book about it.

Transactions of the New York State Medical Association. Volume xiii. Edited by E. D. FERGUSON, M.D. Pp. 624. New York: Published by the Association, 1897.

This very welcome addition to our medical literature still maintains the standard erected at the start. Careful research, original views and lucid statement are prominent features of the contributions. Among the writers are the well known names of Drs. J. W. S. Gouley, Joseph D. Bryant, T. D. Crothers, J. E. Janvrin, John Shrady, J. Lewis Smith, George T. Harrison, Nathan G. Bozeman, H. O. Marcy of Boston, and the editor himself. The addresses of Dr. Darwin Colvin, the retiring President, and Dr. Charles Phelps, President elect, are thoughtful, chaste and suggestive. Dr. Reginald H. Sayre on "Roentgen's Discovery as Applied to Surgery," gives a masterly résumé of its present status, while the participants in the discussion of prostatic enlargement, all of whom deserve more than the usual meed of praise, certainly a passing note. These were, besides Dr. Gouley, Drs. Samuel Alexander, W. G. Bronson and Douglas Ayers. Drs. John G. Truax, Thomas H. Manley, T. M. Ludlow Chrystie, Nelson L. North, F. H. Wiggins, E. B. Dench, Frank S. Milburn, Sidney Yankaver, Robert Aberdein, William M. Bemus, Alvin A. Hubbell, T. J. Acker, Florince O'Donohue, Z. J. Lusk, Samuel E. Milliken, E. H. Squibb and Irving D. LeRoy have also ably fulfilled the duties entrusted to them.

The Semi-Centennial of Anesthesia, Oct. 16, 1846—Oct. 16, 1896. Boston, Mass., General Hospital, 1897.

We have already adverted to the Semi-Centennial of Anesthesia as celebrated by the Massachusetts General Hospital in Boston in October last (See JOURNAL, Vol. xxvii, p. 768), and we now have a handsome book, printed on Japan paper, exquisitely finished, having for its frontispiece a picture of the old Hospital and immediately following the title a reduced copy of the invitation to attend the exercises and a reproduction of all papers read on that occasion, which were as follows:

1. Address of welcome by Charles H. Dalton, President of the Massachusetts General Hospital.
2. Reminiscences of 1846 by Robert T. Davis, M.D., Fall River.
3. Surgery before the days of anesthesia, by John Ashhurst, M.D., LL.D., of Philadelphia.
4. What has anesthesia done for surgery, by David W. Cheever, M.D., LL.D., of Boston.
5. Relation of anesthesia and obstetrics, by John P. Reynolds of Boston.
6. The influence of anesthesia upon medical science by W. H. Welch, M.D., LL.D., of Baltimore.
7. Surgery of the future by Charles McBurney, M.D., of New York.

8. The birth and death of pain, a poem, by S. Weir Mitchell, M.D., LL.D., of Philadelphia.

The portraits of Dr. J. C. Warren and William T. G. Morton are inserted, and as well an engraving showing the first public demonstration of surgical anesthesia, which occurred Oct. 16, 1846, and in which the portraits of those present are seen grouped about the patient (George Abbott), who is lying on the table at the period where Morton has completed the anesthesia and the patient is just ready for the knife of Dr. Warren. The figures present are those of Drs. H. J. Bigelow, A. A. Gould, J. C. Warren, J. Mason Warren, W. T. G. Morton, Samuel Parkman, George Hayward and S. D. Townsend. Of these, J. C. Warren was at the time professor of surgery in the Medical Department of Harvard University; J. Mason Warren and H. J. Bigelow afterward became such. Dr. Parkman was murdered by Webster; Dr. George Hayward was at the time the chief surgeon of the Massachusetts General Hospital; Dr. Townsend was then surgeon of the Marine Hospital at Chelsea, having succeeded his father, Dr. David Townsend, in that capacity.

As a souvenir of one of the most interesting events of modern medical history, the book will find a welcome in the library of every progressive surgeon who is fortunate enough to obtain it.

NECROLOGY.

WILLIAM THOMPSON LUSK, M.D., born May 23, 1838, in Norwich, Conn., died of cerebral apoplexy at his residence in New York city, June 12. Having entered Yale College in 1859 he left it after his freshman year to enlist in the Union army but in 1872 he received his honorary degree of A.M. from this institution and in 1893 that of LL.D. During the war he rose from the humble rank of private to that of Captain of the 79th Infantry N. Y. Volunteers, otherwise "the Highlanders" from which regiment he was mustered out Feb. 28, 1863. He was graduated from the Bellevue Hospital Medical College in 1864 and afterward pursued his studies in Heidelberg, Berlin, Edinburgh, Paris, Vienna and Prague. Dr. Lusk won his reputation from many pursuits, having been contributor and medical editor, lecturer and professor in the Long Island Hospital Medical College, the Harvard Medical School and the Bellevue Hospital Medical College, a visiting and consulting physician of many hospitals and an active member of several scientific bodies. His most enduring distinction in all likelihood is his treatise on "The Science and Art of Midwifery" (1880), which has been made familiar abroad in several languages. He leaves three daughters and two sons.

FREDERICK J. McNULTY, M.D., Georgetown Medical College 1860, died in Boston, Mass., June 14, at which date he was Superintendent of the Austin Farm Insane Asylum. He was born in Richmond, Va., in 1835 and was an officer with a record of a service under four flags, to-wit, the United States, the Confederate, the Chilian and the Cuban. Recovered from wounds in battle, with a diplomatic training and an experience in Ludlow Street jail under bonds not to enter the Cuban army he finally settled in Worcester, Mass., and in 1879 removed to Boston. He was a member of Camp Lee, Confederate Veterans of Richmond and the Massachusetts Medical Society.

HENRY LOEWENSTEIN, M.D. University Giessen, Germany, 1857, for many years a police surgeon, died at his home in Brooklyn, N. Y., June 10, aged 59 years.

SAMUEL S. TROTH, M.D., Jefferson, Philadelphia, 1849, died in that city June 11. He was long a member of the Pennsylvania Medical Society.

GEORGE KERR EDWARDS, M.D., son of a regular army surgeon, a Princeton graduate of class 1889, and an alumnus of the University of Pennsylvania, died in Princeton, N. J., June 14. After attaining his medical degree he spent a year in hospital work in Philadelphia and subsequently in the Johns Hopkins Hospital. After nine months devotion to duty in the latter institution tuberculosis manifested itself, since when in his own words he kept "chasing health and hope." A sojourn

in California was unavailing and in obedience to a sentiment of his own he was carried to die in his old college room not long after a speech made at a class reunion. His last residence was Newcastle, Delaware.

JOHN P. ATWATER, M.D., last surviving member of the class of 1834 at Yale College, died at his home in Poughkeepsie, on May 23. He was born in 1813 at Carlisle, Pa., where his father, the Rev. Jeremiah Atwater, after completing his professional studies, settled. In 1870 he removed to Poughkeepsie.

JOEL WASHINGTON SMITH, M.D., Charles City, Iowa, June 6, aged 72 years. Dr. Smith was a member of the AMERICAN MEDICAL ASSOCIATION, Iowa State Medical Society, Cedar Valley, and Wapsia Valley Medical Societies; International Medical Congress, Philadelphia 1876, and Washington 1887; American Public Health Association, American Association for the Advancement of Science, etc.

ALONZO D. TAGERT, M. D., June 16, aged 53 years; graduated in 1864 from Medical Department of the University of Vermont. He practiced in his native State until 1884, when he settled in Chicago and remained up to the time of his death.

—Wm. Allison Todd, M.D., Chariton, Iowa, March 24, at one time president of the Iowa State Medical Society.—Isaac Van Tyle Goltra, M.D., Springfield, Ill., June 12, aged 77 years.

—R. J. Goodman M.D., Sparks, Ga., June 16.—Victor S. Jourdon, M.D., St. Louis, June 13, aged 80 years.—Samuel M. Martin, M.D., Greenfield, Ind., June 14, aged 55 years.—M. M. Powell, M.D., Collinsville, Ill., June 19.—Nicholas Schenkel, M.D., Allegheny, Pa., June 9, aged 40 years.—Asa F. Pattee, M.D., (instead of Asa F. Potter, JOURNAL, p. 1202).

PUBLIC HEALTH.

The Scarlet Fever Epidemic in Plainfield, N. J.—The health authorities, aided by the city physicians, are investigating the sources of the epidemic, which seems to have been of a mild form and found to exist among all classes of the people. No favors have been shown in the general quarantine, and as a consequence the epidemic has so far abated as to allow a few days opening of the schools previous to the summer vacation.

Draining New Jersey Marshes.—The reclamation of the Passaic and Hackensack meadows is under discussion. The two are about eighteen miles long, extending from Elizabeth to Hackensack, and their width averages four miles. The surface is in general five feet above low water level and a trifle above high tide. The soil is either blue clay or peat, the depth of the former ranging for the most part from ten to fifteen feet and the depth of the latter being generally less than eight feet. Mr. C. C. Vermeule of the State Geological Survey in his report discusses the relative cost of plans, and averages the price at about \$47 an acre. The accruing advantages to commerce, manufacturing and agriculture would more than counterbalance the estimated outlay of \$1,268,400. The health and welfare of the whole meadow district and contiguous territory, it is suggested, can best be promoted by a single public authority planning to improve navigation and drain by the same work. The newspapers in their comments can not forego the tempting allusions to offensive odors, omnipresent malaria and "Jersey mosquitoes," but vote the proposition of redemption as feasible.

A Yellow Fever Menace.—A San Francisco telegram to the *N. Y. Herald*, dated June 13, reports the arrival of the *City of Para* flying the yellow flag. When one day out from Panama, a lady passenger died from yellow fever, and a few days thereafter the captain also succumbed. None of the twenty passengers showed symptoms of the disease, but a quarantine was very properly ordered. Health officer Dr. Doty maintains that a fever epidemic in New York is out of question and that the present menace, if such it may be called, began on the

Pacific side of the Isthmus of Panama; the cases originated in two sailors who deserted a ship from Peru. On the Atlantic side of the Isthmus, where the *Advance* shipped her cargo of fruit, there is no yellow fever. (JOURNAL, p. 1202). The steamer *Vigilancia*, with eleven second-cabin passengers, arrived at New York June 14 from Havana. These were sent to Hoffman Island for observation. Owing to the sudden death of a Chinese passenger on board the *Vigilancia*, and the lack of a satisfactory history of the case, Health Officer Doty decided to detain the steamer for disinfection. In the case of ships from Cuba, "white certificates" are used as permits to land in New York. The only class on board ship requiring surveillance are white passengers who may have contracted the disease ashore. The crew and natives are practically immune. Others without certificates are detained for a day and a half away from their surroundings and thereby they complete the period of incubation, which is five days, the voyage from Cuba being three days. In this way commerce, the local god, is propitiated.

MISCELLANY.

Determination of the Xanthin Bases in the Urine.—It is announced in the *Deutsche Med. Woch.* of June 3 that the universally adopted Krüger-Wulff method is not reliable. Comparative tables are given which show that the results attained with it are seven times too high in some cases, while this exaggeration is too variable to be accepted as a mathematical factor in computing the results.

Prof. Axel Key of Stockholm has been honored by his friends with a "Fest Band" on the occasion of the completion of his thirty-fifth year as professor of pathologic anatomy at the Karolinska Med. Kir. Institute. It forms two bulky volumes bound uniform with the *Nord. Med. Arkiv* of which he is editor, price 16 kronor. It contains thirty-seven able articles on important subjects, finely illustrated.

Moscow International Congress.—The Committee on Accommodations report 3,000 rooms at the disposal of the members of the Congress, ranging in price from 3 to 10 francs a day, which includes breakfast. A special committee has been appointed to attend to the entertaining of the ladies accompanying members, to render their stay in Moscow agreeable.—*Therap. Woch.*, May 30.

Floating Kidney in Children.—Comby asserts that the accepted causes of floating kidney must be erroneous in many cases, as he has found it occur quite frequently in children since he began looking for it recently. This shows that the condition in adults may date from the earliest years and may be congenital. The *Bull. Soc. Méd. des Hop.*, May 27, contains his observations of six cases, ranging from infants to girls of 14, and he urges others to cooperate in obtaining further information in regard to this condition in children.

Capacity of the Human Stomach.—There were removed from the stomach of Harry Whallen, "the human ostrich," who underwent an operation June 12 at the German Hospital, Kansas City, Mo., two pocket knives, three knife blades, three ounces of fine glass, and tacks, nails, screws and staples to the number of seventy. He died a martyr to his latest miracle not quite two days thereafter.

The Statue to Charcot.—Germane to the thought expressed by Governor Hastings at the last convention, we find that the French people are not omitting their artistic duties toward those who work for preventive medicine. The *New York Herald* says that the sculptor Falguière is putting the finishing touches to a magnificent statue of Dr. Charcot, which will be placed at the Salpêtrière. The Pasteur monument fund has reached the sum of \$60,000, nearly. At the request of

Paul Duhois, who was first asked to execute the monument, the work has been intrusted to Falguière.

Explanation of the Variations in the Intracellular Secretion of Bile in the Liver.—Professor Browicz announces that he has established a fact that explains his former announcement of the peculiar differences in the chemie constitution of the bile secreted at one time by a liver cell in certain abnormal conditions. He finds that there is a connecting system of delicate intranuclear and intraprotoplasmic passages in the chromatin of the nucleus of the hepatic cells, connecting closely with the intercellular biliary passages. This discovery shows that the biliary passages commence in the nucleus, and also explains the pathologic vacuolization in certain pathologic conditions.—*Deutsche Med. Woch.*, June 3.

The New York Medical League puts the Brake on More Dispensaries.—We glean from the press of New York that the New York Medical League has commenced active operations in the matter of medical charities abuses. On April 19, a committee of the League appeared before the New York State Board of Medical Charities in opposition to the application for a charter for the St. Bartholomew Dispensary, claiming that the institution of a new dispensary in a neighborhood already amply provided for by medical and surgical services, was unnecessary and tending to promote pauperism. The Board accepted the views of the League and refused the grant of charter. The Pasteur Institute also applied for a license to open another dispensary, and the League objecting, urged the refusal of recognition by the Board. Here, as in the preceding case, the League was sustained by the State Board of Charities and the charter was not granted. Let the good work go on.

Lesions of the Spinal Cord in Cases of Amputations of the Fingers.—The necropsy of a recent case has strikingly confirmed the modern assertion that the section of a nerve determines lesions at a distance, in the nerve's originating center. In this case, described and illustrated in the *Presse Méd.* of June 2, the lesions in the spinal cord corresponded in every particular and almost exclusively to the innervation of the parts amputated. An interesting feature of the case was that the amputation was congenital. The woman was 60 and a cancer was located in the cervix uteri.

Estate of Deceased Insane Person not Liable.—In Missouri the duty of supporting the indigent insane is devolved by statute upon the counties of which they are inhabitants. Section 5557, of the Revised Statutes of that State of 1889 provides that "in all cases of appropriations out of the county treasury for the support and maintenance of confinement of any insane person, the amount thereof may be recovered by the county from any person who, by law, is bound to provide for the support and maintenance of such person, if there be any of sufficient ability to pay the same." But because there is no express statutory provision therefor, the supreme court of Missouri holds, in *Montgomery County v. Gupton*, March 9, 1897, if a county has paid for the support of an insane person at the State Lunatic Asylum, it can not recover the amount from such person's estate after his death. There is no principle of statutory construction, it declares, that will warrant the assumption that, a legal liability being upon others, if they are able pecuniarily to pay for the patient's support, the law will imply a promise on the part of the patient to pay for it himself, if able pecuniarily. At common law, it explains, it is well settled that the provision made by law for the support of the poor is a charitable provision, from which no implication of a promise to repay arises, and moneys so expended can not be recovered of the pauper in the absence of fraud, without a special contract for repayment.

Societies.

THE midsummer meeting of the Madison County Medical Society was held at Huntsville, Ala., June 15.—Seventy-five physicians and surgeons of the Santa Fé Hospital Association,

which is maintained by the A. T. & S. F. Ry., have organized as the Santa Fe Medical and Surgical Society. Dr. J. P. Castor, Topeka, Kan., was chosen president.—The Sioux Valley Medical Association met in annual convention at Rock Rapids, Iowa, June 15.—The South Dakota State Medical Association met at Mitchell, June 9.—The Kansas City District Medical Society held a meeting June 10.—The Manchester (N. H.) Medical Association held its first annual session June 11.—The annual meeting of the Delaware State Medical Society was held at Rehoboth, June 10.—The Franklin County (N. Y.) Medical Society held its session at Malone, June 8.—The Ontario Medical Association held its seventeenth annual meeting at Toronto recently.

Colleges.

INDEPENDENT MEDICAL COLLEGE THREATENED.—Attorney-General Akin of Illinois has been asked by the Board of Health of Milwaukee to have the charter of the Independent Medical College of Chicago revoked.—Harvey Medical College, Chicago, graduated nine new physicians June 15.—At the thirteenth annual commencement of the National University, Washington, D. C., June 10, ten received the degree of Doctor of Medicine.—The medical department of Hamline University, Minnesota, held its fourteenth annual commencement June 10.

Hospitals.

THE STATEN ISLAND HOSPITAL. "Greater New York," is to hold a "birthday party" on June 19. A little silk bag accompanies an invitation to the lawn, this article being for the reception of pennies indicating the contributor's age in years. Music and refreshments are the temptations.

MARY O'MALLEY, M.D., Niagara University, 1897, has been appointed on the resident staff of the Buffalo (N. Y.) Hospital of the Sisters of Charity.—Finley Hospital, Dubuque, Iowa, reports 120 patients for the year ending March, 1897. Of these sixty-four were surgical, forty-nine medical. Seventy-eight were cured, twelve improved and fourteen died.

Washington.

HEALTH OF THE DISTRICT.—From the report of the Health Officer for the week ended June 12, we find the mortality of the District continues below the average. The total number of deaths during the week was 82, while those of the previous week were 94, of which 48 were white and 36 colored; total death rate per thousand 15.2. Diseases of the nervous system caused 13 deaths, those of the circulatory organs 6, those from the kidneys 9. There were 3 deaths from diphtheria, 3 from whooping cough, 3 from acute lung diseases, 1 from typhoid fever. Of the 6 deaths by violence 3 were by suicide.

MEDICAL SOCIETY.—At the recent meetings of the Society the following papers have been presented: Dr. Nordhoff-Jung, "The Thure-Brandt System in Gynecology Practically Applied"; Dr. Forwood, "Fracture of the Skull, case and specimen"; Dr. Kleinschmidt, "Thoughts on Modern Physiology; Its Aim and Limits"; Dr. Lamb, "Ulcerative Endocarditis."

WASHINGTON OBSTETRICAL SOCIETY.—The Washington Obstetrical and Gynecological Society at its meeting June 18 adjourned until October next, when President Dr. J. B. Harrison will read the annual address.

BOARD OF MEDICAL EXAMINERS.—The Commissioners of the District have appointed Dr. John H. McLain to succeed himself as a member the Board of Medical Examiners.

NEW QUARANTINE STATION.—A quarantine station has been established at Alexandria, Va. Dr. Arthur Snowden, formerly of Washington, has been appointed officer in charge.

TO PROTECT THE MEDICAL LICENSING BILL.—The Commissioners of the District, on the advice of Health Officer Woodward, have reported adversely on Senate Bill 1134, to restore medical "freedom" to the District of Columbia. They append to their report a criticism by the health officer which clearly shows the wisdom of their adverse recommendation.

TRAINED NURSES FOR THE POOR.—A number of very prominent trained nurses in this city recently organized an association among themselves for the purpose of supplying first-class nurses to the poor and middle classes. The nurses, when off duty, propose to nurse the poor by daily or nightly visits for a nominal fee per visit. Where an operation is to be performed one or more will attend during the actual time of the operation for a fee of \$3 to \$5, during actual labor and delivery \$5, and subsequent visits \$1 for the first and 50 cents for subsequent visits. These reductions are to be made only on the certificate of the attending physician that the families are unable to pay the regular fees. The association will do a great deal of good to the poor classes by thus permitting them to have the services of nurses, whose high prices formerly barred them. The advantage to the physicians will be incalculable.

A FAITH CURE DOCTRESS IN TROUBLE.—Quite recently a patient ill with diphtheria died while under the care of a faith-cure doctress. The Health Department and Board of Medical Examiners assert that she thus violated the Medical Practice Act and have accordingly issued a warrant for her arrest, so charging her. Her personal bonds have been accepted, pending the trial before the police court. She claims not to practice medicine nor to have violated the Medical Practice Act, and alleges exercising a religion by prayer.

THE PUBLIC SERVICE.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from June 12 to June 18, 1897.

First Lieut. Charles Lynch, Asst. Surgeon, is granted leave of absence for one month, with permission to apply for an extension of one month, to take effect upon his relief from duty at Ft. Robinson, Neb.
First Lieut. Benjamin Brooke, Asst. Surgeon (Ft. Thomas, Ky.), is granted leave of absence for four months, on surgeon's certificate of disability.
Major William C. Shannon, Surgeon U. S. A. (Jackson Bks., La.), is granted leave of absence for one month, on surgeon's certificate of disability, with permission to apply for an extension of one month.
Capt. William F. Lipplitt, Jr., Asst. Surgeon (Ft. Leavenworth, Kan.), is granted leave of absence for one month, to take effect about July 24, 1897.
